The second essential in order that the cause of infantile ophthalmia be abolished is that a solution of the necessary silver salt be prepared under the authority of some body capable of inspiring universal confidence and that it be distributed by the health department of every state gratuitously to every obstetrician, physician or midwife qualified to care for the parturient woman. The nature of the solution, together with the character of the descriptive card which should accompany it, should be determined by a committee chosen by the President of the American Medical Association and should have among its members at least one representative ophthalmologist, one obstetrician and one sanitarian. The conclusions of this committee should be reported back to the House of Delegates so that the preparation and its text should carry with it, on the great authority of this association, the assurance that the solution is entirely safe and necessary and that its use should invariably be part of the toilet of every new-born child. The solution, probably silver nitrate, could be put up either by the state itself or by some trustworthy pharmacist at an insignificant cost; its purity and sterility should be vouched for by the board of health of the state. It should be enclosed in specially prepared receptacles, each containing a special quantity and so arranged that it may be used drop by drop. These, properly enclosed, accompanied by a brief lucid explanation of the danger of the disease, the necessity of this germicide, the method of its employment, and the right subsequent care of the eyes should be sent to the obstetrician on the receipt of each birth certificate. As with antitoxin, these preventive packages should be placed at various stations where they could be easily ob-

tained, and those by whom they might be used should be urged to secure them. In order that none who should use them should fail to get them, they should be supplied free of cost. Such further supplies as might be needed for further treatment in the proportionally few cases in which prevention did not prove wholly effective should be made readily obtainable at minimum cost. In other words, every facility should be afforded for the early destruction of the infectious germs.

Similar cards should be posted in every maternity hospital and ophthalmic dispensary, and efforts should be made to have the Credé method of prevention by the use of silver nitrate regularly employed as a routine measure in every public and private institution in which children are born.

Special cards should be sent to midwives, giving them more detailed instructions in several languages. These cards should be in the form of return postals, having space for the date on which the ophthalmia appeared, the condition of the cornea, and whether or not preventive measures were employed.

The distribution of these cards should lie with the public health authorities, and the failure to report promptly should constitute a misdemeanor.

Fig. 1.—Sample light-proof hermetically sealed ampoules for the distribution of the silver; made in different sizes. The glass tips are to be broken off, the rubber tubing being retained to prevent injury of the eye by untrained or careless hands.

On the filing of each birth certificate the department of health should at once send to the accoucheur an ophthalmia card, with a supply of silver nitrate for immediate use. It would probably, by reason of delay on the part of physician or midwife, be delivered too late for that particular case. Each card, sent, however, would be a constant reminder and the preparation would be on hand to be employed when the next case occurred.

Correspondence with some of the principal pharmacists has shown that the nitrate, which is the most efficient of the silver salts, is also the most permanent. It can be prepared in light-proof ampoules so arranged that a sterile preparation may be easily and safely employed even by inexperienced hands. Such a filled receptacle can be prepared and placed in the hands of the health officers and distributed at a nominal cost. If, however, the sum required to put this valuable preventive in the hands of every accoucheur was much greater than it is, it could still be done with great economy to the state.

In the year 1901-2 there were 129 pupils in the New York State School for the Blind; of these the ophthalmic examiner reported 43 as having lost their sight through suppurative ophthalmia. The next year, among 29 new pupils, 11 were catalogued as blind from this cause. In 1903-4, among 24 new pupils, 6 came in the same list, and in 1904-5, of the 23 new pupils, 7 were also so described. A careful re-examination developed the fact that, while all those cases were due to suppurative infections, and, therefore, almost if not all preventable or curable, some of them occurred later than in infancy, but several ophthamologists agreed that it was quite within the facts to say that 25 per cent. of the pupils in the school had lost their sight as a result of ophthalmia neonatorum. If a like proportion exists in the school in New York City, as is quite probable, these, together with the large number receiving state and city aid through other channels, would easily make an annually increasing budget of now not less than twenty-five thousand dollars paid for the education and maintenance of blind people who, had a tithe of that money been expended for prevention, need never have been blind.

In the city of Buffalo in 1905 there occurred about nine thousand births. During the year four children from the same place were newly entered in the State School for the Blind. Of these one boy had lost his sight through ophthalmia neonatorum. The cost of the maintenance of that one child by the state will far exceed the amount which would have been required to protect the eyes of the entire nine thousand.

As we leave the cities the proportion of children blind from this cause entered throughout the state multiplies prodigiously. There can be no question, therefore, as to the economy on the part of the state in instituting general preventive measures. The cost would be infinitesimal, the benefit prodigious, immeasurable. The present time is peculiarly propitious for the successful execution of such a plan.

I have said that responsibility for the indifference that is annually resulting in such frightful disaster lies primarily with the state, the public and the medical profession.

The state is already aroused to the necessity of taking effective measures to wipe out this ecntrollable plague. Bills have been introduced in the legislature of Massachusetts and of New York providing for the appointment of commissions for the blind, one of whose duties will be to study the causes of unnecessary blindness and to suggest preventive measures.

The public has been awakened and a society for the Improvement of the Condition of the Blind and the Prevention of Blindness has been organized in New York under the distinguished direction of Dr. Lyman Abbott and having on its directorate the names of many eminent citizens. The more generally to popularize its work a meeting, at which Mark Twain will preside and the Hon. Joseph H. Choate be the chief speaker, will be held at the Waldorf-Astoria, New York, in the present month.

To make these efforts more effective, the hearty cooperation of the medical profession is essential. The magnificent organization of the American Medical Association makes possible as never before an effective movement to abolish ophthalmia neonatorum as a cause of blindness. Let registration of every case be first secured through the health boards of every state in the Union, then through these same boards have placed gratuitously in the hands of every accoucheur the simple remedy through which protection can be secured, and multitudes whose lives through needless blindness would otherwise result in hopeless failure and untold misery may be saved to their families and the state through the combined efforts of the state, the people and the medical profession. This great thing can be done quickly and effectively. The state and the people are ready. The

third, the most powerful element, is the medical profession. Such a happy combination of conditions may never again recur. May not the powerful influence of this Association at this opportune moment be invoked?

PSYCHOSES RESULTING FROM COAL GAS ASPHYXIATION.*

SANGER BROWN, M.D.
CHICAGO.

For the past ten years at least, reports of cases of psychoses from coal gas poisoning are few. They are frequent enough, however, to demonstrate an apparent relation of cause and effect.

Greidenberg[1] reports 3 cases. The first patient, a woman of 58, whose symptoms were headache, vomiting, apathy, refusal of food, dysentery and, finally, death. The symptoms were thought to be of such a nature as to warrant a diagnosis of acute dementia. The second patient was also a woman who did not actually lose consciousness, the most prominent symptom being whining, apathy and weakness of memory. Recovery supervened after four months. The third was the case of a man of 45 who, in earlier life, had been intemperate. Ten days after asphyxiation he became forgetful, rambling, restless, excitable, sleepless and apathetic. His articulation was indistinct; he gave incorrect answers to simple questions and made incorrect statements. Urine and feces were passed in bed from inattention and there was hemiparesis. The term pseudoparalytic dementia was applied to this case.

Agostini[2] reports two cases with permanent retrograde amnesia. Hedren[3] reports a case in which the patient felt well for a short time after recovery from the acute symptoms. Then followed headache, pains in the extremities, peevishness, weakness of memory, staggering gait, incontinence of urine, complete apathy, muscular rigidity, exaggeration of the knee jerks, fibrillary spasm of muscles and, finally, death from bronchopneumonia.

The following changes were found in the nervous system:

1. Numerous small hemorrhages in the pia of the brain and in the cord.

2. Small bloodless patches throughout the whole cord, in some of which actual softening had taken place.

3. Thrombi in the small vessels of the optic thalamus.

4. Fatty degeneration of the endothelium of the small vessels of the central nervous system.

5. Chromalytic and atrophic changes in the large motor cells of the cord.

6. Partial thickening of the pia of the brain.

7. Degenerative changes throughout the nervous system.

Sibelius[4] reports a case of severe poisoning followed by dementia, paresis, visceral disturbance and death, in which the postmortem findings were similar to those reported in the preceding case. In fact, I find much similarity of the findings in most postmortem reports.

Patient.—S. E., aged 34, single, was admitted to the Kenilworth Sanitarium April 6, 1905. Patient was a real estate dealer, of correct habits. His family history was negative and previous health good.

History.—Nov. 7 patient was found at 7:30 a. m. in a sitting posture leaning against the wall near a gas stove from which gas was freely escaping. He was accustomed to prepare a light breakfast in his rooms and he was evidently so engaged when overcome.

When discovered he was unconscious, the face a deep purple, and the body entirely flaccid. He was picked up and carried to a bed in a nearby room when a general and intense tonic spasm set in which lasted several hours. By the diligent use of active restorative measures, including free inhalation of oxygen, he regained consciousness at the end of three days, and in three weeks he was able to be up and about. His pulse was about 140 and he suffered from dyspnea on slight exertion. His face continued purple and his expression dull and stolid. He complained of no pain, ate enough with slight urging, and slept well. The friends who accompanied him said that his bodily and mental symptoms on admission to the sanitarium were essentially the same as they had been prior to that time.

Examination.—On examination the following notes were made: Height, scarcely five feet; weight, 147 pounds. No abnormalities could be discovered in the viscera and careful examination of the urine was negative. Analysis of the blood showed: Percentage hemoglobin, 80; number of red cells per c.mm., 5,224,000; percentage of red cells, 104.48; corpuscle hemoglobin index, 70.7; number of white cells per c.mm., 14,200; polymorphonuclears, 82; large mononuclears, 4; small mononuclears, 15; eosinophiles, 1.

Vision was good in the right eye and the pupil reacted to light and accommodation. The left was injured by an accident in childhood and rendered useless. The fundus was not examined. Motion, sensation, superficial and deep reflexes, gait and station presented no variations worthy of note. The pulse varied from 108 to 140 throughout his residence at the sanitarium; nearly always over 120. The temperature was normal. The appetite, sleep and condition of the bowels were satisfactory.

Further History.—He had no recollection of anything that transpired for from thirty-six to forty-eight hours prior to the time when he was discovered in his room, though it is known he was at the baths in the Palmer House in the evening of Nov. 6.

He recognized his old acquaintances and repeated their names and discussed correctly with them various matters relating to a period prior to the asphyxiation. He repeated incidents of early life and childhood usually well, but retained practically nothing since the afternoon of Nov. 6. He could not remember what took place from hour to hour, even the visit of an old friend whom he was very glad to see. By dint of constant practice he finally remembered the name of his nurse and his way to the toilet and dining rooms. He could read and make simple computations in arithmetic. He realized his disability and wanted to recover, but was not emotional or complaining. He would read the newspaper, but could not discuss current topics. Though he retained some few impressions in his memory enabling him to find his way about the house and when out walking, there was no material improvement while under my observation, a period of fourteen weeks.

After leaving the institution he returned to the care of Dr. Upton, who reports no notable change either in the bodily or mental symptoms, till about two weeks prior to Dec. 31, 1905, when he died. He began to suffer from severe attacks of dyspnea so that he had to be under constant observation. He was more comfortable for two days before his death, which occurred suddenly, soon after he had retired, and while alone in his room. The bedding was not disordered in a way to suggest any sign of a struggle. The autopsy showed no significant macroscopic changes in the brain or cord, and unfortunately

the parts were not preserved for microscopic examination. The lungs were markedly emphysematous, the heart considerably dilated, and there was a cyst of the left suprarenal capsule the size of a large walnut.

It might reasonably be assumed that some deleterious influence not demonstrable by present methods of examination had been exerted on certain of the cerebral neurons so that they were no longer able to retain new impressions as before, and, indeed, the impressions made on them some hours prior to the action of this influence were effaced by it, while impressions of longer standing were not dislodged nor their relationship with each other interrupted. This hypothesis appears more rational than to assume that such multiple capillary hemorrhages or thrombi as have frequently been found postmortem scattered at random throughout the brain and cord might have been accountable for the peculiar mental symptoms. Similarly the tachycardia might be explained by assuming an interference with the nutrition of the neurons which naturally regulate the heart's action.

It would be quite difficult to determine to just what extent the mind was affected as a whole, but no doubt there was some sensible impairment. I have been unable to find in the literature any autopsy report of cases in which retrograde amnesia had been a prominent symptom, and hence regret the brain and cord in this case were not preserved for microscopic study, though, as already suggested, my expectation that such examination would shed very much light on the subject at the present time would not have been very sanguine. The work would have been in the line of progress.

The existence of retrograde amnesia, its intimate causes and medicolegal aspects have been discussed by Wagner,[5] Möbius[6] and others. The peculiar brain changes which give rise to the phenomenon are not at present demonstrable, but that the phenomenon actually occurs under certain conditions the foregoing case pretty plainly shows. Hence its possible importance in medicolegal relations is obvious. For instance, two people might be found together in a state of asphyxiation, one of whom might die without recovering consciousness, the other might recover and actually have no recollection of anything that transpired for a number of hours prior to the period when he was overcome, though circumstances might make it appear probable that he wished to conceal facts within his knowledge covering that time. Instances of retrograde amnesia have been recorded after strangulation from suicidal attempts by hanging. Some authorities claim that only those cases in which severe convulsions were produced were followed by this result.

So far a careful study of the conditions which give rise to the phenomenon is much more valuable than scientific speculation as to the actual changes in the nervous system which produce it.[7]

MALARIAL INFECTION IN CERTAIN NATIVE VILLAGES OF THE CANAL ZONE.

ARTHUR I. KENDALL, PH.D.

Acting Chief, Board of Health Laboratory, Isthmian Canal Commission.

PANAMA.

(*Concluded from page 1154.*)

III. MALARIAL PARASITES AND SPECIES OF MOSQUITOES.

The greatest confusion still attends the classification of the malarial parasites. I follow the terminology which seems most closely to conform to the rules of zoological nomenclature. Schaudinn[1] outlines the terminology which at the present time seems to be the most generally accepted one:

Plasmodium malariæ (Laveran), the quartan parasite.

Plasmodium vivax (Grassi and Feletti), the tertian parasite.

Plasmodium immaculatum (Grassi and Feletti), the estivo-autumnal parasite.

At the same time it is much more convenient for the sake of brevity and clearness to refer to the organisms described in this paper by their clinical manifestations, and the terms tertian, quartan and estivo-autumnal will be used, bearing in mind that these terms, although in a way unscientific, are distinctive and explicit.

Before describing the parasites in detail it may be well to say a few words about the general differential diagnosis between tertian and estivo-autumnal parasites. Every one who has worked with malarial blood will acknowledge that at times it is almost impossible to differentiate between very young forms of the tertian and estivo-autumnal parasites. During the course of the work here there have been several cases in which it was quite impossible to make more than a probable diagnosis at best; at the same time the majority of instances we have been able to find either more adult forms present or there have been full-grown parasites so that the diagnosis was comparatively a simple matter.

The presence of several stages in the life history of a parasite in the blood at one time is not to be wondered at. If one will consider that the natives use no mosquito bars or screens and that absolutely no measures are taken to kill or remove infected mosquitoes, one will readily see that the chances are greatly in favor of successive, irregular inoculations from infected mosquitoes the same night or on successive nights. Parasites introduced into the blood at different times would naturally have a tendency to run their cycles at different intervals with the result that several stages would occur in the same individual at the same time. Indeed, it is not uncommon to find two or even three distinct stages in development of the tertian parasite in the blood of a patient at the same time, giving rise to a double or even triple tertian infection. When three cycles are present at the same time, however, the infection loses, to a considerable extent, its periodicity and becomes more like an estivo-autumnal infection in its clinical manifestations. It is even not uncommon to see two different stages of the tertian parasite in the same blood corpuscle at one time.

The great preponderance of estivo-autumnal infections, as shown both in the tables here and in the Ancon Hospital Report for the period corresponding to that in which this investigation was carried out, is well borne

1. Arb. a. d. kais. Gesundhts., vol. xix, p. 2, 1902.

out by the findings in the dispensaries along the line, and by all odds this infection is the most common in this country. With the arrival of Americans and, in general, people from the more northern climates, there has been a gradual relative increase in the tertian malaria; the estivo-autumnal infection still, however, is the prevailing type among the natives and those exposed to mosquitoes which have become infected in the native villages and which consequently bear the native type of the disease.

The Quartan Parasite.—The quartan parasite is very uncommon here; during the course of this investigation not a case of quartan fever or quartan parasites was encountered, nor was there a case which in any manner resembled a quartan infection. There have been, however, a few cases reported in the hospitals, although they occurred in the majority of instances among men who undoubtedly contracted the disease in the United States.

Estivo-autumnal Parasites.—There are two recognized cycles in estivo-autumnal malaria, respectively twenty-four and forty-eight hours, giving rise to the so-called quotidian and subtertian varieties.

The periodicity in estivo-autumnal malaria, however, is less regular than that of the benign tertian, and there is a distinct tendency for attacks to "anticipate," particularly if medication or resistance on the part of the patient be not sufficiently great to prevent the action of the parasites; furthermore, the attacks tend to become fused; i. e., there are sufficient groups of parasites continuously reaching maturity to keep up a more or less steady stream of toxin, which is manifested clinically as a prolonged elevation of temperature, in which the quotidian or tertian tendency is manifested by major elevations, the lesser cycles by smaller excursions of temperature. This is particularly true of the subtertian type.

One may also have more or less regular, well-marked double or triple subtertian attacks, or double quotidian attacks, although the latter are much less well defined and uncommon.

The parasites are endoglobular during practically the entire course of their development. The earliest forms are minute, rather irregular, refractile bodies, with at times a tendency to assume the shape of a clover leaf; their form changes slowly at first, later with considerable rapidity. This body is located, as a rule, near the edge, on the edge (best and most clearly seen in stained preparations), or even lying in an apparent nick in the periphery of the red blood cell. The parasite changes its position in the corpuscle, grows gradually larger and coincidently the rapidity of the ameboid movement increases.

Not infrequently in grave cases of malaria one sees red blood cells which are shrunken and dark colored—the so-called "brassy corpuscles." They do not occur in every case, nor do parasites in severe cases necessarily give rise to this change in the erythrocytes. They do not occur exclusively in a grave infection either, and there is nothing to warrant the assumption that they are but of occasional occurrence and of no other diagnostic importance than any estivo-autumnal parasite. The ameboid stage may last for several hours; longer if the preparation be kept warm on a suitable warm stage, a shorter time if the slide cools. In the body the change is brought about in a few hours, giving rise to the ring form.

There is some dispute as to the mechanism of the formation of the ring. Marchiafava and Celli believe the rings are merely ameboid bodies which have become attenuated at the center, with a corresponding thickening at the periphery. The thin, central portion allows the hemoglobin to show through, giving the dark appearance so familiar in these bodies. Osler, Councilman and Antoisei believe the ring is formed by the inclusion of a portion of the red blood cell; the parasite first assumes a horse-shoe formation, the ends gradually penetrate through a portion of the erythrocyte, and the coalescence of the two horns of the crescentic parasite includes the small portion of the red blood cell. Marchiafava and Bignami, while not denying that this process may occur, believe that rings formed in this manner are not permanent; that they tend to return to the ameboid stage. In two instances I have seen the process described by Osler and Councilman occur. The ring so formed lasted in one instance for three hours. The preparation was cast aside after that time. From the fact that the center of the ring seems darker than the peripheral portion of the erythrocyte Marchiafava and Celli argue that the center must be of different material. But this is not a necessary assumption; the central portion may seem darker by contrast.[2]

The estivo-autumnal ring is small, rarely more than one-fifth the size of the red blood cell, and comparatively refractile. It is, as a rule, slightly fusiform or shaped like a clover leaf, particularly in the early portion of its existence. In the older rings there is usually a small amount of dark-colored pigment, arranged generally at the periphery of the parasite, and having only very slight movement; the rings themselves at this stage are less like the "signet ring" of the tertian parasite, being much thinner and less conspicuous.

The ring stage is succeeded by another ameboid stage; the parasite at this time is larger than the first ameboid and less actively motile. The production of pseudopodia at this time is, to a considerable extent, replaced by a sort of mobility; the parasite changes shape, but as a whole rather than by the protrusion and withdrawal of portions of its substance. The second ameboid stage is, except in rare cases, the last appearance of the parasite in the peripheral circulation. In severe cases, rarely in cases which are not severe, one may occasionally see the segmental process, but, with the exception of the crescent, one practically must follow the further development with parasites obtained by splenic puncture or from autopsies.

The localization of the parasites in the body, after they have left the peripheral circulation, has much to do with the clinical manifestations of the attack, gastric, cerebral, etc.

In the many autopsies I have seen and examined while engaged in this work, extending over eighteen months, there have been many so-called cases of malignant or pernicious malaria. The localization of the parasites in the brain, heart or stomach will, as a rule, explain in part the symptoms, but in no instance have there been any forms of the parasite noted which suggest even remotely that one is dealing with anything but the regular types of organisms already known to the profession.

In some cases there have been bizarre forms which stain with the metachromatic stains in a manner to suggest new forms, but they are not in sufficient numbers in any one case or of common occurrence in simi-

2. It should be mentioned that the estivo-autumnal ameboid is more refractile than the corresponding stage in the tertian parasite.

cases to warrant the assumption of any relation, however remote, with the illness or death of the patient. I have no reason to believe that pernicious or malignant malaria is other than the resultant of the following factors: (a) Large numbers of estivo-autumnal parasites; (b) comparatively exalted virulence of the parasites; (c) relatively low resistance on the part of the patient.

In some instances of extremely severe attacks of malaria, there have been only a very few parasites in the peripheral circulation; it may even be impossible to find them, but at autopsy they will be found in the bone marrow, spleen, heart, brain or some other internal organ. In the majority of severe or pernicious cases, however, there are many organisms in the peripheral circulation.

The so-called Chagres fever, a severe type of malaria, is caused by the estivo-autumnal parasite.

Crescents and Ovoid Bodies.—One usually associates crescents and ovoids with estivo-autumnal malaria; at least they are said to occur with a considerable degree of regularity, and one would expect to find them frequently in more or less protracted cases of malaria caused by this parasite.

The observation is general in Panama that the crescents and ovoids are comparatively uncommon.

There is no apparent reason for this. One would surely expect to find them in the blood of natives who have repeated attacks, and particularly among the young natives who have malaria almost continuously during certain periods of the year.

I have observed many cases of this kind, and particularly a gang of men who were working under my immediate direction. The men were under 25 years of age, and came from Martinique, which, except for a few locations along the sea coast, is said to be free from malaria. The blood of all these men was examined as soon as they arrived; they were landed from the steamer in the middle of the day, and brought to Panama in daylight. The blood was examined for three days and there was not the slightest indication of malaria. The men themselves declared they had never been sick with fever of any sort. They were lodged in a house which had been inhabited by some Jamaican laborers, from whose ranks there had been several severe cases of estivo-autumnal malaria. In two weeks, in spite of six grains of quinin solution a day per man, five came down with severe attacks.

During the three months they were under observation all were in the hospital at least twice, most of them three or four times. In only one case, which was one of those having only two slight attacks, were there crescents.

The distribution of crescents and ovoids among the natives of different ages will be described in another section of this paper.

The fact that these bodies are relatively uncommon would suggest that either the parasites develop into the crescents or ovoids in the mosquito from some antecedent form or else there is some other sexual form in virtue of which the parasites are able to complete their sexual cycle in the majority of cases in Panama.

I am engaged in a series of experiments to throw more light on this phase of the problem.

Tertian Malaria.—As its name implies, the tertian cycle takes approximately forty-eight hours to complete, although the time is not absolutely definite. In some cases, particularly those of rather more than moderate severity, the tendency is for the cycle to become shortened or to "anticipate." Conversely, as the attack is abating, in many instances the period is lengthened, giving rise to paroxysms more than forty-eight hours apart.

More than one cycle may be in progress at the same time, so that one may see two or even more series of parasites in various stages of development; in fact, a typical, single tertian fever is comparatively rare. Almost always one sees at least two sets of parasites in different stages of development. Conversely, in some of the more severe types the combination of several cycles and the tendency to anticipate cause a more or less marked fusion of excursions of temperature, with a resulting continuity of fever. This is not, however, as marked as is the case with the estivo-autumnal fevers.

As already stated, the younger stages in development of the tertian parasite are difficult to distinguish from the corresponding periods in development of the estivo-autumnal parasites. They are, however, somewhat larger and less refractile than the average estivo-autumnal organisms and rather more actively motile. The rapid succession of irregular, ameboid body, ring-shaped forms and linear forms occurring in the same parasite within a very few minutes is quite characteristic. This is most noticeable when the blood is fresh and kept in a fairly warm atmosphere.

The pigmented forms appear relatively earlier and are much more common; the pigment is very fine, and, as a rule, situated more or less peripherally, particularly in the ends of the pseudopodia. The rapid succession of forms involves the change in position of the pigment, and I believe that to a considerable extent this is the cause of the so-called motility of the pigment. In stained preparations the cytoplasm is much greater in extent in the tertian parasites, stage for stage; the chromatin body more pronounced; there are more vacuoles, and there is a more strongly marked clear zone around the chromatin than in the estivo-autumnal organism.

Comparatively early in the life of the tertian parasite the red blood cell usually becomes pale and swollen; this is probably the cause of the apparent lesser refractility of the tertian parasite, whereas in the estivo-autumnal organism there is a tendency for the red blood corpuscles to become darker, probably thus increasing the apparent refractility. Ewing has noted the not infrequent occurrence of so-called conjugating forms; two rings have apparently fused and he interprets this as an actual reproductive stage. While such forms are not rare, there seems to be no evidence in favor of this view; not infrequently one will see two centrosomes in one ring or one centrosome in a double ring, so situated as to preclude the possibility of fusion of centrosomes within any comparatively recent time.

The tertian parasite increases rapidly in size, mostly by growth of cytoplasm; the centrosome does not grow in proportion. The organism finally occupies four-fifths of the cell, sometimes almost the entire corpuscle, so that only with the closest scrutiny can one see the edge of the erythrocyte. The pigment increases in amount and finally becomes arranged more or less peripherally, preparatory to segmentation. Inasmuch as these forms (segmenting) are relatively uncommon, no detailed description will be made here. In stained specimens, one frequently sees in the older forms a peculiar red stippling of the erythrocyte; this is by no means a new observation, but it seems to be characteristic of the tertian infection, and I do not remember having seen it in the estivo-autumnal parasites.

Bodies, free in the blood serum, having the exact morphology and staining reactions of one-third to one-half grown tertian parasites, are seen occasionally. I

am inclined to believe they are, in reality, organisms which have been expressed by some means from the red blood cells, not that they represent an extracellular stage in development comparable to the full-grown parasite. At the same time one must consider the possibility of degenerated leucocytes.

Anopheles.—Without intending to discuss mosquitoes in this paper, I must mention the more common species of the genus *Anopheles*, the only genus of the *Culicidæ* known at the present time to play an important part in the transmission of malaria.

There are two anopheles in Panama which are relatively common: *A. albipes* and *A. pseudopunctipennis.* Of these the former is much the more important and abundant.[3]

I have strong circumstantial evidence that *A. albipes* is a very important mosquito in malarial transmission on the Isthmus, as the following case shows:

There is a row of small houses on the north side of Ancon Hill which originally were intended as quarters for lepers; they were used, however, for temporary barracks for some Jamaican laborers, one of whom suffered from a severe attack of malaria shortly before leaving the place. The houses were vacated for a week and turned over to a force of seven men who were brought in a steamer directly from Martinique to these quarters under my personal supervision. The journey from the ship to these houses was made in the middle of the day, when mosquitoes do not bite as a rule, and there is no probability that the men contracted malaria at this time. The blood of each man was very carefully examined for three successive days and found negative.

The men had lived in a portion of Martinique which is said to be free from malaria, and all claimed never to have suffered from fever of any kind. None had enlarged spleens, which are very common in this part of the world. Their work was purposely confined to a region immediately about their houses, and their only excursions from this place were to go to meals, about a quarter of a mile; this trip was always made before dark; they ate with a number of other negroes in a place which was as free from mosquitoes as could be found.

At the end of ten days malaria appeared; four were sent to the hospital suffering from severe estivo-autumnal infections; in six weeks all except one of the number had been in the hospital, all with precisely the same symptoms and running practically the same course, a typical estivo-autumnal infection which was clinically like that of the Jamaican who had lived in the house before them. Investigation of the house showed enormous numbers of *A. albipes;* the first day I removed fifty-six in about an hour. Two days later as many more were taken. The men had complained bitterly about the insects, and these mosquitoes were almost without exception engorged with blood. Very few male mosquitoes were seen. The other three houses, although within a few feet of the one inhabited by the Martinique men, were free from mosquitoes. No one had lived in them up to that time.

The house was screened, the ground round about cleared for a distance of seventy-five yards in every direction, a few marshy spots abolished and a general fumigation of the place made. The larvæ of the anopheles, which abounded within a few yards of the door of the house, were killed, the drains improved and the men placed on a regular quinin treatment consisting of three grains of quinin solution three times a day; this was taken in the presence of the foreman, and kept up for three months, at the end of which time the malaria had practically disappeared from all the men except two who contracted the disease in a chronic form and who later on were deported. In every case only *A. albipes* was found; no other anopheles being observed in all the insects removed from these houses.

In the huts of the natives along the line the same results have obtained; in almost every dwelling one may find albipes by simple sweeping with a broom along the roof of the house; the native huts are made of cane, with thatch for a covering, and the latter makes an excellent hiding place for the mosquitoes who remain quiescent during the day, but bite vigorously during the night. In fully 90 per cent. of such houses I found albipes, rarely any other species of anopheles.

IV. RESULTS OBTAINED IN THIS INVESTIGATION.

Race, Age and Sex.—Almost all writers agree that the very young suffer more than the adolescent and very old from malaria in tropical and subtropical countries. Koch found in New Guinea that 100 per cent. of the new-born were infected, and that the percentage of infected individuals gradually diminished up to the twenty-first year; from that age the natives suffered little from malaria. There seemed to be no perceptible distinction in the native population between males and females; each equally infected or free from parasites. He noted that many children with huge spleens and blood teeming with malarial organisms were running about "in rude health." Stephens, Christophers and Daniels, apparently confirming Koch's work in central Africa, believe the new-born and very young children are the most frequent sources from which mosquitoes are infected; they do not state the age limits when this tendency disappears, but one is led to infer that older children were relatively free from parasites in the peripheral circulation.

Schelling places the limit at which malarial parasites tend to disappear from the blood at 35 years; this is certainly less in harmony with the conditions here. While agreeing that the young are the most susceptible, most writers do not consider any age free from infection. We have found young urchins here, not more than 12 years of age, running about "in rude health" with temperatures from 101 to 103 where blood was literally filled with malarial parasites, usually estivo-autumnal rings. Marchiafava and Bignami write: "Malaria spares no age; but infants and children are more subject to this disease than adults. This is explained, in part at least, by the predilection of mosquitoes to attack delicate skins and by the very deep slumber of infants." Scheule is inclined to attribute the relative immunity in negroes, particularly the older ones, to their thick skin and pungent odor which, unless no more desirable subjects are available, drives away the mosquitoes. It is interesting to note that certain French observers have made similar observations; with *Stegomyia fasciata* they found the order of biting was as follows: Infants, young well-nourished individuals, well-nourished old people, anemic persons, all white; then young negro babies, children and finally adults. In Panama I have had the greatest difficulty in causing *Anopheles, Stegomyia* or *Culex* to bite adult negroes, while they would bite with the greatest eagerness any white individual exposed to their action.

Celli gives the following table of mortality according to age in Italy. It should be noted that this result, while having a bearing on the subject, is not comparable with the results mentioned above and not necessarily with the data tabulated in this paper:

Birth-5 yrs.	5-10 yrs.	11-20 yrs.	20-40 yrs.	40-60 yrs.	60-80 yrs.
19.4	48.9	38.6	24.3	23.9	23.9

3. It may be of interest to tabulate the species of anopheles which at the present time are supposed to transmit malaria. The information is drawn largely from Theobald, Howard and Giles.

Africa: *A. costalis, funestus, paludis.*
Europe: *A. bifurcatus, superpictus, maculipennis (clavigci).*
India: *A. simensis (pseudopictus) Rossii, fuliginatus, culifacis, barbitilis,. Stephensii, Theobaldi, barbirostris, Turkhudi.*
America: *1. argyrotarsis, albipes.*

Therefore, no age is spared. The above statistics enable us not only to affirm that the highest mortality is between the ages of 5 and 20 years, but that malaria is relatively more prevalent in the older children than in the very young. Notter says: "As regards age and sex, males appear to suffer more than females, but possibly this is due to increased exposure to attack. No age seems to be exempt, although attacks are certainly less frequent among the very young and the very old." Stephenson and Murphy make practically the same statements as Notter, and, while laying stress on the fact that no age is spared, imply that the very young and very old are less liable to malarial attacks than the intermediate ages. Beim, Kohlstock and F. Plehn claim that malaria can exist *in utero*. They cite the case of a pregnant woman who had simple tertian malaria with chills every other day; on the alternate days the fetus had chills which were plainly felt through the abdominal wall of the mother. Bignami, Bastianelli, Caccini and Thayer, in a series of autopsies on pregnant women, found that the fetus shows no signs of malaria either in the blood or in pigmentation of the spleen or other organ. I saw a perfectly similar case.

The results of my observations in Panama, while comprising *in toto* a fairly large number of cases, are based on relatively few observations for each age-period. At the same time the results are fairly conclusive, particularly when they are compared with the observations made by writers in different countries.

With respect to age, the percentage of infection is very high at birth (including all individuals from birth to 1 year of age in this connection) and diminishes slightly and progressively until the fifteenth year is attained. From 15 years to old age the number of infected individuals decreases markedly in comparison with the previous years, but never goes so low as to warrant the statement that adolescence and old age are comparatively free from malaria. In fact, at any age over one-third of the inhabitants at the time these results were obtained harbored malarial parasites in their peripheral circulation. This does not necessarily mean that the same high general average would obtain all the year. In fact, the reverse is probably true. These observations were made during the height of the malarial season (October to January), and this period agrees well with the period of highest malarial illness in the hospitals. During the dry season the natives all agree that malaria is much less prevalent and much less severe.

The malarial infection is greatest during the first year of life and diminishes slightly up to the age of 15; from 15 on there is a rather abrupt drop, which remains practically the same through adolescence and old age, but at no time or in any age does the infection disappear entirely (Tables 1, 2, 3 and 4).

The statements concerning *sex* made by some observers do not obtain in Panama; instead of males being much more susceptible to malaria, there is very little difference between the males and females. Averaging the whole series of results, probably the males would show a slight increase over the females in infection, but the difference is so slight and so unevenly divided between the different periods of life that it is not safe to hazard an opinion on this subject.

Concerning the different *races*, the results show conclusively that the natives are much less infected after the first year than the foreign element. This is a point of great importance and will be discussed at greater length in the section on immunity. It will be sufficient to state here that the native born seem to be equally prone to malaria during the first year of life, and the symptoms are quite as severe as in the foreign born in the cases I have seen. From the first year, however, the cases, as a rule, are less severe, and even when the

* Indicated Panamanians, i. e., natives. † Jamaicans, i. e., foreign born. This includes natives of the West Indies.

parasites are present in the blood the individuals suffer relatively less than the foreign born; they enjoy a "rude health," to repeat Koch's epithet.

Table 4 is a summary of the results of this investigation tabulated according to race and sex; for convenience the natives are contrasted with all other peoples, not native born. When the data on which this table is based were obtained, particular attention was paid to the question of birthplace and place of residence of each individual. This plan was carried out even to the very youngest; under the heading "Panamanian" is included all those whose parents are natives of Panama or Colombia, while the term "Jamaican" includes all other individuals. Usually, in fact almost exclusively, the latter are natives of the West Indies and have lived in this climate a comparatively short time. The very young of this class were, however, as a rule, born in Panama.

We have, then, two distinct groups of cases—one whose parents are native born and who have been exposed to the type of malaria prevalent in Panama from earliest infancy; the other those of foreign parentage and not exposed to this type of malaria.

The fact that the very young of both classes are born in Panama might at first sight seem to be prejudicial to exact results, but the fact that the young of both classes suffer equally from this disease simplifies what otherwise would be a serious objection to the table herein outlined.

Of the 355 natives examined, 202 were positive and 153 negative; this is very nearly 4 positive to every 3 negative, or 57 per cent., with malarial parasites in their blood as contrasted with 43 per cent. without parasites. Of the foreigners, on the other hand, 135 cases, 98, or about 73 per cent., were positive, while 37, or 27 per cent., were negative. In other words, of the native born (all ages) three out of five were positive to malaria, while the foreign born had three out of four with malarial parasites. Table 4 shows quite clearly that up to 15 years of age both native and foreign born children suffer severely from malarial infection. The effect of long-continued residence in this particular climate is shown in Table 5.

Even in the very young, under 5 years of age, there is a noticeable difference in the percentage infected between natives and foreigners, but this is much less marked than the differences obtaining after one reaches the age of 15; from that time on the ratio of infected to non-infected is much different; the natives have less infected than non-infected in the proportion of about three to four, while the foreign born have more infected than non-infected in the proportion of five to three.

TABLE 5.

Totals	26	31	34	50	40	20	13	8
Grand totals	94	60	108	93	71	22	27	15

This fact is very significant; in the native born, at the age of about 15, the proportion of infected to non-infected changes from nearly two to one to a ratio of about three positive to four negative; in the foreign element the ratio of five infected to one non-infected, up to 15 years, changes to five infected to two non-infected during the later years of life. This can mean but one thing: That in extreme youth the children or, more properly, infants are all extremely susceptible to malaria; as they become older this susceptibility seems to diminish, or at least there are fewer cases in our series relatively showing malarial parasites in their peripheral circulation: the change to relative immunity begins much younger in the natives and is developed to a much higher degree, so that in the older individuals actually less than one person is infected for about every two infected while in the foreign population, although there is a distinct tendency toward an acquired immunity, the change never becomes marked, and at no time does the latter class begin to show the resistance and the lessened infection to the malarial parasites that we see in the natives.

We have, then, among the natives a distinct acquired immunity; this is manifested by the greatly lessened number of infected individuals to non-infected individuals as one chooses later periods of life for comparison. At the same time there is strong evidence to show a tendency at least toward congenital or inherited immunity. This is amply shown by the above statistics; the differences between the groups of individuals is extremely well marked, and there can be no doubt whatever that the inferences drawn by previous investigators concerning the existence of an acquired immunity among those who have lived in countries where they are continually exposed to malaria are correct.

Occupation.—Malaria is an environmental rather than an occupational disease; while text-books enlarge on the evil effects following certain occupations, one must not infer that the vocation *per se* is the essential factor. For example, the pastoral population of certain portions of Italy suffer excessively from malaria, but, aside from certain lowering of the body resistance by exposure, the malarial mosquito is the infecting agent, and this disease occurs merely because the people, of necessity, must live in places where such insects abound. If the laborers can return, after the working day, to locations free from anopheles, the suffering from malaria is reduced to a minimum.

In order to determine, if possible, the relation between occupation and malaria in Panama, the natives were questioned at the time of their examination concerning their occupations. In many instances no information could be gained; those individuals, however, who did have an occupation were questioned closely concerning the character of the work, and the table shows the results of our observations in this direction.

There seems to be no general rule with regard to the percentage of infected individuals in any trade; the results are extremely varied and from one point of view inconclusive; what they do show, however, is the fact that no one occupation is really less conducive to malaria than any other. In other words, my results simply confirm the statement that malaria is environmental, and occupation, as a rule, has no effect on the general tendency toward this disease.

Immunity.—This is one of the most interesting, perplexing and important problems, even aside from its probable relation to acclimatization, that one has to do with in tropical countries.

This table comprises only a small fraction of the total number of individuals examined; the majority, however, would give no occupation when asked; only those acknowledging a calling are included in the table.

After discussing certain factors supposedly predisposing to malaria, in which he lays considerable stress on those factors which tend to lower the vital resistance, Celli discusses to considerable length the question, "Are there races immune from malaria"? He cites the case of bovine malaria in the cattle in the Campagna; they are rarely attacked by this disease, while cattle imported from Holland, Switzerland, Lombardy and other neighboring countries are rapidly decimated. Concerning human malaria, he cites Maurel, who says: "Practically no human race is immune to malaria, not even the black race, said by some to be immune. In places where severe malaria exists, certainly the black population which inhabits them acquires a relative immunity to the disease; but if in these same places another black population arrives which previously inhabited non-malarious places it is decimated by the fevers. A white population, also, which for centuries has lived in regions of intense malaria, finally acquires a relative immunity against malaria; that is, adapts itself to resist it. By this means a remarkable population, whose ancestors have lived in the Pontine Marshes for centuries, has become resistant to malaria; while a colony of Venetians, who lately were brought thither, were literally decimated by the fevers." Again, the poorly fed, poorly housed so-called hut dwellers, although much less physically fit than the agricultural peoples living in relatively healthy surroundings, suffer to a much less extent than the latter. Therefore, the fact of a natural relative immunity of some races from malarial infection is evident. This comes about apparently by habits and customs appropriate to such conditions and partly, no doubt, by an acquired tolerance to the malarial toxin or organism brought about by repeated attacks and recoveries.

Marchiafava and Bignami have summarized the status of malarial immunity thus:

We have seen that even when placed under the same conditions not all races are equally prone to contract malaria. Although there are no races originally immune to malaria, we are forced to recognize the fact that the various races present a varying degree of resistance to malarial infection; thus negroes inhabiting malarious regions in the tropics are less subject than white men in the same place to grave forms of malaria, and having once been infected they acquire, so it has been asserted, a relative immunity more readily than whites. Writers do not agree that negroes are racially immune; probably this is not true. The residents of the Kamerun coast, according to F. Plehn, seldom have malaria, and when they do the paroxysm rarely lasts more than a few hours. A change of residence deprives them of this relative immunity, at least temporarily. The relative immunity enjoyed by the natives of Abruzzo, in Italy, seems to be partly at least an acquired characteristic and partly congenital. This is explained by a process of natural selection, whereby in past generations those more fitted to withstand the malarial infection survived the ordeal and transmitted their acquired relative immunity to their offspring. The acquired factor is, however, less marked than would seem at first sight, while instances are known in which an active, acquired immunity has apparently been produced; these well authenticated cases are rare, and one can safely count only on the racial relative immunity as a whole.

Koch has confirmed the relative immunity of the negroes of the west coast of Africa, and has noted the course of the estivo-autumnal fevers (tropical fevers) in them and the occurrence of a spontaneous cure.

Cinchonization Experiments.—These experiments were undertaken to see if moderately small doses of quinin repeated daily for a short time would cause malarial parasites to disappear from the peripheral circulation in individuals who had no severe symptoms in addition to the organisms. Children, whose ages ranged from 6 to 16, were chosen for this work, and for convenience those attending school were especially selected. Such individuals would, to a certain extent, have acquired a tolerance for the malarial parasite without the development of immunity to any considerable degree.

Forty-one children took sulphate of quinin, 4 gr., in the form of a tabloid for six successive days. The drug was administered at the local dispensary, where the children reported at a definite time each day, and was taken in the presence of the attendant at that time, who made a record for each case. Six of the forty-one patients showed no malaria after three examinations made on successive days, and they were used as controls. It is perfectly possible that, existing in a latent form, malaria might be brought out by the drug, and it was for this reason that the controls were brought in. At the end of six days thirteen showed malarial parasites; this examination was repeated the next day with the same results, so there can be no doubt that in certain cases, at least, in which no definite febrile symptoms exist, quinin will not, in the dose given and in the given time, remove the parasites completely from the

blood. None of the controls showed parasites at the end of the six days.

SUMMARY AND CONCLUSIONS.

1. Malaria existed in certain towns of the Canal Zone at the time this work was done to such an extent that over 50 per cent. of the native born and 70 per cent. of the foreign born harbored parasites in their peripheral circulation.

2. This high percentage of infection does not necessarily mean that a corresponding number present febrile symptoms; in fact, many do not.

3. This high percentage of infection is a menace to the health of those who, by reason of their work, may be compelled to remain in such towns, particularly because of the wide distribution of the *Anopheles albipes*, a mosquito shown to be capable of transmitting malaria. Other anopheles to a lesser extent may also be factors in distributing malaria.

4. The estivo-autumnal malaria is the prevalent type; the Chagres fever is, in all probability, a severe estivo-autumnal infection. Pernicious malaria is not caused by a new parasite, but by an estivo-autumnal organism of exalted virulence.

5. Natives and their descendants or, in general, the descendants of those who have lived continuously on the Isthmus of Panama for many years, at birth have, to a certain degree, an inherited immunity; an active immunity, which is by no means absolute, is generally acquired, becoming manifest at about the age of 16. The foreign born acquires a tolerance to the malarial organism; this tolerance, however, is not as great nor does it begin as early as is the case with natives.

6. Malaria is an environmental disease; occupation has very little to do with the cause of this disease.

7. Quinin in moderate daily doses, while not absolutely guaranteeing freedom from malaria, or completely driving organisms from the circulation, has an important preventive and curative effect.

In conclusion, I wish to express my indebtedness to Col. W. C. Gorgas, Chief Sanitary Officer, and to Major H. R. Carter, Director of Hospitals, for their advice and kindly criticism during the progress of this work.

A REVIEW OF CANCER IN THE UNITED STATES, ACCORDING TO THE TWELFTH CENSUS.*

GUTHRIE McCONNELL, M.D.
Pathologist to the St. Louis Skin and Cancer Hospital.
ST. LOUIS.

There is no question before the profession or the laity that commands so much interest and even anxiety as that of the presence and mortality of carcinoma.

For many years there have been more or less sporadic efforts toward the investigation of the subject, but it is only within the last decade that serious attempts have been made in that direction. In that period various institutions have been established for the specific purpose of investigating this disease in all its relations, social, biologic, physiologic, chemic and pathologic. Although there has been no one discovery to stand forth beyond all others, yet valuable work has been done and is being done. The question was such a comparatively new one that much labor had to be expended in clearing the field from dead wood. Many ideas and theories had to be eliminated. With the field once cleared progress can be made much more rapidly and successfully.

The discovery that malignant tumors exist in the lower animals in their wild states has removed many of the beliefs concerning the effects of civilization on their formation. By the experiments conducted on mice in regard to the transplantation of carcinoma much may be reasoned out in its analogy to neoplasms in mankind.

Besides the laboratory investigations there is still much of value to be obtained from the statistical reviews concerning the prevalence of carcinoma in relation to the population of given countries or sections.

A question that still remains, to a certain degree, unsettled is whether carcinoma is actually on the increase. The opponents of that belief argue that the increase is an apparent one only and not real. They claim that the present figures represent merely an improvement both in the methods of diagnosis and in the registration of cases. Such objections may hold good to a certain degree if the figures of forty and fifty years ago are compared with those of to-day. Our methods of the present are more accurate in every way and may be answerable for some of the increase. If, however, the figures of the past two decades are taken into consideration the objections can not hold to such an extent. The improvements in diagnosis in that time have not advanced so wonderfully.

Further, as laboratory methods have improved many tumors have been removed from the category of malignant growths and have been put in the benign class. It would seem reasonable to expect that improved diagnoses would decrease the number of carcinoma cases. Instead of every tumor present in a person dying being considered the cause of death, and consequently cancerous, their true nature is now disclosed.

For the sake of comparison the death rates from consumption and pneumonia have been included with that of cancer in Table 1. This shows the principal reported causes of deaths in the United States in the census years of 1900 and 1890, in the order of their frequency, with the proportion from each cause per 100,000 from all causes.

TABLE 1.

	1900.		1890.	
Cause of death.	Number.	Proportion.	Number.	Proportion.
Consumption.	111,059	10,688	102,199	12,146
Pneumonia	105,971	10,198	76,196	9,091
Cancer	29,475	2,837	18,536	2,203

The census table, of which Table 1 is a part, also shows an increase over 1890 in the proportion of deaths due to pneumonia, heart disease, diseases of the kidney, typhoid fever and cancer and a decrease in consumption and diarrheal diseases. In this table cancer ranks sixth.

For the registration area in 1900 and 1890 the number of deaths from certain causes and the death rates due to each cause per 100,000 of population were: In 1890 the number of deaths from cancer was 9,410 and the death rate was 47.9. At that time cancer came thirteenth on the list of causes of death. In 1900 there were 17,296 deaths, with a death rate of 60.0 and a position of seventh on the list. The figures for the corresponding years from consumption were, for 1890, 48,236 deaths and a death rate of 245.4; for 1900, 54,898 deaths and a rate of 190.5. From being first it dropped to second on the list. From pneumonia there were in 1890, 36,552 deaths and a rate of 186.9; for 1900, 55,296 deaths and a rate of 191.9, thus displacing consumption from the first place. The tables from which these figures are obtained show an increase in the relative mortality from diseases most frequent in adult life and advanced age and a decided decrease incident to infancy and early youth.

* Compiled from the last census of the United States. Figures concerning other countries have been obtained from various sources.

The death rate from consumption, pneumonia and cancer in the registration area and its subdivisions per 100,000 of population in 1900 in comparison with 1890 is shown in Table 2.

TABLE 2.

	Pneumonia.		Consumption.		Cancer.	
	1900.	1890.	1900.	1890.	1900.	1890.
Registration record...	191.9	186.9	190.5	245.4	60.0	47.9
Registration, cities..	210.5	201.4	208.2	265.6	58.3	47.1
Registration, states:						
Total	193.3	197.3	179.4	249.9	62.1	50.9
Cities	233.1	234.1	249.0	208.7	59.8	51.3
Rural	135.9	141.1	137.1	181.0	65.3	50.3
Registration, cities in other states	189.9	171.1	207.7	239.9	57.0	43.2

From this table it is seen that the decrease in the death rate per 100,000 of population in consumption in the past ten years was 51.9. In that same time the death rate in cancer has increased 12.1 and pneumonia 5.0 per 100,000, as shown in Table 3.

TABLE 3.

	Total.	Cities.	Registration Total.	States: Cities.	Rural.	Cities in Other States.
Consumption, decrease..	54.9	57.4	69.6	84.8	43.9	32.2
Pneumonia, increase....	5.0	9.1	4.0*	1.0	5.2	18.8
Cancer, increase	12.1	11.2	11.2	8.5	15.0	13.8

* Decrease.

According to the rate of increase, cancer comes fifth, being led by the increase in diseases of the kidney, in fluenza, apoplexy and heart disease. The following tables and conclusions deal more definitely with the social and economic phases of carcinoma.

Deaths from cancer and tumor are first considered because it is impossible to distinguish them as they are commonly reported. Other points will be taken up more especially from the figures in the registration area. In Table 4 deaths from cancer are set forth for the census year of 1900.

TABLE 4.

	United States.		Registration area.	
	Male.	Female.	Male.	Female.
Cancer	11,436	18,039	6,388	10,908
Tumor	1,305	2,122	694	973

The total number was 32,902, of which 12,741 were males and 20,161 females. The proportion of deaths from these diseases in 1,000 deaths from a known cause was 32.9. In 1890 the corresponding proportion was 25.4.

In the registration area the number of deaths reported as due to cancer and tumor was 18,963, of which 7,082 were males and 11,881 females, giving a proportion of 37.4 deaths from these causes in every 1,000 deaths. A death rate of 65.8 per 100,000 of population. In 1890 the death rate was 53.1.

In the census years of 1900 and 1890 the death rates from cancer and tumor in the registration area and of its subdivisions show that the mortality from these two diseases was highest in the rural districts of the registration states (1900, 71.1 per 100,000; 56.0 in 1890) and lowest in the cities in the non-registration states (63 per 100,000 in 1900; 48.2 in 1890). It was higher among the whites (66.7 in 1900; 53.9 in 1890) than among the colored (47.7 in 1900; 36.7 in 1890). It was much higher in the native whites of native parents (66.9 in 1900; 58.6 in 1890) than in those of foreign parents (25.7 in 1900; 17.9 in 1890) and highest of all in the foreign whites (124.6 in 1900; 93.3 in 1890).

The relatively higher death rates of females (white, 83.2 in 1900; 69 in 1890; colored, 66.2 in 1900; 53.6 in 1890) than of males (white, 50.1 in 1900; 38.8 in 1890; colored, 28.6 in 1900; 19.2 in 1890) are due to the greater tendency of these diseases to attack the female mammary and generative organs. In comparison with 1890 there was a decided increase in the death rates due to cancer and tumor, ranging from 15 per cent. in the cities in the registration areas to 27 per cent. in the rural districts.

Deaths from cancer alone from the registration area and its subdivisions, which comprise certain states and cities in which the returns were sufficiently accurate to allow more definite tabulations, will now be considered. This area is composed of Maine, Vermont, New Hampshire, Massachusetts, Rhode Island, Connecticut and Michigan and fifty cities not in the above states. In this latter class are included all of the largest cities in the respective states, such as Philadelphia, St. Louis, Baltimore, San Francisco, Milwaukee, St. Paul, New Orleans and others.

According to the death rates from cancer alone per 100,000 population, the registration states rank as follows:

Maine	83.7	Rhode Island	62.3
Vermont	81.8	New York	61.2
District of Columbia	71.8	Connecticutt	61.1
New Hampshire	66.8	Michigan	58.0
Massachusetts	66.4	New Jersey	50.4

The average death rate in these states, according to the districts and sex, was:

		Males.	Females.
Cities	59.8	41.7	77.2
Rural	65.3	47.7	83.7

The highest death rate (113.3) was among the females in the rural districts in New Hampshire and lowest (31.5) among the males in the cities in New Hampshire. The total number of deaths reported due to cancer alone in the United States during the census year of 1900 was 29,475, of which 11,436 were males and 18,039 were females, and the proportion of deaths from this disease in 1,000 deaths was 29.5. In 1890 the corresponding ratio was 22.5. In the registration area there were 17,296 deaths from cancer. Of these 6,388 were males and 10,908 females, giving a proportion of 34.1 deaths from this disease in 1,000 deaths from all known causes, and a death rate of 60 per 100,000 of population. In 1890 the death rate was 47.9. The proportion of 34.1 is made up of 12.58 or 36.9 per cent. males and 21.51 or 63.1 per cent. females. Of the 17,296 deaths 16,758 were white and 538 colored. In England and Wales the death rate from cancer in the year 1899 was 82.9 (males 67.2; females 97.7). The increase in the English rate between 1890 and 1899 (15.3 per 100,000) was greater than the increase in the registration area of the United States between 1890 and 1900 (12.1). The death rate from cancer during the census year for the registration area and its subdivisions per 100,000 of white population by birthplace of mothers is given in Table 5.

TABLE 5.—DEATH RATES BY BIRTHPLACES OF MOTHERS.

Birthplaces of Mothers.	Total.	Cities.	Registration record. States.			Cities in Other States.
			Total.	Cities	Rural.	
United States	48.3	40.4	52.4	45.4	58.2	30.4
France	92.8	96.4	83.6	85.3	79.7	117.3
Scotland	81.8	74.4	87.3	83.2	96.0	50.2
Germany	78.2	79.7	79.6	82.6	70.5	74.7
Ireland	76.4	75.0	76.4	71.7	82.5	76.6
England and Wales.	72.0	70.9	71.4	69.6	74.9	75.1
Canada	40.3	37.8	40.6	38.0	43.8	36.0
Hungary, Bohemia ..	31.5	33.1	27.4	29.3	16.0	39.0
Scandinavia	31.1	32.8	30.7	33.7	25.3	31.9
Russia, Poland. ...	25.7	25.9	26.2	26.6	23.5	23.1
Italy	22.8	23.3	21.7	22.0	20.1	34.3
Other countries...	48.5	49.1	49.0	49.9	46.8	46.0

This table shows that the death rates due to cancer were highest among those whose mothers were born in

France, 92.8; in Scotland, 81.8, and in Germany, 78.2; and were lowest in those whose mothers were born in Scandinavia, 31.1; in Russia and Poland, 25.7, and in Italy, 22.8.

CANCER IN CITIES.

The increase in the death rate in the cities and rural districts is not equally rapid, as in the latter the advance over the returns of 1890 has been decidedly more rapid than is the case in the cities. In 1902 the five following cities led the list in regards to the number of deaths from cancer in every 1,000 deaths from all causes:

	1902.	1903.
Brockton, Mass.	80.6	61.2
Davenport, Iowa	79.9	50.6
Auburn, N. Y.	71.9	73.1
Jackson, Mich.	67.2	56.4
Rochester, N. Y.	65.8	...

In 1903 the following five cities were at the head:

	1903.	1902.
Saginaw, Mich	73.2	65.5
Malden, Mass.	73.1	57.0
Auburn, N. Y.	73.1	71.9
Quincy, Mass.	69.4	...
Grand Rapids, Mich.	69.2	55.7

In regard to the size of the cities, the death rate in the two years of 1902 and 1903 per 1,000 deaths in the ten largest was as follows:

	1903.	1902.
New York	38.7	35.9
Chicago	41.9	44.4
Philadelphia	38.2	38.2
St. Louis	40.3	31.8
Boston	50.9	45.7
Baltimore	38.3	39.8
Cleveland	37.4	34.3
Buffalo	47.0	45.3
San Francisco	58.1	59.4
Cincinnati	44.5	43.2

It therefore seems that the death rate from cancer averages less in the larger cities than in the smaller ones.

DEATH RATE AT VARIOUS AGES.

According to four-year periods, there is a gradual increase in the number of deaths up to 25 to 29 years. There is then a rapid rise up to 55 years, when it remains nearly stationary till 70, at which point the mortality begins to fall rapidly.

TABLE 6.—DEATHS FROM CANCER AT EACH AGE PER 1,000 DEATHS.

	1900.		1890.	
Age.	Male.	Female.	Male.	Female.
20-24	7.5	4.3	6.5	7.0
25-29	10.5	13.3	15.7	16.3
30-34	19.9	30.8	23.7	39.0
35-39	34.5	60.4	43.8	59.3
40-44	58.0	89.3	54.2	95.2
45-49	84.1	115.6	86.3	115.7
50-54	117.5	122.8	111.6	133.5
55-59	131.2	133.3	130.3	121.3
60-64	136.6	124.9	148.5	122.9
65-69	139.5	112.0	143.9	100.9
70-74	113.1	83.2	100.5	77.4
75-79	81.0	58.9	70.3	53.9
80-84	37.3	31.1	33.3	30.2
85-89	14.6	11.0	13.3	13.9

The figures of Table 6 show that the cancer mortality among females takes on a more rapid increase at an earlier period than in males, and that the female mortality is about a single four-year period ahead until the 55-59 period is reached, when the figures are approximately the same. From then on the mortality of females decreases while that of the males remains fairly stationary till 69 years, when it also diminishes, and the two death rates again approximate during the 85-89 period. It would seem that if a woman lives to be 60 years of age she is much more likely to escape having cancer than is a man, as that seems to be the age in men at which the mortality from cancer is the greatest. The average age at death from cancer in the registration area in 1900 was 58.1 years. In 1890 it was 57.2. For those dying at 15 years of age and over the average age in 1900 was 58.3 and in 1890 was 57.5.

TABLE 7.—DEATH-RATE FROM CANCER PER 100,000 OF POPULATION OF CORRESPONDING AGES, BY BIRTHPLACES OF MOTHERS.

	Age.		
Birthplaces of mothers.	15-44	45-64	65 and over.
Scotland	27.2	151.	533.8
France	23.9	212.1	428.3
Germany	22.8	226.2	530.4
Ireland	22.2	215.1	452.1
Russia	21.6	245.3	654.6
England and Wales	21.4	171.5	415.5
Canada	17.1	176.0	434.0
Scandinavia	16.1	148.1	371.8
United States	14.7	145.1	349.4
Italy	14.5	115.0	....
Hungary and Bohemia	13.4	209.0	....
Poland	9.4	88.5	263.5

If those of 65 years and over are noted it will be seen in Table 7 that the rates were highest in those whose mothers were born in Russia, 654.6; in Scotland, 533.8; in Germany, 530.4; and were lowest in those whose mothers were born in the United States, 349.4; in Hungary, 280.9; and in Poland, 263.5.

TABLE 8.—DEATH RATES FROM CANCER FOR THE REGISTRATION AREA AND ITS SUBDIVISIONS DURING THE CENSUS YEAR, IN EACH OF FIVE AGE GROUPS PER 100,000 OF POPULATION OF CORRESPONDING AGES BY SEX.

Registration areas.	Under 5	5-14	15-44.	45-64	65 and over.
Total	1.3	0.8	20.5	194.8	454.3
Males	1.5	0.7	11.5	136.6	417.0
Females	1.1	0.9	29.4	253.0	487.6
Cities	1.0	0.9	21.6	212.3	482.4
Males	1.0	0.7	12.4	155.6	456.5
Females	1.0	1.0	30.6	269.2	503.5
States	1.5	0.9	19.6	183.5	447.3
Males	1.8	0.9	10.2	122.9	394.0
Females	1.2	0.8	29.0	244.3	495.7
Cities	1.0	1.1	21.4	209.8	494.2
Males	0.9	1.2	11.3	147.3	439.2
Females	1.1	1.0	31.2	269.8	536.9
Rural	2.3	0.5	16.6	153.2	412.9
Males	3.1	0.6	8.5	96.1	365.3
Females	1.4	0.5	25.2	213.4	461.4
Cities in other States	1.0	0.7	21.8	214.8	470.7
Males	1.0	0.4	13.5	163.2	472.8
Females	0.9	1.0	30.1	268.7	468.9

Table 8 shows that the mortality from cancer was greatest in persons of 65 years and over, and at this age it was higher in females (487.6) than in males (417.0), and was higher in the cities (494.2) than in the rural districts (412.9) of the registration states.

TABLE 9.—DEATH RATES AT CERTAIN AGES, BY CONJUGAL CONDITIONS.

	15-44.			45-64.			65 and over.		
Sex.	Single.	Married.	Widowed.	Single.	Married.	Widowed.	Single.	Married.	Widowed.
Total	8.7	28.6	69.6	192.1	175.6	256.4	518.7	426.0	455.8
Males	6.5	15.7	40.3	142.1	125.8	200.8	512.5	388.0	433.7
Females	11.3	39.8	80.7	248.8	238.8	275.9	523.1	496.7	464.9

Table 9 shows that from 15 to 44 years of age the death rate of the married of both sexes was higher than that of the single. Above 44 years the rate for the single was higher in both sexes than for the married, and at 65 years and over it was higher in the single of both sexes than in either the married or the widowed.

CANCER OF VARIOUS ORGANS.

Table 10 shows, for the registration area, the number of deaths at certain ages from cancer of certain specified organs or parts per 1,000 total deaths at the same age, from cancer for which the organ or part is known, by sex.

This table also shows that in each 1,000 deaths of males at all ages from definitely located cancer—

436.6 were due to cancer of the stomach.
145.6 were due to cancer of the liver.
104.2 were due to cancer of the head, face and neck.
95.5 were due to cancer of the mouth tongue and throat.
92.4 were due to cancer of the abdomen.
54.9 were due to cancer of the rectum.

In females the distribution per 1,000 deaths from cancer was as follows:

276.2 were due to cancer of the uterus.
244.7 were due to cancer of the stomach.
157.8 were due to cancer of the breast.
125.9 were due to cancer of the liver.
76.9 were due to cancer of the abdomen.
35.5 were due to cancer of the rectum.

The excess of deaths from cancer of the female generative and mammary organs reduces the proportions due to cancer of the other organs or parts, as compared with the proportions given for the males. If, however, cancer of those organs is excluded the death rate of males from other forms of cancer exceeds that of the females.

Table 11 divides the 17,296 deaths that occurred from cancer in the registration area according to the organ or part that was affected and according to sex and to color.

TABLE 10.—PROPORTIONS OF DEATHS FROM CANCER OF CERTAIN ORGANS.

Organ or Region of Body.	All Ages.			24-44 years.			45-64 years.			65 years and over.

Cancer of the Breast.—The death rate per 100,000 population was much higher in the females (9.1) than in the males (0.3); it was also much higher for the age group 15 to 64 years (30.7) than at lower ages, and was still higher in those 65 years of age and over, females 59.6, males 2.0.

The death rate from this cause at all ages was higher in white females (9.1) than in colored females (7.9). Under 15 it was higher in the colored females (7.2) than in the whites (3.9), but after that age it was higher in the whites. In white females from 45 to 64 years of age the death rate was about the same in the native born (30.3) and the foreign born (30.9). At 65 years of age and over the death rate for the same classes was higher, natives, 66.6; foreign born, 50.1.

Cancer of the Liver.—The returns indicate that the death rate at all ages was higher in females (7.2) than in males (5.2), and this difference was especially marked in those from 45 to 64 years of age, females 24.0, and males 17.1. As primary carcinoma of the liver is decidedly uncommon, the above figures are what one would naturally expect, inasmuch as the greatest number of cases of cancer occur in women between the years of 45 and 64. Consequently a higher rate of secondary involvement of the liver would occur.

Cancer of the Head, Face and Neck.—Of the total number of cases in this region 531 were in males and 260 in females. The death rate for this group was much higher in males (3.7) than in females (1.8), and was highest in persons 65 years of age and over, males 38.6 and females 23.5.

Cancer of the Mouth, Tongue and Throat.—This was three and a half times more frequent in men than in women. Of the 626 cases 57 occurred at 20 to 44 years, 300 at 45 to 64, and 263 at 65 and over. The death rates for both males and females were highest in the age group of 65 years and over, males 33.1, females 9.7. These results, together with those of the group immediately preceding, might be considered as further supporting the theory that chronic irritation is an important factor, particularly in the origin of superficial carcinoma. The natural conclusion would be that the greatest number of the above cases were of the squamous epitheliomatous type. This variety is in so many cases preceded by a history of chronic irritation that it would seem as if such an etiology must be taken into serious consideration.

Cancer of the Stomach.—A greater number of deaths than was brought about by carcinoma in any other situation arose from this cause. Out of the total number of deaths from cancer, 29,475, there were 4,220 due to carcinoma of the stomach, 13.9 per cent. The two sexes were practically equally involved, males, 2,195; females, 2,025. The death rate was very low in persons under 45 years of age, and was more than twice as high in persons of 65 years as in those between 45 and 64 years of age. In those 65 years and over it was higher in the males (138.3) than in females (105.9); much higher in whites (122.4) than in the colored (77.1), and higher among the foreign born whites (153.2) than among the native born whites (96.6).

Cancer of the Uterus.—Of all cases of carcinoma 2,291 deaths, constituting 7.9 per cent. of the total and 12.6 per cent of those occuring in women resulted from cancer of the uterus. The death rate in those from

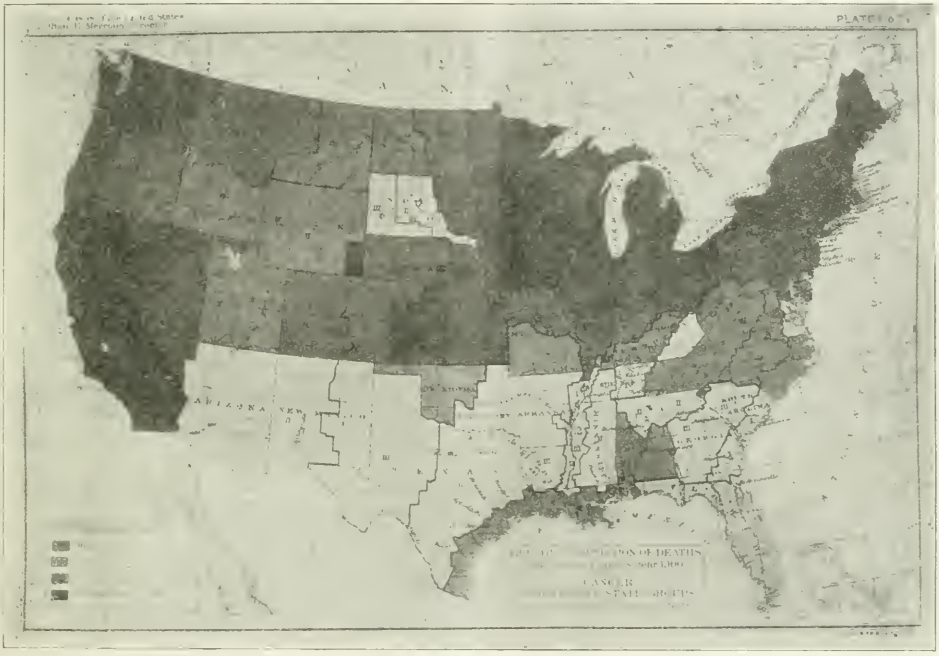
20 to 44 years was 10.7. It was highest (59.1) in those from 45 to 64, but continued high (55.7) in those of 65 and over. It was much higher in the colored than in the whites of each group and it was higher in the native white at 45 to 64 years of age (59.6) than in the foreign white (55.5).

THE RELATION OF CANCER TO OCCUPATION.

The following list shows, for the registration states, the death rate from cancer in males per 100,000 of population engaged in the specified pursuits:

Miners and quarrymen	33.4
Sailors, fishermen, etc.	113.1
General average for occupied women	49.7
School teachers	47.8
Bookkeepers and clerks	15.1
Laundresses	23.3
Nurses and midwives	165.0
Servants	99.6
Textile operatives	9.9
Dressmakers	38.4

The percentage of death from cancer in relation to the entire number of deaths from all causes in the United States in the registration area and its subdivisions, is given in Table 12.



General average for all occupied males	57.1
Professional	51.7
Clergymen	162.2
Lawyers	52.5
Physicians	67.5
Clerical	37.3
Bookkeepers and clerks	28.0
Bankers, brokers	41.4
Collectors, auctioneers, and agents	58.1
Mercantile and trading	52.0
Merchants and dealers	81.3
Hucksters and peddlers	62.7
Public entertainment	35.3
Hotel and boarding-house keepers	60.1
Saloon and restaurant keepers	28.0
Personal service, police and military	42.9
Janitors and sextons	66.7
Policemen, watchmen and detectives	60.3
Laboring and servant class	66.5
Laborers other than agricultural	126.6
Servants	44.3
Manufacturing and mechanical industry	53.3
Bakers and confectioners	51.0
Blacksmiths	107.3
Cabinetmakers and upholsterers	72.6
Carpenters and joiners	77.7
Iron and steel workers	31.5
Machinists	52.2
Masons, stone and brick	98.0
Textile operatives	34.5
Painters	45.0
Tailors	58.4
Agricultural, transportation and other outdoor class	69.2
Draymen, hackmen, drivers, etc	22.6
Farmers, planters and farm laborers	87.7
Gardeners, florists, etc.	72.9
Stablemen	46.1

TABLE 12.

	White males. per cent.	Colored males. per cent.	Females. per cent.
In the United States	3.63	0.78	4.40

Non-registration record	3.3	0.60	3.22

THE GEOGRAPHICAL DISTRIBUTION OF CANCER AND TUMOR IN THE UNITED STATES.

Table 13 shows for each grand group in the United States the proportion of deaths from cancer and tumor, during the census year, per 1,000 deaths from known causes, in the aggregate and by sex, for the cities and rural districts.

According to this table the proportion of deaths due to cancer and tumor was greatest in the Pacific coast region, 51.9; in the heavily timbered region of the Northwest, 46.8; in the Northeastern hills and plateaus, 44.5; and in the Prairie region, 43. It was least in the Southern interior plateau, 18.1; in the Southwest central region, 15.8, and in the North Mississippi River belt, 11.3.

TABLE 13.—NUMBER OF DEATHS PER 1,000 DEATHS FROM KNOWN CAUSES.

Grand group.	Rural.			Cities.	
	Total.	Males.	Females.	Males.	Females.
Pacific Coast region	51.9	36.5	69.4	43.6	70.3
Heavily timbered northwest region	46.8	34.4	58.8	39.9	64.6
Northeastern hills and plateaus	44.5	33.8	65.1	24.4	47.9
Prairie region	45.0	36.4	50.3	33.2	60.2
Region of great northern lakes	41.6	37.3	57.1	30.6	49.7
North Atlantic coast region	41.5	34.3	67.9	23.4	52.3
North Mississippi River belt	37.3	29.7	46.7	27.0	49.8
Interior plateau	34.4	25.2	50.7	21.3	43.5
Central Appalachian	34.4	26.8	48.2	18.3	44.4
Ohio River belt	34.2	24.4	39.8	26.4	50.7
Central region, plains and prairies	34.1	25.1	42.9	22.9	49.9
Cordilleran region	32.1	25.7	41.5	31.3	40.8
Missouri River belt	31.0	27.2	37.3	24.2	38.8
Middle Atlantic coast region	31.0	20.9	39.2	21.2	42.9
Region of western plains	26.5	19.9	32.9	26.7	42.4
Gulf coast	20.2	13.1	25.3	15.0	30.9
Southern Central Appalachian	20.0	13.5	26.8	6.5	30.6
South Atlantic coast region	18.7	10.2	25.2	10.5	32.3
Southern plateau region	18.1	9.1	26.8	...	...
Southwest central region	15.8	12.7	18.7	22.7	25.8
South Mississippi River belt	11.3	6.3	12.5	12.2	30.7

Reviewing certain of the United States census statistics, a writer[1] says: "The question of nationality will be found to furnish an explanation of the very high mortality in those states in which the greater number of immigrants from Europe make their home." It also states that "it is obvious that the Atlantic states, which receive every year a mass of immigrants from Great Britain and Germany would be expected to show from this cause alone a distinctly higher cancer rate than those inhabited by native born population." Unfortunately such reasoning is not supported by the facts. By comparing certain of the grand groups, according to their proportion of native born, we find the conditions set forth in Table 14.

TABLE 14.

Grand group.	Deaths from cancer per 1,000 deaths.	Native white.	Foreign white.
Pacific coast region	51.9	73.7	21.7
Heavily timbered northwest region.	46.8	76.6	22.1
Northeastern hills and plateaus.	44.5	79.0	20.3
Prairie region	43.0	84.0	14.3
Region of great northern lakes	41.6	70.6	28.3
North Atlantic coast	41.5	about 75.0	about 23.6
North Mississippi River belt	37.3	79.2	17.3
Interior plateau	34.4	76.7	12.2
Ohio River belt	34.2	87.8	6.5
Central region, plains and prairies	34.1	87.8	4.4
Cordilleran region	32.1	76.8	16.8
Middle Atlantic coast	31.0	65.0	25.2
			Colored.
Gulf coast region	20.2	55.4	38.6
South Central Appalachian	20.0	81.7	...
South Atlantic coast	18.7	...	53.0
South interior plateau	18.1	46.3	53.4
South Mississippi River belt	11.3	32.9	65.9

From this table it is seen that the two regions that have the greatest per cent. of foreign population occupy respectively the fifth and twelfth positions as regard the cancer death rate. Again the South Carolina Appalachian region is the fourth lowest and its population is composed of 81.7 per cent. native white; on the other hand the native white population of the Prairie region is 84 per cent. and it is the fourth highest. In the Southern states where the colored population is very great the average cancer rate is the least. This is a condition to be expected, knowing the lesser mortality in that race from cancer. Hyde in a recent article concludes that, "Physiological pigmentation of the skin seems to furnish relative immunity against cancer of that organ;" and also, that "The colored races apparently suffer less than the whites from cancer of other organs than the skin. This relative immunity may be due to the protection from actinic rays of light furnished by the pigment of the integument." It would seem evident from Table 14 that the death rate from cancer in the different parts of the United States has no direct relation to the number of foreign whites in the population.

By an examination of a cancer map of the United States one's attention is immediately attracted by the fact that, with the one exception of California, the area is divided into two great divisions in regard to the mortality per 1,000 deaths from known causes. South of the latitude of 37° the number of deaths from cancer is under 16 per 1,000. This includes Arizona, New Mexico, Texas, Indian Territory, Arkansas, Mississippi, Louisiana, South Carolina, Georgia and Florida, the Western end of Tennessee and the Northern end of Alabama. In the following areas the death rate is a little higher, from 16 to 24, the coast line of Texas, Louisiana, Mississippi, the Southern part of Alabama and Oklahoma. Above the latitude of 37° the cancer mortality in that portion between the Missouri River and California and the Western half of Washington and Oregon varies from 25 to 39 per 1,000 deaths. East of the Missouri River to the Atlantic Coast the mortality is generally from 31 to 40 and over.

GENERAL SUMMARY.

In the registration area in 1890 cancer was thirteenth in the list of causes of death and the death rate was 47.9 per 100,000 of population. In 1900 it had moved up to seventh, with a death rate of 60.0.

In the United States in 1900 the proportion of deaths from cancer in 1,000 deaths of known causes was 29.5. In 1890 the corresponding proportion was 22.5. In England and Wales the death rate in 1899 was 82.9, an increase of 15.3 per 100,000 from 1890 to 1899 as against a corresponding increase of 12.1 between 1890 and 1900 in the registration area of the United States.

TABLE 15.—DEATH RATE PER 100,000 OF POPULATION.

	1900.	1890.
Rural district of registration states	71.4	56.0
Cities in non-registration states	63.0	48.2
Among the white	66.7	53.9
Among the colored	47.7	36.7
Native whites of native parents	66.9	58.6
Native whites of foreign parents	25.7	17.9
Foreign whites	124.6	93.3
Females, white	83.2	69.0
Females, colored	66.9	53.6
Males, white	50.1	38.8
Males, colored	28.6	19.2
Males	36.9	...
Females	63.1	...
Average age at death from cancer	58.1	57.2

Mortality greatest at 65 years, and at this age was higher in females than in males.

The death rates were highest in those whose mothers were born in Russia, Scotland and Germany; and lowest in those born in the United States, Hungary and Poland.

According to conjugal condition and age the death rate from 15 to 44 years of age was higher in the married of both sexes than in the single. Above 44 years the rate for the single was higher in both sexes than for the married. At 65 years and over it was higher in the single of both sexes than in either the married or widowed.

In each 1,000 deaths of males of all ages from definitely located cancer:

430.6 were due to cancer of the stomach.
145.6 were due to cancer of the liver.
104.2 were due to cancer of the head, face and neck.
95.5 were due to cancer of the mouth, tongue and throat.
92.4 were due to cancer of the abdomen.
54.9 were due to cancer of the rectum.

In females:

276.2 were due to cancer of the uterus.
211.7 were due to cancer of the stomach.
157.8 were due to cancer of the breast.
125.9 were due to cancer of the liver.
76.9 were due to cancer of the abdomen.
75.7 were due to cancer of the rectum.

1 Medical Journal, May 2, 1903.

When the occupations are compared there are seen to be great variations in the cancer mortality. With one exception, to be mentioned later, the greatest mortality from cancer occurs in those who do hard work out of doors. Leading the list with a rate of 126.6 come the laborers other than agricultural, then sailors and fishermen 113.1, blacksmiths 107.3, masons 98.0, and farm laborers 87.0. The one exception is the average for clergymen, 102.2. This may possibly be explained by the fact that this class commonly attains a higher average age than most of the other classes. It would seem that there is some direct relation between occupation and cancer mortality. It is difficult to say what it has to do with hard work and exposure unless it has a bearing on the theory of chronic irritation. Before that point could be argued it would be necessary to know the location of the new growths.

A point against the theory of alcohol having something to do with cancer is that the average in those of the public entertainment class is 35.3. This is the lowest of all the groups. The average under this heading for saloon and restaurant keepers is only 28.0. If the consumption of beer or other alcoholic drinks had anything to do with the disease a higher average should be found.

It can also be shown that the consumption of beer has no direct influence on cancer rate by comparing the rates in certain of the cities that are largely inhabited by Germans and that are centers of brewing. In Milwaukee the rate per 1,000 deaths was 52.5, in Cincinnati 44.5, and in St. Louis 40.3. These cities come below San Francisco 58.7, Syracuse 57.2, Springfield 56.2, Hartford 53.9 and others, and are about equal to that of Detroit 49.4, Los Angeles 47.6, Buffalo 47.0, and New Haven 46.8.

The opinion of certain investigators that cancer is more common along the banks of rivers or streams is not well sustained by the figures. Those sections in the United States along the various great rivers, as the Mississippi, Missouri, Ohio, Rio Grande and numerous others, have, with a few exceptions, a lower mortality than the other parts of the country. The only points in common in the widely scattered areas of high mortality are that these regions are generally hilly or mountainous and are both well timbered and well watered by many streams and lakes.

The increase in cancer mortality in immigrants in the United States as compared with the rate in their own country may very readily be an apparent and not a real one. Those who come to this country are adults as a rule and consequently have a higher cancer death rate than the average of all ages. The only way in which comparisons of value could be made would be to compare the death rate of a large number of immigrants of a certain age with a corresponding number of similar age in their native country.

CONCLUSIONS.

1. That cancer appears to have actually increased in the United States 12.1 deaths per 100,000 population in the past ten years.

2. That the death rate is higher in the rural districts and small towns than in the cities.

3. That native whites suffer much less than the foreign whites.

4. That the death rate amongst the foreign whites in the United States is only apparently greater than in their own homes.

5. That 63.1 per cent. of all cancer cases are in women and 36.9 per cent. in men.

6. That those employed in hard outdoor work have a higher cancer mortality than the sedentary classes.

7. That the areas showing the greatest mortality are mountainous regions that are well watered and timbered.

8. That cancer does not seem to be generally more prevalent along rivers.

9. That those cities in which there are both a large German population and large brewing interests do not show a corresponding increase in cancer mortality.

10. That cancer mortality is greatest in persons of 65 years and over.

11. That the average age at death is 58.1 years.

THE PHARMACOPEIA AND THE PHYSICIAN.

CHAPTER XVIII.

GENERAL TONICS.

Tonics are defined by Gould as "medicines or agents which promote nutrition and give tone to the system."

Since these conditions are met by any improvement in the general health, the use of the term is often an admission of our want of exact knowledge of the mode of action of the drugs or remedies so classed.

Strychnin increases the reflexes and may thus improve the muscular tone. Bitters may increase the impaired appetite and digestion, which will, of course, improve the general condition, hence these agents may be spoken of as tonics; and, if we were not acquainted with the organism which causes malarial fever, and with the effect of quinin on that organism, but merely knew that this condition was relieved by quinin, we would be justified in attributing the action to the tonic effect of quinin. Therefore, as our knowledge of the exact mode of action of the various remedies of this group increases, the importance of the term itself will correspondingly decline.

Among the tonics we may include stomachics (which have been discussed in Chapter XIV); hematinics, or agents which assist in the regeneration of blood, including iron, arsenic, cod-liver oil and hypophosphites; and the alteratives, the mode of action of which is unknown.

Hematinics.

Ordinary food is the most important of the hematinics, if, indeed, we have any others which are of considerable importance, especially if we accept the definition which includes iron in any assimilable form as food.

IRON.

Most of the iron in the body, amounting to from 2½ to 3 grams (38 to 45 grains) occurs as a constituent of hemoglobin, an extremely complex substance in which the iron is much more firmly bound than in the ordinary iron albuminate. In addition to that found in the blood, iron is an important constituent of the body cells, though present only in very minute quantity.

The animal body is generally supposed to be incapable of building up complex organic molecules from elementary substances, and it seems more than probable that all the iron in the hemoglobin is derived from the vegetable kingdom, and that inorganic salts of iron do not take part directly in its formation, though they may influence it markedly.[1]

The absorbability of inorganic iron was not questioned before the investigations of Kletzinsky, about fifty years ago, and it is even more recently that the subject began to attract considerable attention, but the literature at the present time is rather extensive and many contradictory results have been obtained.

It is perfectly obvious that iron as it exists in vegetables is capable not only of being absorbed, but of being utilized in

1. Prior to the discovery by Wöhler of the synthesis of such a comparatively simple substance as hippuric acid in the kidney, it was supposed that no synthesis could occur in the animal body.

the formation of hemoglobin, and it is only when the appetite or digestion is greatly impaired that there can ever exist any marked deficiency in the supply of iron, only about 10 milligrams (1 6 grain) being required daily under ordinary conditions, but there may arise the necessity for a stimulation of the function concerned in the utilization of the iron taken in the food; if inorganic iron stimulates this function, and it apparently does under certain conditions, then it acts as a medicine.

Many efforts have been directed toward determining whether iron, other than that existing in the food, is absorbed from the alimentary canal. Attempts to measure the difference between the amount ingested and that excreted proved inconclusive. Iron is probably excreted into the intestine after absorption, though Tartakowsky doubts if the iron found in the intestinal epithelium is in course of excretion, and the amount excreted often considerably exceeds that administered.

Microchemic means have been employed to solve the problem, and A. B. MacCallum has found that only a slight degree of absorption in the first few inches of the duodenum follows the administration of small doses of inorganic iron, nearly all being precipitated by the mixed chyme, pancreatic juice and bile, but when large doses are taken absorption appeared to take place through the whole length of the small intestine, while Tartakowsky found that inorganic iron was also absorbed from the rabbit's stomach.

MacCallum found that iron, in the form in which it exists in yolk of egg, is absorbed, while Marfori's albuminate and the commercial peptonate seemed to stimulate the leucocytes to invade the epithelial layer of the villi in the guinea-pig, but many investigators now believe that absorption occurs mainly by way of the lymph channels and not by the blood.

Since iron, like any other foreign substance, may be excreted without having been utilized after absorption, the question is not one of absorption alone, but of the form in which iron must be absorbed in order that it may take part in the formation of hemoglobin, and be utilized in the body cells.

In addition to the food irons, the assimilation of which it is not necessary to discuss at present, certain other forms have been found capable of being converted into hemoglobin, and we may say that many physiologic chemists believe that there is no reason to suppose that inorganic salts of iron are not as readily assimilated as are the organic, and Tartakowsky does not believe that even the food irons are absorbed in the form of the complex combinations in which they exist in plants.

Socin, working in Bunge's laboratory, proved that iron, in the form in which it exists in yolk of egg (hematogen, as it is called by Bunge, who isolated it), is capable of assimilation. He fed this, and no other form of iron, to mice for a period of 100 days, during which time they gained in size and weight without becoming anemic.

Bunge considers that hematogen is the undoubted precursor of hemoglobin, but his views have not been universally accepted. Hematogen, according to the investigations that have been made by Bunge, is more stable than the combinations of iron that are found in vegetables and it is also more easily isolated.

Schmiedeberg isolated an organic iron compound, which he named ferratin, from the liver, and which he considers the true precursor of hemoglobin. Ferratin may be prepared synthetically from an alkaline solution of albuminate of iron, and is usually considered merely as an ordinary albuminate, but Schmiedeberg strongly insists that it is iron-acid-albumin, and calls attention to certain chemic differences between it and the ordinary albuminate. Marfori isolated the compound containing 0.7 per cent. of iron, but as most easily prepared it contains from 4 to 8 per cent., which strongly suggests that the precipitate carries down mechanically some other form of iron.

The examples quoted serve to show the diversity of opinion among authorities as to the actual precursor of hemoglobin, but the question is of less therapeutic importance than it would seem at first thought, in view of the fact that it is a comparatively infrequent occurrence that a patient is unable to take a sufficient amount of iron in the food. We have devoted so much space to the subject mainly because the manufacturers of certain nostrums, used as hematinics, are prone to quote such results as those obtained in Bunge's laboratory only so far as they show that organic iron preparations are assimilable while the inorganic are not, but we have not yet seen any mention made in the free circulars of the statement made by Bunge that inorganic iron does stimulate the functions concerned in the assimilation of iron when it is abundant in the food, and that organic iron preparations are without beneficial effect under similar conditions.

This, however, is of the very greatest importance from a practical point of view, because we can nearly always select a suitable diet containing an abundance of iron, and organic iron in any other shape is, therefore, seldom if ever required.

As evidence of the rôle played by inorganic iron we may mention the results obtained by Abderhalden.

He found that the iron of hematin and hemoglobin is not so readily assimilated as is that of the ordinary food. Animals were fed on a diet in which a deficiency of iron was made up by hematin and hemoglobin, and they did not thrive so well as those which received food containing a sufficiency of iron, though those which received hematin and hemoglobin did thrive better than those in which the deficiency was made up by an inorganic iron. This might be easily considered as conclusive proof of the value of organic iron nostrums, but when we repeat that it rarely happens that the patient can not take food containing an abundance of iron the fact loses most of its significance.

When the food was rich in iron the addition of hematin and hemoglobin (which may be considered the best type of organic iron) had no effect on the assimilation of the food iron, but when inorganic iron was added to such iron-rich food the assimilation was stimulated.[2]

When inorganic iron is added to the food or to organic iron, it combines with the hydrogen sulphid in the intestine and spares the organic iron from precipitation. Inorganic iron should thus prove beneficial even if Schmiedeberg were correct in contending that inorganic iron is not absorbed from the intestine except after corrosion of the mucous membrane. He claims that corrosion occurs even when such a salt as ferric chlorid is administered after free dilution, because the water is rapidly absorbed, leaving the salt in concentrated solution.

Other investigators have also called attention to the corrosive action of hydrochloric acid when liberated from a metallic salt in contact with the tissues, and it may be found that the ferrous sulphate or carbonate may be found to be preferable to the more widely used ferric chlorid.

OFFICIAL PREPARATIONS OF IRON.

The list of official preparations of iron is a long one and comprises a number of substances that are not generally used as hematinics.

The use of the salts of iron as astringents has been referred to in Chapter XIII, and need not be recapitulated at this time more than to enumerate the preparations that may be so used.

Among the official preparations that are useful as astringents or as styptics are the following:

LIQUOR FERRI TERSULPHATIS and LIQUOR FERRI SUBSULPHATIS.—U. S.—The solution of ferric subsulphate, in addition to being used as an astringent and styptic, has also been recommended as a hematinic.

Average dose: 0.2 c.c. (3 minims).

FERRI CHLORIDUM and LIQUOR FERRI CHLORIDI.—U.S.—These were both more fully discussed under astringents, Chapter XIII.

---

2. Cushny: "Pharmacology and Therapeutics" says: "The words organic and inorganic in connection with these preparations have no reference to the combination to which iron is attached, but to the method of attachment. Thus the acetate and albuminate of iron are both classified among the inorganic iron compounds, because they are capable of dissociation, and the iron is precipitated by ammonium sulphid. Masked iron is a preferable term for organic iron, but has not been so widely used. A large number of the proteid compounds that have been introduced in the last few years promise to be relegated to merited oblivion in the near future. The albuminate of iron and the peptonate of iron are generally prepared by the action of the chlorid on egg albumin or on peptone, and differ very considerably in the percentage of iron. These preparations are not organic iron in the sense defined above, for the iron can be split off easily, and is precipitated by sulphids almost as readily as the ordinary salts."

Probably the most widely used of the several preparations of iron, is:

Tinctura Ferri Chloridi.—U. S.—This preparation contains 35 per cent. by volume of solution of ferric chlorid and should be prepared at least three months before being used. Tincture of ferric chlorid, or tincture of iron, as it was formerly called, has long been considered one of the most efficient of the inorganic iron preparations.

Average dose: 0.5 c.c. (8 minims).

Ferri Sulphas and Ferri Sulphas Granulatus.—U. S.—These differ only in the size of the crystals; they consist of ferrous sulphate containing 7 molecules of water of crystallization. Ferrous sulphate is soluble in less than one part of water, but is insoluble in alcohol.

Average dose: 0.2 gm. (3 grains).

Ferri Sulphas Exsiccatus.—U. S.—Exsiccated ferrous sulphate is a grayish-white powder that is slowly but completely soluble in water. About 65 grams of the exsiccated preparation are equivalent to 100 grams of the granulated.

Average dose: 0.12 gm. (2 grains).

Pilulæ Aloes et Ferri.—U. S.—Each pill contains 0.07 gm. (about 1 grain) each of exsiccated ferrous sulphate, purified aloes and aromatic powder.

Average dose: 2 pills.

Pilulæ Ferri Carbonatis.—U. S.—This preparation is variously known as Blaud's pills, Griffith's pills or Vallet's pills. Each pill contains about 0.06 gm. (1 grain) of ferrous carbonate, with potassium sulphate, althea tragacanth and glycerin.

Average dose: 2 pills.

Ferri Carbonas Saccharatus.—U. S.—The saccharated carbonate of iron should contain not less than 15 per cent. of ferrous carbonate.

Average dose: 0.25 gm. (4 grains).

Massa Ferri Carbonatis.—U. S.—Mass of ferrous carbonate, better known as Vallet's mass, contains nearly 5 per cent. of ferrous carbonate.

Average dose: 0.25 gm. (4 grains).

Mistura Ferri Composita.—U. S.—Compound iron mixture, or Griffith's mixture, is much more popular in England than in this country. It contains freshly precipitated ferrous carbonate suspended in a mixture of potassium sulphate, myrrh, syrup, spirit of lavender and rose water.

Average dose: 16 c.c. (4 fluidrams).

Of the several official preparations containing ferrous carbonate the pill of ferrous carbonate, more generally known as Blaud's pill, is probably the most efficient and most satisfactory. This pill should be freshly prepared and should not contain free or unchanged ferrous sulphate or potassium carbonate. The practice that has been adopted by some manufacturers of massing these pills without allowing the chemical reaction to take place is a reprehensible one, as it is not at all probable that the necessary reaction will take place as readily in the acid medium of the stomach as it would in a test-tube or mortar.

All the preparations of ferrous carbonate have the decided advantage over the previously mentioned preparations of iron that they are not astringent and, therefore, are not likely to cause digestive disturbances.

Another preparation that is free from the objectionable feature of being astringent is:

Ferrum Reductum.—U. S.—Reduced iron occurs as a fine grayish-black lusterless powder without odor or taste. It is insoluble in water or in alcohol and, therefore, is generally directed to be dispensed in powders, capsules or pills.

Average dose: 0.05 gm. (1 grain).

SCALE SALTS OF IRON.

Ferri Citras.—U. S.—The ferric citrate occurs in thin garnet-red scales that are slowly but completely soluble in water.

Average dose: 0.25 gm. (4 grains).

Ferri et Ammonii Citras.—U. S.—Iron and ammonium citrate is much more freely soluble in water than the simple citrate, and has the added advantage that it is not likely to lose this property on keeping.

Average dose: 0.25 gm. (4 grains).

Ferri et Ammonii Tartras.—U. S.—This occurs in thin transparent scales varying in color from garnet red to reddish brown. It is freely soluble in water but insoluble in alcohol.

Average dose: 0.25 gm. (4 grains).

Ferri et Potassii Tartras.—U. S.—This is very similar in physical properties to iron and ammonium tartrate.

Average dose: 0.25 gm. (4 grains).

Ferri et Quinin Citras.—U. S.—Iron and quinin citrate contains about 11.5 per cent. of quinin and ferric citrate corresponding in amount to 13.5 per cent. of metallic iron. It is slowly but completely soluble in water.

Average dose: 0.25 gm. (4 grains).

Ferri et Quinin Citras Solubilis.—U. S.—This preparation has practically the same composition as iron and quinin citrate, but with ammonium citrate present to insure its ready and complete solubility.

Average dose: 0.25 gm. (4 grains).

Ferri et Strychnin Citras.—U. S.—Iron and strychnin citrate contains about 1 per cent. of strychnin. It is readily and completely soluble in water.

Average dose: 0.12 gm. (2 grains).

These several scale preparations of iron are comparatively free from astringent properties, are generally freely soluble in water or in aqueous liquids, do not attack the teeth, and are not obnoxious to the taste. They are preferably directed to be dispensed in aqueous solution, with or without the addition of elixir or some other flavoring admixture.

LIQUID PREPARATIONS OF IRON.

Vinum Ferri.—U. S.—This contains 4 per cent. of iron and ammonium citrate with syrup and white wine, flavored with tincture of sweet orange peel.

Average dose: 8 c.c. (2 fluidrams).

Vinum Ferri Amarum.—U. S.—This preparation contains 5 per cent. of soluble iron and quinin citrate with syrup and white wine, flavored with tincture of sweet orange peel.

Average dose: 8 c.c. (2 fluidrams).

Glyceritum Ferri, Quinin et Strychnin Phosphatum.—U. S.—The glycerite of the phosphates of iron, quinin and strychnin contains 8 per cent of the soluble ferric phosphate, 10 per cent. of quinin and 0.08 per cent. of strychnin with phosphoric acid, glycerin and water.

Average dose: 1 c.c. (15 minims).

Syrupus Ferri, Quinin et Strychnin Phosphatum.—U. S.—This syrup contains 25 per cent. of the glycerite of the phosphates of iron, quinin and strychnin in syrup.

Average dose: 4 c.c. (1 fluidram).

Elixir Ferri, Quinin et Strychnin Phosphatum.—U. S.—This popular ferruginous bitter tonic contains soluble ferric phosphate, quinin and strychnin. The average dose—4 c.c. (1 fluidram)—contains nearly 0.07 gm. (1/16 gr.) of soluble ferric phosphate, 0.035 gm. (7/12 gr.) of quinin, and 0.001 gm. (1/60 gr.) of strychnin.

Average dose: 4 c.c. (1 fluidram).

Liquor Ferri et Ammonii Acetatis.—U. S.—This solution of iron and ammonium acetate, more popularly known as Basham's mixture, contains a double salt of iron and ammonium acetate and is directed to be made by mixing 4 parts of tincture of ferric chlorid, 6 parts of diluted acetic acid, 50 parts of solution of ammonium acetate, 12 parts of aromatic elixir, 12 parts of glycerin and a sufficient quantity of water to make 100 parts. This preparation being quite dilute, is not very stable and should be freshly prepared when wanted.

Average dose: 16 c.c. (4 fluidrams).

There are two additional preparations of iron that, while they are not prescribed as hematinics, might well be mentioned in this connection.

ANTIDOTES FOR ARSENIC.

Ferri Hydroxidum.—U. S.—This is the hydrated oxid of iron of the previous Pharmacopeia and is directed to be made by precipitating 100 parts of solution of ferric sulphate with 133 parts of ammonia water that has been diluted with 1,000 parts of cold distilled water. The resulting precipitate is directed to be washed until free from soluble sulphates. This preparation is not particularly adapted for extemporaneous preparation, and, as it does not keep well, the following has been added as an efficient, extemporaneous antidote for arsenic.

FERRI HYDROXIDUM CUM MAGNESII OXIDO.—U. S.—This is directed to be made by diluting 40 parts of solution of ferric sulphate with 125 parts of water, and kept in a large well-stoppered bottle. The magnesia mixture is directed to be made by rubbing 10 parts of magnesium oxid with sufficient water to make a smooth and thin mixture, then diluting it to about 700 parts. When wanted for use the magnesium oxid mixture is to be well shaken and then gradually added to the solution of ferric sulphate and the resulting mixture again well shaken.

Average dose: Arsenical antidote, 120 c.c. (4 fluidounces).

INDICATIONS FOR IRON.

Hematinics are demanded when the amount of blood or of any of its essential constituents have been greatly reduced.

After severe hemorrhage involving the loss of less than half the blood, regeneration takes place rapidly, if the general condition of the patient is otherwise good and the food ample.

In accordance with a vast amount of clinical experience and the results obtained by many investigators medicinal iron (if we may use the term) is indicated. If the patient is able to take an abundance of food rich in iron, inorganic iron alone may suffice, but if he is unable to digest such food, then hematin and inorganic iron should both be given.

Iron has long been used in chlorosis, and experience has shown that it is more useful in those forms of anemia in which the loss of hemoglobin is greater than that of red blood cells; in other words, when the red blood cells present, whether in normal or diminished number, are individually poor in hemoglobin.

As to the form of iron to be given, of first importance is the selection of food. Reference to the table given below, selected from Bunge's Physiology,[3] will enable the physician to compute approximately the amount of food iron which the patient is receiving, and by computing the daily normal loss at 10 milligrams he can see about how much of this is left for the regeneration of hemoglobin. The figures given are for dried material, and it is to be remembered that green vegetables may lose 75 per cent. or more of their weight on drying, while fatty substances (nuts) will lose but little.

If the food contains an insufficiency of iron hematin should be added, but if the food supply is abundant one of the inorganic forms of iron will prove beneficial. In our choice of medicinal iron we must be guided by the individual case in selecting the one which causes the least disturbance of the digestion. In the absence of fever it will seldom occur that the patient can not take a selected diet containing an ample supply of iron. If the appetite and digestion are deficient stomachics are indicated.

Inorganic iron very often gives better results in the first few weeks of the administration than it does later, which may possibly be explained by its interference with the digestion—a matter to be guarded against carefully. Large doses, if they do not disturb the digestion, are often required.

Bunge distinctly warns the physician against using high-priced pharmaceutical preparations of iron and calls attention to the advantage of beef, blood sausage and blood.

While warm blood may be tolerated by some individuals, the aversion to it is frequently unconquerable and hematin seems to be equally serviceable in any case.[4]

The etiology of some of the anemias is so obscure that treatment must be mainly empirical, but we may feel reasonably certain that we shall do more harm than good if we depend on the nostrums so glowingly advertised instead of directing our efforts toward improving the appetite and digestion. The selection of a proper diet, together with proper doses of inorganic iron in most cases, or of organic and inorganic iron in comparatively few cases in which they are needed, will usually be found to be all that is required.

When iron tends to cause constipation laxatives must be employed, preferably one of the preparations of cascara sagrada, or the pills of aloes and iron, one of which may be given three times daily.

As examples of the innumerable combinations in which iron may be prescribed we give the following:

℞ Ferri sulphatis exsic. 5i 4
Extracti nucis vom.
Extracti rhamni pursh. ää . . . . . gr. xv 1
M. Ft. pil. No. lx. Sig.: One pill half an hour after meals.

Reduced iron or ferric citrate, may be substituted for the dried ferrous sulphate, and a slightly larger amount of aloes (20 grains—1.3 gm.) can be used in place of the extract of cascara sagrada. Clinical experience seems to show that a formula of this kind is not so useful in those conditions in which there is a deficiency of hydrochloric acid in the gastric secretions; in such cases small doses, from half to one teaspoonful, of the solution of iron and ammonium acetate may be given, after meals. This preparation rarely gives rise to constipation or other symptoms of indigestion.

The pills of ferrous carbonate, Blaud's pills, may be given either alone or the mass of ferrous carbonate, which is practically identical, may be used in combination with such a laxative as the extract of cascara sagrada, in the dose mentioned above. If desirable a bitter substance such as the extract of nux vomica may also be included as follows:

℞ Massa ferri carbonatis 5ii 8
Extracti nucis vom.
Extracti rhamni pursh. ää . . . . . gr. xv 1
M. Ft. pil No. lx. Sig.: One pill half an hour after eating.

Other bitter extracts, or other bitter substances, such as quinin or strychnin, and other laxatives may be substituted for those given above. A representative formula for a pill of this general composition would be as follows:

℞ Ferri reducti
Quininæ sulphatis
Aloe purificat. ää . . . . . gr. xlv 3
Strychninæ sulph. . . . . gr. i 06
Ext. gentian q. s. Ft. mass et dividenda in pil. No. lx. Sig.: One pill three times a day, after eating.

While it is true that the salts of the alkaloids might better be substituted by the alkaloids themselves, the amount of acid present is so small that it is really of very little moment.

In this same connection it might be pointed out that the dried ferrous sulphate or the ferric citrate may be substituted for the reduced iron, or, by omitting the extract of gentian, the mixture may be directed to be dispensed as a powder in capsules.

The tincture of ferric chlorid is best given well diluted with water, a glass tube being used to prevent the corrosive action of the acid on the teeth, and the mouth should then be well rinsed with water, or a dilute solution of an alkali such as lime water.

The scale salts of iron, being, generally, combinations with organic acids, are much less corrosive than the chlorid, or either of the sulphates, and may frequently be used with advantage in their stead. A representative formula for a simple solution of this kind would be as follows:

℞ Ferri et ammonii citratis 5i 4
Aquæ dest. . . . . fld. 3xii 50
Elixir q. s. ad . . . . . fld. 3iii 100
M. Sig.: One teaspoonful three times a day, before eating.

Any one of the soluble scale salts of iron can be substituted for the iron and ammonium citrate, and one of the aromatic waters can be used in place of the distilled water, or of the water and the elixir.

The bitter wine of iron, given a few minutes before meals, is an excellent ferruginous stimulant of the appetite and digestion which women will usually find acceptable.

3. The following table, taken from Bunge's Physiology, gives the iron content in milligrams per 100 grams of the dried substance. Such substances as grapes will evidently yield but little iron, since they consist mainly of water.

Sugar	0.0	Cabbage (dark green leaves)	17.0-30.0
White of egg	0.0		
Rice	1.0-2.5	Almonds (blanched)	4.9
Barley (hulled)	1.4-4.5	Almonds (whole)	9.5
Barley (whole)	4.5	Grapes (Malaga)	5.6
Oranges	1.5	Potatoes	6.4
White bread (wheat)	1.5	Peas	6.2-6.6
Apples	1.9	Beans (white)	8.3
Cow's milk	2.3	Carrots	8.6
Human milk	2.3-3.1	Dandelion leaves (used as salad)	14.3
Figs	3.7-4.0	Beef	16.9
Hazel nuts (blanched)	4.3	Asparagus	20.0
Hazel nuts (whole)	12.7	Yolk of egg	10.0-24.9
Rye	3.7-4.9	Spinach	33.0-39.0
Cabbage (etiolated)	4.5	Blood of swine	226.0
Cabbage (light green leaves)	5.6		

4. A practical method for the economic preparation of a hematin product was described by Torald Sollmann, in the Am. Jour. of Pharm., June, 1902, p. 275.

Clinical Notes, New Instruments, Etc.

A PROTOZOÖN GENERAL INFECTION PRODUCING PSEUDOTUBERCLES IN THE LUNGS AND FOCAL NECROSES IN THE LIVER, SPLEEN AND LYMPHNODES.

SAMUEL T. DARLING, M.D.
Pathologist, Ancon Hospital.
ANCON, CANAL ZONE, ISTHMUS OF PANAMA.

On Dec. 7 1905, while examining smears from the lungs, spleen and bone marrow in a case that appeared to be miliary tuberculosis of the lungs, I found enormous numbers of small bodies generally oval or round. Most of them were intracellular in alveolar epithelial cells, while others appeared to be free in the plasma of the spleen and rib marrow. Tubercle bacilli were absent. The following is an account of the case:

Patient.—C. D., negro from Martinique, aged 27, occupation carpenter; address, Paraiso, a village in the Canal Zone.

History.—The patient had been a resident of the zone three months. While in Martinique he had suffered from some mental disturbance. His present illness dates from Sept. 15, 1905, when he complained of fever and vomiting.

Condition on Admission to Hospital.—On entering Ancon Hospital Dec. 5, 1905, he was mildly delirious and incoherent. Lungs were clear; abdomen was scaphoid; spleen was enlarged.

Blood: Negative for malarial parasites, leucocytosis, 2200. Hemoglobin: 60 per cent. (Dare's).

Feces: Negative.

Temperature: On admission, Dec. 5, 12:30 p. m., 101, pulse 120; Dec. 6, 8 a. m., 95, pulse 96; 4 p. m., 98, pulse 100.

The patient died Dec. 6 at 11:30 p. m.

AUTOPSY.

December 7, 8:30 a. m.

Macroscopic and Microscopic Examination.—Body of negro, moderately emaciated; length, 5 feet 8¾ inches; inter nipple distance, 7 3 16 inches; rigor mortis was plus.

The odor on opening thorax was suggestive of pulmonary tuberculosis. The right and left pleuræ were free. There were numerous red blotches (ecchymoses) beneath the visceral pleura of both lungs 8 mm. in diameter. Many small nodules could be felt under the visceral pleura.

The lungs on section were found studded with pale gray hyaline miliary tubercles from 2 to 3 mm. in diameter. The lungs were heavier and more voluminous than normal. The tubercles were not as closely packed or so numerous as is often found in miliary tuberculosis, and the general color of the lungs was bright red.

The peribronchial lymphnodes contained a few small soft recently caseated tubercles. The nodes were enlarged and pigmented.

Heart: This organ was small and normal.

Liver: The liver was enlarged and pale, and there was slight atrophic cirrhosis.

Spleen: This was enlarged to three times the normal in size; the pulp was very firm. The malpighian bodies were distinct. Here and there were a number of small yellow nodules resembling tubercles.

Kidneys: There were a few depressions in a cortex diminished to 8 mm. in depth.

Pancreas: Normal.

Bladder: Normal.

Rib bone marrow: Normal and dry.

Brain: The pia-arachnoid was slightly edematous and more generally adherent to the cortex than normal. The calvarium was very thick.

Intestines: Several specimens of *Tricocephalus dispar* were found in the cecum. There were a few small superficial circular ulcers from 2 to 4 mm. in diameter in the cecum and ileum.

The mesenteric lymphnodes and those at the hilum of spleen were enlarged and pale.

Bacteriologic Examination.—Spleen smears were negative for malarial parasites or pigment. Oval and round bodies were free in the plasma.

In rib bone marrow smears there were traces of intracellular malarial pigment. A number of bodies similar to those in the spleen were seen.

In lung smears tubercle bacilli were absent.

There were myriads of intracellular and extracellular bodies similar to those found in the spleen and the marrow.

A moist coverslip preparation from intestinal ulcers showed motile amebæ.

Anatomic Diagnosis.—Acute miliary tuberculosis, pulmonary type. Tuberculous lymphadenitis, peribronchial. Chronic interstitial splenitis. Atrophic cirrhosis. Chronic interstitial nephritis, slight. Lymphadenitis, mesenteric. Chronic leptomeningitis. Edema of pia-arachnoid. Ulcerative enterocolitis. Amebiasis. General infection by protozoön.

APPEARANCE OF THE PARASITE IN SMEARS.

Lung: This specimen was stained by carbolfuchsin and Gabbet's methylen blue, overstained with polychrome methylen blue, and washed with eosin.

The polychrome blue was prepared as follows:

Methylen blue, pure medic. Grüb.....g.	1.
Sodium carbonate, pure.....g.	.5
Distilled water .....g.	100.

This was placed in thermostat one week, and kept at room temperature for six months.

The excess of blue was removed by washing the smear alternately with alcoholic solution of eosin (.5 per cent in 60 per cent. ethyl alcohol) one second and distilled water a few seconds, until the internal structure of the parasite showed plainly.

The parasite is oviform or round, and is surrounded by a clear refractile non-staining rim, in thickness about 1 6 the diameter of the parasite. This refractile rim is present in all smears, whether previously treated with acid blue or not. The structure is not homogeneous, but consists of a faintly staining substance and a deeply staining one: a clear space or spaces; and chromatin granules. The chromatin granules are generally single, sometimes two or more are counted. One large parasite appeared to have six such dots of chromatin. The granules are often situated in a clear non-staining zone at one side of the darker staining substance: at other times they are situated on the margin or within this substance; and also frequently appearing in the clear refractile capsule. The chromatin granules are generally dot shaped, very rarely elongated. Occasionally two chromatin dots placed together simulated a rod form.

The clear space or spaces resemble vacuoles: at times they resemble the clear non-staining spaces seen in filaria embryos and trypanosomes. The staining substance almost entirely fills the capsule or refractile rim of the parasite. The circular contour of the staining substance is at times broken on one side or place by the clear non-staining zone.

This zone varies in shape, size, and in its relation to the staining substance: being circular, oval, or irregular in form; being three-fourths the size of the entire parasite, or at times barely perceptible on account of its minuteness; being centrally located or excentric; and being single or multiple—two or three.

In size the parasites are from 1 to 4 microns through their greatest diameter; commonly this diameter is 3 microns.

The parasite appears to divide by fission into two equal or unequal elements. One parasite appeared to be dividing into four equal elements. Several parasites with chromatin dots scattered through their substance appeared as pre-segmenting bodies—ready to divide into five or six elements. Occasionally a smaller parasite may be seen close beside a larger one, as though separating from it, the smaller one being about 1 micron in diameter.

Although oval or round in outline, the staining substance,

together with the clear non-staining zone and chromatin granules, give a varying picture, depending on the point of view. Forms suggesting the appearance of familiar objects, such as the eye, a shield, a conch shell, a bullet, or a shuttle are seen. The resemblance of certain parasites to a mammalian embryo in "fetal attitude" is very striking.

In the lung smears the parasite is apparently always intracellular, and the cells contain from 10 to 100 or more parasites. The appearance of free parasites is probably due to the squeezing and breaking up of infected epithelial cells by pressure in making the smear. One unbroken alveolar epithelial cell occupied one-third the diameter of the field. 1/12 oil im. No. 1 oc. B. & L. Parasites had invaded the cell nucleus as well as the cytoplasm, and it was estimated that this cell contained more than 300!

Spleen and rib marrow smears showed fewer parasites, two or three to a field, and they appeared to be extracellular. The

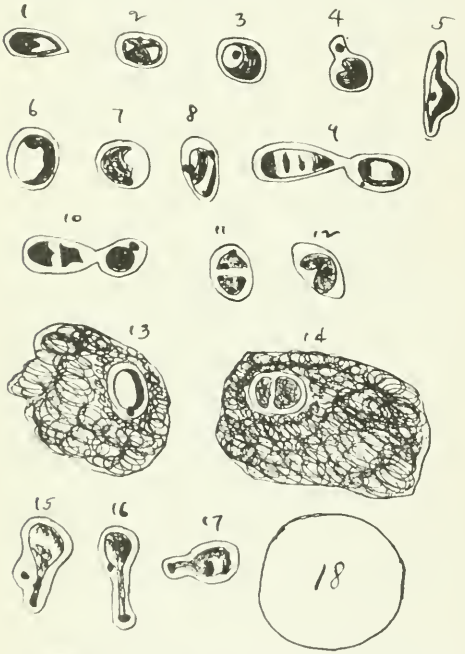

Fig. 1. (× 2000), 1 to 8, forms of parasite; 9, 10, 11, 12 manner of subdivision; 13, 14, parasites within nuclei of spleen cells; 15, 16, 17, flagellate forms; 18, alveolar epithelial cell containing parasites.

nucleus of a spleen or marrow cell appeared now and then to have been invaded. Each parasite had a definite refractile rim, as in the lung smears, and its internal structure could be well made out.

Red blood corpuscles were never invaded.

Three flagellated forms were seen in a lung smear. The distal extremity of one of the flagella contained a rod of chromatin placed at right angles to the flagellum, simulating the relation of centrosome to chromatin filament in *Trypanosoma Lewisi*. The flagella were single, short and thick, without chromatin filaments, and were enclosed by the refractile capsule, continuous with that of the body of the parasite.

EXAMINATION OF SECTIONS.

Sections were fixed in Zenker's solution and stained by eosin and hematoxylin, Van Gieson's method and polychrome-methylen blue.

Lung: The alveolar capillaries are tortuous and engorged with red blood corpuscles. In places the walls are broken down, stretched, or greatly distended. No leucocytes were seen within the capillaries. The epithelial cells of the alveolar walls are desquamating or completely shed. In places there appears to be merely a single layer of endothelial cells separating the circulating blood from the alveolar contents. The alveoli are seen to be filled with red blood corpuscles, generally having a washed out appearance; red blood corpuscles and serum; or red blood corpuscles, serum, and large swollen alveolar epithelial cells containing many parasites.

Polymorphonuclear leucocytes are rarely observed in the alveolar contents; a few mononuclear elements are noted. There are no tubercles. The pseudo tubercular areas are made up of alveoli with broken, distorted, or collapsed walls, containing many alveolar epithelial cells distended by parasites. Small vessels or capillaries are seen to pass through the pseudotubercles, but there are no evidences of the hemorrhages seen in other alveoli. Within these areas there are enormous numbers of parasites generally contained within epithelial cells—rarely free. The nuclei of invaded cells stain well, though often more faintly than normal. The cytoplasm of badly infected cells is wanting, and there are numerous distended epithelial cells devoid of cytoplasm and parasites. The infected cells have a distinctly staining rim of cytoplasm, even when their nucleus and cytoplasm are gone.

Liver: There are numerous faintly staining areas ranging in size from that of a single glandular epithelial cell to those one-third the size of a lobule; in which the liver cells and endothelial cells of the portal capillaries are completely transformed by invading parasites. In the larger areas the cytoplasm and nuclei of the invaded cells have disappeared or do not stain. There is a mass of débris, imbedded in which are myriads of parasites. In places the liver cells are normal, in others they have suffered cloudy change. In these latter localities there appears to be a stasis of blood in the portal capillaries due to occlusion of capillaries by enormously distended endothelial cells filled with parasites. The red blood corpuscles are here "washed out."

There is a distinct primary invasion of liver cells in places, although oftener it would seem that many liver cells become invaded after they have had their nutrition cut off by infected overlying endothelial cells.

Around the portal spaces the connective tissue is increased in amount and there is a recent round cell infiltration. The bile capillaries and their epithelium are normal.

Spleen: The splenic spaces are greatly engorged with red blood corpuscles. The connective tissue is moderately increased, its cells are swollen, cloudy, and at times contain parasites. There is cloudy swelling of cells in small areas here and there, and many of these cells contain parasites. There are also numerous free parasites.

Lymphnode from hilum of spleen: The cortical follicles and medullary cords of the dense lymphoid tissue are, with the few exceptions noted, below normal. The capsule and reticulum throughout the node are the seat of degenerative changes. The reticulum of the loose lymphoid tissue encloses many large mononuclear cells possessed of distinctly staining nuclei, and containing many parasites.

There are two cortical follicles, and portions of a medullary cord which have undergone cloudy swelling and necrosis, amid the débris of which are cells containing parasites. The margins of these areas show beginning degenerative changes; many fragmented nuclei are seen, as well as mononuclear cells distended by parasites.

Peribronchial Lymphnode: This node contains several old fibro-caseous tubercles, and one giant cell. The reticulum and capsule of the node are greatly thickened in places. A lymph vessel beneath the capsule contains mononuclear cells infected by parasites.

There is seen to be a general infection by a parasite having a predilection for endothelial and epithelial cells.

The lesions are those of scattered focal necroses of liver, spleen and lymphnodes, with foci of catarrhal pneumonia and hemorrhages in the lungs, in which the lungs play a very passive part, there being absolutely no leucocytic infiltration of the miliary pneumonic nodules.

The infection was a fatal one, there being no other

lesions sufficiently grave to have caused death. The anatomic diagnosis of tuberculosis not being confirmed on examination of sections, save in peribronchial lymph-nodes.

The parasite, as studied from smears, presents certain resemblances to those found by Leishman, Donovan, Marchand, Ledingham and Wright, but the differences are so marked and the lesions so unusual that I feel the case is a unique one.[1]

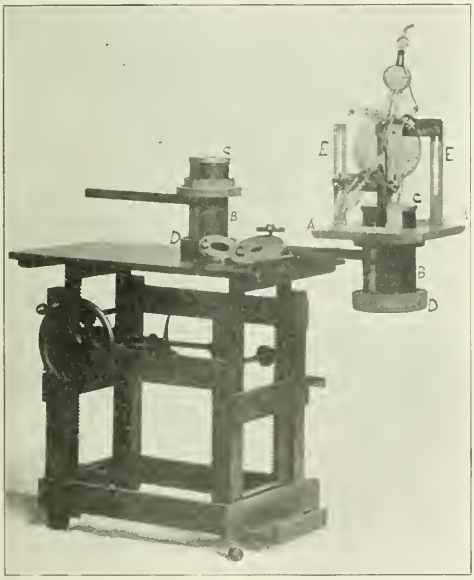
For the parasite the name *Histoplasma capsulata* is proposed.

I wish to thank Acting Chief Sanitary Officer Dr. H. R. Carter for his kind permission to publish this report.

A MODIFICATION OF GOCHT'S COMPRESSION DIAPHRAGM.*

MAX REICHMANN, M.D.
CHICAGO.

Shortly after he had presented his first paper on *x*-rays to the physiomedical society at Würzburg, Roentgen found that *x*-rays do not emanate from the platinum of the anti-cathode only, but also from the walls of the glass tube, from the air which the rays penetrate, in fact that they fill every space in the room in which the Roentgen tube is operating. These secondary rays, as they are called, or diffused rays, as they should be called, affect the sensitized plate, and the blurred and flat negatives which we so often see must be ascribed to these unwelcome secondary rays.



Modified compression diaphragm.

Roentgen himself recommended lead diaphragms to be put between tube and body to annihilate the effect of the secondary rays, and an American investigator, Charles Finley Easton, was the first (1896) to cover his tubes with a lead shell into which a changeable opening was made. Rumpel, in Hamburg, covers the body with thick lead plates, except the region which is to be Roentgenographed. Walter, in Hamburg, constructed a box made of lead, Levy in Berlin, Gocht in Halle, and many others have made original and valuable inventions in this field, but no one was so successful as Albers-Schönberg, in Hamburg, who constructed an apparatus which enabled him to exclude the secondary rays almost completely, and at the same time to reduce the thickness of the body as much as the patient could endure.

Unfortunately, this compression diaphragm of Albers-Schönberg is a very complicated mechanism, besides being so high in price that only a few operators are able to add it to their Roentgen instrumentarium.

Gocht has endeavored to simplify the apparatus, but his arrangement has added greatly to the weight of the instrument so that it is unhandy. I have taken up Gocht's idea and devised an apparatus (see illustration) as follows: A heavy board (A), covered on both sides with lead sheet, has in the center an opening in which two brass cylinders (B), lined inside with lead foil and of the same dimensions as the original Albers-Schönberg tubes, can be tightly inserted. The upper aperture of the cylinder is covered with lead diaphragms (C) of different sizes, while the rim of the lower aperture is covered with a heavy rubber ring (D). On the wooden board are two uprights (E), erected at such a distance from each other that a seven-inch tube can be supported so that the focus of the platinum target falls exactly in a vertical line drawn through the middle of the cylinder, and thus only the most effective rays are allowed to penetrate the body.

As I am working only with seven-inch tubes I had these uprights made steady. Of course, they can be made sliding so that a tube of any size can be used. If an operator is very anxious to avoid any evil effect on his own body these uprights can be connected with lead glass, but I think this is unnecessary.

The whole apparatus is firmly attached to an ordinary camera table, which, by a system of cog wheels, can be raised and lowered at will. As the table runs on castors, which can be arrested by a small lever-break, the whole apparatus can be easily transported to any part of the room. At the same time it can be made stable while in use. The apparatus combines cheapness with effectiveness.

406 Schiller Building.

CASE OF CHRONIC SUPPURATIVE ETHMOIDITIS, SARCOMA OF RIGHT TEMPORO-SPHENOIDAL LOBE, WITH MISLEADING SYMPTOMS.*

J. A. STUCKY, M.D.
LEXINGTON, KY.

On account of the extensive and serious pathologic condition, involving vital structures and very confusing and misleading symptoms, the following case is considered of sufficient interest for discussion:

Patient.—On Dec. 7, 1905, J. J. H., aged 51, was brought to me by Dr. E. V. Seay, of Salvisa, Ky., with the following history: He had been troubled for many years with nasal catarrh; at times large quantities of pus would discharge from nose, and this would be followed by great relief for some days or weeks. Six months previously he had a prolonged attack of malarial fever. Two weeks ago he began suffering excruciating pains in frontal region between the eyes, pain being aggravated by jarring the bed or when in a stooping position. He suffered greatly from nausea, mental depression and insomnia.

Examination.—His gait was unsteady, inclining to the right as he walked across the room. Skin was of muddy, septic appearance; right eye protruding and moved sluggishly. Very slight pressure or tapping over frontal sinus or at inner canthus gave rise to acute pain. The right nares was filled with mass of bluish red granulations, through which pus exuded. There was no evidence of the middle turbinates. The left nares

1. Since writing this article I have found the parasite in a second case.

* Presented at a meeting of the Chicago Surgical Society.

* Read before the Eastern Section American Laryngological, Rhinological and Otological Society at Syracuse, N. Y.

was much congested, but otherwise normal. Transillumination of the maxillary and frontal sinus was positive on right side. Ophthalmoscopic examination showed nothing abnormal in the fundus. The pulse was slow and full; articulation difficult and mind sluggish. He insisted that nothing was wrong but right side of his head. The tongue was heavily coated and breath foul. Blood count showed leucocytes of 19,000.

Diagnosis.—He was sent to the hospital and Drs. G. P. Sprague, F. H. Clarke and J. Estell saw him in consultation. All agreed on diagnosis of chronic suppurative sinusitis, with probable meningeal involvement of right temporofrontal base in purulent inflammation. The apparent aphasia at that time was thought to be due to stupor.

Course of Disease.—The urine was scant, loaded with indican and contained some albumin. A large dose of calomel and salol was given, followed by castor oil ℥j and salts ℥ss in six and eight hours alternately. He had a good night's sleep after taking 15 gr. each of salicylate and bromid of strontium. Patient was purged freely. Nasal irrigation followed by application of adrenalin solution gave some relief to pain, and breakfast was eaten with apparent relish. Two hours after eating he complained of increased pain, yawning and gaping constantly while awake. There was distinct aphasia—he is right-handed—with very frequent slight convulsions of the right hand and arm, and tongue deviates to the right. Constant pain is referred entirely to the right fronto-orbital region. A brain tumor of the left side was thought probable by one of the consultants. Late in the afternoon of December 8 symptoms of brain pressure came on. There was deep stupor and more bulging of the right eye. After consultation it was decided to operate at once.

Operation.—Patient was etherized without difficulty or excitement, pulse and respiration being improved by the anesthetic. I made the usual incision for entering the frontal sinus after Killian's method. The sinus was found free from granulations or pus, but the lining membrane was greatly thickened and congested and of a very dark bluish color. The naso-frontal duct was completely blocked by firm granulations, which, when removed, showed a completely degenerated ethmoid, having the appearance of polypoid degeneration so frequently seen. The whole of this was removed with curette and forceps. The maxillary sinus was found to be blocked by firm tissue, which I supposed to be polypi and granulations. To facilitate the removal of this, the sinus was entered through the canine fossa, and very offensive pus and firm granular tissue removed, which had the appearance of sarcoma. The nasal wall and floor of the orbit was involved in the process of necrosis. After completely cleaning out as far as possible all pathologic tissue and thoroughly cleaning the parts, the usual gauze packing and dressing was applied and patient put to bed in good condition. Duration of operation was one hour and twenty minutes. One hour after the operation patient was conscious, with normal temperature and pulse.

At 8 a. m. the following morning, ten and a half hours after the operation, pulse and temperature were normal, mind was clear, there was no pain, and no hesitancy in speech. Patient censured me for not operating on him sooner. He was thirsty and hungry, and there being no nausea a cup of coffee and a slice of toast were given, which he ate with a relish. These symptoms continued until 9:45 p. m. (twenty four hours after the operation) when alternate stupor and restlessness came on, followed by yawning and grinding of teeth, and extreme restlessness. This condition increased until his death, thirty-one hours after the operation. There was no return of intense pain and no complete loss of consciousness, notwithstanding the deep stupor until a few moments before his death, which came without a tremor.

Autopsy.—Four hours after death the autopsy was held by Dr. Julian Estell in the presence of Dr. Sprague and myself, and the report of the latter from a neurologic and the former from a pathologic standpoint is given.

DR. SPRAGUE'S REPORT.

"I saw Mr. J. J. H. at the Good Samaritan Hospital December 8, at 11:30 a. m. At that time he was very feeble, the skin was sallow, mouth and eyes were dry, and tongue covered with a dense, dry brown coat. His pulse was 55 and respiration 15. The pupils were equal, moderately contracted, and reacted slowly to light and accommodation. Because of his weakened condition, his other reflexes were not tested. His mind was very sluggish, and he would lapse into unconsciousness while answering questions, but he complained of very severe pain under the right eye, and of severe but vaguely outlined pain over right frontal region. He insisted that he had no pain elsewhere, but was too nearly stuporous to discuss his condition further. There were no focal symptoms, although a slurred articulation and the occasional loss of a word suggested aphasia more than stupor.

He was operated on that night and I saw him again at noon December 9, at which time he was rather less dull than before the operation, but gave such irrelevant answers to questions that no statements could be gotten from him. His tongue, at the time, deviated to the right, and the right hand and arm were slightly convulsed every minute or less. He located the pain as before, but said it was less severe. His articulation was more impaired, and the aphasia, deviation of the tongue, and tremor of the right arm suggested disease in the third frontal and anterior central convolutions of the left side.

"At the autopsy, four hours after his death, December 11, part of the third frontal convolution and the lower part of the anterior central convolution of the right side were discolored from light red to nearly black from hemorrhages. A very small part of the region mentioned appeared normal, but most of it was more dense than normal. On section it gave the impression of being fibrous. The ventricular fluid was slightly in excess of normal, and of a clear, blood-tinged color. There was no involvement posterior to or below the fissures, and no disease as far as could be determined by naked eye examination in any other part of the brain. His son stated that he was right-handed."

DR. ESTELL'S REPORT.

"Skull cap was removed. Right temporosphenoidal lobe of brain was adherent to floor of middle fossa. Slight adhesions along vertex of longitudinal fissure extending about two inches in front and behind fissure of Rolando and down about one inch over cortex. Whole of right temporosphenoidal lobe of a red gray mottled color and meninges adherent over base of the lobe.

On section the lobe seemed entirely replaced by an encapsulated mottled red and gray mass of semisolid, pasty consistency. Closer inspection showed trabeculæ of firmer fibrous like bands running through the mass with soft pasty, dark red gummy material in the spaces, giving an alveolar structure to the mass. The tumor gave the gross appearance of an 'infected sarcoma.' Tumor was examined microscopically and proved to be sarcoma, both small round and small spindle cells being found. The whole tumor was far advanced in process of degeneration, and showed evidence both of inflammatory infiltration and necrosis, the indication being that the infection had extended from the nasal accessory sinuses."

I have reported this case as briefly as possible without omitting important detail, although every hour the patient was under my care was filled with more or less interesting and peculiar symptoms. From the time I saw him until within four hours of his death, the temperature, pulse and respiration were recorded every three hours. The temperature varied from 96 to 98 F., pulse 56 to 68, respirations 15 to 19. Four hours before he died the temperature rose to 103, pulse 120, respirations 21.

Some of the most interesting points to me, and those selected for discussion, are (1) relation of cause and effect—was the cerebral condition the result of sinus condition or *vice versa*? (2) The confusing and misleading symptoms indicating pressure in left side of the brain. (3) Could general intracranial pressure exist without producing a motor symptom referable to right-sided pressure. (4) What would have been the probable result if the sinus disease had been eradicated months before?

DOUBLE EMBOLIC GANGRENE OF THE LOWER EXTREMITIES AS A COMPLICATION OF PNEUMONIA.

FRED F. ATTIX, M.D.
LEWISTON, MONT.

Patient.—A. J., aged 56, male, medium height, weight and figure.

History.—The patient has always used alcoholic beverages in moderation. The present illness began Jan. 20, 1906. Twelve days previously, he developed what he thought to be a cold; he used domestic remedies, but was not careful to avoid needless exposure. This state of affairs lasted for ten days. On the eleventh day he sent word that he could not leave his bed and a physician was summoned.

Examination.—Auscultation and the physical signs showed that there was pneumonia in the right lower lobe which was approaching resolution. The temperature was 103, pulse 160, and respiration 60. There was cyanosis and the lower extremities were cold.

Consultation.—On the following day I was called in consultation. At that time there was mental apathy and moderate effort was necessary to rouse the patient who then showed mild delirium. The pupils were moderately contracted and equal; the tongue was red, dry and fissured. Rectal temperature was 102.5, respiration varied from 46 to 50, and the pulse was 146, regular, of medium volume and with no signs of arterial sclerosis.

The area of cardiac dullness was normal, with moderate strength of heart muscle and no signs of endocarditis or of pericarditis. The lower lobe of the right lung was in the stage of resolution. There was moderate orthopnea. The urine was voided in large quantities on an average of every hour and the feces passed once daily.

During the night before I saw him the patient had suddenly developed pain in the right thigh, which was still present when I examined him. Tenderness and hyperesthesia were also present. There was a perceptible swelling about the center of Scarpa's triangle on the right side, and on palpation an indurated mass could be detected, below which there was no femoral pulse. Complete anesthesia of the skin was present to a point 2 inches above the knee, where the skin was hyperesthetic and cyanotic. The skin of the leg was very dry, cold and clammy, with a tendency to ulceration over the ridge of the tibial bone. The left leg was in much the same condition, although the embolus had lodged in the lower portion of the popliteal space on this side.

Termination of the Disease.—The toxemia developed and the patient died 14 hours later.

Autopsy.—A partial autopsy was made forty-eight hours after death by Dr. Tice, who made the following report: "At the profundal branch of the femoral artery an embolus had lodged and extended for one-half inch down the profundal branch and one inch down the main artery. Below this point the artery was patulous. Above (as far as opened to Pouparts' ligament) the artery was filled with loose clotted blood. No further autopsy was allowed." No bacteriologic examination has been made of the emboli at this time to determine if they were infected.

CONGENITAL SARCOMA OF THE ORBIT.

G. BETTON MASSEY, M.D.
Attending Surgeon American Oncologic Hospital.
PHILADELPHIA.

The clinical report of a sarcoma in a child of 3 years, contributed to THE JOURNAL, March 3, 1906, by Dr. Spearman, of Whiting, Iowa, recalls a still more youthful case under my care at the Oncologic Hospital last summer. In this case the growth was strictly congenital, having been noticed at birth.

Patient.—Helen K., aged 6 weeks, was admitted to the hospital from Tyrone, Pa., July 3, 1905.

History.—Her parents were healthy and there was no history of malignant disease in the family. At birth a tumor the size of the tip of the little finger projected from the edge of the right upper eyelid. Two days after birth the tumor was removed by the attending physician, but recurrence immediately took place, and when the baby was admitted to the hospital six weeks after birth a tumor the size of a golf ball projected from the orbit, the eye being pressed downward and inward. The origin of the growth seemed from the history to have been in the middle structures of the eyelid, though conditions on admission showed that the whole orbit was infiltrated.

The general health of the little patient being apparently good, save for abnormal restlessness, it was decided to attempt a cataphoric destruction of the growth by a major operation of mercuric cataphoresis. The passage of a sufficient current through the head to accomplish this result was of course out of the question; hence it was necessary to confine the circuit to the growth itself by placing both poles within its substance.

Operation.—On July 5 the baby was placed under chloroform, a pointed electrode connected to the negative pole of the apparatus was pressed against the center of the tumor, and six fine zinc points coated with mercury and attached to the positive pole of the apparatus were inserted around the periphery of the tumor (which practically corresponded to the walls of the orbital cavity). With the electrodes thus placed a current of 350 milliamperes was gradually turned on and maintained for sixty-five minutes. The cataphoric destruction of the diseased eyeball was aimed at, as well as destruction of the tumor and sterilization of its edges. These purposes were apparently accomplished in the time mentioned, with no disturbance of the pulse and respiration and no loss of blood.

Subsequent History.—The baby was less fretful the following day than before the operation, and when recovered from the anesthetic nursed regularly. The slough came away July 18, including the eye-ball, though the devitalized optic nerve had to be clipped with scissors; this was done while the patient remained in a natural sleep in the nurse's arms. It was nevertheless seen that some disease remained higher up within the orbit, and, more significant of the futility of attempts at eradication, a metastatic tumor developed about this time in the cheek beneath the eye. A second major application of bipolar cataphoresis was made to both spots July 20, under chloroform, 160 milliamperes being used for twenty-five minutes.

In spite of the apparently vigorous growth of the little patient evidences of metastasis increased, a tumor developing beneath the jaw. An extension to the brain was later indicated by the occurrence of convulsions and coma, death supervening Aug. 30. A specimen of the tumor removed prior to the first application showed the growth to be a round-celled sarcoma.

1831 Chestnut Street.

Examination of Heart of Rameses II.—The French have recently purchased for the museum in the Louvre four urns containing the viscera of the king Rameses II of Egypt, the Sesostris of the Greeks. He died 1,254 years before the Christian era and his mummy has thus been embalmed for 3,164 years. The *Semaine Med.* states that Lortet and Renaut examined the urns. Nothing was found in the urns supposed to contain the stomach, intestines and liver except strips of linen and resinous substances, with a quantity of indeterminate dust. But in the urn supposed to contain the heart, the viscus was found in comparatively good condition. It had become flattened, forming an oval plaque about 4 cm. wide by 8 long, extremely hard and horny. It had to be sawed to obtain sections for examination. Thin slices could then be shaved off with a razor. Under the microscope these sections showed the arrangement of the muscle fibers characteristic of the heart. The anatomic texture of the organ was thus preserved by the embalming process.

SATURDAY, APRIL 28, 1906.

HEALTH OR DISEASE IN SAN FRANCISCO.

Not the least important among the problems the citizens of San Francisco are facing is the prevention of infectious disease. In catastrophes such as the one which has overtaken the great city of the Pacific coast, two factors are especially active in increasing the prevalence of diseases of germ origin. These are: First, the close physical association, even involving personal contact, into which a very large proportion of the population are forced, and, second, the diminished powers of resistance due to hunger, thirst, exposure, fatigue, and all the other accompaniments of the situation. The men, women and children exposed to infection become, so to speak, more inflammable at the same time that the opportunities for exposure are enormously multiplied. It needs no ghost to come from the grave to tell us of the danger. A difficult task lies before those on whom falls the responsibility for maintaining the public health in the present crisis.

Respect of property is being enforced in San Francisco with military rigor, and the method of shooting down petty marauders at the start had a wholesome effect on the baser sort, but the lives as well as the property of the decent citizens are at stake, and the need of decisive action is as urgent in the one case as in the other. There is no time for "barking up the wrong tree." The disposal of kitchen refuse should at present cause no particular concern. Disease does not "breed" in piles of garbage, however offensive the stuff may be to the senses. We are reading in the newspaper dispatches that "the miasma from putrefying corpses" is fast becoming a "menace" to the health of the city, but, while it is well to act as though this were actually true, it must be remembered that the emanations from decomposing animal matter, horrible though they are, have no power to cause typhoid fever or smallpox or any other infectious disease.

It is clear that the recognition and isolation of cases of infectious disease is of the first importance. The living human being is the culture medium in which disease germs thrive and from which they are transmitted to new centers. It is essential to detect the existence of infection as early as possible and then to enforce a quarantine with a promptness and thoroughness that leave nothing to be desired by the most exacting martinet. Halting and half-hearted measures have no place in San Francisco just now.

Besides the search for and supervision of diseased individuals, the authorities will doubtless watch carefully the disposal of all the excretions from the human body. It is now well known that some apparently normal persons may harbor pathogenic micro-organisms and may be the means of spreading disease just as widely as those who are frankly infected. The "chronic carriers of typhoid bacilli" several times referred to recently in THE JOURNAL[1] are an instance of this sort. No mistake will be made in assuming that the discharges from the bowels and bladders of seemingly healthy persons contain possibilities of mischief and in treating them as potentially infectious. Sources of drinking water will, of course, be carefully protected and all dubious supplies remorselessly cut off. The rôle played by the common drinking cup in promoting the spread of diphtheria and other infections will doubtless be kept in mind. The influence of the daily press, always great at a time like this, has already been brought to bear with good advantage in educating the public in an unhysterical fashion to the especial dangers of the situation. It would be a great triumph for the cause of preventive medicine in the United States if the San Francisco tragedy were allowed to go no further. Pestilence must not be permitted to claim more victims than the earthquake itself.

THE CALIFORNIA HORROR—AN APPEAL.

It is unnecessary to enlarge on what has already appeared in the public press relative to the conditions in California, especially in San Francisco, and to the need of help. The money and the necessaries of life sent by the nation at large for the general relief of all who were suffering is probably ample for the time being; but many thousands who were in good circumstances are now penniless, consequently without means to resume their occupations. This is true of many of the physicians who have lost not only their homes and all contained therein, but also their offices, libraries, instruments, etc., leaving them without the means to resume practice. The condition of many is undoubtedly desperate. There has never been a time when our profession could show its regard for its professional brethren in distress better than now. The Board of Trustees of the American Medical Association has authorized that THE JOURNAL's columns be opened for the acceptance of subscriptions for the California physicians.

An appeal is, therefore, made to the profession throughout the land so that each one may have an opportunity of contributing something directly to help his professional brethren who have been so unfortunate in this terrible calamity. In many localities the county society will take up this matter; in such cases some will send their contributions direct to San Francisco; others may find it more convenient to send through the American Medical Association fund. In the latter case we

1. THE JOURNAL, Feb. 3, 1906, p. 365; March 10, 1906, p. 759.

all be glad to print the total amount contributed by ch a society, together with the amount given by each dividual member.

It has been impossible thus far to get sufficiently in uch with physicians in San Francisco to make definite rangements in regard to the distribution of the fund, t it is presumed that the officers of the Medical ociety of the State of California and of the San rancisco County Medical Society will jointly create a mmittee to look after the matter. We hope that every ember of the profession will do something in this hour need. A list of the amounts already received will be und on page 1297.

LIMITS OF HUMAN ENDURANCE.

Physicians as well as the general public were startled the sensational headlines in the newspapers last week hich announced that, after twenty-five days of imprisnment in the mine at Courrières in northern France,[1] fourteenth survivor had shocked one of the salvage arty engaged rather in repairing the mine than in escue work by placing his hand on his shoulder and sking aid. Some five days previously thirteen others, nought long dead, had been found alive. Such survials for prolonged periods are not so rare as might be nought. A miner in the hard coal regions of Northastern Pennsylvania was confined for even a longer eriod than these French miners and recovered comletely from his trying experience. The failure of the uthorities in charge of the rescue work in France to ealize the possibility of such long survival eminently nerits the disapproval which has been aroused among ne people, and it is not surprising that social disturbnces of various kinds should have been the result.

While it is not explicitly stated, it would seem that he physicians, who were summoned at the beginning f the rescue work to assist in caring for whatever victims might be taken out, were not sufficiently strenuous n their objections to the abandonment of efforts at escue. Had they insisted on the possibility of some of he supposed victims of the accident being still alive, ven after the end of a week or ten days or even longer ollowing the accident, there seems no doubt that the escue work would have been prosecuted with more igor and with a concentration of purpose that would ndoubtedly have saved many lives. Most of the bodies hat have been found during the last week of search efore the meeting with this survivor who had been wenty-five days confined showed evidence of comparaively recent death. But for the feeling of hopelessness hat had been allowed to establish itself many of these victims would undoubtedly have been rescued.

Physicians' experience generally would seem to be sufficient to establish the possibility of survival for three weeks without food, provided that a sufficient supply of liquid can be obtained to maintain vitality at the expense of the tissues themselves. In the absence of water, death within five days is the rule, but otherwise there is no definite limit. Certain experiences with hysterical patients and with the sufferers from lethargic conditions, besides the well-known demonstrations by such fasters as "Dr." Tanner, would seem to show that human beings may very readily survive even for from forty to sixty days without food. Such survival is dependent to a large extent on an absence of physical effort to any noteworthy degree during the course of the abstinence from food. Miners, therefore, who are confined in an out-of-the-way part of a mine by an accident are likely to do much more toward their own ultimate rescue alive by avoiding efforts at helping themselves out if they are behind a thick barrier and waiting patiently for the salvage party than by exhausting their strength in what is almost sure to be misguided labor.

There are lessons in this sad experience in France that should not be lost, especially on physicians and mine authorities who are likely to find themselves face to face with such an awful responsibility. Fortunately mine accidents with us involve many less lives than were at stake in the French catastrophe, but the rescue problem is none the less important, since in such circumstances even the saving of a single life is a triumph not to be despised. In this sad affair human lives have undoubtedly been sacrificed because the limits of human endurance of privation were set too low—a mistake almost unpardonable with our present knowledge of Nature's possibilities.

THE PROPOSED CRUSADE AGAINST BLINDNESS DUE TO PREVENTABLE OPHTHALMIA NEONATORUM.

For many years past sporadic efforts to reduce the amount of blindness in the country have been made by physicians. Either acting alone or in the mass as medical societies, they have done their best to spread the good news of a successful prophylaxis, so well stated by Dr. Park Lewis in his article on unnecessary blindness in this issue of The Journal.[1] Boards of health, also, have issued instructions to midwives; city councils have even enacted ordinances, while other agencies, lay and professional, have done their share in directing the attention of those most interested to the dangers inherent in leucorrheal discharges to the eyes and eyesight of the new born, to the symptoms that herald these dangers and to the most effective methods for preventing threatened blindness.

Doubtless these attempts to limit or to abolish preventable disease have had some effect, but in the United States the proportion of blind-asylum inmates to the population still continues to be about the same that it was ten years ago.

During the years immediately following Credé's discovery, the total and proportionate amount of ophthalmia neonatorum—especially in public lying-in hospitals—had greatly decreased. Since Credé's an-

1. The Journal A. M. A., April 28, p. 1262.

nouncement, also, in the private practice of well-informed medical men, the plan of instilling silver nitrate into the eyes of the new-born child whose mother has any form of leucorrhea has been pretty generally and thoroughly carried out. In quite a large percentage of such cases, too, the vaginal discharges are examined, and when the gonococcus is found particular care is observed in treating the mother with germicidal applications.

It has consequently followed that among the well-to-do a serious infantile ophthalmia is rather rare. In the homes of the improvident, the ignorant, the careless — and these are generally the poorer class in the community—the story is a different one. Their accouchements are usually attended by midwives or by overworked physicians who see their patients but once or twice after the birth of the child. A thorough anteparturient examination is often wanting and the mother may easily have had a neglected infection of the genitals at the time of her accouchement. Among this class, hygienic precautions are the exception rather than the rule, so that we can easily understand how its members still continue to contribute to our blind asylums. As Dr. Park Lewis points out, we seem in late years to have abandoned the crusade against preventable ophthalmia neonatorum, although the need of it is quite as palpable as it was twenty years ago and the remedy just as effective. It is quite as true to-day as it was when Credé announced his discovery, that a few minims of a 2 per cent. solution of silver nitrate dropped into each eye of a new-born infant is as harmless to its sight as it is preventive of blindness from gonorrheal or other dangerous infection.

Let us once more sound the note of warning until every accoucheur and every midwife in the land is fully informed of his or her duty. Let it be widely advertised that a free and effective remedy is at the ready disposal of the poorest mother in every part of the country. Allow the responsible parties no excuse for non-performance of duty, and then see to it that neglect of these precautions is strictly punished. If the movement be successful, a campaign of education must precede the enactment of laws on the subject. The American Medical Association may well act as the prime mover in this war against blindness, and there seems no room for doubt that if the plan suggested by Dr. Park Lewis is adopted by it and vigorously agitated by its constituent branches the country will be relieved of a great burden, while the happiness and effectiveness of many lives will be infinitely increased.

THE FLAT FOOT SERIES.

The specialization of modern medicine, while of inestimable value both to the patient and to scientific medicine, has its drawbacks. The most important of these, and one which has been recognized since specialties existed, is the danger that after a time the specialist grows narrow, is always on the lookout for diseases which come within his specialty, and overlooks changes in other organs. That there is a reaction against these narrowing tendencies is shown by the tendency of modern surgeons to have their patients looked over by medical men, and *vice versa*, and by the appearance of journals dealing with the subjects on the borderline between medicine and surgery.

Among the conditions which are to be regarded as borderline conditions must be mentioned what Berry[1] calls the "Flat-Foot Series." We heartily agree with this author that it is a mistake to label all these cases flat foot, for in their earlier stages, and it is during these stages that the deformity should be recognized, the arch of the foot is not lost. Furthermore, there is little doubt that the very use of the term flat foot has led innumerable practitioners astray, the diagnosis being considered as ruled out because the arches of the feet seemed, and indeed were, undeformed. The condition is such a common one, its manifestations are so protean, and its relief, in most instances, is so easy that it is high time that the general mass of the profession became acquainted with the symptomatology and physical signs of its various phases.

So far as the symptoms are concerned, the most important point to be recognized is that the various phases of the flat-foot series may produce pain and other results at a considerable distance from the real lesion. Even pain in the pubic region and herpes progenitalia have been ascribed to weakened or flat feet. While some observers have doubtless been too enthusiastic in their advocacy of the condition as a cause of distant symptoms, there is little doubt that pain in the calf, knee, leg and thigh may all be signs of this pedal infirmity. Without question, some of the cases which are described under the head of sciatica also belong in this category, and the peculiar nervous symptom-complex known as meralgia paresthetica is said to be usually associated with the flat-foot series. In most cases it is apparent enough that the feet are at fault. There is loss of the elasticity of the walk, pleasure in walking becomes a thing of the past, pain, aggravated by wet weather, appears, walking becomes painful, even at night and in bed the feet ache, and there may be distressing nocturnal cramps in the calves. In advanced cases with marked muscle spasm and swelling of the feet, a diagnosis of tuberculosis of the foot may be made, but most of these patients are treated for rheumatism, gout, or arthritis.

In detecting the signs of the flat-foot series it is to be borne in mind that at one end of the series is the pronated foot, with little or no weakening of the arch, and at the other the rigid flat foot. In the later stages, diagnosis, of course, is easy; but in the earlier ones it may present considerable difficulties. The most important points to be noted are the gait and the position of

1. Albany Med. Ann., 1906, vol. xxvii, p. 250.

e foot at rest. The most characteristic thing about
ie gait is the outward rotation of the feet and the
lling in of the ankles. In the standing position,
ith the observer behind the patient, the prominence of
e internal malleoli and the turning out of the foot are
riking, and one gets the impression that the weight of
e body passes far within its normal line, as indeed it
es. Imprints of the foot on smoked paper, according
Berry, are worthless in determining the degree of
e trouble.

The causes of this common condition are manifold.
he fact that many cases occur during rapid growth,
in middle-aged people at the time when they take on
t, shows that a disproportion between the weight and
rength of the foot is an important factor, and practi-
lly the same effect is produced when people of normal
eight suffer from general muscular weakness or local
ot inflammations. Again, some people may be born
th a tendency to weakened feet, for feet may be de-
ctive just as well as lungs or arteries. In many re-
ects, the most important factor is improper shoes,
d it is especially important because it is preventable.
oubtless the trouble is partly with the shoemakers,
io have been working along rule-of-thumb lines for
ars, but reform in this, as in other hygienic subjects,
ist come from the medical profession, and surely here
form should be easy, for it is just as easy to make a
operly constructed shoe as an improperly constructed
e.

THE SCIENTIFIC EXHIBIT AT BOSTON.

It is planned to have in the Scientific Exhibit at the
ning session of the Association a representation of the
thods and progress of medical science in America.
ie exhibit will be held in the spacious new laboratory
ildings of the Harvard Medical School. These labora-
ries with the new museum will furnish unusual space
d light for exhibition purposes. The exhibit will con-
t of specimens, models, diagrams, etc., and a large
mber of special demonstrations will be given. In
rt these will be on special subjects and will be given
small rooms adapted for the purpose, microscopes
ng used; in part, on subjects of general interest, the
itern and projection microscope being used in one of
large amphitheaters. There will be a laboratory in
eration, showing laboratory methods as applied to
gnosis in medicine and surgery and to investigation.
w of the men working in special fields realize how
merous the methods are and how dependent modern
dicine and surgery are on them. The exhibit in
thologic anatomy will be large and will be classified
as to show thoroughly individual diseases and special
thologic processes. In certain lines, as in neuro-
hology, the exhibit promises to be particularly good.
e modern methods of photomicrography with subse-
ent enlargement of the negatives make it possible to
w all the finer details of pathologic conditions. There
lso a large exhibit in anatomy, histology and embry-
gy promised, a special feature of which will consist
reconstructions of large wax models. Our knowledge
in human medicine has largely depended on the study of disease in animals and on the experimental production of disease. The diseases of plants have also been of importance in showing modes of infection and the action of pathogenic organisms on tissues. There will be a full exhibit both of the diseases of animals and of plants, of those naturally acquired and those produced experimentally. A part of the exhibit will be of historical interest, and this will, in part, illustrate the lives and works of illustrious medical men, and, in part, consist of collections of surgical instruments, showing the evolution from the crude instruments of the past. The exhibits of the boards of health will be part of the general scientific exhibit and will illustrate water supply, sewerage, and the general subjects pertaining to public health and preventive medicine. In bacteriology there will be shown methods of diagnosis and investigation and also demonstrations of bacteria by means of cultures, photographs and diagrams. It is believed that the exhibit will do much good in many ways. It will bring together those whose work consists chiefly in laboratory investigation and enable them to see the methods and the results of others. It will especially stimulate those working in special lines of medicine or surgery, for they will see methods in other lines of work which might be used advantageously in their own. It will increase knowledge of disease, for the product of the work of many will give different points from which disease may be viewed. It will increase the sympathy and mutual respect of men for one another. Those who are willing to contribute to this exhibit should write either to Dr. F. B. Wynn, Indianapolis, or to Dr. W. T. Councilman, Boston.

THE UNRULY PRESS.

In the present state of public thirst after medical sensations and with the license allowed itself by the yellow press, it is dangerous to say anything startling or novel in relation to medical or surgical matters within the range of a reporter. A distinguished eastern surgeon relates an experience in point. Having mentioned in a lecture massage of the heart as a means of resuscitation, he was interviewed by telephone in regard to it, but carefully explained that he had never successfully employed the method, the patient on whom he had tried it having died. The next day's newspaper contained an account of his marvelous discovery and of his bringing the dead to life, and in the middle of the article was an account of an interview with his patient who had died two years before. In spite of President Cleveland's demand for a shedding of the esoteric in medicine, we have abundant reason to think it is still advisable for physicians to bridle the unruly member when reporters are near by.

A SURGICAL DILEMMA.

We have commented[1] on the outcome of a case in which a surgeon was sued because he performed an operation which was not on the program when he first began to operate. Though the procedure was entirely in her interest, the patient considered herself damaged because her consent had not been asked, and wanted to get something out of the surgeon as remuneration. Another case

1. The Journal A. M. A., April 14, 1906, p. 1116.

is of interest in this connection. A surgeon diagnosed appendicitis calling urgently for interference, but on preparing for operation he had reason to change his diagnosis and allowed the patient to return home. She thereon went to another hospital and was successfully operated on for an entirely different condition, and afterward brought suit against the first surgeon for not having been operated on, or, for what is practically the same thing, the correction of the wrong diagnosis. If the surgeon had proceeded and done what seemed to him required, the patient would probably have sued him for doing an operation to which she had not consented and possibly, having in his mind the precedent of the three first trials of the Minnesota case previously referred to, he naturally did not care to take the risk. Verily the way of the surgeon is sometimes hard. If he discovers it necessary to perform anything but an absolutely life-saving operation not contemplated in the beginning, without taking the patient out from under the anesthesia, he may still be liable to troublesome litigation. If, on the other hand, he pursues the other course, it seems he may be mulcted in damages for not making the diagnosis before.

AN UNUSUAL VACCINATION ACCIDENT.

We have all probably heard of the unfortunate individual who mistook an ivory vaccination point for a toothpick and the unpleasant consequences which resulted. A rather more striking and uncomfortable, but not inexcusable, accident is reported from Great Britain. A physician, preparing to vaccinate an infant, was struck in the eye by a little fragment of glass from the breaking of a tube of vaccine. Though he immediately washed his eye, the virus took and he had a vaccine pustule, presumably on the conjunctiva, as it is said that his eyesight is not likely to be affected.

INFLUENZA AND APPENDICITIS.

It is often difficult, in medicine as in the ordinary affairs of life, to distinguish between coincidence and cause and effect. Medical men have been accused on more than one occasion of being particularly obtuse in this connection, but we can not see that they are worse than the rest of mankind. It will be remembered that in the winter of 1889-90 influenza reappeared among us, and that about the same time McBurney's point began to creep into the literature, and appendicitis became fashionable. The coincidence caused a not inconsiderable number of physicians to declare that the great increase in the incidence of appendicitis was due to influenza, and that this was capable of proof. To read many of the articles on the subject one might suppose that the matter was beyond question. Rostowzew,[1] who has recently gone over the whole subject very carefully, states that the belief that influenza causes or predisposes to appendicitis is absolutely ungrounded, except in the extremely rare cases in which the influenza bacilli have been found in the lesions. Too much has already been thrown on the shoulders of the influenza bacillus, and one feels strongly inclined to paraphrase the well-known remark and say: "Oh, influenza, how many crimes have been committed in thy name."

Medical News

ARKANSAS.

State Meeting.—The Arkansas State Medical Society will hold its annual meeting at Hot Springs, May 8-10, and a good meeting is expected. Dr. Joseph M. Mathews, Louisville, Ky., will be the guest of honor and will deliver a popular lecture on the night of the 9th to which the public is invited.

COLORADO.

Children's Hospital Organized.—A children's hospital association was organized in Denver, April 5, with Dr. Minnie C. T. Love at the head of the institution.

New Dispensary.—The directors and faculty of Gross Medical College, affiliated with Denver University, held a meeting April 9, at which it was decided to erect a new dispensary in connection with the college at Fourteenth and Arapahoe streets.

Personal.—Dr. Seymour D. Van Meter, secretary of the State Board of Medical Examiners, and Mrs. Van Meter, who were in San Francisco April 18, have telegraphed that they are "safe, not even scratched."——Dr. Orville M. Clay, Montrose, suffered a fracture of the wrist and severe lacerated wounds in a runaway, April 1.

War on Tuberculosis.—At a meeting held at the headquarters of the Charity Organization Society, Denver, April 9, the following resolution was adopted:

WHEREAS, It appears to the Charity Organization Society of Denver that more efficient means should be devised and inaugurated for the prevention and relief of tuberculosis in the city and county of Denver and throughout the state of Colorado, as affecting conditions in the city and county of Denver. Now, therefore, be it

Resolved, That the president of this society appoint a committee consisting of nine physicians residing in the city and county of Denver, well known for their ability and interest in this subject, which committee, with the president of this society as member ex-officio, shall be known as the Committee of the Charity Organization Society of Denver, for the Control of Tuberculosis.

That such committee shall be authorized and empowered to co-operate with the Charity Organization society and its co-operating institutions, to take all necessary steps to inaugurate such methods as in their judgment will best accomplish the purpose of their organization.

CONNECTICUT.

Bequests.—Danbury Hospital has received a bequest of 100 shares of stock, valued at $5,000, by the will of the late Edward E. Gilbert, Georgetown.——The Hartford County Medical Society has, it is understood, received a gift of $10,000 by the will of the late Dr. William T. Bacon. He also bequeathed $5,000 to establish a free bed in the eye and ear department of the Hartford Hospital.

GEORGIA.

The State Meeting.—The fifty-seventh annual meeting of the Medical Association of Georgia was held at Augusta, April 18-20, under the presidency of Dr. William Zellars Holliday, Augusta. The following officers were elected: President, Dr. Henry H. Martin, Savannah; vice-presidents, Drs. Theodore E. Oertel, Augusta, and Jarrett W. Palmer, Ailey; secretary-treasurer, Dr. Louis H. Jones, Atlanta; delegates to American Medical Association, Drs. Thomas D. Coleman, Augusta; George R. White, Savannah; Henry F. Harris, Atlanta. Savannah was selected as the place for holding the next annual meeting. The following preamble and resolution were adopted:

WHEREAS, It has been brought to the attention of this body that there is a pure food bill at present before the Congress of the United States, known as the Hepburn Bill; and

WHEREAS, This bill meets with the approbation of this body representing the medical profession of Georgia; therefore, be it

Resolved, That this body earnestly requests the senators and representatives in Congress from the State of Georgia to vote for the said bill, and that they use all their influence to further its passage.

The following was likewise unanimously adopted:

Resolved, That it is the sense of this association that the minimum fee for life insurance examinations should be $5.

An account of the scientific proceedings will be given next week.

ILLINOIS.

Personal.—Dr. James A. Egan, secretary of the State Board of Health, who has been ill for the past three weeks, is greatly improved.——Dr. and Mrs. W. H. McClure, Sheldon, have recently returned from California.

State Society Meeting.—The Illinois State Medical Society will meet in Springfield on the date originally set, May 15, 16 and 17. The order changing the date of the meeting to May 22, 23 and 24 has been rescinded.

Epidemic Diseases.—A large number of additional cases of smallpox have appeared at Fairhaven and Milledgeville.——The public schools of Metcalf have been closed on account of an epidemic of diphtheria.——Smallpox has broken out in Montgomery County and it is reported that in one family seven members are victims of the disease.

Chicago.

May Alter Interneship Ratio.—Action may be taken by the board of Cook County commissioners revising the apportionment of internes to the County Hospital, owing to the lack of eligible appointees in the eclectic and homeopathic schools.

Personal.—Dr. Eugene S. Talbot was unanimously made an honorary member of the Belgian Society of Stomatology at its meeting, April 8.——Dr. R. R. Campbell, who has been away from the city during convalescence after an operation for appendicitis, has returned.

Deaths of the Week.—For the week ended April 21, 645 deaths were reported, 24 deaths more than for the preceding week and 87 more than for the corresponding week of last year. The mortality was at the annual rate of 16.40 per 1,000. Pneumonia, as usual, far exceeds any other death cause, with 123 deaths; consumption follows with 75, and then come violence, including suicide, with 42; heart disease with 40; nephritis with 35; acute intestinal diseases with 32; bronchitis with 21; nervous diseases with 39, and cancer with 28 deaths. Diphtheria caused 11 deaths during the week; measles, 2; scarlet fever, 13; typhoid fever, 10, and whooping cough, 1 death.

KANSAS.

Offered Hospital Site.—The Sisters of Charity, Leavenworth, have been offered a site for a new hospital on South Second Street, overlooking the river. The site contains 20 acres and is valued at about $35,000.

Personal.—Dr. W. F. Schoor, Hutchinson, has been appointed coroner of Greenough County, vice Dr. Henry M. Stewart.——The residence of Dr. Edwin T. Shelly, Atchison, was damaged to the extent of $2,000 by fire, March 25.

Smallpox.—More than 40 cases of smallpox were reported from Wichita for the five weeks ended March 22. No deaths have thus far occurred and stringent quarantine regulations are being enforced.——Smallpox has broken out among workmen in a cement plant in Iola.

Graduating Exercises.—The graduating exercises of the Kansas Medical College, the medical department of Washburn University, Topeka, were held April 18, when a class of 18 received diplomas from Dr. William S. Lindsey. Dr. Herbert L. Alkire delivered the faculty address.

Charter Revoked.—The state charter board on April 14 revoked the charter of the Kansas State Medical and Surgical Institute, an institution which it is alleged is deceiving the public by giving out the impression that it is a state institution. Dr. William J. Bonesteel is president, and Dr. C. A. Bonesteel, manager, of the institution.

Society News.—The Southeastern Kansas Medical Society, at its meeting in Fort Scott, March 3, elected Dr. Elmer E. Liggett, Oswego, president; Dr. James C. Cummings, Bronson, vice-president; Dr. Andrew J. Roberts, Fort Scott, secretary, and Dr. J. E. Jewell, Moran, treasurer. The society passed resolutions condemning in unmeasured terms the sale of "patent medicines" by druggists.——At the annual meeting of the Golden Belt Medical Association, held at Abilene, April 5, the following officers were elected: Dr. Edgar L. Simonton, Wamego, president; Dr. Frank M. Gaines, Solomon, vice-president; Dr. Howard N. Moses, Salina, secretary, and Dr. William S. Yates, Junction City, treasurer.——At the last meeting of the Sumner County Medical Society a resolution was adopted against allowing insurance companies to fix the fee for medical examination.

MARYLAND.

Baltimore.

Deaths from Lung Disease.—For the week ended April 21 there were 23 deaths from pneumonia and 29 from consumption. The usual proportion of 5 to 2 was observed between the mortality of colored and whites.

Personal.—Dr. John C. Hemmeter addressed the Medical Association of Greater New York, April 10, on "Diseases of the Intestines That Are on the Border-line Between Internal Medicine and Surgery."——Dr. Hugh C. Trout, resident physician at the Union Protestant Infirmary, and Dr. Robert Nelson, assistant physician, will soon leave for Europe. Dr. Theodore F. Riggs will succeed Dr. Trout.——Dr. James Cooper has returned home after a year and a half of sea travel.——Dr. William Lee Howard has moved to Westboro, Mass., and will devote himself to literature and literary work.——Dr. Robert H. P. Ellis has returned from a trip to Mexico.——Dr. George W. Mahle, assistant resident physician of Bayview Hospital, is convalescent from typhoid fever.

MASSACHUSETTS.

Bequests to Hospitals.—By the will of the late James F. Redington, Boston, $1,000 each is devised to the Children's Hospital, Carney Hospital and the Little Sisters of the Poor.

Personal.—The health board of Ware has organized and elected Dr. Adolph A. Auger, chairman, and Dr. Worthington W. Miner, secretary.——Dr. Martin M. Brown has been elected to fill the vacancy in the advisory board of the medical staff of North Adams Hospital.——Dr. George L. Black, city physician of Lawrence, has resigned.——The board of health of Adams has organized with Dr. Alfred Desrochers, chairman.——Dr. Samuel B. Strickland has resigned from the Waltham board of health.——Dr. H. Gordon-Forbes, Chicopee Falls, is taking a trip to the Bermudas.

MINNESOTA.

Trip to the Orient.—A party of 100 physicians and their families propose to take an eighty-one-day trip to the Orient, leaving St. Paul June 25 and sailing from Seattle on one of the Great Northern Steamships.

Refuses to Pardon Malchow.—The President has announced that he will not interfere in the case of Prof. C. W. Malchow, formerly professor in Hamline University, sentenced to two years' imprisonment on the charge of sending improper literature through the mails.

Ask Same Fee for All Examinations.—At the semi-annual meeting of the Brown and Redwood Counties Medical Association, held in New Ulm, April 17, it was decided to ask the State Medical Society to co-operate in having all physicians refuse a rate lower than $5 for examinations for life insurance.

Hospital Notes.—The Wilcox homestead, East Minneapolis, has been selected as the site for a new hospital, and liberal subscriptions toward the $10,000 required have already been obtained. The St. Anthony Medical Society is taking a great interest in the enterprise.——Negotiations are in progress for the establishment of a hospital at Aitkin.——William H. Kelly, Sr., has presented the Owatonna City Hospital with $10,000, hampered by no conditions.——Immanuel Hospital, Mankato, will be built at the corner of Fourth and Walsh streets, work being begun as soon as the spring opens.

Personal.—Dr. R. Ignatius Hubert, St. Cloud, has been appointed physician of Stearns County.—Lieutenant William H. Tefft, assistant surgeon, U. S. Army, stationed at Fort Snelling, sustained a fracture of the leg in an informal wrestling match at the Officers' Club, March 24.——Dr. Frederick O. Gronvold, Gary, will soon leave for Germany to take a postgraduate course.——Dr. Francis R. Woodard, Minneapolis, who has been ill with pneumonia, is reported as improving but not yet convalescent.——Dr. Oswald Leicht, Winona, has declined to accept the appointment tendered him by the government as a member of the State Board of Medical Examiners.

Teachers and Tuberculosis.—The State Board of Health, at its meeting January 9, took action advising that those suffering from tuberculosis be not employed as teachers:

1. Because they can not hope to recover while following such an occupation.
2. Because they are a menace to the school children under their care.

And that children suffering from tuberculosis be excluded from school:

1. Because their recovery is not probable while they are kept under the strain of school life.
2. Because the importance of fresh air, rest and good food is even greater for the growing child than for the adult, and the child attending school does not get the necessary amount of any of these.
3. Because close confinement in school may be followed by other forms of tuberculosis than consumption, and may cause permanent deformities or death.
4. Because school children with consumption (pulmonary tuberculosis) are a decided menace to their associates.
5. Because by excluding tuberculous children from school and allowing them to recover and at the same time preventing the infection of others, many lives of value to the state may be saved.

The secretary was instructed to send these suggestions to every school board, health officer and to the superintendents of city and county schools throughout the state.

MISSOURI.

Licenses Revoked.—The license of Dr. A. F. Keeler, St. Louis, and of Annie Newland and Mrs. Matilda Myers, midwives, of St. Louis, were revoked by the State Board of Health for unprofessional methods, April 12.

NEW YORK.

Smallpox.—Three cases of smallpox have developed in Middletown within forty-eight hours. The house in which the cases occurred is quarantined and there is no fear of a spread of the disease.

Diseased Cattle Slaughtered.—Under the direction of the state authorities 23 head of cattle suffering from tuberculosis were killed at Rome. All the cattle had responded to the tuberculin test, and the postmortems showed that all were diseased.

To Restrict Sale of Poisons.—Health Commissioner Green of Buffalo appeared before the aldermanic committee on ordinances April 12 and spoke in favor of the proposed ordinance for the restriction of the sale of carbolic acid and cocain in the city.

Medical Club Organized.—Physicians of Poughkeepsie, all members of the Dutchess County Medical Society, have formed a local club, known as the Dutchess Club, with the following officers: President, Dr. John C. Otis; vice-president, Dr. Charles W. Pilgrim; secretary, Dr. Frederick J. Mann, and treasurer, Dr. James E. Sadlier. The object of the club is to take up and consider all matters looking to the improvement of the sanitary condition of Poughkeepsie.

Personal.—Dr. and Mrs. Henry L. K. Shaw, Albany, sailed for Europe, April 3.——Dr. William W. Carleton has been elected health officer of Waterloo.——Drs. A. LeRoy Chapin, Niagara Falls, Flavius J. Baker, Lockport; E. P. H. Griswold, Niagara Falls, and John H. Miller, Niagara Falls, were elected delegates to the eighth district branch of the New York Medical Society by the Niagara County Medical Society.——Dr. James M. Rutledge, Syracuse, has been appointed district physician in place of Dr. Albert S. Hotaling, resigned. ——Dr. Horace M. Edmonds has been reappointed health officer of Tonawanda. ——Dr. Thomas D. Collins has been reappointed health officer of Ballston Spa.

Illegal Advertisements Barred.—The United States postoffice authorities and the Medical Society of the County of New York are continuing their campaign against illegal advertising medical practitioners. The recent order of the department, denying the use of the mails to about 50 persons and firms in Manhattan and Brooklyn, accused of such practices, has been followed by a notice served on three Manhattan newspapers to the effect that if they continue publication of such advertisements they will not be permitted to send their papers through the mails. The three papers referred to have complied with the order.

New York City.

Bequests.—By the will of Mrs. Sarah E. Sands of Lakewood, N. J., March 30, St. Luke's Hospital is given $15,000 to be used for the endowment of three beds in memory of the testator's husband, Abraham B. Sands.

Deaths from Violence.—The report of deaths by violence for the first quarter of 1906 in the Borough of Manhattan shows an increase in homicides during each month, there having been 18 more reported in March than in January.

Hospital Conference.—A conference has been organized for the purpose of preventing the extravagance and waste in hospital maintenance. Circular letters have been sent to the superintendents of the various hospitals asking for details regarding the financial management of the hospitals.

Personal. Dr. J. Richard Kevin has been appointed assistant surgeon of the Fourteenth Infantry, N. G. N. Y., vice Dr. Arthur H. Bogart, resigned. —— At a meeting of the New York Academy of Medicine, April 5, Dr. Wendell C. Phillips was elected vice president, succeeding Dr. George Ryerson Fowler, deceased.

Patients in Bellevue Hospital Vaccinated.—All patients who were in fit condition were vaccinated this week. There were nearly 900 patients and all submitted readily except the alcoholics, the majority of whom, not being prisoners, beat a very hasty retreat when told they would have to be vaccinated if they remained.

Rockefeller Institute for Medical Research.—Invitations are out for the opening of the laboratories at Avenue A and East Sixty-sixth Street, on May 11 at 4 p. m. Addresses will be made by President Charles William Eliot of Harvard University, President Nicholas Murray Butler of Columbia University, Dr. William H. Welch, president of the board of directors, and Dr. Luther E. Holt, secretary of the board of directors.

Hospital Finance and Economy.—A second meeting of representatives of all the hospitals of Greater New York was held at the Academy of Medicine, April 18, at which the report of the committee on constitution and by-laws was received, the permanent organization completed and a program for the ensuing year adopted. The chief object of the meeting was to endeavor to establish and maintain a healthy state of affairs in hospital administrations by means of the Hospital Conference of the City of New York.

Opposition to Hospital Transfers.—Coroner Harburger, in charging a jury in a case in which death is said to have been due to the transfer of a patient in a precarious condition from one hospital to another, said that he thought this practice was nothing short of murder. The jury in its verdict sustained the board of coroners of the borough of Manhattan in its attempt to abolish the system of transferring from one hospital to another patients whose condition was critical.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended April 14, 1,512 cases of measles, with 47 deaths; 390 cases of tuberculosis, with 183 deaths; 328 cases of diphtheria, with 35 deaths; 220 cases of scarlet fever, with 20 deaths; 93 cases of varicella, with 1 death; 41 cases of cerebrospinal meningitis, with 30 deaths; 34 cases of pertussis, with 6 deaths; 30 cases of typhoid fever, with 10 deaths, and 5 cases of smallpox, making in all 2,653 cases, with 332 deaths.

New Jewish Hospital.—This hospital, which is the successor of the old Memorial Hospital for Women and Children, and is situated in Classon Avenue, Brooklyn, will open its dispensary May 3 and the entire hospital will be ready for occupancy October 1. The wards will have room for about 175 beds and there will be 29 private rooms. The dispensary will have 11 clinics and a staff of 30 physicians. Both dispensary and hospital will be free to all, regardless of color or creed. The cost of maintenance will be about $100,000 annually, of which the city will contribute about $7,000.

NORTH DAKOTA.

State Society Meeting.—The annual meeting of the North Dakota Medical Society will be held in Fargo, May 16 and 17.

Smallpox.—Smallpox is reported to have broken out near Litchville. The disease is said to have originated among a party of Dutch immigrants. Strict quarantine regulations are being enforced.—— There have been three cases of smallpox in Cando.

Hospitals Planned.—Drs. W. H. M. Philip and Harwood have purchased a residence in Hope in which they will establish a hospital. ——Provided the city of Grand Forks will appropriate $15,000 and donate a block of land, a Catholic sisterhood will erect a hospital with all modern equipments and accommodation for 60 patients.

OHIO.

Defendant Wins Suit.—In the suit brought by William Bowers against Dr. William Z. Kumler, Cincinnati, in which $10,000 damages was claimed for alleged malpractice in the setting of a broken shoulder, the jury found for the defendant.

Personal.—Dr. George Mykinger, an interne in the City Hospital, Cincinnati, was assaulted by a delirious patient recently and had a rib fractured.——Drs. Magnus A. Tate and Charles L. Bonifield have been elected delegates from the Hamilton County Medical Society to the Ohio State Medical Association, and Drs. Robert Carothers and E. Gustav Zinke have been elected alternates. ——Dr. Francis Dowling, Cincinnati, has been commissioned a member of the board of examiners for the sixth civil service district, which includes the states of Ohio, Indiana and Kentucky.——Dr. Colston L. Dine, Minster, who was operated on several weeks ago, has recovered and resumed practice. —— Dr. Floyd F. Swimley, Forest, is improving and it is hoped that he may not lose his eyesight. —— Dr. Charles M. Hendricks, Toledo, at present house physician of the National Jewish Hospital for Consumptives, Denver, has been appointed to the staff of Phipps Sanitarium in that city.—— Dr. Francis M. Murray, Delaware, while making a professional call April 16, was struck by a passenger train on the Hocking Valley Railway, his horse killed, his buggy demolished and he himself sustained a fracture of the arm and numerous contusions. ——Dr. Arthur F. Osmond has been appointed successor to Dr. John F. Stemler as receiving physician of the Cincinnati City Hospital. —— Dr. Parker F. South

wick has been reappointed city physician of Sandusky.——Dr. Frank S. Pomeroy, Chardon, who has been critically ill with typhoid fever, is reported to be improving.——Dr. Harry R. Geyer, Zanesville, has been elected delegate to the Ohio Medical Association from the Muskingum County Medical Society.

OKLAHOMA.

Association Meeting.—The Cleveland County Medical Association at its meeting elected Dr. David W. Griffin, Norman, president; Dr. Halshaw, Denver, vice-president, and Dr. Silas T. Burch, Norman, secretary and treasurer.

Personal.—Dr. J. K. Julien, Covington, has been made coroner of Garfield County, vice Dr. Sarben, resigned.——Dr. H. K. Wilson has been made county superintendent of health vice Dr. Henry C. Bowers, Enid, resigned.——Dr. Samuel A. Lively, Wakita, is seriously ill in a hospital in Wichita, Kan.

Hospital Notes.—An addition of 20 rooms is being made to each building of the Territorial Sanitarium, Norman. There are at present nearly 500 patients in the institution.——It is proposed by the hospital commission of the Methodist Episcopal Church to purchase the City Hospital, Guthrie, to double the capacity of the institution and to establish a nurses' training school in connection with it.

License Revoked.—Judge Burford on April 5 decided against Dr. Calvin D. Gully in the proceedings brought against him by the attorney general, and revoked his license to practice medicine in Oklahoma. In revoking the license the judge held that it had been obtained by fraud, as the school from which Dr. Gully obtained the diploma was the Independent Medical College and a diploma mill. The attorney general showed that the school mentioned was chartered Oct. 20, 1896, and that Dr. Gully obtained his diploma 15 days later.

OREGON.

Fined for Failure to Report.—Dr. John Madden, Portland, was fined $25, March 30, for failure to report a case of contagious disease. Dr. Madden held that the malady was chickenpox and City Health Officer Dr. Cortez H. Wheeler declared it to be smallpox.

New Hospitals.—A hospital is to be started in Forest Grove.——The Sisters of St. Francis will begin the erection of a hospital building in Klamath Falls in the autumn.——The Hot Lake Sanitarium, Le Grande, is to be improved by the erection of a three-story building with a glass-covered conservatory, the installation of a cold-water system and other conveniences at an expense of $100,000.

Personal.—Dr. Andrew J. Gusy, Portland, has gone to New York for treatment of a serious affection of the eyes.——Dr. Edward B. McDaniel, Baker City, has been appointed surgeon of the Oregon Railway & Navigation Company vice Dr. Taylor N. Snow, resigned.——Dr. John Wright, Roseburg, is critically ill.——Dr. John J. Fisher was dangerously wounded in an attempted holdup in Portland, March 20.

Condemns Contract Practice.—The Portland City and County Medical Society at a recent meeting adopted the following resolutions:

Resolved, That the City and County Medical Society of Portland, Ore., condemns the following forms of contract practice:

First.—Any form of contract to treat the members of any association or corporation, whose membership is composed of persons obtained from the general public by solicitation of agents or otherwise.

Second.—Any form of contract to treat the members of any lodge or order or their families.

Resolved, further, That we recognize the right of contract on the part of members of this society with firms or corporations whose sick benefits are limited to the employés of said firms or corporations, or in the case of states, counties or municipalities to the indigent poor; provided, however, that in the case of firms and corporations such contract shall be for a sum that shall not be less, in the aggregrate, than that provided for as a minimum charge in the schedule of fees adopted by this society.

PENNSYLVANIA.

Typhoid Fever Prevalent.—There are at present more than 400 cases of typhoid fever in Pittsburg and Allegheny, the majority of the cases being in the latter city.

Typhoid on the Wane.—During the twenty-four hours ended April 18, only 15 cases were reported to the Pittsburg bureau of health, showing a marked decrease.

Sentenced for Malpractice.—Dr. Edwin S. Cooper, New Castle, was sentenced on March 24 to 15 months' imprisonment, having been twice convicted of conspiracy to perform criminal operations.

Gifts to Hospitals.—Mrs. Lizzie B. Plumer has given $12,500 to the Franklin Hospital for the purpose of establishing and endowing a free room to be known as the Henry Baldwin Plumer room.——Plans have been prepared for a new ward at the Chester Hospital, to be given by Alfred O. Deshong.

Personal.—Dr. W. Albert Nason has been re-elected secretary of the Nason Hospital, Roaring Springs.——Dr. William W. Cole has been appointed surgeon of Allegheny, vice Dr. T. L. Hazard, and Dr. Francis X. Straessley succeeds Dr. Daniel I. Jamieson as city physician.——Dr. Isaac N. Taylor has been elected president of the Meadville board of health; Dr. Joshua M. Cooper, secretary, and Dr. Howard V. Merrell, health officer.——Dr. John M. Sheedy has been reappointed a member of the Altoona board of health.——Dr. Ulysses S. G. Heil has been elected president, and Dr. Sydenham P. Uhler, vice-president, of the board of health of Easton.——Dr. Herbert S. Van Kirk has been elected president of the McKeesport board of health.——Dr. Hamilton K. Beatty has been appointed superintendent of the Allegheny bureau of health.——Dr. Francis X. Weil, York, has been elected treasurer of the York County Medical Society, vice Dr. Lawton M. Hartman, York, resigned.——Dr. John B. Groh has been re-elected health officer of Lebanon.——The mayor of Franklin has appointed the following board of health: Drs. Edward W. Moore, Samuel G. Foster, Harry F. McDowell and P. H. Conradson, and Mr. M. S. McKinzie.

Philadelphia.

Personal.—Dr. James W. Holland, dean of Jefferson Medical College, has resigned his deanship, but will retain the chair of chemistry.

Money for Hospital.—The sixth annual charity ball given for the benefit of Mount Sinai Hospital, April 18, netted $2,000 for the institution.

Medical Club Reception.—The Medical Club of Philadelphia tendered a reception to Dr. William H. Hartzell, president of the Medical Society of the State of Pennsylvania, and Dr. Oscar H. Allis, April 20.

Wins Malpractice Suit.—In the case of Dr. Walter Browning, sued by Elias B. Smith for $10,000 damages for alleged improper and unskillful treatment, the plaintiff was nonsuited in the Court of Common Pleas, April 11.

Pennsylvania Relief Fund.—The monthly report of the Employés' Relief Fund for the Pennsylvania Railroad Company's lines east of Pittsburg and Erie shows that the payments of benefits to its members and the families of deceased members for March, 1906, aggregated $150,694.15, of which $63,835.50 was on account of death and $86,858.65 on account of disablement by sickness and accident. The payments thus far have amounted to $14,750,045.51, of which $6,059,112.20 was on account of death of members, and $8,690,933.31 on account of disablement.

Fraudulent Oil Dealers Arrested.—Fifteen individuals were arrested, April 15, charged with selling oil represented as olive oil. In the specimens analyzed no trace of olive oil was discovered. They consisted wholly or in part of cottonseed oil, sesame oil, lubricating oil and other inferior substances. They were held by the magistrate for their appearance at court. It was shown at the hearing that the material sold as olive oil was deleterious in its effects on persons in health, and that it is almost certainly of no value and is perhaps dangerous to individuals with impaired powers of digestion.

Health Report.—The total number of deaths reported for the week ended April 21 aggregated 568, as compared with 588 for the previous week, and 455 for the corresponding week of 1905. The principal causes of death were: Typhoid fever, 20; measles, 6; whooping cough, 6; diphtheria, 5; consumption, 73; cancer, 21; alcoholism, 5; apoplexy, 17; heart disease, 54; acute respiratory disease, 97; enteritis, 16; Bright's disease, 32; suicides, 5; accidents, 26; marasmus, 5. There were 357 cases of contagious disease reported, with 27 deaths, as compared with 272 cases and 40 deaths in the preceding week. Typhoid fever is still prevalent and slightly on the increase; 222 cases were reported for the week. In the previous week 198 cases were reported, with 24 deaths. The prevalence of measles is not so severe. The cases reported this week numbered 351, as compared with 389 reported during the previous seven days.

Anatomists Meet.—The Association of American Anatomists, at the regular meeting held in Wistar Institute, April 18, decided that the institute should strive to develop a high grade of research work, maintaining a small corps of the most able investigators in the country. Those present at the meeting were Drs. M. G. Conkling and H. H. Donaldson of the Wistar Institute, Drs. E. P. Mall and Llewellys F. Barker of Johns Hopkins, Drs. G. Carl Huber and J. P. Murich of the University of Michigan, Dr. Charles Minot of Harvard, Dr. George S. Huntingdon of Columbia, Dr. S. H. Gage of Cornell and Drs. E. G. Conkling and George A. Piersol of the University of Pennsylvania. It was decided by the advisory board that the Wistar Institute be hereafter the center of brain

research in America. In order that the work may be properly carried on it will be necessary to collect brains of every race or every mixed race. Dr. H. H. Donaldson of the University of Chicago was elected to take charge of the neurologic work, with Dr. G. S. Strecter of Johns Hopkins University and Dr. S. Hatai of the University of Chicago as assistants.

SOUTH CAROLINA.

Fined for Assault. In the case of Dr. Edgar S. McDow, Lancaster, charged with assault and battery with intent to kill, and with carrying concealed weapons, the jury brought in a verdict of guilty, and he was sentenced to pay a fine of $250 or to be imprisoned for four months in the penitentiary.

Commencement. The Medical College of the State of South Carolina, Charleston, held its seventy-sixth annual commencement exercises April 11, when a class of eight received diplomas in medicine. Dr. Francis L. Parker delivered the doctorate address and the degrees were conferred by Major Theodore B. Barker, president of the board of trustees.

TENNESSEE.

Cornerstones Laid.—The faculty of the College of Physicians and Surgeons, Memphis, laid the cornerstone of the new college building with appropriate ceremony, April 22.——The laying of the cornerstone of the Lucy Brinkley Hospital, Memphis, took place March 14.

Presentation.—The senior class of Memphis Hospital Medical College on March 29 presented Dr. Dudley D. Saunders, for many years a prominent member of the faculty, with a goldheaded cane. The occasion was the closing lecture of the fiftieth year of medical teaching of Dr. Saunders.

Academy Meeting. The annual meeting of the Nashville Academy of Medicine and Davidson County Medical Society was held April 3. The following officers were elected: Dr. William R. Sifford, president; Dr. William Litterer, vice-president, and Dr. Holland M. Tigert, secretary and treasurer.

New Staff at Erlanger Hospital.—The following summer staff came on duty at Erlanger Hospital, Chattanooga, April 1: Dr. Fred B. Stapp, chief of staff; Drs. Thomas E. Abernathy, Clarence A. Cobleigh, Joseph W. Johnson, John S. B. Woolford, Raymond Wallace, German P. Haymore, Robert H. Tatum and William A. Duncan.

Physicians and Dentists Organize.—The physicians and dentists of Humboldt have formed an organization for mutual benefit by study and discussion. Dr. James H. Preston has been elected president; Dr. Benjamin S. Penn, vice-president, and Dr. J. H. Meeks, secretary, of the organization. It was decided also to reorganize the Humboldt Medical Society, amending its constitution so as to provide for the admission of regularly graduated dentists.

Commencements.—The fifty-fifth annual commencement exercises of the University of Nashville, Medical Department, were held March 29. Dr. S. F. Crockett delivered the faculty address after which Chancellor Porter conferred degrees on a class of 42. Meharry Medical College, Nashville, held its thirteenth annual commencement exercises April 4, when a class of 67 received diplomas. The doctorate address was made by Rev. M. C. B. Mason, Cincinnati.

Federal Control of Quarantine. The Memphis and Shelby County Medical Society, at its regular meeting, March 20, adopted the following resolutions in regard to the federal control of quarantines:

> Believing that federal control of maritime and inter-state quarantine offers the only solution of the prevention and control of epidemic yellow fever, and that this is now the most vital question before the South; be it
>
> *Resolved*, That the Memphis and Shelby County Medical Society place itself on record as advocating the placing of such quarantines completely in the hands of the federal government. And be it
>
> *Resolved*, That copies of this preamble and resolutions be sent to the leader of the minority of the U. S. House of Representatives and to the senators and representatives in Congress from Tennessee. And be it further
>
> *Resolved*, That copies of this preamble and resolutions be sent to the various medical societies of this state and their co-operation in the securing of this action by Congress be solicited.

VIRGINIA.

Want Tax Removed. A committee from the Petersburg Medical Society has appeared before the finance committee of the council to ask for a removal of the special license tax of $25 on physicians.

Unlicensed "Patent-Medicine" Vendor Fined. W. H. Burrell, Washington, was arrested April 3 for selling "patent medicines" without a license and fined $30. In default of payment he was committed to jail.

New Hospital.—The Colonial Coal and Coke Company is building and equipping a hospital at Dorchester, to be known as the Kammerer Memorial Hospital. Dr. Morand L. Stallard, Norton, will be at the head of the institution.

Acquitted of Malpractice.—In the case of Dr. Francis M. Morgan, Berkeley, on trial at Norfolk on the charge of criminal malpractice on Mrs. Josephine Davis, the jury acquitted the defendant, March 21, after a deliberation of fifteen minutes.

Gifts for the University of Virginia.—Charles Steele of the firm of J. Pierpont Morgan & Co. has given $50,000, and Miss Helen Gould of New York City, $10,000, to be expended in the completion of the Hospital of the University of Virginia, Richmond. The gift of Miss Gould is to provide a ward for colored patients at the hospital.

Comply with Standard Requirements.—Matriculants at the Medical College of Virginia will hereafter be required to be graduates of a high school or some educational institution of at least equal rank. The same rule applies to the University College of Medicine, that both institutions may be members of the American Medical College Association.

Personal.—Dr. George Ben Johnston, the eminent railroad surgeon, has been elected to the chair of surgery in the University of Virginia and has been made chief of the hospital staff of the university, his services to begin at the opening of the next session.——Dr. William M. Randolph has been elected adjunct professor of surgery in the University of Virginia, vice Dr. William G. Christian, resigned.——Dr. J. S. De Jarnette, Youngs, has been elected superintendent of the Western State Hospital, Staunton.——Dr. William R. Purvis has been reappointed coroner of Alexandria.——Dr. George S. Walker has resigned as assistant superintendent of the Western State Hospital, Staunton.——Dr. Frank S. Hope has qualified as health officer of Portsmouth, succeeding Dr. Norfleet.——Dr. Ennion G. Williams has been appointed a member of the Committee of Health of Richmond.——Dr. Lewis C. Bosher has been elected president of the Memorial Hospital, Richmond, vice Dr. George Ben Johnston, resigned; Dr. John P. Davidson has been elected vice-president and Dr. Charles R. Robbins, secretary and treasurer of the institution.——Dr. Z. Curtis A. Burwell, Salem, physician for the Tidewater Railroad, has resigned and Dr. Johnston has been appointed to fill the vacancy.——Dr. Hack U. Stevenson, Toano, has been elected a member of the State Examination Board, vice Dr. Junius E. Warinner, Brook Hill.——Dr. Ernest Woolfolk, Lahore, who has been under treatment in the Garfield Memorial Hospital, Washington, D. C., is reported to be improving.

WYOMING.

Smallpox. In the farming districts of Lyman and Bridge, in Uinta County, 57 cases of smallpox are reported. The entire mining town of Jelm, southwest of Laramie, is under quarantine for smallpox.

Sheridan County Society Meeting.—At the annual meeting of the Sheridan County Medical Society the following officers were elected: President, Dr. F. A. Hodson; vice-president, Dr. C. W. Lawrence; treasurer, Dr. A. G. Hurd, and censor, Dr. F. A. Dolan, all of Sheridan.

Deplores Counter Prescribing. At a recent meeting of the Sheridan County Medical Association the following resolution was unanimously adopted: "It is the sense of this society that we deplore the too prevalent practice among druggists of counter prescribing and refilling prescriptions without orders; and that we will no longer tolerate the laxness in these things that up to this time has existed."

Personal. Dr. Harry S. Finney, Rawlins, who has been ill in a hospital in Omaha with typhoid fever, has recovered.——Dr. E. E. Levers has tendered his resignation as superintendent of the Sheridan State Hospital.—— Dr. William A. Burgess, Cheyenne, has succeeded Dr. John H. Conway as physician of Laramie County.——Dr. Darwin E. Brown, Laramie, has been appointed surgeon in charge of the hospital of the Diamondville Coal and Coke Company.

State Association Meeting. At the annual meeting of the State Medical Association, held in Cheyenne, the following officers were elected: Dr. William A. Wyman, Cheyenne, president; Drs. Fred Horton, Newcastle, and Ernest A. Crosbery, Wheatland, vice presidents; Dr. A. Francis Hoff, Casper, treasurer; Dr. Henry L. Stevens, Laramie, delegate to the American Medical Association, and Dr. Alfred C. Godfrey, Lander, alternate. The next meeting of the association will be held in Casper.

THE SAN FRANCISCO CATASTROPHE.

Earthquake and Fire in California—The Problems of Relief and Sanitation.

As all the world knows, San Francisco suffered a violent earthquake at 5:13 a. m., April 18, which wrecked a large number of buildings and broke gas and water mains and electric wires. Fires immediately started which burned for three days and devastated the entire city with the exception of a small portion of the residence section called the "Western Addition," rendering many thousands homeless. A large number, the exact figures being as yet unobtainable, were killed by falling buildings or burned to death. Many hundreds were injured. As all but three or four hospitals in the city were destroyed, the Mechanics Pavilion, a large wooden building, was utilized as a receiving hospital, but only for a short time, as the fire soon reached and destroyed it. The fires broke out simultaneously in so many places and spread so rapidly that all means of communication were cut off and each was obliged to shift for himself. The patients in the various hospitals were removed, some to the Presidio and some to Oakland.

There are probably 125,000 refugees in Oakland, whose citizens are responding nobly to the call for help. Probably 200,000 refugees are quartered in Golden Gate Park, the Presidio, along the water front and the city dumps.

Many hundreds of children are lost and hundreds of others are suffering or dying from exposure and lack of water. One physician reported 75 stillbirths in two days. The sufferings of women, and especially of children, are too horrible to describe.

There is little danger now of suffering from starvation, as supplies are being rushed in by military authorities, by relief trains from New York, Chicago, Denver and other cities, and by the Masonic fraternity, the Elks, Odd Fellows and other fraternal organizations. It will be some time before the homeless people have shelter, although tents have been supplied by the government and the city has started the erection of barracks in Golden Gate park to accommodate 15,000.

No Epidemic.

Although there has been considerable smallpox in the city for several months, only a few cases are now reported. Scarlet fever and typhoid fever have appeared among the refugees, but this is no epidemic. General Funston has ordered a large supply of vaccine virus, and 10,000 points were sent from Chicago on the relief train which started April 23.

Valuable Co-operation of Military Force.

Soldiers, sailors, marines and national guardsmen have been rushed into the city, but still there are not enough adequately to protect life and guard property. General Funston at once took command of the situation and co-operated with the local authorities in bringing order out of the chaos following the disaster. The United States General Hospital at the Presidio and the barracks were at once offered for the sick and injured, and the work of relief is being carried out under proper discipline and with military exactness. Tents have been sent from the various Army posts, and hundreds of thousands of rations have been furnished by the various commissaries.

Water and Sewers.

The water supply of the system was at first entirely cut off by breaks in the city mains, but now, by adjustment and repair, a daily supply of about 7,000,000 gallons is available. The sewer system is damaged to an unknown extent. The manholes in the streets have been screened and are used for water closets.

As practically all chimneys in the city are ruined, all cooking, even in the unburned section of the city, is done in the open air, on the streets.

Physicians Do Noble Work.

The medical profession of San Francisco, Oakland, Berkeley, and other cities have done noble and self-sacrificing rescue work and are now caring for the sick and injured with untiring zeal. Physicians have come in from neighboring cities, and at least two more distant cities have sent medical aid. Portland has sent 10 physicians, 20 nurses and large quantities of medical supplies, under the charge of Dr. Kenneth A. J. Mackenzie. Chicago sent 27 physicians, 75 nurses, and large quantities of disinfectants, medicines, dressings and invalid foods, on trains which should arrive there April 26. This party is sent by the American White Cross First Aid Association, under the auspices of the Citizens' Association of Chicago, and is in charge of Major P. J. H. Farrell, late U. S. V. and Captain Joseph B. Greene, late of the U. S. P. H. and M. H. Service, and includes Drs. F. W. Phelps, N. Reed, G. W. Mosher, J. D. C. Hill, Milton Mandel, Rex Brown, F. W. Alpin, J. S. Nagel, B. von Wedelstadt, George Ruben, Orville W. McMichael, F. G. Harris, Clyde D. Pence, Arthur Claggett, Joseph Replogle, J. C. Cowan, Edgar Lee, F. J. Otis, Thomas W. Lewis, W. H. Witherstine, D. A. Smalley and H. J. Haiselden.

A special train left Los Angeles for San Francisco April 19, with 75 physicians and nurses.

Medical Society of the State of California.

The society met for its fiftieth annual session in San Francisco, April 17. The program was unusually good and the attendance large. On the morning of April 18 a violent earthquake occurred, wrecking a large number of buildings, including the Y. M. C. A. building in which the meetings were being held. At 9:30 the same morning the president, Dr. Robert F. Rooney, the secretary, Dr. Philip Mills Jones, San Francisco, and Drs. H. Bert Ellis, Los Angeles, James H. Parkinson, Sacramento, and Fitch C. E. Mattison, Los Angeles, met in front of the wrecked building and declared the society adjourned sine die.

All records and files of the society are a total loss, but the accounts and funds are safe. The library of the San Francisco County Medical Society and its records are destroyed.

The Dead.

It is impossible as yet even to estimate the mortality, but our correspondent believes that the deaths will exceed 5,000. On April 24 a list of 277 dead was reported. The coroner of San Francisco County estimates the dead at 1,000.

Dr. J. C. Stinson was killed in the California Hotel by falling bricks, and Dr. Charles F. Taggart, Los Angeles, who had charge of a corps of nurses at the Crocker School Relief Hospital, died from a gunshot wound caused by his own revolver, which fell from his pocket and was discharged. These are so far the only deaths of physicians in the city.

Personal.

The president of the state society, Dr. Robert F. Rooney, Auburn, was at the Palace Hotel, but was obliged to leave, and went to the St. Francis Hotel, and was ordered out on account of the danger. His present whereabouts are unknown, but he is reported to be safe.——Dr. Philip Mills Jones and wife are safe in Oakland.——Dr. George H. Evans started for New York April 21 and reached Chicago April 24. ——Dr. Donald McC. Gedge has been made chief of the newly-organized vigilance committee, which has in charge the Golden Gate valley district near the Presidio.——Dr. William C. Voorsanger has been placed in charge of the committee on food supplies.

Effect at Quarantine Station.

Passed Assistant-Surgeon Hobdy reports that a moderate amount of damage was done by the recent earthquake at the San Francisco Quarantine Station, but that no one was injured. The service at quarantine will not be interrupted. Surgeon Sawtelle reports, in *Public Health and Marine Hospital Reports*, that all the Marine Hospital buildings are more or less damaged, though the hospital can still be used. No one was seriously injured at the station. As many injured citizens as can be accommodated are being admitted to the marine hospital, the city institutions being unable to care for the large number of the wounded. Dr. Sawtelle also states that the buildings in which the branch marine hospital was located in the city is entirely wrecked.

THE CALIFORNIA FUND.

Subscription List Opened for Relief of Physicians in Need.

As announced in the editorial columns, the Board of Trustees has authorized that the columns of THE JOURNAL be opened for subscriptions to a fund for the relief of those physicians of San Francisco and other points in California who have been left in destitute circumstances through the earthquake and fire. A local committee has been created in Chicago to have supervision of the fund in behalf of the American Medical Association. This committee consists of: Dr. Frank Billings, Treasurer of the American Medical Association, Chairman; Dr. M. L. Harris, Resident Trustee of the American Medical Association; Dr. C. S. Bacon, Chairman of the Section on Obstetrics and Diseases of Women, and President of the Chicago Medical Society; Dr. R. B. Preble, Chairman of the Chicago Medical Society Committee; Dr. George H. Simmons, Editor of THE JOURNAL of the American Medical Association.

The following telegram was received April 24 through Surgeon General O'Reilly of the United States Army:

To the Editor: About five hundred San Francisco physicians destitute, diplomas destroyed. Brave, resolute, still working like Trojans for fellowmen. Association should come handsomely to relief. Many will emigrate. All states should receive qualified without cruel restrictions. My subscription one hundred dollars.

KENNETH A. J. MACKENZIE.
Second Vice-President American Medical Association, in charge of Harbor View Hospital for contagious diseases

The following letter was received April 23:

To the Editor:—I would suggest that the American Medical Association appeal to the physicians of the United States for financial assistance in order to aid physicians in San Francisco, who have lost all they possessed in the recent horrible disaster. A committee of physicians living in San Francisco could be appointed to carry out any or all suggestions made by the A. M. A. I gladly send my check for $2, and trust the fund will rapidly grow.

Rochester, N. Y. W. D. WOLFF, M.D.

Subscriptions are solicited from those who feel able to give. Make checks payable to the American Medical Association, marking the check "California Fund." Also mark envelope in lower left-hand corner, "California Fund." An acknowledgment will be made in THE JOURNAL of each contribution. Local or county societies that wish to make a contribution as a body and prefer to send it through the American Medical Association Fund, may do so and credit will be given to the society and the names of the individual contributors will also be printed.

The following contributions have been received:

INDIVIDUAL CONTRIBUTIONS.

T. J. Happel, Trenton, Tenn.	$ 5.00
Kenneth A. J. Mackenzie, Portland, Ore.	100.00
Phillip Marvel, Atlantic City, N. J.	50.00
Lewis S. McMurtry, President American Medical Association, Louisville, Ky.	100.00
E. E. Montgomery, Philadelphia	25.00
Miles F. Porter, Fort Wayne, Ind.	10.00
William H. Welch, Baltimore	25.00
W. D. Wolff, Rochester, N. Y.	2.00
A. L. Wright, Carroll, Iowa	25.00
Total	$312.00

CHICAGO MEDICAL SOCIETY CONTRIBUTIONS.

The following amounts were received through the committee appointed by the Chicago Medical Society:

Adolphus, Phillip	$10.00	Harris, M. L.	$25.00
Bacon, C. S.	25.00	Hecht D'Orsay	10.00
Banga, Henry	25.00	Holz, P. C.	25.00
Bann, W. L.	50.00	Jackson, Thomas J.	5.00
Bailey, E. F.	2.00	Kahlke, Charles F.	15.00
Beard, Charles H.	5.00	Kerr, J. Norman	5.00
Blayney, F. H.	5.00	Kleene, F.	5.00
Billings, Frank	100.00	Leenheer, C. A.	2.00
Broell, A. C.	10.00	Linnell, R. M.	5.00
Brown, Heman H.	10.00	McGaire, J. W.	10.00
Brown, Richard H.	10.00	Miller, R. B.	5.00
Burroughs, W. M.	2.00	Monash, D. F.	5.00
Campbell, James T.	10.00	Morf, Paul	5.00
Carter, J. M. G.	5.00	Murphy, John B.	100.00
Chamberlain, George M.	100.00	Nelson, Daniel T.	5.00
Coleman, W. F.	5.00	Noble, W. L.	5.00
Danforth, L. N.	25.00	Oyen, A. B.	5.00
Deming, H. H.	10.00	Paddock, Charles E.	10.00
Elliott, Arthur	5.00	Patton, J. Allen	5.00

Total			$1,023.00
Grand total			1,365.00

GENERAL.

Plague in the Philippines.—Dr. J. M. Banister, U. S. A., in an article on "Medical and Surgical Observations in the Philippines," in the *Journal of the Association of Military Surgeons*, states that bubonic plague is a disease of which the medical officer in the Philippines has little fear. It is practically confined to certain districts in Manila and attacks chiefly Chinese and natives. A Caucasian is seldom attacked. Dr. Banister states that since the American occupancy he has been able to discover only three soldiers who have fallen victims to this disease.

Health Report of the Philippines for November.—During the month 820 births were registered in Manila; this represents a birth rate of 45.38 per 1,000. During the same period 988 deaths were registered. The number of deaths among children under 30 days and between 30 days and 1 year of age reached 527, representing 53.34 per cent. of the total number of deaths; the same shows a slight increase compared with the number of deaths, 468, occurring at the same ages during the preceding month. This difference against November can be attributed to the lowered temperature during various days of the month, which, although it may not have affected the health of robust and well-cared-for children, had a distinctly harmful influence on those who were weak and improperly fed and unprotected. The report contains a warning that the cool nights are particularly favorable to colds, which lead to bronchopneumonia and kindred troubles, and that chilling of the abdomen is a common predisposing cause of bowel troubles among both children and adults. There were only 18 cases of cholera during November, a decrease of 50 per cent. The health department has followed the infection from center to center, isolating the sick, and taking every possible precaution against the further dissemination of the disease. One hundred and thirty five thousand units of vaccine virus were distributed during the month among the 16 provinces of the archipelago.

CANADA.

Branch of British Medical in New Brunswick.—The St. John (N. B.) Branch of the British Medical Association has been organized with Dr. Murray MacLaren as provisional chairman and Dr. J. H. Scammell as secretary. Twenty practitioners in that city signified their intention of becoming members. The other branches of the British Medical Association in Canada are the Halifax, Montreal and Toronto branches.

Hospital News.—Some difficulty is being experienced in getting the bill regarding the Toronto General Hospital through the Ontario legislature, owing to the fact that there is a strong opposition to the clause which states that only the medical students of Toronto University shall have clinical privileges in this hospital. As McMaster University, a Baptist institution, has some ambition to embark on medical education, having gone so far as to make an offer for a fine site for a building, in the vicinity of their university, it is felt by some of the legislators that this privilege of clinical instruction should not be exclusive. In all likelihood the clause will be amended to provide for other students as well as those of Toronto University, availing themselves of the privileges of the hospital.——Grace Hospital, Toronto, at one time a homeopathic hospital, but now a general hospital, will shortly erect a substantial addition at a cost of $200,000. It will provide for an additional 100 patients. This hospital has a staff of 45 doctors and 35 nurses.——The Victoria Hospital for Sick Children, Toronto, will receive $2,000. The famous bribery money handed into court three years ago, when the notorious Causey political investigation was in process of ventilation, has been disposed of in this way.——The Toronto Western Hospital will erect two large additional wards for charity patients, with accommodation for 100 patients.——Winnipeg General Hospital treated 348 patients during the week ending April 14, 201 being men, 99 women and 48 children.——A new general hospital was opened at Moosejaw, Sask., on April 17.——The Vancouver General

Hospital is seeking a new medical superintendent, Dr. Robertson having resigned to enter private practice. The Vancouver Medical Society has forwarded to the board of trustees a recommendation that only a registered practitioner of British Columbia be appointed.——New Westminster, B. C., will erect a new $50,000 hospital, toward which the provincial government of British Columbia has contributed $15,000.

FOREIGN.

Fifth International Antituberculosis Conference.—The central committee of the society in the Netherlands organized for war against tuberculosis has invited the authorities to hold the international tuberculosis conference for this year at The Hague in September.

Homeopathy and Regular Medicine in Germany.—The federation of medical societies in Germany, known as the *Deutscher Aerztevereinsbund*, was recently asked to admit the Association of Homeopathic Physicians. The federation formally declined, stating that homeopathy is the negation of medical science.

Association of Medical Legislators. There are always a large number of medical men elected to the French national legislature. About twelve years ago they organized an extraparliamentary association for discussion of matters especially affecting the public health and the sociologic aspects of medicine. Italy has followed with the organization of a similar group and the physicians in the British house of commons have just taken a similar step.

Treatment of Seasickness.—F. Wolf, the German explorer, says that very hot compresses applied to the brow and constantly renewed will relieve and cure seasickness almost without fail. The patient must lie still, eat nothing except, possibly, unsweetened tea and toast. An hour or so of the hot applications to the brow have always cured in the severest cases of seasickness in his experience, even in the stormiest weather.

Honors to Americans.—At the formal session of the Royal-Imperial Medical Society of Vienna, Austria, on March 30, honorary membership was conferred on Nicholas Senn of Chicago, W. H. Welch of Baltimore and O. Schmiedberg of Strasburg. Six corresponding members in this country were appointed: J. J. Abel and John C. Hemmeter of Baltimore, C. Herter, L. Emmett Holt and Graham Lusk of New York, and J. Loeb of the University of California. The official title of the society is the Königliche-Kaiserliche Gesellschaft der Aerzte in Wien.

His to Take Ebstein's Place.—Wilhelm Ebstein retires from the chair of medicine at Göttingen this spring, and W. His of Basle has been invited to take his place. Ebstein will be 70 years old next November. The list of his important publications is a long one and includes a number showing great historical research. Among the latter is one on the "Plague of Thucydides." His "Manual of Practice of Medicine" has passed through numerous editions since first published in 1899. His name is especially connected with diabetes, leukemia and gout. Wilhelm His is 43 years of age at present, and was assistant to Curschmann at Leipsic until called to Basle. He has published works on gout, on the embryonal heart and the development of the cardiac nerves in the vertebrates. One of his most recent communications was a study of pleural and other effusions.

Fifteenth International Medical Congress.—This international gathering of physicians and surgeons was formally opened at Lisbon, April 19, by the king of Portugal. Each civilized country had sent delegates, and more than 250 men of international fame had been invited to deliver the official addresses on 140 of the vital medical topics of the day, and nearly all had accepted and were present on the opening day. Nicholas Senn's address on the "International Study of Carcinoma," published elsewhere in this issue, was delivered at one of the five general assemblies. He proposed to offer a prize of $1,000 for research on carcinoma. The delegates appointed by the German government were Quincke, Curschmann, von Behring, Neisser, Loeffler, Garré, Verworn, Heller, Rubner and Posner. The army was further represented by Kern, the navy by Elste and Martini. France and Great Britain sent equally representative delegations. The American delegation was mentioned recently on page 1044.

Death of Professor Curie of Paris.—The cable brings word that the great chemist who shared with his wife the honor of the discovery of radium, was run over by a dray in the streets April 19. The story of his life has been often told: his marriage to the young Polish woman who was such an ardent student in the laboratory for physical research in his charge, their six years of research together on the uranic radiation discovered by Becquerel, terminating in their announcement in 1898 of the discovery of the new substance, radium, which shook the foundations of some of the most fundamental scientific theories, including the atomic theory and that of the conservation of energy. The Nobel prize for scientific research was awarded to them in 1903, and the Osiris prize of $12,000 was later given to Mme. Curie. Professor Curie was convinced that all the wonderful properties of radium have not yet been learned, and he and his wife were still deeply engrossed in its study. His shrinking from publicity was so great that he seldom accepted any of the numerous invitations to lecture which came to him, and he was a poor speaker. The cable dispatch says that the premature death of this simple-lived, retiring scientist before he had completed his research on the possibilities of radium may be an event of greater actual importance to humanity than the horrors of earthquake and fire. Nothing is known at this moment of the special research on which he was engaged at the time of his death, but his mental absorption in it may have been in part the cause of the fatal accident. He leaves a daughter 8 years old.

August Bier.—Few names have been mentioned more frequently in our columns during the last year or so than that of Professor August Bier of Bonn. He has led the way into new fields where few, if any, had preceded him, and no one mentions spinal analgesia, or the application of superheated air or artificial passive congestion in therapeutics without some reference to Bier's pioneer work. His latest revolutionary announcements in regard to the importance of artificial hyperemia or passive congestion as an aid in the treatment of acute inflammations have attracted world-wide attention. As recently mentioned, he has been awarded the newly-founded Kussmaul prize. On this occasion the *Muenchener med. Wochft.* published an excellent portrait of him which we herewith reproduce. Much of his training was received under Esmarch. He is now 45 years of age. Summaries of his communications are scattered through the last volumes of The Journal. In vol. XLI, on page 68, paragraph 146, and in vol. XLII, on page 807, paragraph 81, will be found summaries of his communications in regard to hyperemia as a curative measure. On page 1260 of vol. XLII his pioneer work on spinal analgesia is reviewed. His more recent announcements in regard to the value of passive congestion in treatment of acute inflammations were reviewed on pages 914 and 1075 of vol. XLIV, and also on page 1206 of vol. XLV. See also page 1524, paragraph 48, in this issue.

AUGUST BIER.

Escape of Miners Buried for Twenty Days at Courrieres.—The *Presse Médicale* states that thirteen of the miners were rescued after having been buried in the mine for twenty days, and another miner was found alive five days later. The thirteen miners were together and managed to keep alive by eating oats, bark and rotten meat, the only edibles within their reach. Their survival in the toxic gases of the mines, without light and almost without air, subsisting on rotten meat, quenching their thirst with urine, defies scientific theories. Besides their endurance and resistance, the spirit of discipline and comradeship which they displayed was equally remarkable as they wandered around in the closed subterranean galleries of the mine, crowded with the corpses of their mates. The Paris *Tribune Médicale* is preaching the necessity for supplies of oxygen to be kept on hand in mines and in submarine boats, etc. All the survivors testified to the fact that the air in the mine was absolutely irrespirable only during the first few hours after the explosion. If there had been a supply of oxygen to have tided them over the first few hours, hundreds more might have been saved. The editorial states that the hygiene of mines should be entrusted to medical men, to physicians trained in physiology and hygiene. The mechanical mining engineer has charge of the mechanical part of the business, but medical skill should guide the exploitation of the human motor. Whenever an explosion has taken place it is generally

learned that the air had been impregnated with firedamp for some time. It frequently happens that the air in a mine is at times so loaded with firedamp that only a spark is needed to produce an explosion. The absence of the spark prevents any trouble. The editorial urges that three samples of air should be taken at a time, three times a day. One sample should be tested, and one sample be kept by the officers of the mine, and the other sample by a delegate from the miners. In this way it would be possible to detect increasing contamination of the air, and, in case of an explosion, to place the responsibility where it belongs. Then, if any explosion occurs, the survivors should have supplies of oxygen within reach at different points in the mine. (See editorial in this issue, p. 1289.)

The Lost Lambs of Medicine.—The *Progrès Médical* of Paris and some other medical journals occasionally devote space to interviews with more or less prominent people who began life as physicians, or at least completed their medical course, but were then diverted into other fields. All express great appreciation of the remarkable aid their medical training has proved in their later life-work. Writers especially have found it of great benefit. The latest sketches of the kind are of the director of a Paris theater and of a member of the Comédie Française. The latter, Dr. Paul Mounet, remarked in the course of his interview, that the medical course is the most difficult of all, but it prepares for anything and everything.

Comparative Study of Tropical Hygiene.—The *Semaine Médicale* for April 11 contains an article by a French navy surgeon, Dr. Gloaguen, who has been cruising in the waters along the eastern coast of Africa, making a special study of the medical conditions in the various English, German and French colonies. He says that he was surprised to find that the British are behind the Germans in the matter of making and keeping their possessions healthy. The English fall back on their egotism and individual hygiene; the Germans on their inflexible militarism, and the French on their proverbial heedlessness. The English conception of prophylaxis is very simple. It is based on two things: entire separation of the native and the European villages, and strict application of the principles of private hygiene. The English lead an active life, with athletics, etc., to keep mind and body in a healthy condition; they reside in comfortable cottages, but they make no effort to render the country healthier and improve the sanitary conditions of the natives. There is no attempt at a general plan of campaign against tropical diseases. The native quarters are left in their filth and fall an easy prey to diseases. Plague is installed in nearly all the British colonies on the Indian ocean, and with the exception of Isle Maurice, no satisfactory measures have been taken even against malaria. The Germans, on the other hand, have undertaken the task of exterminating disease among the natives and Europeans alike. The same sanitary measures are enforced in the native as in the European quarters. Hospitals are being organized at the main points, and the country is divided into districts, each in charge of an agent empowered to enforce the sanitary regulations. Medical stations are organized along the caravan routes, and the natives are examined and registered and given certificates. Laboratories are numerous. The streets in the native quarters have been made wide and airy and are kept clean. The garbage is carted away daily instead of being allowed to accumulate around the houses as in the English and other colonies. Standing waters are drained or oiled. The French are now trying to introduce some semblance of the German measures into their colonies and with some success. Quinin prophylaxis has been introduced by the Germans on an extensive scale at Dar Es-Salaam. The native quarter is divided into 22 precincts, and they are visited by trained men and women, who obtain blood for bacteriologic examination. In 1897 between 50 and 60 per cent. of the Europeans had malaria. The antimalaria campaign was commenced in 1901, and in two years the number of cases of malaria among the Europeans had dropped to 10 per cent. with no mortality. Scarcely one in a thousand of the natives now harbors the malaria parasite, and the results are considered a brilliant success. Gloaguen prefaced his article with the statement that wherever he went in the French colonies he constantly heard the complaint: "If only this country belonged to England, it would have been made healthy long ago." In his criticisms he overlooks the British idea in regard to governing colonies. The general aim of the British is to make the yoke light and to disturb the native habits and customs as little as possible. Their ideal is education, principally by example.

Correspondence

The Death of Dr. Stinson at San Francisco.

CHICAGO, April 24, 1906.

To the Editor:—The Dr. Stinson who was one of the first victims of the San Francisco horror was the author of the automobile article in your last issue. At the time I addressed the San Francisco County Medical Society last July I was the recipient of exceptional courtesy at his hands. An hour after my arrival he was at my hotel with the car he describes and his experienced chauffeur. He insisted that I make use of his car during the few days I was in San Francisco as if it were my own. He asserted kindly and positively that he needed exercise and would walk.

Many members of the American Medical Association who were visiting San Francisco directly after the Portland session will now recall, with a saddened interest, the delightful excursions to the Presidio and Golden Gate Park which Dr. Stinson's extreme courtesy made it possible for them to make with me. I am informed by his friends that the walls of the California Hotel fell on him while he was asleep and killed him instantly. He was a brilliant practitioner, a successful surgeon, and his death will mean much to many of the first families of San Francisco. He was a stranger to me when I arrived in California, but his hospitality was so genuine and sincere that his sudden taking off is in the nature of a personal bereavement. DENSLOW LEWIS.

Need for Additional Nomenclature.

NEW YORK, April 21, 1906.

To the Editor:—Permit me to say to Dr. Thomas G. Atkinson's proposition under the above heading in THE JOURNAL, April 21, that wherever additional nomenclature is needed we should not accept terms like Dr. Atkinson's hematfecia and pyofecia; our onomatology is disfigured already by such monstrosities and needs reform instead of new horrors. A. ROSE.

Warns Against Alleged Impostor.

NEW YORK, April 20, 1906.

To the Editor:—A physician calling himself "Dr. Ernest Sachs" is traveling about the country as an agent of "The Swiss Goat-Lymph Serum Compound," recommending its use in the treatment of locomotor ataxia and other nervous diseases. He claims to be a brother of mine and is using my name in order to palm off this serum on a credulous public. I wish to state that the man is no relative of mine, that I do not know him, and that those who know me will not need to be told that I am not one of those likely to recommend "goat-lymph serums" or any other similar remedies (?). I have every reason to believe that the man is an impostor. He claims to have been connected formerly with the German Hospital in New York City, and I understand that at that institution his name is entirely unknown.

B. SACHS, M.D.

Medical Men in Congress.

WASHINGTON, D. C., April 21, 1906.

To the Editor:—An item with the above title appears in the last issue of THE JOURNAL, April 21, under the head of "Medical Legislation." The author may not have intended to name therein all the medical men who are at present members of the Fifty ninth Congress, in which event he succeeded; it it was intended to include them all, and this might be inferred from the title, the person who prepared the article was rather careless or did not have access to the Congressional Directory. In the last thirty years there has scarcely been a congress without more or less medical men, some having retired from active practice long before entering congress, while many have gone from the active practice of their profession to the highest legislative body in the land.

One of the latter class—and he is not mentioned in this article—is Edmund William Samuel, M.D., of the sixteenth

istrict of Pennsylvania. A part of his biography, which may e found in the Congressional Directory, is as follows:

"Edmund William Samuel, M.D., Republican, of Mount Carmel, was born Nov. 27, 1857, in England; at the age of 2 ears moved with his parents to Ashland, Pa.; at 8 years he as employed as a slate picker in a coal breaker, worked bout the coal mines in summer and attended the public hools in winter. He entered Jefferson Medical College in 878, at Philadelphia, and graduated therefrom March 13, 880; the same year began the practice of medicine, which he as followed continuously to the present time."

Drs. Burton, Barchfield and Samuel (Regulars) are members f the House, going directly from active practice to this body, his being their first term. John Wesley Gains, sixth district f Tennessee, graduated in medicine from the University of Tashville and Vanderbilt University in 1882, and immediately egan the study of law; he never practiced.

Dr. Gallinger (Homeopath), the medical member of the enate, has not been in active practice for many years.

More of the members of the Fifty-ninth Congress may be raduates of medicine, but I am unable to trace them.

W. F. Wagner, M.D.

The N. S. Davis Memorial.

Boston, April 23, 1906.

To the Editor:—I am sure your readers will be glad to now, through the columns of The Journal, something of he progress which is being made by their committee in the aising of funds for some suitable memorial to the late Dr. N. S. Davis of Chicago.

I am delighted to report that the committees from each of he several states have already taken up the work with enhusiasm. It is the purpose of your committee to make this novement in honor of the founder of our great Association n especial honor and privilege to every member. The sum of 25 cents each would aggregate a total ample for this purpose, and your committee feels that such universal remembrance would be an honor and a privilege to every one of the great army of over 100,000 physicians to be sharers. It is he desire of your committee that the contributions shall be small from the many rather than large from the few. It s preferred that these contributions be sent through the state committees, but any one who desires to contribute for this purpose directly to me will receive proper acknowledgment herefor.

Henry O. Marcy, Chairman.

180 Commonwealth Avenue.

Association News

Transportation.

The railroad rates to the Boston session from the eastern half of the country will be one fare, plus $1.00, for the round trip. In the Trans-Continental Passenger Association territory the rate will be about a fare and one-third to Chicago, Minneapolis, New Orleans and St. Louis, and from these points on to Boston the rate above mentioned. The southern passenger associations are yet to be heard from, but they will probably make the same rate of one fare, plus $1.00, for the round trip. A more detailed announcement will be given in The Journal May 5.

Hotels in Boston.

A list of the hotels and headquarters in Boston, with the cost of rooms, was given in The Journal, April 7, page 1046, and this list will reappear next week, May 5, in the special Boston Number. The committee on hotels states that members of the Association are still writing them for information which is contained in this announcement and we, therefore, call attention to the list. Last week, April 21, supplementary announcement concerning the boarding places was given.

The Boston Number.

The issue of The Journal, May 5, will be the Boston Number, containing a specially written article concerning its historical points and the special medical opportunities. This article will be liberally illustrated with fine pictures. There will also be preliminary programs of the general meetings and sections, list of hotels and headquarters, particulars of railroad rates, excursions, entertainments, and all possible other information. The indications are that there will be a very large attendance.

Second Annual Conference of Council on Medical Education.

The second annual conference of the Council on Medical Education of the American Medical Association will be held at the Auditorium Hotel, Chicago, May 12, 1906. There will be two sessions, beginning at 10 o'clock and 2 o'clock. A large delegation is expected, representing state examining boards, government medical services, medical college associations, colleges of liberal arts, and teachers' associations. Besides the report of the year's work by the council, the program will consist of addresses from prominent educators and others. The subjects of preliminary educational requirements, the granting of advanced standing for work done in colleges of liberal arts, and what constitutes a proper medical curriculum will be discussed.

Miscellany

FRAUDULENT USE OF THE MAILS.

Another Pseudo-Medical Company Is Debarred by the Government from Use of the Mails.

The postoffice department is continually investigating fraudulent companies which use the United States mails to further their schemes. Whenever the business of a concern is shown to be fraudulent the firm is forbidden the use of the mails. Many of these companies are medical, reports in regard to some of which we have already published. This week we give space to the report of the investigation of the Nutriola Company, made by R. P. Goodwin, assistant attorney general for the postoffice department. In accordance with this report a fraud order was issued Nov. 24, 1905, debarring the Nutriola company from the use of the mails. From this report we quote as follows:

The Nutriola Company is a Maine corporation, organized about 1894, with authorized capital stock of $150,000, divided into 150,000 shares of the par value of $1 each. The capital stock has since been increased to $500,000. Edward F. Hanson is the promoter of this scheme, with principal offices at 142 to 148 West Madison Street, and branch office at 130 Dearborn Street, Chicago, Illinois. The principal business of the company is that of selling its stock on the installment plan to small investors throughout the country; its ostensible business is the manufacture and sale of certain medical preparations known as "Nutriola" and "Nutriola Preparations." The mail is the principal instrumentality used in the conduct of the business, and practically all of the stock that has been disposed of has been sold through that medium. The sale of stock has been accomplished by advertisements, and the dissemination of various pamphlets and circulars through the mail.

I have examined and considered very carefully the report of the inspectors, giving the result of their investigation of this matter, together with the papers submitted therewith; the written statements and briefs of the attorneys for the company, and the matters adduced in the oral argument of its counsel; the reports of the department of agriculture as to the therapeutic qualities of the medicine of the company, and the other circumstances and facts disclosed in the case, and am convinced that the sale of capital stock of this company has been, and is being accomplished through the mails as a result of misrepresentation and deceit. The reasons for this conclusion are stated below:

1. One of the principal arguments made by the company to induce the purchase of its stock is that investors will secure

an interest in a company which will earn tremendous profits by reason of the fact that the medicines sold by it are new and wonderful, and that they were only discovered after years of study and research, made by the most skilled chemists and physicians, whom the company had employed, and after the expenditure by the company for such expenses of over $50,000 in cash. The representation that the formulas for these medicines were only discovered by the company after the expenditure of over $50,000 in cash I find is false and unwarranted. In a pamphlet used by the company for the promotion of the sale of its stock, and entitled, "Health, How Gained and How Retained," on the third page appears this statement:

"THE TRIUMPH OF PHYSIOLOGY AND CHEMISTRY.

"For nearly ten years our Chemists—aided by the best physicians in the U. S.—worked with these facts ever before them. Worked to aid nature by creating perfect Digestion and perfect Assimilation. By increasing the army of Leucocytes and giving them strength to destroy all disease germs, by supplying Nature power for perfect Elimination of Dead diseased matter. By supplying constructive material to make Red Blood Corpuscles from which Nature could draw material to replace every warnout and diseased cell, thus making *the body new all over.*

"*Cost us $50,000 cash.*

"It was a great undertaking, worthy of the age. It cost us $50,000.00 cash, but *we succeeded,* and to the world we give the greatest Chemical-Medical Preparation ever prepared by the skill of man. It's Nature's right arm of power. We named it *Nutriola,* and we emphatically state that *Nutriola and Nature are the only invincible conquerors of disease ever known.*"

Some of the circumstances and facts which satisfy me of the falsity of this representation are as follows:

Mr. Hanson was asked this question by the inspectors:

"Q. It is noted in your literature that you have expended something like $50,000, or a large sum of money for experimenting and perfecting the Nutriola remedies. A. The amount stated in our literature should be approximately $40,000, and it covers the entire formative and experimental period during which preparations were prepared in various forms. The company advertised for so-called incurable cases, supplying treatment free, where necessary employing physicians to give the remedies and watch the results. Among these physicians was Dr. L. W. Hammons, city physician of the City of Belfast, Maine; Dr. McCurdy, of Searsmont, Maine, now deceased; Dr. Hitchcock, of Rockland, Maine; Dr. Lace, of Boston; Professor E. L. Patch, of Stoneham, Massachusetts, was the chemist who prepared the Nutriola Ointment known as Skin Food, and under whose supervision every particle offered for sale is now made. Dr. Stockwell, Parke, Davis & Company's leading chemist, rendered valuable assistance. The amount paid the chemists I am unable to state, as I have no record or vouchers therefor, and the original books of the company were burned in the fire in 1895 or 1900, with all papers and vouchers. Q. Please name the chemists who now manufacture the remedies of the Nutriola Company. A. Parke, David & Company, Detroit; E. L. Patch Manufacturing Company, Stoneham, Massachusetts; Seabury & Johnson, New York."

Regarding these statements of Mr. Hanson, the inspectors report:

"The proposition that it cost $50,000 for the services of chemists and physicians in the making of this discovery is explained and modified by Mr. Hanson on page 3 of his statement.

"It might be mentioned that Professor Patch, of Stoneham, Mass., is presumed to be connected with the manufacturing chemists firm of E. L. Patch & Company, Stoneham, Mass. Dr. Stockwell is the chemist of Parke, Davis & Company, also manufacturing chemists. It is commonly known that large manufacturing chemical houses have always in their employ erudite and competent chemists who render their services and advice free to patrons of the house in the matter of suggesting desirable formulæ for proprietary medicines, which are subsequently to be manufactured at a profit to them."

The representation of the company is that as the result of the expenditure of this $50,000 it has discovered certain preparations which are new and not known to the medical world, and which possess wonderful curative properties. For report as to the therapeutic qualities of these medicines and to ascertain if there was anything new or wonderful about them, samples of the same were submitted to the department of agriculture. The formulæ for the medicines were later secured from the company and also submitted to that department for its consideration in connection with its analysis of the medicines. The report of the department of agriculture, dated Oct. 13, 1905, has been received, and I quote from it as follows:

"From a careful investigation of the formulæ submitted, the chemical analyses made and the advertising literature, I am led to the following conclusions.

"1st. There is nothing new or wonderful in the agents used in the preparation of the several remedies. All of them have been in use for many years, excepting 'Phytiline' 'Sicklenceen' and 'Ferrum Aceline' No reference in literature to either 'Phytiline' or 'Sicklenceen' could be found, and I believe they are either misspelled words or 'blinds.' 'Ferrum Aceline' may be used by this firm in the treatment of disease, but no medical authority recognizes it as a therapeutic agent.

"2nd. The proportions used of the various agents in the several mixtures are withheld, but even so, it may be safely stated that there is nothing particularly new in the combinations of the various ingredients, the forms of the combinations or methods of combination. They differ no more from other similar combinations than one physician's prescription differs from that of another, using the same or similar active constituents, or the procedure of one pharmacist in filling a prescription differs from that of another pharmacist.

"3rd. Remedies prepared according to the formulæ which are submitted by the Nutriola Company, as the ones used in the manufacture of its remedies, are well known and useful combinations employed in the treatment of diseases.

"4th. The Company makes numerous exaggerated and misleading statements relative to the efficiency of these remedies in various parts of its advertising literature, some of which can not possibly be construed as coming within the domain of privileged business methods. It is believed that fraud would be imputed by the court, to many of the assertions, if brought to an issue.

"There is certainly nothing in any one, or all of the mixtures combined, which would warrant the claim of this firm to be able to cure 'cancer, rupture, stricture, etc., without pain or knife.'

This report of the department of agriculture, of itself, is convincing evidence of the falsity of the representation that this company has expended over $50,000 in discovering these medicines. . . .

The failure of the company to offer any evidence whatever of the truth of this representation, despite the opportunities which have been given it to do so, indicates clearly that the company has no such proof to submit. Surely, if it be true that for years this company employed the most skilled chemists and the best physicians of the country to work on these formulas, and expended over $50,000 in cash for this purpose, full and satisfactory evidence of that fact would be available and would be promptly adduced. On the contrary, the company makes no attempt to show that this representation is true, and beyond the simple averment that the "statement as to the work of chemists, etc., is true," seeks to dismiss the matter with the mere statement that "the expenditure may not have been as great as indicated." But even though this fact itself satisfies me of the falsity of this representation, the report of the department of agriculture as to the character of these preparations indicates plainly that the representation is not true. The analyses of these medicines and the formulas therefor disclose that these medicines are commonly and well-known to the medical profession, and that there is nothing whatever about them that is new or unusual. In the light of these analyses, the falsity of this representation is apparent. The suggestion of the inspectors that these medicines were prepared for this company by the chemists of Parke, Davis & Company and E. L. Patch Mfg. Company, well-known manufacturing chemists, under the commonly known practice of these houses of furnishing such formulas free to persons proposing to commence a medicine business, in consideration that the supplies be purchased from said houses, is shown to be undoubtedly correct by the report of the department of agriculture as to the character of the medicines, and especially by the fact that Mr. Hanson is unable to name any other chemist who worked on the formulas other than the chemists of these two houses, which are now manufacturing these medicines. . . .

2. In connection with the representation above noted, the company pretends that its medicines are new, that they are of a character different from anything now known to the medical world, and that they possess superior and wonderful curative properties, and that therefore the medicines of the company will create a large demand, with the result that the stock of the company will earn large profits. The representation that these medicines are new and wonderful permeate the entire literature of the company. The representation that the formulas cost $50,000, is used for the purpose of creating such impression. The impression is also created by such statements as the following:

In the pamphlet styled "Nutriola Nature's Power The Fountain of Life," at page 10, references are made to the present system of medicine in a way to lead the reader to believe that this concern has discovered something new, differing from the present methods employed in the practice of medicine, and has discovered something new and different from the present medicines. On page 12 of this same booklet it is pretended that "Nutriola and Nature are the only invincible conquerors of disease."

On page 16 of this same pamphlet, after representing that only temporary relief can be afforded patients by the methods at present known in the practice of medicine, the literature pretends that the relief secured by using Nutriola is something entirely different from the temporary relief which is all that medicine up to the present time has been able to give and that by the use of Nutriola the system is made "new all over."

On page 18 of this same booklet, referring to a depleted condition of the nervous system, the representation is made that "the old young man will find in Nutriola the only restorer of life, vigor and health. . . . There has been no permanent health for this class until Nutriola was discovered. . . . Nutriola will do for this class when used in connection with our special treatment what nothing else on earth can do."

On page 20 of this same pamphlet, under the heading "Nature and Chemistry," the impression is clearly conveyed that in Nutriola Preparations, a discovery has been made of something new and wonderful, that possesses unusual and powerful curative properties. Especially is this true of the following statement made in that article: "It is no marvel when you understand it; it is simply the result of supplying Nature material that she could use. It costs thousands and thousands of dollars, years of experimentation, testing and treating of disease in whatever form, studying the action of certain combinations of chemical-medicinal properties before the perfect combination known as Nutriola could be ready to go forth in its mission to the world."

On pages 21 and 22 of this same pamphlet, the literature referring to the conditions of motherhood, the idea is clearly sought to be established that Nutriola is a discovery of something new and wonderful. Especially is this true of the statement that "Could we take the future mothers of the world understand that there is *now* no need of bearing sickly children, what a step would be made toward banishing sickness and suffering. How proudly would dawn the morning for future generations."

On page 26 of this same pamphlet the difference between Nutriola and the medicines now known to the medical world is stated in this emphatic language:

"Have you passed the candle era? Do you prefer the electric light or even a good gas-jet or, if no better, an oil lamp, to a tallow dip? Would not think of ignoring modern improvements and going back to the tallow candle, would you? Did you ever stop to think that when candles were the best light, doctors prescribed the same drugs and gave the sick practically the same treatment as to-day? The results were the same, too. Nutriola is as far in advance of all other preparations for the relief and cure of mankind as the electric light is in advance of the tallow candle. Forget it not. *Forget it not.* Some day it will be worth everything to you to remember it."

[We omit the remainder of the quotation to the same effect.]

That the effect of all these references, statements and processes is to create the impression in the mind of the reader that the medicines of this company are new and wonderful is positively shown by the fact that the inspector addressed inquiries to a number of investors in this company, wherein this question was asked:

"Please state whether statements in circular matter received by you to the general effect that thousands of dollars had been spent in experimenting to discover and perfect Nutriola remedies, that they were new and never known before, that they were specifics and cures for many stated diseases, and that for these reasons so large a demand for them would be made that the stock of the company would increase many fold in value, and pay large dividends at an early date, was or was not the inducing cause that led to your investing in stock."

The answers received are herewith. They are in the affirmative and show that they invested in this company by reason of their reliance on such impression obtained by them from the literature of the company. . . .

To determine whether there is anything new or wonderful about the medicines and preparations of this company, samples of the medicines in question, and formulas therefor, were obtained and submitted to the department of agriculture. The report of the department of agriculture, giving the results of its investigations, has been quoted above in connection with the representation that $50,000 was expended in the discovering of these formulas. This report shows that there is absolutely nothing about these medicines which in any way warrants the representation that they are new or different from the medicines now known to and commonly used by the medical profession.

The attempt of this company, therefore, to impress proposed purchasers of its stock with the idea that its preparations are new and wonderful is misleading, deceptive and fraudulent. While some of the literature in question is couched in the form of alleged expressions of opinion, but are simply made to prospective purchasers of stock, who are uninformed, and who rely upon the superior knowledge and information of the company as to the quality and character of the medicines, with the intent that such parties shall rely on such statements and be deceived thereby, and be thus influenced to purchase this stock, which they would not otherwise buy.

3. Throughout the literature of this company, used by it to promote the sale of its stock, alluring and unwarranted prospects of enormous profits are held forth, while at the same time the true condition of the company's business is concealed. If the true condition of the business were known, it would have a material effect on the glittering prospects and promises of large returns. In this way the company has induced purchases of its stock, which would not be made if the real facts and conditions were thoroughly understood and truthfully represented.

[Part of the remainder of the report included under this third heading is omitted, not being of medical interest. It quotes the extravagant promises of the company's literature, analyzes the actual financial condition and the possibilities of the business, based on the history of the company and its development thus far, and concludes as follows:]

This literature is sent broadcast over the country, and it is calculated to induce remittances, which would not otherwise be made, except for the very confident manner in which the prospects of great returns are set forth, and especially is this true of the class of people to which such matter appeals. The concealment of the true condition of the company, of the fact that its capital is seriously impaired, of the fact that, although it had been in existence for ten years, it had never earned a profit or paid a dividend, and of the fact that the company is at the present time being operated from the receipts of the sales of stock, and not from the conduct of the company's business—all of which facts have a material effect on the prospects of the company to earn the enormous returns represented—while at the same time promises and prospects of enormous returns are set forth in confident and emphatic language, and the purchaser of stock led to believe that he is offered an exceptional opportunity to become interested in a company that is absolutely safe as an investment, and yet assures tremendous profits, and that each dollar invested by him will earn not less than $220, is unquestionably misleading and deceptive, and manifestly shows that the purpose of the parties promoting this scheme is to mislead and deceive, and thereby effect sales of stock which could not be made if the true condition of the company were disclosed.

While counsel for the company have admitted that these representations are largely exaggerated, they have claimed that the company should not be held responsible therefor, for the reason that they are made as an expression of opinion. I find, however, that these statements are dishonest expressions of opinion, and made with intent to mislead and deceive. Such opinions pretend to be founded on facts which do not exist, and untruthful representations as to the character of the medicines proposed to be sold, and the business of the company; and, furthermore, the true financial condition of the company is concealed, although the facts concealed have a most material bearing on the prospects of the company to earn the returns promised.

4. A further ground on which the company undertakes to assure prospective investors of large returns from the business is pretended to arise from the fact that Mr. Hanson will operate the company, and owing to his exceptional ability in this line of business will make the business of the company extremely profitable. The pretenses carrying the idea that Mr. Hanson possesses unusual and exceptional ability in this line of work are found principally in the advertisements of the company and the pamphlet entitled, "A Guide to Full Pockets." The principal representations made regarding Mr. Hanson in this connection refer to his experience with a business called "Dana's Sarsaparilla." It appears that in that case a profitable sale of the business was effected after Mr. Hanson became charged with the conduct of that company's affairs, and that as the result of such sales the parties interested in the company made a large profit on their investments. The fact, however, that Mr. Hanson has since been unsuccessful in his undertakings and has lost most, if not all, of the money that he had out of Dana's Sarsaparilla business is concealed. This fact would have most material bearing or the representations carrying the idea that Mr. Hanson possesses unusual ability. The representations of this character regarding Mr. Hanson, and made by the company to influence sales of stock, are, therefore, deceptive, in so far as they attempt to show the exceptional ability of the man, because of the concealment of the remainder of his personal history, which greatly modifies it. As a matter of fact, since Hanson sold out Dana's Sarsaparilla he has not been successful, and has been obliged to pass through bankruptcy and be discharged of his debts. Furthermore, he has been operating, in a moderate way at least, the

Nutriola proposition for about eleven years, with the result not only that no profits have been made, but that the capital is impaired from $50,000 to $60,000, and the company is even in debt to him for back salary to a very considerable amount. These representations are, therefore, calculated to mislead and deceive.

Much of the matter formerly used by Hanson to promote the sale of stock and medicines of this company was of an obscene and improper character, and it appears that an indictment is at the present time pending against Hanson at Chicago for the mailing of such matter. It is understood, however, that this objectionable literature is not being used at the present time. This fact is not, however, definitely shown by the inspector's report.

The evidence and circumstances in this case satisfy me that the stock of this company is being sold through the mails by means of pretenses, representations and promises which are false and fraudulent. I therefore recommend that a fraud order be issued against the Nutriola Company at Chicago, Ill.

R. P. GOODWIN,
Assistant Attorney General for the Postoffice Department.

Accordingly a fraud order was issued by Postmaster-General Cortelyou on Nov. 24, 1905.

Attached to the report is the following letter from the Bureau of Chemistry of the Department of Agriculture concerning the analysis of the Nutriola products:

WASHINGTON, D. C., Aug. 10, 1905.

To the Honorable Postmaster General:—In reply to your favor of June 27, in which you requested that an analysis be made of the Nutriola Company's medicines submitted by your department and an expression of opinion given as to the value of the medicines, and also whether the advertising literature contains any false or misleading statements, I have the honor to advise you that the Bureau of Chemistry has made the necessary investigations and I herewith submit its findings.

The Nutriola Company's medicines consist of the following products: "Skin Food," "Liver and Kidney Treatment," "Vaginela," "Laxative Granules" and "Blood and Nerve."

BLOOD AND NERVE.

Blood and Nerve consists of three separate kinds of tablets, which for convenience will be designated in this letter by their colors, namely, Red, White and Yellow.

These remedies presented numerous analytical difficulties, and some of the following results are at best only approximated.

SKIN FOOD.

Skin Food is an ointment-like substance and contains:

	Per cent.
Petrolatum (vaselin) and other unctuous bodies soluble in ether	90.77
Inorganic matter (zinc compounds chiefly)	7.24
Volatile matter at 100 C.	2.00

No real valid complaint can be charged against this compound, except that the term "Skin Food" is rather questionable as to accuracy. It is also an exaggeration to state that this skin food will cure cases that have been given up as hopelessly incurable.

LIVER AND KIDNEY TREATMENT.

This medicine comes in the form of brown tablets and on analysis shows the following products:

	Per cent.
Ash	41.6
Sugar and starch	27.2
Oleoresin (probably buchu)	12.2
Moisture, carbon dioxid, nitrogen gases and undetermined organic bodies	18.9

The probable combination of the inorganic component constituents are as follows: Sodium phosphate, potassium nitrate, magnesium sulphate, calcium carbonate, iron sulphate and a small amount of siliceous matter.

This combination contains drugs (oleoresin of buch and potassium nitrate) that have a distinct action on the kidneys. Nothing having a selective action on the liver was detected, but this is not surprising, for there are a good many agents having such an action, yet can not be detected chemically.

I think this medicine will serve a good and useful purpose.

VAGINELA.

This compound consists of greenish-colored, highly aromatic tablets, and an analysis gives the following results:

	Per cent.
Starch	56.4
Inorganic compounds (consisting chiefly of borax and boric acid)	17.0

Salicylic and tannic acids amounts not determined. Aromatic bodies and essential oils amounts not determined.

The agents present in this medicine are recognized as jointly having astringent, antiseptic and soothing qualities. While the literature accompanying the package of medicine contains a few statements that are, in a measure, extravagant, yet no decided criticism could be offered.

LAXATIVE GRANULE.

This medicine comes in the form of red pills and an approximate analysis indicates that it is composed of well-recognized laxatives, such as cascara, jalap, an alkaloidal drug, and possibly rhubarb.

No particular criticism can be offered to this combination, except that it is probably an exaggeration to say that it is a "nourishing laxative," although this may be a possible figurative interpretation of the results obtained.

NUTRIOLA BLOOD AND NERVE—RED.

This is a red tablet and consists of the medicinal mixture known as "Blaud's mass," with such associated substances as are frequently used in the making of pill masses. There is no doubt but this is a valuable medicine.

NUTRIOLA BLOOD AND NERVE—WHITE.

This remedy consists of small, white, bitter tablets, and an approximate analysis shows it to contain strychnin and possibly damiana. This is a well-recognized combination of valuable medicinal agents and is, therefore, a medicine of good quality.

NUTRIOLA BLOOD AND NERVE—YELLOW.

This medicine comes in the form of yellowish tablets, which do not possess any taste characteristic of a commonly used medicine, excepting ginger, and ginger is the only product I have been able to definitely make out as being present. I am, therefore, unable to express any opinion as to the value of this medicine, except so far as it resides in the ginger. Ginger is recognized as having a stimulating effect when introduced into the alimentary canal.

I have also read over with care Exhibit C, entitled "A Guide to Full Pockets," and must confess that so far as the medicinal and pharmaceutical sides are concerned there does not seem to be any decidedly exaggerated statements. On page 8 will be found a statement which conveys the idea that Nutriola is not composed of drugs. This is certainly not correct. On page 9 are a number of questionable statements, namely, that Nutriola is a "tissue-tormer" and "nerve-builder" and the "very essence of life." The statement found on page 10 of "Full Pockets" near the bottom leads to the belief that Vaginela is absolutely different from other remedies of this character. This, however, is not correct, because the constituents found are frequently employed by practicing physicians for diseases similar to those for which Vaginela is recommended by the Nutriola Company.

I would call your attention, however, to several advertisements found in the packages containing the medicines themselves. . . . I have placed a number of lead-pencil marks opposite many unwarranted and exaggerated statements. Before forming a decided opinion on these statements it should be borne in mind that they are, in a measure, mitigated by an introductory clause, namely, "Temporary relief and permanent cure," near the bottom of page 2 of exhibit No. "M."

According to exhibit No. "N," near the middle of the page, this firm claims to be able to cure by the use of Nutriola and different forms of electricity "cancers, tumors, rupture, stricture, etc., without pain or knife."

It might be well also to make a remark relative to the impression made by the literature concerning the large returns for investments. It is well known that many proprietary remedies have netted the owners very handsome profits. It is also only fair to say, judging from the success of ordinary business ventures along this line, that this firm would find it difficult to pay a profit of $220 on every dollar invested.

This letter is signed by the acting secretary.

Marriages

Barton H. Potts, M.D., to Miss Florence L. Borie, both of Philadelphia, April 18.

William J. Abbott, M.D., to Miss Mary Crozier, both of Cleveland, Ohio, April 12.

Frank E. Hicklin, M.D., La Salle, Ill., to Miss Mary Fickle of Sandwich, Ill., April 11.

Harold Barclay, M.D., to Miss Hellen Fuller Potter, both of New York City, April 14.

James R. Bishop, M.D., Nanticoke, Md., to Miss Elizabeth Pyle, at Baltimore, April 14.

Samuel Claggett, M.D., Petersville, Md., to Miss Jeannette B. Chew, at Baltimore, April 18.

Dell E. Graham, M.D., Bradgate, Iowa, to Miss Manta Shellenberger of Humboldt, Iowa.

Albert Charles Clauser, M.D., to Miss Mary Hawkins Sims, both of Delphi, Ind., April 19.

Oliver B. Van Fassen, M.D., Humphreys Mo., to Miss Zenith Moyers of St. Louis, April 11.

Henry C. Wright, M.D., Nashville, Tenn., to Miss Julia Morrell of Los Angeles, Cal., April 10.

Gustaf Richard Egeland, M.D., to Miss Lydia Alvira Anderson, both of Ephraim, Wis., April 18.

St. George T. Grinnan, M.D., Richmond, Va., to Miss Susan Fitzhugh Dabney, at Charlottesville, Va., April 18.

Charles J. Marquette, M.D., Nova, Ohio, to Miss Evelyn Kelsey of Huntington, Ohio, in Cleveland, February 10.

Deaths

Milton Curtis Wedgewood, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1859; assistant surgeon of the Eleventh Maine Volunteer Infantry during the Civil War; president of the Maine Medical Association, and in 1897 president of the Maine Academy of Medicine and Science; president of the Adroseoggin County Medical Association; one of the organizers of the Central Maine General Hospital, Lewiston; a member of the International Health Association; a member of the executive council of Maine under two administrations, and once a member of the State Board of Health, died at his home in Lewiston, April 9, from brain disease, after a long illness, aged 73.

J. Coplin Stinson, M.D. University of Trinity College, Toronto, 1893, Fellow Trinity Medical College, 1893; member of the College of Physicians and Surgeons Toronto, 1893; first silver medallist Trinity Medical College; a member of the American Medical Association, Medical Society of the State of California; San Francisco County Medical Society and San Francisco Clinical Society; physician to the British Benevolent Association, San Francisco; surgeon to the Pacific Sanitarium; a member of the Board of Health of San Francisco, is reported to have been killed by falling bricks at the California Hotel, San Francisco, April 18.

George W. Beggs, M.D. Rush Medical College, Chicago, 1862; a pioneer physician of Sioux City, Iowa; surgeon of the One Hundred and Sixth Illinois Volunteer Infantry during the Civil War; a member of the local and state medical societies and of the Association of Military Surgeons of the United States; surgeon general of the Union Veteran Army of the United States in 1885; for many years local surgeon for the Illinois Central and Chicago, Milwaukee & St. Paul railroads, and president of the Sioux City College of Medicine for ten years, died at his home in Sioux City, April 10, from kidney disease, after an illness of two years, aged 69.

Charles Ferdinand Taggart, M.D. Medical Department of Washington University, St. Louis, 1884, of Los Angeles, a member of the American Medical Association; Medical Society of the State of California; Southern California Medical Society; Los Angeles County Medical Society; National Association of Railway Surgeons and Pacific Coast Association of Railway Surgeons; chief surgeon of the San Pedro, Los Angeles and Salt Lake Railroad, died in San Francisco, April 8, from a gunshot wound caused by his own revolver which fell from his pocket and was discharged.

Eugene Beauharnais Harrison, M.D. Jefferson Medical College, Philadelphia, 1856; a member of the American Medical Association, Ohio State Medical Society, Henry County Medical Society, and the Society of the Army of the Tennessee; major and surgeon of the Sixty-eighth Ohio Volunteer Infantry throughout the Civil War, died at his home in Napoleon, Ohio, April 15, nineteen days after a suprapubic prostatectomy for prostatic hypertrophy and vesical calculus, aged 74.

Nicholas D. Richardson, M.D. Vanderbilt University, Medical Department, Nashville, 1899; acting assistant surgeon, United States Public Health and Marine-Hospital Service; a member of the Association of Military Surgeons of the United States; quarantine inspector at San Francisco; formerly of Athens, Ala., died from tuberculosis at his home in San Francisco, April 9, after a long illness, aged 34.

G. Ray Hoff, M.D. Bellevue Hospital Medical College, New York City, 1893; some-time professor of materia medica in Denver University and assistant professor in Gross Medical College; a member of the state and county societies of New York, of the Denver and Denver County Medical Society, and the Colorado State Medical Society, died at his home in Utica, N. Y., April 14, after a prolonged illness, aged 38.

Elias De Spelder, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1882; a member of the American Medical Association, of the Michigan State Medical Society, and second vice-president of the Ottawa County Medical Society, died at his home in Zeeland, Mich., April 11, from meningitis, after an illness of one week, aged 49. The society attended the funeral in a body.

Edwin A. Kelly, M.D. Medical College of Ohio, Cincinnati, 1878; assistant superintendent of the Agnew State Hospital for the Insane, Agnews, Cal.; in 1882 assistant superintendent of the Columbus (Ohio) State Hospital, and later assistant superintendent of the Athens (Ohio) State Hospital, was crushed to death in the collapse of the building due to the earthquake, April 18, aged 55.

Matthew T. Gaffney, M.D. College of Physicians and Surgeons, Baltimore, 1897; for several years district physician of Newark, N. J.; a member of the visiting staff of St. Michael's Hospital, and surgeon for the North Jersey Street Railway Company, died at his home in Newark, April 16, from kidney disease, after an illness of two weeks, aged 36.

Robert C. Davis, M.D. New York University, New York City, 1880; for many years inspector in the New York health department; a member of the New York County Medical Society and of the New York Academy of Medicine, died April 13, in Roosevelt Hospital, New York City, from pneumonia, after an illness of five days, aged 47.

Richard D. Webb, M.D. Starling Medical College, Columbus, Ohio, 1865; a practitioner of Nortonville, Kan., for more than a quarter of a century; assistant surgeon of the Seventy-eighth Ohio Volunteer Infantry during the Civil War, died in a hospital at Topeka, April 6, two days after an operation for cholelithiasis, aged 67.

Louis Mackall, M.D. University of Maryland, School of Medicine, Baltimore, 1851; a member of the American Medical Association; for many years professor of physiology and clinical medicine at the University of Georgetown, Medical Department, Washington, D. C., died at his home in Washington, April 19, aged 75.

Joseph K. Milbourne, M.D. State University of Iowa, College of Medicine, Iowa City, 1881, of Clinton, Iowa, past president of the Iowa State Medical Society and president of the Clinton County Medical Society, died at Agatha Hospital, Clinton, April 13, from peritonitis, five days after an operation for appendicitis, aged 54.

William J. Rhymes, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1899; formerly of St. Martinville, La.; superintendent of the Maricopa County Hospital, Phoenix, Ariz., died at his home in that city, February 1, from pneumonia, after an illness of ten days, aged 33.

Theophilus R. Carter, M.D. College of Physicians and Surgeons in the City of New York, 1892, a member of the Westchester County Medical Society, died at his home in Mount Vernon, N. Y., from progressive muscular atrophy, after an illness of about two years, January 22, aged 42.

Emma D. Cook, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1892; a member of the Wayne County and Michigan state medical societies; state examiner for the Ladies of the Maccabees, died at her home in Detroit, April 14, from anemia, aged 58.

Hugh Alexander McEachren, M.D. Detroit College of Medicine, 1892, a member of the American Medical Association and a prominent specialist in diseases of the nose, throat and

lungs, died April 8, at his home in Detroit, from tuberculosis, after an illness of several years, aged 36.

Richard Jones Price, M.D. Medical College of Virginia, Richmond, 1898; acting assistant surgeon, United States Army, and on duty in the Philippine Islands; formerly of Wilmington, N. C., died in Asheville, N. C., April 4, from tuberculosis, after a prolonged illness, aged 35.

John Bruce MacCallum, M.D. Johns Hopkins University, Medical Department, Baltimore, 1900, assistant professor of physiology in the University of California, died at his home in Berkeley, Cal., from nephritis, after an illness of more than three years, aged 30.

Joseph W. Harris, M.D. Miami Medical College, Cincinnati, 1874, a veteran of the Civil War, and for eighteen years a resident of Los Angeles, Cal., died at his home in that city, April 12, from overwork, after an illness of two years, aged 65.

John Forshee Halsted, M.D. Eclectic Medical College of Philadelphia, 1857; member of the College of Physicians and Surgeons of Ontario, 1869, formerly of Berlin and Grand Valley, Ont., died at Winnipeg, Man., March 3, aged 82.

Robert Corbin Wintermute, M.D. Eclectic Medical Institute, Cincinnati, 1881, and professor of obstetrics, gynecology and pediatrics in his alma mater, died from cerebral hemorrhage, at his home in Norwood, Cincinnati, April 15, aged 44.

John H. Tanner, M.D. University of Buffalo, Medical Department, 1863, formerly a practitioner of Spencer, N. Y., died at his home in Harford, N. Y., March 12, from the effects of a self-inflicted gunshot wound of the head, aged 70.

Alexander J. Bowser, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1890, died at his home in New Baltimore, Pa., April 11, from heart disease, after an illness of several months, aged 43.

James W. Gardner, M.D. Pennsylvania Medical College, Philadelphia, 1867; one of the oldest and best-known practitioners of East Liverpool, Ohio, died suddenly at his home in that city, April 13, aged 79.

Stephen E. Wentworth, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1868, one of the oldest practitioners of Auburn, Maine, died suddenly in that city from heart disease, April 10, aged 69.

James J. Cole, M.D. Miami Medical College, Cincinnati, 1870; a practitioner of Indianapolis for nearly thirty years, died at his home in that city April 10, from valvular heart disease, after a long illness, aged 62.

Leonard Keehn, M.D. Medical Department of Washington University, St. Louis, 1899, of St. Louis, Mo., died in Los Angeles, Cal., from tubercular meningitis, April 9, after a prolonged illness, aged 36.

Cary K. Parker, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1895, formerly of Pollock, La., died in Bonita, La., April 10, after a prolonged illness, from tuberculosis, aged 34.

John P. Waste, M.D. Charity Hospital Medical College, Cleveland, 1865, a charter member of the Southern Minnesota Medical Association, died at his home in Plainview, Minn., April 17, aged 69.

Henry L. Stone, M.D. University of Maryland School of Medicine, Baltimore, 1868, a veteran of the Civil War, died at his home in Montgomery, Ala., January 12, after a long illness, aged 59.

Edward F. Perkins, M.D. Medical Department of the University of Missouri, St. Louis, 1855, state senator in 1878, died at his home in Linneus, Mo., April 4, after a prolonged illness, aged 72.

Edward R. Wallizer, M.D. Baltimore Medical College, 1884, of Des Moines, Iowa, a veteran of the Civil War, died in the Clarinda State Hospital, April 4, after an illness of two years, aged 60.

Alexander Fitzpatrick, M.D., a Confederate veteran, and for several terms representative from Nelson County in the Virginia legislature, died at his home in Rockfish, April 11, aged 79.

Charles V. Holsclaw, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1886, formerly of Lovilia, Iowa, died suddenly at his home in Merriman, Neb., recently.

W. C. Tinsley, M.D. Georgia University, Medical Department, Augusta, 1857, of Flint, Ga., died suddenly at Americus, Ga., April 12, from cerebral hemorrhage, aged 72.

Joseph G. Weaver, M.D. Howard University, Medical Department, Washington, 1899, died at his home in Newark, N. J., after a protracted illness, March 28, aged 41.

Charles A. Delander, M.D. Iowa College of Physicians and Surgeons, Des Moines, 1902, died at his home in Des Moines, April 12, from rheumatic endocarditis, aged 36.

Paul Pritchard, M.D. Medical College of the State of South Carolina, Charleston, 1841, a Confederate veteran, died at his home in Pritchardville, S. C., April 4, aged 86.

H. I. Liesch, M.D. Western Reserve University, Medical Department, Cleveland, Ohio, 1881, died suddenly from heart disease, in his room in Nodaway, Mo., April 10.

Robert Pearson, M.D. University of the City of New York, Medical Department, 1860, a veteran of the Civil War, died at his home in Morganton, N. C., January 26.

Anna C. Rees, M.D. Woman's Medical College of the New York Infirmary, New York City, 1898, died at her home in Union Hill, N. J., Oct. 25, 1905, aged 29.

J. A. Mullen, M.D. Jefferson Medical College, Philadelphia, 1893, died suddenly in Huntington, W. Va., from heart disease, January 23, aged about 45.

Frank S. Turner, M.D. University Medical College of Kansas City, Mo., 1894, died at his home in Monroe City, Mo., from peritonitis, March 12, aged 37.

Frederick A. Smart, M.D. Albany (N. Y.) Medical College, 1899, died at his home in Cobleskill, N. Y., April 14, from cerebral hemorrhage, aged 35.

George R. Weston, M.D. National Medical University of Illinois, Chicago, 1891, died at his home in San Antonio, Texas, January 30, aged 51.

John Skivington, M.D. Medical College of Ohio, Medical Department, Cincinnati, 1857, died at his home in Morganza, Pa., January 18, aged 76.

John S. Neville, M.D. (Examination, Ohio), died at his home in Roundhead, Ohio, March 2, after a short illness, from senile debility, aged 75.

D. P. Stradley, M.D. (Examination, Colorado), formerly of Longmont, Colo., died in Albuquerque, N. M., from tuberculosis, January 4.

J. E. Coyle, M.D. University of Tennessee, Medical Department, Nashville, 1892, is reported to have died recently in Wewaka, I. T.

William Osborne, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1882, died at his home in Chicago, April 19.

Michael A. Glennan, M.D. Rush Medical College, Chicago, 1878, died at his home in Ludlow, Ill., from kidney disease, April 11.

Ira C. Sawyer, M.D. Dartmouth Medical School, Hanover, N. H., 1864, died at his home in Springvale, Maine, April 13, aged 66.

Samuel Sprecher, M.D. Illinois Medical College, Chicago, 1901, died recently and was buried in Springfield, Ohio, January 14.

George Smith Gould, M.D. Rush Medical College, Chicago, 1896, died suddenly in Cleveland, February 10.

Daniel L. Dakin, M.D. Rush Medical College, Chicago, 1870, died suddenly at his home in Detroit, April 2.

W. T. Campbell, M.D. Marion-Sims-Beaumont College of Medicine, died recently in St. Louis, aged 80.

Book Notice

PRACTICAL SANITARY SCIENCE. A Handbook for the Public Health Laboratory. By D. Sommerville, B.A., M.D. Cloth. Pp. 310. Price, $3.00. New York: William Wood & Co.

This book is described in its subtitle as "a handbook for the public health laboratory." As such it does not seem adapted to fill any long-felt want of American workers. Considerable space is devoted to elementary physical and chemical data. In the chapter on air analysis, for example, we are told that there are three thermometric scales in use and what the respective freezing points and boiling points are. It has been thought necessary to take up space with pictures of a hot air oven (p. 12) and a chemical balance (p. 15). In general the methods seem somewhat perfunctorily described; this is particularly true on the bacteriologic side. Loose statements are noticed here and there. On p. 150, in the section on pathogenic organisms in milk, it is asserted that "unless the disease (tuberculosis) affects the udder, no bacilli are found in the milk."

Queries and Minor Notes

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

QUININ TREATMENT OF PNEUMONIA.

Baltimore, April 17, 1906.

To the Editor:—Since reading Dr. Galbraith's article on this subject, I have had occasion to use this treatment in half a dozen cases, and it gives charming results when Dr. Galbraith's rules regarding administration are carried out. The average duration of the disease is about three days. Under the old form of treatment I had treated just previously about the same number of cases with the result that it was from three to six weeks before the patients could get out of bed. Now I would rather have a case of pneumonia with my quinin and iron than a case of malarial fever, for I know that I have a specific. Norman H. D. Cox, M.D.

CONTRACT PRACTICE.

Alexandria, La., April 9, 1906.

To the Editor:—At a recent meeting, the Rapides Parish (La.) Medical Society adopted the following resolutions:

We, the members of the Rapides Parish Medical Society in special session convened, after due deliberation, have reached the conclusion that a fee of less than $5 is not commensurate with the services rendered in making an examination for life insurance companies. Realizing the important relation existing between the medical examiner and the life insurance companies, we believe that a fee of not less than $5 for any medical examination should be charged. Therefore be it

Resolved, That we herewith pledge ourselves not to make an examination for a fee less than $5 in future. Be it further

Resolved, That a fee of not less than $3 be charged for fraternal and benevolent orders. It is further

Resolved, That it shall be deemed a breach of professional dignity on the part of any physician to make an examination for fees less than above mentioned.

We memorialize the Louisiana State Medical Society to take cognizance of this matter, and urge all constituent societies to indorse this action.

C. M. G. Stafford, M.D., Secretary. J. A. White, M.D., President.

Orange, N. J., April 11, 1906.

To the Editor:—At the last annual meeting of the Essex County (N. J.) Medical Society, held April 3, 1906, a resolution was passed condemning lodge or contract practice, and making any member engaging in such practice subject to expulsion from the society.

At the last monthly meeting of the Orange Practitioners' Society of Orange, N. J., a committee was appointed to secure the signatures of all the physicians in the Oranges to an agreement not to engage in lodge or contract practice. At present some 3,000 people in the Oranges are receiving medical treatment for less than nine (9) cents a month.. Edgar C. Seibert.

THE AUTOMOBILE FOR THE PHYSICIAN'S USE.

Dr. James E. Taylor, Ovid, Mich., writes: "I enjoyed very much the various opinions and experiences of medical men in the use of the automobile. I am convinced that they are not yet practical for use in this locality. I am considering the purchase of an automobile to use in my practice, and would request, if practical, that The Journal gather and publish as soon as can be done the experiences of medical men in the use of this machine in practice. I believe many physicians are interested in this."

Drs. A. M. and C. R. Clark, Youngstown, Ohio, say: "We agree that tires are the greatest source of trouble, but we have been afraid to try solid tires yet. This experience meeting of yours is one, and should open the eyes of some manufacturers."

Dr. R. H. Sherwood, Bowen, Ill., writes: "I have enjoyed the articles and think that they will be of great benefit to some of us who are thinking of investing."

Dr. A. J. Horson, Hampton, Iowa, says: "I have read with much interest the articles on automobiles. I have been using an automobile in my practice for the last three years, and must say I have not met with as good luck as most of these doctors report. I have had two machines, and plenty of trouble with each. I may have been unfortunate in selecting my car. Thank you for your favor in helping us out on this hard problem."

Dr. D. M. Reynolds, Clayton, Ind., writes: "I read with much interest the several letters from physicians in regard to use of the automobile. I think such timely discussion of business topics will make The Journal more interesting and valuable."

Dr. Oliver C. Smith, Hartford, Conn., reports: "Five years ago I purchased an electric vehicle, weighing 2,000 pounds, with a speed on smooth, level roads, of twelve miles per hour. During the past five years, the negative and positive plates have each been replaced at a cost of $280. During the third year, the tire expense became excessive, and I replaced the inflated tires with hard, rubber tires. With this exception there has been no renewal or change of parts. The cost for electricity, with daily use of vehicle, averages from $10 to $12 per month. The most serious bill of expense, aside from tires, is the minor repairs to pinions, gears, bushings, fingers and controller. My carriage has been continually kept at a garage, which furnishes day and night service. It is my opinion that a modern electric vehicle is the most satisfactory equipment for a physician practicing in a city. It can not supplant the horse and carriage through heavy roads, it can not compete with the gasoline car in country use or in long runs, but is ideal for short trips over smooth, macadamized or asphalt pavements."

TOY PISTOLS AND OTHER SIMILAR DEVICES.

Claremont, N. H., April 14, 1906.

To the Editor:—I thank you for the information given regarding toy pistols, etc. [The Journal A. M. A., April 14, p. 1132]. Inasmuch as this question is rather indefinite and the authorities will want to know more definitely what devices are safe and what are dangerous, could you not give me a little more information as to some of the devices usually considered dangerous, and some of the explosives which should be avoided? It is generally assumed that the canes which explode dynamite or powder, and the earthenware or iron balls covered with an explosive coating, which is exploded by knocking the balls together when held in the hands, and various similar devices, are all dangerous and should be avoided. The different forms of powder are, I believe, some safe and some dangerous, and I would be pleased to have any suggestions in this line which you can make. Thomas W. Fry.

Answer.—It may be stated in a general way that any explosive with power enough to lacerate the skin is dangerous as to tetanus and infection, and that any explosive so prepared that it leaves ignited paper or other materials about is dangerous to property. The idea that tetanus results from any particular sort of powder or other explosive is incorrect; it is the wound, and not the nature of its cause that is important. The danger of the Fourth (as regards loss of life) will disappear if the three chief offenders are removed: these are the blank cartridge, the cannon cracker, and the toy cannon. The exploding canes mentioned for the most part use blank cartridges, and are dangerous. We doubt if the cracking balls mentioned cause much trouble.

State Boards of Registration

COMING EXAMINATIONS.

Tennessee State Board of Medical Examiners, Memphis, Nashville and Knoxville, May 2. Secretary, T. J. Happel, Trenton.

Illinois State Board of Health, Metropolitan Block, East St. Louis, May 2-4. Secretary, J. A. Egan, Springfield.

Louisiana State Board of Medical Examiners, New Orleans, May 3-4. Secretary, F. A. Larue, New Orleans.

Boston Board of Registration in Medicine, State House, Boston, May 8-9. Secretary, E. B. Harvey, Boston.

Oregon State Board of Medical Examiners, Portland, May 10-12. Secretary, Byron E. Miller, Portland.

Kentucky State Board of Health, Galt House, Louisville, begins May 15. Secretary, J. N. McCormack, Bowling Green.

Indiana Board of Medical Registration and Examination, Indianapolis, May 22-24. Secretary, W. T. Gott, Indianapolis.

New York State Boards of Medical Examiners, Albany, May 22-25. Secretary, Charles F. Wheelock, Albany.

Illinois State Board of Health, Coliseum Annex, Chicago, May 23-25. Secretary, J. A. Egan, Springfield.

Nebraska State Board of Health, State House, Lincoln, May 29-30. Secretary, George H. Brash, Beatrice.

Approve Reciprocity.—The County Medical Society of Barbour, Randolph and Tucker counties, W. Va., at its last meeting adopted the following resolution:

Resolved: That we heartily approve of the work being done by the American Confederation of Reciprocating, Examining and Licensing Medical Boards. Especially do we approve of that part of the work known as "Qualification No. 2," the object of which is to give reciprocity to the older practitioners.

Indian Territory April Report.—Dr. J. B. Smith, secretary of the Central District Medical Examining Board, reports the written examination held at South McAlester, April 2-3, 1906. The number of subjects examined in was 12; total number of questions asked, 130; percentage required to pass, 75. The total number of candidates examined was 12, of whom 10 were undergraduates; 6 passed and 6 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED.		
College of P. and S., Indiana	(1906)	78.5
Ft. Worth University	(1906)	83
Undergraduates	75, 76.2, 77, 83	
FAILED.		
Undergraduates	61.5, 62, 65, 68, 70, 73	

Iowa March Report. Dr. J. F. Kennedy, secretary of the Iowa State Board of Medical Examiners, reports the written examination held at Des Moines, March 21-22, 1906. The number of subjects examined in was 8; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 11, of whom 10 passed and 1 failed. The following colleges were represented:

PASSED. College.	Year Grad.	Per Cent.
American Med. Miss. Coll.	(1899) 81	86
College of P. and S., Baltimore	(1903)	87
College of P. and S., Chicago	(1899) 75	75
Hahnemann Med. Coll., Chicago	(1887)	78
Hering Med. Coll., Chicago	(1904)	75
Northwestern University	(1900)	85
Queen's University, Ontario	(1905)	92
Rush Med. Coll.	(1903)	89
FAILED.		
Meharry Med. Coll., Nashville	(1902)	73

Maine March Report.—Dr. William J. Maybury, secretary of the Maine Board of Registration of Medicine, reports the oral and written examination held at Portland, March 13, 1906. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 15, of whom 13 passed and 2 failed. The following colleges were represented:

PASSED. College.	Year Grad.	Per Cent.
Harvard University	(1901) 80.4, 93.5	
College of P. and S., Boston	(1904)	84.6
Woman's Med. Coll., Pennsylvania	(1905)	85.9
Tufts Coll. Med. School	(1905) 85, 85.3,	86.7
Bellevue Hosp. Med. Coll.	(1905)	86.3
Baltimore Med. Coll.	(1905)	75.2
Medico-Chirurgical Coll., Pennsylvania	(1903)	84.5
Baltimore University	(1901)	81.3
College of P. and S., New York	(1890)	84
University of Michigan	(1889)	84.3
FAILED.		
College of P. and S., Boston	(1905)	57.2
Harvard University	(1904)	74.4

Montana April Report.—Dr. W. C. Riddell, secretary of the Board of Medical Examiners of Montana, reports the written examination held at Helena, April 3-4, 1906. The number of subjects examined in was 10; total number of questions asked, 50; percentage required to pass, 75. The total number of candidates examined was 27, of whom 14 passed and 13 failed. The following colleges were represented:

PASSED. College.	Year Grad.	Per Cent.
University of Michigan	(1904)	84.8
College of P. and S., Baltimore	(1904)	75.6
University of Pennsylvania	(1894)	75.4
St. Louis University	(1905)	75.9
College of P. and S., Chicago	(1904)	90.2
Rush Med. Coll.	(1900) 79.8;	(1904) 76.5
Johns Hopkins Medical School	(1901)	75.1
College of P. and S., New York	(1893)	80.3
Maryland Med. Coll.	(1904)	78
George Washington University	(1905)	79.8
Medical College of Ohio	(1904)	83
American Med. Miss. Coll.	(1905)	78.4
Illinois Med. Coll.	(1898)	75.9
FAILED.		
Alexander University, Helsingstors, Finland	(1896)*	
Wooster University	(1891)	54.9
Beaumont Hosp. Med. Coll	(1901)	65.4
College of P. and S., Chicago	(1902)	70.1
Missouri Med. Coll.,	(1884)	66.3
Medical College of Ohio	(1899)	56.9
Barnes Med. Coll	(1898)	62.1
Creighton Med. Coll.	(1900)	55.1
Laval University, Quebec	(1903)	40.1
Jefferson Med. Coll.	(1897)	69.8
University of the City of New York	(1893)	55.3
University of Vermont	(1895)	55.9
Marion Sims College of Medicine	(1895)	54.2

*Did not complete examination on account of sickness.

North Dakota April Report. Dr. H. M. Wheeler, secretary of the North Dakota State Board of Medical Examiners, reports the written examination held at Grand Forks, April 3-5, 1906. The number of subjects examined in was 14; percentage required to pass, 75. The total number of candidates examined was 17, of whom 15 passed and 2 failed. The following colleges were represented:

PASSED. College.	Year Grad.	Per Cent
Sioux City Coll. of Med	(1904)	76
University of Illinois	(1904)	81
Queen's University, Ontario	(1896)	88

FAILED.		
Hamline University	(1901)	
Hering Med. Coll., Chicago	(1902)	

*Year of graduation not given.
**Licensed by reciprocity with Illinois.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending April 21, 1906:

Perley, Harry O., deputy surgeon general, granted leave of absence for two months on relief from duty at West Point, N. Y.

Lynch, Charles, surgeon, detailed member of the General Staff Corps.

Ruffner, E. L., asst.-surgeon, granted thirty days' leave about June 1, with permission to apply for an extension of two months.

Hanner, John W., asst.-surgeon, leave of absence extended ten days.

Tukey, William H., contract surgeon, returned to Boise Barracks, Idaho, from leave of absence.

Enders, William J., contract surgeon, returned to Fort Morgan, Ala., from leave of absence.

Brown, Wilmont E., contract surgeon, left Boise Barracks, Idaho, for duty at Fort Walla Walla, Wash.

Koyle, Fred T., contract surgeon, left Fort Bliss, Texas, on leave of absence for ten days.

Kuhn, Charles F., contract surgeon, returned from Fort William H. Seward, Alaska, to Fort Lawton, Wash., his proper station.

Long, Charles J., dental surgeon, arrived at Fort Missoula, Mont., for duty, from Fort William Henry Harrison, Mont.

Long, Stephen M., contract surgeon, ordered to Philippine service, and sailed on the *Sheridan* from San Francisco, April 16.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending April 21, 1906:

Langhorne, C. D., surgeon, ordered to Washington, D. C., for duty in attendance on course of instruction at the Naval Medical School.

Woods, E. L., asst.-surgeon, ordered to the Naval Academy.

Nelson, H. T., Jr., asst.-surgeon, detached from the Naval Academy and resignation accepted to take effect April 14, 1906.

Pease, T. N., asst.-surgeon, detached from the *Columbia* and ordered home to wait orders.

Brooks, F. H., asst.-surgeon, ordered to the *Columbia*.

Schaller, W. F., asst.-surgeon, ordered to the Naval Hospital, Mare Island, California.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending April 18, 1906:

Gutteras, G. M., surgeon, granted leave of absence for one day, April 15, 1906.

Young, G. B., P. A. surgeon, directed to proceed to Saginaw and Bay City, Mich., for special temporary duty, on completion of which to rejoin station.

Young, G. B., P. A. surgeon, designated to represent the service at the Council on Medical Education of the American Medical Association, Chicago, Ill., May 12, 1906.

Kinz, W. W., P. A. surgeon, five days leave of absence revoked, and directed to rejoin his station in Washington, D. C.

Amesse, J. W., P. A. surgeon, relieved from special temporary duty at New Orleans, La., and directed to rejoin his station at Ellis Island, N. Y.

Rucker, W. C., asst.-surgeon, relieved from special temporary duty at New Orleans, and directed to proceed to Vineyard Haven, Mass., and assume temporary command of the Service.

Ward, W. K., asst.-surgeon, granted leave of absence for five days, from April 4, on account of sickness.

Ebersole, R. E., asst.-surgeon, granted leave of absence for four days, from April 11, under the provisions of Paragraph 191 of the Regulations.

Smith, F. C., asst.-surgeon, relieved from special temporary duty at New Orleans, La., and directed to rejoin his station at Detroit, Mich.

Smith, F. C., asst. surgeon, granted fourteen days' leave of absence on route from New Orleans to Detroit.

Jackson, J. M., acting asst.-surgeon, granted leave of absence for five days, from April 17.

Kentley, H. W., acting asst surgeon, granted leave of absence for three days, from April 16, 1906, under the provisions of Paragraph 191 of the Regulations.

Gibson, F. L., pharmacist, relieved from duty at San Francisco, Cal., and directed to proceed to Honolulu, T. H., reporting to Dr. W. R. Brinckerhoff, director of the Leprosy Investigation Station, for duty at Molokai, T. H.

Bierman, C. H., pharmacist relieved from duty at Tampa Bay Quarantine Station, and directed to proceed to Portland, Me., reporting to the medical officer in command for duty and assignment to quarters.

Keen, W. H., pharmacist, directed to proceed to Tampa Bay Quarantine Station for duty and assignment to quarters.

APPOINTMENT.

Walter H. Keen was reinstated as Pharmacist of the third class on April 11, 1906.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague ve been reported to the Surgeon-General, Public Health and rine-Hospital Service, during the week ended April 20, 1906:

SMALLPOX—UNITED STATES.

California: San Francisco: March 31-April 7, 41 cases, 1 death.
District of Columbia: Washington, April 7-14, 1 case.
Louisiana: Shreveport, April 7-14, 1 case.
Missouri: St. Louis, April 7-14, 6 cases; West Plains, March 8, ase.
Montana: Beaverhead County, March 1-31, 2 cases; Park County, ase.
New Jersey: Rutherford, April 7, 1 case.
New York: New York, April 7-14, 5 cases.
North Carolina: Greensboro, April 7-14, 2 cases.
Pennsylvania: Pittsburg, March 31-April 7, 2 cases.
Texas: Houston, April 7-14, 1 case.
Vermont: Richford, April 12, 2 cases.
Wisconsin: Appleton, April 7-14, 5 cases.

SMALLPOX—FOREIGN.

Brazil: Rio de Janeiro, Feb. 18-March 18, 2 cases, 3 deaths.
China: Canton, March 3, present; Hongkong, Feb. 24-March 3, cases, 5 deaths.
France: Paris, March 24-31, 6 cases, 1 death.
Germany: Bremen, March 25-April 1, 2 cases.
Great Britain: Bristol, March 25-31, 2 cases; Glasgow, March April 6, 1 case.
Greece: Athens, March 15-22, 2 deaths.
India: Bombay, March 13-20, 18 deaths; Calcutta, March 3-10, 2 deaths; Karachi, March 11-18, 33 cases, 17 deaths; Madras, rch 10-16, 39 deaths; Rangoon, March 3-10, 101 deaths.
Italy: General, March 15-22, 35 cases.
Mexico: Tuxpam, March 27-April 3, 1 death.
Russia: Odessa, March 25-31, 10 cases, 2 deaths; St. Petersg, March 10-24, 12 cases, 2 deaths.
Spain: Barcelona, March 21-31, 6 deaths.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Feb. 18-March 18, 10 cases, 6 deaths.
Honduras: Choloma, April 6, 6 cases.
Nicaragua: Managua: March 10-17, 1 death.

PLAGUE—UNITED STATES

Delaware: Reedy Island Quarantine, April 6-11, 2 cases 1 death n Steamship *Burrisfield*, from Bombay).

PLAGUE—INSULAR.

Hawaii: Honolulu, April 14-15, 2 deaths.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Feb. 18-March 18, 10 cases, 6 deaths.
China: Hong Kong, Feb. 24-March 3, 8 cases, 7 deaths.
Egypt: General, March 24-29, 7 cases, 5 deaths.
India: General: March 3-10, 2,623 deaths; Bombay, March 13-20, 2 cases, 572 deaths; Calcutta, March 3-10, 83 deaths; Karachi, arch 11-19, 52 cases, 44 deaths; Rangoon, March 3-10, 48 deaths.

CHOLERA.

India: Bombay, March 13-20, 2 deaths; Calcutta, March 3-10, 44 aths.

Indiana State Medical Association, Winona Lake, May 23-25.
Michigan State Medical Society, Jackson, May 23-25.

ST. LOUIS MEDICAL SOCIETY.

Regular Meeting, held April 21, 1906.

This meeting was largely attended, the subject of the evening for discussion being "Criminal Abortion, Its Medical, Religious, Moral, and Legal Aspects." Members of the clergy, bar nd bench, and some laymen were in attendance, and took part n the discussion.

The St. Louis Campaign Against Abortion.

Before the regular essayists read their papers, the report of the committee on public health and legislation, Dr. C. M. Nicholson, chairman, rendered its report, showing what work has been done in securing enforcement of the law, and what is further proposed in this direction.

In a preliminary way the St. Louis Medical Society had employed an attorney to prosecute violators of the city ordinance which forbids the placing of indecent or obscene advertisements in the public press. A case against Dr. Nathaniel King, one of these advertisers, was made a test case. Dr. King advertised to treat the private diseases of men. He admitted the publication of his advertisements, but denied the constitutionality of the law forbidding same. He was adjudged guilty in the police court and fined. The case was appealed to the court of criminal correction, where Judge Hiram Moore sustained the previous conviction. The case was then appealed to the supreme court of Missouri, where it is now pending.

The attorney was then authorized to proceed against the newspapers publishing the objectionable advertisements. Informations were prepared against all the papers of St. Louis. As here again the constitutionality of the ordinance was brought into question, one paper was selected for prosecution as a test case. Unfortunately, the information was prepared against the least conspicuous of the St. Louis papers, the St. Louis *World*—this through no fault of the attorneys, however, of the society. This paper was fined, and like the case of Dr. King, the case was appealed to the supreme court.

These prosecutions have already borne fruit. The advertisements of these charlatans have been "censored" and made less indecent. The space usually devoted to these advertisements in the public press has been gradually reduced until now it is 50 per cent. less in amount than was formerly the case.

The committee on public health was then authorized to raise funds to carry on this work. About $500 has already been subscribed by members of the society.

March 24, 1906, a resolution was adopted directing the attorney to proceed against all illegal practitioners in the city. April 12, at the meeting in St. Louis of the State Board of Health of Missouri the licenses of two physicians and three midwives were revoked. One of the midwives, Anna Myers, had already been convicted in the state court for criminal abortion. Another, the Newland woman, had been convicted in the federal court for violation of the postal laws. Another midwife, Mary Murphy, had been served with charges by the state board to appear before it and show cause why her license should not be revoked. On request of her attorney her case was continued for trial until the next meeting of the board in Kansas City.

It will be the policy of this committee to secure revocation of license of illegal practitioners rather than convictions in the criminal courts, because the way is easier and evidence can be presented in a broader way than is allowed in the courts of record. In addition, nine midwives have been arrested on informations charging them with advertising to practice medicine. One has already plead guilty and has been fined.

The attorney is now preparing informations against all the incorporated medical companies doing business in the city, where the incorporators live out of town and hire other men to do their work for them. These will be in the nature of "ouster" proceedings. There are about 175 of such companies doing business in the state of Missouri. These informations will be filed next week.

Negotiations have already been started with the postal authorities to punish those using the mails in their indecent and illegal undertaking. The postmaster general has assured the committee of his hearty co-operation. The attorney of the society will also prepare a brief to be submitted to the attorney general relative to the practice of midwifery in general. The attorney is now considering the drafting of a law designed to be far-reaching and to cover all the charlatanry which is not punishable by the laws already on the books.

Medical Aspects of Criminal Abortion.

After the reading of this report, the subject proper of the scientific program was then approached.

Dr. John M. Grant read the first paper, with the above title. In his experience, over 35 per cent. of pregnant women tried to abort. Their excuses are many. One is that there is no life in the fetus, to their minds, until movement is felt; therefore it is no crime. Poverty, drunkenness of the father and ill-health are other excuses. He called attention to the drugs and instruments promiscuously advertised to make women "regular," which are simply thinly-disguised advertisements of abortifacients.

He had treated over 250 cases of criminal abortion, only ten of which were in young, unmarried women. Statistics prove that the people who are in the best shape to have large families try every means to avoid it.

There are two classes of abortionists: (1), the midwives and illegal practitioners; (2), certain members of the medical profession who are generally considered men of repute. The difficulty of detection of the crime lies in the steady refusal of these women to tell who has committed the abortion.

As remedies to stop the tide of this race suicide, Dr. Grant proposed a united effort of the medical profession, the clergy and the legislators. Women should be educated to realize that life exists in the fetus from the time of conception. They should be taught the danger to life of the performance of this operation. The newspapers should not be allowed to print the advertisements alluded to above. There should be conferences of the profession and the clergy.

Religious and Moral Aspects of Criminal Abortion.

Rev. James Sullivan, S. J., of St. Louis University, then read a paper urging that, logically, the regular physician who, with consultation, decides to perform a "therapeutic" abortion is as guilty in the eyes of the law and of God as the man or woman who performs a so-called "criminal" abortion for mere filthy lucre. He denied that the physician has the right to decide that the mother's life is more important to save than the unborn child's. He defended the doctrine of the Catholic church which does not legitimize any form of abortion. To the question that in a case where birth is impossible, must we stand by and lose the life of both mother and child, his answer was that we may not do evil that good may follow. He said that science can not decree the death of a human being in the womb nor out of it.

Criminal Abortion from a Legal Standpoint.

Mr. Fickheisen, assistant circuit attorney of the city of St. Louis, discussed this subject. Two good points in his address were: (1) The law should be changed in regard to the matter of "privileged" communications so that a physician may be allowed to testify what he has learned in the treatment of a case of criminal abortion so that the guilty man or woman who has performed the abortion may be reached; (2) a statute should be enacted in Missouri making the performance of abortion a felony and not simply a misdemeanor, as is the case now. Criminal abortion is at present only a felony when death of the victim follows, making it manslaughter. A statute making all abortions felonies should be put through by the legislature.

DISCUSSION.

In the general discussion that followed several clergymen said that they believed the remedy lay entirely with the medical profession, i. e., that the doctors should brand all whom they know practice abortion and ostracise them in every way.

JUDGE O'NEIL RYAN of the circuit court said that the doctrine of the Catholic church was as indisputable from its legality as it was from a theological standpoint.

NEW YORK ACADEMY OF MEDICINE.

Regular Meeting of the Section on Surgery, held April 6, 1906.

DR. SAMUEL LLOYD in the Chair.

Congenital Dislocation of Patella.

DR. CHARLES GOODMAN showed a boy, 13 years old, whose right patella was freely movable, and when the limb was extended the finger could be inserted beneath the inner margin of the bone. When the limb was flexed the patella overrode the external condyle, and by voluntary contraction of the quadriceps the patella could be dislocated outward completely.

Omental Hernia, with Suppuration; Operation.

DR. FORBES R. MCCREERY presented a patient, 25 years old, who was kicked in the lower abdomen by a horse. Four or five months after a lump appeared in the right inguinal region which worked down into the scrotum. At operation this mass was found to be surrounded by old cicatricial tissue, and while attempting to separate it openings were made into a cavity filled with grumous fluid. The entire mass of omentum appeared to be riddled with small abscesses. The pus had no odor and contained no tubercle bacilli. The pathologist reported that the condition was due to interference with nutrition. There was some thickening of the vessels and small foci of calcification in dead tissue.

Perineal Lithotomy for Large Vesical Calculus.

DR. C. C. SICHEL reported the case of a negro child, $2\frac{1}{2}$ years old, who had an infected foreskin following circumcision. Later, much pus was found in the urine and the child suffered greatly at urination. Pus continued to increase in amount and bladder drainage was instituted. No stone was found. The child improved and left the hospital, but returned later for the cure of an umbilical hernia. At operation a greatly distended bladder was found with a large calculus in its neck freely removable. After operating on the hernia, he closed the abdominal wound and then enlarged the perineal opening and delivered a calculus, of oval shape, measuring $3\frac{1}{2}$ inches by $2\frac{3}{4}$ inches. Calculus of this size was better removed by the suprapubic incision; but in this case the perineum had previously been opened and he also avoided any danger of infecting the hernial wound; therefore, the perineal lithotomy was performed.

Heteroplastic Ovarian Grafting; Pregnancy; Delivery of Living Child.

DR. ROBERT T. MORRIS said that the patient was 21 years of age, began menstruating at 15, and stopped at 19. Previous to the cessation of menstruation the function had been of average character. She was married at the age of 18 and had become pregnant soon after, miscarrying at the third month. During the two years previous to her admission to the hospital she had suffered the common symptoms of menopause. These symptoms had steadily increased and were most marked at the time when the monthly flow should have appeared. A diagnosis of cirrhotic oöphoritis was made, and the patient was asked to remain in the hospital until opportunity was offered to obtain ovarian grafts to replace her own ovaries which were to be removed.

Shortly afterward there was occasion to operate on a patient, who was 33 years old, the mother of three children, for uterine prolapse, the ovaries being normal, except for the congestion common to uterine prolapse. Dr. Morris removed some ovarian tissue in the form of a wedge-shaped ribbon. The grafts were placed in physiologic saline solution at a temperature of 100 F. The ovaries were removed from the first patient with Tuffier's angiotribe, because the ligation methods are apt to be incomplete in securing absolute removal of all ovarian tissue. When the broad blades of the angiotribe close on the pedicle of the ovary, it is crowded away from its seat and rises above the blades, thereby avoiding the possibility of leaving any ovarian tissue behind. He did not allow even a particle of scraping from a detached ovary to fall back into the peritoneal cavity, because a single detached ovum might live long enough to invalidate the experiment. A slit was made through the peritoneum of the broad ligament on either side, parallel with the oviduct. Into each slit was placed a segment of ovary about one-half inch long and one-fourth-inch wide. A single catgut suture was placed so as to hold each graft in place. The grafts were so placed that the cut surface of the ovary lay in contact with the cut surface of the broad ligament, in order that the nutrition of the graft might be maintained through lymph circulation, pending the formation of new capillaries. The uncut surface of the ovary was allowed to project into the free peritoneal cavity, to facilitate free escape of ova. The uterus and oviducts were apparently normal.

About a month after leaving the hospital, the patient was reported as feeling well, except for hot and cold flashes. On

June 18, 1902, four months after the grafting she had menstruated, the menstruation lasting for five days. She did not menstruate again until November 16 of the same year, when she flowed for one day. The following month she flowed for four days. After that menstruation became regular. In March, 1906, the patient was delivered of a daughter weighing 7½ pounds.

Dr. Morris said that in his experiments on animals he has noted a varying degree of tolerance of one animal for the tissue from another. One animal will absorb ovaries of another animal very rapidly, while another may carry the ovaries of a third for several months. He has planned experiments along the line of preparing animals for tolerance of tissues of another animal. He carried on one line experiments suggested by the known principles of hemolysis. A series of rabbits were made immune to each other's serum, and their ovaries were then exchanged. These ovaries absorbed more readily than in animals not immune to each other's serum. Morris has done homoplastic and heteroplastic ovarian grafting in women in 14 cases, and in one case of fibro-nodular oviduct he made a homoplastic graft of the fimbricated extremity of an oviduct. The fimbricated end was fastened to the cornu of the uterus after excision of the nodular area, which included nearly all of the tube. So far as he knew there has been but one case of conception among his grafted patients, and the patient miscarried at the end of the third month. His efforts turned to homoplastic grafting for the purpose of avoiding the precipitate menopause, retaining the influence of the internal secretion of the ovary, and the normal sexual attitude of the patient, in selected cases where for any reason both ovaries have to be removed. There seems to be a fair probability also that pregnancy may sometimes occur.

DISCUSSION.

Dr. C. G. Cumston, Boston, said that Limon in a recent article claims that microscopically two stages followed ovarian grafting. During the first stage the ovary is nourished by the interstitial fluids of the surrounding tissues. These fluids do not reach the central portion of the gland, hence the cortex alone retains its vitality. The medullary zone degenerates and disappears. At the end of three months when their nutrition is again normal, the ovaries again give evidence of functional activity, and take on the appearance characteristic of their physiologic state. In view of these facts a properly performed heterotransplantation of an ovary may result in fecundation and pregnancy.

Dr. E. B. Cragin said that three tests should be applied to Dr. Morris' case: 1. More light might have been thrown on the condition of the ovaries at the time of the removal in regard to the presence of any developing Graafian follicles. 2. Menstruation might be absent for a number of years and yet the woman not attain to the menopause. Such ovaries might have recent corpora lutea. 3. It might be possible that a little of the ovarian tissue remained in the stump in spite of the use of the angiotribe. He thought, however, that Dr. Morris' case would stand the tests and that it is a distinct contribution to science.

Dr. Henry C. Coe believes the case to be one of suspension of ovarian function, rather than one of premature menopause. He spoke of amenorrhea occurring in young women who became unusually obese. With a reduction in their weight and certain treatment the menstrual function returns, although he could not recall an instance of pregnancy following this return of ovarian function. In conservative work on the ovaries he has often noted that where only a small portion of an ovary had been left, there is a decided tendency to atrophy or cystic degeneration, and that menstruation is often irregular or even ceases.

Dr. Herman J. Boldt said that the fact that there were no evidences of functionating ovarian tissue in the sections made by no means proved that there was no functionating ovarian tissue present. Knowing the case and seeing the operation performed, he did not think it likely that any ovarian tissue was left behind. It was most probable and positive that the subsequent menstruation was established and caused by the ungrafted ovarian tissue.

Dr. Robert H. M. Dawbarn said, in connection with Dr. Morris' proposed experiment of injecting the blood of one rabbit into another with the idea of establishing tolerance, that Surgeon Arnold of the United States Navy, published a communication from Metchnikoff's laboratory in which it was found that a small amount of blood from the male animal injected beneath the abdomen of the female animal rendered her sterile, so far as that particular male animal is concerned. This has been tried on dogs and other animals and was found to be true in every instance. Although it has not been tried on human beings, it might open up a new field both for beneficial and dangerous work.

Operative Treatment of Fractures; Description of a New Method.

Dr. Charles A. Elsberg presented patients to show the success which has attended the treatment of fractures by absorbable aluminum cylinders. These cylinders should fit tightly in the medullary cavity, filling it completely. They should be hollow and should have many more perforations to allow the circulation of fluids.

Dr. Robert H. M. Dawbarn has tried the metal magnesium in the form of staples, but found it less absorbable than aluminum.

Dr. A. A. Berg questioned the value of any mechanical contrivance in cases of non-union in bone. The cause should be sought for and treated before good results can be obtained by these methods.

Fractures of the Tarsus.

Dr. Leonard W. Ely presented six patients with fractures of the tarsus and reported eleven cases of fracture of the calcaneum and three of the astragalus. The treatment was by strapping, heat and cold, massage, and sometimes a Whitman brace.

Self-Retaining Trocar and Canula for the Aseptic Evacuation of Distended Viscera.

Dr. Howard Lilienthal described this instrument. The crucial test of its value was shown in a case of chronic intestinal obstruction with acute symptoms. Two punctures were made and nearly a gallon of fluid feces was evacuated without soiling the peritoneum.

TENNESSEE STATE MEDICAL ASSOCIATION.

Seventy-third Annual Meeting, held at Memphis, April 10-12, 1906.

Under the Presidency of Dr. Cooper Holtzclaw, Chattanooga.

(*Continued from page 1216.*)

Cholecystectomy.

Dr. Battle Malone, Memphis, said that practically all surgeons agree that excision of the gall bladder is clearly indicated (1) in primary carcinoma of the gall bladder; (2) in gangrene, phlegmon or empyema of the gall bladder; (3) where the viscus is badly lacerated, as from gunshot wounds, etc.; (4) in impaction of stone in the cystic duct, which can not be displaced; (5) where the gall bladder is greatly thickened and contracted. The operation can be done in the average case just as quickly and in many cases more quickly and with as little danger to the patient as cholecystostomy. After drainage of the gall bladder, there are necessarily adhesions which must be a source of more or less discomfort to the patient. In view of the present accepted theory of the etiology of gallstones, it would seem that the adhesions by constant tugging on the gall bladder tend to cause a recurrence of cholecystitis and the reformation of stones. As illustrative of this, he reported two cases that came under his observation in which cholecystectomy was performed. While he would not advocate the removal of the gall bladder as a routine measure, he believes that if the operation is done more frequently, there will be less unpleasant postoperative symptoms and fewer patients will be subjected to a secondary operation. He feels less anxiety for the future of a patient whose gall bladder has been removed than when it has been drained.

DISCUSSION.

DR. JOHN L. ALLEN, Brownsville, endorsed the position taken by the essayist with regard to removal of the gall bladder. In connection with drainage of the gall bladder, if a stone is impacted in the cystic duct, drainage would give more trouble than the removal of the gall bladder.

DR. J. A. CRISLER, Memphis, quoted Dr. Murphy as saying that the ideal operation should be drainage of the gall bladder, leaving the gall bladder itself in its proper place; that it acts as a drainage tube. He thinks the removal of the gall bladder without drainage is almost a useless operation, unless the operation is done for gangrene or for gunshot wound or for some traumatic lesion.

DR. M. C. MCGANNON, Nashville, said that he has come to the conclusion that cholecystectomy is being done less and less. He does not think it is essential to remove every gall bladder that is found to be diseased. A better method of dealing with this subject is to study pathology as it is found.

DR. J. A. GAINES, Nashville, emphasized the fact that empyema of the gall bladder, unless the organ is markedly contracted, does not ordinarily demand cholecystectomy, but drainage. However, cholecystectomy is often indicated in gangrenous or traumatic conditions.

DR. LUCIUS E. BURCH, Nashville, said that in a case of gangrene or gunshot wound of the gall bladder, the gall bladder should be removed. On the other hand, if there are stones in the gall bladder, without any involvement of the cystic duct or of the common duct, drainage should be instituted.

Coprostasis.

DR. T. J. HAPPEL, Trenton, reported the case of a married woman, who gave a history of indigestion, with suffering in defecation, accentuated at each menstrual period. The patient's condition was such that it was necessary to resort to laparotomy. The author emphasized the following points: 1. The necessity of a careful examination by rectum and vagina of all cases presenting evidence of long-continued disturbance of the bowel not relieved by medicinal measures. 2. When this is refused, to dismiss the patient so as to assume no further responsibility. 3. If the patient remains in one's care, insist on laparotomy being done promptly, not allowing the patient to get *in extremis* before an operation is permitted. 4. In this case the gut was found so full that it could not be moved without tearing it. 5. The rapid improvement in the condition of the patient after operation. 6. The passage of feces from the rectum after the formation of an artificial anus. 7. The apparent discharge of feces from the bladder on two occasions, and then the cessation of this condition, with the complete stoppage of all leaks into the bladder. 8. Recovery of the patient from what seemed to be, when the abdomen was opened, a hopeless condition.

DISCUSSION.

DR. JOHN L. ALLEN, Brownsville, reported two similar cases, although their condition was not so marked or distressing. It was difficult, however, to move the bowels of these patients, even with enemas. The condition was due to an hypertrophy of Houston's valves, and he succeeded in curing both patients by clipping the rectal valves. Since then he has resorted to this procedure in many cases of obstinate constipation, with successful results. He is inclined to the belief that fully 50 per cent. of the cases of constipation are due to a thickening of these valves.

Nephrolithotomy, with Subsequent Nephrectomy.

DR. W. D. SUMPTER, Nashville, said the early recognition of renal calculi is important to prevent atrophy, hydronephrosis, infection, pyonephrosis, perinephritic abscess, fistula, anuria, and a timely operation before the patient is in a weakened state is desirable; yet the difficulty is clearly shown in Doran's report that in twenty-four kidneys and stones found, only 11 had had symptoms of calculi. Aseptic concretions may remain a long time, with no evidence of their presence. The author's patient had no definite pain when the four calculi were in the pelvis of the kidney, until the gravid uterus of six and a half months had pressed on it, and an abscess resulted. The quiescent state of the kidney, with sixteen stones remaining after nephrolithotomy, was corroborated by the citation of similar statistics. Although pain is of great diagnostic value, it is often absent or deceptive. At no time was blood detected in the urine. Frequent urination was absent until two weeks before nephrectomy, but never necessitating emptying the bladder during the night.

In nephrectomy for suppurating kidney, drainage is of great importance. Whatever the renal lesion, whatever the incision chosen, careful, conservative methods, especially avoiding the causation of shock, which is the greatest factor in the fatal termination of kidney surgery, will be productive of results that are satisfactory in the hands of the painstaking surgeon.

The Day's Work.

DR. COOPER HOLTZCLAW, Chattanooga, selected this subject for his presidential address. He said that the day's work in the life of a busy practitioner of medicine brings forth many things for consideration. It brings many thoughts, good, bad and indifferent, mostly bad and indifferent. It brings him nearer to actual life than it does most men, and if Pope is correct in saying that "The proper study of mankind is man," certainly the physician's day's work gives greater opportunity to observe both sides of life, the outside as well as the inside. In order that we may be better fitted to more correctly and accurately observe the wonderful phases and phenomena of life and death, it is proper that physicians should be better educated and prepared for this. A college education and a four-year medical course are absolute prerequisites to the practitioner, but to be most successful he must possess the heart of a lion, the brain of an Apollo, the eye of an eagle, and the gentle touch of a lady's hand.

Extrauterine Pregnancy.

DR. RICHARD BARR, Nashville, reported a case of double uterus, with extrauterine pregnancy. The patient was a negress, aged 17 years. The specimen exhibited showed a distinct double uterus, with two cavities without connection. Each cavity is connected with the corresponding Fallopian tube, and each must have opened separately into the vagina, although careful search of the vagina failed to show the opening of the right organ. The blood cyst of the right tube was taken to be an extrauterine pregnancy, with intratubal hemorrhage, and death of the ovum. The unusual features about the case are the double uterus and extrauterine pregnancy; the fact that the pregnancy had occurred by a route almost impossible of demonstration after removal of the uterus; while on the other side the way was wide open, so to speak. The pregnant tube was twisted around, swinging forward, so that it pointed to the left and rode on the anterior wall of the uterus, while its ovary lay in Douglas' cul-de-sac under the uterus, and was so uninvolved as to be without adhesions to any structures. The shutting-off of Douglas' pouch by adhesions left the pocket which contained the right ovary perfectly normal. The cecum and appendix were mobile; the latter organ was located in a vertical position just behind the median line of the abdomen.

Traumatic Lesions of the Brain and Skull.

DR. JERE L. CROOK, Jackson, limited his remarks to fractures of the vault of the skull. The symptoms of these injuries vary materially. All suspected cases are to be operated and inspected. The only occasion where doubt can exist is in fracture of the inner table alone, and here, if there are any localizing symptoms or evidence of intracranial injury, the use of the trephine is justified and demanded. If the case be one of depressed fracture, a medium-sized trephine should be used and the depressed portion elevated, thus restoring the normal convexity of the skull. If the fracture is a comminuted one, the particles should be entirely removed and the edges of the fracture smoothed with the rongeur forceps. The author reported four cases of traumatic lesions of the skull and brain, all of which demonstrated the necessity for prompt exploratory operations in all instances of cranial injury when a positive diagnosis can not be made from the original wound. He said the truest conservatism is that which gives the patient the best chance for a rapid and perfect recovery.

Osteosarcoma of the Lower Jaw.

Dr. Duncan Eve, Nashville, removed this tumor of the jaw, which was enormous in size, being 10½ inches in its vertical diameter and 9 inches in its transverse, from a negress. The surface of the tumor was perfectly smooth, and the mass was hard and incompressible over its entire extent. The skin over the tumor was intact, and there was no enlargement of the superficial veins or infiltration, except on the cheek of the affected side.

Local and Regional Anesthesia in Rectal Surgery.

Dr. A. B. Cooke, Nashville, pointed out some of the advantages of local anesthesia in rectal surgery. It is simple, safe and effective. It eliminates the dangers and discomforts of general anesthesia. Pain at the time of operation is usually absent, and when present is so slight as to be easily borne. Postoperative pain is less by far than after the old methods. The time required for the operation is greatly reduced. Confinement to bed is rendered a matter of expedience rather than necessity. The period of detention from business is diminished fully one-half. Under this method the hospital becomes a convenience and luxury rather than a dreaded essential. It is a thoroughly reliable means of affording relief in many cases which otherwise would be unsuitable for operation. It robs these operations of their terrors, and makes it possible to reclaim this work from the hands of the "no-knife advertisers."

Doctor, Druggist and Proprietary Medicines.

Dr. J. L. Andrews, Memphis, said that the greatest danger in "patent medicines" is in their indiscriminate use. As conditions are now, exactly the same thing is true of proprietary medicines. He introduced a resolution, which was adopted unanimously, to the effect that the society looks with favor on the establishment of a drug store for physicians' prescriptions and the sale of staple drugs and sickroom accessories; no counter prescribing; no patents; no side lines, cigars or soda water.

The druggist derives only a small profit from the sale of "patent medicines." Recently an elaborate system was put in operation by which any druggist, who varies in the slightest particular from a fixed price, can be detected, and in the future he can buy no more of the system's goods. In the face of these restrictions the druggists ought to decline to sell "patent medicines." Let the department stores have the "patent medicine" business. According to a recent statement of a "patent medicine" maker, women buy and use nearly all the "patent medicines" that are sold. In the department stores they can buy "Rupena" and Lydia Pinkham's Pills at bargain day prices to their heart's content.

There can be no question that physicians are now prescribing proprietary medicines to an extent that is reprehensible. Give the druggist a chance to elevate and dignify his entirely worthy profession by efforts at scientific and elegant pharmacy. The medical student ought to be taught everything possible without drugs. Dignify extemporaneous prescription writing. Teach more medical chemistry. The physician ought to be able to tell at a glance whether or not his prescription has been properly compounded. The druggist is overworked and underpaid, and he is in favor of any legitimate measure which will alleviate these conditions. Dr. Andrews has a firm conviction that the druggist's best hope of professional elevation and advancement lies with physicians, and it is the plain duty of every physician to exert himself to bring about this end.

Surgical Treatment of Uterine Fibroids.

Dr. J. W. Barksdale, Memphis, claimed that operations on fibroids have a mortality of approximately 5 per cent., which is not very much in excess of the average percentage of cases in which the abdominal cavity is invaded for all causes; yet Dr. T. B. Eastman, Indianapolis, in 117 cases operated on, found 43 that presented complications that might have terminated fatally. The author endorsed the position taken by some of the foremost workers in the field of gynecology who lay down the broad rule that all fibromyomata should be removed as soon as diagnosed.

Appendicostomy.

Dr. G. C. Trawick, Nasnville, said that the purpose of the operation is to utilize the appendix as a means of irrigation and the introduction of medicaments through its lumen into the large intestine. That this procedure is justifiable in cases of chronic colitis and sigmoiditis after internal medication and high irrigations have proved ineffectual, the author demonstrated. The most usual disease for which this operation is performed is amebic colitis; but it has also been done for syphilitic ulcerations of the colon, multiple papilloma, chronic diarrhea with bloody stools, and mucous colitis. The author's experience with this operation has been very favorable. Out of twenty-four reports of this operation there have been 20 cures, with one death, and one result unknown, and one death from pulmonary tuberculosis.

Treatment of Amebic Dysentery.

Dr. John L. Jelks, Memphis, disinfects the entire colon by flushing through a tube of his own design with an acid formalin solution, fifteen to thirty minims of formalin, and a teaspoonful of boracic acid to each quart of warm water, which fluid passes out through the drainage tube. He then introduces through a small tube with a piston syringe one ounce of olive oil and a dram of bismuth subnitrate. This latter mixture relieves the painful effects of the formalin solution, and furnishes a protective coating to be inflamed viscus. Later, when the patient is placed in the genupectoral position, the proctoscope or sigmoidoscope is introduced and all ulcers are cauterized with silver nitrate, thirty to sixty grains to the ounce. The entire inflamed area is then sprayed with a mild alkaline solution, dried and insufflated with boracic acid.

Other Papers Read.

The following papers were also read:

"The Significance of Disturbed Reflexes," by Dr. Michael Campbell, Bearden; "Hemorrhage in and Around Nerve Tissue," by Dr. Hazel Padgett, Nashville; "Injuries of the Eyeball, with Report of Cases," by Dr. J. W. Price, Memphis; "Pterygium, Its Relation to the Refraction of the Eye," by Dr. George H. Savage, Memphis; "The Treponema Pallidum of Syphilis," by Dr. Wm. Litterer, Nashville; "Vesical Fistulas in Women," by Dr. W. A. Bryan, Nashville; "Recto-Vaginal Plastic Surgery," by Dr. M. C. McGannon, Nashville; "Notes on Cases of Gastroenterostomy for Chronic Digestive Disorders," by Dr. W. D. Haggard, Nashville; "What Are the Safest Criteria for the Estimation of Renal Lesions?" by Dr. R. Wallace, Chattanooga.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Uremia.

In considering the treatment of uremia, A. R. Edwards, in the *Therapeutic Gazette*, states that no systematic outline of treatment can be given, as the actual causes of uremia are imperfectly known. On the basis that it is an autointoxication, associated with circulatory changes or increased intracranial pressure, he considers the treatment from the following different standpoints:

First.—Prevention. All irritating foods, excessive eating, intemperance, overwork, and tendencies to dyspepsia are considered in this class.

Second.—Rest and Exercise. The kidneys should be relieved by rest in the horizontal position, as the erect position not infrequently causes an increased albuminuria. The rest should be absolute as long as the heart is weak, the urine scanty or the edema considerable. Rest in bed lessens the amount of waste products to be eliminated by the kidneys, and also protects the skin and dilates the cutaneous vessels, and in this way increases its function. The vascular tension in the renal circuit is also by this means very much lessened. He speaks in this connection of treating cases of parenchymatous nephritis with rest in bed for a year, with absolute recovery. Fatigue

and exposure to damp and cold must be avoided, and relative rest and warm clothing are necessary in cases of moderate severity. He states in this connection also that practitioners do not sufficiently insist on psychical as well as physical rest. In men who are undergoing severe mental strain the nephritis markedly decreases and sometimes entirely disappears when this nervous tension has been avoided.

Third.—Springs and Climate. Only those individuals without edema and without serious heart involvement should be sent to medicinal springs. A change of climate, however, to one that is more equable and warm is advised.

Fourth.—Diet. The diet must be non-irritative, it must not tax the kidney in its elimination, the circulation must not be burdened, and at the same time the nutrition must be maintained. Disease of the glomeruli alone may be compensated by vicarious excretion of water through the lungs, skin and intestines, but the disease of the tubules whose function is the elimination of end products of the albuminoid metabolism can not so well be compensated by other functions. Consequently there is a marked necessity for the limitation of albuminous foods, and their place is taken by fats and carbohydrates. The albuminous substances are restricted only to spare the irritation of the excreting renal cells. No absolute rule can be laid down for all cases, consequently the amount of albumin intake must correspond to the condition of the individual case. He mentions the fact that too often the severity of a nephritis is measured by the amount of albumin present in the urine, which is a mistake. He recommends fats in the form of butter, olive oil and cod-liver oil, cream, etc., as very important articles of diet. Anemia and disturbed nutrition are perhaps the most distinguishing features of the parenchymatous form of nephritis as contrasted with the interstitial type. Consequently the individual patient must be considered and not the type of the disease. He speaks of a strictly milk diet as being too bulky, over four quarts being necessary to maintain nutrition; consequently it may cause marked gastrointestinal disturbance; it lacks iron, and the four quarts contain an excess of proteids; it contains too much water, thereby overloading the blood and straining the heart. The presence of phosphates and chlorids also tends to overtax the kidneys. He, therefore, regards the purely milk diet as one that is much abused. He recommends from one to one and a half quarts of milk, with a pint of cream, fats and carbohydrates, as a diet that will meet the needs of metabolism. In order to prevent the elimination of phosphates by the kidneys, he recommends that from 5 to 10 grains of calcium carbonate be given internally in order to precipitate the phosphates in the intestine.

Regarding the meat diet, the average amount recommended by him, as previously recommended by von Noorden, is 100 grams daily. He does not distinguish between the red and white meats, as the purin bodies in each are about the same. Some meat is better than too much vegetable diet, as the latter is liable to overload the stomach and bowels, and in that way to bring about intestinal disturbances. All substances containing nitrogen should be restricted. This applies not alone to meat, but to leguminous vegetable and to some extent to milk. He advises that not more than two eggs be allowed a day. He mentions the fact that raw eggs increase and in some cases induce albuminuria. The chlorids are especially to be avoided in the parenchymatous form of nephritis when edema is present. Irritants, such as cheese, relishes, horse radish, onion, rhubarb, asparagus, spices, sauces, broths, beef tea and alcoholics should be absolutely avoided. Tea and coffee should be taken only with the greatest moderation, since they aggravate or tend to produce nephritis.

Fifth. Water. An excessive amount of water overtaxes the heart and renal system. Water can only be excreted by the kidneys when the blood pressure is increased, and many weak hearts, according to the history of cases, are produced by prolonged and excessive water drinking. The water in most of these cases should be limited to about 1,500 c.c. daily.

Sixth.—Symptomatic Therapeutic Measures. Diuretics, as a rule, should be avoided in the treatment of nephritis. In some cases diuretics are indicated with increasing edema, scanty urine and imminent uremia. In such instances he recommends cream of tartar and potassium citrate as alone being safe. They are supposed to abstract water from the tissues and to convert urea and uric acid into more readily excreted substances. Basham's mixture as a tonic and diuretic may be given in doses ranging from 1 to 2 drams (4-8) each.

Seventh.—Hydrops. Edema in so many cases threatens suffocation by pulmonary or laryngeal disturbances, increases the danger of secondary infection, such as erysipelas, and embarrasses the circulation by pressure on the afferent capillaries, and, therefore, demands treatment. It also interferes with digestion and increases the dangers of uremia to a marked degree. Edwards speaks of the value of cathartics as good eliminants of fluids as well as solids, at the same time drastic purgatives must be given great care. Sweating is not so much in vogue as in former times. While the reciprocal functions of the skin and kidneys are of great value, profuse sweating eliminate fluids rather than solids, and, quoting Leube, he holds that sweats concentrate the blood and, therefore, rather predispose to uremia. The symptoms under such circumstances may show at least great aggravation, and in some cases a fatal issue may result, rather than relief of the condition. He therefore recommends the old-fashioned full warm bath, together with the hot air or alcoholic sweat. With this method he recommends the application of the icebag to the head to prevent brain congestion, commencing with the water at the body temperature and raising it five or six degrees. After the patient has been in the bath for from twenty to thirty minutes he may be removed and wrapped without drying in the blankets. Edwards speaks of pilocarpin as an unsafe preparation. It tends to produce profuse salivation, vomiting, diarrhea, syncope and sometimes pulmonary edema. He regards incisions as superior to all other measures for the relief of the edema by mechanical means, as it extracts the fluid from the tissues with the urea and other solids. He recommends the employment of deep incisions over the lower extremities whenever the hydrops is extensive. In this way quarts of fluid may seep out during the first twenty-four hours, and one is well justified in thus incising the legs, regardless of the fact that there is always danger of an occasional infection. Sweats and drugs can never produce the same result, and the incision is less dangerous than punctures or the Southey capillary tubes.

TREATMENT OF THE CIRCULATION.

The treatment of the circulation consists in watching the heart and administering proper stimulation, and the avoidance of those things which tend unnecessarily to aggravate the heart's action. Whenever cardiac overaction is present, as is especially observed early in uremia, the high tension may be corrected by vasodilators. The iodids are recommended when no urgency is present. When extreme tension and uremia are at all likely to exist he recommends the tincture of veratrum viride in from 5 to 10 minim (.30-.65) doses every half hour for three or four doses; or large doses of nitroglycerin grs. 1 50 to 1 20 (.0012-.003). Bleeding may relieve the intracranial blood pressure, and in this way remove some of the uremic symptoms for a time. Vomiting and diarrhea may demand gastric lavage and colonic flushings, but it should be kept in mind that they are often vicarious as well as cerebral and should not be checked too quickly. Convulsions demand the administration of morphin hypodermically or chloral in 15-grain (1.00) doses every hour for not more than four doses. These preparations, however, should be used with great caution. As a rule, bromids act too slowly.

Treatment of Acute Nephritis.

Prof. A. Robin, in *Med. Press*, recommends, in the treatment of acute nephritis or edema of the kidney, that blood letting be resorted to in the acute stage. Milk and infusions, he states, only tend to stimulate an organ which can not work. Instead of stimulating the function of a diseased gland, the smallest possible amount of work should be given to it. The patient should be permitted to drink only as much pure water as will relieve his thirst.

Wet cupping or leeches are recommended by Robin, applied over the region of the kidneys. Purgatives are indicated and if these do not act sufficiently the following mixture is recommended:

℞ Jaborandi fol. ..... ℥i 4
Aquæ bullientis ..... ℥vi 180
M. Ft. infusum. Sig.: One-third the amount at a dose, and the same size dose repeated every half-hour.

This will produce some salivation and profuse sweating.

Molliere, in the same periodical, recommends an ointment containing pilocarpin, applied over the surface of the body, as follows:

℞ Pilocarpinæ hydrochlor. ..... ℥i 4
Lanolini ..... ℥iv 120
M. Ft. unguentum. Sig.: Apply locally to the abdomen and lumbar region.

To stimulate the liver, Robin recommends a few drops of ether three or four times a day, given in a capsule. Cold enemas are of value to stimulate the intestines. To correct the dyspnea an inhalation of the nitrite of amyl, a pearl broken on a handkerchief and inhaled, is advised.

Treatment of Gout.

The following combinations are recommended by *Clin. Therapeutics* in the treatment of gout:

℞ Potassii iodidi ..... ℥ii 8
Potassii bicarb. ..... ℥vi 24
Vini colchici ..... ℥ii 8
Aquæ camphoræ ..... ℥xii 360
M. Ft. mistura. Sig.: One tablespoonful three times a day, after meals, in a wineglassful of water. Or:

℞ Tinct. seminis colchici
Tinct. aconiti rad.
Tinct. guaiaci
Elix. simplicis, āā ..... ℥ss 15
M. Sig.: One-half a teaspoonful in water after meals.

The following combination is recommended, administered in the form of pills:

℞ Ext. colchici acetici ..... gr. xv 1
Ext. colocynth. comp. (B. P.)
Pulv. ipecac. comp., āā ..... gr. xviii 1|20
M. Ft. pil. No. xii. Sig.: One pill night and morning. Or:

℞ Ext. colchici acetici ..... gr. vi |40
Ext. rhei
Ext. aloes, soc., āā ..... gr. v |30
Ext. belladonnæ ..... gr. i |06
M. Ft. pil. No. vi. Sig.: One pill twice a week at bedtime.

As a liniment in acute gout the following combination is recommended:

℞ Morphinæ hydrochlor ..... gr. x |6
Linimenti belladonnæ ..... ℥iii 90
M. Ft. linamentum. Sig.: A teaspoonful mixed with a tablespoonful of hot water and applied on lint under oil silk every four hours. Or:

℞ Atropinæ ..... gr. iii |20
Morphinæ hydrochlor. ..... gr. xv 1
Acidi oleici ..... ℥i 30
M. Ft. linimentum. Sig.: To be painted over the painful joint and the joint wrapped in cotton wool.

Medicolegal

Liability of Imbecile's Estate for Medical Services.

The Court of Appeals of Kentucky holds, in D. M. Smith's Committee vs. Forsythe, that, as to a physician's claim, so much of it as was a reasonable charge against the imbecile for necessary medical services to himself and family should have been adjudged against this committee, to be levied of assets not exempt from execution. It says that for necessaries furnished to a lunatic and his family a recovery of their value will be allowed, even though his condition was known by the other party. A lunatic is liable for necessaries, not on his express contract, but on the one implied by law.

Validity of Physician's Claim Allowed in Part.

The Court of Appeals of Kentucky says, in Center's Administrator vs. Breathitt County, where the fiscal court allowed $200 on a physician's claim for $650 for treating twenty-four cases of smallpox under employment of the county board of health, that it was insisted that the physicians acting as the county board of health had not been properly appointed, or at least that no record of their appointment was produced. But the court considers it enough that the proof showed that they were at least de facto (acting) officers, were acting as a board of health, and were recognized as such by the state board. Lastly, it was urged that the physician received the $200 allowed him by the fiscal court, and, as it was allowed in full of the claim, he, when accepting it, necessarily took it on the terms on which it was allowed, and that he could not for that reason sue the county for a greater allowance. But the court says that there was no evidence that he accepted the $200, or that it was paid to him. The only evidence was that the account in the Circuit Court was credited with the sum of $200 allowed by the fiscal court. The credit may have been given on the idea that this much of the claim was no longer in controversy. In order to raise this question the defendant must show that the $200 was paid to the plaintiff under the order of the fiscal court.

Privilege Where Third Person Present at First Visit.

The Court of Appeal, First District, California, says that it was claimed in the case of Murphy vs. Board of Police Pension Fund Commissioners, that error was committed in sustaining the defendant's objection to a question asked of a physician for the purpose of showing statements or information given by a policeman at the time he attended him after he had been fatally injured. It seemed to be conceded that the object of the question was to obtain information acquired by the physician in attending the policeman, which was necessary to enable him to prescribe or act for the patient. The California Code of Civil Procedure expressly provides that a physician can not be examined in such cases, and the court has so held. It was insisted, however, that this information and statements were given in the presence and hearing of the patient's wife, the plaintiff here, and hence that they were not privileged because made in the presence of a third person. But, the court says, the question was not confined to what was said at the first visit of the physician and in the presence of the plaintiff and during that visit. The physician made in all about twenty visits. No one was present at any of the visits after the first one except the physician and the patient. The question asked included all of the time during which the patient was under the care of the physician, and hence the question did not come within the exception claimed by the plaintiff.

Individual County Officers Can Not Employ Physician.

The Supreme Court of Wisconsin says that in the case of Hittner vs. Outagamie County, an action brought by a physician to recover $317 for professional services and medicine furnished to an alleged poor person, the plaintiff charged that he was employed by three members of the county board and the district attorney of the county to furnish this aid and care. It was not alleged that these officers were given authority by the county board to employ the plaintiff or any other person in providing county aid to poor persons. There is nothing in the provisions of the statues under which poor persons are to be relieved at the expense of the county, indicating that individual members of the county board or the district attorney have any authority or power to act for the county, unless express authority be granted them by the action of the county board. As held in the case of Patrick vs. Town of Baldwin, 109 Wis. 342: "The statute creates a liability to relieve destitute persons, but not a liability to individuals who may voluntarily perform that service. It empowers appropriate agents of municipalities to make their liability effective by necessary contracts to that end, and imposes on such agents the duty to exercise such power. . . . Performance of that duty by the person designated by law is absolutely essential to create a binding obligation on the municipality to compensate one for relieving a poor person legally entitled to relief at its expense." It appearing that the county officers whom the plaintiff alleged employed him to furnish the relief at the county expense had no authority to make such a contract, the complaint must be held to state no cause of action.

Making Autopsy in Order to Procure Burial Permit.

The Court of Appeals of Kentucky says, in the case of Meyers vs. Clarke and others, which was brought by a mother

to recover damages for an alleged unauthorized autopsy on the body of her daughter, who had died suddenly at a charity hospital to which she had been sent the day before by the city, that the mother and stepfather were notified of the death. The stepfather employed an undertaker to go to the hospital and take charge of the body and remove it to the girl's home and prepare it for burial. The undertaker, or one of his assistants, went to the hospital, and was told that the body was in the morgue, and after conference with the interne at the hospital, went to the home of the girl and notified the stepfather that the body was in bad condition and that a speedy burial was necessary, and suggested that the physicians at the hospital had to make an autopsy to ascertain the cause of death in order to procure a burial permit from the board of health. Before he could report to the physician in charge of the hospital what the stepfather had said, two physicians took it for granted that there were no objections, because of the silence of the undertaker's assistant, and proceeded to hold an autopsy, which disclosed that the death was from perforation of the bowels, caused by typhoid fever. The jury were instructed that they should find for the plaintiff, unless they believed from the evidence that the physicians in making the autopsy did so for the sole purpose in good faith of ascertaining the cause of death in order that they, or one of them, might be able to correctly give a certificate stating the cause of death for the purpose of obtaining a permit for the burial of the body. They should also find for the plaintiff, unless they believed from the evidence that the autopsy was properly and decently performed with due regard to the sex of the deceased, and without making any unnecessary incisions into, or mutilations of, the body. If they found against the two physicians, they should also find against the undertaker, provided they further believed from the evidence that the undertaker, after having custody of the body, consented that an autopsy might be made, and voluntarily gave to either of the physicians, or both of them, permission to make the autopsy. But, if they believed, from the evidence, that the physicians in making the autopsy made it decently, with due regard to the sex of the deceased, making no unnecessary incisions into or mutilation of the body, and that the autopsy was made in good faith for the purpose of ascertaining the cause of death in order that such a certificate might be given as would procure a permit for the burial of the body, the jury should find for the defendants. The court holds that these were proper instructions, and affirms a judgment for the defendants. It says that there was nothing in the record to show that the undertaker or the physicians purposely mutilated or disfigured the body, but that their sole purpose was to comply with the rule of the board of health, so as to enable the undertaker or physicians in authority to procure a burial certificate, which was required by the board of health under the charter and ordinances of the city. The court sees no reason in law or otherwise why the city authorities or the board of health should not make the requirements as above set out.

2 *Saline Beverages in Typhoid Fever and Their Effects on Heat Dissipation. J. B. Todd, Syracuse, N. Y.
3 Diagnosis of Surgical Diseases of the Kidney. A. A. Berg, New York.
4 *Turbinectomy. E. H. Griffin, New York.

2. **Saline Beverages in Typhoid Fever and Their Effects on Heat Dissipation.**—Todd declares that if a proper amount of fluids and alkaline salts is given in the earliest stage of the disease they will prove of advantage. If they are withheld, however, the efforts of the protective forces of the body are hampered. The germicidal powers of the blood are preserved by saline beverages. If water is not given in abundance, heat dissipation is lessened. Todd administers a saline beverage, consisting of eight ounces of water, ten grains of sodium chlorid, five grains of potassium bicarbonate and a teaspoonful of lemon juice, which produces a mild effervescence. There is about two-thirds of a grain of free citric acid in each dose.

4. **Turbinectomy.**—Griffin does not believe in complete turbinectomy. He declares that only so much of the bone should be removed as is necessary to restore the normal canal and to give back to Nature the proper function of the nose. The great objection to the complete operation is that it makes the passage too large and removes something which belongs there and which has a function to perform. Partial turbinectomy restores the normal anatomy.

11 Aims and Limitations of Intranasal Surgery in the Treatment of Chronic Non-suppurative Affections of the Middle Ear. T. J. Harris, New York.
12 *Influence of Certain Antipyretics on Nitrogen Metabolism. H. Morgenbesser, New York.
13 Two Cases of Postpartum Eclampsia Due to Diabetes. S. J. Essenson, New York.

9. **Radical Tympano-Mastoid Operation.**—Bryant reports several cases to show that the idea which is more or less prevalent in the profession that the radical operation is seriously complicated when the sigmoid sinus approaches the external auditory meatus is unwarranted. The author describes his method of operating fully.

12. **Influence of Antipyretics on Nitrogen Metabolism.** The results obtained by Morgenbesser differ in many respects from those reported by other investigators. For sodium salicylate he did not get as high an increase in the total nitrogen, only 9 16 per cent., while he obtained no increase in uric acid; in fact, a slight diminution. In the case of quinin he obtained a total nitrogen decrease of 13 to 19 per cent., urea decreased 22 to 28 per cent., uric acid decreased 40 to 50 per cent., purin bases decreased 40 to 50 per cent. In the case of acetanilid he obtained: Total nitrogen increased 14 to 21 per cent., urea increased 19 to 35 per cent., uric acid increased 12 to 44 per cent. The metabolism decreased after ceasing the administration of acetanilid.

15 *Traumatic Defects of the Skull, Their Relation to Epilepsy: A Clinical and Experimental Study of Their Repair. D. P. Allen, H. L. Sanford and D. H. Dolby, Cleveland, Ohio.
16 Defensive Properties of the Organism. S. C. Dickerson, New Bedford, Mass.

15. **Traumatic Defects of the Skull.** The authors urge that all traumatisms to the skull resulting in bone defects should be repaired as soon as possible, not awaiting the possible development of epilepsy, and should epilepsy follow trauma, thus making the removal of bone necessary for its relief, the defect caused by operation should be repaired at once. The method proposed by Allen for covering defects of the skull is as follows: The scalp is removed from over the defect in the skull and the connective tissue covering the brain is carefully dissected away. In certain cases in which the injury to the brain tissue has occurred as the result of traumatism, it may be necessary to trim away a portion of the brain with the scissors, since the connective tissue may be firmly connected with the brain tissue itself. The borders of the opening are carefully examined to see if any portion of the bone projects downward, and if so it is removed by means of Rongeur forceps. All hemorrhage should be controlled before the bone flap is inserted.

The scalp is removed from an added area of the skull of equal size with the opening, care being taken that the peri-

steum covering the skull is left intact and that the portion f skull laid bare is as thick as possible. Thus the posterior arietal region is preferable to the temporal region. On the rea thus laid bare a circular or elliptical incision is made. locking out a portion of periosteum equaling in form and size ie defect which is to be covered. A sharp, narrow chisel is hen employed to split from the outer surface of the skull ie portion of bone adherent to the overlying periosteum. By lacing the graft thus obtained between two gauze sponges noistened in warm normal salt solution and laying it on the able it may be flattened out by a few slight blows of the nallet. The plate of bone thus prepared is laid on the open- ig in the skull, the bone being next to the brain. The wound s then closed by drawing over it the scalp and suturing it oosely in place. A cigarette drain made up of gauze and sur- ounded by gutta percha protective tissue is inserted through ie incision at the dependent point, so that any excess of lood may be drained away into the dressing. The dressings re changed ordinarily on the second day in order to remove ie cigarette drain, after which a second bandage is applied. his bandage remains in place for perhaps six or eight days nger, or until the wound has entirely healed. By this method ven patients have thus far been operated on.

20 *Ether Anesthesia by the Drop Method. F. N. Shipp, Columbus.

17. See abstract in THE JOURNAL, June 17, 1905, p. 1958.

20. **Ether Anesthesia by Drop Method.**—During the past ourteen months Shipp has administered ether 337 times by the pen-drop method. The average time of inducing anesthesia as 6 minutes and 10 seconds. The time varied from 40 seconds o 12 minutes. Initial vomiting did not occur in a single case. n 65 per cent. of the cases there was no struggling or chok- ng, in the remaining 35 per cent. excitement and choking was f a mild degree. No patient needed stimulation, the cause of hich could have been attributed directly to the anesthetic. o operation was delayed, even for a moment, on account of ie condition of the patient. Forty-eight per cent. of the pa- ients had no nausea or vomiting following the administra- ion; 40 per cent. were slightly nauseated, vomiting once or wice, but were comparatively free from all sickness within wo or three hours. A fraction of over 11 per cent. were quite l, being nauseated from 12 to 24 hours. In less than 1 per ent. severe vomiting followed, lasting from 3 to 6 days. There as no postoperative pneumonia in any case. Nephritis oc- urred in the case of three patients; one was a woman suffer- ng from melancholia, which developed during pregnancy; the econd was a patient suffering from appendicitis of ten weeks' tanding; the third was a woman with a large uterine fibro- yoma. In all three patients the physical condition was an xtremely poor one.

32 *Non-parasitic Cysts (Congenital) of the Liver, with a Study of Aberrant Bile Ducts. E. Moschcowitz, New York.

24. **Hodgkin's Disease.**—The easiest and surest method of diagnosis, according in Ruffin, lies in the removal and histologic study of a diseased gland. It may be impossible to make a conclusive diagnosis during life in any other way. Glandular tuberculosis may be excluded by the tuberculin test. Some cases of Hodgkin's disease are characterized by a typically relapsing fever.

25. **Bacteriologic Findings in Epidemic Cerebrospinal Meningitis.**—In a study of fifteen cases of epidemic cerebrospinal meningitis made by Robinson, the organism isolated from the spinal fluid, circulating blood, pus from the conjunctiva and from the central nervous system at autopsy agrees in all respects to the *Diplococcus intracellularis meningitidis* of Weichselbaum. It was isolated in pure culture from the spinal fluid of the 14 cases in which lumbar puncture was performed and is to be considered the causal agent in all the cases. This organism was obtained from the circulating blood of two of the four investigated cases, but in one only did it grow on the various culture media. Robinson thinks that the organism is probably only an occasional invader of the circulating blood, although it may be present in the blood for many days during the course of the disease and does not occur only as an agonal invader of the blood. The *Diplococcus intracellularis meningitidis* may occur in the pus of purulent conjunctivitis, a complication not infrequently seen in meningitis. It was isolated from one of two cases which showed this complication. Secondary lung infections with pyogenic organisms are frequent, and a terminal bronchopneumonia was found in 5 of the 6 cases that came to autopsy, all of which showed the presence of pyogenic cocci.

28. **Poisoning from Belladonna Plasters.**—Doland reports three cases in which belladonna poisoning followed the application of belladonna plasters. The symptoms were typical. In the case of two of the patients the symptoms appeared after a few days. The third patient showed evidences of poisoning two hours after a small belladonna plaster had been placed on the chest.

30. **Osteoarthritis.**—Nathan discusses the etiology and pathology of certain forms of joint disease and presents a scheme for the classification of joint diseases generally which divides them into two groups, the first according to their generic pathology and the second according to the primary location of the disease in the bones or the synovia. The classification based on the generic pathology divides these affections into (1) the inflammatory or infectious and (2) the trophic. Each division is subdivided further into (a) the synovia and (b) the osseous forms. Included under the inflammatory type are tuberculous, syphilitic, gonorrheal and typhoid arthritis, the group name being infectious arthritis. These are the synovial forms of arthritis. The group name for the osseous forms is infectious osteoarthritis. The subdivisions are the same as for the synovial forms. The group name for the synovial forms of the trophic type is trophic arthritis, which includes the metabolic or autotoxic arthritis, senile, arteriosclerotic and toxemic arthritis. The trophic osteoarthrites include the same forms, but are characteristic of the osseous type of trophic arthritis. The classification according to the location of the disease is made on the same basis and includes the same forms and type.

32. **Non-Parasitic Cysts of Liver.**—Moschcowitz studied 87 cases of non-parasitic cysts of the liver recorded in the literature. He found that they are associated with congenital anomalies in other parts of the body, especially with cysts of the kidney. Such cysts of the liver are always associated with congenital anomalies of the liver, consisting in aberrant bile ducts, which may be extrahepatic or intrahepatic. These aberrant ducts are embryonal "rests," formed in the course of development of the liver, and have thus far been found only in cystic livers or in livers associated with cystic kidney. Non-parasitic cysts of the liver have their origin in these aberrant ducts and may assume two forms; one arising from inflammatory hyperplasia of the ducts, the other by retention of fluid in these ducts, as the result of congenital obstruction.

33. **Status of Pelvimetry.**—Ehrenfest believes that this useful method of examination would find a wider application, both at the hands of the general practitioner and the specialist obstetrician, if the actual value of mensuration of certain pelvic diameters were more appropriately appreciated and if writers would be more careful not to create erroneous and exaggerated ideas concerning the utility and accuracy of the various methods of pelvimetry.

34.—See abstract in THE JOURNAL, Jan. 13, 1906, p. 151.

35. **Operative Aids in Abdominal Work.** Experience has taught Balloch the necessity of a very thorough preliminary examination of all patients, the desirability of simplicity in technic, the value of rapidity in operating and the benefits accruing from attention to little things. For sterilizing the hands he has found Harrington's solution, composed of bichlorid of mercury, alcohol and hydrochloric acid, very effective. He has also used eserin, according to Craig's method, with good results. He sounds a note of warning as to the indiscriminate use of salt solution. He believes that it does as much harm when improperly used as it does good in appropriate cases. In cases where meteorism is a prominent feature he employs an enema, consisting of equal parts of milk and molasses, as recommended by the younger Senn.

36. **Aseptic Removal of Infected Fibroid Uterus.** In order to avoid contamination of the abdomen during the removal of an infected fibroid uterus, Kelly adopted the following plan: He first tied off both broad ligaments down to the cervix and the uterine vessels; then, in order to hold the cervical stump well up in the pelvis, he passed a strong catgut ligature through the tied-off ovarian vessels, under the uterine vessels and out through the round ligaments on each side. When this ligature was tied it served to control the uterine vessels and at the same time to keep the cervix high up in the pelvis after amputation. An additional ligature was applied separately to the uterine vessels. Then, lifting the uterus, which was thus freed down to its cervical portion, strongly upward, he began to amputate through the cervix, first on one side and then on the other, as well as in front and behind. In this way the attachment of the fibroid uterus above was gradually narrowed down to the cervical canal and some of the surrounding tissues until it formed a pedicle about 2 cm. in diameter and perhaps 1 cm. in length. He then grasped the cervical canal thus isolated, but not opened with an artery forceps, and proceeded to amputate just below the forceps with a Paquelin cautery. The uterus was thus removed with its cavity closed in a perfectly aseptic manner. Catgut sutures, which had been applied to the right and left angles of the divided cervix before the amputation, were then tied at once, and with several more sutures the stump was completely and promptly closed. The patient made a rapid and prompt recovery.

37. **New Form of Blood Cell.** The cell described by Stahl is a crescent shaped, nucleated red-blood corpuscle, which he found in a 6 weeks old ovum. In the Bauchstiel area of the chorion in the amniotic cavity, there is a trabeculated tissue of arachnoid delicacy. In these meshes Stahl found this new cell and many multinucleated corpuscles, to which he has applied the term "mulberry form of nucleated red blood corpuscles." In a supplemental paper he expects to show that the three popular theories for the origin of the non nucleated red blood corpuscles are incorrect.

40. **Congenital Absence of Lower Third of Vagina.**—In this case Vineberg found a shallow blind sac occupying the vaginal introitus. The defect was remedied partly by the vulvar and partly by the abdominal route. The operation is described in full.

42. **Cancer of the Breast.**—By bringing the flap which covers the pectoral muscle forward and upward to the intraclavicular horizontal line where the incision is first made, Stone covers the space left by the removal of the breast. The manner of procedure is as follows: A horizontal incision is made, extending from the insertion of the pectoralis major nearly parallel to the clavicle and about two and one-half inches from it to a point below the first and second third of the clavicle. The length of this line is usually about five inches. A circular incision is now made around the breast, which usually has its center at the nipple and a diameter of from four to five inches. If the induration in the gland is at the periphery of the breast the outline must include that portion, and of course, as far beyond as possible, always including the nipple. The downward incision is completed by extending it until it meets the circular outline around the breast. The skin is dissected from the pectoral muscle and the muscle is removed as indicated above, taking the muscle and gland away together.

The second incision mentioned may commence about two inches inward from the insertion of the large pectoral and is made nearly over the vertical incision of the outer portion. After the mass of muscle and gland has been removed, the vessels are tied and the flaps adjusted. There is no necessity for much exposure of the raw surfaces. Drainage is best secured by a combination of rubber tube and gauze wick. In every case there will be need of some liberation of the skin from points where there is excessive traction. The auxiliary flap is brought upward and forward and secured to the infraclavicular flap, and the upper or pectoral flap is brought downward to cover the space by taking away the breast. The result is a line much like the letter "S." Its advantages are mainly to furnish additional skin covering, to permit greater ease in dissection of the axilla and to leave no scar tissue under the arm.

52 Case of Appendicitis with Early Rupture of the Appendix. W. H. Axtell, Bellingham, Wash.

47 and 48.—See abstracts in THE JOURNAL, Jan. 6, 1906, pp. 64-65.

51. **New Method of Intestinal Anastomosis.** Powell has devised a new operation for lateral enteroenterostomy which is equally applicable for the performance of lateral anastomosis of any of the abdominal hollow viscera where immediate anastomosis is not imperative. Up to the point of incising the intestine the operation is the same as that usually performed by suture, but instead of incising the intestine a thermocautery or electrocautery, heated to a dull red, is drawn along the intestine for one and one-half or two inches until the entire thickness of the intestinal wall is devitalized but not perforated. The same procedure is followed out on the opposite portion of intestine, so that when encircled by the suture in completing the operation the two cauterized areas will be in direct apposition. Immediate anastomosis is not secured, but in the course of two or four days, after firm adhesions are formed, the slough separates and the communication is complete. The peritoneal cavity is walled off effectually. The operation so far has been confined to dogs, but has proved successful

57 *Pityriasis Rosea. D. W. Montgomery, Berkeley, Cal.

53. **Eggshell Nail.**—Under this title Hyde describes a condition of a nail in which the color is similar to that of the inner face of an eggshell, an exceedingly delicate combination of white and purple. This condition is seen usually accompanying acne and favus, of which several cases are cited. The patients were all women, all young, all below the standard of sound health, none having any distinct affection of the circulatory system—all, however, exhibiting marked interference with stability of vascular equilibrium, and each suffered from hyperidrosis of the hands and feet. The group represented two social classes—individuals delicately nurtured, not engaged in self-supporting toil, and those employed in more or less exacting labor. To a variable degree in each the nails of both the fingers and toes were involved in the change. None of these patients applied for relief of the nail lesion, but for the skin eruptions mentioned above.

57. **Pityriasis Rosea.**—Montgomery treats these cases according to Jamieson's method. The patient is soaked daily for half an hour in a bath, to which two or three teaspoonfuls of Condy's fluid have been added. A salicylate ointment (from three to five parts of salicylate acid in 100 parts of vaselin) is applied freely to the skin.

61 Detection of Simulated Defects of Vision. W. B. Banister, Jefferson Barracks, Mo.
62 Ear Affections and Military Service. E. Amberg, Detroit, Mich.

59. **Examination of Recruits.**—Adams outlines the method of introduction of the physical examination of recruits for the Illinois National Guard. He says that the results of this physical examination were apparent at the outbreak of the Spanish-American War when, on the mobilization of the Illinois National Guard at Springfield, a larger proportion of recruits was accepted from the First Infantry, I. N. G., than from any other regiment of state troops. The details of the method employed are set forth fully. During the past thirty months 716 men underwent physical examination for enlistment in the First Infantry; of this number 88.4 per cent. were found physically fit for service.

60. **Observations in the Philippines.**—Banister discusses dysentery, sprue, pulmonary tuberculosis, malarial diseases, typhoid, bubonic plague and smallpox. He says that diseases of the respiratory organs, except tuberculosis, are of infrequent occurrence, while scarlet fever, diphtheria and yellow fever are unknown in the Philippines. The prevalence of intestinal parasites in the native population is something remarkable.

64 *Conservative Surgical Treatment for Certain Cases of Enlarged Prostate. F. Cabot, New York.
65 Injuries to the Vena Cava During Nephrectomy. I. Sagols, Montpellier, France.

63. **Rupture of the Bladder.** Loumeau reports three cases. The first case shows that lithotrity, in inexperienced hands, may result in a laceration of the bladder and, on account of non-repair of the accidental lesion, may be followed by a fatal peritoneal infection. The second case is an example of spontaneous perforation of the bladder, the result of a vesical cancer. The third case is an example of a mixed rupture of the bladder, spontaneous in appearance but in reality produced by a trauma dating back thirty years. A hypogastric traumatism received at that time resulted in a contusion of the bladder with a prevesical hematoma followed by adhesions between the bladder and the abdominal wall. These adhesions, under the influence of violent and repeated movements, finally broke away from the walls of the bladder at their point of implantation on the organ, from which resulted a tear in the bladder wall.

64. **Conservative Surgery of Enlarged Prostate.**—The plan advocated by Cabot is first to do a cystotomy, preferably by the perineal route, this to be followed in a week or ten days, the patient's condition warranting it, by a perineal or suprapubic prostatectomy. The method is said to be applicable in the case of men suffering from the effects of an enlarged prostate and whose vital organs have been so damaged that even moderate surgical shock is quickly followed by death. Cabot favors the perineal route and while operating uses continuous hot irrigation through the penile urethra. The irrigation tends to lessen hemorrhage and so decreases the shock.

67. **Educational Treatment of Neurasthenia.**—Fisher urges that the patient be given a full explanation of his condition and the meaning and significance of the different symptoms. The apprehension and fixed ideas must be counteracted by suggestion, and all faulty habits must be corrected. If necessary, individual symptoms should be relieved or dissipated by some mechanical device—electricity or a bitter pill—all given with direct suggestion. A systematic method of life should be insisted on. For every hour of the day some act or task should be prescribed to keep the mind of the patient busy. This acts as a strong moral and physical corrective.

69. **Epididymotomy in Blenorrhagic Epididymitis.**—Bazet has operated on 65 patients. He found the gonococcus in one-third of the cases. He has not had any atrophy, hernia, necrosis of the testicle, nor any mortality. In his opinion epididymotomy affords the greatest and quickest relief in the treatment of blenorrhagic epididymitis. He performed his first operation in 1897 with the following technic: He chose the ligamentum serotalis for the incision, seizing firmly the swollen indurated nodule of the globus minor of the epididymis in the left hand. An incision one inch long is made downward into the cavity of the epididymis. At first the swollen nodules were punctured and the walls of the cavity were stitched to the incised skin; later Bazet adopted the plan of performing an epididymotomy, that is, he opened the cavity of the epididymis, exposed the nodules, relieved the tension, punctured the nodules, if pus were present, and stitched the walls of the epididymis to the skin. The wound is packed with gauze impregnated with one to ten parts respectively of ichthyol and glycerin, and the gland is well supported. The patient is able to be up in from four to seven days. The wound heals in a week. The danger of sterility is lessened by this method.

73. **Delayed Chloroform Poisoning.**—Two cases of toxemia following the administration of chloroform are reported by Madison. The first patient was operated on for appendicitis, the appendix being partly gangrenous. The duration of the anesthesia was about one hour and thirty minutes. The patient died eight days after the operation with symptoms of intense toxemia. During the first three or four days the wound did well, and the condition of the abdomen seemed entirely

satisfactory. With the onset of the symptoms of intoxication the wound did not do so well, and toward the last the discharge became considerable and rather foul. There was no evidence of general peritonitis. Forty-eight hours after the operation both temperature and pulse were normal, then they became subnormal and remained so until the last twenty-four hours, when the temperature rose to 100.6. In the case of the second patient an appendiceal abscess was evacuated, the anesthesia lasting about forty-five minutes. The patient did well until about forty hours after the operation, when she suddenly became delirious. The temperature rose to 100. There was no evidence of a brain lesion. After a few hours the patient grew quiet, but soon passed into a comatose condition, in which she died about fifty-eight hours after the operation. While in the comatose condition it was noticed that the breath had a sweetish odor.

The third patient died in coma seventy-four hours after operation. The operation in this case was a clean and satisfactory one, the appendix being somewhat inflamed but quite markedly distended by a serous fluid. The patient recovered readily from the anesthetic and seemed to be in an entirely satisfactory condition. The temperature was 98.6. The following morning pain was complained of in the upper part of the abdomen; the pulse was rapid; the temperature was 102.5. The patient was quite restless and vomited at intervals, the vomitus being brownish and at times quite dark. There was intense jaundice. In these three cases the immediate effects of the anesthetic were usually recovered from entirely and there followed a period during which the patients were comfortable and appeared to be doing well. The symptoms of toxemia appeared suddenly in each case, death resulting invariably.

80. Amputation in Diabetic Gangrene.—Roberts' patient, a man, aged 55, had been perfectly healthy up to the age of 20, at which time he suffered from erysipelas of both hands and forearms, from which he did not recover completely for about three months. Six years ago he again had what he supposed was erysipelas, beginning on the plantar surface of the left foot. In a short time the whole foot was involved and an amputation was performed through the middle third of the leg. Six months ago a sore appeared on the big toe of the other foot, which was followed in about six weeks by a sore on the little toe. This toe became gangrenous and the gangrene extended to all the toes and the foot nearly to the ankle joint. On examination it was found that the urine was excessive in amount and contained one-half of 1 per cent. of albumin, a large quantity of sugar and many hyaline and granular casts. The leg was amputated through the middle third of the thigh. The wound healed without suppuration, the patient leaving the hospital in eight weeks.

81. Treatment of Sprained Ankle.—The participants in this symposium favor the so-called Gibney dressing of adhesive plaster applied in interlacing crosses around the foot and ankle, beginning about one inch above the junction of the great toe and tarsus, and extending to about two inches above the malleoli.

83. Fatal Injury to Eye.—Ray reports the case of a boy who was hit in the eye, the trauma producing a large jagged triangular wound of the cornea. The lens was protruding through the rupture. The eye was enucleated. A peculiar mental condition existed which steadily became worse. A second operation disclosed a perforation in the orbital plate. The lateral wall of the orbit and the external angular process were removed. In spite of every effort that was made to save the life of the patient, he died seven weeks after the injury with symptoms of brain abscess.

2. **The Cystoscope.**—Newman discusses the cystoscopic appearances in some diseases of the bladder and kidneys, and describes a method of illustrating diseases of the bladder and the appearances in renal disease by the opaque projector. He summarizes his findings as follows:

1. When one orifice is altered and the other normal, the renal lesion is on the side of the abnormal ureter, and the character of the deformity of the orifice may indicate the nature of the renal lesion.
2. Active congestion and swelling of the mucous membrane in the neighborhood of the orifice and along the line of the ureter, also swelling and pouting of the lips, denote acute irritation of the pelvis or parenchyma of the corresponding kidney.
3. A dilated orifice, the lips being sharp and clearly defined, the mucous membrane between the lips acutely congested, while the color of that of the bladder is little changed, denotes recent and acute inflammation or mechanical irritation in the corresponding pelvis.
4. A dilated orifice, the lips being thickened and only slightly rounded, the mucous membrane between the lips of a dark-red color, while the mucous membrane of the bladder is deeply injected and pigmented, especially along the line of the ureter, denotes descending ureteritis with dilatation.
5. An elongated or dilated mouth with hyperemia of the lips indicates acute inflammation of the parenchyma or recent distension of the renal pelvis.
6. A punched-out orifice, marked thickening of the lips, induration and congestion of the surrounding mucous membrane, indicate dilated ureter with ascending ureteritis, the infective process extending along the surface by continuity.
7. A pinhead opening one well-defined ridge of deeply-pigmented mucous membrane denotes induration of the walls of the ureter from ureteritis, the infective material being conveyed from the primary focus in the kidney or bladder, principally through the lymphatic channels.
8. Pinhead contraction of the mouth without other vesical changes denotes spasm induced by the presence of a rough calculus impacted in an irritable ureter.
9. Inflammation of the mouth and thickening of the lips, with inflammatory changes limited to the mucous membrane immediately surrounding the ureter orifice, denotes mechanical irritation of old standing.
10. Simple dilatation of the mouth, without much thickening of the lips and with congestion limited to the orifice and neighboring parts, suggests mechanical irritation of recent origin.

3. **Prognosis in Posterior Basal Meningitis.**—Hildesheim claims that it is almost impossible to give any prognosis early in the disease. Although the prognosis is better the older the child, nevertheless one-third of his patients who recovered either completely or partially were under six months of age at the time of the onset of the disease. In not a few cases the prognosis depends largely on careful and unremitting attention to the artificial feeding of the child, and every effort should be made to avoid setting up a catarrh of the naso-pharynx and respiratory system.

12 Case of Primary Sarcoma of the Lung. H. W. Webber.

8. **Perforated Ulcer of Duodenum.**—Smith reports 14 cases. In 9 of these there was a history of preceding digestive disturbance, but in only 3 were the previous symptoms suggestive of duodenal ulceration. Melena did not occur in any case, and hematemesis occurred in only one case. In most instances the perforation took place while the patient was at work—in 2 cases while lifting a heavy weight. The characteristic sudden severe pain in the abdomen was the initial symptom of perforation in every instance. The pulse rate at the time of examination in 10 cases was from 100 to 144, in 7 of these over 120. Smith regards the following as important localizing symptoms: 1. The history may suggest duodenal ulcer; 2. the localization of the original pain of perforation to the right hypochondrium; 3, symptoms referred to the right side of the abdomen and most marked in the appendix region, but with a definite history of onset in the right hypochondrium.

In 2 cases the ulcer was excised; in 4 cases it was sutured; omental grafts were made use of in 3 cases. In 7 cases general and profuse irrigation of the peritoneal cavity with hot normal saline solution was employed. Of these 7 patients, 5 recovered. In 4 cases the peritoneal cavity was mopped out with moist swabs. Of these 4 patients all died. In none of the cases was drainage dispensed with; in 4 it was suprapubic and epigastric; in 5 it was suprapubic, epigastric and right lumbar; in 2 it was epigastric only. Of the first set, 2 patients recovered, but one of these had to be drained in the right lumbar region after a few days. Of the second set 3 patients recovered. Of the last set none recovered.

9. **Erythema Scarlatiniform and Scarlet Fever.**—Beard and Barlow direct attention to three important points in the differential diagnosis of these two affections: 1. The very early onset of desquamation; 2. the desquamation taking place while the erythema is in the florid stage, and, 3, the erythematous base observed after desquamation and which remains for some time, with its peculiar glistening and greasy appearance.

19 *Operative Treatment of Fractures, Introducing Some Original Methods of Bone-union by Simple Mechanical Means. R. G. Anderson.
20 Occupation for Soldiers in Hospital. E. C. Freeman.

19. **New Method of Bone Union.**—The methods described by Anderson involve the use of simple contrivances and obviate the necessity for drilling bone and using wire. The contrivances employed are called by him the medullary spike and the bone fracture clamp. They depend for their effect in the one case on the support of the medullary cancellous tissue alone, and, on the other, on the sole support of the compact bone. The medullary spike consists of a double-pointed steel spike, divided by a raised flange into two unequal lengths, each from a quarter to two inches long, and varying according to the necessity of the case, alterations being made, if necessary, during the operation by means of a file or cutters. The fracture clamp is a simple instrument, consisting of two toothed jaws, each formed by the junction of small parallel steel rods, armed at their extremities with sharp spikes, and joined centrally by a free pivot, so allowing their close adaptation to any inequality of surface or variation of position which may be considered advisable. The jaws grasp the bone on either side of the fracture and are placed, one superficially, the other deeply. They are joined by a tension-screw of fine steel, which pierces the pivots and passes directly through the line of fracture, to the obliquity of which it accommodates itself accurately. The tension wire, some three or four inches long, is finely threaded and provided with a minute nut, which can be screwed down, thus clamping the jaws firmly home to any required position, after which any surplus is filed off and discarded. The medullary spike, used by itself, is admirably suited to most cases of transverse or moderately oblique fracture in shafts with a small central cavity. These include all the long bones with the exception of the femur, humerus and tibia, and also in all packed cancellous extremities and in one of parallel bones in which the sound bone acts as a natural splint to its broken companion. The fracture clamps are suited to almost any break, if not too oblique or spiral in direction, and if, in such oblique cases, no more transverse position can be utilized. The method of application of both spike and clamp are described in detail.

23. **Serum Treatment of Dysentery.**—Vaillard and Dopter for years have been making a special study of dysentery and its treatment with a prepared serum. Shiga and Kruse used cultures alone to immunize the animals in making their serum, ignorant of the existence of a soluble dysenteric toxin. Vaillard and Dopter immunize their horses by inoculation on alternate weeks with progressive doses of living bacilli and of the soluble toxin. The toxin is obtained by filtering through porcelain a culture in Martin bouillon kept for twenty days at a temperature of 37 C. The injections are made under the skin at first and later in the veins. The serum of the horses acquires immunizing properties against the bacillus of dysentery and against its toxin. Ninety-six patients with dysentery have been treated with this serum. The number includes 50 with from 15 to 20 stools in twenty-four hours; 18 with from 30 to 80; 24 with from 80 to 150, and 4 with from 150 to 288 stools. All recovered except one patient in the last group. The serum has an almost immediate influence on the local and general symptoms of the dysentery, and recovery is complete in two or three days in the mild and in four or six days in the severest cases. Relapses were observed only twice, and in these instances they occurred the tenth day or third week after the last injection of serum, when its effect was exhausted. Some of the patients had been treated for weeks with calomel, lavage of the intestines, etc., without appreciable effect. The condition changed as soon as the serum was injected and the patients were cured in two or three days. The minimal dose is 20 c.c., injected under the skin, repeated once or twice in the severer cases. Its harmlessness has been amply established.

24 25. **Serum Treatment of Typhoid Fever.**—Brunon reports the results of the use of antityphoid serum in 100 children from 3 to 16 years old. The typhoid mortality in his service with other methods of treatment was 17 per cent., but under serotherapy it dropped to 3 per cent. In the fatal cases the serotherapy had not been applied until the fifteenth, sixteenth and thirty-eighth days respectively. It has an unmistakable action on the disease, modifying and attenuating it as a whole, shortening its duration, reducing the chances for complications, and the mortality.

Josias speaks from an experience with 182 cases of typhoid fever in children and the mortality was about the same as Brunon's, 3.8 per cent. He is convinced that the outlook for a typhoid patient is very much better when the serum is injected as an adjuvant to the usual measures. He confirms its absolute harmlessness.

26. **Technic for Absorbing the Carbon Dioxid in Confined Air.** Gréhant's previous communication on this subject of regenerating vitiated air was mentioned in these columns on page 990. He shut up a dog in a cylinder and in four hours found that the air in the cylinder contained 127 times as much carbon dioxid as pure air, and in eight hours 185 times as much as pure air, or 5.5 per cent. The next day he repeated the experiment, but connected the cylinder with his apparatus for absorbing the carbon dioxid. At the end of two hours the air in the cylinder contained 6 times as much carbon dioxid as pure air; at the end of six hours, 5.6 times, and at the end of eight hours only 5.3 times as much. The proportion of oxygen in the air in the cylinder at the end of eight hours was 13.4 and 14 per cent in these experiments. He thinks that the results obtained warrant the assertion that with his absorbing apparatus and a little extra supply of oxygen, it will be possible for human beings to breathe and to live even in absolutely confined air.

27. **Genesis of Thermal Waters.** Gautier describes his conception of the dehydration of the rocks under the influence of the heat in the center of the earth and of chemical affinities, and the escape to the surface of the water thus formed by volcanic action.

28. **Inflammatory Tuberculosis and Its Localization in Bones and Joints.**—Poncet and Leriche have continued their study of tuberculous rheumatism, mentioned on page 139 of the last volume of THE JOURNAL. The pathologic anatomy of the process, they say, has demonstrated that tuberculous rheumatism is after all merely the osteo-articular form of inflammatory tuberculosis. It has three ways of developing: the inflammatory phase may pass into a condition in which the bone becomes rarefied, or a condition of hyperostosis or of softening of the bone (partial or diffuse osteomalacia). The different types of the joint affections of growing children and of the joint deformities of adolescence are frequently of tuberculous origin. Many vague inflammatory lesions of the bones and joints probably have had tuberculosis as the primary agent. This throws a new light on the large group of surgical affections of the bones and joints in the young approaching or just passing puberty, explained by some writers as tardy rickets, by others as the result of overburdening or overwork. This theory of dystrophy or mechanical strain or overwork, has been advanced for genu valgum, painful flat foot, coxa vara, scoliosis, etc., in short, for all the bone and joint deformations of youth. The conception of an inflammatory tuberculosis readily explains them. The condition called tardy rickets is the result of the inflammatory process, passing through the phases of osteomalacia and then of condensing osteitis. The first phase explains the part played by mechanical causes, the overburdening of a softened bone. The second phase explains the definite fixation of the lesions, their final healing leaving deformity, spontaneously incurable. Any infection may realize this anatomo-clinical syndrome, Poncet remarks, but the tubercle bacillus is alone responsible in the large majority of cases. This inflammatory tuberculosis is generally encountered in the "minimal tuberculous," individuals with latent tuberculosis, often almost impossible to detect, but an early diagnosis is frequently of great importance.

29. **New Glandular Function of the Connective Tissue Cells.** Renaut found nearly two years ago that the fixed cells of the connective tissue are endowed with a secretory activity which seems to confer glandular functions on them. Like the cells of the true glands, such as the parotid and pancreas, they elaborate in the heart of their cytoplasm a large number of granules possessing all the histologic and cytologic characters of the "pro-ferments." The granule grows to maturity in the center of a vacuole. The cell does not throw off these granules as such, but acts like a true ferment-producing gland, and redissolves its segregated granules before excreting the substance. He calls this the "rhagiocrinic function," coining the term from the Greek words for granule and select. Such a connective-tissue cell should henceforth be regarded as a true interstitial glandular cell. The cells in question are spherical, are able to migrate, and are the phagocytes *par excellence* of the connective tissue. Their "rhagiocrinic function" is in evidence in early life, and subsides when the organism has reached maturity. It is not lost, but remains latent until aroused by some irritation or other stimulus. The connective tissue thus forms an enormous gland whose elements can be aroused to glandular activity at any time. These elements pass through the stages of the round, migrating "rhagiocrine," then the fixed "rhagiocrine," then the branching, and then the anastomotic "rhagiocrine," growing more and more quiescent with age. The material secreted by the "rhagiocrines" has certainly some relation to the growth of the connective tissue, as the secretion lasts until the organism has reached maturity and is then suspended. A large number of these connective tissue "rhagiocrines" still persist free in the fluids of the serous cavities, even in the adult. They migrate by their own ame

oid movements, and are not dependent on the circulation. hey retain their extremely active phagocytic properties long fter they have settled down into quiescent fixed cells, incor- orating blood corpuscles and foreign bodies with like avidity. he task now before us, he declares, is to learn the means of imulating and controlling this "rhagiocrinic function." It ay prove of far-reaching importance.

Semaine Médicale, Paris.

32 (XXV, Nos. 12-13.) *La lymphangite pulmonaire cancéreuse généralisée. L. Bard.

32. **Generalized Cancerous Lymphangitis of the Lungs.**—In ie 2 cases described by Bard the condition was a surprise hen discovered postmortem. In retrospectively reviewing the ases, however, he noted certain points which might suggest ie diagnosis when encountered again. The anatomy of the arts allows the isolated and almost simultaneous generaliza- on of the process throughout the lymphatic system in the ings in a way impossible in other organs. Two of the few ases of the condition on record were reported as cases of ppurative lymphangitis, the mistake not being discovered ntil afterward (Raynaud and Troisier). Rapidly progressive, itense dyspnea, without explanatory auscultation findings, in patient presenting evidence suspicious of a cancerous or cerative lesion in the stomach, should always suggest the ossibility of the condition under discussion. In some cases a oncomitant bronchitis masked the specific symptoms. The ondition seems to occur mostly in the early stages of cancer. he rapid diffusion is characteristic of cancer in the young. ll the cases on record were in comparatively young persons, etween the ages of 20 and 35, all males. Bard long ago ointed out that in young subjects cancer seems to have a eculiarly rapid growth with unforeseen complications. It is ossible, he adds in conclusion, that the cases described as galloping cancer" of the lungs or "galloping consumption," ay have included some in which the trouble was this gen- alized lymphangitis secondary to an unsuspected cancer else- here.

45 Prussian Contagious Disease Law.—Das preussische Seuchengesetz vom 28. August, 1905. M. Kirchner.

33. **Hygiene in Prussian Army.**—Werner describes the progress of hygiene in the army and the reduction of morbidity. omparing the year 1873 with that of 1902, the statistics show iat nearly 2,500,000 days of treatment of the sick were ved, and 2,462 lives. In 1873 an average of 31.9 out of every 000 men were sick, while in 1902 the average was only 25.3. he morbidity of typhoid in 1902-3 was .85 in each 1,000 ldiers; in France it was 4.3; in Austria, 1.9, and in Italy, 4.1. he mortality from typhoid during the same period was .09 in russia, Saxony and Wurttemberg; .59 in France; .25 in Aus- ia, and .78 in Italy. The average of venereal diseases during is period was 19.4 in Prussia, Saxony and Wurttemberg; 29.3 France; 57.5 in Austria; 91.5 in Italy, and 122.7 in England. he venereal diseases have diminished in the Prussian army 49 per cent. since 1873, and syphilis by 59 per cent.

37. **Therapy According to Nature.**—In Germany there is an ganization of charlatans who call themselves "Nature heal- ers" and claim to cure by "natural methods," without drugs, and who are rabid in their denunciations of regular medicine. Goldscheider's article shows that all their "natural methods" are part and parcel of regular medicine, and have been for ages, and that drugs also come under the head of "natural" measures under certain circumstances. The lessons learned from experience apply only to the conditions under which the experience was gained. Attempts to generalize these lessons under other conditions are liable to prove disastrous. He summarizes the aims of a truly "natural therapy," "according to Nature," as: 1, Imitation or direct support of the natural healing processes, as in serum and antitoxin treatment and vaccination; 2, indirect support of the natural healing process, as by mechanical measures to relieve ascites, digitalis for a weak heart, sedatives and other symptomatic measures; 3, any measure which directly promotes the natural curative reaction of the healing process is therapy according to Nature. Administration of a drug, digitalis or morphin, for instance, at the proper moment may aid Nature as effectually as any mechanical, gymnastic, hydriatic or dietetic measures. The latter do not exhaust the Nature-supporting measures. It is a mistake to suppose that treatment "according to Nature" must necessarily mean without drugs. Medicines are "Nature"; some of them are actually already component parts of our bodies, as phosphorus, iron, calcium and even iodin. Our food consists of substances that are, some of them, foreign to our bodies. Other ways in which the natural healing processes can be promoted are by general treatment and by guidance and regulation of the natural healing process. The latter may occur with excessive intensity, overshooting the mark, or it may require the removal of disturbing or dangerous by-effects. Fever probably is one of those reactions which overshoot the mark. Therapy has to maintain the interests of the organism as a whole against the one-sided tendency of the natural healing process, or substitute the latter in case of its absence. The natural curative process may die down from lack of response to stimuli, in which case therapy interferes to arouse the reaction anew and to start up the natural healing process again, as by massage, electricity, stretching of nerves, passive congestion, etc. The sixth branch of "therapy according to Nature" is by training parts and organs to vicarious function, as, for instance, by compensatory exercise treatment of ataxia, by transplantation of tendons for paralyses and muscular defects, by gastroenterostomy in case of stenosis of the pylorus, etc. All these measures come under the head of "therapy according to Nature," or "natural methods."

39. **Mercury Lamp for Treatment of Skin and Mucons Membranes.**—Kromayer gives an illustrated description of a mercury and water lamp for phototherapy for which he claims many advantages. Among them is the fact that the therapeutic effect is obtained in one-half the time required for the iron lamp and in from one-third to one-fifth of the time of the Finsen lamp. The area that can be treated is much larger, generally 7 by 7 cm. at a time. The lamp can be arranged so as to throw the light on mucosæ of nose, throat, rectum, uterus, bladder, etc. Its application is convenient for physician, patient and attendant, while the expense is much less than that of the ordinary lamps, as only 4 ampères are required. He has used it with good results in a number of cutaneous affections, including eczema, acne, lupus, obstinate syphilitic lesions and in gonorrhea.

48. **Passive Congestion in Treatment of Acute Suppurative Processes.**—Colley has become a staunch adherent of Bier's method of artificial hyperemia, with which he now has had extensive experience. In order to demonstrate the bactericidal action of the procedure, he made a bouillon suspension of pus from an empyema on the elbow, and to one-half the amount he added some edema fluid. He then injected the fluid into mice and found that the animals injected with the bouillon to which the edema fluid had been added did not become so sick as those injected with the untreated bouillon, and none died. He applied passive congestion to the sound arm, and added some of the edematous fluid thus derived to the bouillon, but was unable to detect any influence on the virulence of the bouillon afterward. These and other experiments have convinced him that the limb separated by the constriction from the rest of the body is the seat of biologic processes of a special kind. The edema fluid in the constricted limb contains antibodies which exert a destructive action on microorganisms and aid in the struggle against the invading affection. It is a familiar fact that similar antibodies are found in the serum of blisters formed by application of tincture of iodin. Colley has also noticed that the inguinal glands on both sides and the axillary on the sound side are liable to swell during the period of constriction. The swollen lymph glands are slightly tender, but conditions return to normal when the constriction is removed. The results of passive congestion are good in all acute suppurations, but really remarkable effects are obtained in puerperal mastitis and in inguinal buboes. In one case of encapsulated appendiceal abscess the patient presented indications of a severe septic affection. Under the diagnosis of septic thrombosis of the portal vein operation was deferred, and he was treated by application of a large Bier aspirating cup between the costal arch and the iliac crest, the vacuum was induced with a syringe. The symptoms subsided and the patient promptly recovered. A few months later the appendix was removed and the man has been healthy since. Colley has also applied the aspirating cup in cases of perimetritic exudates and gonorrheal salpingitis. The cup or jar used is a large one, and the pelvis is always raised. The procedure is not applicable to very stout persons. He has had no opportunity to try this technic in actinomycosis, but anticipates that it will prove effectual. The necrotic plug in an advanced furuncle usually comes out the second or third day of aspiration, but incipient furuncles are aborted in a single sitting. His experience with 9 diabetics was not encouraging; the application of the aspirating cup caused a circle of gangrene, which has deterred him from its use in severe cases. Treatment of eczema with the aspirating jar is a promising field, judging from his experience to date. He has found that the action of the passive congestion was enhanced by warm baths (37 C.-98 F.), except in cases of cutaneous affections. The stimulation to the circulation aids in transporting away the last traces of the passive congestion. The physician who hesitates to try the new method in the clinic can test it on himself first. Its future is as assured, Colley thinks, as that of chloroform, diphtheria antitoxin or herniotomy for incarcerated hernia. It seems to be destined to work as great a transformation in the treatment of acute inflammations as Lister's method of treating wounds.

Herhold describes his experience with 35 cases, summarizing his conclusions in the statement that passive congestion may give extremely fine results, especially in case of felons and furuncles. On the other hand, it is not a general panacea, and it may fail. In case of severe phlegmon, it must be applied with caution and with conscientious supervision of the case. The little apparatus described and illustrated by Mindes is a contrivance by which the constricting band can be tightened or loosened with a key.

56. **Toxin Causing Eclampsia.**—Zweifel's later researches have confirmed his previous conclusions as to the importance of zinc paralactate in the urine of eclamptics as the expression of deficient oxidation. His previous communication on the subject was mentioned on page 545. The main indications are, theoretically, to supply oxygen, but inhalation of oxygen has not proved so effectual as anticipated. He has begun to inject it subcutaneously, and although he has not yet observed much benefit its harmlessness has been established. He has lately been pumping air into the mammary glands, like the veterinarians. He has also tried to make the shallow respiration of the unconscious eclamptic deeper by faradization of the phrenic nerves.

Lockemann describes the technic for examining the urine and organs for zinc paralactate, and also reports the findings in 4 eclamptics. The blood in the umbilical cord contained ten times more of the lactate than the maternal blood in one case. The crystals that formed indicated the presence of some other organic acid besides the paralactate.

57. **Pure Milk Supply.**—Hempel describes the conditions in a model dairy near Dresden, in which milk is obtained under such aseptic conditions that it can be sent to Bremen without ice during the summer, and has been found sweet and pure after crossing the ocean in an ice-box. He gives illustrations of a contrivance which ensures the even mixing of the milk in a pail while avoiding drawing the milk at the surface and that at the very bottom of the pail, where germs congregate most. If the milk is to be sent a great distance during hot weather, it is frozen in a freezer. Quite fresh milk does not suffer from freezing, but milk that is a little old curdles as it melts.

60. **Clinical Test for Fat in Feces.**—Hecht describes a modification of Gerber's acido-butyro-metric method for testing milk, adapted for examination of the feces.

78 *Ueber Pankreas-Cirrhose (bei Diabetes). G. Herxheimer.

78. **Cirrhosis of the Pancreas in Diabetes.**—Herxheimer's communication fills 113 pages and is accompanied by several colored plates. He has had opportunity to examine the pancreas in 36 cases of diabetes, and his conclusions are rather against the "islands of Langerhans theory." He is inclined to accept changes in the parenchyma of the pancreas as the cause of diabetes. Recent research by Karakascheff and Reitmann has converted them also to this opinion. In 5 cases described in detail, the alterations in the parenchyma of the pancreas were very pronounced. They were accompanied also by the efforts at regeneration characteristic of cirrhosis of the pan-

creas. This indicates that not only anatomically, but also physiologically, the essential injury inducing the diabetes must be sought in the parenchyma rather than elsewhere in the pancreas.

79. **Determination of Size of Heart by Roentgen Examination.**—Guttmann recapitulates the sources of error in Roentgen examination of the heart. It can never give the actual largest diameter of the heart with precision, as it shows only the largest diameter presented at right angles to the direction of the rays. Examination from the front, from the side and from above has each its advantages and its drawbacks. Orthodiagraphy is so unreliable that it is the rarest exception when two views taken of the same person under the same conditions exactly coincide. In conclusion, he remarks that it is really of comparatively little importance to determine the true size of the heart. At the most, the increase in the size of the heart determined in a given individual, if the possibility of blunders can be excluded, will allow certain conclusions in regard to diagnosis and prognosis. In every case, however, greater stress should be laid on the changes in the shape of the heart as a whole and of its various parts, and on functional tests.

80. **Transplantation of Non-Malignant Tumors.**—Neumann reviews the history of transplantation of living tissue. The transplanted elements display only a limited growth as a rule. Even the new growth of fetal tissue elements is checked. Scraps of fetal cartilage on a foreign soil follow their organforming tendency, but cease to grow when they have attained maturity. In some instances on record the transplanted tissue caused the production of dermoid cysts, but they remained encapsulated. Transplantation on a foreign soil has an undistakable inhibiting effect on the proliferation of the transplanted tissue. The inhibiting effect is greater the higher the vital qualities of the soil. Transplantation on an atrophic soil allows more prolific growth. The success in transplanting cancerous tumors on mice was obtained only on animals of the same species. Even the slightest racial difference was enough to prevent the proliferation of the transplanted elements. It has proved impossible to transplant the Jensen mouse tumors from Copenhagen mice on mice in the Berlin Cancer Research Institute, although they belong to the same species. Lanz has been most successful with transplantation of nonmalignant tumors. On the whole, Neumann concludes, transplanted non-malignant tissue is capable of a certain moderate growth, but sooner or later it retrogresses as a rule. In not a single instance has it been found possible to cause the development of an affection with malignant characteristics from transplantation of non-malignant tissue.

82. **Determination of Albumin in Blood.**—Deycke and Ibrahim have modified the Denigès cyano-argentimetric method of determining the albumin in the urine and applied it to the blood. The results have been so constant and the method permits of such precision that they recommend it in high terms after several years' experience and hundreds of tests on 56 patients. The principle of the test is that the albuminoids in the fluid are found and precipitated by a given amount of a potassium-mercury-iodid solution in the presence of acetic acid. They are precipitated in the form of mercury albuminate. In the filtrate, free from albumin, the loss of mercury from the formation of the mercury albuminate is determined in the albumin-free filtrate by the Denigès silver-cyanid method. It was found that the proportion of albumin in the blood was the same as the proportion of hemoglobin. This allows the exact amount of hemoglobin in the blood to be expressed in absolute figures instead of merely in percentages. The details of the simple technic are given in full, with summaries of the 56 cases tested.

83. **Thyroid Treatment of Obesity.**—Rheinboldt describes experiments with dogs showing the remarkable efficacy of thyroid extracts in reducing weight. The by-effects of thyroid treatment have been most numerous in the past when it was applied in obesity, as it is in this that abuse of the preparation is most common. Some of the symptoms observed have evidently been the result of damaged goods, the syndrome suggesting that of sausage poisoning. These mishaps are growing constantly rarer, as the thyroid is not being used so much in its natural form. Under thyroid treatment, he continues, efforts must be made to insure abundant feeding, especially with copious amounts of albumin. The treatment of obesity is favored by undertaking it during a period when the organism, on account of preceding under-feeding, is inclined to take up more albumin than usual. He will report later his experiences with patients treated on these principles.

86. **Sphygmo-Cardioscope.**—The apparatus described shows on a dial the relative behavior of the pulse, heart-action and sounds, as a demonstration of the physiology of the heart and vascular system in their inter-relations. It is designed particularly for teaching purposes, and a reproduction of the dial can be used for a lantern talk.

87. **Mercurial Inunctions and Their Action on Urinary Organs.** Klieneberger describes the findings in 37 cases after mercurial inunctions. They prove that this method of treatment is not so harmless as generally supposed. Changes in the urine develop almost constantly and are due to the action of the mercury on the secreting parenchyma of the kidneys. As this effect occurs early and after small doses, when manifest albuminuria develops the kidneys are already severely affected and general mercurial intoxication installed. As mercury is such an efficient remedy, we can not dispense with it, he adds, but we should not give it for a long time and without sufficient grounds in chronic nephritis, and even in that case it should be suspended if indications of serious albuminuria develop and casts are found in the urine.

88. **Microscopic Stagnation as Sign of Cancer.**—Ziegler announces that the first and sometimes long the only symptom of cancer in the lesser curvature of the stomach is the discovery of minute remnants of food at a time when the stomach should be empty. Even apparently normal macroscopic motor functions should not overshadow the importance of this sign of cancer in the lesser curvature. The microscopic findings to be conclusive should be repeated at various times and under various conditions. In 2 instances he made a positive diagnosis of cancer of the lesser curvature on this basis alone, contrary to the opinion of the consulting physician. In another case, for the same reason, his diagnosis was incipient cancerous degeneration of an old gastric ulcer in the lesser curvature. No other sign of cancer could be discovered. In these and in other cases the laparotomy confirmed the exactness of his diagnosis. This retention of microscopic relics of the stomach content is characteristic of cancer when, after evacuation of the stomach of the macroscopic remains of the food, microscopic relics persist to the next ingestion of food, not merely for an hour afterward. This daily finding persisted for months in certain patients. The retention is to be distinguished from the old conception of stagnation of stomach contents not only quantitatively but qualitatively as well. As a rule, it

is not even the precursor of the other. In the limited and persistent form to which Ziegler refers, it occurs only under certain conditions, that is, when part of the stomach wall in the lesser curvature or in its vicinity has become rigid by induration and lost its power of peristalsis. This is always the case in malignant disease. The presence of lactic acid bacilli is an early sign of retention, even of these microscopic amounts. Their resistance to lavage of the stomach is another important point for this indirect diagnosis of cancer. In late years his examination of cases of cancer of the lesser curvature has confirmed more and more the great diagnostic importance of the finding of these bacilli when the motor functions of the stomach are still apparently intact. In patients whose stomachs were apparently free from food at latest two and a half hours after a test breakfast without milk and seven hours after a test meal, he examined the stomach an hour or so later and again the next morning fasting. The little mass of mucus found in the opening in the tip of the sound was then examined under the microscope. These few mucous drops contain the evidences of the microscopic stagnation. They are examined for bacilli, for grains of starch, fibers of meat and droplets of fat. Leucocytes are also liable to be present, and suggest the point where the stagnation of the microscopic relics takes place. These findings can be encountered for weeks and months, without other symptoms, if the cancer does not happen to develop toward points where characteristic symptoms must follow. In his typical cases of this isolated microscopic retention there were no traces of blood, no tumefaction, cachexia, ascites nor glandular swelling. At most, only a family tendency, anemia and the peculiar pain in the back were observed. The microscopic stagnation persisted unmodified, even after rinsing the stomach with an infusion of tea or hops or a solution of silver nitrate. In non-cancer cases there is none of this microscopic retention. The stagnation is either macroscopic or entirely absent. The lactic-acid bacilli are also readily banished by one or two rinsings of the stomach. Their resistance to rinsings is characteristic of a malignant process.

90. **Influence of Pancreatic Juice and of Bile on Intestinal Digestion.**—Brugsch concludes his extensive monograph with the statement that processes affecting the functions of the pancreas and reducing the output of pancreatic juice diminish the absorption of fat in the intestines, but scarcely affect the splitting of the fat. He found, further, that uncomplicated exclusion of the bile was accompanied by a loss of about 45 per cent. of the fat in the stools. Consequently, if a larger proportion of fat is lost, it suggests participation of the pancreas in the trouble causing the icterus. When the pancreatic juice is shut off and the bile nearly so, from 80 to 90 per cent. of the fat is lost. The average loss of nitrogen in uncomplicated icterus is about 11 per cent., but when accompanied by a pancreatic affection, about 33 per cent. The carbohydrates are well utilized in cases of pancreas affections. Accelerated peristalsis in the small intestine is liable to entail a loss of fat up to 40 per cent., even when the secretion of bile and pancreatic juice is normal. Catarrh of the small intestine also hinders absorption of nitrogen and fat. When the proportion of dried stool is over 30 per cent., it should arouse suspicion of disturbance in the absorption of fat. The proportion of fat in the dried stools in case of icterus may amount to 80 per cent.; the average in case of a pancreatic affection is 60 per cent. In case of considerable loss of nitrogen the percentage of fat can drop still lower, and hence the proportion of fat in the stools should not serve alone as a sign of a certain disturbance in the absorption of fat. He adds other conclusions from study of diabetics and of dogs after removal of the pancreas. He did not find any essential difference in regard to the absorption of fat and nitrogen in man and in dogs after exclusion of the pancreatic juice. The particulars of his research on 15 patients are given in detail.

96 *Forme anatomiche e cliniche della cirrosi biliare. C. Alessandro.

93. **Antibacillary Serum in Experimental Tuberculosis.**—Liviérato has been treating animals with an aqueous extract of living tubercle bacilli. Their serum acquired antibacillary properties with little antitoxic power, but it agglutinated when diluted 1 to 2,000. About 1.5 mg. of living, virulent tubercle bacilli, all from the same culture, with 1 c.c. of salt solution were put in small collodion sacs. The sacs were then placed between the loops of the intestine in guinea-pigs, one in each animal. The animals were then separated into three groups: the first group received no treatment, the second group was treated with serum from tuberculous patients, and the third group with the prepared antibacillary serum. The latter displayed marked curative power, preventing the development of the experimental tuberculosis in the animals and killing the bacilli in the test tube. The serum of tuberculous patients failed to show any curative action.

96. **Types of Cirrhosis of the Liver.**—Besides the types usually observed, Alessandro has encountered cases of cirrhosis of the liver with chronic icterus, slight hypertrophy of the liver and enormous hypertrophy of the spleen. He reports such a case and also one of still another type of cirrhosis of the liver. In the latter the liver is of normal size or slightly smaller than normal, and the spleen is also normal, but the kidneys are the seat of severe and constant lesions, the result of the severe and chronic icterus. Alcohol probably aids the development of this type also. The case he describes was in a mechanic of 49, addicted to liquor. The influence of the alcohol in these cases is like that of the typhoid toxins in the cases of cirrhosis of the liver following typhoid fever. The long interval that may elapse before the first symptoms appear is not an argument against this etiology, as osteomyelitis and gallstones may likewise remain latent for a long time. In one such case the biliary symptoms developed almost at once, while the cirrhosis did not manifest itself until nine years later. Agglutination was positive, even at the tenth year.

THE EXTENT AND LIMITATIONS OF THE POWER TO REGENERATE IN MAN AND OTHER VERTEBRATES.*

T. H. MORGAN, PH.D.

NEW YORK CITY.

About the middle of the eighteenth century great interest was aroused in the power shown by certain animals to replace lost parts. The remarkable work of Trembley, Bonnet and Spallanzani made known some of the principal results with which we are familiar to-day. Many new facts have also been discovered since their time, but despite the fundamental importance of the phenomena of regeneration, little is known at present in regard to the physiology of the process. Nevertheless, a beginning in the study of the physiology of regeneration has been made, and I invite your attention especially to some of the more general aspects of this side of the problem.

In this connection I should like to discuss also the question why certain animals seem to lack the power to replace lost parts; and since man himself belongs to this class, the meaning of the fact is of direct and, perhaps, even of practical importance to us; for if we could determine why man does not replace a lost arm or a leg, we might possibly go further and discover how such a process could be induced by artificial means.

It has seemed to me that regeneration is only one phase of the general phenomenon of growth. If this is the case why does an animal that has ceased to grow begin to regenerate with great rapidity when a part is removed? If we turn the question around the other way and ask, why does an animal stop growing when a certain size is reached, we may attack the problem at closer quarters.

WHY DOES AN ANIMAL STOP GROWING?

In the first place, an animal stops growing not because its cells have lost their power of further growth. This much seems certain; for, if a part is removed all the cells at the cut surface begin to grow again. Moreover, this new growth does not take place as some writers have assumed from reserve cells, but from the formed tissues of the old parts. We must conclude, therefore, that in many, perhaps in all, animals, the cells, with possibly few exceptions, still possess the power of further growth. In fact the cells seem to have limitless powers in this direction, and something in the body must restrain their activity after a certain size has been reached. What is the nature of this restraint? What retards the development as the size approaches that of normal for the animal?

It has sometimes been assumed that growth is retarded or stopped because the animal can digest only so much food, and that the adult size is the stage of equilibrium between the amount of food digested and the amount of food used up. Now if this assumption is true, we might attempt to test it in the following way: If we remove a part of an animal—a tail or a leg for example—the remainder of the body ought to grow larger, because the food that went to nourish the part removed can now be utilized by the rest of the body. Suppose, for example, that we cut off the tail of a salamander, we would expect, if this view is correct, that the animal would increase in weight by just as much as the weight of the tail removed. As the new tail grows out the whole weight should remain constant; for, what is added to the new tail, day by day, must be lost by the rest of the body. In other words, after the operation the weight should increase rapidly to what it had been before, and then hold its own as the new tail develops.

I have recently carried out an experiment of this kind. The results are given in the accompanying table. Two sets of salamanders were weighed; in one set the tails were amputated and the animals were again weighed. The other set was kept intact as a control. Both sets were kept under the same conditions, and fed exactly the same amount of food. This is possible in the species that I have used, because the animals can be fed by hand and the amount of food thus regulated. As the table shows, the amount of food given at first did not cause an

increase in weight in the check set, but the tailless animals increased in weight and in a week had made good the weight loss in the tails. They also continued to gain weight more rapidly than the check set.

It should be noted that the animals were in an underfed condition when the experiment began, and the difference in the rate of increase in the two cases may not represent what an animal might do that had already reached its maximum size. I have repeated the experiment on the same salamanders in a well-fed condition and have not always found the same difference noted in the preceding case. Since these animals have no definite upper limit of growth, they proved to be not well suited to test the question, although the greater initial increase in the tailless set may, in part, be due to the absence of the tail. The most interesting outcome of the experiment was that the increase in size is not due to the storage of fat, but to growth in all of the organs of the body. It might be supposed that the regeneration of a new part is due to the temporary increase of available

* A lecture delivered before the Harvey Society, New York City.

food, owing to the loss of the old part, but that this is not the explanation is shown by the following experiment: If we amputate the tails in two sets of animals, and starve one set and feed the other, we find that the rate of growth of the new tail is nearly the same in the two sets. After two months the starved animals are greatly emaciated, but the length of their new tails is *almost* as great as that of the well-nourished individuals.

In other words, the new part grows at nearly the normal rate while the rest of the animal is starving to death. Clearly, then, the power of regeneration is not determined by the amount of food digested. It is due rather to the greater assimilative power of the cells of the new part.

In this connection another curious fact should be mentioned. It has recently been shown by Zeleny, for the crayfish and for brittle-stars, that the greater the number of legs or of arms removed the faster each one grows. If one leg is removed it regenerates at a given rate; if two are removed each regenerates faster than when only one is absent, etc. This result recalls Pflüger's celebrated teleologic law; that in living beings the cause of every need is at the same time the cause of the fulfillment of the need. For example, lack of food causes starvation, and the starvation is the cause of the appetite that leads the animal to search for food.

I do not care to advocate this view, but simply to call attention to the neatness with which it covers the case of regeneration just given. The scientific explanation must be sought in some other direction. Zeleny has discussed the question whether his results may not be due to the amount of food. A certain amount of material is required to nourish a leg. If we remove the leg a surplus is present. If we remove two legs so much more surplus is present, which can go to nourish both new legs, and for a time both may grow faster than when only one leg is removed. If this were the real explanation of the increased rate of growth when more legs are removed it would follow that a starved animal would replace the two legs more slowly than a well-fed animal would replace one leg. I tested this possibility. One, two or three legs were removed from my salamanders. One set was starved, the other fed, and the individuals in the two sets compared. Little or no difference between the two sets could be detected; hence, I conclude that the result is not primarily one of food supply.

DIFFERENCE IN THE RATE OF REGENERATION.

Perhaps the most important facts bearing on the problem under discussion are those connected with the rate of regeneration at different levels. If the tail of a fish is cut off near the base the new part grows faster than when the tail is cut off near its outer end. The new tail may be replaced as soon when much is cut off as when less is cut off. The result is independent of food, for it takes place in the same way whether the fish is starved or fed. This relation between the rate of growth and the amount removed is found to occur in widely different groups of animals. King has shown in the starfish that when an arm is cut off near the base the new arm regenerates faster than when the arm is cut off near its tip. In the earthworm the results are the same, for the posterior end at least. If a few segments are cut off from the posterior end they regenerate with extreme slowness. If the worm is cut in two in the middle a very large number of segments regenerate; if the worm is cut in two further forward, behind the girdle, a still larger number of segments is regenerated in the same time.

What is the cause of this difference in the rate of regeneration at different levels? I am not certain that I can answer this question, but I should like to call attention to a remarkable agreement between this result and the normal process of growth. Growth is much greater in youth than in adolescence, and becomes less and less as the adult size is approached. We find this same relation in the newly-regenerated part. It grows less rapidly the nearer the cut surface is to the complete form. It seems, therefore, not improbable that whatever regulates the rate of growth of the animal as a whole also regulates the growth of the regenerating part.

Some writers believe that regulative processes in general are due to a vitalistic principle resident in living matters. In fact, the whole regenerative process has sometimes been referred to a mysterious formative or completing force, but so long as we do not know anything about such a force we gain nothing and lose a great deal. I think, by ending our search in such an empty phrase.

There is at least one physical possibility which in some form or other may explain the regulation of the growth process. Our problem, you will observe, seems to have narrowed itself down to determining an inhibitory factor, since we have assumed that the cells of the body possess unlimited possibilities of growth if given a suitable environment. It seems to me not improbable that the inhibition is caused by a definite response to a condition of mutual pressure or tension of the cells on each other. When this condition is reached further growth comes to an end. When we alter this particular pressure by removing a part, growth begins again.

What the nature of this pressure may be I can not say, nor how the cells respond to it, but taking all the facts into account, this assumption may at least give us an escape from the assumption of a formative force. Indeed, the formative force itself is nothing more, if my view is correct, than the response of the cells to the pressure relations of neighboring cells. The response of the cells to pressure determines their differentiation and the differentiation determines the limitations of the growth process. Thus the adult size of an animal is determined by the differentiation of its cells, and the differentiation is regulated by the mutual pressures of the cells on each other.

I am aware that this view is purely hypothetical and that it may appear somewhat vague, but when we get to the boundary of what is known we must have recourse to provisional hypotheses if investigation is to continue. It is in this spirit that these conclusions in regard to the influence that regulates the growth of new parts are offered.

REGENERATION IN VERTEBRATES.

Let us turn now to the less speculative and purely descriptive side of the problem.

Fish.—Beginning with the lowest group we find that fish have excellent powers of regeneration. The tail regenerates if removed at any level, and in some species even when the end of the vertebral column is also cut off. The lateral fins that correspond to the limbs of higher vertebrates will also regenerate if cut off, as well as the dorsal and ventral fins. In this connection I may recall an elaborate experiment recently carried out on the Pacific Coast. It has been said that salmon return after their sojourn in the sea to the same rivers in which they were born. In order to test this view, V-shaped pieces were cut out of the tail of thousands of individuals of young fish and parts of the dorsal or ventral fin were also cut off. The fish marked in this way was turned

loose in their native streams and their return from the sea awaited. It is needless to point out that the experiment was futile, for whether they returned or not they would regenerate their fins. In order to be sure that these salmon do not behave differently from other fish in regard to their powers of regeneration, I have operated here in the New York aquarium on two of the species of salmon used and have found that they have the power to regenerate the tail, the dorsal and the ventral fins. As yet I have not determined with certainty whether the adipose fin has the same power or not.

Salamanders and Newts.—Salamanders and newts have long been known to have remarkable powers of regeneration. Spallanzani cut off all four legs and the tail six successive times and each time new parts regenerated. He calculated for a single individual that, in all, 647 new bones must have been formed in the course of a single summer. The last time the legs regenerated as quickly as the first.

The eyes also of the salamander regenerate as long as a piece of the optic bulb remains attached to the nerve. In recent years the experiments of Colucci and of Gustav Wolff have attracted much attention. Colucci and Wolff have found that the lens of the regenerating eye does not come from the skin as it does in the embryo, but from the upper edge of the iris. We thus see that an organ may regenerate from a part of the body from which it is never derived in the embryonic development.

One of the most novel of the recent experiments with salamanders is that of Tornier.[4] He has shown how we can produce in the salamander, at will, a supernumerary leg. By cutting through the skin and the muscles at the side of the leg, and at the same time wounding the bone beneath, a new leg develops on the side of the old one. Unless the periosteum of the bone is injured nothing occurs. This shows that the material derived from the periosteum is the most important element in the formation of the new limb, and other results support this conclusion. In still another way a double limb may be produced. If the leg is first cut off and, after the regeneration has begun, a ligature is tied over the new tissue so that it becomes constricted into two parts lengthwise each will produce a new foot. Tornier suggests that the double limbs sometimes found in human embryos may be caused by folds of some of the membranes constricting the limb bud at an early stage of its growth.

Histologic Changes.—At this point I must say a few words about the histologic changes that take place in the regeneration of a new part. The process has been more carefully studied in the tail of the salamander than in any other animal. When the tail is cut off the skin grows over the cut surface in the course of a few days. Those parts of the muscles that lie near the cut end begin to break up. The muscular tissue, as such, disappears, and the protoplasm forms a ball around each nucleus. These are the so-called sarcoblasts, and out of some of them the new muscle-tissue is formed. A little later, or at the same time, the periosteum of the bone begins to thicken, and soon sends forward a cord of cells from the cut end of the bone into the new part. The segregation of the material of this periosteal cord now takes place and the centers of the new bones are laid down. The muscle fibers begin to develop out of the sarcoblasts: the nerve extends into the new structure, and the blood vessels also send out branches into the part. These changes continuing, the elements of the new limb are formed. All these changes must take place synchronously in order that a perfect limb develop. Should any one of the component parts lag too far behind the others a normal product will not be formed. I shall return to this question again.

Tadpoles.—The most striking case of the artificial production of supernumerary parts is that which Tornier has recently described for the tadpole of the frog. By a suitable operation a frog with four or even with six hind legs can be made. The method of operating was as follows: Young tadpoles were selected in which the beginnings of the hind legs were present as small knobs, one on each side of the base of the tail. With a pair of scissors the tail was partially severed at the base so that each leg rudiment was cut into two parts. As subsequent results showed, the blastema of the pelvis was also cut in two by the same operation. In consequence either two pelves developed and four legs, or in some cases three pelves (or their equivalents) and six legs. The results depend on the great powers of regeneration shown by the blastema of the pelvis and legs.

Barfurth has shown that the hind legs of older tadpoles have the power to regenerate, but after the tadpole has changed into the frog this power is rather suddenly lost. It has been generally assumed that none of the legs of the adult frog has the power to regenerate, but I have found that this is not always the case. In two instances I have seen a frog regenerate a new, imperfect fore-leg, but only after several months, and Mr. Goldfarb, who has been working with me, has obtained the same result. This occasional regeneration, imperfect though it be, shows that the power to replace lost parts is still to some extent present in the adult frog, so that it is one of the best subjects for future experiments in attempting to induce regeneration by artificial means. I have already carried out many experiments with this end in view, so far without much success, but enough has been seen to indicate that the quest is far from being hopeless.

Lizards.—Passing now to the higher groups we find that lizards can regenerate the tail, but not the legs. The new tail is imperfect, however, inasmuch as the vertebral column is replaced by only a cartilaginous tube containing a thin filament extending from the end of the old nerve cord. Double-tailed lizards are not infrequently found and can now be produced artificially by making a wound in the side of the old tail.

Birds.—In birds regeneration of new parts is still further limited, the beak alone of external organs having this power to regenerate if broken off.

Mammals.—Finally in the mammals neither the limbs, tail or other external organs have the power to regenerate if lost.

Thus as we ascend the vertebrate scale we find the power of regeneration diminishing.

What is the cause for this loss? Some zoologists seem inclined to believe it to be due to increasing complication of structure, but I do not think this can be the cause. The eye of the salamander is a very complicated organ, and yet it regenerates from a piece only of the bulb. Other zoologists, of whom Weismann is the most noted example, believe that the power to regenerate is something that has been acquired by natural selection in those animals most subject to injury, or in those parts of the body most often destroyed. This view I hold to be utterly erroneous. To give but a single case in point: The eye of the salamander is an organ that is seldom or never injured unless the animal itself is destroyed, yet as we have seen, it has astonishing powers of regeneration. If, then, neither complication of structure nor natural selection will explain why some vertebrates regenerate and others do not, is there any other explanation that can be offered? If, as I think probable,

the power of regeneration is closely related to the power of growth, inherent in the protoplasm, why should this power be lacking in certain forms?

WHY CAN NOT MAN REGENERATE AN ARM OR A LEG?

For several years I have been making experiments and examining this question in various ways. I do not feel that I can give you a satisfactory answer, but the evidence indicates, I think, with some probability, that the failure is due to the fact that the different tissues have very different rates of regeneration. In other words, each tissue in man seems to possess the power to regenerate its kind, but not all at the same pace, hence they fail to co-operate at the proper time to form a new structure. In man the skin regenerates; the muscles regenerate, though less well perhaps; the nerves and the blood vessels regenerate, and the bones even have a not inconsiderable power to mend and even to some extent to regenerate. Hence, as I have said, the failure of the new limb to develop does not appear to be due to the failure of the individual elements to regenerate, but is due to their failure to regenerate concurrently. The bones seem to be the main cause of the trouble, for they produce new material with great slowness.

In this connection it is instructive to observe that in the vertebrate series the failure to regenerate is found in cases in which cartilage begins to change into bone. Within the group of amphibians we find this change taking place. The newts and salamanders, with partly-cartilaginous bones, regenerate readily, and so do the larval frogs, while in the adult frogs, where the bones have become harder, regeneration has almost disappeared. In the lizard the power to regenerate its leg has been lost, but it can regenerate its tail; and the tail vertebræ are less hardened than the bones of the leg.

I do not wish to affirm that this is the only cause of the failure to regenerate in higher vertebrates, including man, but, as I have already said, there is some indication that the main trouble lies in the slowness of the bones to regenerate in time with the other tissues. But if the tissues in man still possess the power to regenerate may we not hope in time so to adjust their rate of regeneration that the replacement of a lost limb may be induced? I can not but think that some day this may be accomplished.

PERFORATION OF DUODENAL ULCER.

OPERATION AND RECOVERY.*

J. H. MUSSER, M.D.

AND

EDWARD MARTIN, M.D.

PHILADELPHIA.

MEDICAL REPORT BY DR. MUSSER.

Patient.—E. C., aged 39, white, American, manager of railroad, was admitted to the University Hospital Sept. 25, 1905, and was in profound shock and suffering much pain when seen by my resident physician, Dr. Keene, to whom I am glad to express my indebtedness for the notes, and the care and skill in attendance on the patient.

Previous Medical History.—For the past nine or ten years the patient has been a constant sufferer from "gastric hyperacidity." During this time he was under constant medication and restricted diet. Five years ago he was operated on for appendicitis.

History of Present Illness.—For five days before admission to hospital he suffered severely from gastric hyperacidity and vomited several times during the day, the vomitus consisting chiefly of highly acid mucus. He obtained relief from alkalies, such as sodium bicarbonate. The day he was admitted to the hospital he was feeling better, and at 12 o'clock, for luncheon, he ate a squab and a plate of soup, and drank a quart of apollinaris water, which is more than he had taken since the onset of this recent attack. He felt perfectly well until 5 o'clock on the evening of admission, when, on attempting to enter an automobile, he was suddenly seized with agonizing epigastric pain, so severe as to cause him to scream and to double him over. He was taken at once to a drug store, where sodium bicarbonate was given, but without relief. He then came to the hospital, about forty-five minutes after the onset of the attack. During the day he had had a good bowel movement resulting from hunyadi water taken in the morning.

Condition on Admission.—At 6 p. m. temperature was 97; pulse, 72; respiration, 24. He was pale, markedly dyspneic and suffering intense abdominal pain, chiefly in the epigastrium; the pain was also referred to the back, between the shoulder blades, and to the right shoulder. The pain was so severe that it was impossible for him to lie quietly, causing him to toss from side to side in bed, with the knees drawn up. On account of increase in pain it was difficult for him to breathe, and impossible for him to take a long breath.

Examination.—On examination the abdomen was found to be markedly scaphoid in shape; extreme general and cord-like rigidity were present. Not a click of peristalsis could be heard. Tenderness was more or less general over the whole abdomen, but the point of most acute tenderness was about the size of a dollar, situated in the right midclavicular line, just below the costal margin, where even the slightest touch would cause agonizing pain. If any difference could possibly be differentiated, rigidity was more marked in this locality.

Preliminary Treatment.—After the examination was made morphin 1/4 gr. and atropin 1/150 gr. were given, and in about five minutes the patient was seized with vomiting, which was gushing in character, very profuse (about three pints), and consisted of undigested food and clear mucus, with no microscopic blood. The pain was relieved somewhat by vomiting, and the man was able to breathe more deeply. In about forty-five minutes the anodyne had relieved the severe pain and he was much more comfortable. He had no more attacks of nausea or vomiting until 10:30 p. m., when he again became nauseated, but could not vomit, and the epigastric pain began to reassert itself. During the entire time the rigidity remained the same, and peristalsis could not be elicited. Simple enemata were given, but were ineffectual; under the opiate general abdominal tenderness seemed largely to subside, and the point of acute tenderness shifted a little to the left.

Examination of Gastric Contents.—On examination of the gastric contents no blood was present to the naked eye or revealed by the occult blood test. The gastric contents were highly acid, but not of a foul odor.

Blood Count.—At 8 p. m., r. b. c., 11,200; at 9. p. m., r. b. c., 16,000; at 10 p. m., r. b. c., 14,680.

Temperature, Pulse and Respiration.—At 6 p. m. temperature was 97.1; pulse, 72; respiration, 24. At 8 p. m. temperature was 98.2; pulse, 90; respiration, 22. At 10 p. m. temperature was 99; pulse, 108; respiration, 24.

Diagnosis and Operation.—The diagnosis of duodenal ulcer was made, and an operation was performed at 11 o'clock by Dr. Martin. An ulcer was found on the posterior wall of the duodenum, just beyond the pyloric orifice of the stomach. The perforation was about the size of a pinhead. There was extensive peritonitis.

The operation of inclusion with fastening of the omentum over the ulcer was done. The inflammation of the peritoneum was too violent and progressive to admit of prolonged operation. (See the remarks of Dr. Martin.) A rapid recovery followed, and to this day (February 1), the patient is without symptoms.

These facts present all the features of the case up to the time of operation. In review, it may be said that I saw the patient about 6:45 p. m. on the day of admis-

* Read before the College of Physicians, Philadelphia.

sion. There was evidently commencing peritonitis due to perforation of some hollow viscera, presumably the duodenum. Time for further brief observation to note the progress of the pulse, the temperature and the leucocytosis was admissible. Hourly reports were given me, and at 10 p. m. I requested Dr. Martin to see him with me and, if he concurred, to arrange for operation.

The diagnosis of duodenal ulcer was made because the pain during his many years of suffering did not take place immediately after food, indeed was often relieved by food; because hematemesis was absent; because there was no vomiting after food, and because of the location of the greatest pain, tenderness and rigidity.

The diagnosis of perforation was based on the history of the case and the mode of onset of the acute symptoms, pain and shock, the situation of the greatest tenderness and rigidity, the pain in the back and the occurrence of acute peritonitis. The pain in the back indicated a posterior perforation. The dyspnea was apparently due to an overloaded stomach and to pain and rigidity.

The diagnosis of peritonitis was made because of the presence of a very probable cause, i. e., perforation of some hollow viscera, because of the local and then diffused pain, the rigidity, the progressive rise in the temperature and pulse and the leucocytosis.

The interesting feature of the case is the fact that if there ever was a person whose gastric symptoms might have been deemed a neurosis this patient was of such type. He was of neurotic temperament; his business invited such a state; he smoked to excess, was accustomed to the use of stimulants and led a social life not conducive to an equanimity of function proper for digestion. At no time were there any objective signs to suggest ulcer. The character of the stools had not been studied before the onset of acute symptoms, and hence no statement can be made as to the occurrence of intestinal hemorrhage. It is true the hyperacidity from which he suffered was in all probability the causal factor in the production of the ulcer, and this, in turn, might have been the product of a neurosis. Against a neurosis his habit of indiscretion and heedlessness as to the mode of eating, time of eating and character of food count for much, so unlike the timid, finicky and apprehensive neurotic subject.

Because of the absence of the symptoms of lesion it behooves one not to put too much stress on the other leg and to allow temperament to be too serious a factor in diagnosis. The same may be said of the duration of the disease. Long duration does not rule out organic lesion.

I have had the privilege of reporting to the college two other cases of perforation of duodenal ulcer with operation and recovery. The first patient was operated on by Dr. Wharton Dec. 18, 1900. This patient is in excellent health, free from gastric symptoms and of greater weight than ever. The operation of inclusion was done. Much the same may be said of the second patient, a woman operated on by Dr. W. W. Keen Nov. 26, 1903. She has no gastric symptoms and is much heavier than before the operation. Dr. Keen sewed up the ulcer and performed a gastroenterostomy with a Murphy button. Somewhere within the abdominal cavity that button still lingers. There is every indication that it is in close proximity to Nature's button and that it makes itself known, notwithstanding the incompatibility of age, by those sensations which are not incomparable to those of the expectant mother.

SURGICAL REMARKS BY DR. MARTIN.

The accurate diagnosis made the surgical procedure in the case comparatively simple.

Of all the symptoms the one which most clearly indicated the need of immediate operation was the increasingly rapid pulse, which in four hours had run from 72 to 108. The leucocytosis was not progressive. The perforation was found without difficulty and was bathed in stomach contents, which had gravitated mainly downward and to the right into a pocket formed by adhesion of the cecum and ascending colon to the parietal peritoneum in front. Into this pocket a drainage tube was passed through the loin and from it drained about an ounce of turbid mucus. Thereafter there was no further discharge from this tube.

At the seat of ulceration there was a ring-like induration about the entire duodenum, forming a distinct stricture. Inversion of the opening was readily accomplished by Lembert sutures, the line of which was further reinforced by a strip of omentum. There were no signs of adhesive inflammation even on the part of the omentum, nor were there evidences of extravasation downward and forward into the pelvis.

A drainage tube was carried to the region of the foramen of Monro, and the wound was closed by large sutures.

Barring an attack of left-sided pleurisy, which strongly suggested an inflammation at the lesser omental cavity, convalescence was uneventful.

FRACTURE OF THE ALVEOLAR PROCESS OF THE RIGHT SUPERIOR MAXILLARY BONE.

WITH REPORT OF A CASE.

WILLIS E. HARTSHORN, M.D.
NEW HAVEN, CONN.

Fractures of the superior maxillary bone may involve the body, the nasal process, the malar process, the palate process or the alveolar process. They are comparatively rare, and for this reason a report of a case of fracture of the alveolar process which recently came to my attention may not be out of place, especially as the employment of the interdental splint and its advantages over other methods of treatment is well illustrated.

ETIOLOGY.

This class of fractures is almost always due to direct violence, a bad fall, a severe blow on the face, a gunshot wound or some other source of direct traumatism. The superior maxillary bone is well protected by the forehead, malar boue and lower jaw, making it less liable to injury than other more prominent portions of the body. The most exposed process of the bone is that including the alveolar margin. This is, therefore, the point where partial fractures most frequently occur. Next to this come fractures of the nasal process in connection with injuries to the nasal bones, fractures caused by dentists in the extraction of teeth and those occurring in operations for the relief of diseases affecting the maxillary sinus. von Bergman says:

The most frequent form of complete fracture is the transverse one. This usually runs backward into the pterygoid process. It results from a severe blow on the face from before backward, beneath the nostrils in the median line or somewhat lateral to this. The entire vault of the mouth with the teeth may be detached and displaced posteriorly. In very marked dislocations the posterior margin of the palate may

even rest on the posterior pharyngeal wall and obstruct the pharynx. Fissuring and splitting of the palate bones from before backward are not uncommon accessory injuries.

The body of the bone rarely fractures. In case the fall is from a height, a vertical line of fracture may occur or even a separation between the two bones. Following a blow from below upward on the upper jaw or from the side, a different type of lesion results, the line of fracture being guided largely in the direction from which the blow comes.

The entire alveolar margin may be detached if the direction of the force is lateral or oblique from above downward and a portion of the body of the bone may be broken off at the same time.

Observations by various authors on the effect of a blow directed from below upward seem to be very limited.

Regarding a severe bilateral injury, von Bergman says:

The entire median portion of the bony face may be broken off along a fracture line which runs from the nasal apertures toward the orbit, then circumscribes the malar bones and finally fractures the pterygoid processes at their base.

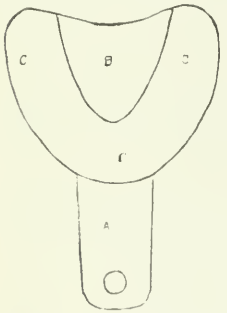

Fig. 1.—Dental impression plate. A, handle which was removed; B, v-shaped portion which was removed; CCC, grooved alveolar margin.

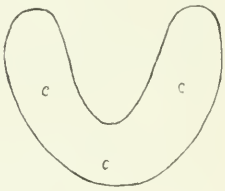

Fig. 2.—Dental impression plate as illustrated in Figure 1, without handle and with v-shaped section removed from the palate portion. Used as a temporary splint after filling the grooved alveolar margin, CCC, with dental modelling composition.

DIAGNOSIS.

This is usually easy, especially in fractures involving the alveolar process. A displacement of the teeth is almost always present. There is mobility of a portion of the alveolar arch, a bloody space between the teeth at the point of fracture, ecchymosis, swelling, crepitation and hemorrhage from the lacerated tissues if the fracture is compound. Pain and tenderness when the patient attempts to use the teeth is a prominent symptom. Emphysema of the soft parts may be present if there are comminuted fragments involving the nasal process with laceration of the mucous membrane. Pressure on the inner plate of the pterygoid process causes pain, and in extensive fractures is reported to be diagnostic.

PROGNOSIS.

The prognosis is generally favorable, even when the fracture is comminuted. Very severe injuries cause remarkably little deformity. Necrosis is very rare, as the alveolar process is thin and covered on both sides by periosteum. When this is removed on one side the other affords the necessary nutrition. Extensive fractures generally unite in from eight to ten weeks, though most dentists who do surgical work advise leaving the interdental splints in place for a considerably longer period. The time, however, depends largely on the severity of the lesion. Fragments of bone and loosened teeth should not be removed, as they soon become fixed in place.

TREATMENT.

The following case will best illustrate the treatment recommended:

Patient.—Male, aged 22, a barber by trade. On Sept. 12, 1905, while riding his wheel he was run into by another wheelman and thrown violently to the ground, striking on his face and receiving a fracture of the alveolar process of the right superior maxillary bone. He was unconscious for a short time after the accident. Owing to a severe attack of tonsillitis the patient did not seek surgical treatment until ten days after the injury, at which time the case first came under my observation.

Examination.—Examination showed contusions of the face and a fracture of the alveolar arch of the right superior maxillary bone, extending laterally from the median line to and including the first bicuspid on the right side. Posteriorly it extended for a distance of three-fourths of an inch. The fragment of bone was entirely separated from the body of the

Fig. 3.—The permanent splint in place.

superior maxilla and freely movable, rendering that portion of the jaw useless. The alveolar margin of the fragment was displaced downward for about one-quarter of an inch in the median line.

Treatment.—The treatment at first was unsatisfactory, but deserves mention as being easy and convenient. A dental impression plate of aluminum (Fig. 1), which could be easily molded to the form of the upper jaw and which can be obtained from any dental supply house, was carefully adjusted to the alveolar border, extending from the last molar tooth on the right side to the last molar on the left. This was accomplished by removing the handle of the plate and cutting a V-shaped section from the palate portion, leaving simply the grooved alveolar margin to act as a splint (Fig. 2).

Chloroform was then administered to the patient and the fracture reduced by constant, strong pressure brought to bear against the displaced alveolar border in the direction of the long axis of the teeth, crushing the partly formed callous until the line of the teeth was exactly even. The splint was then filled with dental modeling composition No. 2 and applied forcibly against the teeth, forming a firm interdental splint. This was removed once, the deformity corrected by filling in with modeling composition the cavity made by the displaced right central incisor, allowed to harden and then reapplied.

The splint, with a moderate amount of adjusting, held firmly in place for two weeks, but did not reduce the deformity satisfactorily, caused the patient a good deal of discomfort and also gave rise to a very considerable gingivitis. At the end of this time is was removed, another of aluminum applied and secured to the teeth by dental cement instead of the modeling composition before used. The method employed was as follows: By means of an impression plate and modeling composition a mold of the entire upper alveolar arch was taken. This mold was then removed from the mouth and a plaster cast made from it in the manner usually employed by dentists in making a plate. This showed exactly the amount of displacement of the fragment. This displacement, as represented in the cast, was reduced by cutting the cast vertically at the point of fracture and cementing the two portions together in the normal relation.

A zinc die was then cast from this and a thin sheet of aluminum, 26 gauge, B and S in thickness, was modeled exactly to fit the die and hammered firmly in place with the aid of a counter die of lead. The patient was again placed under chloroform, the fracture completely reduced by pressure, the aluminum splint forced firmly on the teeth and held in place by dental cement. Figure 3 is from a photograph of the patient with the permanent splint applied. The splint has been worn since without the slightest discomfort and the deformity so nearly reduced as to be hardly noticeable.

German silver or gold may be substituted, if desired, in place of aluminum, but German silver becomes corroded very quickly and gold is too expensive.

With the interdental splint the patient can eat solid food without difficulty and enjoys no more discomfort from its presence than is usually noticed in ordinary bridge or crown work.

The aid of a dentist is required in making and fitting the splint, which must be left in place from two to three months and should fit closely, but not extend so far toward the roots of the teeth as to irritate the gums. This splint can be used with equal advantage in fractures of either the upper or lower jaw.

PROPRIETARY MEDICINES.

SOME GENERAL CONSIDERATIONS*

GEORGE H. SIMMONS, M.D.
CHICAGO.

PROPRIETARY MEDICINES.

A proprietary medicine is a preparation that is owned or controlled by an individual or individuals. This control is held either by a copyright or trade name, or by a patent. Proprietary preparations controlled by copyright or trade names are generally mixtures, and are often secret or semi-secret in character. It is the name of the article that protects it.

There is no objection to proprietary medicines *per se*, if we are to recognize the commercial rights of those who supply us with medicines. The commercializing of the literature relating to our materia medica, however, —which seems to be necessarily associated with proprietary interests—is against a true scientific spirit and is demoralizing, both to pharmacy and to medicine.

The ideal proprietaries are those that are made so by the manufacturers attaching their own and not a fanciful name to the preparation. For instance, Squibb's ergot is a proprietary preparation, in so far that if a physician prescribe for this preparation he will get Squibb's ergot as surely as he would if it were sold under some fanciful name. So with other articles, whether mixtures or simples, if the maker's name is attached. These are the ideal proprietaries and ought to be encouraged, for this means the encouragement of a high standard of quality.

PATENTED MEDICINES.

Patented medicines are those which are made patent or open; in consideration of the owner making known his methods of manufacture he is protected against infringement of his rights for a certain number of years.

Nearly all patented medicines are chemical compounds "made in Germany;" but, incidentally, it might be said they are not much used in Germany; at least not as much so as in this country. Theoretically, there is no objection to patented medicines; at least, they are not secret, nor is there anything mysterious about them. Practically, they have become almost as much of a nuisance as the nostrums because of their vast and ever-increasing number, and especially because the manufacturers are so extremely anxious to get physicians to prescribe them that they often stretch the truth to the breaking point in the literature describing their value as therapeutic agents.

"PATENT MEDICINES" AND PROPRIETARY MEDICINES.

Proprietary medicines, theoretically at least, may be divided into two classes: those that are sold directly to the public, and those that are put up for and advertised only to the medical profession. The former are called "patent medicines." This is an arbitrary, absurd, and meaningless term, but one that will doubtless continue to be used. The latter, those advertised to physicians, are usually called "proprietaries." But when the Proprietary Association of America, an organization made up principally of "patent medicine" men, discusses the preparations put up by its members, it always calls them "proprietary," and there is no reason why it should not. The fact is, there is no technical difference between "patent medicines" and "proprietary medicines." But it is generally understood that the term "patent medicine" refers to those that are advertised and sold direct to the public; and "proprietary medicines" to those used by physicians. For the time being we are concerned with the latter only.

NOSTRUMS AND ETHICAL PROPRIETARIES.

Every one acknowledges that there are some proprietaries which are fraudulent, or which, for some reason or other, should not be used by physicians. Even those who most bitterly oppose the work undertaken by the Council on Pharmacy and Chemistry acknowledge that there are some proprietaries on the market that are not what they ought to be; in other words, are not "ethical." But what are they, and why are they not "ethical"? Are all of the thousands of proprietaries offered to physicians good and worthy of their patronage? If not, why not?

The fact that we use such terms as "nostrum" and "ethical proprietary" indicates that there are good and bad proprietaries. Would it not relieve the situation if we could agree on some definition of these terms Had we a general understanding of what we mean when we say a certain medicine is a nostrum, or an ethical proprietary, we would be able to discuss matters relating to this proprietary medicine question with a better understanding than is possible under present circumstances. In fact the whole problem rests on what we mean by these two terms. We know that a nostrum is a medicine that should not be used by a physician, and that an ethical proprietary is supposed to be all right. But why?

Nostrum (*noster*) literally means ownership, and thus should be synonymous with proprietary; and when we

* Read in part in a symposium on the Proprietary Medicine and Nostrum Evil before the Chicago Medical Society.

get away from this original meaning we begin to flounder among arbitrary definitions. Webster defines nostrum as "a medicine, the ingredients of which are kept secret for the purpose of restricting the profits of sale to the inventor or proprietor, a quack medicine;" Dunglison as "a secret or quack medicine." The term is certainly one of reproach and is meant as a slur on the medicine to which it is applied. And it is easy to understand how this meaning of reproach came when we realize that, even in the early days, any medicine that was controlled for profit by keeping its composition secret was regarded with disapprobation. Of course, secrecy was then necessary to ownership, as it is to-day with simple mixtures. And no matter how much we may labor to give a different meaning now, our forefathers considered any medicine a nostrum whose ownership was controlled by keeping its method of manufacture secret. This definition would be considered too narrow to-day; we must be satisfied if the ingredients and their quantity are given; the details of manufacture may be kept secret. But what proportion of proprietary medicines on the market to-day would escape coming under even this liberal definition of the word nostrum?

And what of ethical proprietaries? Are all medicines whose composition is given, including the amount of each ingredient, "ethical" proprietaries? Then Ayer's Sarsaparilla, and other "patent medicines" which publish their formulas, would be "ethical." And what about those proprietaries that are advertised to cure incurable diseases, and which are exploited under false and extravagant claims with the deliberate intention of misleading physicians? Are these to be classed with "ethical" proprietaries? Is there no standard by which we may judge what are and what are not "ethical proprietary medicines?"

It seems to me there must be some such standard, and I wish to submit the following propositions as a basis for a definition for such preparations.

1. There should be no secrecy or mystery connected with their composition.
2. There should be no secrecy or mystery regarding the firm which makes them or the place where they are made.
3. There should be nothing in the advertising literature concerning their therapeutic value which is untrue or misleading.
4. They should not be advertised, directly or indirectly, to the public.

I believe that no one who has any regard for the rights of physicians, for scientific medicine, or for legitimate pharmacy, will deny the correctness of the principles of the above propositions.

NO SECRECY OR MYSTERY.

1. Whatever is secret or mysterious is suspicious. This is a truism that needs no demonstration. Secrecy and mystery are the bulwarks of quacks and humbugs, and behind secrecy and mystery the "patent medicine" sharpers hide while they swindle the public; and with them the exploiters of nostrums delude and humbug unthinking physicians. Remove the secrecy and mystery connected with these preparations, and physicians who now prescribe some of them would be ashamed to acknowledge that they had ever been so foolish.

A physician not only has the right to know what he is giving his patient, but he has no moral right to prescribe a preparation of which he does not know the exact composition. Incidentally, we are facing a rather peculiar condition: the public is demanding and we are urging that the label on all "patent medicines" shall state the actual composition; and yet some of us are prescribing and so compelling our patients to buy and take preparations about whose composition we ourselves are ignorant. We are rightly demanding that the people shall be told exactly what they are taking when they prescribe for themselves. What will a layman say when he discovers that his physician is giving him a medicine whose composition his physician does not know?[1]

Another fact should be mentioned, incidentally also, in this connection: The legislation for the protection of the public against frauds in "patent medicines" and foods, provides for the examination of these articles by experts, so that the statements of the manufacturers may be verified. Should there not also be experts to examine medicines offered to physicians and to verify the statements regarding the composition of medicines they use? Evidently not, judging from the vehement protests from certain quarters when the American Medical Association secured for this purpose the services of experts and created the Council on Pharmacy and Chemistry. It should be noted that in all proposed or enacted legislation—national or state—the medicines used by physicians are exempt from its provisions; it is presumed that physicians know enough to take care that the medicines they use are what they ought to be. A sadly mistaken presumption this, judging from the past!

It is claimed that if the owner of a proprietary medicine should divulge the exact ingredients and the amounts of each, his rights would be gone, since others would make it. In reply, let me assure you that there is hardly a nostrum put on the market whose composition can not be detected by the bright fellows connected with other manufacturing pharmaceutical houses, who, if they desire, can put up practically the same product, and this is actually done pretty generally. But it is true that if the formulas of at least 90 per cent. of the secret, or semi-secret, proprietaries on the market were made public, and if all secrecy and mystery regarding their actual composition were removed, there would be no more call for them by physicians, for there would be revealed to physicians what is known to experts who have looked into the matter, viz.: that these wonderful preparations are very ordinary prescriptions which any educated pharmacist can compound. I am referring now to the thousands of articles that are foisted on our profession by what I shall refer to later as pseudo-chemical and pseudo-pharmaceal companies; I do not include the so-called "elegant" non-secret pharmaceutical preparations, such as elixirs, syrups, tablets, capsules (especially when containing liquids), bougies, etc., that require more skill, or greater facilities, in their manufacture than is usually found in the ordinary retail drug store, and

1. The members of the Proprietary Association of America are fully alive to this weakness of the medical profession, as is shown in the editorials appearing in various newspapers throughout the country, which are obviously dictated by the press committee of the "patent medicine" men. The following quotation from the Newburgh *Daily News*, March 26, may serve as an example: "The article speaks of secret preparations which are sold to physicians only under high-sounding and coined names and which are prescribed by them in utter ignorance of their ingredients. "The name is intentionally puzzling and the drug may be composed of morphia, cocain, digitalis, strychnin, or any other deadly drug for all the doctor knows: Arsenauro, Neurosine, Phennigin, Svapnia, Firwein, Celerina, Dioviburnia, Ammonol, Peptenzyme, Bondyptol, Alctris Cordial, Apiolline, Peacock's Bromids, Alkalithia, Urceden, Frellgh's Tonic. These and many hundreds of others, including a number of coal tar derivatives under different names, with their deadly heart depressing effects, which have been directly responsible for hundreds of sudden deaths, are blindly prescribed by the physician."

that are made by pharmaceutical houses which employ skilled and scientific chemists and pharmacists and which have every facility for such work.

A common argument offered by the promoters of secret proprietaries is that they have spent time and money in developing them and, hence, can not afford to give up their secrets. As regards this, I assert that the only expense attached to the development of ninety-nine out of every hundred of these preparations is that which has gone into bottles, labels, advertising literature, and in wages paid to smooth-tongued detail men to visit and delude the doctors. In this they have undoubtedly spent money—lots of it, and successfully. But aside from this, all the talk about the time and money invested in developing these preparations is the veriest bosh. The capital required to start Antikamnia, a combination alleged to have been suggested by a physician, and which has netted a fortune to its owners, was simply that which was necessary for advertising. The ingredients were cheap and no skill was required to mix them. Ammonol, we are told, was the result of the suggestion of a physician that carbonate of ammonia should be used in the place of caffein to counteract the action of acetanilid on the heart; and Phenalgin, it is alleged, is simply the result of another "company" branching off from the Ammonol Company with practically the same mixture under another name. The amount of time and money required to work out the acetanilid mixture, Sal Codeia-Bell, I leave to your imagination. How much knowledge, time and money do you suppose were necessary to originate Tongaline, Neurilla, Pasavena, Anasarcin, Manola, Sanmetto, Ecthol, Neurosine, Benzol Capsules, and thousands—I am not exaggerating when I say thousands—of analogous preparations? Are these anything more than ordinary simple mixtures of well-known drugs? Do they require more than ordinary pharmaceutical skill to compound them? Are they any better combinations of drugs than the average physician is prescribing every day?

RELIABILITY OF MANUFACTURERS.

2. Next to knowing what is in the combination we are using is the knowing who makes it, whether the manufacturer is competent, reliable and has the necessary equipment. Ordinarily, when we buy an article of commerce, regarding the quality of which we have no confidence in our own judgment, we select a responsible, established firm, one which has a reputation, and we take the firm as a guarantee that the article will be up to the standard and one on which we may rely. Should we not do the same when we select medicines to prescribe for our patients? And yet one of the most noticeable facts connected with the nostrum business is that the vast majority of these preparations are supplied us by firms about which we know little or nothing, and which, for a better name, I designate "pseudo-chemical" or "pseudo-pharmacal" companies—companies which are created solely to exploit this class of medicines. These companies are not in the true sense manufacturing chemists or manufacturing pharmacists, if by these terms we mean that they are in the regular business of manufacturing the various chemical and pharmaceutical preparations. The latter have their catalogues or price-lists, which include preparations official and non-secret, called for in the regular course of such business. They have more or less complete laboratories and expert chemists and pharmacists. While some of them put out preparations of a secret and more or less doubtful character, this is a side issue with them. Some "pseudo" companies are really connected with regular manufacturing and pharmaceutical houses, through which these houses exploit doubtful preparations, that, for reasons best known to them, they are ashamed to exploit openly. But the nostrum output of all the regular manufacturing pharmaceutical and chemical houses is trifling compared with the vast number that are foisted on our profession by companies that are in no sense regular manufacturing pharmacists.

If we should get behind the scenes we should find that the personnel of most of these "pseudo" companies consists of men who have no interest in, or knowledge of, either medicine or pharmacy. Many are merely promoters who have created a fictitious "company" through which to exploit to our profession some cheap nostrum. Once in awhile the "company" will be found to consist of a doctor or a druggist, who sees in this "specialty business" easy money. Ex-advertising agents in several instances form the personnel of such "companies." One "company" that I have in mind consists of a real-estate agent and a lawyer; originally it was a real-estate agent and a druggist, but the lawyer and the real-estate agent put up a job on the druggist and he was squeezed out. The preparation this "chemical company" exploits is made by a regular manufacturing firm, and the "company" does not have to attend to even the labeling or boxing of its preparation. And yet this is a "chemical" company!

Some of our "ethical proprietaries" are furnished us by the same men who, under other names, are supplying the public with "patent medicines." Certain homeopathic pharmacies are running "pseudo" companies as a side line, and exploiting nostrums to the regular profession. And, as I have stated, a few old established pharmaceutical houses and retail druggists, under anonymous names, are doing likewise.

But while there is mystery connected with the personnel of many of these pseudo-companies, there is just as much mystery connected with the place of manufacture. Some of the "companies" have their preparations made for them by regular manufacturing houses just as many "patent medicines" are made. In other instances the "laboratory" is a back room in a business block not far removed from the business office; an ordinary store room on a side street often answers the purpose.

Let me suggest, therefore, that before prescribing a preparation we not only should know what it is, but also who makes it and where it is made. If the name of the manufacturer is not known let us find out something about him. If the "company" or individual is not a legitimate manufacturing concern, but is merely putting up one or two "specialties,"—often a dignified name for nostrums—we should be suspicious. We should be very suspicious if a detail man calls on us representing a "company" which bears the same name as the product he is cajoling us to prescribe for our patients.

I am not making a plea for manufacturing pharmacists, at least so far as claiming that they are what they should be. On the contrary, I am sorry to say that too many of them are putting out "specialties" that are the veriest nostrums. Examination of some of the products of a few of the supposedly reliable houses has shown that our profession has been sadly deceived and humbugged by even such houses. But the number of regular manufacturing firms who have been practicing this deception is probably small, and the total number of nostrums or fraudulent preparations from all these houses

is insignificant compared with those that emanate from the "pseudo" concerns.

The nostrum, or secret "specialty," is a side issue with legitimate manufacturing houses, and when they find that our profession is awake, they will stop this dishonorable business. While some of them will dislike to do this—for these "specialties" are very profitable—they will do so rather than have their legitimate business injured by exposure of their illegitimate. But what about those whose business consists entirely in making and exploiting nostrums? Will they give up willingly? Will they stop for fear of exposure? By no means. It is their livelihood. It is too lucrative a proposition to give up without a desperate fight. And as there are some three or four hundred of such concerns in this country, is there any wonder that this movement has met with tremendous opposition, an opposition which, combined, represents millions of dollars!

I want to emphasize this phase of the problem, and to declare as emphatically as I can, that the great bulk of the nostrums are put out by "companies" that are neither chemical or pharmacal, and that these "pseudo" concerns bear the same relation to legitimate pharmacy that the ignorant quack doctor bears to an educated honorable physician. And one is as great a curse to pharmacy and chemistry as the other is to medicine.

Just a word in regard to imported mixtures. There seems to be an impression among many of us that if an article is imported, it must be something good, reliable, "ethical" and above suspicion. As a matter of fact, during recent years England, France and Germany—especially the latter two—have been sending mixtures to this country—mixtures that have been made especially for the American market, at least their sale is practically limited to this country—which are on a par with the nostrums of this country. Some of these foreign preparations are foreign in name only. Others are imported in a concentrated form and diluted here, and still others are imported as put up abroad. There are so many disreputable preparations among them, and they are advertised and exploited so often with such utter disregard for truth, that it is well to be suspicious of all. Further, while we are willing to recognize the superiority of the German chemists in certain lines, American pharmacy for a third of a century, has been leading the world—and is leading to-day. It is certainly not necessary to go abroad for our pharmaceutical mixtures; but if we do, let us be sure that they are at least as good as, if not better than, those made by our own people.

EXAGGERATED STATEMENTS.

3. Of course, every one—including the manufacturer—will agree with the third proposition: that no untruthful claims should be made regarding the therapeutic value of medicinal articles. And yet, what a reflection on the veracity of the manufacturer, and especially on the credulity and tolerance of the physician, is the great bulk of the advertising "literature" furnished by the manufacturers of proprietary medicines. I won't take time to illustrate, by quotations, the correctness of this statement. If any of you would criticise it, look at the "literature" that has come to your office during the past week, or at the advertising pages and "write-ups" in some of our medical journals. It is to our disgrace that we have so long put up with the foolish and extravagant claims and falsehoods of proprietary medicine men.

INDIRECT ADVERTISING TO THE PUBLIC.

4. The fourth proposition is the one to which a certain class of proprietary men most object; but to the physician it is the most important. The Council on Pharmacy and Chemistry incorporated this principle in Rule 4, which is:

> Rule 4.—No article will be admitted whose label, package or circular accompanying the package contains the names of diseases, in the treatment of which the article is indicated. The therapeutic indications, properties and doses may be stated. (This rule does not apply to literature distributed solely to physicians, to advertising in medical journals, or to vaccines and antitoxins.)

It is a manufacturer's business to sell his wares; it matters little to him who buys them. This is business. The manufacturer of drugs is no exception to this general proposition. Consequently, we can not blame him if he tries to get the public to buy the wares he puts up—ostensibly "for physicians' use only." But physicians object to the advertising of medicines direct to the public—not for selfish reasons, but because their indiscriminate use by the public is more likely to be injurious than beneficial.

It is not necessary to give the reasons why the indiscriminate use and self-prescribing of medicines containing active or poisonous ingredients is detrimental to public health. Knowing the harmfulness of it, physicians emphatically object to the advertising of such medicines to the public.

Hence, few proprietary medicine manufacturers, who want physicians to use their preparations, do thus advertise. But practically all of them have been advertising indirectly to the public, until now without a protest on our part. This indirect advertising is by circulars accompanying the preparation and by labels on the bottles or containers, as well as by having the name of the preparation blown in the bottle.

Samuel Hopkins Adams charges that physicians are indirectly responsible for a large part of the "patent medicine" taking, and undoubtedly his charge is just. While the catchy name of the nostrum prescribed by the physician is partly to blame, it is the advertising matter which the layman gets with the medicines that does the work. The labels and circulars tell him of the various diseases in which the medicine is indicated. This is the kind of advertising that costs nothing; and, evidently, it is considered "ethical" advertising. But, above all, this is the advertising that pays. The patient has confidence in his doctor; his doctor, the patient reasons, has confidence in this particular medicine, and, therefore, it must be good; and if it is good for the particular trouble for which the doctor prescribed, it must be good for the other diseases indicated—and their name is usually legion—on the label and in the circular. If those of you who are in the habit of prescribing proprietaries will examine a package at your drug store—just as the patient will get it, too often, in spite of your directions to the druggist to remove the label—you will not wonder that so many of the proprietaries that have been on the market for any length of time are bought directly by the public, in much greater quantities than on physicians' prescriptions.

The manufacturer argues that the doctor himself wants to know what a preparation is good for. I reply, the doctor is not supposed to go to a drug store to learn his therapeutics. The manufacturer will see that the physician gets enough literature to keep him informed of the value of his preparation in every disease in which it is possible to use it. It is not usual for labels on official drugs and standard pharmaceuticals to contain the names of diseases in which the article should be

used; neither should such indications be permitted on proprietaries. But so long as we tolerate this abuse, just so long will the manufacturers keep it up; and we can not blame them; it is business. It is a method of exploitation that costs them nothing; they get the doctor not only to prescribe their preparations, but to put their literature in the hands of the public at the same time. And this literature has another and decidedly important effect: it aids and abets the druggists in counter prescribing. Has the time not arrived for us to demand of the manufacturer that he give us a square deal in this matter? Should we not insist that this indirect method of exploitation to the public shall cease?

Let us not blame the manufacturers for this nostrum business. We, and not they, are to blame. We have been allowing ourselves to be deluded without a protest. We have accepted commercialized literature in the form of therapeutic hints without question, and have been prescribing cheap drugs under a fanciful name, for which either we or our patients pay ten times their worth, without so much as a murmur.

The nostrum evil has grown until it is a curse to our profession. The use of proprietaries has become so common that the intelligent prescribing of well-known official drugs in their simpler form by many intelligent practitioners has become a lost art. The literature of the proprietaries has developed in many physicians an optimism and a contented spirit that has checked intelligent thought, independent action, and an ambition to progress. The nostrum business has cast a blight on our literature, debauched our medical journals, checked advance in scientific methods of treatment, and suborned the art of prescribing to the aggrandizement of commercial promoters.

Can we not rid our profession of at least a part of this blight?

THE SUBORDINATION OF MEDICAL JOURNALS TO PROPRIETARY INTERESTS.*

J. H. SALISBURY, A.M., M.D.

Assistant Professor of Chemistry, Rush Medical College; Professor of Medicine, Chicago Clinical School.

CHICAGO.

It would be difficult to overestimate the important influence of medical journalism on the opinion and action of the medical profession. The medical school is attended, as a rule, but once in a lifetime; the meetings of the medical society are usually infrequent, but the medical journal, like the newspaper, is an ever-present friend whose influence and advice are potent for good or evil. Whoever gains control of the medical press goes a long way toward securing a paramount influence on the entire medical profession. The control of the medical press by the proprietary medicine interests is, therefore, a matter of vital interest to every physician, and it is worth while to inquire how great and of what character this influence is.

PROPRIETARY ADVERTISEMENTS.

An extensive influence of this sort may be assumed from the fact that most medical journals are supported by advertising, and, while the necessity of this may be deplored, it is nevertheless an important fact to be reckoned with both in considering the reason for the subserviency of the medical press and in suggesting a remedy for the nostrum evil. It can be asserted as an axiom that no paper supported by advertising can pursue a policy antagonistic to the interests of its advertisers and retain their patronage which is necessary to its existence, and no paper dependent in part on advertising can escape the influence of its advertisers. A liquor advertisement would appear with bad grace in a prohibition paper, and it may be assumed that a journal which accepts the advertisements of proprietary preparations will observe a certain discretion in its advocacy of pharmaceutic reform, confining its denunciations to glittering generalities, firing blank cartridges, or at least directing its aim so as to be sure not to injure its friends.

That the majority of American medical journals can not in the nature of things be unfavorable to proprietary medicines is evident from an inspection of their advertising columns. Practically all medical journals carry advertisements of proprietary remedies. In one journal which is supposed to exhibit the highest ideal in the ethical conduct of medical journalism, 20 out of the 36 advertising pages were devoted to advertisements of proprietary articles; in another of high grade 9 out of 26 pages were used in the same way.

SUBSERVIENCY OF MEDICAL JOURNALS.

The extent of the subserviency of medical journals to the proprietary interests is further shown by the fact that a large proportion of medical journals have a department devoted to advertisements under the guise of reading notices, commercial news, therapeutic notes, etc. No pretense is made that these are genuine scientific articles, and it is tacitly understood that these columns are under control of the advertisers and that the articles are disguised advertisements. We note that financial advantage or necessity has compelled the paper, presumably devoted to the propagation of truth, to descend to the utterance of a commercial fiction, if we may not call it by a harsher name, and to become a silent partner to what frequently amounts to a scientific and commercial fraud.

A number of journals do worse and put such material under the heading of "Abstracts" and print so-called select original articles culled from other journals. This department is the reading notice concealed under a name which leads the reader to expect valuable summaries of medical progress and seems to put the stamp of approval of the editor on its contents.

In the next step, taken by a considerable number of journals, the editor and his contributors exhibit themselves as the willing slave of their proprietary master, having been bought and paid for. The write-up and the apologetic editorial exhibit the lowest stage of journalistic depravity. An estimate of the extent of this evil can be gained from the statement of a recent writer that the journals subsidized by the proprietary interests comprise one-half of those published in the United States.

I went through 27 medical journals, covering the past six years, and found one preparation, viz., "peptomangan," as the subject of forty-five original articles. In addition there were six editorial indorsements of the remedy. One editor went so far as to take up arms in defense of his patron against the aspersions of a rival firm which were likely to injure the business. In a somewhat cursory survey covering about 15 medical journals for the last 5 years, I have found about 300 so-called original articles written in praise of the various proprietary remedies, and the list is by no means complete. I think that the evidence is sufficient to show

* Read in a symposium on Proprietary Medicines and Nostrums before the Chicago Medical Society.

that the medical press of the country is profoundly under the influence of the proprietary interests.

It may be objected that it is only the second-class journals which publish such articles. This is not entirely true, for such articles have been repeatedly found in the columns of some of the best periodicals in the country, although it must be said that there is a marked difference between different journals in their apparent relation to the nostrum traffic. Some openly uphold it; others silently consent; while a few, but an increasing number, positively condemn it. It must be remembered that the so-called second-class journals have, individually, a considerable and, collectively, an enormous circulation.

DEGRADATION OF MEDICAL JOURNALISM.

We have next to inquire what is the character of the influence exerted on medical journalism by these nostrum vendors?

The scientific and practical value of the literature is markedly lessened. The clinical reports presented in behalf of some preparations, peptomangan for instance, make the claim and have the appearance of giving the results of careful clinical and experimental work. The sincerity of the authors of some of these articles we are not disposed to deny, but the scientific value of their work is much impaired by its one-sided character and the lack of comparison and critical judgment. After an imposing array of blood counts, clinical histories, etc., the only fact established is that a certain set of patients recovered under the use of a preparation of iron. No comparison is made between the results obtained by the use of other forms of iron and those due to the administration of the remedy under consideration, and when such a comparison has been made, as was done by the Commission for the Study of Uncinariasis in Porto Rico, the results, not particularly favorable to peptomangan, are distorted to form the basis of the claim that the United States government authorities have endorsed a proprietary preparation.

The result of inserting such one-sided articles is to encumber the reading pages of the journal with worthless stuff and to create an uncritical habit of mind in the reader. Nothing but careless reading can be expected of the doctor who peruses such an article as "The Skin a Factor in Diagnosis" to find it an advertisement of a nostrum, or who hopes to learn something of value in regard to prophylaxis from "How to Assist Young Girls to Womanhood," but finds that the sum of the author's valuable advice is to give them peptomangan! Finding his time wasted in the careful reading of such articles, it is very natural for him to give little attention to the really valuable matter which may be interspersed between proprietary articles. What shall we say of the scientific character of a journal made up of such articles as that of W. C. Derby on the "Treatment of Chronic Gastritis"? This author tells us that he easily verified his suspicion that the patient had chronic gastritis, but does not think it necessary to tell us how he knew and gives no gastric analyses nor blood count. He does tell us, however, that he succeeded in the treatment by means of zymacin, nuclein, papain, manola tonic, bovinin and sanguiferrin! Surely, with such an equipment the Pharmacopœa may be relegated to the ash box. American medical writers have occasion to blush for some of their confrères.

The journal which is ready to sell its columns to the nostrum vendor can not be relied on to give the best editorial advice or to take a firm stand on the right side where the interests of the public or of its subscribers are opposed to the interests of the proprietary manufacturers. The editor of such a publication can not be a worthy leader of medical thought. And he may expect to find his paper quoted to support sentiments that he never uttered. In a pamphlet published by the promoters of peptomangan various journals are quoted as sustaining the superiority of the peptomangan as shown in the Porto Rico trials. In reference to the journal quoted, it is found that the enterprising manufacturer has simply quoted his own advertisement attributing its statements to the journal as if it were an editorial utterance!

The journals by giving their space to extravagant statements regarding the effects of such remedies are fostering blind reliance on drugs and delaying the advance of truly rational therapeutics.

WHAT IS THE REMEDY?

What remedy can be proposed for this state of things? Can we demand that medical journals shall exclude advertisements of proprietaries altogether? This would probably be too rigid a rule, but some regulation might be adopted as to the form of advertisements and the character of the remedies which should be admitted to the advertising columns. If the consensus of opinion of the medical profession could be crystallized into some definite requirements in regard to the advertisements that should be admitted to the pages of a reputable medical journal, we might have some criterion by which we could determine whether a journal is worthy of our patronage.

If, instead of inserting in his reading columns concealed advertisements of proprietary remedies, the space were devoted to lessons on pharmacy and chemistry, the editor might educate his readers to a point where they could rationally decide on the true value of the novelties proposed for their use without making disastrous experiments on their patients. The editor who fails to protect his readers against concealed frauds, which is the only proper characterization for many of these "write-ups," is false to the trust reposed in him by the medical public.

EFFECT OF PROPRIETARY LITERATURE ON MEDICAL MEN.*

N. S. DAVIS, M.D.
CHICAGO.

The printed matter issued by the manufacturers of proprietary and exclusive medicines is as various as are their products. The smaller part has a high scientific value; the larger part is a more or less clever advertisement of wares for sale.

Naturally, as a monopoly of a good thing is sure to bring wealth to the manufacturer, almost every drug maker endeavors to place on the market one or many specialties of his own. To insure his exclusive right to manufacture them, it is usual for him to patent the process or trademark the name.

The clever manufacturers employ able men of science to test with care the physiologic and therapeutic actions of their drugs, and these reports, when given to us in full, are of genuine value. In subsequent advertising, however, the results obtained are summarized and often so skilfully that disagreeable effects are lost sight of or minimized. Moreover, these summaries are imbedded

* Read in a symposium on Proprietary Medicines and Nostrums before the Chicago Medical Society.

in a mass of optimistic writing by the advertiser or by physicians who record their impressions; not observations made with the accuracy which science demands.

Therefore, even the best of this printed matter, of which we all receive so much, is not to be trusted. On the other hand, so many things of value first come to us in this way that we can not reject it all.

Often, unfortunately, rank nostrums, disguised as chemicals of definite composition, are described in print that is a perfect imitation of the best class of advertising matter which I have just described.

That we may not be duped, it is necessary to know by reputation the chemists who vouch for the character of the drugs, also the reputation of the pharmacologists and clinicians who test their action.

The remainder of nostrum literature consists of descriptions of the impressions of various physicians as to the therapeutic effects of mixtures, which any clever pharmacist could duplicate if given the opportunity. The nature of the remedy is hidden, as a rule, in the brief statement that it is an especially pure preparation of some well-known drug. Although many therapeutic virtues are claimed for it, it is often inert or so potent as to be dangerous, unless its nature is fully understood. Such mixtures never should be used. If all members of the medical profession would absolutely refuse to prescribe ready-made mixtures, either in liquid, pill or powder form, they would destroy one, if not the greatest, hindrance to successful and rational therapy.

In the first place, it is impossible properly to adapt the dose of drugs to individuals if one dose is given to all. Moreover, ready-made prescriptions lead to slovenly therapeutic reasoning and practice. For instance, a mixture of digitalis, strophanthus and nitroglycerin is often given when the effects of the latter are not wanted, though those of the former are, because the giver is accustomed to dispense the combination whenever a cardiac tonic is needed.

The prescription recently copied by The Journal of the American Medical Association[1] from the original column of another and advocated by its author as sovereign in pneumonia illustrates a common ignorance of the composition of widely advertised and used proprietaries and an inclination to use them as though they were definite chemicals, not mixtures. The prescription to which I refer contains, first, a fair dose of acetanilid; second, sodium bicarbonate, and, third, bromo seltzer. The writer evidently did not know that the last also contained a fair dose of acetanilid and that in his combination he was giving a large dose of this powerful drug. Many physicians use nostrum mixtures at first because the sample is at hand, and later because it is easily dispensed, and the practice becomes a habit.

We can not blame manufacturing chemists for finding new things or advertising them as cleverly as possible. That they and the nostrum vendor are surprisingly successful in selling their wares is largely our fault.

Proprietaries are used in enormous quantities. All medical men are, to a greater or less extent, employing them; and it is skillful advertising which has made this so.

Assuredly, it is legitimate practice to try a new drug or chemical which promises to be useful, for if we did not there would be no progress in therapeutics. Unfortunately, a prompt recapitulation of results is rarely made, and useless drugs are not discarded as they should be. However, sometimes this does happen, notably in the case of Bergeron's treatment of tuberculosis and later in that of tuberculin and the *x*-ray. In a few months the whole medical world was apprised of the real value of these remedial agents.

We should see to it that all drugs are similarly weighed and labeled with their true value. Even our pharmacopeia contains inert and useless drugs retained because still prescribed and for which, therefore, a standard must be established.

Medical men are too prone to accept new drugs as they accept new ideas, because they are new, without sufficiently testing them or demanding the approval of recognized authorities.

I make a conservative statement when I say that on the desks of each of us from three to ten advertisements such as I have described are placed daily, but the education of medical men in therapeutics by manufacturers does not stop here. Drummers are about as numerous as circulars, and each gives a brief, carefully prepared lecture on the wares which he carries. A lecture which is often interesting and if it told the whole truth would be instructive. Unfortunately, only that which will help to sell the goods is told. It is often surprising, too, how ignorant the detail man is when questioned as to his wares on other points than those in the lecture which he has committed to memory.

It is not surprising that medical men have surrendered to manufacturers and accept their teaching, since their goods are advertised in almost every medical journal and not infrequently well exploited in so-called original articles in these publications.

Manifestly, the condition in which we find ourselves must be changed. That this may be accomplished we must, first of all, recognize the disease, so to speak, of which we suffer. Second, we should insist that the teaching of pharmacology and therapeutics in medical schools be confined to the drugs of the pharmacopeia. Third, we should take more interest in the pharmacopeia and demand that it contain only drugs of genuine worth, and that it be revised often enough to insure the admission of all valuable new ones. Let the pharmacopeia be made a standard for both the medical and pharmaceutical professions.

Lastly, a greater amount of pharmacologic and therapeutic research should be stimulated. During the second and third quarters of the last century a very large amount of knowledge of this kind was accumulated by painstaking research; but in the last twenty-five or thirty years the attention of those medical men who have been contributing to our knowledge has been centered almost exclusively on etiology, bacteriology and pathology.

It is not surprising that in proportion as the most original minds among us neglect the field of pharmacology and therapeutics the manufacturer seizes this opportunity to instruct us. For he can do his teaching in his own way almost unchallenged by authorities.

1. The Journal A. M. A., Jan. 27, 1906.

Good Advice on Writing Papers for Medical Meetings.—When writing your paper for the state meeting, remember several things; select a subject with which you have had rich and practical experience—anyone can read text-books without going a hundred miles, leaving work and business, and paying $3 a day to hear you read extracts from one; collect your thoughts, clarify and simplify them, boil them down and then write your paper; go over it again and cut out all non-essentials, and all self-evident data—and you will then have a paper from which everyone will learn something—and you will go home thoroughly satisfied and proud of your effort.—*Southern Medicine and Surgery.*

THE NOSTRUM FROM THE VIEWPOINT OF THE PHARMACIST.*

W. A. PUCKNER.
Professor of Chemistry, University of Illinois School of Pharmacy.
CHICAGO.

While the responsibility of the medical teacher for existing conditions will be discussed by another speaker, I can not resist this opportunity offered me, a pharmacist permitted to address physicians, to say that without question the insufficient instruction in materia medica, pharmacology, pharmacy and chemistry offered by schools of medicine is the direct cause of present conditions.

I wish to point out to you how this lack of proper training along the lines indicated has made the physician dependent on ready-made remedies, proprietaries and nostrums, and how this, again, has been the making of "patent medicines," has led to self-medication and to counter prescribing, and has been the cause of making pharmacists forget their professional standing.

As a teacher, I would like to add that not only has the instruction in these subjects been inadequate because of the limited time alloted to them and because the student is led to attach too little importance to them, but often also because of the instructor's lack of familiarity with the subject which he is supposed to teach. This condition is but too frequently brought to my notice by former students who, having graduated in pharmacy, have taken up the study of medicine. As an illustration, I may refer to an article by Dr. Galloway[1] in which he protests against some haphazard, incorrect statements made by teachers in schools of medicine. Dr. Galloway reports statements made in favor of a certain brand of chloroform as opposed to another kind; statements so unfair and unwarranted that they can but be taken to show the lecturer's unfamiliarity with the subject he teaches. Other instances are cited which show that the lecturers, not being sufficiently familiar with the chemistry and pharmacy of medicines, are led to draw on the imagination and to offer to students statements which are entirely at variance with the facts.

Since the newly-graduated physician, therefore, has but a limited acquaintance with the remedies which he must employ, his prescriptions are liable to be unsightly, nauseating or, because of incompatibilities, perhaps inert. As a result of this two consequences are probable: First, if the patient discovers the physician's incompetency, when again in need of treatment he will go to his pharmacist for advice, since the pharmacist at least is familiar with the remedies which are used in the treatment of disease; second, when the physician comes to realize his lack of familiarity with medicines then he most probably will fall back on the proprietary remedies, ready-made, with the dose on the label, of pleasant odor and taste and said to possess marvelous virtues.

The lack of familiarity with the common remedies often shown by physicians was strikingly brought to my attention recently. I was suffering from an attack of acute indigestion and called a physician; in due time the attendant placed a powder on my tongue and requested me to swallow it. The powder, which I later learned contained magnesium carbonate, at once formed a compact mass, firmly adhering to the tongue, much as plaster-of-Paris would. I asked for a little water and was informed that the physician had prohibited all food and drink, but that I might have a teaspoonful of water on promise not to swallow it. Naturally I removed the concretion still adhering to my tongue and made no further attempt to take the medicine.

Were such physicians but competent to judge the effect of the remedies which they administer the dependence on proprietaries would not be so bad, since most, or at least, many possess some merit. Unfortunately, however, the physician's training is likely to be such that he can not distinguish the rank fraud from the efficacious remedy, honestly made and sold. It is this inability to judge the effect of medicine which has brought about the custom, now almost universal, of outrageously exaggerating the virtues of these proprietaries. The following will illustrate how a physician often is led to use absolutely worthless remedies: Some years ago a preparation was placed on the market under the name of "Flora China," which was claimed to be "pure quinin sulphate," but to be tasteless and to do all that the bitter quinin would do. In appearance the substance resembled quinin sulphate and it certainly was tasteless, but on examination[2] I found it to be nothing but crystallized calcium sulphate. Yet some five years later a student told me that a certain physician prescribed it and had used no other kind of quinin for years.

In this way a large portion of the medical profession has become dependent on the advertising literature and the detail men of proprietary dealers for the treatment of their patients. They listen to tales of the wonderful virtues of "bracemup" or "stimuline," written probably by a person having no knowledge of medicine whatever or perhaps compiled from obsolete medical works.

Recently a letter sent by a pharmaceutical house to its salesmen ("detail men") came to my notice. This letter, after stating that a successful salesman must be a student of human nature, etc., went on to say that the educated physician should be approached something like this: "Doctor, I have here a preparation of —— ——: if you employ this drug in your practice you will find that this preparation of the drug, manufactured by reliable and skillful pharmacists, contains the very best quality of the drug and is combined in such a way as to obtain the greatest good from the remedy." Then it went on to say that, as pharmacists, it is the business of the manufacturing pharmacists to put into the hands of physicians drugs of the highest quality, knowing well that physicians will know what use to make of them. The letter continued that, unfortunately, however, there were a great many physicians of inferior education along lines of materia medica and therapeutics with whom such arguments would fail and who must be told that a certain preparation is good for a certain kind of cough, that another remedy is a "winner" in the treatment of a certain brand of this or that disease and who like to read glowing testimonials of wonders accomplished. This letter in conclusion suggested that the salesman must judge which of these two methods to adopt in approaching the doctor. That in any case it would do no harm to flatter by assuming that the doctor knew his business, and later to change the mode of attack if they should find that he did not know his business.

Finally, let me illustrate how the use of proprietaries by the physician must cause a lack of confidence on the part of the patient, and induce self-medication, or cause counter prescribing by the druggist, and be the making of "patent medicines." While practicing pharmacy one day I was asked to prescribe for a man who said that he had contracted gonorrhea. Instead I advised him to

* Read in a symposium on Proprietary Medicines and Nostrums before the Chicago Medical Society.

1. Philadelphia Medical Journal, 1899, vol. iv, p. 995.

2. Abst. Proc. Amer. Pharm. Assoc., vol. xlv, p. 719.

consult a physician. Soon after I was summoned to the telephone and asked by a well-known surgeon for the name of "those black capsules that come in a flat box." In due time I was requested to fill the prescription, and although the capsules were taken out of their container and placed in an ordinary pill box, yet the patient recognized the familiar remedy at a glance and in no complimentary manner commented on the time and money wasted in consulting the physician.

Imagine the frame of mind of the patient who, having consulted his physician and paid his fee, learns that his prescription calls for orangeine or antikamnia, with which the daily press has made him familiar.

What do you suppose he will do when next he has neuralgic pain or any other pain; or if his sister or his brother or his aunt has any kind of pain?

But you say: "We do not prescribe remedies advertised in the lay papers. Yes, but how did Fellow's syrup, or worse still, McMunn's elixir, become a "patent medicine?" Because they were prescribed by physicians, who thus assumed the rôle of "advance agents." Rest assured that whenever a physician prescribes any of these remedies with nice, smooth, catchy names, no matter how illegible his writing, and even though he does not follow the advice of the promoters to direct that they be dispensed in original containers, with the "name blown in the bottle," patients will, sooner or later, learn what they are taking. If the remedy has the desired effect and cures this or that trouble the patient when next indisposed will purchase his medicine direct and dispense with the physician's services. Furthermore, he will recommend it to his friends, using the physician's name as a guarantee of its virtues. Next its advertisements will be transferred from the medical journals to the daily press and the physician will have officiated at the birth of another so-called "patent medicine."

A practice still more reprehensible, it seems to me, is that of supplying patients with "physicians' samples." Seeing that his physician tries on him remedies about which he plainly knows nothing, it is small wonder if in the future the patient will prefer to consult the "patent-medicine" literature of the daily paper or will study the placards on fence posts and in street cars to find some remedy fitted to cure him, since to him it must seem that his physicians did this when last consulted.

THE PROBLEM OF THE SYNTHETIC CHEMICAL COMPOUND.*

JULIUS STIEGLITZ, Ph.D.
Professor of Chemistry, University of Chicago.
CHICAGO.

In the attention given recently in the medical and lay press to the manufacture of drugs and medicines, interest has centered naturally in two classes of manufacturers; on the one hand those who appeal directly to the ignorance or the vices of the public to buy their patent medicines and nostrums, on the other hand, those manufacturers who, under the ethical mantle of dealing only with the medical profession, have been palming off on it under false names and titles mixtures as bad as any produced by the first class. There is a third most important class of manufacturers requiring serious consideration, the manufacturers of the legitimate, so-called synthetic chemical compounds which are being so largely exploited in medicine. The most serious problem confronting us arises from the enormous increase in the numbers of such compounds. We may well ask ourselves: Why are there so many new synthetics? Have they any legitimate reason for existing? What safeguards if any need the medical profession insist on in dealing with these products of legitimate houses?

The source of the rapid increase in the number of these preparations lies undoubtedly primarily in the competition for trade, in the desire for gain. The phenomenal commercial success of such synthetics as antipyrin, phenacetin, saccharin, etc., stimulated enormously the search for similar treasure-bringing discoveries, both in commercial and in university laboratories. At the same time the great commercial houses understand very well that for real and continued success they must offer preparations of real, intrinsic medical value, and to secure these they have been compelled to make science their handmaiden, and to go at the commercial problem through scientific experimentation. In this way, they undoubtedly are doing a service to humanity as well as to themselves.

Speaking as a chemist, there is a legitimate, ideal goal toward which this branch of science has a right to strive; we have every reason to believe that with patient work we can improve vastly on the valuable alkaloids and similar compounds offered us by Nature. With out ability to establish the complex structure of these organic molecules, to modify practically at will any detail or part of the molecule, to create, synthetically, any new forms we wish to have—a systematic study of the physiologic effect of every characteristic part of such compounds ought to lead ultimately to a rational and systematic theory and practice of the effect of synthetics in medicine. The great work of Fischer on the vital relations between the configurations of the sugar molecules and their ability to ferment and support life shows us the goal is not an impossible one. It is true that we have made comparatively little progress toward this goal—chemists have given to the medical profession a number of more or less valuable febrifuges, some hypnotics, they have modified some alkaloids, given the profession homatropin as an occasional useful substitute for atropin, hydrastinin as a scientifically evolved improvement on hydrastin, and a few more advanced preparations, but their successes have been on the whole very few and this would be discouraging if history did not teach a lesson of patience. I think I can make my point clearest by referring to the parallel case of the anilin dyes. Chemistry has succeeded in wresting from Nature the supremacy in the preparation of these dyes, we can make at will more beautiful, more lasting, more washable colors of every conceivable shade than Nature has produced, and this has been accomplished through the slow, careful mastery of scientific principles and details, discovered through a great many original investigators. And yet, it took our greatest organic chemist, Professor Baeyer, fourteen years to determine exactly the nature of indigo, and it took about fourteen more years to develop methods for the successful manufacture of this one compound.

That one fact ought to teach us patience in our progress toward the goal of medical chemistry. The problem here is a far more complex one and a far more important one, but we do not see why it should not lead ultimately even to the chemical preparation of those specific antitoxins which we must now draw from animals. We are far from our goal, but the feverish competitions of great houses and university investigators form the hotbed in which the germs of success must ultimately grow.

This brings us to the main point of my remarks: In the evolution of the dye industry bad dyes were often

* Read in a symposium on Proprietary Medicines and Nostrums before the Chicago Medical Society.

thrown on the market, dyes that faded quickly, that would not wash, that we would now consider ugly; the cost of experience in this case was borne by the pocketbooks, perhaps by the tempers of the people. In the manufacture of synthetics, however, it is far more difficult to separate the good from the bad, and experience obtained at the expense of the one life, the one health of individuals, is too costly, and physicians do well to hesitate before this array of new synthetics. The manufacturers are interested parties—as they were in unloading bad dyes—many so-called investigations and write-ups under unknown names are as likely to be the bait in the trap. What are physicians to do? Shall they seek safety in standing still, or hesitate to take a forward step from fear it might prove a backward one? The only scientific solution of the problem as it seems to me would lie in the establishment of some institutions, perhaps international, for the impartial testing of promising new synthetics; or in default of such, in the formation of central bureaus of critical disinterested review.

The need of a check even on our great houses was brought home forcibly to my mind in some recent examinations I had occasion to make as a member of the Council on Pharmacy and Chemistry of the A. M. A.: a preparation from one of our great American houses bore in its literature the truthful statement that it is acetylamidobenzene-trimethylxanthine. I wonder how many physicians recognize that these thirty-five letters spell in simple English acetanilid plus caffein, a mixture as bad as any of those recently exposed, but coming from a great reputable firm and parading correct chemical synonyms other than those usually employed by physicians. This same firm widely advertises to the profession a certain hypnotic as being much safer than chloral—it bears in its description the statement that it is a compound of chloraethanal with a higher polyatomic alcohol, which is true. To a chemist that spelled at once chloral combined with glycerin—what physician, who would hesitate about prescribing chloral, would not like to use his own judgment as to whether chloral plus glycerin would be any safer? It seems to me, then, that physicians ought to insist that all chemical compounds whatever should pass before some reviewing board which will insist that the manufacturers give the plain truth, the whole truth and nothing but the truth!

THE RESPONSIBILITY OF THE MEDICAL TEACHER FOR EXISTING CONDITIONS.*

CHARLES SPENCER WILLIAMSON, M.D.

Professor of Clinical Medicine and Associate Professor of Medicine, College of Physicians and Surgeons; Consulting Physician to Cook County Hospital and Dunning Institutions.

CHICAGO.

THE TEACHER'S INFLUENCE.

The question of the influence of the medical teacher in the prescribing of nostrums goes hand in hand with the question as to how great an influence the medical teacher exerts on the student after he has graduated.

It may be said that the young practitioner is, in all essential details, an epitome of the ideas of his teachers. The more capable the practitioner, the greater his opportunities for practice and observation, the more extensive his reading, the more quickly does he become emancipated from this influence. After all, this is but natural and right. In the early days of practice, of what else should the tyro think when face to face with a difficult case, but of the teachings of his college days?

Just at this point it is essential that we emphasize something which is only too commonly lost sight of. The student of arts and letters, or the humanities in general, goes to an institution of learning essentially for the purpose of acquiring the methods which pertain to the investigation of his subject. It is of no sort of importance to him that he be familiar with any given detail. He is dealing rather with principles and generalities. He might be ranked as a very fair classical scholar and yet be totally unable to read at sight a given selection from a well-known classical author. It is all-important to the student of political economy that he know the method of that science, but it is by no means essential that he be familiar with any given set of statistics. These are in his books, to which he always has time to refer for the desired information.

PRACTICAL DEMANDS OF THE PROFESSION.

With the medical student the situation is vastly different. Not only must he thoroughly comprehend the methods of medicine, and be able to understand and apply the great fundamental principles, but in addition he must master the minutest detail of practice. It is by no means sufficient, to put the matter more concretely, that he have only a general knowledge of asepsis, but he must be able to put into instant practice all the minutiæ of rendering a room, a patient, an instrument aseptic. He may understand very well the general principles of the action of digitalis on the heart, or of iron on the blood composition, and yet practically be a complete failure unless he have at his fingers' ends the precise dose, mode of administration, and clinical effects of both. The medical student, therefore, must learn methods, *plus* the details of putting these mehods into practice.

The physician differs again from most of his brethren in other professions, in that his knowledge must be so coördinated and correlated as to be available for instant use, without reference to any authority. Now, the application of these facts to the question at issue is tolerably plain. The thoughtful teacher recognizes that the principles of the art and science of medicine must come first. They are the *sine qua non* for the successful understanding of any given medical topic. The surgeon very properly takes up, first, the problems of general surgical pathology. These once mastered, he may proceed to the details of practice. The professor of practice or of materia medica treats of the general action of drugs, and, when these are thoroughly understood, proceeds to the application of the knowledge acquired, by discussing their use in a given case. When one reflects on the enormously overcrowded medical curriculum of today, when every teacher on the faculty is clamoring for more hours for his especial subject, it is easy to understand that some things must suffer, and therapeutics is too frequently the one affected.

How is it with the clinical side of instruction? The professor of practice presents a given medical case, discussing in full its etiology, pathology and diagnosis. And then how about the treatment? In the main this is dismissed with a short reference to the general principles involved. Let us assume the case has been one of influenza. The student may be told that in addition to the ordinary precautions to be taken in any infection, the treatment should be supporting, with cautious use of the antipyretics, and stimulation when necessary. The trained clinician knows precisely what such general directions mean, the student has a very hazy and im-

* Read in a symposium on Proprietary Medicines and Nostrums before the Chicago Medical Society

perfect understanding of them. In consequence, when he receives his diploma he has a fairly large amount of theoretical, and some practical knowledge of pathology and diagnosis, with a very hazy and indistinct idea as to just precisely how he will treat a given case. This is not said in any sense of criticism of our clinical teachers. On the contrary I firmly believe that the very men whom we respect most for their ability, the men who are admittedly our most skilful diagnosticians and consultants are probably most at fault. The very profundity of their knowledge in regard to the pathology and diagnosis of disease, coupled with the fact that most of our recent advance in knowledge has been along the line of diagnosis rather than treatment, makes them reduce the time they devote to the medicinal therapy to a minimum.

THE NOSTRUM MAN'S OPPORTUNITY.

Time and again our most brilliant teachers will finish a clinic on chlorosis with the statement that the patient has been getting iron, and has been improving under its use. In one sense the details of its administration are unimportant, but it is exactly such teaching as this which leaves the student's mind in a receptive condition for the literature on the thousand and one iron nostrums which will pour in on him from the day he hangs out his shingle. The nostrum man thoroughly appreciates this fact. He takes particular pains to send with the very attractive looking samples precise information as to dose, administration, etc. Our young physician knows that iron is indicated. Why then should he not give preference to a preparation which, as the circular of information very distinctly tells him, will produce results far beyond anything contained in the pharmacopeia?

If in that clinic on chlorosis the teacher had spent ten minutes telling the essential facts in regard to the iron preparations; and, further, that many of the newer iron preparations are intrinsically worthless, the value of that clinic from a practical standpoint would have been doubled. If the student were told plainly, and without any equivocation, that the claims of many nostrums are absurdly extravagant, and that it is not in the least difficult to find for every nostrum so vaunted a better and simpler preparation from the pharmacopeia, he would hesitate before putting his signature to a prescription for any such preparation. He should be taught to estimate at their true value the opinions of physicians whose principal claim to fame rests on the fact that their name is continually seen signed to a report on the efficacy of somebody's cure-all. Indeed, even at the risk of having the student's opinion of the medical profession slightly lowered, it might be well to tell him in plain Anglo-Saxon terms that more than one person has written laudatory reports of somebody's preparation for no other consideration than that he was well paid for it.

It may be objected that the medical teacher's influence reaches only to the men in their first few years of practice. It may be said, "Oh, it is of no consequence what the very young practitioner does, for in the first year or two of his professional career he has little or no practice, and by the time he has acquired a practice he will have learned better." The reverse of this is apt to be the case. "As the twig is bent, the tree is inclined"—and the man who has acquired the habit of prescribing nostrums is likely to continue it.

NOSTRUMS PRESCRIBED BY PRACTITIONERS.

It seems to me that the very best possible way to ascertain just how extensively nostrums are being prescribed by the profession at large, is to go over the files of any reputable pharmacist and see what proportions of prescriptions call for such nostrums. In order to avoid any possibility of personalities I have requested a friendly pharmacist to go over some hundreds of recent, consecutive prescriptions, with the result that just 20 per cent. of these prescriptions call for some of these objectionable nostrums. I do not for a moment lose sight of the fact that a considerable number of proprietary preparations may be found by our Council on Pharmacy and Chemistry to have sufficient value to entitle them to consideration. But the nostrums to which I refer are such as are wholly objectionable because of their mode of advertisement, or because of the absurdly extravagant claims made for them. From this it will be perfectly apparent that the nostrum evil is one which has touched to a greater or less extent, not only the young and inexperienced practitioner, but also men of years of experience and reputation, in some cases the very elect. It would serve no useful purpose to give a list of the nostrums which I found as constituting 20 per cent. of the prescriptions just referred to. Nor is it part of my task to comment on these individually as this has been relegated to the Council on Pharmacy and Chemistry, which has much better sources of information, and therefore better judgment, than anyone working singly could possibly have.

THE CURRICULUM AT FAULT.

Another standpoint from which the medical teacher may be regarded as in a measure responsible for existing conditions, is to be found in the very anomalous position occupied by the subject of medicinal therapeutics in a large number of our medical schools in bygone years, and which, to the best of my knowledge, still obtains to a considerable degree. I refer to the very loose connection which has existed between medicinal therapeutics and the practice of medicine. Materia medica and drug therapeutics have been hitherto regarded as essentially elementary branches, and as such, usually relegated to the freshman and sophomore years in the curriculum, while the study of the practice of medicine is deferred to the junior and senior years.

Granting that materia medica, so-called, may be regarded as a distinctly elementary subject, the same thing can not be said of therapeutics. It seems utter folly to tell a sophomore student, for example, that the nitrites are useful in angina pectoris, when that same student has not had a single lecture on the practice of medicine, and has not the remotest idea what angina pectoris is, how it is produced, or in what way the nitrites might prove serviceable. Or, again, how absurd to tell another sophomore that digitalis is a most valuable drug in many heart lesions in the stage of decompensation, when he has no conception whatever as to what decompensation means. These are not theoretical points, but practical difficulties encountered in teaching that subject. In order to have our curriculum pedagogically logical, the teaching of therapeutics must go hand in hand with the teaching of internal medicine. All of us will admit, I think, that our students on graduation are more deficient in therapeutics than in anything else. The reason seems to me to be self-evident, and to lie in the fact, already stated, that the instruction in therapeutics and practice is separated by an interval of a year or more instead of being given simultaneously.

CONCLUSION AND SUMMARY.

I am well aware that it is much easier to point out defects than to suggest the remedy, but it seems to me that a considerable portion, if not all of the instruction in therapeutics proper, should be under the auspices of

the chair of practice, and closely correlated with it. This would certainly be of much greater advantage to the student than the crowding of a host of minor specialties into the senior year of the curriculum, a practice now so generally in vogue in our schools. He would come to the day of graduation with his knowledge of therapeutics and practice both equally fresh in his mind, and with a feeling of sturdy independence in regard to the claptrap literature dispensed by the nostrum vendor.

To sum up the situation, the medical teacher can not escape the reproach of having contributed in one way or another his share to the creation of the existing deplorable state of affairs. This responsibility is, I believe, of a purely negative character.

1. The subject of medicinal therapeutics in general has been subordinated in an undue degree to pathology and diagnosis.

2. In his teachings of therapeutics clinically the medical teacher has contented himself too often with vague general statements instead of recognizing that the subject is essentially one of detail, and entering on its discussion in the most minute way.

3. The teacher has presented the subject of therapeutics at the psychologically wrong moment instead of in direct connection with the subject of practice.

4. The teacher of materia medica has often failed to do his complete duty in not acquainting the student with the situation in regard to nostrums as it actually exists, and by thus sounding a note of warning, sending him out forewarned and forearmed.

WHY THE WORK OF THE COUNCIL ON PHARMACY AND CHEMISTRY IS NECESSARY.*

J. H. LONG.
Professor of Chemistry, Northwestern University Medical School.
CHICAGO.

When it has been made plain that the public or some section of the public has been systematically outraged for years the question arises, What are you going to do about it?

There was a time when most of the medicines used by physicians were prepared by themselves or by methods with which they were familiar, just as there was a time when every family prepared most of the food which it consumed. But those days are past, and trusting others to manufacture our foods and our medicines has led to gross abuses in which the general public, the physician and the patient all suffer. The food problem and the medicine problem have much in common, and a study of what has been done in the one case suggests what may be done in the other.

Just here it must be remarked that the trouble is not because of lack of supply of good food or good medicine. The reverse is true. In the world to-day there is more good sugar, good meat, good flour and good vegetables than ever before. Agriculture has advanced. So there is more good quinin, good calomel, good opium or good chloroform in the world than ever before; manufacturing pharmaceutical chemistry has also advanced. This is not the difficulty, but it is right here: We are being ridiculed, mystified and sometimes even bribed into believing that the thousand and one new things are so much better than the dozen or fifty old things with which we have been long familiar and the virtues and faults of which we know. The root of the whole evil may be referred back to the advertising mania which has taken possession of this country. It seems to be a practical truth that any article, no matter how bad it is, may be sold by sufficient advertising. With great gain to the people as a whole, 95 per cent. of all advertising might be dispensed with.

"CONCENTRATED" FOODS.

Indirectly the growth of the science of chemistry is responsible for the acceptance of some false notions. In the early days of physiologic chemistry people were taught to believe in the possibility of certain extracts or concentrated forms of food, and before scientific men could clear up the matter the general public caught the idea and has held it more or less tenaciously ever since. Hence the possibility of convincing a man by blatant bill-boarding or some other objectionable form of advertising that a pound of a cheap mixture of glucose and toasted bread contains more nourishment than ten pounds of meat. Hence the possibility of persuading a man to think that a concentrated, so-called predigested or otherwise doped-up breakfast food is better than honest oatmeal or bread and butter. Parallel to this blind faith in highly advertised and often very inferior foods is the common faith among physicians in the virtues of the so-called synthetic remedies, especially if they are made in Germany. In too many cases there is little justification for this faith.

But these evils, bad as they are, are being cured, and in spite of the Illinois Food Commission. The able men connected with the Department of Agriculture at Washington and with some of the food commissions outside of Illinois are gradually educating the public. Some day we shall have a national pure food law, and such frauds and misrepresentations as are now frequently heard of will become rare.

THE ADVERTISING OF NOSTRUMS.

But how is it with drugs and medicines? I spoke a moment ago of advertising, and it so happens that the overzeal of the advertiser has suggested the way to begin the correction of the whole matter. The manufacture of standard drugs is a legitimate and long established business which requires no special advertising. Good goods sell themselves with very little booming. They are like wheat. But fake medicines, like fake foods, must be advertised, and widely advertised, to sell. If the publicity can be checked the frauds must fail. The medicine manufacturer naturally looks to the medical journals as his advertising medium. If in the minds of the publishers of such journals the right sentiment against fraud can be created the battle for honesty and decency here is practically won.

But in striving to shut out the advertising of fake medicines there is always some little danger of excluding also a really meritorious article, and occasionally something of the sort appears. The physician can not now be expected to discriminate between the good and the bad which is offered him; that would require far too much special knowledge. The nature of food stuffs and the limitations in the manufacture of foods are pretty well known, and false claims are very easily disproved. But it is not so with most drugs. Some of the newer things are powerful and excellent remedies. With the advance of organic chemistry greater possibilities are developed, and we must admit that we do not know the limitations here at all. Hence when the manufacturer or his agent offers a description of his new ware for advertisement the publisher is not, off hand, justified in rejecting it unless the claim made is on its face inconsistent and absurd. There should be some way of proving the truth or falsity of the claim before accepting

* Read in a symposium on Proprietary Medicines and Nostrums before the Chicago Medical Society.

or rejecting an advertisement, and such considerations were among the first to suggest the value and importance of work like that undertaken by the Council on Pharmacy and Chemistry.

It may be said that the publisher is not responsible for the truth of what goes into his advertising columns. That depends on what he publishes. The daily papers may advertise real estate, or $10 hats marked down to 39 cents, and the buyer can see for himself. But with the advertising of drugs and medicine the case is wholly different and the responsibility great. This responsibility is very great if the advertising medium happens to be a medical journal, for from such a publication we have the right to expect consistency if nothing more. Until recently few publishers of medical journals gave much thought, apparently, to what went into their advertising columns, since most of these journals carried, and some continue to carry, advertisements of medicines as preposterous as Lydia Pinkham's, Peruna, and Wine of Cardui. This shameful fact points to a peculiar conception of "ethics" in medical journalism and makes us wonder where, in the code of the medical editor, lies the distinction between an honorable profession and a conscienceless trade.

WORK OF THE COUNCIL ON PHARMACY AND CHEMISTRY.

Two or three years ago the editor and others connected with THE JOURNAL of the American Medical Association began to talk of systematically controlling the character of the matter in the advertising pages. A number of pharmacists and chemists were consulted as to ways and means. Finally the various suggestions took tangible shape and about a year ago the Council on Pharmacy and Chemistry was organized. This council consists of three committees—one on pharmacy, one on pharmacology and one on chemistry. The men constituting the council are active in different lines of scientific work related to medicine, and with this division of labor it is possible to scrutinize an article from several standpoints. Very often samples of the articles to be advertised have been sent to all members of the council for study. Already some good results have been reached and a number of frauds have been publicly exposed. I recall, for illustration, the acetanilid mixtures, but these are not all. They were merely the beginning of a series, and as the work of the council progresses it will do for medicines what those connected with some of the state food commissions are doing for what we eat. Surely the medical man should know the exact nature of what he is asked to prescribe, and the work of the council is to find out and publish as far as possible the true nature of all articles of remedial nature offered to the physician.*

This is a difficult undertaking and haste can be made but slowly. Above all things else, the work of the council must be correct, since great interests are at stake and justice to all must be done. The council does not care to pry into the secrets of the manufacturer's business, but it does insist on knowing the truth about the article manufactured if it is to be used in the treatment of disease. Hundreds of routine analytical and other examinations have been made and a good part of the time of the council has been consumed in investigating and, in some instances, showing up the fraudulent mixtures described as synthetic, which bear about the same relation to real synthetic preparations that a mixture of tacks, paving stones and ostrich plumes would bear to gold watches. Legitimate medicines have nothing to fear, but trash, hiding behind false descriptions, must be brought out into the light.

THE PARASITISM OF THE TUBERCLE BACILLUS AND ITS BEARING ON INFECTION AND IMMUNITY.

THEOBALD SMITH, M.D.
George Fabyan Professor of Comparative Pathology in the Harvard University Medical School.
BOSTON.

(*Concluded from page 1254.*)

To return to our subject of focal immunity. This, as contrasted with a general resistance, is probably the chief stumbling block to successful artificial immunization. To bring about the latter the whole body has to be exposed to the immunizing (and toxic) substances, as there is no other way of reaching certain avenues or portals of entry which are exposed to invasion. We might, for instance, cause the inhalation of an impalpable dust or spray of ground tubercle bacilli to increase the resistance of the lungs in the healthy and the diseased, but then the greatest care would have to be exercised not to give an overdose to an affected lung; otherwise a very severe or even fatal congestion due to the local tuberculin reaction might result.

This problem of local immunity and its relation to a general immunity has occupied my attention for a number of years. Beginning in 1898 I carried out a long series of experiments on guinea-pigs with bacilli killed at 60 degrees and 100 degrees centigrade to see how far a focal or local immunity contributed to a general resistance. These experiments have been frequently interrupted and are still incomplete partly because the equipment needed to protect attendants has not been available. So far only dead bacilli have been employed throughout. The animals used were guinea-pigs. No striking results have been obtained, and hence the work has remained unpublished. The experiments bear, however, on the subject before us and I shall briefly refer to them here.

If we inject a certain amount of a suspension of tubercle bacilli in some different fluid, and killed at 60 degrees centigrade, into the peritoneal cavity of guinea-pigs, no immediate effect is produced. There may be at first slight loss in weight or none at all. After four to eight weeks the guinea-pig, outwardly well, is sensitive to tuberculin. An ordinary dose may kill it or reduce its weight considerably. At this time the peritoneal cavity may or may not show any local proliferation. In the omentum some nodules may be found centrally disintegrated, soft, like pus, but consisting only of the usual fatty débris. The inner wall of the nodule is smooth, there are no signs of a progressive disease anywhere recognizable with naked eye or in sections with the microscope.

If we now inject a second similar dose, the guinea-pig within twenty-four hours begins a prolonged tuberculin reaction associated with fever and rapid loss in weight. If we examine the peritoneal cavity after one or more weeks, we now find considerable hyperplasia of the omentum, more rarely eruptions on the peritoneum of the abdominal wall. The omentum may become very large and adhesions may bind it to various organs, especially to the upper small intestine and lead in some cases to intestinal hemorrhage and rapid loss in weight, even death.[12]

This second severe reaction I regarded as due to the rousing of a local immunity by the first reaction. The

12. Since making these observations I have asked myself whether some of the tubercular eruptions of the peritoneum, cured by operation, may not have been due to dead or nearly dead bacilli discharged from an old focus on a promptly reacting, because partly immunized, membrane.

bacilli first injected into a neutral territory were probably largely carried off into different tissues before any local reaction took place, for I found histologic traces of their presence in the liver, spleen and bronchial glands. The phenomenon is thus similar to the invasion of the lymph nodes in the neutral body. At the same time many bacilli remained in the omental tissue and in the immediate neighborhood of the abdominal cavity. The second injection caused a prompt reaction on the part of the tissues first invaded and the bacilli were largely held there; hence the great proliferation of the omentum.

This increased local reaction following invasion is a general phenomenon, not limited to tuberculosis. When animals of more than the usual resistance are inoculated with septicemic organisms, the local reaction is always more severe and the disease more prolonged than in the most susceptible. If very susceptible animals are first partly immunized, the local reaction following the test inoculation grows more severe, parallel with the immunity, up to a certain point.

The question now arose, How much immunity have other distant tissues gained by this intraperitoneal local vaccination? If more or less general resistance is gained, why not induce with dead bacilli focal foci in the periphery of the body under the skin, for example, where they can be controlled and watched? To test this, the abdominal cavity and the subcutis were used. A long series of guinea-pigs were inoculated, some into the abdomen, some under the skin, some with bacilli killed at 60 degrees centigrade, others with those killed at 100 degrees centigrade. The cultures were all relatively young cultures, both human and bovine, grown on dog's serum. The conditions were made as uniform as possible. In order to estimate the relative reaction caused by the subcutaneous and the intraperitoneal injections the subcutaneous focus and the omentum were examined histologically. In general it may be stated that there was evidence that one injection had some influence on distant parts of the body, but this was distinctly below the influence imparted locally.[13]

IV. SOME SUGGESTIONS CONCERNING THE PRACTICAL APPLICATION OF METHODS TO PRODUCE IMMUNITY.

The experiments made on cattle with human tubercle bacilli by Behring, Pearson, Koch and others have shown that a pronounced resistance to living bovine cultures may be established even in young animals. This procedure is, of course, inapplicable to man. In the immunization of cattle two factors operate very strongly toward the success of the process: First, the intravenous injection of the bacilli which carries them to every part of the body and especially to the lung tissue where we know the bacilli are likely to be held back in large numbers. Here they are most needed to produce a local resistance in the most frequently exposed and diseased organs (lungs and lymph nodes) of the body. It is doubtful that the bacilli multiply at all after injection.[14] In the second place, the postmortem examination of spontaneously and artificially infected cattle has led me to believe that cattle are in a fair state of equilibrium with their bacillus and that there is needed but a relatively slight impulse at the right place to establish a resistance which will promptly suppress the invaders.

The investigations of Nägeli, Necker and others which reveal a very high percentage of latent or arrested infection in the human subject also indicate that the normal human being possesses considerable resistance and that after infection only a slight impulse efficiently applied may suppress the disease at an early stage. This encouraging possibility leads me to believe that there is a great opportunity for some form of preventive inoculation before the disease has fastened itself on the predisposed subject, if such a process could be introduced. This vaccination should be equally applicable before and after infection, and for the purpose of discussion for the time being may be regarded as identical. The general outcome of the investigation with bacilli killed at various temperatures has encouraged me to suggest their use for immunization. The very fact that they are so much more efficacious than the old tuberculin in rousing the antagonism of the body is significant But it may be said the injection of dead bacilli will lead to a local focus, an objection which Koch tried to overcome at the start by extracting the bacilli and so producing the old tuberculin. It may also be asked what advantage can there be over the ground and crushed bacilli which have been subjected to no heat whatever and which are now being used by A. E. Wright and others in the treatment of chronic skin affections. It may even be urged that immunity or increased resistance has been attained in exceptional cases by the repeated injection of the old tuberculin. Macfadyan and C. Sternberg refer each to such a case. A relatively high degree of resistance has been reported by Koch to be attainable with his new tuberculin TR. There can be no doubt that all the preparations emanating from tubercle bacilli or the culture fluids contain substances which induce some resistance. If the reaction of the body is made up of several factors, as I have tried to explain, then the strengthening of any one factor may favor the final resistance produced.

The advantages which, I believe, will flow from the use of bacilli killed at a low temperature are twofold:

1. The creation of a local focus of ever so slight a character, let us say in the subcutis, may lead to the production of immune bodies which, radiating from

13. In connection with these I tried to see if the injection of tubercle bacilli heated to one hundred degrees centigrade would produce any impression on a rapidly fatal infection with living bacilli. Eighteen guinea-pigs were used. In the first half of the experiment some received one injection of boiled bacilli into the abdomen, others the same into the subcutis. After eight weeks they and controls received a surely fatal dose of living bovine bacilli into the abdomen. I knew that none would resist this dose and I simply wished to see what differences might appear. The abdominally immunized pigs lived longest, next came the subcutaneous cases and then the controls. The gain in prolonged life averaged only about seven days for the protected pigs. But the significant features of the experiment were exhibited in the course of the disease. The controls became feverish on the ninth day, yet even sixteen days later than this the vaccinated pigs were still well and active. Soon, however, they became ill and died suddenly. Here the immunity held the disease in check for a time, but when the resistance was finally overcome the process was very rapid. In the second half of the experiment, the guinea-pigs received two preliminary doses of boiled bacilli: one into the abdomen, the other under the skin. The same early checking of the disease was seen, a decided difference between treated and untreated being noticeable. All, however, succumbed, the average survival of the treated was about fifteen days longer than that of the untreated. The contrast would probably have been more striking if I had limited the test to a small number of fatal doses of bovine bacilli rather than to the large dose actually given. Experiments similar to this have probably been made by many others before

14. It is of interest here to note that according to Behring the intravenous injection of these human bacilli into adults may cause a fatal pulmonary edema, which we may explain as a local tuberculin reaction in infected animals. I described a similar condition in rabbits several years ago. After intravenous injection of certain cultures mid-way in virulence between the bovine and the human types, a fatal pulmonary edema and hyperemia may appear after four or five weeks. This is probably a true tuberculin reaction of the lungs due to the extensive destruction of tubercle bacilli and the liberation of poisons. Similar pulmonary accidents in goats were described by Arloing.

the focus, may prove efficacious. These foci may be multiplied by simply changing the point of injection. It may be that the very objection urged by Koch against a local focus, namely, that the immunizing substances remain there, is the very essence of the whole process. At any rate, we have no reason for believing that the crushed or ground bacilli or even the tuberculin TR. is diffused more rapidly after the reaction of the body has been roused. Levene found that even fats repeatedly injected subcutaneously finally led to a local reaction with induration. In looking over the literature recently I was surprised and gratified to learn that Maragliano had recommended some such mode of treatment in his Philadelphia address.[15] Such local foci can be watched and their behavior correlated with the general subjective and objective symptoms.

The second advantage to which I wish to call attention concerns the material to be injected. In the production of immunity the tubercle bacilli to be used should be as recently isolated as possible and grown on blood serum to which pieces of sterile animal tissues may be added if desirable. If the theory I have advanced be true, that the body first acts on some product of secretion in the bacillus which has taken the form of a protective envelope, then the more recently isolated the culture and the more nearly the culture medium approximates the living body the more likely the active production of this envelope. This, of course, should be present in the bacilli to rouse to greater activity the antibody or opsonin after injection. The products in the market are prepared on a large scale from actively multiplying bacilli. A long experience leads me to the inference that there is an inverse relation between virulence and activity of multiplication. I have also pointed out that the slow accustoming of tubercle bacilli to media on which they at first absolutely refuse to multiply suggests the throwing off of some restraint (such as an envelope) either by all bacilli gradually or through the selection of a few which more quickly adapt themselves. The use of such early cultures of tubercle bacilli, grown on appropriate media, carefully killed at 60 degrees centigrade and tested with proper precautions before application, is within the reach of every hospital or sanatorium dealing with tuberculous patients.

My reason for presenting a method which I myself have not tried is because I have no opportunities for such trial, and I am convinced that the delicate methods of immunization can not be successfully tested on any animals, except perhaps monkeys and cattle, and there are obvious objections and difficulties to be met in the use of either species. I believe that this method should at least be given a trial, although its execution will require considerable personal care and the observance of minute details which the medical profession is inclined to throw on the commercial bodies who manufacture biologic products, but from whom such kind of work can hardly be expected. Of especial importance is the test that the heated bacilli are actually dead, for the temperature of 60 C. is the critical temperature, below which tubercle bacilli are probably not destroyed. Experiments still incompleted indicate that bacilli killed in this way possess properties approaching the living organisms.

CONCLUSION.

In conclusion, I wish to allude briefly to the struggle against tuberculosis from the point of view of the bacillus itself, for the slight changes which this parasite undergoes are writ large on the history of mankind. By spying about the enemy's camp we may learn much for our own safety.

The tubercle bacillus is undoubtedly open to modification, and we may safely believe that there are a large number of races or varieties in existence. Even among the small numbers which we are able to study carefully in the laboratory, there are constant differences indicated by biologic and pathogenic tests. These must be the result of natural selection and brought together perhaps by the great immigration movements of the present era.

The thesis which I tried to discuss recently is that the tendency of infectious diseases is toward a balanced parasitism, with a reduced mortality, but not necessarily a reduced morbidity as a result. This is due to the selective adaptation of both host and microbe. For the latter the most important need is the establishment of a definite mode of entry and exit. In the case of the tubercle bacillus the chronic infection of the lungs is the most favorable type of disease for the microbe itself. This selective adaptation will go much farther, I believe, and we shall undoubtedly meet with bacilli of very low invasive power which find a favorable nidus for multiplication in bronchial secretions. There is already some evidence that tubercle bacilli in sputum do not always signify serious consequences.

The only way to determine the relation between pathogenicity and character of the disease would be a study of the bacilli themselves. This would throw such an additional burden on clinical medicine that we can hardly hope for much progress in this direction. These very attenuated forms would become, as it were, the parasites of the sick lungs rather than of the normal ones. They would take the same position which pneumococci, streptococci and staphylococci occupy in the upper air passages.

The influence which a possible immunization of the human race might have on the destiny of the tubercle bacillus is open to debate. In the first place, all immunization is a confession that the parasite has broken through barriers and has come to stay. The only way to suppress an infection is to do so rather than to establish a compromise by simply increasing our resistance. The latter is admirable from every point of view, but it is not by itself going to eliminate tuberculosis. The only way to accomplish this is to prevent the bacillus from attacking a new subject. Immunization, combined with isolation and other preventive measures, would probably place a decided check on the disease, while immunization by itself alone would lead eventually toward the selection of especially virulent races of the tubercle bacillus which, producing a mild disease in the partially immune, would probably cause a very severe disease in the unprotected or unvaccinated. If the method of immunizing cattle now made generally possible by the commercial exploitation of Behring's bovovaccine should become widespread, we would be treated to a most valuable object-lesson of the effects of this process on the protected and unprotected. With the introduction of such a method there is likely to come a slackening of the usual preventive measures and a more indiscriminate dissemination of tubercle bacilli followed eventually by the appearance of more virulent races of bacilli.

In this fragmentary exposition of the parasitism of the tubercle bacillus I have left many phases of the subject untouched, many statements undeveloped and cer-

15. Medical News, lxxxiv, 1904, p. 625.

tain theories quite unprotected. My purpose in presenting them is not so much to produce conviction as to stimulate others either to develop them further or else to rout them and to put something better in their place. They may be regarded as working hypotheses through which I have attempted to correlate existing data, my own studies serving merely as a guide through this Babel of theories.

The best that the laboratory worker can do is to suggest principles or laws which must be intrusted to the clinician, if he will accept them, to be developed and applied to the many variations which actual spontaneous disease manifests. It is also true that the working out of methods in the laboratory and their clinical application are two wholly different problems. Experimental and clinical medicine must work hand in hand, with the closest co-operation, if one does not wish to disappear in pitfalls known only to the other.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN.

CHAPTER XIX.

TONICS (CONTINUED).

Manganese.

Manganese is not absorbed from the alimentary canal after ordinary doses, hence it acts as a hematinic only in so far as it spares iron by uniting with the sulphur which occurs in the intestines in the form of compounds.

Manganese, therefore, would hardly deserve consideration here if it were not for its widespread use, thanks mainly to the skilful and none too scrupulous methods often employed in the exploitation of certain nostrums containing it.

It is not probable that manganese possesses any advantage whatsoever over the numerous official preparations of iron.

The so-called peptonized manganese preparations, generally solutions of peptone to which some salt of manganese has been added, may be obtained from reputable dealers in chemicals, or may be made by any retail pharmacist who has the necessary educational qualifications to conduct even the very simplest chemical experiments.

A mixture containing iron peptonate and manganese, and one that in many respects is superior to the preparation so extensively sold to the laity, in this country, as "Peptomangan Gude," has been included in the new edition of the National Formulary, now in press. Where it is desired to use a simple solution of manganese peptonate, it may be prescribed as follows:

R. Mangani peptonati	3v	20
Syrupi aurantii	3xii	50
Aquæ dest. q. s. ad	℥x	300

M. Sig.: One tablespoonful after each meal.

It should be remembered, however, that dry preparations of peptonates of iron or manganese, do not keep well, and it will usually be found to be preferable to have a reliable pharmacist prepare a solution, similar to the compound solution of peptonate of iron with manganese, of the National Formulary, which is preserved by the addition of a small quantity of alcohol, with sugar and aromatics.

OFFICIAL PREPARATIONS OF MANGANESE.

The official preparations of manganese are limited in number, and, as suggested above, are even more limited in their practical application as tonics or hematinics; they are:

MANGANI DIOXIDUM PRÆCIPITATUM.—U. S.—Precipitated manganese dioxid is a new preparation that has been added to replace the formerly applied crude product. Manganese dioxid, as now official, is directed to be made from manganese sulphate and should contain not less than 80 per cent. of manganese dioxid.

Average dose: 0.25 gm. (4 grains).

MANGANI SULPHAS.—U. S.—This occurs as colorless or pale pink crystals that are soluble in less than one part of water, but insoluble in alcohol.

Average dose: 0.25 gm. (4 grains).

POTASSII PERMANGANAS.—U. S.—This substance has been mentioned in the chapters on disinfectants and antiseptics. In connection with tonics or hematinics it is of interest only as the source of some of the now popular organic preparations of manganese.

Arsenic.

It is not positively known whether arsenic is an essential constituent of the human body or not.

Segale, using penicillium brevicaule, with which infinitesimal quantities of arsenic may be diluted, found it widely distributed in animal tissues, and Bertrand found it in eggs, particularly in the yolk.

Wieser concluded that arsenic is not a constant constituent in animal and human tissues, but that it is accidentally present.

When one considers the distribution of arsenic in plants, in sea water and in many springs, it is apparent that abundant opportunity occurs for its entrance into the body, and, owing to its slow excretion, the organism may rarely be without traces of it.

If minute traces of arsenic are essential to the well-being of the body we may be sure that the ordinary food insures an abundant supply.

Gies found that those members of a litter of rabbits which received arsenic grew faster than the others, while female rabbits under its influence bore larger young. This increased rapidity of growth has been observed by some, but not all, subsequent investigators. In this connection the observation of arsenic in the yolk of egg is at least suggestive.

The toxicology of arsenic is of peculiar interest because of its frequent use with fatal effect and because the appearance of the earliest symptoms are used as a guide in the therapeutic use of the substance.

The most striking effect of acute arsenical poisoning is seen in the symptoms closely resembling those of Asiatic cholera, and which are explainable by the characteristic action on the capillaries, particularly those of the abdominal region.

The capillaries appear to suffer a peculiar paralysis and dilation, resulting in an enormous increase in permeability. The escaping plasma of the blood makes its way into the intestine and, congulating, gives rise to the "rice-water" stools. The withdrawal of the blood from the rest of the body into this region and its loss, as mentioned, causes the usual symptoms of collapse.

The direct effects on the heart are too slight in such cases to be considered as important, and the corrosive action of arsenic is too slowly developed to be concerned in the immediate effects just described, which rapidly follow the absorption of a poisonous dose. When the poisoning is more slowly developed, however, as after frequently repeated smaller doses, catarrh of the gastrointestinal tract is seen and fatty degeneration of various organs takes place, the picture somewhat resembling that seen after phosphorus poisoning.

Even therapeutic doses frequently repeated give rise to effusion of liquid, commonly noticeable in the swollen eyelids.

Arsenic is said to be capable of increasing the number of erythrocytes in anemia through its action on the bone marrow, but Engel found no increase in the mature red blood cells in anemia; other observers failed to see any change in the red blood cells or in the hemoglobin, though it is acknowledged that the bone marrow is stimulated to unusual activity.

It has been claimed that arsenic actually diminishes the number of red blood cells in chlorosis without altering the total amount of hemoglobin.

It has been suggested that the influence of arsenic on metabolism is due to alternate reduction and oxidation, arsenous and arsenic acids being repeatedly formed, but this seems hardly probable.

OFFICIAL PREPARATIONS OF ARSENIC.

Arseni Trioxidum.—U. S.—Arsenic trioxid was formerly official as Acidum Arsenosum. It consists of not less than 99.8 per cent. of pure arsenic trioxid. It may occur in transparent masses, like glass or in opaque masses resembling porcelain; more frequently, however, it is found as an odorless and tasteless white powder that is slowly but completely soluble in 100 parts of water but very sparingly soluble in alcohol. The presence of either alkalies or halogen acids facilitates the solution of arsenic trioxid, and this fact is taken advantage of in the preparation of the several official solutions. White arsenic, as it is still called, was not known in Europe until some time after the eleventh century. It was scarcely well defined until 1733, when Brandt accurately determined its nature and leading chemical properties.

Average dose: 0.002 gm. (2 mg. 1/30 grain).

Arseni Iodidum.—U. S.—Arsenous iodid occurs as an orange red, inodorous crystalline powder. It is soluble with partial decomposition, in about 12 parts of water and in about 28 parts of alcohol.

Average dose: 0.005 gm. (5 mg. 1/10 grain).

Sodii Arsenas.—U. S.—This occurs as colorless, transparent, odorless prisms that are soluble in less than two parts of water, but very sparingly soluble in alcohol.

Average dose: 0.005 gm. (5 mg. 1/10 grain).

Sodii Arsenas Exsiccatus.—U. S.—This should contain not less than 98 per cent. of pure anhydrous Di-sodium-orthoarsenate. It occurs as an amorphous white powder, permanent in dry air; it is soluble in about three parts of water and is practically double the strength of the hydrous or crystalline preparation mentioned above.

Average dose: 0.003 gm. (3 mg. 1/20 grain).

SOLUTIONS OF ARSENIC.

While several of the preparations of arsenic appear to have been known and used, from time immemorial, as topical applications, the internal use of arsenic, in Europe, appears to date from the introduction of the solution of potassium arsenite, popularly known as Fowler's solution, about 1786. During the following decades a number of modifications of this solution of arsenic were suggested, by medical practitioners and apothecaries, all of which had, or were supposed to have, some distinctive properties. Of these almost innumerable solutions that have been proposed during the past century, the following are now official:

Liquor Potassii Arsenitis.—U. S.—The solution of potassium arsenite, universally known as Fowler's solution, as noted above, was the first of the several solutions to be used and is even now the most popular, being known in every civilized country in the world.

Solution of potassium arsenite contains the equivalent of 1 per cent. of arsenic trioxid, with a sufficient amount of the compound tincture of lavender to give the preparation a distinctive color and flavor.

Average dose: 0.2 c.c. (3 minims).

Liquor Acidi Arsenosi.—U. S.—This solution of arsenous acid contains the equivalent of 1 per cent. of arsenic trioxid, with 5 per cent. of diluted hydrochloric acid. This preparation was introduced, about the end of the eighteenth century, by Dr. DeValanquin, a native of Switzerland, who was practicing medicine in London; it was the first of the several acid preparations of arsenic.

Average dose: 0.2 c.c. (3 minims).

Liquor Arseni et Hydrargyri Iodidi.—U. S.—This preparation, more popularly known as Donovan's solution, contains 1 per cent. each of arsenous iodid and mercuric iodid.

Average dose: 0.1 c.c. (1½ minims).

Liquor Sodii Arsenatis.—U. S.—This solution of sodium arsenate, also known as Pearson's solution, contains 1 per cent. of exsiccated sodium arsenate.

Average dose: 0.2 c.c. (3 minims).

THERAPEUTICS OF ARSENIC.

While the probability of favorably influencing nutrition under certain conditions, by means of the action of arsenic on the capillaries can not be doubted, its therapeutic use for such purposes is empirical. The use of arsenic as a local caustic has a rational basis, but that will not be discussed here.

Arsenic has long been used in the treatment of a great variety of complaints in which anemia is a prominent symptom. Among these conditions is remittent fever, in which it is given in connection with quinin. It is preferable to give the two separately, arsenic being used in the form of the solution of potassium arsenite, which has a wide range of pharmaceutic incompatibility, being virtually an alkaline solution. This solution may be given in large doses—ten drops—gradually reduced, or in small doses rapidly increased until intestinal symptoms or swelling of the eyelids is seen, after which the drug is to be discontinued for a time, and then given in doses of from three to five drops three times a day. It is of importance that the dosage be watched so that no serious disturbance of digestion may occur. The frequently made suggestion to combine preparations of opium with the preparation of arsenic, so as to establish a tolerance for the latter, is one that is of doubtful utility in view of the fact that opium would be likely to mask the symptoms that occur as forerunners of more serious disturbances.

In chlorosis, arsenic seems to be useful in connection with iron. The combination most frequently prescribed is a pill of ferrous carbonate with arsenic trioxid. For this purpose the latter may be combined with the official pill of ferrous carbonate or with the mass of ferrous carbonate, as follows:

℞. Massæ ferri carbonatis .....3i 4|
Arseni trioxidi .....gr. i |05
M. et div in pil No. xl.
Sig.: One pill three or four times a day.

Pernicious anemia may show some temporary improvement under arsenical treatment, but the effect is not permanent.

It has been said that lymphosarcoma has shown improvement under its use, and the following conditions are enumerated among those in which it has been employed: Dyspepsia, diseases of the skin dependent on nutritional derangements, cachectic conditions resulting from diabetes, tuberculosis and a number of other more or less well-defined diseases.

The use of arsenic among veterinary surgeons for improving the appearance of horses by increasing the glossiness of the hair and adding to the fat under the skin is well known.

Phosphorus.

Phosphorus, in both inorganic and organic combination, is widely distributed in the body. Lecithin, a compound of cholin with phosphoric and fatty acids, occurs in nearly all living animal and vegetable tissues, while the nucleins, which are also rich in phosphorus, are likewise widely distributed.

While some observers have found that when lecithin or nuclein was added to the food of animals the latter grew faster than the controls which were not given these compounds, these results are not universally accepted as proving their value, and we have the classic research of Miescher, which proves that the animal organism is abundantly able to form those compounds from others normally existing in the body.

Miescher found that the mass of eggs in the salmon increased from 0.4 per cent. to from 19 to 27 per cent. of the total body weight during some months when the salmon took no food, while the muscles showed a corresponding loss in weight. Much more nuclein and lecithin are found in the eggs than previously existed in the muscle, which, however, are rich in other phosphoric-acid compounds, probably potassium salts which are loosely bound to the proteid.

Miescher concludes, and the evidence seems incontrovertible, that the newly formed combinations characteristic of the egg (including lecithin and nuclein) are formed by chemic action from the albumin, fat and phosphates of the muscle.

It will be readily seen how the makers of nostrums can use such results as those quoted in regard to the action of lecithin in causing an increase in the body weight, while the much more important and generally accepted results of Miescher are ignored.

Phosphorus and its preparations might be omitted without

serious detriment to these articles but for the fact that they have been so widely used and therefore require at least a passing notice, particularly as the toxicology of phosphorus is of considerable interest.

The heart suffers greater direct injury in phosphorus poisoning than does any other organ, while the accumulation of fat which it causes in the liver is apparently an infiltration, resulting from a peculiar disturbance of metabolism rather than the result of any change in the organ itself.

Hemorrhages may occur from degeneration of the capillary walls, while a similar effect on the mucous membranes of the stomach and intestine causes pain, vomiting and diarrhea.

Minute doses of phosphorus, long continued, induce a peculiar change in the growth of bones in the young, leading to the deposition of dense bone where cancellous is being formed, or the change of the latter, when already formed, into the compact form.

The phosphates are of the very greatest importance in the plant and animal bodies, but they occur so abundantly in the soil and in ordinary food that there is seldom any deficiency in the supply, and any want of them in the human body must be due to the inability to use that which is offered. Schmiedeberg calls attention to the formation of the egg shell as evidence of the great capacity of the animal organism to supply a special demand.

Sollmann states that there is absolutely no scientific foundation for the popular belief that the hypophosphites improve nutrition in anemia and beginning phthisis, while Cushny states that most reliable investigators deny that they have any other influence on nutrition and digestion than that of the better known and cheaper salts of lime, soda or iron and Schmiedeberg appears to think them entirely unworthy of notice.

Many clinicians, on the other hand, appear to have observed a distinct improvement in the appetite and digestion under the influence of the hypophosphites, but even if such is the case, there seems to be absolutely no reason or excuse for our employing such a high-priced, unsightly and unscientific preparation as the muddy-looking Fellow's syrup, since any competent pharmacist can make a more presentable and more satisfactory preparation at a very much smaller cost. In fact, if the hypophosphites do possess any distinct medicinal properties, the official preparations afford an ample choice for any condition or need.

OFFICIAL PREPARATIONS OF PHOSPHORUS.

PHOSPHORUS.—U. S.—A translucent, nearly colorless solid, having at ordinary temperatures about the consistency of beeswax.

Phosphorus is nearly insoluble in water, but is soluble in 350 parts of alcohol and in 50 parts of a fatty oil.

Average dose: 0.0005 gm. (0.5 mg. 1/128 grain).

PILULÆ PHOSPHORI.—U. S.—Each pill contains 0.0006 gm. (0.6 mg. 1/100 grain).

Average dose: 1 pill.

ACIDUM PHOSPHORICUM.—U. S.—This contains 85 per cent. of absolute orthophosphoric acid. It is usually prescribed as:

ACIDUM PHOSPHORIC DILUTUM.—U. S.—This contains 10 per cent. of absolute orthophosphoric acid.

Average dose: 2 c.c. (30 minims).

Phosphoric acid has many of the properties of other (inorganic) acids, and probably has no evident advantage over them as a tonic.

The official salts of phosphoric acid usually partake of the properties of the base rather than the acid, and need not be mentioned in this connection.

ACIDUM HYPOPHOSPHOROSUM.—U. S.—This contains 30 per cent. of absolute hypophosphorous acid and is chiefly used in preparing:

ACIDUM HYPOPHOSPHOROSUM DILUTUM.—U. S.—This contains 10 per cent. of absolute hypophosphorous acid.

Average dose: 0.5 c.c. (8 minims).

The official salts of hypophosphorous acid are:

CALCII HYPOPHOSPHIS.—U. S.

POTASSII HYPOPHOSPHIS.—U. S.

SODII HYPOPHOSPHIS.—U. S.

Average dose of any one of the above: 0.50 gm. (7½ grains).

Potassium hypophosphite is soluble in about 0.5 part of water and in 25 parts of alcohol, and calcium hypophosphite is soluble in about 7 parts of water, but is almost insoluble in alcohol.

In addition to the alkali hypophosphites, we also have official:

FERRI HYPOPHOSPHIS.—U. S.—and:

MANGANI HYPOPHOSPHIS.—U. S.

Average dose of either: 0.20 gm. (3 grains).

The ferric hypophosphite is soluble in 2,300 parts of water, but is much more readily soluble in solutions of hypophosphorous acid or of the alkali citrates. Manganese hypophosphite is soluble in about 7 parts of water.

SYRUPUS HYPOPHOSPHITUM.—U. S.—Syrup of hypophosphites contains in 100 c.c. 4.5 gm. of calcium hypophosphite and 1.5 gm. each of sodium and of potassium hypophosphites.

Average dose: 8 c.c. (2 fluidrachms).

SYRUPUS HYPOPHOSPHITUM COMPOSITUS.—U. S.—Compound syrup of hypophosphites contains, in each average dose (8 c.c. = 2 fluidrams) about 0.25 gm. (4 grains) of calcium hypophosphite, 0.12 gm. (2 grains) each of potassium hypophosphite and of sodium hypophosphite, 0.015 gm. (¼ grain) each of ferric hypophosphite and of manganese hypophosphite 0.008 gm. (⅛ grain) of quinin, 0.0008 gm. (1/80 grain) of strychnin with sodium citrate, hypophosphorous acid and syrup.

Average dose: 8 c.c. (2 fluidrams).

SYRUPUS CALCII LACTOPHOSPHATIS.—U. S.—This syrup contains in 100 c.c. about 3 gm. of calcium lactophosphate with free lactic and phosphoric acids.

Average dose: 8 c.c. (2 fluidrams).

The several salts of glycerophosphoric acid which are being advertised so extensively at the present time, as the active constituents of a number of nostrums, are as yet not official. It is quite probable, however, that longer experience will demonstrate that they have absolutely no advantages over the hypophosphites or the lactophosphates, and that their widespread use at present is but a passing fad.

THERAPEUTICS OF PHOSPHORUS AND ITS SALTS.

There is at least a rational basis for the use of phosphorus in rickets, osteomalacia and fracture of bones in which union fails to occur, since a deposition of lime salts in bone has been shown to result from its use.

It must not be given in doses large enough to cause serious gastrointestinal disturbance.

When we say that phosphorus or the hypophosphites are used empirically in the following conditions it is not to be understood that we recommend them, but merely that they may possibly be worthy of a trial. Thus some clinicians have used phosphorus in a variety of nervous disorders, and the hypophosphites are very often used as general tonics. The treatment of tuberculosis by the hypophosphites has no place in modern therapeutics.

Pure phosphorus is so slightly soluble that it was often dissolved in oil, but the phosphorated oil is no longer official. The pills of phosphorus, each containing 0.6 milligrams (1/100 grain) afford a very convenient form for administration.

The compound syrup of the hypophosphites, with its eleven ingredients, including water, affords an example of the concessions made, by the revision committee of the Pharmacopeia, to popular prejudice, and in time to come it will no doubt be relegated to its proper resting place with other polypharmaceal preparations of the centuries long passed.

The claim has been made that the hypophosphites are effective only when the chemically pure salts are used; this claim, however, seems scarcely credible in view of the fact that our ordinary food contains much greater quantities of just such salts as are said to render the hypophosphites useless.

From one to two teaspoonfuls of the compound syrup of the hypophosphites may be given before meals, as a stimulant to the appetite and digestion. Acids and acid fruits are to be avoided.

The following may be taken as a type formula for an extemporaneous preparation of the hypophosphites:

℞. Calcii hypophosphis		
Sodii hypophosphis		
Potassii hypophosphis, āā	℥i	4
Acidi hypophosphor	℥i	4
Aquæ dest	℥vi	200
Elixir q. s. ad	℥vi	200

M. et filtra. Sig.: One or two teaspoonsful three times a day, before eating.

The elixir in this prescription may be replaced by glycerin, or an aromatic water, the combination of the hypophosphites may be varied, within reasonable limits, and the hypophosphorous acid substituted by citric acid or by an alkali citrate. When desirable sufficient bitter may be added to make the medicine more palatable or to act as a bitter tonic. For this purpose the tincture of nux vomica, or one of the bitter alkaloids, may be added.

Cod-Liver Oil.

The consideration of cod-liver oil rightly belongs under the subject of dietetics, as nearly all pharmaceologists are agreed that it is merely a food, but it is so frequently lauded as a medicine that some mention of it is necessary in this place.

On the discovery of traces of certain alkaloids or ptomains it was suggested that they possessed extraordinary value, but, as these substances are usually present in infinitesimally small quantities in good oil, and as there is no reason to suppose that they possess any beneficial effect whatsoever, it cannot be said that the so-called fat free or tasteless cod-liver oils can, in any sense of the word, represent cod-liver oil.

The crude dark-colored oil often contains a much larger proportion of free fatty acids than the white does, and it should, therefore, be more readily emulsified in the intestine and absorbed, but its disagreeable odor and taste render it peculiarly disgusting to all patients with delicate stomachs. Small doses of cod-liver oil can usually be borne, especially if it be given in the form of an emulsion, but even this is not always tolerated.

OFFICIAL PREPARATIONS OF COD LIVER OIL.

Oleum Morrhuæ.—U. S.—This preparation is official in some of the foreign pharmacopeias as Oleum Jecoris Aselli, a name that may be useful on occasions. Cod-liver oil is a fixed oil obtained from the fresh livers of *Gadus morrhuæ* and of other species of *Gadus*.

Average dose: 15 c.c. (4 fluidrams).

Emulsum Olei Morrhuæ.—U. S.—The emulsion of cod liver contains 50 per cent. of the oil, with mucilage and syrup, and is flavored with oil of gaultheria.

Average dose: 8 c.c. (2 fluidrams).

Emulsum Olei Morrhuæ cum Hypophosphitibus.—U. S. This contains 50 per cent. of cod liver oil, 1 per cent. of calcium hypophosphite, and 0.5 per cent. each of potassium hypophosphite and of sodium hypophosphite. It is flavored with oil of gaultheria.

Average dose: 8 c.c. (2 fluidrams).

Cod-liver oil is often useful in anemias due to faulty nutrition and in the general debility which so often precedes tuberculosis. For this reason, perhaps, it has acquired a particular reputation in the treatment of tuberculosis. It can have no beneficial action on the bacillus of tuberculosis, nor on the course of the disease, except in so far as it is a readily assimilable food.

It is often found to be useful in rickets. The pure oil, the emulsion, or the emulsion with hypophosphites may be used, the dose to be regulated according to the capacity for assimilation of the individual case.

It may be added here that the petroleum oils alone, or in the form of emulsions, are wholly devoid of nutrient properties. They are mineral oils, and, therefore, non-saponifiable and can take no part in animal nutrition.

The Automobile's Advantages to the country physician are so manifest that I look forward, writes a Toronto physician, during the coming season to a very large increase in the motor ranks by members of the profession throughout the province of Ontario.

Clinical Reports

EXTRAGENITAL AND URETHRAL CHANCRE.

REPORT OF FIVE CASES, INCLUDING ONE WITH MULTIPLE LESIONS OF THE BREAST.*

FRANK CROZER KNOWLES, M.D.
PHILADELPHIA.

There is no phenomenon of syphilis more interesting to the general clinician than its inception in the one typical initial lesion. When this lesion has an unusual characteristic, such as prolonged incubation, extragenital location, unaccustomed appearance, particularly if of a multiform variety, our study is of even greater interest.

Before the description of these cases it might be well to give a few general statistics on extragenital and urethral chancre, in so far as they bear on this paper. Montgomery[1] states that 5.5 per cent. of his cases of syphilis were of extragenital origin, or 67 out of a total of 1,217. Bulkley[2] of New York gives the same percentage, 5.5 per cent., or 113 extragenital in 2,000 cases.

Fournier's[3] statistics show that 6.33 per cent. of his total cases of chancre were of extragenital location. While out of 887 cases of primary syphilis occurring among women in his private practice,[4] 45, or 5.07 per cent., of the initial lesions were extragenitally situated.

All authorities agree that the major number of extragenital lesions occur on the cephalic region, chiefly in close proximity to the mouth. According to the statistics collated by Poray Koschitz,[5] 632 out of 852 primary extragenital lesions occurred on the head, or practically 75 per cent., and of 29 cases of the above authority in 9, or 31 per cent., the lesions were on the lips. Montgomery[6] records slightly over 42 per cent. of his extragenital cases as occurring on the lips. According to Bulkley's[2] statistics, a little over 13 per cent. of his extragenital chancres were located on the finger. Multiple lesions may occur on any part of the body, most frequently on the genitaliæ and breast. According to Taylor,[7] in fully one-third of all cases of syphilis occurring in women the lesions are multiple. Fournier[8] states that 39 out of every 100 cases of primary syphilis of the breast show multiple lesions.

According to Dr. Dimey,[9] in 206 cases of initial lesions of the breasts, one breast was affected in 132 cases, while both were involved in 74. In this last reference, which Prince A. Morrow kindly furnished me from his "System of Genito-Urinary Diseases Syphilology and Dermatology," Jullien[10] has tabulated 1,773 cases of primary specific lesions compiled from the statistics of Bassereau, Fournier, Clerc and Léon le Fort. Of these chancres 89 were located at the meatus; while 17, or less than 1 per cent., were in the urethra proper. The few statistics, quoted from nine authorities both in

this and foreign countries, show the comparative frequency of unusually located initial lesions and teaches us to be constantly watchful that no mistake be made.

Of the following cases two were seen in the Dermatologic Clinic of Dr. Chas. N. Davis at the Pennsylvania Hospital, one in the Genitourinary Clinic of Dr. H. M. Christian at the Polyclinic Hospital, one in the Dermatologic Clinic of Dr. M. B. Hartzell at the University of Pennsylvania Hospital, and one in my own practice.

CASE 1.—Walter T., mulatto, age 26, clerk, born in Philadelphia. First seen in Surgical Dispensary of Pennsylvania Hospital on June 20, 1904. At that time he had a quarter-dollar sized, elevated, sharply marginate, fungating, crusted, slightly indurated lesion on posterior surface of right index finger, over phalangeal-metacarpal articulation. This lesion was of six days' duration. No glandular or other specific symptoms were present. The treatment consisted of mild, local, antiseptic applications. The induration of this lesion was more marked on each successive visit. On July 17 the patient returned after an absence of ten days, with a typical roseolar eruption, general glandular enlargement, pharyngitis and pains in body. The patient had been referred to the Cutaneous Clinic, after a few dressings in the surgical dispensary, where the following history was discovered: On April 18 this man engaged in a fight, hitting his opponent in the teeth, causing an abrasion at the site of the present lesion. This abrasion subsequently healed, but on June 14, or eight weeks following this injury, the present lesion appeared. The secondaries appeared precociously in four and a half weeks.

CASE 2.—C. D., an Italian girl, aged 22, married, came to the Cutaneous Clinic at the Pennsylvania Hospital on May 1, 1905, showing the following: Just below left nipple, in areolar formed by glands of Montgomery, were two dime-sized, sharply marginate, raised, markedly indurated, crusted lesions, separated by about one inch of sound skin. On the right breast one other lesion of the same character and location was seen. The duration was fifteen days. The only subjective sign was pain all over the body. No objective sign of syphilis was present. The patient was seen three times during the next ten days with no new developments except an increase in the button-like induration of the lesions and in severity of muscular and osseous pain. After an interval of almost three weeks the patient returned on June 27 with a macular eruption of one week's duration, covering the entire body and face; numerous mucous patches of lips, tongue, soft palate and tonsils were present, also general glandular enlargement and pains in entire body. Unfortunately no history was obtainable in this case. Her only child, a girl of 11 months, was apparently in perfect health, although still breast-fed.

CASE 3.—F. P., male, aged 30, came to my office May 29, 1905, complaining of a urethral discharge of ten days' duration. On examination an irreducible phimosis was found, also a profuse muco-purulent discharge. Of still greater interest, on palpating the penis, a hazelnut sized, firmly indurated, button-like mass was found one and a half inches behind the meatus, on the roof of the urethra and partially surrounding the same, this latter mass being of three weeks' duration. After cleansing the foreskin with potassium permanganate solution, the two glass test was tried, the first glass only showing cloudy urine with shreds. The only subjective sign was bilateral enlargement of inguinal glands. No primary incubation period could be determined, for the man was extremely promiscuous in his intercourse. On June 19 the patient again appeared in my office, after an absence of three weeks, with a profuse, ham colored, multiform eruption, chiefly small, flat, papular in type, general glandular enlargement, husky voice, pharyngitis, slight thinning of hair, and generalized pains in bones and joints. These secondary symptoms appeared ten days before this present visit. No microscopic examination having been made for the diplococcus of Neisser, a superadded gonorrhea can not be positively stated.

CASE 4.—S. M., male, aged 22, came to Genitourinary Clinic at the Polyclinic Hospital on Aug. 15, 1905, with a dime sized, sharply marginate, crusted, slightly raised indurated lesion, slightly to left of median line of lower lip. The duration was ten days. The incubation period was indefinite. There were no other signs of beginning syphilis. On September 12 the patient returned, after an absence of five weeks, with a marked pharyngitis, the post-cervical, submaxillary and inguinal glands were enlarged, and a faint macular eruption of one day's duration was on chest, abdomen and back. The generalized eruption in this case followed a secondary incubation period of just six weeks.

CASE 5.—Charles T., aged 42, blacksmith. This patient first came to the Cutaneous Clinic of the University of Pennsylvania Hospital on Feb. 23, 1906, complaining of a large swelling of the lower lip. On the vermilion of the lower lip just to the left of the median line, a quarter-dollar sized densely indurated, slightly crusted, raised, button-like lesion was found. The post-cervical and submaxillary glands were enlarged and an extragenital chancre was diagnosed. The man stated he had no eruption on the body. As in all cases, not trusting to the patient's own observation, we made the man disrobe. One glance at the patient's body was sufficient to see a generalized macular eruption over arms, legs, trunk, and a few lesions of the same character on the forehead. The throat showed a pharyngitis, with small mucous patches of post-pharyngeal arches. The exact primary or secondary incubation period, or the duration of the initial lesion and secondary eruption could not be determined. The patient stated that the lesion had appeared on the lip three weeks ago; probably twice that length of time would be nearer the truth. The macular eruption could have had a duration of but a few days. This man, being separated from his wife, was in more danger of being exposed to contagion.

Only those cases have been reported in this series in which the diagnosis was proved by the appearance of the secondary eruption and concomitant signs of syphilis.

During this same period three other cases were seen, in each of which the provisional diagnosis of extragenital chancre was made, two of these cases having indurated, single, lesions on the fingers and in one case on the upper lip. Unfortunately, as each of these patients made but the one visit, our provisional diagnosis could not be conclusively proved.

332 South Seventeenth Street.

A CASE OF PRIMARY SYPHILITIC INFECTION IN THE NOSE.*

JAMES T. CAMPBELL, M.D.

Professor of Otology, Rhinology and Laryngology in the Post-graduate Medical School.

CHICAGO.

Chancre of the nose is one of the rarest of lesions. Krefting[1] gives statistics of 2,916 cases of chancres, of which 539 were instances of extragenital infection, and Salsotto[2] records 201 cases of extragenital chancre with no case of primary nasal infection. Bulkley[3] gives a table of 9,058 cases of extragenital chancre in which primary infection of the nose occurred ninety-five times. Bosworth[4] states that in 2,244 cases of chancre observed by Bosserean, Clerq, Lefort, Fornier and Ricord, the primary lesion was found twice in the nose. Le Bart[5] reports thirty-seven cases of primary nasal chancre, of which twenty-one were external and sixteen within the nostril.

The earliest recorded case I can find is that of Mc-

Carthy.[6] Spencer Watson[7] reported a case of a nurse in attendance on a woman who gave birth to a syphilitic child. The sore could not be distinctly seen, on account of the swelling within the nostril. Severe pain, fever and mental depression was followed by the ordinary symptoms of secondary syphilis. The vehicle of infection in all probability, was the patient's own finger.

Intranasal inoculations occur most frequently in the lower and anterior part of the nasal septum, next in frequency on the ala, and then, as in the case I am about to report, on the inferior turbinated body. The location modifies the chancre's appearance. On the septum it displays a flat, reddish or greenish, fungiform mass with indurated circumference. The surrounding mucous membrane is, to a greater or less degree, swollen, and there flows from the ofttimes stenosed nostril, a bloody, fetid discharge. When the ala is involved the infiltration and induration often causes it to be of a cartilaginous consistency. When the inferior turbinated is primarily inoculated, the appearance resembles, mostly, a severe localized influenza, or a fibrinous or diphtheritic rhinitis. Usually the submaxillary, sublingual and preauricular glands early show marked indolent swelling.

Characteristic of this infection is an aggravated general febrile disturbance, malaise and depression of spirits. The chancre may be mistaken for an abscess of, or injury to, the septum; for a furuncle, to which for a time, it is not dissimilar; for vaccine inoculation; for tubercular ulceration; for malignant disease.

The existence of an ulcer in the nose with a peculiar hard base and granular surface, bleeding easily on touch and of limited extent, would suggest tuberculosis, malignant disease or syphilis. Tubercular ulceration occurs only as secondary to a pulmonary deposit and examination of the discharge would show characteristic bacilli. In malignant disease glandular enlargement is a late development, and the progress of the disease is liable to be accompanied by profuse epistaxes. In syphilis the chancre is followed shortly by characteristic secondary symptoms.

CASE REPORT.

History.—On Oct. 19, 1905, a surgeon in perfect health circumcised a patient, on whose prepuce was a large indurated chancre.

On December 16, nearly two months later, he first noticed stuffiness of the right nostril, and headache from brow across vertex to occiput. This was accompanied by malaise, anorexia, chilly sensations and constipation, a condition from which he never before had suffered. For a period of two weeks his temperature ranged from 100 to 100.2 F. He had worked very hard for a few weeks prior to December 16, and he attributed his condition to overwork and a grip-like attack. During Christmas week he visited his old home, but the rest ga not improve his condition.

rec-*amination.*—I first saw him on Dec. 28, 1905. At that beca I made the notation, "Superficial necrosis of the mucous even brane covering the anterior end of the right inferior pre nate body; the fibrinous membrane, when raised, revealed a sp ulcerating bleeding surface." Neither suprarenalin 1 to 1,000 nor 10 per cent. cocain solution caused any appreciable blanching or shrinking of the turbinated body. Lacrimation was present on the right side and one gland below the angle of the right jaw was enlarged and tender.

The condition resembled fibrinous rhinitis, but it was limited to the inferior turbinated body and there was no ichorous discharge from the nostril. The swelling practically occluded the nostril, which is narrow on account of septal deviation, the result of traumatism in childhood.

The treatment employed was a cleansing alkaline spray followed by sprays of peroxid of hydrogen and lime water.

Course of Disease.—On Jan. 8, 1906, eighty days after the probable inoculation, a macular rash appeared on the abdomen. Four days later, when I was shown the rash, I made a positive diagnosis of syphilis and was confirmed in this by Dr. Joseph Zeisler and Dr. T. Melville Hardie. The "leanham" macular and papular rash, more marked on his chest and abdomen, covered practically the whole body with the exception of the exposed portions of head and hands. There were papules at the base of the uvula, but no soreness or congestion of the fauces and no glandular enlargement or soreness excepting the before-mentioned submaxillary gland. Disappearance of the fibrinous membrane and healing of the ulceration took place under the simple sprays, before constitutional symptoms appeared. Coincident with the appearance of the rash, the headache ceased and the general feeling of well-being began.

On diagnosis of syphilis being made, inunctions of mercurial ointment, one dram, at bedtime were begun and after six rubbings all evidence of the disease had disappeared.

A CASE OF MULTIPLE CHANCRES.

S. R. MALLORY KENNEDY, M.D., A.A.S.
Public Health and Marine-Hospital Service.
PENSACOLA, FLA.

Cases of multiple chancres are rare. Chiefly because of their infrequency they are often unrecognized, and so the report of a single case, though adding nothing to the present-day knowledge of the subject, may call attention to the existence of a condition which might otherwise be overlooked. It is for this reason that I report the first case that, to my knowledge, has been treated in this section of the country.

Patient.—J. I. C., aged 22, presented a good family history.

History.—He had never been sick in his life except for an acne which bothered him but little, and for which he had done nothing. He first came under my care in August, 1904, when I treated him for a chronic form of gonorrhea. This, though stubborn, yielded after a time and the patient, after many tests, was discharged as cured. I did not see him again until August, 1905.

Examination.—On making an examination I found a purulent discharge about the urinary meatus, and a single, enlarged, painless, indurated, freely movable gland in the left inguinal region. The discharge, however, did not come from the meatus, but from beneath the prepuce, which was slightly swollen, tending to phimosis. On inserting a small, blunt probe several rough surfaces could be detected, and on questioning the patient I was somewhat surprised to learn that he had not had sexual intercourse for more than a month before noticing the discharge.

Treatment.—Realizing that with the existing phimosis local treatment would amount to little or nothing, I advised an incision through the dorsum of the prepuce to expose the glans and to aid in making topical applications. He consented, and on the following day, with local anesthesia—ethyl chlorid and a 2 per cent. solution of cocain—the incision was made, disclosing nine ulcers. Each lesion presented a typical picture. Their edges were sloping (cup shaped), they had a firm, cartilaginous, or woody feel. Their bases were covered with a thin, scanty, sero-purulent discharge which had no offensive odor. Each lesion was fully developed, separate and distinct. There was no tendency whatever to coalesce.

I was convinced that the picture before me was one of multiple chancres, and, realizing that all nine could be gotten rid of by a circumcision (all being located on the glandular surface of the prepuce), the primary incision was continued under cocain and a circumcision was done. The operation was followed by some little swelling and pain, but no more than would ordinarily occur after the performance of this operation on a perfectly healthy penis, the wound healing by first intention.

Bacteriologic Examination.—Smears from the nine lesions were made and examined for the bacillus of chancroid (bacillus of Ducrey) with negative results. Further tests were made

6. These dé Paris, 1844.
7. *Medical Times and Gazette*, 1881, vol. 1, p. 428.

to isolate the bacillus in culture tubes containing fresh blood, after the method of James Homer Wright of Harvard University, with negative results.

Subsequent History.—The patient was told of my suspicions and was instructed to report at my office for inspection when any of the lesions of the "active period," which were thoroughly explained to him, might put in an appearance. This he promised to do, but was compelled to leave the city and I did not see him again until Jan. 8, 1906, when he came to my office, not because he felt that his health was impaired, for he stated that he had not had an ache nor a pain since I had seen him last, but because he had returned to the city "and wanted me to examine him to satisfy myself that he was all right."

The skin presented nothing suspicious, the acne which he had had for the past five or six years was no better, nor was it any worse. There was no other form of eruption present. I found, however, that the post-occipital glands on both sides were much enlarged, as were also the cervical, axillary and inguinal glands. On examining the throat I found a bald patch in the roof of the mouth and two typical patches on both tonsils. They were oval, gray in color, moist, and looking as though silver nitrate had been applied; the whole faucial surface was engorged.

Not until I told the patient what I had discovered did he admit that his throat had bothered him for a day or two. I told him that in my opinion he had syphilis. Although having been acquainted at the time of performing the circumcision with my suspicions, the fact that he had suffered from no prodromes, or eruption (which he had been looking for) did not help to lessen the shock caused by my positive diagnosis.

Having to go to New Orleans he urged me to accompany him in order that I might give a detailed account of the case to Dr. Rudolph Matas, in whom he has the utmost confidence. This I willingly agreed to do. Dr. Matas listened attentively to the history, made a careful examination, and pronounced the case syphilis beyond a doubt. He was impressed, as I had been, with the mildness of the case, and attributed it to the fact that in performing the circumcision, nine points of infection were removed at once.

I believe, of course, that the chancre is a local manifestation of a constitutional disease, and that when it appears a large amount of the poison has already entered the system. This in no way opposes the duality theory, as I do not contend that the removal of the chancres would prevent chancroid from forming, for I believe, with Fournier, Cooper, von Zeissl, Taylor, Lydston and a host of others, that the poisons are not one and the same; nor do I believe for one instant that the removal of chancres will prevent the appearance of the active period (secondary stage) or the period of sequelæ, but I do contend that in this particular case their immediate and complete removal mitigated the attack.

In his excellent article on syphilis Lydston has this to say in favor of excision:

> The excision of the chancre should be performed only after the induration has matured, that is, after it has attained full development, and remained in *statu quo* for some days, otherwise induration is apt to recur in the edges of the wound. By the excision we remove a constant focus of infection that is present so long as the induration lasts. We at once remove a large mass of syphilized cells that would otherwise only be removed by the slower process of fatty degeneration, absorption and elimination. We obviate the possibility of transmission of the disease to others by means of the initial lesion (a point sometimes of great importance in married persons); we lessen the danger of suppurating bubo in case the chancre should become inflamed or pus-infected; we remove a constant source of irritation and lessen the danger of phagedena and inflammation that might disable the patient.

I return to the narration of the case:

Treatment.—Principally for its rapidity of action and on account of the existing acne, I used the inunction plan of treatment, rubbing into the patient one dram of mercurial ointment in one dram of lanolin every twenty-four hours, followed the next night by a warm bath with German green soap.

Dr. Matas suggested touching the mucus patches with pure carbolic acid, followed with alcohol or with a mixture of carbolic acid and iodin in equal parts. I used the pure carbolic and in eleven days from the time I started to make these applications not a trace of the patches on the tonsils could be seen. The bald patch in the roof of the mouth did not take kindly to this treatment and I changed to lunar caustic, putting the patient on a short, brisk course of potassium iodid, with good results. The iodid, however, made the acne worse, and after a week I stopped it and relied entirely on the inunction and the lunar caustic, with the result that at the present writing there is but one-sixteenth of an inch to heal. As a mouth wash and gargle the patient is using equal parts of an alkaline solution and a solution of peroxid of hydrogen five or six times a day; he also uses a chlorate of potash tooth paste after each meal.

He objected to the use of the curette, the best treatment I know of for acne; so I am using a sulphur ointment, and if the acne ever gets better the patient will wear a mercurialized shirt; the inunctions will be discontinued and the patient put on granules of protoiodid of mercury (each 0.01 gm.).

The plan I follow in giving these granules differs somewhat from the ordinary in that I do not reach the full physiologic action and then cut the dose in half, but, instead, when the patient reaches the limit, he is instructed to reduce the dose one granule a day until he has reached the original starting point, when he commences to increase the dose as before. It is astonishing how nicely this method agrees with the majority of patients. I have one who, following these directions, worked up to thirty-two granules a day before beginning to reduce his dose, and this without disturbing his digestion in the least.

Unless there are contraindications, I generally have my patients follow this plan of treatment for one year, when they are instructed to skip a month, taking a course of potassium iodid in the off month. In this way any mercury that is stored up in the tissues will be liberated, rendered active and eliminated. It is well to bear in mind the possibility of the injurious effects produced by the cumulative action of the drug.[1] I do not give the iodin simply and solely for its alterative effect, but because it is an established fact that the iodids alone are capable of effecting a cure in syphilis. That this view is correct is shown by the beneficial effects produced by potassium iodid in cases of late syphilis in which mercury has never been administered. Hassing[2] reports seventy cases of syphilis in which the patients were cured by potassium iodid alone without mercury at any stage. These experiments have since been frequently repeated by various observers, and by myself, with like results.

At the end of the second year the patient is agai[n] given a course of mercury for six months, during wh[ich] time he again alternates; mercury one month, po[tas]sium iodid the next. Then I let him rest and watch [the] results. If all goes well, and all should go well if [he] has followed out directions, I discharge him, feeling reasonably sure that he can marry and beget healthy children. It goes without saying that the physician can not effect a cure alone; the patient must do his share, and the best advice that can be given to a syphilitic after he has been put in possession of all the facts concerned in his case is this: "To thine own self be true."

1. The text-books are notoriously deficient regarding the physiologic action of this drug and for the benefit of those who are looking for cause and effect and not a mere history of symptoms following large or small doses of mercury, I take pleasure in referring to the recent papers of S. V. Clevenger on the subject.
2. British and Foreign Medical Review, October, 1845.

A CASE OF CESAREAN SECTION IN ECLAMPSIA.

WILLARD SMITH, M.S., M.D.
LA GRANDE, ORE.

In October, 1903, I was called to attend Mrs. J. W., who had typhoid fever and was about four months' pregnant. She aborted in the course of her fever and had considerable difficulty owing to the small size of her pelvis. I lost sight of her after her recovery until September, 1904, when I was called to treat her for hydrorrhea gravidarum, which had been present for about a month. She expected confinement September 10, but as she did not enter into labor at that time I waited until September 23 and then induced labor. My reason for doing this was that there was unmistakable evidence that she had exceeded her full term and the delay seemed to be due to deformity of the pelvis. I measured her pelvis and found the internal conjugate to be only two and one-eighth inches. After long effort to secure delivery without forceps, I applied them and with great difficulty succeeded in delivering her of a six-pound child. The child was delivered alive, but was so crushed and mutilated in the process that it died after six hours. Again I lost sight of the patient until in April, 1905, she came to me and asked me if there was any way by which she could have a baby. She said that she was very anxious to become a mother and was willing to undergo almost anything in order to do so. I told her that there was only one way—Cesarean section—and explained to her what it meant and the danger of it. She asked me if I would do this operation for her if she should become pregnant. I told her that she had better not attempt it, but if I were ever again called on to attend her in labor I certainly would not attempt to deliver her in any other way. About the last of June she again appeared and informed me that she believed herself pregnant, having last menstruated on May 7, and further said that she had become pregnant with the definite intention of having Cesarean section done. I accepted the situation and instructed her to report every ten days, which she did faithfully up to December 8, the date of her last visit to my office. At about two months she had slight albuminuria, which disappeared under treatment. Otherwise she showed no abnormal signs.

Family History.—The patient, aged 21, was the eldest of a family of eleven children. Her mother had also had seven miscarriages. Her father comes of a rachitic family and shows many signs of rickets and has had a chronic leg ulcer since he was 9 years of age. One of her mother's sisters has lost seven children at birth owing to a contracted pelvis.

History of this Pregnancy.—On December 14 the patient began to act queerly, and she afterward stated that she had no recollection of any of the events succeeding that date. She became progressively duller and more apathetic until the evening of December 17, when she began having labor pains prematurely. The pains became more frequent and were interspersed with convulsions of increasing frequency and severity until 2 a. m. on December 18, when I was called to see her.

Treatment.—On examining her I found a considerable degree of dilatation. I gave her morphin sulphate ⅜ gr., hypodermatically, and removed her to the hospital. The morphin caused a temporary cessation of both pains and convulsions. Preparation was made to do whatever might prove necessary, and the advice and aid of Drs. Hall, Bacon and Hawke were secured. At 9 a. m. she began having pains again and soon had a very severe convulsion. The urine showed a large quantity of albumin. Casarean section was decided on and was at once performed, the technic of the modern Porro operation being followed. Three pints of normal saline solution were left in the abdomen, two pints were given subcutaneously under the breasts, and three pints were introduced into the rectum. She was at once placed in a hot pack, which was continued for thirty-six hours, and as vomiting did not occur, she was encouraged to drink water freely, taking almost three gallons by mouth in thirty-six hours.

Postoperative History.—On the morning of December 19 she had three hard convulsions. The administration of veratrum viride was begun at this time, and three pints more of normal saline solution were infused under the breasts. The veratrum was given in variable hourly doses so as to keep the pulse rate below eighty, and this was continued for three days, after which digitalis was used in sufficient dose to produce the same effect on the pulse, this being continued for almost a week until the pulse remained at this point unaided. Magnesium sulphate was given in such doses that prolonged purgation was maintained. No further convulsions occurred, the albumin disappeared from the urine in five days, the further course of the case was uneventful, and the patient was able to leave the hospital at the end of three weeks from the operation.

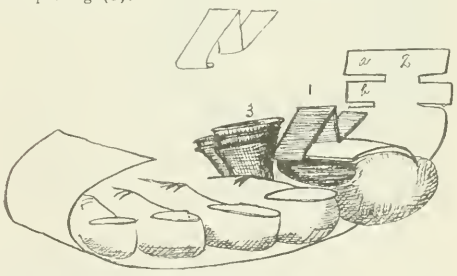
Fate of Child.—The child lived for two and a half hours and died from convulsions which resembled those from which the mother had suffered. It is my belief that the death of the child was caused more from toxic material which it had received from the mother than from its prematurity.

New Instruments

LEVER FOR INGROWING TOENAIL.

J. T. LELAND, M.D.
HERMAN, MINN.

The lever here illustrated has given satisfaction in the treatment of ingrowing toe-nail. It consists of a piece of galvanized tin 1½ in. long and ¼ in. wide, bent as illustrated (1). The edge is inserted under the nail and held by a piece of adhesive plaster (2), cut transversely into arms *a* and *b*. Arms marked *a* are made fast to the nail to prevent slipping. Arms *b* are attached to arm of lever. The plaster is then carried round the foot while the desired downward pressure is being made. To separate the granulating surface from the adjoining toe I insert gauze packing (3).



The advantages of my lever are:

1. The nail is permitted to grow.
2. The lever can be applied to any nail, regardless of whatever mutilation it may have received.
3. No packing under the nail is necessary.

Action of X-Rays on the Blood.—Gramegna and Quadrone (*Arch. Gén. de Méd.*), have studied the effect of the *x*-rays on the blood in rabbits and guinea-pigs, and found marked changes in the white corpuscles and diminution of their number, together with increased coagulability of the blood. The red corpuscles were less affected, the chief change observed being a diminution of resistance. The hemoglobin ratio was very little affected. The practical suggestion would be that of the possible utility of the *x*-rays in increasing the density and coagulability of the blood in hemophilia and other hemorrhagic conditions.

THE BOSTON SESSION

American Medical Association, Fifty-Seventh Annual Session, Boston, Mass., June 5 to 8, 1906.

OFFICIAL CALL

ANNOUNCEMENT OF THE FIFTY-SEVENTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, TO BE HELD AT BOSTON, JUNE 5-8, 1906.

CHICAGO, April 14, 1906.

To the Officers and Members of the Constituent State and Territorial Associations of the American Medical Association:

The fifty-seventh annual session of the American Medical Association will be held at Boston, on Tuesday, Wednesday, Thursday and Friday, June 5, 6, 7 and 8, 1906.

HOUSE OF DELEGATES.

The House of Delegates of the American Medical Association will convene in the Boston Medical Library, Boston, at 10 a. m., on Monday, June 4, 1906.

The following is a list of the constituent associations and the number of delegates to which each is entitled:

State.	Delegates.	State.	Delegates.
Alabama	3	Montana	1
Arizona	1	Nebraska	2
Arkansas	2	Nevada	1
California	4	New Hampshire	1
Colorado	2	New Jersey	3
Connecticut	2	New Mexico	1
Delaware	1	New York	..
Dist. of Columbia	1	North Carolina	2
Florida	1	North Dakota	1
Georgia	2	Ohio	5
Hawaii	1	Oklahoma	1
Idaho	1	Oregon	1
Illinois	8	Philippine Islands	1
Indian Territory	1	Pennsylvania	8
Indiana	4	Rhode Island	1
Iowa	4	South Carolina	1
Kansas	2	South Dakota	1
Kentucky	3	Tennessee	3
Louisiana	2	Texas	5
Maine	1	Utah	1
Maryland	2	Vermont	1
Massachusetts	6	Virginia	3
Michigan	4	Washington	1
Minnesota	2	West Virginia	2
Mississippi	2	Wisconsin	3
Missouri	3	Wyoming	1
U. S. Public Health and Marine-Hospital Service			1
Medical Department, U. S. Army			1
Medical Department, U. S. Navy			1
Each of the scientific sections, one delegate			12

FIRST GENERAL MEETING.

The first General Meeting, which constitutes the opening exercises of the scientific functions of the Association, will be held at 10:30 a. m., Tuesday, June 5.

REGISTRATION DEPARTMENT.

The Registration Department will be open from 8:30 a. m. until 5 p. m., on Monday, Tuesday, Wednesday and Thursday, June 4, 5, 6 and 7, and from 9 to 10 a. m., on Friday, June 8.

Those who desire to join the Association at the annual session should bring certificates of membership in their state associations.

L. S. McMURTRY,
President.

GEORGE H. SIMMONS, Secretary.

PRELIMINARY PROGRAMS OF SECTIONS.

The Papers to Be Read at Boston—Announcement About the Official Program.

The following is a partial list of titles of papers to be read before the various sections at Boston. The order here is not necessarily the order which will be followed in the Official Program. This Official Program will be similar to those issued in previous years and will contain the final program of each section, with abstracts of the papers, lists of committees, programs of General Meetings and House of Delegates, lists of entertainments, map of Boston, etc. To prevent misunderstandings and to protect the interests of advertisers, etc., it is here announced that this Official Program will contain no advertisements. It is copyrighted by the American Medical Association and will not be distributed before the session. A copy will be given to each member on registration.

SECTION ON PRACTICE OF MEDICINE.

CHAIRMAN, HERBERT C. MOFFITT, SAN FRANCISCO; SECRETARY, JOSEPH L. MILLER, 100 STATE STREET, CHICAGO.

Recent Advances in Physiology of Circulation. Joseph Erlanger, Baltimore.

True and False Angina. James M. Anders, Philadelphia.

The Diagnosis and Treatment of Some Unusual Heart Affections. H. A. Hare, Philadelphia.

Mutual Relations of Heart and Kidney. N. B. Potter, New York.

The Diagnosis of Heart Insufficiency Apart from Valvular Disease. R. H. Babcock, Chicago.

Pericarditis. N. S. Davis, Chicago.

A Study of the Heart in Chorea. W. S. Thayer, Baltimore.

Address: Dr. Krehl, Strassburg, Germany.

Symposium on Joints.

Acute and Chronic Articular Rheumatism. Lewis Conner, New York.

Gonorrheal Arthritis and Gonorrheal Septicemia. J. A. Witherspoon, Nashville.

Differential Diagnosis of Rheumatoid Affections. A. B. Herrick, Chicago.

Joint Affections in Nervous Disease. L. F. Barker, Baltimore.

The Treatment of Chronic Joint Affections. Locke and Osgood, Boston.

Symposium with Surgical Section.

Etiology and Diagnosis of Ulcer. Frank Billings, Chicago.

Treatment of Ulcer. Alexander Lambert, New York City.

Demonstration of Ulcer Cases Treated Medically or Surgically in Massachusetts General Hospital. H. F. Hewes, Boston.

When Do the Gastric and Duodenal Ulcers Require Surgical Treatment and What Procedures Are Advisable? W. L. Rodman, Philadelphia.

The Results of the Surgical Treatment of Gastric and Duodenal Ulcers. W. L. Mayo, Rochester, Minn.

Meeting with Section on Pathology and Physiology.

Some Newer Methods in the Examination of the Thoracic Cavity. J. A. Capps, Chicago.

Border-line Affections of the Lung. J. H. Musser, Philadelphia.

The Treatment of Pleurisy with Effusion. F. Forschheimer, Cincinnati.

Chronic Non-tubercular Affections of the Lungs and Pleura. S. G. Bonney, Denver.

Bacteriology of Pleural Effusions. L. W. Ladd, Cleveland.

Cytology of Pleural Effusions. Percy Musgrave, Boston.

Studies on Cardiospasm. Bertram W. Sippy, Chicago.

Intermittent Fever in the Convalescence of Typhoid. J. Dutton Steele, Philadelphia.

Value of Tests for Occult Blood in the Diagnosis and Treatment of Diseases of the Digestive Organs. F. W. White, Boston.

Non-calculous Cholecystitis. A. O. J. Kelly, Philadelphia.

Indications and Contraindications to the Use of X-Rays in Medical Cases. D. L. Edsall, Philadelphia.

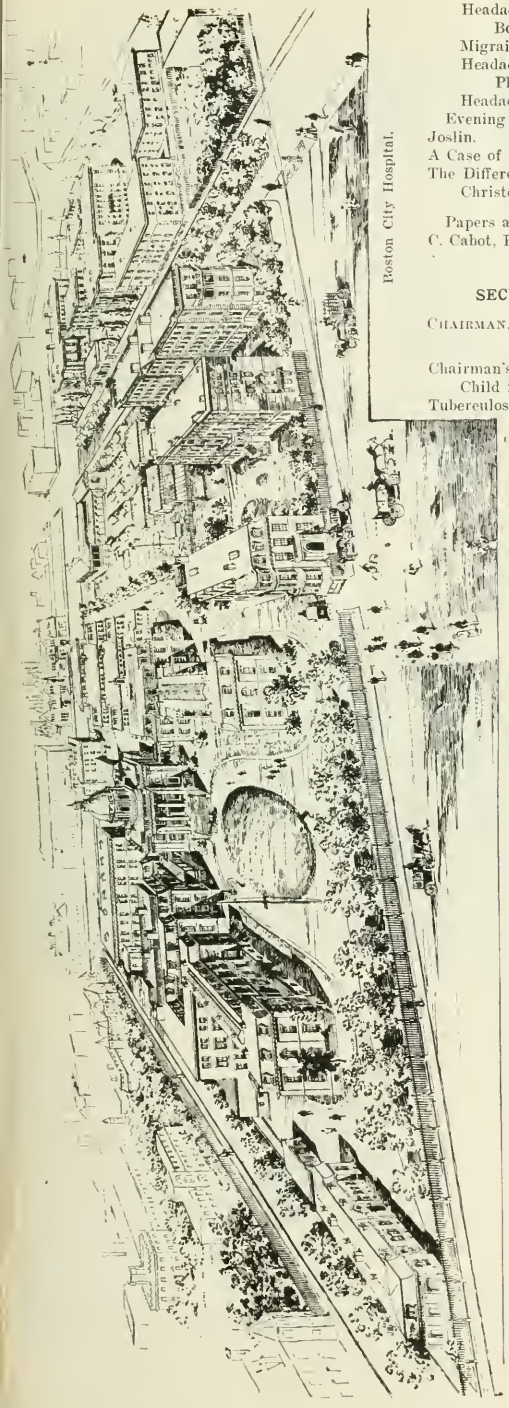
Acute Leukemia. Philip Marvel, Atlantic City, N. J.

Posteritical Fever and Other Sequelæ of Croupous Pneumonia. J. E. Talley, Philadelphia.

The Opsonic Index in Medicine. Norman Ditman, New York.

Discussion on Chronic Headache: Its Causes and Treatment.

Nose and Sinuses. Cornelius G. Coakley, New York City.
Eye. George Gould, Philadelphia.
Ear. Philip Hammond, Boston.
Chronic Nervous Headaches. G. L. Walton, Boston.



Headache Due to Affections of the Pelvic Organs. F. H. Davenport, Boston.

Migraine. Joseph Collins, New York City.

Headache Due to Distnrbance of the Digestive Tract. Joseph Sailer, Philadelphia.

Headache of Renal Origin. A. C. Croftan, Chicago.

Evening Demonstrations are to be made by Drs. R. C. Cabot, Locke and Joslin.

A Case of Septicemia from Colon Bacillus. DeLancey Rochester, Buffalo.

The Differential Diagnosis Between Duodenal Ulcer and Gallstone Disease. Christopher Graham, Rochester, Minn.

Papers are also to be read by Drs. George Dock, Ann Arbor, and Richard C. Cabot, Boston, the titles of which are not yet received.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

CHAIRMAN, C. S. BACON, CHICAGO; SECRETARY, W. P. MANTON, 32 WEST ADAMS AVENUE, DETROIT.

Chairman's Address: The Legal Responsibility of the Physician for the Child in Utero. Charles S. Bacon, Chicago.

Tuberculosis of the Kidney. Charles P. Noble, Philadelphia.

The Treatment of Tuberculosis of the Urinary Tract in Women. Edgar Garcean, Boston.

The Formation of a Vesico-vagino-rectal Fistula Combined with Closure of the Introitus Vaginæ for Certain Forms of Urinary Incontinence. Reuben Peterson, Ann Arbor.

Report of Committee on Nomenclature of Endometritis. Ernest F. Tucker, Chairman, Portland, Ore.

Success, the Surgical Desideratum. A. Ernest Gallant, New York.

The Pathology of Uterine Cancer. Thomas S. Cullen, Baltimore.

The Early Symptoms of Uterine Cancer. John G. Clark, Philadelphia.

The Operative Treatment of Cancer of the Cervix Uteri. Emil Ries, Chicago.

The Radical Operation in Uterine Cancer. Alfons von Rosthorn, Heidelberg, Germany.

Report of Committee on Uterine Cancer. John G. Clark, Chairman, Philadelphia.

Opening Discussion on Uterine Cancer. James F. W. Ross, Toronto, Canada.

The Operative Treatment of Cancer of the Rectum. Matthew D. Mann, Buffalo.

The Preservation of the Functions of the Broad Ligaments in Pelvic Surgery. E. C. Dudley, Chicago.

The Function of the Uterosacral and Round Ligaments. J. Wesley Bovée, Washington, D. C.

The Conservative Surgery of the Ovaries. Edward Reynolds, Boston.

The Present Status of Conservatism in the Surgical Treatment of Tubes and Ovaries. J. E. Cannaday, Paint Creek, W. Va.

Hernia of the Ovary and Fallopian Tube. Frank T. Andrews, Chicago.

Lung Complications Following Abdominal Operations. Hunter Robb, Cleveland.

The Stem Pessary for Amenorrhea and Dysmenorrhea. Some Further Observations. J. H. Carstens, Detroit.

Choice of Methods for Dilating the Gravid Uterus. Edward P. Davis, Philadelphia.

Manual and Instrumental Dilatation of the Pregnant and Parturient Uterus. J. Clifton Edgar, New York.

Instrumental Dilatation of the Parturient Uterus. Franklin S. Newell, Boston.

The Indications for the Use of the Bossi Dilator and the Technic of Its Use, with a View to Avoiding Serious Lacerations. Barton Cooke Hirst, Philadelphia.

Progress in Obstetrics and Gynecology. A. Duhrssen, Berlin, Germany.

Uterine Myomata Complicated with Pregnancy, with Cases. E. E. Montgomery, Philadelphia.

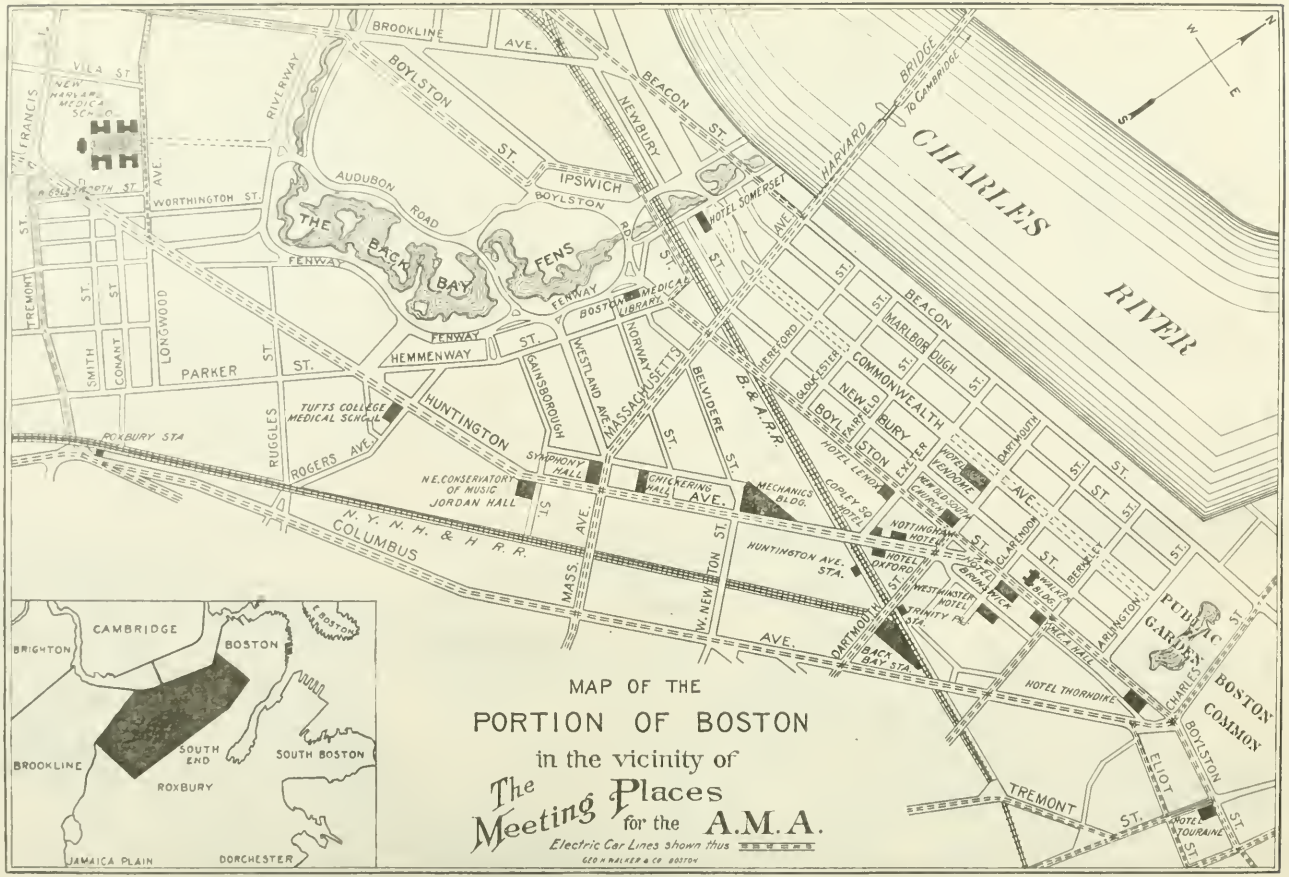
Pregnancy and Labor Complicated by Anterior Fixation of the Uterus. George M. Boyd, Philadelphia.

The Surgical Treatment of Puerperal Sepsis. R. W. Stewart, Cincinnati.

To What Extent Can the Gynecologist Prevent and Cure Insanity Among Women. W. O. Henry, Omaha.

The Best Method of Closure of Aseptic Wounds, Especially of the Abdomen. Henry O. Marcy, Boston.

Retroperitoneal Cysts; Developing Possibly from the Wolffian Body. Report of Cases. Francis D. Donaghue, Boston.



HEADQUARTERS.

Vendome: General Officers.
Somerset: Practice of Medicine.
Copley Square: Obstetrics and Pathology.
Brunswick: Surgery and Anatomy.
Thorndike: Hygiene and Laryngology.
Lenox: Ophthalmology.
Nottingham: Children and Cutaneous.

MEETING PLACES.

Mechanics Hall: Opening Session, Registration, Clinical Exhibit, etc.

Boston Medical Library: House of Delegates.

Jordan Hall: Evening General Session. Section on Surgery, Tuesday evening.

New Harvard Medical School: Scientific Exhibit; Sections

Tufts College Medical School: Sections on Hygiene, Stomatology, Pharmacology.

Y. M. C. A. Hall: Section on Practice of Medicine.

Chickering Hall: Section on Obstetrics.

Huntington Hall: Section on Surgery, Wednesday, Thursday, and Friday p. m.

New Old South Church: Joint Session of the Sections on Medicine and Surgery, Wednesday p. m.

New Harvard Medical School Buildings, Longwood Avenue, where the Scientific Exhibit, the meetings of six sections and three afternoon entertainments will be held.

SECTION ON SURGERY AND ANATOMY.

CHAIRMAN, ROBERT F. WEIR, NEW YORK; SECRETARY, ARCHIBALD MACLAREN, 110 LOWRY ARCADE, ST. PAUL, MINN.

Chairman's Address. Robert F. Weir, New York.
Address. Prof. F. Trendelenburg, Germany.
The Results of the Partial Occlusion of Large Arteries, Especially of the Thoracic and Abdominal Aorta. W. S. Halstead, Baltimore.
Tumors of the Carotid Gland. W. W. Keen, Philadelphia.
Appendicostomy. James P. Tuttle, New York.
Surgical Treatment of Femoral Hernia. A. J. Ochsner, Chicago.
Surgical Diseases of the Sigmoid. H. D. Niles, Salt Lake City.
Neoplasms of the Colon. A. F. Jonas, Omaha.
Additional Experiences in the Treatment of Aneurism by the Author's Method of Intrasaccular Suture (Endo Aneurismorrhaphy). R. Matas, New Orleans.
Capillarity in Intestinal Suturing. F. Gregory Connell, Salida, Colo.
Treatment of Exophthalmic Goiter by a Specific Serum. Its Preparation. John Rogers and S. P. Beebe, New York.
Indications for Prostatectomy and Its Results. Alexander Hugh Ferguson, Chicago.
Prostatic Hypertrophy. E. Hurry Fenwick, London, England.
The Clinical Importance of Variations of the Bones of the Hands and Feet. Thomas Dwight, Boston.
Cardiac Stimulation for Suspended Animation by Direct Digital Manipulators. Report of Cases and Illustrations. B. M. Ricketts, Cincinnati.
Five Years' Use of an Original Filigree for the Prevention and Repair of Abdominal Hernia. Willard Bartlett, St. Louis.
Radium in Surgical Work. Robert Abbe, New York.
A New Primary Position in the Bloodless Treatment of the Congenital Hip Dislocation. Frederick Mueller, Chicago.
Further Considerations of the Surgery of the Spinal Cord and Peripheral Nerves. Experimental and Clinical. J. B. Murphy, Chicago.
Treatment of Fractures of the Patella. J. Ransohoff, Cincinnati.

The Massachusetts General Hospital on Blossom Street. In the dome of this building the use of ether for surgical anesthesia was first demonstrated by Morton in 1846.

Causes and Diagnosis of Gastric and Duodenal Ulcer. Frank Billings, Chicago.
Medicinal Treatment of Gastric and Duodenal Ulcer. Bertram W. Sippy, Chicago.
When Do the Gastric and Duodenal Ulcers Require Surgical Treatment and What Procedures Are Advisable? W. L. Rodman, Philadelphia.
The Results of the Surgical Treatment of Gastric and Duodenal Ulcers. W. J. Mayo, Rochester, Minn.
Results of Medical and Surgical Treatment of Gastric Ulcer in Massachusetts General Hospital from 1896 to 1906. H. F. Hewes, Boston.
Tabulation of Ulcer Cases Recently Treated in Massachusetts General Hospital and Demonstration of Patients. H. F. Hewes, Boston.
The Recognition and Surgical Treatment of Duodenal Ulcer. W. D. Haggard, Nashville, Tenn.
Report of Cases of Uterine Fibroids Associated with Gallstones. A. Vanderveer, Albany, N. Y.
Surgical Intervention in Affections of the Biliary Tract. John B. Deaver, Philadelphia.
Some Experiences in the Surgical Treatment of Exophthalmic Goiter. F. I. Shepard, Montreal, Canada.
Results from the Surgical Treatment of (a) Facial Palsy, (b) Brachial Birth Palsy. Alfred S. Taylor and L. Pierce Clark, New York.
Treatment of Fractures of the Patella. Joseph Ransohoff, Cincinnati.
Diseases of the Urachus. J. F. Binnie, Kansas City.
Spontaneous Intracranial Hemorrhage Associated with Trigeminal Nevi. Harvey Cushing, Baltimore.
Tuberculosis of the Kidney. Arthur D. Bevan, Chicago.
The Surgical Aspects of Congenital Cystic Kidney. F. B. Lund, Boston.
Treatment of Bone Cavities. James E. Moore, Minneapolis.
The Technic of Operations on the Head and Neck. George W. Crile, Cleveland.
Dislocation of the Outer End of the Clavicle; Its Pathology and Treatment. Charles L. Scudder, Boston.
Hour-glass Duodenum. K. A. J. Mackenzie, Portland, Ore.
Surgical Treatment of Congenital Hydrocephalus, with Report of a Case of Meningocele and Hydrocephalus. J. Shelton Horsley, Richmond, Va.

A paper is also to be read by A. J. McCosh, New York, the title of which has not been received.

SECTION ON OPHTHALMOLOGY.

CHAIRMAN, LEWIS H. TAYLOR, WILKESBARRE, PA.; SECRETARY, ALBERT E. BULSON, JR., FORT WAYNE, IND.

Chairman's Address. Lewis H. Taylor, Wilkesbarre, Pa.

Symposium on the Bacteriology of the Eye.

The Bacteriology of the Eyelids. George S. Derby, Boston.
The Pathogenic Bacteria of the Conjunctiva. E. A. Shumway, Philadelphia.
The Diplobacillus of Morax-Axenfeld. Brown Pusey, Chicago.
Pathogenic Bacteria of the Eyeball. John E. Weeks, New York City.
The Staining and Examination of the Bacteria of the Eye by Simple Practical Methods. E. S. Thomson, New York City.

The Differential Diagnosis and Prognosis of Tumors of the Uveal Tract. H. V. Würdemann, Milwaukee.
So-Called Leucosarcoma of the Iris. E. V. L. Brown, Chicago.
The Treatment of Simple Chronic Glaucoma with Miotics. William C. Posey, Philadelphia.
The Relation of Disease of the Nasal Accessory Sinuses to Disease of the Eyes. F. E. Brawley, Chicago.
A Demonstration of the Fundi of Some Birds, with Remarks on Their Eyes and Eyesight. Casey A. Wood, Chicago.
Conjugate Lateral Deviations. J. H. Claiborne, New York City.
Dendritic Keratitis of Malarial Origin. E. C. Ellett, Memphis.
Some Axioms Concerning Ocular Rotations. G. C. Savage, Nashville.
The Ripening Operation for Immature Senile Cataract. Its Place. F. C. Todd, Minneapolis.
The Eye Injuries of Independence Day, and What Has Been Accomplished in Baltimore Toward Lessening Them. A Further Contribution to the Subject. R. L. Randolph, Baltimore.
Ocular Injuries from Foreign Bodies, with Report of 420 Cases. William M. Sweet, Philadelphia.
The Use of the Secondary Cataract Knife. M. Black, Denver.
A New Phenomenon of Color Conversion. G. T. Stevens, New York City.

Mechanics Hall, on Huntington Avenue, where the Bureau of Registration and Information, the Opening Session, the Commercial, Clinical and Public Health Exhibits, and a ladies' rest room will be situated, and where a reception to the President and members of the American Medical Association will be held.

Paraffin Plates as an Aid in Operations for Extensive Symblepharon and the Restoration of Cul-de-Sacs for Prothesis. William H. Wilder, Chicago.
Autointoxication in Relation to the Eye. G. E. de Schweinitz, Philadelphia.
Exhibition, by Means of the New Opaque Projector of Original Colored Ophthalmoscopic Drawings. Charles H. Beard, Chicago.
A Study of Convergence and Its Defects, Including an Analysis of 441 Cases of Exophoria. Wendell Reber, Philadelphia.
Some Personal Experiences in the Use of Electricity in Ophthalmic Practice. W. F. Coleman, Chicago.
The Value of X-Rays in Ocular Therapeutics. G. Oram Ring, Philadelphia.
Some Important Considerations in the Extraction of Cataract. Mark D. Stevenson, Akron, Ohio.
Incurable Eyestrain. George M. Gould, Philadelphia.
A New Supplementary Test for Color Vision. Nelson M. Black, Milwaukee.
Some Unusual Ocular Manifestations of Arteriosclerosis. William Zentmayer, Philadelphia.
Injuries of the Eye with Birdshot. W. B. Marple, New York City.
Unioocular Inflammations of the Optic Nerve and Retina. A. A. Hubbell, Buffalo.
The Treatment of Progressive Atrophy of the Optic Nerve, Due to Acquired Syphilis, by Subconjunctival and Intravaginal Injections of Sublimate of Mercury. C. S. Bull, New York City.
Physical Economics. E. E. Holt, Portland, Maine.
Ophthalmic Practice of the Present Time. T. Valk, New York City.
Cataract Extraction with Modified Iridotomy. F. H. Verhoeff, Boston.
Relations of the Superior and Inferior Recti Muscles to Convergent Squint. Edward Jackson, Denver.
Retrobulbar Optic Neuritis Following Childbirth. C. J. Kipp, Newark.
A More Uniform Standard of the Illumination of Visual Test-Types. C. H. Williams, Boston.

SECTION ON HYGIENE AND SANITARY SCIENCE.

CHAIRMAN, DENSLOW LEWIS, CHICAGO; SECRETARY, ELMER E. HEG, SEATTLE, WASH.

Chairman's Address: The New Hygiene. Denslow Lewis, Chicago.

The Fetich of Disinfection. C. V. Chapin, Providence, R. I.

Health Inspection as Applied to the Individual. Louis Faugeres Bishop, New York.

The Plague. Ashburton Thompson, Sydney, N. S. W.

The Pathology of the Plague. Maximilian Herzog, Manila, P. I.

The Plague of American Cities. N. K. Foster, Sacramento, Cal.

Symposium on the Rational Prophylaxis of the Venereal Diseases.

Publicity as a Factor in Venereal Prophylaxis. Prince A. Morrow, New York; Max Joseph, Berlin, and William J. Herdman, Ann Arbor, Mich.

The Guarantee of Safety in the Marriage Contract. Albert H. Burr, Chicago, and Prof. A. Dührssen, Berlin.

The Study of Stirpiculture as a Preventive of Degeneracy. G Stanley Hall, President Clark University, Worcester, Mass.

Education as a Factor in the Prevention of Criminal Abortion and Illegitimacy. Henry O. Marcy, Boston; J. Henry Carstens, Detroit, and Joseph Price, Philadelphia.

The Protection of the Innocent. Charles A. L. Reed, Cincinnati; William Lee Howard, Baltimore, and Edward L. Keyes, Jr., New York.

The Restoration of the Fallen. Miss Eva Booth, Commander of the Salvation Army in America; Graham Taylor, of Chicago Commons, and Jacob A. Riis, Long Island, N. Y.

Symposium on the Hygiene of Tuberculosis.

The Duty of Municipalities and States in the Prevention and Control of Tuberculosis. G. Walter Holden, Denver.

Faneuil Hall, the "Cradle of Liberty," of Revolutionary fame.

The Duty of the State in Reference to Venereal Diseases. W. C. Chapman, Toledo, Ohio; G. Shearman Peterkin, Seattle, Wash.; Henry D. Holton, Brattleboro, Vt., and Prof. T. Tuffier, Paris, France.

What Shall We Teach the Public Regarding Venereal Diseases? Albert E. Carrier, Detroit; George S. Whiteside, Portland, Ore., and Bransford Lewis, St. Louis.

Venereal Diseases in Children. Judge Ben. B. Lindsey, of the Juvenile Court, Denver, and Alfred C. Cotton, Chicago.

The Etiology of the Social Evil. Charles Chassaignac, New Orleans, and G. Frank Lydston, Chicago.

A Practical Lesson in Reglementation. William E. Harwood, Eveleth, Minn.

The Prostitute Problem. Charles G. Cumston, Boston, and Ludwig Weiss, New York.

Symposium on the Duty of the Profession to Womankind.

The Physical and Evolutionary Basis of Marriage. Bayard Holmes, Chicago.

The Duty of the Railroads in Transportation and Care of Tuberculous Passengers. John R. Haynes, Los Angeles, Cal.

The Value of the Sanatorium in the Crusade Against Tuberculosis. Clarence L. Wheaton, Chicago.

Some Ways to Prevent the Spread of Tuberculosis. William M. Beggs, Denver.

Compulsory Registration. Herman M. Biggs, New York.

Symposium on the Alcohol Question.

The Effects of Alcohol on the Human System.

(a) Relating to Physiologic Effect. John Madden, Portland, Ore.

(b) Relating to Effect on School Children. T. Alex. MacNicholl, New York.

(c) Relating to Tuberculosis. T. J. Mays, Philadelphia.

(d) Relating to Degeneracy. E. S. Talbot, Chicago.

(e) Relating to Epilepsy. Matthew Woods, Philadelphia.

The Value of Instruction Regarding Alcohol. Henry F. Hewes, Boston, and Mrs. K. Stevenson, W. C. T. U., Boston.
The Limitation of Intemperance. Samuel Dickie, President Albion College Albion College, Michigan; E. C. Lovering, U. S. Navy, and Charles E. Woodruff, U. S. Army.
The Care of the Inebriate. T. D. Crothers, Hartford, Conn.; C. E. Woodbury, Foxborough, Mass.; George F. Butler, Chicago, and L. A. Mason, Brooklyn.

SECTION ON DISEASES OF CHILDREN.

CHAIRMAN, W. C. HOLLOPETER, PHILADELPHIA; SECRETARY, W. J. BUTLER, 1487 JACKSON BOULEVARD, CHICAGO.

Address of Welcome. Thomas Morgan Rotch, Boston.
Chairman's Address—The Pediatric Outlook. W. C. Holloppeter, Philadelphia.
Injuries to the Child's Head During Labor and the Duties of the Obstetrician in the Matter. B. Sachs, New York City.
Heredity and Environment. C. F. Wahrer, Ft. Madison, Iowa.
Hemorrhage in the Newborn. H. McClanahan, Omaha.
The Value of Blood Cultures in the Diagnosis of Acute Infections in Children. Thomas Morgan Rotch, Boston.
Fever and the Place of Salines in Treatment. J. Madison Taylor, Philadelphia.

T Wharf, with the schooners of the fishing fleet. One of the characteristic sights of the Boston water front.

Bacteriologic and Blood Findings in 36 Cases of Bowel Infection in Infants. J. C. Cook, Chicago.
A Further Contribution to the Study of Stools in Starch-Fed Infants. C. G. Kerley and N. H. Mason, New York City.
Sodium Citrate in Infant Feeding. A. C. Cotton, Chicago.
Recent Landmarks in the Artificial Feeding of Infants. Thomas S. Southworth, New York City.
Whole Milk Versus Laboratory Feeding. A. McAllister, Camden, N. J.
Tuberculosis in Infants and Children. E. E. Graham, Philadelphia.
Open-Air Treatment of Pneumonia. W. P. Northrup, New York City.
An Analysis of 40 Cases of Meningitis in Infants. J. L. Morse, Boston.
Cerebral Syphilis in Childhood. Arthur W. Fairbanks, Boston.
Modification of Milk, Simple and Accurate. Daniel Brown, Salem, Mass.
Simplicity in Infant Feeding. C. Townsend, Boston.
Report on Certified Milk Dairy of Elmira, N. Y. C. W. M. Brown, Elmira, N. Y.
Pleuritic Exudate in Children. Melinda Germann, Quincy, Ill.
Rhinitis in Children. Louis Fischer, New York City.
Bacteriology of Upper Respiratory Tract, with Special Reference to Influenza Bacillus. D. J. Davis, Chicago.
Contribution to the Study of Congenital Laryngeal Stridor. A. Friedlander, Cincinnati.
Rheumatism in Children. J. Ross Snyder, Birmingham, Ala.
The Clinical Aspects of Acute Rheumatism in Childhood and Their Significance in the Question of Specific Etiology. C. H. Dunn, Boston.
Superstition in Teratology. E. T. Shelley, Atchison, Kan.
The Opsonic Content of the Blood of Infants. Samuel Amberg, Baltimore.
Neuroma and Neurofibroma. W. E. Darnell, Atlantic City, N. J.
Congenital Word-Blindness. J. H. Claiborne, New York City.
Constitutional Low Arterial Tension in Children. L. F. Bishop, New York City.
The Value of Small Amounts of Human Milk in the Treatment of Infantile Atrophy and the Infections of Infants. Frances P. Denny, Brookline, Mass.
Tetanus Neonatorum—a Statistical Study. James M. Anders and Arthur C. Morgan, Philadelphia.
Some Unheeded Principles Involved in the Dietetic Management of Infants in Hot Weather. G. R. Pisek, New York City.

SECTION ON STOMATOLOGY.

CHAIRMAN, H. P. CARLTON, SAN FRANCISCO; SECRETARY, EUGENE S. TALBOT, 103 STATE STREET, CHICAGO.

Chairman's Address. H. P. Carlton, San Francisco.
The Structure of the Jaws of the Lower Vertebrates. J. S. Kingsley, Boston.
Development of the Human Jaw. Charles L. Minot, Boston.
Palates of the Feeble-minded. Walter Channing, Brookline, Mass.
The Reflexes of Dentition from the Physician's Standpoint. Charles Hunter Dunn, Boston. Discussion opened by Thomas Morgan Rotch, Boston, and A. C. Cotton, Chicago.
Gingival Manifestations of Metabolic Disorders. Alfred C. Croftan, Chicago.
Interstitial Gingivitis Produced by Autointoxications as Indicated by the Urine and Blood Pressure. Eugene S. Talbot, Chicago.
Treatment of Loosened Teeth. M. L. Rhein, New York City.
Conservatism in the Treatment of Infants with Harelip and Cleft Palate. G. V. I. Brown, Milwaukee, Wis.
Conservative Surgery of the Lip. Thomas Fillebrown, Boston.
The Prevention of Disfiguring Scars About the Face. M. I. Schamberg, Philadelphia.
Some Pathologic Features of the Pulp. V. A. Latham, Chicago.
The Relation of Systemic Diseases to the Conditions of the Oral Cavity. James E. Power, Providence, R. I.
Medical Phases of Dental Disorders. Samuel A. Hopkins, Boston.
The Botanical Diagnosis of Leptothrix Racemosa and Its Relations to the Modern Doctrine of Bacteriology. Filandro Vincenti, Chieli, Italy.
Practical Innervation of the Trifacial Nerve. M. H. Fletcher, Cincinnati.
Two Cases of Infantile Scurvy. Alice M. Steeves, Boston.

NERVOUS AND MENTAL DISEASES.

CHAIRMAN, WHARTON SINKLER, PHILADELPHIA; SECRETARY, T. H. WEISENBERG, 2030 CHESTNUT STREET, PHILADELPHIA.

This program appears about fifteen pages further on.

SECTION ON LARYNGOLOGY AND OTOLOGY.

CHAIRMAN, OTTO T. FREER, 288 HURON ST., CHICAGO; SECRETARY, W. S. BRYANT, 57 WEST 53D STREET, NEW YORK.

Diagnosis, Prognosis and Treatment of Laryngeal Tuberculosis. Herman Stolte, Milwaukee, Wis.
Certain Facts Concerning Faucial Tonsils. Charles M. Robertson, Chicago, Ill.
Tracheal Inflammation. Emil Mayer, New York City.
The Examination and Surgery of the Upper End of the Esophagus. Harris Peyton Mosher, Boston.
Atrophic Rhinitis. George L. Richards, Fall River, Mass.
The Treatment of Hypertrophic Intumescent Rhinitis. E. Fletcher Ingals and Stanton S. Friedberg, Chicago.
Physiology of Coryza. F. C. Cobb, Boston.

Acute and Chronic Suppuration of the Ear and Nose the Direct Cause of Facial Erysipelas. Cullen F. Welty, San Francisco.

The Use of Tuning Forks in the Diagnosis and Treatment of Deafness Due to Ossicular Rigidity. Philip D. Kerrison, New York City.

Tuberculosis of the Middle Ear and Mastoid. Eugene A. Crockett, Boston.

Exhibition of New Instruments. (a) Protection Sheet for Mastoid Surgery, (b) An Algesimeter. H. O. Reik, Baltimore, Md.

Results of Improved Technic in Otological Surgery. W. Sohier Bryant, New York City.

A Modification of the Simple Mastoid Operation which Shortens Convalescence by Facilitating Wound Repair. E. M. Plummer and H. H. Germain, Boston.

Technic in the After Care of the Radical Mastoid Operation. Philip Hammond, Boston.

Treatment of Intracranial Complications of Middle Ear Suppuration. Edward B. Dench, New York City.

Otology in Its Relation to Rhinology and Larynology. Clarence J. Blake, Boston.

Lumbar Puncture in Ear Disease. Seymour Oppenheimer, New York City.

Killian Operation. Frederick L. Jack, Boston.

The Frontal Sinus and Some of Its Variations. M. H. Cryer, Philadelphia.

Skiagraphy of the Air Sinuses. Cornelius G. Coakley, New York City.

Some Conclusions on the Submucous Window Resection of the Nasal Septum, Based on a Series of Cases. Lee Maidment Hurd, New York City.

The Submucous Resection of the Nasal Septum. J. F. Byington, Battle Creek, Mich.

A Second Report (after ten years) of the Experiences, Procedures and Results in Subperichondrial and Subperiosteal Operations on the Cartilages and Bones of the Nasal Septum. Robert C. Myles, New York City.

A paper, the title of which is not yet received, will be read by Sir William Macewen, Glasgow, Scotland.

A paper, the title of which is not yet received, will be read by D. Bryson Delavan, New York City.

SECTION ON CUTANEOUS MEDICINE AND SURGERY.

CHAIRMAN, DOUGLAS W. MONTGOMERY, SAN FRANCISCO. SECRETARY, R. R. CAMPBELL, 100 STATE STREET, CHICAGO.

The Age at Which Syphilis is Acquired. Douglas W. Montgomery, San Francisco.

Leukoplakia in Its Relation to Other Dermatoses. Max Joseph, Berlin, Germany.

Four Cases of More or Less Complete Alopecia in a Family of Eleven. Henry W. Stelwagon, Philadelphia.

The Therapeutic Nature of Chrysophanic Acid in Dermatology. Charles James Fox, Hartford, Conn.

A Case of Pemphigus Affecting the Mucous and Serous Membranes Only. Edmund L. Cocks, New York City.

On the Relations of Nerve Impulse to Cutaneous Inflammation. Ernest L. McEwen, Chicago.

Pemphigus Neonatorum. O. H. Foerster, Milwaukee, Wis.

Lichen Planus of the Mouth and Lips, with Report of a Case. David Lieberthal, Chicago.

Eczema. Henry G. Anthony, Chicago.

The Consequences of Lupus Vulgaris of the Ear. A. Ravogli, Cincinnati.

An Unsolved Postmortem in Syphilis. A. H. Ohmann-Dumesnil, St. Louis.

Aids to Accuracy and Efficiency in Radiotherapy. Henry G. Piffard, New York City.

Exhibition of Wax Models Cases of Leprosy. F. R. Day, Honolulu.

Endothelioma. William S. Gottheil, New York City.

Generalized Multiple Pigmented Sarcoma Originating in the Skin. William Frick and Frank J. Hall, Kansas City, Mo.

Myomata Cutis. M. L. Heidingsfeld, Cincinnati.

The Cure of Psoriasis. L. Duncan Bulkley, New York City.

Some Conditions of the Skin in Which the High Frequency Spark is Efficacious. Charles W. Allen, New York City.

A Record of Some Unusual Cases. William S. Gottheil, New York City.

Papers will also be read by Drs. Ludwig Weiss, New York City, and Jay F. Schamberg, Philadelphia.

SECTION ON PHARMACOLOGY AND THERAPEUTICS.

CHAIRMAN, THOMAS F. REILLY, NEW YORK CITY; SECRETARY, C. S. N. HALLBERG, 355 DEARBORN STREET, CHICAGO.

The Therapeutic Uses of Thyroid Preparations. Oliver T. Osborne, New Haven, Conn.

The Pharmacology of Digitalis and Its Principles. Robert A. Hatcher, New York.

The Prevention and Cure of Relapsing Fever. Frederick G. Novy, Ann Arbor, Mich.

The Back Swing of the Pendulum. James N. Butler, New York.

The Treatment of Asthma. Delancey Rochester, Buffalo, N. Y.

Normal Peristalsis of the Stomach and Intestines and the Effects of Certain Drugs on It. Results of Experimental Work. F. Pfaff and L. Nelson, Boston.

The Value of Predigested Food Preparations. A. L. Benedict, Buffalo, N. Y.

The Diet in Albuminuria, a Clinical and Experimental Study. Heinrich Stern, New York.

Prescribing versus Dispensing. M. Howard Fussell, Philadelphia.

Methyl-thionin Hydrochlorid in Inoperable Cancer. A. Jacobi, New York.

The Use of Eucalyptus in Actinomycosis and Filariasis. Glentworth Butler, Brooklyn.

Statue of the "Minute Man" at Concord.

Solanin. William F. Waugh, Chicago.
Discussion to be opened by G. F. Butler, Chicago.

Dietetic Treatment of Diabetes Mellitus. Max Einhorn, New York.
Discussion to be opened by J. C. Hemmeter, Baltimore.

Suggestions as to the Revision of the U. S. P. and a Plea for Strong Medical Representation. Martin I. Wilbert, Philadelphia.

The National Formulary in Its Attitude to Pharmaceutical Proprietaries. C. Lewis Diehl, Louisville, Ky.

The Chemistry of the Organic Silver Compounds. W. A. Puckner, Chicago.
Discussion to be opened by Solomon Solis-Cohen, Philadelphia.

The Internal Treatment of Skin Diseases. C. H. Bangs, Lynn, Mass.

Palatable Prescribing. Herman Sheffield, New York.

The External Preparation of the U. S. Pharmacopeia VIII. C. S. N. Hallberg, Chicago.

A Novel Method of Using Strychnin and Hydrastin, Particularly in Vesical and Sexual Weakness. William J. Robinson, New York.

The Quinin Treatment of Cholera. Erskine B. Fullerton, Columbus, Ohio.

Addenda to Therapeutic Measures in Certain Forms of Nephritis. E. M. Johnson, Boston.

Methods and Description of Treatment in a Tuberculosis Dispensary. Edward O. Otis, Boston.
The Bad Results of the Nauheim Treatment. Morris Manges, New York.
Nostrums: Fraudulent Methods of Exploitation. Lyman F. Kebler, Washington, D. C.

Symposium on the Roentgen Rays.

Therapeutic Uses and Dangers. Charles Lester Leonard, Philadelphia.
Application in Treatment of Superficial Lesions. Russell H. Boggs, Pittsburg, Pa.
Treatment of Malignant Disease. Ennion G. Williams, Richmond, Va.
Discussion to be opened by Bray Brown, Boston.

SECTION ON PATHOLOGY AND PHYSIOLOGY.

CHAIRMAN, HENRY A. CHRISTIAN, BOSTON; SECRETARY, WALTER L. BIERRING, IOWA CITY, IOWA.

Experiments on Blood Plates. George T. Kemp, Urbana, Ill.
Motor Activities of the Alimentary Canal After Splanchnic and Vagus Section. W. B. Cannon, Boston.
Address in Physiology. Max von Frey, Würzburg, Germany.
Albumins in Urine. T. W. Hastings, New York.
Urine in Diabetes. Mortimer Warren, New York.
Conditions Under Which Dextrose Appears in the Urine During Experimental Ether Anesthesia. Holmes C. Jackson, Albany, N. Y.
Clinical Report of Examination of Urines Excreted Before and After Ether Anesthesia, Together with an Analysis of the Causes of the "Pseudo" Reduction in Fehling's Test. H. E. Robertson and C. W. L. Hacker, Albany, N. Y.
The Physiology and Pathologic Relation Between Phosphoric and Uric Acids. G. W. McCaskey, Fort Wayne, Ind.
The Elimination of Creatinin, Uric Acid and Phosphorus. Holmes C. Jackson and K. D. Blackfan, Albany, N. Y.
Lactic Acid in Metabolism. Graham Lusk, New York.
A Problem in Physiologic Chemistry. Wm. J. Gies, New York.

Harvard Hall and the Johnston Gateway, at the entrance of Harvard College Yard.

Chairman's Address: Recent American Work in Pathology and Physiology. Henry A. Christian, Boston.
A Study of Acute Leptomeningitis (Streptococcus Pyogenes). E. E. Southard and R. R. Stratton, Boston.
Study in Meningococcus Infections. D. J. Davis, Chicago.
Ehrlich's Theory of Immunity Regarded from the Standpoint of His Experiments. F. P. Gay, Boston.
Lantern Slide Demonstration. (a) Spirillum Obermeieri; (b) Bird Malaria; (c) Insect Trypanosomes. F. G. Novy, Ann Arbor, Mich.
Tuberculosis of an Adenomyoma of the Uterus. R. M. Pearce and J. L. Archambault, Albany, N. Y.
The Blastomyces Group of Organisms. S. B. Wolbach, Boston.
Melanotic Carcinoma. Henry Albert, Iowa City, Iowa.
Mouse Tumors. E. E. Tyzzer, Boston.
A Study of Bone Marrow in the Terminal Stages of Acute Infections. Warfield T. Longcope, Philadelphia.
Cause of Fatigue in Certain Pathologic States. Frederic S. Lee, New York.
The Treatment of Emaciation. L. Breisacher, Detroit.
Experiments on Venous Blood Pressure. Henry Sewall, Denver.
A Physician's Creed, Past and Present, as to the Physiology of the Heart. Wesley Mills, Montreal, Canada.
Lantern-Slide Demonstration of Ultra-Violet Photomicrography. H. C. Ernst, Boston.
The Bacteria of Scarlatinal and Normal Throats. G. F. Ruediger, Chicago.
Studies on Phagocytosis. D. H. Bergey, Philadelphia.
The Cause of Sudden Death Following the Injection of Horse Serum. M. J. Rosenau, Washington.
Studies in Experimental Phagocytosis. Joseph McFarland, Philadelphia.
A Study of Blood in Banti's Disease Before and After Splenectomy. W. L. Bierring and Anfin Egdahl, Iowa City, Iowa.
Relation of Clinical Pathology to the Actual Practitioner. Louis F. Bishop, New York.
An Improved Operative Method of Forming an Experimental Accessory (Pawlow) Stomach on the Dog. John C. Hemmeter, Baltimore.

Studies in Physiology and Experimental Medicine by Winfield S. Hall and Associates.

(a) The Normal Temperature and Closed Inguinal Fold as Compared with the Rectal Temperature. A. H. Parks, Chicago.

(b) How to Detect Abdominal Hemorrhage. H. S. Hollenbeek, Chicago.

(c) Will Blood in the Peritoneal Cavity be Best Absorbed When Left in Clot or When Dissolved in Physiologic Saline Solution? M. Jampolis, Chicago.

(d) Normal and Pathologic Physiology of the Vagus Nerve. R. J. Pickard, Chicago.

Specific Therapy in Typhoid Fever. Mark W. Richardson, Boston.

Pathologic Findings in Two Cases of Mycosis Fungoides. Samuel T. Orton and Edwin A. Locke, Boston.

A paper will also be read by Dr. Alfred Stengel, Philadelphia, the title of which is not received.

PROGRAMS FOR THE GENERAL MEETINGS.

Opening Meeting.

TUESDAY, JUNE 5, 1906, IN MECHANICS HALL.

9:30-10:30 a. m.—Music.

10:30 a. m.—Call to order by President, Lewis S. McMurtry, Louisville, Ky.

Addresses of Welcome:

President Eliot of Harvard University.

President A. T. Cabot of the Massachusetts Medical Society.

Governor Curtis Guild of Massachusetts.

Mayor John F. Fitzgerald of Boston.

The report of the Committee of Arrangements, Dr. Herbert L. Burrell, Chairman.

Revere Beach Reservation. One of the popular seashore resorts which are a part of the Metropolitan Park System. "Wonderland," an amusement enterprise which will rival Coney Island, will be opened on the 30th of May.

Joint Session Medicine and Pathology.

Bacteriology of Pleural Effusion. Lewis W. Ladd, Cleveland, Ohio.

Cytology of Pleural Effusions. Percy Musgrave, Boston.

Introduction and installation of the President-elect, Dr. William J. Mayo, Rochester, Minn.

Annual address of the President.

Adjournment.

Music.

Second General Meeting.

Tuesday Evening, June 5, 7:30 p. m.

The Second General Meeting will be held Tuesday evening in Jordan Hall.

At this meeting the Oration on Medicine, by Dr. F. C. Shattuck of Boston, and the Oration on Surgery, by Dr. Joseph D. Bryant of New York, will be delivered.

Third General Meeting.

Wednesday Evening, June 6, 7:30 p. m.

The Third General Meeting will also occur in Jordan Hall. At this meeting the Address on State Medicine, by Dr. W. H. Sanders of Montgomery, Ala., will be delivered.

OTHER SOCIETIES.

Some Other Medical Bodies to Meet in Boston the Week of the Session.

At or about the time of the session of the American Medical Association the following societies will also hold their meetings in Boston:

Association of United States Pension Examining Surgeons

American Academy of Medicine.

American Gastro-Enterological Association.

American Neurological Association.

American Association of Life Insurance Examining Surgeons.

American Urological Association.

American Medical Editors' Association.

And a number of others, of which the Committee of Arrangements has, as yet, received no notice.

Historic Boston.

A BRIEF DESCRIPTION OF THE MEETING PLACE AND ITS POINTS OF INTEREST.

The selection of Boston as the meeting-place of the American Medical Association in 1906 ensures such a multitude of attractions that already the gathering bids fair to surpass in popularity and in attendance all previous sessions of the Association.

On all sides objects of historical and educational interest will attract the visitor's attention. From the days of the Pilgrim Fathers, until after the Revolution, the Old Colony of Massachusetts was the scene of action for many events which make the history of our country. Here Adams, Franklin, Hancock, Warren and Paul Revere gave each his service to the cause of freedom, and here on the battle-fields of Lexington, Concord and Bunker Hill flowed the blood of the patriots in which our independence was baptized.

As a center of educational and literary achievement Boston has long borne the title of the "Athens of America." It has been the home of our greatest poets, and of many of our most distinguished writers. Memories of Lowell, Longfellow, Holmes, Emerson and Whittier are again and again brought to mind by the scenes that gave them inspiration.

The Boston Art Museum, Copley Square. Special facilities for visiting the Museum will be provided for the members of the Association.

In Cambridge, across the historic Charles River, is Harvard College; that city within a city; where the ivy-covered brick buildings with their revolutionary memories look down through the shades of the elm trees on the green sward of the college yard. The development of Harvard College to its present position as the greatest of the universities of the western world has involved the construction of many splendid buildings, covering a great extent of territory, in Cambridge, Boston, Brookline and other places near at hand, and of these the new medical school buildings are the most recent and most glorious example. This magnificent group of marble buildings, dedicated to the advancement of medical science, and equipped with every facility for instruction and for research, will be thrown open for the first time on the 5th of June for the reception of the members of the American Medical Association, and here the greater number of the section meetings will be held.

It is not on Harvard University alone, however, that Boston is dependent for her reputation in matters educational. The Massachusetts Institute of Technology holds a preëminent position among schools of applied science; the public school system of Boston is a model for many cities, and the Perkins Institute for the Blind, and the School for Crippled and Deformed Children are noted examples of schools for special education.

To the medical profession Boston will always be a city of peculiar interest. The names of Warren, Jackson, Bigelow and Holmes are identified with the early progress of medical science in this country, and the Harvard Medical School, from its beginning in Harvard Hall in Cambridge, to present magnificent accommodations in the new school buildings at Longwood, forms no small part of the history of medicine in America. It is the hospitals of Boston, however, which have contributed most generously to her fame in medicine. They have always been closely associated with her medical schools and they have provided clinical instruction to countless students. The Massachusetts General Hospital has stood for nearly a century as a center for instruction and research in medicine and surgery. In the old operating room under the dome of this hospital, in 1846, Morton first gave to the world the demonstration of surgical anesthesia by the inhalation of ether vapor. The City Hospital, with its splendid department for infectious diseases and its relief station in the down-town district for the care of accident and emergency cases, is a unique example of a Municipal Hospital which has been kept free from the abuses of political control by the enlightened policy of its trustees. The Carney Hospital in South Boston, the Children's Hospital, the Boston Lying-in Hospital, the Infants' Hospital, the Boston Dispensary, the Massachusetts Eye and Ear Infirmary, and many of the smaller institutions will also throw open their doors to members of the Association, and in many cases special programs of demonstrations and operations will be given during the session.

The Boston Medical Library, with its handsome building on the Fenway, its collection of medical books and pamphlets, second only in this country to the library at Washington, and its many relics and treasures in the way of letters, manuscripts, medals and pictures, represents the harmonious devotion of generations of medical men to the common interests of their profession. The spacious halls of the library building serve as meeting places for many of the medical societies of Boston, and at the time of the session of the Association will be set apart for the deliberations of the House of Delegates. The officers of the Boston Medical Library have extended a cordial invitation to the members of the American Medical Association to visit the library during the session and to inspect its valuable collection of books, medals and medical souvenirs.

In the hospitals of Boston and in the laboratories of the Harvard Medical School a complete series of courses of instruction in all the branches of medical science is given every year. The courses which are given during the summer months are intended primarily for the instruction of graduate students, and many members of the Association are already planning to avail themselves of this opportunity to pursue the study of their special subjects by prolonging their visit in the city, or

by establishing themselves with their families at one of the many seashore resorts which are close at hand.

To the stranger in Boston the places of interest are so numerous and embrace such a variety of different subjects that a choice must be made to suit the individual. Opportunities will be given to visit the different places of historic interest under the leadership of competent guides provided by the Committee of Arrangements. The Old State House, Faneuil Hall, Kings Chapel and Old South Church, the Granary Burying Ground, the Common, and many other historic spots may thus be seen. Special facilities will also be given to the members of the Association and their guests to enjoy the treasures of the Museum of Fine Arts, and the wonderful mural paintings of Abbey, Sargent and Chavannes in the Boston Public Library.

The Navy Yard at Charlestown will be thrown open to the members of the Association, and special facilities will be provided for the inspection of its many points of interest. Here the historic frigate *Constitution* lies at rest after the many years of service which gained for her the title of "Old Ironsides." At the time of the session a number of modern warships from the North Atlantic Squadron will be stationed here.

For the benefit of the ladies who will accompany the members of the Association a special series of excursions and amusements will be arranged during the hours of the section meetings. There will be trolley rides to Cambridge, Lexington, Concord, and other places of interest in the vicinity of Boston, and automobile and coaching trips through the wonderful Metropolitan Park System which surrounds the city on every side. Sea bathing may be enjoyed at Revere Beach and Nantasket, the seashore resorts which form a portion of the Park System, or excursions may be made by steamboat down the harbor and along the shores of Massachusetts Bay, to Nahant and Salem, or to Plymouth and Cape Cod. No one need hesitate to bring his wife with him to the Boston session for fear that time will hang heavy on her hands. A committee of Boston ladies has been formed to take in charge the arrangements for the comfort of the visiting ladies, and to provide for their entertainment. A rest room will be set apart for the ladies at the general meeting-place of the Association, where everything will be provided that can contribute to their comfort and convenience.

Longfellow House in Cambridge, the home of the poet Longfellow.

It must not be forgotten that Boston stands at the gateway of the greatest summer playground of the country. Expeditions to the coast resorts of the north or south shores of Massachusetts, to the rugged coast of Maine, or to the woods and hills of the White Mountains, can easily be arranged. There are undoubtedly many members of the Association who will make the Boston session but an incident in a vacation for themselves and their families among the mountains or beside the sea. The Committee on Transportation has succeeded in securing special privileges in the way of an extension of time during which the return tickets will be accepted by the railroads, and many will avail themselves of these advantages. To those who wish to go abroad for their vacation the opportunity is also given by many steamship lines which run from Boston to England and the Continent.

The entertainments which will be offered to the members of the Association and to the ladies and guests who may accompany them are on a most extensive scale. The invitations to the American Medical Association to come to Boston for its session of 1906 were given by the Massachusetts Medical Society and the Harvard Medical School. These invitations, however, have received the unanimous support of the people of New England. Not only by giving financial assistance, but by the expenditure of a large amount of thought and time and trouble the members of the medical profession, the ladies of Boston, and many public spirited men who are not members of the profession, have joined in the preparations for this great convention.

On Tuesday, Wednesday and Thursday afternoons the grounds of the new Harvard Medical School buildings will be devoted to the entertainment of the visitors. There will be music in the central court, and tea and light refreshments will be served by the young ladies of Boston on the terraces. Here the members who have been attending the meetings of their sections in the halls and amphitheaters of the different buildings will spend a restful hour with their friends or wander through the long corridors and spacious laboratories.

On Wednesday evening a reception and promenade concert will be given to the President and to the members and guests of the Association, by the medical profession of New England. This reception will be held in Mechanics Hall, where many thousands of guests can be accommodated. A special attraction which is promised is the singing of a trained chorus of one hundred physicians, which will probably be unique in the annals of the Association.

To complete the arrangements for the comfort and convenience of the members who attend the 1906 session, a special "Guide Book to Boston" has been prepared expressly for this occasion and will be issued gratuitously to every member on registration, together with the official program and the unique and beautiful members' badge which has been designed for the Boston session. The Guide Book contains about two hundred pages and is profusely illustrated with views of historical and modern interest. It will provide information concerning the many places of historical interest in Boston and its suburbs, and special attention has been devoted to hospitals and other places of interest to the medical profession. Four maps and a number of lists of hotels, theaters, restaurants and recreation places will be included. It is hoped that this Guide Book may serve to make the visit in the city more enjoyable, and that it may also constitute an agreeable souvenir of the Boston session of the American Medical Association.

TRANSPORTATION.

Favorable Railroad Rates Secured from All Parts of the United States—Sight-Seeing Opportunities.

The Committee on Transportation of the American Medical Association makes the following announcement:

Arrangements for reduced rates on railroad transportation for the Boston session of the American Medical Association have been secured from nearly all of the passenger associations of the country. These rates will vary according to the different starting points, and the arrangements for each district will be announced in detail. It is hoped, however, that a rate of approximately a single fare, plus a fee of from 25 cents to $1, may be obtained for the round trip, with return extension privileges at a further expense of $1, up to June 30, from all important points.

Satisfactory and complete arrangements will be made at Mechanics Hall, Boston, for the validation of railroad tickets for members of the Association.

JOHN C. MUNRO, Chairman.

NEW ENGLAND PASSENGER ASSOCIATION.

(Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut.)

The New England Passenger Association announces: Within a radius of one hundred and fifty miles or less, convention rates. Between the one hundred and fifty miles and the termini (including the termini) of the New England Passenger Association, fare one way, plus 25 cents, for the round trip. No rate to be less than the convention basis applied at the one hundred and fifty mile radius. Tickets to be sold and good going in New England June 2-8 inclusive, good returning June 3-11 inclusive.

An extension of final return limit to June 30, 1906, inclusive on all tickets will be granted, provided they are deposited with the joint agent not later than June 11 and a fee of $1 paid at time of deposit.

On tickets sold from Pacific Coast points by lines in Trans-Continental Passenger Association an extension of final return limit to leave Boston not later than midnight of Aug. 31, 1906, will be granted, provided tickets are deposited with joint agent not later than June 11 and a fee of $1 paid at the time of deposit, and provided further that all other joint agency requirements, form of ticket, etc., are complied with. Further details and form of ticket to be announced later.

The Old State House, State Street, now a museum of Colonial antiquities.

TRUNK LINE ASSOCIATION.

(New York, New Jersey, Pennsylvania, Delaware and West Virginia.)

This association authorizes one first-class fare, plus $1, for the round trip; tickets to be sold and good, going, June 1 to 6; returning, leaving Boston to June 11 inclusive. The extension of return limit is to be under same conditions as above.

CENTRAL PASSENGER ASSOCIATION.

(Ohio, Michigan, Indiana and part of Illinois.)

This association grants the same rates and same conditions of extension. Ironclad tickets to be sold June 2, 3, 4 and 5, passengers not to reach gateways of the New England Passenger Association earlier than June 2, nor to arrive in Boston later than June 8. Tickets via New York allow stopover there.

The Richelieu & Ontario Navigation Company advise that on presentation of rail excursion ticket to agent of R. & O. N. Co. at Toronto, or to purser on board steamer, same will be accepted on payment of following arbitraries: Toronto to Montreal, $6.50; Kingston or Clayton to Montreal, $3.50.

TRANS-CONTINENTAL PASSENGER ASSOCIATION.

(Pacific Coast States.)

Members from Pacific Coast may avail themselves of either or both of the following sets of rates and conditions:

First: Account of Knights of Columbus, New Haven, Conn., June 3-9, 1906, excursion tickets will be sold from California May 25, 26 and 27, and from North Pacific Coast points and Spokane May 24, 25 and 26, to New Haven, Conn., and return, with going transit limit June 9, 1906, and final return limit Aug. 31, 1906, at the following rates and on the following conditions.

Rates from California via direct routes to be made on basis of one thirty-day first-class fare; to points east of eastern terminals of T. C. P. A., rates to be made on basis of one thirty-day first-class fare to T. C. P. A. eastern terminals, added to excursion fares authorized east thereof.

Examples of thirty-day fares from California.

To Chicago	$72.50
To St. Louis	67.50
To Memphis	67.50
To New Orleans	67.50
To Omaha	60.00
To Kansas City	60.00
To St. Paul	70.00

Rates from North Pacific Coast points via direct routes to be made on basis of $10 higher than the lowest first-class limited fare; to points east of eastern terminals of T. C. P. A., rates to be made on basis of $10 higher than the lowest first-class limited fare to T. C. P. A. eastern terminals, added to excursion fares authorized east thereof.

Examples of rates from North Pacific Coast common points: Portland, Oregon, Seattle and Tacoma, Washington, Vancouver and Victoria, B.C.:

To Chicago	$71.50
To St. Paul	60.00
To St. Louis	67.50
To Omaha	60.00
To Kansas City	60.00

Rates from Spokane, Washington to St. Paul, $52.50; Missouri River common points, Omaha to Kansas City inclusive, $52.50; to St. Louis, $60; to Chicago, $64.

Such rates to apply over same diverse routes west of T. C. P. A. eastern terminals, Chicago, St. Louis, Memphis, New Orleans and St. Paul, as the direct routes nine months' tourist rates apply. East of said terminals routing to conform to authority extended by the eastern lines and promulgated by chairman T. C. P. A.

For tickets from California via direct route one way, and via Portland, Ore., in opposite direction (using either Shasta Route or S. F. & P. S. S. Co. between Portland and San Francisco), rates from San Francisco, Tracy, Lathrop, Stockton, Sacramento, Redding and their intermediates, will be $13.50 greater than rates for tickets via direct routes both ways.

Tickets to be good going from starting point only on date of sale. East of T. C. P. A. eastern terminals tickets to be limited going and returning in conformity with regulations prescribed in eastern lines.

If members avail themselves of above they will require to rebuy at New Haven to Boston and return to New Haven, and their trip to and from Boston should be regulated according to the conditions of the New Haven tickets.

Second: Regular nine months' tourist rates, approximating

two cents per mile in each direction, or about one fare and one-third for the round trip, are in effect daily from California and North Pacific Coast common points to Chicago, Kansas City, Mo., Memphis, Minneapolis, New Orleans and St. Louis.

The following are examples of the rates over direct routes from California and North Pacific Coast common points:

From.	To.	Rate.
California and North Pacific Coast and common points	Missouri River points named and return	$ 90.00
California	St. Paul and return	105.00
North Pacific Coast points	St. Paul and return	90.00
California and North Pacific Coast common points	Chicago and return	110.00
California and North Pacific Coast common points	St. Louis and return	102.00
California	Memphis and return	102.00
North Pacific Coast points	Memphis and return	111.60
California	New Orleans and return	102.00
North Pacific Coast points	New Orleans and return	117.00

Proportionately higher rates are made to New York, Philadelphia, Washington, Boston, Montreal, etc.

The nine months' rates apply only to what are known as the eastern gateways of the association, such as those named. Agents will advise as to the eastern points named above to which it will be most advantageous to purchase nine months' tickets in rebuying to place of meeting. These nine months' tourist tickets are sold only from California, Nevada, Oregon, Washington, and west of and including Mission Junction B. C.; also from what are known as Kootenay common points, namely, Nelson, Rossland, Sandon, Kaslo and Grand Forks, B. C.

Reports from the southern passenger associations will be published later.

For special trains, see about the eighth page following this.

THE BOSTON SESSION.

Announcement of Headquarters and List of Hotels, with Prices.

While Boston is liberally supplied with hotels of the first class, many of which are in the immediate neighborhood of the meeting places selected by the Committee of Arrangements for the annual session of the American Medical Association, June 5-8, 1906, the Committee on Hotels deems it wise to bring to the notice of those expecting to attend, the advisability of securing accommodations well in advance, since the time chosen for the session is not far from the commencement days of Harvard, Tufts, Boston University, and the Massachusetts Institute of Technology, and during the same week it is expected that Christian Scientists to the number of some thousands will visit Boston to open a new "temple." The committee urges members of the Association, therefore, not to postpone too long the securing of rooms, and it engages to act in the matter for all who will make their desires known; but the final engagement must be made in all cases by the applicant directly with the hotel managers.

In addition to the hotels included in the list below are many of perfect respectability, but not of such excellence as to entitle them to be rated as of the first class.

Bunker Hill Monument, Charlestown.

LIST OF HOTELS WITH PRICES.

The following are the hotels included in the first class, with terms, and the number for whom it is estimated that there will be accommodations at the time of the session:

ADAMS HOUSE, Washington Street. European plan. Single rooms, without bath, $1.50 to $4 per day; with bath, $2.50 to $4. All rooms cost $1 additional when occupied by two persons. Accommodations, 200.

AMERICAN HOUSE, Hanover Street. European plan, $1 to $4 per day. Accommodations, 200.

BELLEVUE, Beacon Street. European plan. Single rooms, $1.50 to $2.50 per day; with private bath, $3 to $5. Double rooms, $2 to $3 per day; with private bath, $4 to $6. Accommodations, 150.

BRUNSWICK, Boylston Street. American plan. Rooms, without bath, $5 per day; with bath, $6. Accommodations, 300.

The Brunswick has been chosen headquarters for the Section on Surgery and Anatomy.

BUCKMINSTER, Commonwealth Avenue and Beacon Street. American and European plans. American: $4 per day, European, $2. Accommodations, 40.

CARLTON CHAMBERS, 1138 Boylston Street. European plan. Single rooms, without bath, $1.50 per day; with bath, $2. Double rooms, without bath, $3, per day; with bath, $4. Accommodations, 50.

CECIL, Washington Street. European plan. Single rooms, $1 and upward per day; for two persons, $2 and upward; with bath, $1.50 to $4. Double rooms, with bath, $2.50 to $5. Accommodations, 75.

COMMONWEALTH CHAMBERS, Bowdoin Street. European plan. Rooms, with hot and cold water and free public bath, $1 and $1.50 a day for one person; $2 and $2.50 for two persons. Rooms with private bath, $1.50 to $2 for one person, $2 to $2.50 for two persons. Accommodations, 175.

COPLEY SQUARE HOTEL, Huntington Avenue and Exeter Street. European plan. Rooms, $1.50, without bath, to $3 and $4 with bath, according to number of persons. Accommodations, 200.

The Copley Square has been selected as headquarters for the Sections on Obstetrics and Diseases of Women and on Pathology and Physiology.

CRAWFORD HOUSE, Scollay Square. European plan. Single rooms, with two persons in a room, $2 to $3 per day. Accommodations, 75.

ESSEX, Atlantic Avenue. European plan. Single rooms, $1.50 and upward; with bath, $2 and upward.

HEMENWAY CHAMBERS, Westland Avenue. European plan. Single rooms, with bath, $1.50 to $3 per day. Double rooms, with bath, $2.50 and $4.50. Three rooms, with bath, $4 and upward. Accommodations, 75.

LANGHAM, Worcester and Washington streets. European and American plans. European plan, $1 and upward per day. American plan, single rooms, $2 per day; single rooms, with two persons, $3. Accommodations, 100.

LENOX, Exeter and Boylston streets. European plan. Single room, without bath, $2.50, to $3 per day; with bath, $4 and $5. Accommodations, 50.

The Lenox has been chosen as headquarters for the Section on Ophthalmology.

LEXINGTON, 13 Boylston Street. European plan. Single rooms, $1.50 to $2 per day; for two persons $2.50 to $3. Accommodations, 75.

NOTTINGHAM, Copley Square. European plan. Single room, $1 and $1.50 per day; with bath, $2; two persons, without bath, $2 and $2.50; with bath, $3. Accommodations, 150.

The Nottingham has been selected as headquarters for the Sections on Diseases of Children and on Cutaneous Medicine and Surgery.

OXFORD, Huntington Avenue. American and European plans. Singue rooms, $1, $1.50 and $2 per day. Accommodations, 100.

The Oxford has been chosen as headquarters for the Section on Pharmacology.

PARKER HOUSE, School Street. European plan. Single rooms, without bath, $1.50 to $3 per day; for two persons, $2.50 to $4.50. Single rooms, with bath, $2.50 to $4; for two persons, $4 to $6. Accommodations, 75.

QUINCY HOUSE, Brattle Street. European plan. Rooms, $1 per day and upward. Accommodations, 300.

REVERE HOUSE, Bowdoin Square. European plan. Single rooms, $1 per day; for two persons, $1.50; with bath, $2; for two persons, $3, with parlor and bath, for two persons, $5. Accommodations, 200.

SOMERSET, Commonwealth Avenue. European plan. Single rooms, $2.50 per day; with bath, $3. Double rooms, $3.50; with bath, $4. Accommodations, 100.

The Somerset has been chosen as headquarters for the Section on Practice of Medicine.

THORNDIKE, Boylston Street. European plan. Single rooms, with detached bath, $1.50 per day and upward (a few single rooms at $1.00); double rooms, with detached bath, $2 and upward; single, with connecting bath, $2 and upward; double, with connecting bath, $3 and upward; suite of two chambers and bath (or parlor, chamber and bath), $5 and upward. Accommodations, 125.

The Thorndike has been chosen as the headquarters for the Sections on Hygiene and Sanitary Science and on Laryngology and Otology.

TOURAINE, Boylston Street. European plan. Single room, without bath, one person, $3 per day; two persons, $4.50; double, with bath, one person, $4 to $6; two persons, $5.50 to $8. Accommodations, 40.

The Touraine has been chosen as the headquarters for the Section on Nervous and Mental Diseases.

UNITED STATES HOTEL, Beach Street. American plan; two in a room, $2.50 per day and upward for each person. European plan, two in a room, $1.00 and upward, for each. Accommodations, 150.

VENDOME, Commonwealth Avenue. American plan. Single rooms, without bath, $5 per day; with bath, $6. Accommodations, 200.

The Vendome has been chosen as the headquarters for the General Officers.

VICTORIA, Dartmouth Street, corner Newbury. European plan. Single rooms, with use of bath, $2 per day and upward; with private bath, $3.50; double, with use of bath, $3 and upward; with private bath, $4.50 and upward. Accommodations, 50.

WESTMINSTER, Copley Square. European plan. Single rooms, $2 per day; with two persons, $3 and upward; three-room apartments, $9 to $12. Accommodations, 50.

The Westminster has been chosen as the headquarters for the Section on Stomatology.

YOUNG'S HOTEL, Court Square. European plan. Single rooms, without bath. $1.50 to $2 per day; for two persons, $2.50 to $4; with bath, $2.50 to $4.50; double room with bath, $4 to $7.

The Boston Public Library, Copley Square. A reception to the members of the Association will be given by the Trustees of the Library, and special facilities will be provided daily for the benefit of the members of the Association.

The following hotels are within a few minutes' walk of the general meeting places; the others are not more than 15 minutes' distance by trolley cars:

Brunswick.
Carlton Chambers.
Copley Square.
Hemenway Chambers.
Lenox.
Nottingham.
Oxford.
Somerset.
Thorndike.
Touraine.
Vendome.
Victoria.
Westminster.

The following hotels have been selected as headquarters for the general officers and for the sections:

General Officers	Vendome.
Practice of Medicine	Somerset.
Obstetrics and Diseases of Women	Copley Square.
Surgery and Anatomy	Brunswick.
Hygiene and Sanitary Science	Thorndike.
Ophthalmology	Lenox.
Diseases of Children	Nottingham.
Stomatology	Westminster.
Nervous and Mental Diseases	Touraine.
Cutaneous Medicine and Surgery	Nottingham.
Laryngology and Otology	Thorndike.
Pharmacology and Therapeutics	Oxford.
Pathology and Physiology	Copley Square.

ACCOMMODATIONS NEAR OCEAN.

Many members of the Association from the interior states, away from the ocean, may be glad to learn that arrangements have been made, if a suitable number can be got to take rooms, for from three to five hundred members at Winthrop Beach, directly on the ocean, and thirty minutes' ride from Boston by boat and rail or by trolley. The rates will be on the American plan, from $2 to $3.50 a day, according to accommodation, but the secretary of the Hotel Committee must be notified at the earliest practicable moment by those members who wish to obtain these accommodations, for these houses are not ordinarily opened until later in the season, and will have to be opened especially for this occasion. This is an excellent opportunity to enjoy the sea air and view, and yet to be within a few minutes travel of the Association headquarters in the city.

BOARDING AND LODGING HOUSES.

The Committee on Hotels and Transportation has secured a list of 521 private houses where board and lodging can be secured. Many of these houses are in the neighborhood of the general meeting places. These, and many more still to be secured, will soon have been critically inspected and rated. The committee will gladly act for those who desire its assistance in securing rooms and board in these houses. A list of them with rates will be furnished in a later number of THE JOURNAL.

RESTAURANTS.

By reason of the fact that many thousands of persons, residing elsewhere, conduct their business in Boston, the city is unusually well supplied with restaurants, which are equal to all possible demands on them. These are situated in all parts of the city. Naturally the greater number of them are located in the business section, but there are many in the neighborhood of the general meeting places. Ample accommodations will, therefore, be provided in a sufficient variety to suit all.

CHARLES HARRINGTON, Chairman.
DAVID D. SCANNELL, Secretary, 8, the Fenway.
Committee on Hotels and Transportation.

MEETING PLACES.

Ample and Comfortable Quarters Provided for the Various Meetings and Exhibits.

As will be seen by a glance at the following list, the accommodations selected for the meetings of the different sections, for the general sessions of the Association, and for the exhibits, will be unusually comfortable and convenient of access from the railroad stations and the hotels and headquarters of the different sections.

Mechanics Hall, which will be the central meeting place, and which will contain the Bureau of Information and Registration, Postoffice, Telegraph Office, Railroad and Theater Ticket Offices, the Commercial Exhibit, and a special rest room for ladies, is situated on Huntington Avenue, close to the railroad stations and the principal hotels. Here, also, the opening session will be held on Tuesday morning and a reception and promenade concert on Wednesday evening. From this point the other meeting places are all readily accessible; distributed as they are along Huntington Avenue from its junction with Boylston Street at Copley Square to Longwood Avenue, where the new buildings of the Harvard Medical School will provide accommodations for the Scientific Exhibit and for a number of the section meetings. An extra service of

electric cars, both ways, on Huntington Avenue, will be provided for the accommodation of the members of the association.

The large sections on medicine and surgery will hold their meetings in the halls in the vicinity of Copley Square. The section on Obstetrics and Diseases of Women will meet at Chickering Hall, near Massachusetts Avenue, and the other sections in the lecture rooms of the Tufts College Medical School, a short distance further on, or in the new Harvard Medical School. A special restaurant will be opened at Symphony Hall, Huntington Avenue and Massachusetts Avenue, where members may obtain their lunch without returning to their hotels. Jordan Hall, near Massachusetts Avenue, will be used for the evening sessions on Tuesday and Wednesday, and for the first meeting of the section on Surgery and Anatomy on Tuesday afternoon.

Special luncheon restaurant for the A. M. A. ..... Symphony Hall, Huntington and Mass. ave.

SECTIONS.

Practice of Medicine, Y. M. C. A. Hall, Boylston and Berkeley sts. Wednesday a. m. (Joint Session with Surgery), New Old South Church, Boylston and Dartmouth sts.

Obstetrics and Diseases of Women, Chickering Hall, Huntington ave., near Massachusetts ave.

Surgery and Anatomy, Tuesday p. m., Jordan Hall, Huntington ave., near Massachusetts ave.
Wednesday a. m. (Joint Session with Medicine), New Old South Church, Boylston and Dartmouth sts.
Wednesday, Thursday and Friday p. m., Huntington Hall, Walker Bldg., Boylston st.

Hygiene and Sanitary Science ... Tufts College Med. School, Huntington ave.

Ophthalmology ..... New Harvard Med. School, Longwood ave.

Diseases of Children ..... New Harvard Med. School, Longwood ave.

The State House of Massachusetts, on Beacon Hill, overlooking Boston Common.

MEETING PLACES.

	Halls.	Location.
Opening Session	Mechanics' Hall,	Huntington avenue.
Registration and Bureau of Information		
PostOffice, Telegraph and Telephone		
Railroad and Theater Ticket Offices		
Commercial Exhibit		
Clinical Exhibit		
Public Health Exhibit		
Ladies' Rest Room		
President's Reception		
House of Delegates	Boston Medical Library, Fenway.	
General Sessions	Jordan Hall, Huntington ave.	
Army Hospital Exhibit	Huntington ave.	
Scientific Exhibit	New Harvard Med. School, Longwood ave.	
Afternoon Teas	New Harvard Med. School, Longwood ave.	

Stomatology ..... Tufts College Med. School, Huntington ave.

Nervous and Mental Diseases .... New Harvard Med. School, Longwood ave.

Cutaneous Medicine and Surgery. New Harvard Med. School, Longwood ave.

Laryngology and Otology ..... New Harvard Med. School, Longwood ave.

Pharmacology and Therapeutics .. Tufts College Med. School, Huntington ave.

Pathology and Physiology ..... New Harvard Med. School, Longwood ave.

The Boston Medical Library Building on the Fenway, will be set apart for the House of Delegates, and may most conveniently be reached by electric cars to the corner of Massachusetts Avenue and Boylston Street.

The convenience and comfort of the members of the different sections at their several meeting places will be looked after by special reception committees of Boston members of the Asso-

ciation, who will be on hand during the meetings to provide for any unexpected need that may arise.

Special American Medical Association Restaurants.

NEW MEDICAL SCHOOL RESTAURANT.

Arrangements will be made to install a caterer at the new Harvard Medical School buildings, in order that the members who are in attendance at section meetings in these buildings may obtain their luncheon there if they so desire. A table d'hote lunch, costing about 60 cents, will be served on Tuesday, Wednesday and Thursday from 12 to 2 p. m.

SYMPHONY HALL RESTAURANT.

On Tuesday, Wednesday, Thursday and Friday, Symphony Hall, at the corner of Massachusetts and Huntington avenues, will be open to the members and guests of the Association from 12 to 2 o'clock. Light refreshments, beer and light wines will be obtainable and smoking will be permitted.

ENTERTAINMENTS.

Receptions, Concerts, Entertainments, Excursions and Afternoon Teas for the Pleasure of Visitors.

It is the purpose of the Boston Committee to facilitate the entertainment of the members of the Association and their friends in every way during and after the time of the session. Entertainments will be arranged for members in the afternoon and evenings, and for ladies during the entire time of the session.

The afternoon teas at the Harvard Medical School will be held on Tuesday, Wednesday and Thursday afternoons, from 4 to 6 o'clock. On Tuesday evening, after the evening session in Jordan Hall, a reception will be given to the members of the Association by the trustees of the Boston Museum of Fine Arts in the Museum in Copley Square. The trustees of the Boston Public Library have also invited the members of the Association to a reception in the Library Building to meet the Mayor of Boston on Tuesday evening at 9 o'clock.

On Wednesday evening, at the close of the General session in Jordan, Hall, a reception and promenade concert will be given in Mechanics Hall by the medical profession of New England, to the President, members and guests of the American Medical Association from 9 to 12 o'clock. A light supper will be served and there will be dancing. The Commercial Exhibit will be open during the evening on this occasion.

Professor Rosthorn.

Thursday evening arrangements have been made to reserve the theaters of Boston for the members of the American Medical Association, and special performances will be given in a number of them. The "Pop Concert" at Symphony Hall will also be reserved for the members of the Association on Thursday evening, and an orchestra, composed of members of the Boston Symphony Orchestra, will play popular music. Smoking will be permitted and light refreshments may be obtained.

Boston Public Library.

The trustees of the Boston Public Library extend a cordial invitation to the members of the Association to visit the library at any time between 9 a. m. and 5 p. m. during the meeting. A special collection of pictures of medical subjects and portraits will be on exhibition, and arrangements will be made to send personally conducted parties of visitors over the library at hourly intervals throughout the day.

A reception to the members of the Association will also be given by the trustees on Tuesday evening from 9 to 11 o'clock to meet his Honor, the mayor of Boston.

Seeing Boston.

Walking parties, with competent guides, will be made up every day, at frequent intervals, to conduct visitors through the historical portions of Boston, visiting the old State House, the old Granary Burying Ground, King's Chapel, the old South Church, Faneuil Hall, Paul Revere's house, the old North Church, and other points of interest.

Special "Seeing Boston" cars will leave Park Square at frequent intervals, enabling visitors to obtain a comprehensive view of Boston and its suburbs, visiting the oldest parts of the city, Charlestown, Somerville, Cambridge, Back Bay and Brookline.

Automobile and coaching trips through the Metropolitan Park System may be arranged at the Bureau of Information.

Steamboat Excursions.

Harbor excursions by steamboat may be made to the different places of interest in Boston Harbor and Massachusetts Bay. Bass Point and Nahant, Nantasket Beach, Plymouth, Provincetown and Gloucester offer attractive expeditions.

The steamer *Monitor* will visit the various harbor institutions daily and will carry free the members of the Association to the limit of the capacity of the boat.

The battleships of the United States Navy, stationed at the Charlestown Navy Yard, and the ocean steamers of the Cunard line, in East Boston, will be open for inspection by the members of the Association. Bunker Hill Monument, the receiving ship *Wabash*, the new granite dry dock, the naval museum and the frigate *Constitution* offer other attractions in a visit to Charlestown.

Trolley and Rail Excursions.

Norumbega Park at Riverside, on the Charles river, is reached by electric cars in three-quarters of an hour, and is a popular resort for canoeing, boating, and such amusements.

Sea bathing, "Rhode Island clambakes" and fish dinners are provided at Revere Beach, a part of the Metropolitan Park Reservation, which can easily be reached within an hour's time by rail or trolley. "Wonderland," a great amusement enterprise, which rivals Luna Park at Coney Island, will be open at the time of the session.

Excursions to Plymouth, under the supervision of Dr. Myles Standish, will be arranged for each day of the session, and will prove especially attractive to those who are interested in the history of the early settlement of New England and the landing of the Pilgrims.

Lexington and Concord will be reached by special trolley trips, and Newburyport, Salem and Marblehead by rail.

Visits to New England Colleges.

Special arrangements will be made for visits to the New England colleges. At Harvard College, in Cambridge, guides will be provided by the college authorities, and afternoon tea will be served in Phillips Brooks' house, or the Harvard Union, on one of the days of the meeting.

Radcliffe, Tufts and Wellesley Colleges are within easy reach. Yale, Brown, Dartmouth, Williams, Amherst, Clark and Smith Colleges can be visited in a day, and the University of Vermont, Bowdoin, Colby, and the University of Maine in a slightly longer time.

Clambake and Fish Dinner.

A Rhode Island clambake and fish dinner has been planned for the members of the Association in Crescent Park, Providence, R. I., on Saturday, June 9, the members leaving the south terminal station in the morning by a special train and returning in the afternoon.

Excursions to Other New England Resorts.

At the close of the session excursions to Nantucket Island, Newport, R. I., Isles of Shoals, Mt. Desert, the White Mountains, Plymouth and Gloucester, will be provided, and facilities will be given for the arrangement of trips to the other summer resorts of the New England Coast.

American Medical Association Outing Club.

Among the many pleasant trips out of Boston a nine days' tour in New Brunswick, Nova Scotia, Maine and New Hampshire should be among the most enjoyable. The party will visit for a day or two such resorts as St. John, New Brunswick, Digby, Nova Scotia, Bar Harbor, Maine, and Portsmouth, N. H., and touch for a short time the ports of Portland, Eastport and Lubec. Returning by rail the fine coast scenery north of Boston is seen at its best. The deep-sea fishing trip in Nova Scotia will afford unique sport for those members who reside inland.

Send stamp to Dr. Edward R. Campbell, Bellows Falls, Vt., for booklet describing trip.

Banquets.

The Section on Nervous and Mental Diseases has arranged for its annual banquet. "Smokers" have been arranged for the sections on Ophthalmology and on Laryngology and Otology.

Other special section celebrations are to be arranged.

EXHIBITS.

An Unusually Complete Group of Pathologic, Clinical and Hygienic Expositions.

Commercial Exhibit.

The Commercial Exhibit in Mechanics Hall will be of great interest. The exhibits displayed will be of the highest character, and will include only such as conform to the standards of the American Medical Association. Books, apparatus, instruments and therapeutic agents which will be of interest and value to the profession will be shown. A special exhibit, which it is thought will appeal to many members of the profession, will include motor cars and carriages adapted to physicians' use.

Professor Max Joseph.

Scientific Exhibit.

The Scientific Exhibit, the program of which will be found elsewhere, will be housed in the spacious galleries of the Warren Anatomical Museum, and in the adjacent laboratories at the new Harvard Medical School.

Historical Loan Exhibition of Medical and Surgical Instruments.

As a portion of the Scientific Exhibit, a loan exhibit of medical and surgical instruments of historical interest will be collected for the Boston session. Dr. J. Collins Warren is chairman and Dr. Townsend W. Thorndike is secretary of the committee having this matter in charge.

It is felt that there are many instruments and collections of instruments now obsolete which would have great interest for the medical profession if gathered together and arranged in such a way as to show the evolution of the different instruments to-day in use. It is hoped that the instruments gathered for this meeting may serve as a nucleus for a permanent collection.

With the foregoing object in view, the committee extends to the readers of this article a cordial invitation to co-operate with them, either by advice as to where exhibits may be secured or by loaning those that they may have in their possession.

It is requested of those who send their collections to the exhibition for the session of the American Medical Association that they specify whether they desire to have their collections returned to them at the end of the meeting, or whether they will permit the committee to place them in a permanent collection.

All communications should be addressed to the secretary, Dr. Townsend W. Thorndike, 22 Newbury Street, Boston.

Clinical Exhibit.

A special feature of the Boston session will be the so-called Clinical Exhibit. It is proposed to establish in Mechanics Hall a series of demonstrations of the most recent methods of precision in clinical diagnosis, which may here be studied in active operation. Examinations of the blood, urine, sputum and other fluids, methods of diagnosis, bacteriologic and chemical, the use of the sphygmomanometer, the *x*-ray, cystoscopy and many other methods of diagnosis will be shown. At the hospitals, also, special programs of demonstrations and of operations will be provided during the time of the session for the benefit of the members of the Association.

Public-Health Exhibit.

The Public-Health Exhibit will be one of the utmost interest to the general public, as well as to students of hygiene and sanitary science. At Mechanics Hall a special collection of maps, plans, apparatus and other features of importance in sanitary science will be displayed, and this will be further supplemented by the exhibit of the Massachusetts State Board of Health installed in the Museum of Hygiene at the new Harvard Medical School.

Army Hospital Exhibit.

One of the most interesting and instructive features will be a completely equipped field hospital, which will be sent from Washington especially for the session of the Association by courtesy of the Surgeon-General.

The hospital will be equipped with all of the latest appliances known to medical and surgical science, and will be installed and administered by Company A of the Hospital Corps of the United States Army, under the command of Captain H. L. Gilchrist, assistant surgeon, assisted by First Lieutenant William T. Davis, assistant surgeon. This field hospital will be placed on Huntington Avenue, where it can be conveniently visited by members passing to and from their section meetings. It will cover about five acres of ground and will include among its fifty tents six wards, with a total of 108 beds of the latest design, with mosquito-bar attachment; dispensary and operating rooms; kitchen, mess-tents and administrative offices.

Demonstrations will be given of ambulance and first-aid drills, field exercises, and all of the details of the operation of an army hospital in time of war.

A conspicuous feature of this exhibit will be the compactness and portability of the hospital equipment, and the ease and rapidity with which it can be moved from place to place, or expanded to meet the requirements of an emergency.

COMMITTEE OF ARRANGEMENTS.

General Committee.

Dr. Herbert L. Burrell, Chairman, 22 Newbury Street, Boston.
Dr. Robert B. Greenough, Secretary, 8 The Fenway, Boston.

Dr. George B. Shattuck, Dr. David D. Scannell,
Dr. Frank B. Harrington, Dr. J. Collins Warren,
Dr. Reginald H. Fitz, Dr. John C. Munro,
Dr. Elliott P. Joslin, Dr. Charles S. Minot.
Dr. Charles Harrington, Dr. Wm. T. Porter.

Subcommittees.

COMMITTEE ON FINANCE.

Dr. George B. Shattuck, Chairman; Dr. Frank B. Harrington, Secretary; Dr. James B. Ayer, Treasurer.

COMMITTEE ON SECTION MEETING PLACES, GENERAL EXHIBIT, PRINTING AND PROGRAMS.

Dr. Reginald H. Fitz, Chairman; Dr. Elliott P. Joslin, Secretary.

Subcommittee on Section Meeting Places.—Dr. Horace D. Arnold, Chairman; Dr. Ralph C. Larrabee, Secretary.

Subcommittee on Scientific Exhibit.—Dr. W. T. Councilman, Chairman; Dr. Frank B. Mallory, Secretary.

Subcommittee on Historical Loan Exhibition of Medical and Surgical Instruments.—Dr. J. Collins Warren, Chairman; Dr. Townsend W. Thorndike, Secretary.

Subcommittee on Clinical Exhibit.—Dr. Richard C. Cabot, Chairman; Dr. Edwin A. Locke, Secretary.

Subcommittee on Public Health Exhibit.—Dr. Charles Harrington, Chairman; Dr. George B. Magrath, Secretary.

Subcommittee on Commercial Exhibit.—Dr. Joshua C. Hubbard, Chairman; Dr. R. L. DeNormandie, Secretary.

Subcommittee on Printing, Programs and Guide Book.—Dr. Robert B. Osgood, Chairman; Dr. F. C. Kidner, Secretary.

COMMITTEE ON HOTELS AND TRANSPORTATION.

Dr. Charles Harrington, Chairman; Dr. David D. Scannell, Secretary.

COMMITTEE ON ENTERTAINMENTS, BANQUETS, LADIES.

Dr. J. Collins Warren, Chairman, Dr. J. C. Munro, Secretary.

Subcommittee on President's Reception and Promenade Concert.—Dr. Francis S. Watson, Chairman; Dr. Richard F. O'Neil, Secretary.

Subcommittee on Afternoon Teas.—Mr. J. Grafton Minot, Chairman; Dr. Farrar Cobb, Secretary.

Subcommittee on "Pop Concert" and Symphony Hall Restaurant.—Dr. Samuel J. Mixter, Chairman; Dr. Lincoln Davis, Secretary.

Subcommittee on Banquets.—Dr. John G. Blake, Chairman; Dr. John T. Bottomley, Secretary.

Subcommittee on Theaters.—Dr. Morton Prince, Chairman; Dr. Percy Musgrave, Secretary.

Subcommittee on Excursions.—Dr. Harold Williams, Chairman; Dr. G. W. W. Brewster, Secretary.

Subcommittee on Public Library Reception.—Dr. Thomas Dwight, Chairman; Dr. Samuel Robinson, Secretary.

Subcommittee on New Medical School Restaurant.—Dr. Farrar Cobb, Chairman.

LADIES' COMMITTEE.

Mrs. Roger Wolcott, Chairman; Mrs. John C. Munro, Secretary.

COMMITTEE ON REGISTRATION, BADGES, BUREAU OF INFORMATION.

Dr. Charles S. Minot, Chairman; Dr. Wm. T. Porter, Secretary.

Professor Trendelenburg.

REGISTRATION.

Suggestions and Rules for the Guidance of All Who Will Attend the Session.

The registration department will be near the main entrance to the Exhibition Hall, at Mechanics Building on Huntington Avenue.

For admission to the different section meetings, exhibits and entertainments, it will be necessary for every member of the Association to register his name, and those of his guests, and to obtain the official badges provided by the Committee of Arrangements. *No one will be admitted to any meeting or entertainment without a badge!*

The registration department will be open from 8:30 a. m. to 5 p. m. on Monday, Tuesday, Wednesday and Thursday, June 4, 5, 6 and 7, and on Friday, June 8, from 9 to 10 a.m.

Members are requested to observe the following directions:

1. Each physician desiring to register will fill out a registration card.

2. Each member who has paid his annual dues in full will present his pocket card and this registration card at a window marked "Registration by Receipt."

3. The registration of members who have paid their dues, but who have lost their receipts, will require a moment or two extra time, while the records are consulted.

4. Members who have not yet paid their dues will present registration card and make payment at a window marked "Cash."

5. Each applicant for membership will present his registration card at a window marked "New Members Make Application Here," with a certificate that he is a member in good standing in his state society. [Every such prospective member, however, will save himself delay and annoyance by sending in his application before the session. All such letters should be *mailed not later than May 25* to the American Medical Association, 103 Dearborn Avenue, Chicago, as the records have to be packed and shipped to Boston early.]

6. Each member on registration will receive a badge, a copy of the Official Program, a Guide Book, and such other announcements as may be necessary.

7. The guests of members, either ladies or gentlemen, must be registered by name. A special registration card will be provided, to be filled out for each guest. These cards will be presented at a window marked "Guests," but only after the member has completed his own registration. A guest badge will be issued for each guest registered.

8. Members of the Massachusetts Medical Society, who are not yet members of the American Medical Association, will register their names at a special booth marked "Massachusetts Medical Society," in the entrance to the Exhibition Hall, where they will receive a special badge, admitting them to all meetings of the Association. Members of the Massachusetts Medical Society who are not members of the American Medical Association and who desire to become members may fill out registration cards and present themselves at the window marked, "New Members Make Application Here," referred to above. Certificates of membership in the Massachusetts Medical Society will be provided at this window for all members in good standing, and payment of the annual dues to the American Medical Association alone will be required. All members of the Massachusetts Medical Society are urged to avail themselves of this opportunity.

BUREAU OF INFORMATION.

A Bureau of Information will be maintained at the General Meeting Place in Mechanics Hall, where information with regard to hotels, transportation, registration, meeting places, exhibits, entertainments, theaters, etc., may be obtained. In connection with this bureau, the postoffice of the American Medical Association, telegraph and telephone offices, an office for the sale of railroad tickets for excursions from Boston, and an office for the sale of theater and concert tickets will be maintained. An emergency station, for the care of any members of the Association in need of medical attendance will also be placed in close proximity to the Bureau of Information. A large space will be set apart in the vicinity of the registration booths, where desks and tables will be found, and all the conveniences for a writing room.

POSTOFFICE AND TELEGRAPH.

Mail matter and telegrams addressed in care of the American Medical Association, Boston, will be sent direct to the postoffice in Mechanics Hall. Telegrams and special delivery letters will be forwarded from there to the hotels or other stopping-places of those whose addresses are recorded at the Registration Department or the Bureau of Information.

THE FOREIGN GUESTS.

Many Distinguished Medical Men Will Come from Abroad to Speak at Section Meetings.

The American Medical Association is to be honored by the presence of a number of distinguished guests at the Boston session. Many have already accepted invitations, and of some of these we present brief sketches below. Following is a list of the guests as far as now known:

Geh. Hofrat Prof. Dr. von Rosthorn, Heidelberg, Germany, will be the guest of the Section on Obstetrics and Diseases of Women. A photograph of him is given herewith.

Professor Dr. Dührssen, Berlin, Germany, will be a guest of this Section and will also address the Section on Hygiene and Sanitary Science.

Dr. Wesley A. Mills, McGill University, Montreal, Canada, will speak before the Section on Pathology and Physiology.

Dr. Max von Frey, Physiologisches Institut, Würzburg, Germany, will also be a guest of this Section.

Professor Max Joseph, Berlin, Germany, will speak before the sections on Cutaneous Medicine and Surgery and on Hygiene and Sanitary Science. A sketch of him appeared in THE JOURNAL, April 14, page 1125.

Herr Geheimrat Prof. F. Trendelenburg of Leipzig, Germany, will be the guest of the Section on Surgery and Anatomy.

Dr. Simon W. Tunstal, Vancouver, British Columbia.

Dr. Murray MacLaren, St. Johns, New Brunswick.

Dr. James Bell, Montreal, Canada.

Dr. George A. Peters, Toronto, Canada.

Dr. Alexander Primrose, Toronto, Canada.

Dr. George A. Armstrong, Montreal, Canada.

Dr. Francis J. Shepherd, Montreal, Canada.

Dr. Richard A. Reeve, Toronto, Canada, president British Medical Association.

MAX VON FREY.

Professor Max von Frey of Würzburg, Germany, born in Salzberg, Austria, in 1852, is a German of the Germans, of noble birth and courtly bearing. He was educated in the gymnasium of his native city, and carried on his medical studies in Freiburg, Leipzig and Vienna; he supplemented his medical studies with courses in mathematics and mechanics in the Polytechnic School of Munich.

He accepted the call of Leipzig University, where he became the assistant of Karl Ludwig, the physiologist, first as privat docent and then as adjunct professor. In that capacity he directed all of the laboratory work in physiology besides conducting extensive researches.

He was later called to the University of Zurich, in Switzerland, as professor of physiology and was associated with Justus Gaule.

On the death of Adolph Fick, head professor of physiology in the University of Würzburg, the question as to who should be invited to fill his place was no easy one. When they finally chose Max von Frey, the pupil and associate of the great master, Karl Ludwig, the news was received by physiologists the world over with hearty approbation. For the most part his researches and his publications have been on the problems of the circulatory system and the pulse, physiology of the muscular system and the special senses.

ALFRED DÜHRSSEN.

Professor Alfred Dührssen may be regarded as one of the best known modern German gynecologists. Physicians of the whole world are more familiar with his name than that of the older German gynecologists, who together with those of other countries have done the real work in building up this branch of medicine as a special science. There are two achievements which tend particularly to make his name so well known. First, the recommendation of the vaginal route for gynecologic operations, and second, the application of methods of rapid evacuation of the uterus in obstetrics.

It is somewhat difficult to give a sketch of the life of a man who is still in the prime of his years and from whom we may still expect new and progressive ideas. Still Dührssen can reflect with satisfaction on the past in regard to some of the operations devised by him. The rapid evacuation of the uterus in eclampsia, recommended by him among one of the first which lately is frequently put to Bumm's credit, has today invaded the clinics of even the most conservative obstetricians. On the other hand, it would seem wrong to judge the life work of a physician and teacher only by his improvements of operative technic. Dührssen's merit in medical science may be found to a great part in conservative obstetrics.

While teaching obstetrics for many years as first assistant to Gusserow he did his share to transform the municipal hospital, the Charité, into a modern clinic. Grown up in the antiseptic era, he was fortunate to take active part in the great work which the Berlin school of obstetrics aimed at and accomplished so thoroughly, namely, the formulation of exact indications, valid rules for the various obstetric operations, by which the practitioner should be guided. Highly esteemed by his hearers, he has by lecturing for many years to students and physicians, sown seed that has borne manifold fruits. His "Vade Mecum" is a brief but complete exposition of the teachings of the Berlin school of great value to the practitioner in obstetric emergencies.

Out of the great number of literary contributions published by Dührssen only a few can be mentioned here. Together with his teacher, Gusserow, he investigated the nature of the liquor amnii. Recognition of the absolute helplessness of the obstetrician in case of an insufficiently dilated os inspired in him the idea of deep cervical incisions. Confidence in antisepsis and his great gynecologic experience led him to evolve vaginal Cesarean section from the method of cervical incisions. Dührssen's method of iodoform gauze tamponade for combating postpartum hemorrhages has found many admirers.

Graduated in the year 1885 and soon after admitted to the teaching faculty as "privat docent," he received comparatively young the title of professor. The severe criticism to which he was subjected by the influential part of the profession, on account of his retroflexion operations, led him to establish his own policlinic and clinic in Berlin. There he commands a large patronage, which he places in a most liberal manner at the disposal of everyone, also of foreign physicians.

Dührssen has almost as many friends in America as in Germany, and all who have seen him operate or have listened to his lectures, will gladly renew this acquaintance.

Medical science should be international, and visits of eminent medical men from abroad will only further the mutual respect and inspire new ideas. America is the home of operative gynecology and welcomes Professor Dührssen most heartily as one of the foremost German exponents of operative gynecology.

ALFONS EDLER VON ROSTHORN.

Prof. Alfons von Rosthorn of Heidelberg is about 48 years old and is one of the best known and appreciated German gynecologists.

He was born in Vienna, Austria, and there received his

general and medical education. He first contemplated an academic career in the study of natural history, and was for over a year assistant to the well-known zoologist, Professor Klaus. He then took up medicine and served some time as assistant to Professor Langer in anatomy. Later he became *Operationszoegling* in the surgical clinic under Billroth for two years, and then went to Gratz as assistant in surgery to Woeltler. Next he returned to Vienna as assistant to Breisky, and then to Chrobak in obstetrics and gynecology, whence he was called to Prague in 1891 as successor to Schauta. He remained in Prague eight years, during which time a new clinic was built. During this period a considerable number of American physicians visited Prague and became acquainted with him. In 1899 he was transferred to Gratz at his own request, where he remained three years, when he accepted a very flattering call to Heidelberg and the honorary and prized title from the German government of "Geheimrath."

In addition to numerous contributions to the literature of his specialty in the special and general medical journals, Professor Rosthorn has written several books. In co-operation with Professor Chrobak, he has written the book on gynecology in Nothnagel's "System of Medicine." In Veit's "Handbook of Gynecology" and in von Winckel's "Handbook of Obstetrics" he has written important chapters. He has been associated with A. Martin in the publication of the *Monatsschrift fuer Geburtshilfe und Gynaekologie* for the last four years. He has devoted especial attention to normal and pathologic anatomy and is considered the first authority on the structure and diseases of the pelvic connective tissue.

Professor Rosthorn's long training in anatomy has helped to make him a good operator. He has adopted the radical operation for cancer of the uterus, and his large experience, controlled by an unusually careful judgment, make his opinion on this subject of much interest.

As a teacher, Rosthorn has won a reputation approaching that of his own early teacher, Billroth. While very strict and exacting, he inspires an enthusiastic attachment that has created for him a loyal band of disciples. He speaks English perfectly, with a slight English accent, having studied and lived some time in England when a student.

As a scientist and scholar, as an operator and teacher, as a man in close touch with the present achievements and tendencies in German medicine, Professor Rosthorn represents perfectly the best in his specialty in his present home, Germany, and in his native home, Germany-Austria.

MAX JOSEPH.

Max Joseph of Berlin was born Jan. 2, 1860, in Gerdauen, East Prussia. He studied at Königsberg, and there he won a faculty prize for his essay, "Zeitmessende Versuche ueber Athmungsreflexe." He graduated in 1883 and attained his specialistic training with Kaposi at Vienna. Later he became assistant to Westphal and Köbner in Berlin, and became intimately associated with the Berlin Physiological Institute, where he worked for three years under Gad and Fritsch. In 1888 we find him attached to the zoological station at Naples under Dohrn.

Since 1889 he established himself in Berlin as a specialist for skin diseases and soon won enviable reputation in his specialty, both as a teacher and writer. He conducts one of the most popular private clinics and histologic laboratory for skin diseases. The number of patients reaches from 75 to 100 on week days and comes up to the high-water mark of 150 to 200 on Sundays, when the laboring class attends in large numbers. This enormous material, which can compare only with some of the most popular clinics of the Hospital St. Louis in Paris, is amply and systematically utilized by Joseph by individual teaching, which he understands in a masterly way. There are always plenty of Americans attending these, who carry away with them the conviction that they had profited by their attendance at this unique clinic.

In 1898 he was sent to Norway at the expense of the Bose foundation for the study of leprosy, as a result of which he published his essay "On Visceral Lepra."

Joseph is a man of imposing physique, of pleasant address and winning attitude. As to his characteristics, he is modest and unassuming to a fault; sympathetic to his patients, true to his friends, and chiefly, wedded to his specialty. His many friends and admirers tender him herewith a hearty and well-deserved welcome to America.

WESLEY MILLS.

Prof. Wesley Mills of McGill University, Montreal, was born in Ontario, Canada, and received his preparatory education in the schools of that province. In the University of Toronto he took an extensive collegiate course, receiving from that institution the degrees of bachelor of arts and master of arts. He studied medicine at McGill University, from which institution he received the combined degree of doctor of medicine and master of surgery. He also received from the same institution the degree of doctor of veterinary surgery, and from London the degree of L.R.C.P. He is a fellow of the Royal Society (Canadian Branch), and is also a member of many learned societies in Canada.

Dr. Mills has been engaged extensively in medical research in McGill University, and was made professor in that institution in 1886, retiring from general practice at the time he entered on his professorship. Dr. Mills has made extensive contributions to medical literature. The majority of his writings deal with comparative anatomy, physiology and psychology. He has also contributed to the literature on the blood and blood-forming organs.

FRIEDRICH TRENDELENBURG.

Prof. Friedrich Trendelenburg is chief of the surgical clinic at the University of Leipsic, Germany. All who have had the pleasure of making his acquaintance in former years will be delighted to welcome him to our shores; those who will meet him for the first time will be glad to shake hands with the man who devised the world-famous "Trendelenburg posture."

Friedrich Trendelenburg was born in Berlin May 24, 1844. He is the son of Friedrich Adolf Trendelenburg, professor of philosophy at Berlin, who did so much for the advancement of German universities, and was one of the most esteemed scientists of his time. Professor Trendelenburg studied medicine in Edinburgh, Glasgow and Berlin, under Allen Thomson, Bernhard von Langenbeck and others. After taking his diploma as M.D. (1866), with a dissertation, "The Surgery of the Ancient Hindoos," he again visited Glasgow to see Lister. From 1868 to 1874 he was assistant to the surgical clinic at Berlin under von Langenbeck, the renowned surgeon, whose assistants were always in eager demand as professors of surgery at the various universities and clinics of Germany. During this period Trendelenburg devoted much time to experimental surgical research work on a basis of general pathology. Thus he demonstrated the possibility of infecting animals with diphtheria by means of transplanting diphtheritic membranes from the human fauces.

In 1874 he was made chief of the surgical division of the "Krankenhaus am Friedrichshain" in Berlin. In the following year he accepted a call to the University of Rostock to fill the chair of professor of surgery. Seven years later he was called to the University of Bonn, to succeed the famous Wilhelm Busch, also a pupil of von Langenbeck, and since 1895 he has occupied the chair of surgery at the University of Leipsic, succeeding Karl Thiersch, who had then just died, after twenty-eight years of splendid work.

Trendelenburg has contributed largely to surgical literature. Among his more elaborate works may be mentioned: "Diseases of the Neck and Their Operative Treatment," and "Injuries and Surgical Diseases of the Face." His essays, and those published from his clinic by his assistants, are legion. In his "Contribution to the Operations on the Air Passages," he describes his well-known tracheal tampon-canula.

In 1881 he published, through his first assistant, an article fully describing and illustrating the "Trendelenburg posture," (Beckenhochlagerung), which has so greatly facilitated operative work within the small pelvis. The posture was carried out for the first time after its conception at the surgical clinic in Bonn, 1883-84. Since then many operating tables, portable and otherwise, have been constructed here and abroad, provid-

ing for this posture. Trendelenburg himself designed one which was shown at the exhibition connected with the International Medical Congress at Berlin in 1890.

Now Trendelenburg comes to the United States "to learn," as he recently wrote to one of his friends here. He may be sure of a hearty welcome by the medical profession of America.

SPECIAL TRAINS.

Some of the Trains and Routes to Boston and Their Advantages.

NEW YORK CENTRAL SPECIAL.—The New York Central Lines will run a special train through to Boston without change by way of the Lake Shore and Michigan Southern, the New York Central and the Boston and Albany railroads. This train is to be made up with a specially fine equipment similar to that used on the Twentieth Century and the Lake Shore Limited, consisting of observation compartment cars, standard sleeping cars, dining and library cars. The train is to leave Chicago at 10:30 a. m., Sunday, June 3, and to arrive in Boston at 2 p. m., Monday, June 4. There will be allowed stop-overs at Niagara Falls, Put-in-Bay and Chautauqua, N. Y. Additional information may be secured from Mr. L. F. Vosburgh, General Western Passenger Agent, Room 529, La Salle Street Station, Chicago.

CANADIAN PACIFIC.—A combination route over the Wabash to Detroit, thence over the Canadian Pacific, offers an attractive route to Boston, with the advantages of the scenery of the Thousand Islands, Rapids of the St. Lawrence, Toronto, Ottawa, Montreal, Quebec, and the White and Green mountains. A trip through Lake Ontario, the Thousand Islands and the Rapids can be made at a nominal addition to the rail rate as referred to on page 1368. Further particulars may be had from Mr. A. C. Shaw, General Agent of the Canadian Pacific Railway, Chicago.

WABASH SPECIAL.—The Wabash Railroad will run a special train of fine Pullman coaches and dining car through to Boston without change. This will leave Chicago, Sunday, June 3, at 10:30 p. m. and reach Boston Tuesday, June 5, at 7 a. m., having stopped at Niagara Falls for two or three hours. The feature of this train is the fact that although two nights are spent on the road, no extra charge is made for sleeping car, and the arrival in Boston early Tuesday morning will effect a saving of one night's lodging at Boston over other arrangements which anticipate arrival in Boston on Monday. In addition, this service will allow all of Sunday to be spent in Chicago. A special representative of the railroad will accompany the train. Reservations and further particulars may be secured through Mr. F. H. Tristram, Assistant General Passenger Agent, 97 Adams Street, Chicago.

PENNSYLVANIA LINE VIA WASHINGTON.—The Pennsylvania Railroad expects the patronage of many because of the fact that it offers by the Baltimore and Ohio Railroad the opportunity of stop-over at Washington en route to Boston. Further information may be secured from Mr. C. L. Kimball, Assistant General Passenger Agent of the Pennsylvania Railroad, 2 Sherman Street, Chicago.

MISSOURI VALLEY SPECIAL.—A special train will run over the Chicago and Alton, the Grand Trunk and the Boston and Maine Railroad, certain cars of which will leave Kansas City, St. Joe and Omaha May 31. The forenoon of the next day will be spent in Chicago and the departure over the Grand Trunk will be at 3 p. m. on a special train, arriving in Boston, June 4, morning. This trip includes a stop at Niagara Falls, a boat trip down the St. Lawrence River, through the Thousand Islands, and runs through the famous Green Mountain scenery. An optional return trip may be arranged through New York City via Fall River steamboat. Particulars of this train may be obtained from Dr. Charles Wood Fassett, St. Joseph, Mo.

Return Limit Time Extended.

Later announcement is made of arrangements by which an extension of the final limit may be secured so as not to leave Boston till July 15. To secure this it is only necessary for the purchaser of the ticket to deposit it in person with the validating agent at Boston not later than June 18, paying $1.

Stop-Over at New York on Return Trip.

The Trunk Line Association announces: "Stop-over at New York may be obtained on return trip on tickets reading via New York, provided ticket has been validated by validating agent at Boston and is deposited by original purchaser in person with joint agent at New York not later than one day after validation at Boston, and on payment of fee of $1.00 at time of deposit, but in no case shall the stop-over at New York extend beyond July 15. Joint agent at New York will attach stop-over certificate to ticket, which shall not be delivered to passenger earlier than two hours before departure of train on which return trip will begin (except that for trains leaving after 6 p. m. and before 9 a. m. ticket will be delivered to passenger before 6 p. m.). Ticket will not be good leaving New York later than the day following date of leaving Boston unless stop-over certificate is attached by joint agent at New York. Mr. W. F. Holwill is joint agent, 182 Fifth Avenue, New York City. Office hours, 8 a. m. to 6 p. m., week days and Sundays."

SECTION ON NERVOUS AND MENTAL DISEASES.

CHAIRMAN, WHARTON SINKLER, PHILADELPHIA; SECRETARY, T. H. WEISENBURG, PHILADELPHIA.

The following program was received too late to be inserted in its order on a previous page:

Chairman's Address. Wharton Sinkler, Philadelphia.

Manic-depression, Insanity and Visceral Disorder. Henry S. Upson, Cleveland, Ohio.

The Motor Degenerative Sequence in Dementia. H. A. Tomlinson, St. Peter, Minn.

Lucid Intervals in the Insane and Their Medicolegal Importance. D. J. McCarthy and W. W. Hawke, Philadelphia, Pa.

Affections of the Spinal Cord in Epileptics. W. N. Bullard, Boston.

The Pathology of Uremic Hemiplegia. J. H. W. Rhein, Philadelphia.

The Paranoid Group. F. X. Dercum, Philadelphia.

The Blood Pressure in Paresis. G. L. Walton, Boston.

The Anatomic and Physiologic Results of Experimental Nerve Suture. L. Pierce Clark, New York City.

Cases of Basilar Thrombosis. E. E. Southard and N. K. Wood, Boston.

Paralysis of the Pharynx, with Four Years of Feeding with the Tube. S. Weir Mitchell, Philadelphia.

Discussion to be opened by Joseph Collins, New York City.

Unilateral Ascending Paralysis, Its Clinical Varieties, and Their Pathological Causes. Charles K. Mills, Philadelphia.

A Contribution to the Symptomatology and Diagnosis of Spinal Cord Tumors. J. Ramsay Hunt, New York City.

Hydrocephalus as the Result of the Occlusion of the Aqueduct of Sylvius. William G. Spiller, Philadelphia.

Myasthenia Gravis. C. Eugene Riggs, St. Paul, Minn.

Migrainic Psychoses, apropos of Twelve Cases. Alfred Gordon, Philadelphia.

Multiple Neuritis Resembling Progressive Muscular Atrophy, with Report of Cases. Julius Grinker, Chicago.

Collective versus Individualized Treatment of Neuroses and Psychoses. Richard Dewey, Wauwatosa, Wis.

Tumor of the Right versus Tumor of the Left Frontal Lobe of the Brain. W. C. Krauss, Buffalo, N. Y.

Conjugate Deviation of the Eyes and Head and Disorders of the Associated Ocular Movements in Tumors and Other Lesions of the Cerebrum. T. H. Weisenburg, Philadelphia.

Discussion to be opened by William G. Spiller, Philadelphia.

Palliative Operations (Cerebral Decompression) in the Treatment of Tumors of the Brain. William G. Spiller and Charles H. Frazier, Philadelphia.

The Present Status of Brain Surgery. M. Allen Starr, New York City.

A Contribution to the Localization of the Motor Area Derived from a Study of Three Cases of Jacksonian Epilepsy. H. C. Gordinier, Troy, N. Y.

(Continued under The Boston Session on page 1388.)

SATURDAY, MAY 5, 1906.

PREVIOUS BOSTON SESSIONS—A RETROSPECT.

The coming session of the American Medical Association will be the third in the history of the Association held in Boston. Organized in 1847 in Philadelphia, following a preliminary convention in New York City the preceding year, the Association held its first regular session in Baltimore, May 2, 1848. The second annual session convened in Boston May 1, 1849, just fifty-seven years ago. The official minutes show that the Association met in the hall of the Lowell Institute at 11 o'clock on the morning of May 1, and was called to order by the President, Dr. Alexander H. Stevens, president of the Faculty and Emeritus Professor of Surgery of the College of Physicians and Surgeons of New York. Dr. John Collins Warren of Boston, who was elected on the following day as the third president of the American Medical Association, delivered the address of welcome on behalf of the Committee of Reception of the Massachusetts Medical Society.

It is interesting to look over the list of those present at this second session of the new Association. As would naturally be expected, most of the members came from the eastern states and especially from near the place of meeting. In accordance with the provisions of the constitution then in force, the Association was composed of delegates representing state and county societies, medical colleges and hospitals. Those in attendance numbered 658 and were distributed among the various states as follows: Maine, 3; New Hampshire, 53; Vermont, 75; Massachusetts, 160; Rhode Island, 14; Connecticut, 46; New York, 135; New Jersey, 12; Pennsylvania, 50; Delaware, 54; Maryland, 14; Virginia, 6; North Carolina, 1; South Carolina, 6; Georgia, 6; Alabama, 5; Louisiana, 3; Tennessee, 2; Ohio, 5; Indiana, 3; Illinois, 2; Missouri, 2; Iowa, 1. There were only 15 delegates present from west of the Allegheny Mountains, and only 3, those of Iowa and Missouri, from west of the Mississippi River.

Glancing over the list of the Massachusetts delegates, one notices the name of Oliver Wendell Holmes, who sat as a representative of the Medical Department of Harvard University and of the Tremont Street Medical School; of Dr. Samuel Cabot and Dr. Samuel Parkman, representing the Boston Society for Medical Improvement; and of Dr. Henry I. Bowditch, who, with Dr. Warren, represented the Massachusetts General Hospital. In the New York delegation sat Dr. N. S. Davis as a representative of the "New York Medical Association," and Dr. Austin Flint, representing the Buffalo Medical Association and the Buffalo Hospital; from Pennsylvania came Dr. George B. Wood and Dr. Alfred Stillé, representing the Philadelphia College of Physicians; Dr. Samuel Jackson, as a delegate from the University of Pennsylvania, and Dr. Charles D. Meigs, representing the Pennsylvania Hospital. In the Virginia delegation sat Dr. Hugh H. McGuire and Dr. G. Lane Corbin, as representatives of the Medical Convention of Virginia, and Dr. John P. Mettauer, representing the Randolph-Macon Medical College. South Carolina sent Dr. J. Moultrie and Dr. Thomas G. Prioleau. From Ohio came Dr. Reuben D. Mussey, later chosen President of the Association. Illinois had two delegates present, Dr. John F. Sanford, representing the Rock Island Medical School, and Dr. John Evans, representing Rush Medical College.

At this session the following officers were unanimously elected: President, Dr. John C. Warren, Massachusetts; vice-presidents, Drs. John P. Harrison, Hugh H. McGuire, Austin Flint and R. S. Steuart; secretaries, Drs. Alfred Stillé and Henry I. Bowditch.

It is interesting to note that problems confronting the Association at its second session were evidently very similar to those which confront it to-day, and that the changed conditions and the marvelous growth and development of the country in the fifty-seven years which have elapsed since the first Boston session do not seem to have affected in any way the duties or responsibilities of the Association either to its members or to the public. The report of the standing committee on medical education, presented on the afternoon of the last day of the session, was evidently considered and discussed at length. The committee, of which Dr. Stevens was chairman, reported in favor of increasing the requirements for medical students before admission to medical schools; also that the course be increased to six months and that state medical societies be asked to recognize only those physicians who had obtained a degree in medicine or a license from some regular medical body after due examination. Dr. U. Parsons, chairman of the committee appointed at the Baltimore session the previous year, made a report on the subject of adulterated and spurious drugs, and recommended the appointment of a committee, consisting of two delegates from each state, "to note all the facts that come to their knowledge with regard to the sophistication of drugs, medicines, chemicals, etc., and to report at the next annual session." Following the adoption of this report, Dr. J. B. Johnson introduced a resolution providing for the establishment of schools of pharmacy, in the preamble of which he said: "Numberless and important evils result . . . from the universal traffic in patent and secret remedies." Dr. Stevens submitted the following resolution: "*Resolved*, That the American Medical Association recommend medical men in the Association indi-

vidually, by public lecture and otherwise, to enlighten the public in regard to the duties and responsibilities of the medical profession and their just claims to the confidence of the public." The matter of preparing a list of physicians who were recognized as regularly graduated practitioners, as well as the establishment of a bureau on American medical biography, were discussed. It is only this year that these ideas are being put into effect.

The following is also interesting reading at the present time: "Dr. Thomas Wood presented the following resolution, which was adopted: '*Resolved*, That the Committee on Medical Science for 1849 be instructed to inquire into the expediency of establishing a board to analyze the medicines and nostrums now palmed on the public, and to publish their results of their examinations in a newspaper to be established for this purpose; and, further, to append such plain views and explanations thereto as will enlighten the public in regard to the nature and danger of such remedies.'"

Sixteen years later—June 6-9, 1865—the American Medical Association again met in Boston. The country at that time had barely emerged from the confusion of the Civil War, the meeting being held only two months after Lee's surrender at Appomattox. The Association assembled in the Massachusetts State House and was called to order by the President, Dr. N. S. Davis, then of Illinois, who also sat as delegate from Rush Medical College. Dr. Henry J. Bigelow, chairman of the local committee on arrangements, delivered an address of welcome. Roll call showed 616 present, of whom 555 were delegates and 61 were "permanent members," who as delegates to some previous meeting had the right to take part in the proceedings, but not the right to vote, distributed among the various states as follows: Connecticut, 31; Delaware, 1; District of Columbia, 9; Illinois, 6; Indiana, 5; Iowa, 2; Maine, 27; Maryland, 7; Massachusetts, 261; Michigan, 7; Missouri, 1; New Hampshire, 31; New Jersey, 12; New York, 102; Ohio, 9; Pennsylvania, 30; Rhode Island, 19; Tennessee, 1; Vermont, 40, and the Army and Navy, 10. These figures are interesting as showing the unequal representation under the old constitution. Although the Association was made up of delegates elected from county and state societies in the proportion of one to every ten members and of representatives from medical colleges, it necessarily followed that the state in which the meeting was held had an overwhelming proportion of delegates present. At this meeting, for instance, Massachusetts, Connecticut and New York together had 257 delegates, or nearly a majority of the entire voting membership. As the constitution at the preceding meeting in New York City had been amended so that the president elected at each meeting did not assume the chair until the following meeting, Dr. N. S. Davis, who was elected President in June of 1864, retained the chair through both sessions, giving way at the close of the Boston session to Dr. Humphrey Storer of Boston, who was elected President on the last day of the session. It is worthy of note that practically the entire attendance was from the eastern states, immediately contiguous to the place of meeting. None of the southern states were represented, as the entire medical profession of the South had been doing military service for four years past. The representation from the western states was also small, there being only thirty present from west of the Allegheny Mountains, and but three from west of the Mississippi River.

Much of the time was devoted to argument and discussion over two questions: First, The action of the Association in expelling from membership Dr. Montrose A. Pallen of New York, who was accused of complicity in the plot to poison the water of the Croton reservoir. Second, Criticism and arraignment of Surgeon-General Barnes, who was accused of consulting with a homeopath in the case of Senator Seward and his son. In spite of the evident tendency to bitter feeling and plain speaking, which would be expected at such a time, a considerable amount of valuable work was done. A large number of committees reported on various subjects. Among these were the reports of the committee on diphtheria, on spotted fever, on membranous croup, on compulsory vaccination, etc. Dr. T. Antisell of Washington presented a report to the Committee on Medical Education, which was referred to the Committee on Publication without discussion. Among other things, the report states that the committee attempted to obtain new and reliable data regarding medical colleges then in existence. Only thirty-three medical schools could be reached at the time, and of these, twenty replied, representing 3,209 matriculates and 1,001 graduates. The committee estimated that the entire number of medical students of the United States at that time was about 5,000. Of these twenty schools, dissections were required in but twelve, microscopy was taught in six, and pathology in only two. The committee recommended the passage by each state of a medical practice law, establishing a board of examiners, which should be the licensing body, entirely separate from the medical college or graduating body. On the afternoon of the fourth day, Friday, June 9, the Association was addressed by John A. Andrews, governor of the state of Massachusetts.

There are two facts which impress one in reading the reports and transactions of these previous sessions: First, That the American Medical Association in former years drew its attendance from a much smaller section of the country than it does to-day, which, of course, was to be expected; and that the attendance was more strictly limited to the territory immediately contiguous to the place of meeting. Second, That the problems which confronted the Association when it met in Boston in 1849 and 1865 were much the same as those which confront it to-day. Ever since the organization of the American Medical Association, the questions which have been most constantly and prominently

before it have been those connected with medical education, medical licensure and the purity and integrity of the drugs offered to the physicians by manufacturers and dealers. Much progress has been made along all of these lines since the Association last met under the shadow of the Massachusetts State House. It is to be hoped that the coming session will not only be the most successful and enjoyable of any of the annual sessions heretofore held, but that much definite progress will be made in solving the problems which have been of vital importance to the Association ever since its organization.

TUBERCULOUS INFECTION AND IMMUNITY.

Prof. Theobald Smith's lecture on problems in tuberculous infection and immunity[1] contains much of interest to students of tuberculosis, and a restatement and discussion of some of the points considered seem desirable more by way of emphasis than criticism.

The modes of invasion of the body by the tubercle bacillus are now regarded generally as fairly well understood. In most cases the bacilli are inhaled either in the form of dried sputa or as moist particles. This appears to be the case in cattle as well as in human beings. Baumgarten has long championed the view that many cases are the result of congenital infection, the bacilli being carried by the blood to various parts of the body, where they sooner or later give rise to evidences of morbific activity. In this way he explains the occurrence in children of primary tuberculosis of lymph nodes and other internal structures without disease at what would be the portal of entry in case the bacilli entered from without after birth. Based on the results of animal experiments, Baumgarten holds that tubercle bacilli always cause lesions at the point where they enter the body, but this contention is opposed by the majority of the investigators of the localization of primary tuberculous infection in children, notably Harbitz. Theobald Smith's study of bovine tuberculosis from this point of view has led him also to conclude that tubercle bacilli may pass through mucous membranes without being detained. His observations on this point are quite striking. Emphasis may also be put on his conclusion that Behring's theory that tuberculosis starts early in life through the digestive tract is not, as a rule, applicable to the bovine disease, which may enter by way of different channels, the respiratory tract being the most important.

As regards immunization against tuberculosis, Smith's lecture makes it very clear that in spite of the stupendous amount of study given to this subject we are still at the beginning. The relation of the secretions, metabolic products and component elements of the bacillus to the production of immunity has been investigated, with the result that now the attention is being turned to the whole bacillus, more particularly the living attenuated bacillus; in other words, we are going back to the old principle established by Pasteur in 1880 in his protective inoculation against fowl cholera. Unfortunately, the procedure, or its analogue, by means of which cattle may be made resistant to living cultures of bovine tubercle bacilli, namely, the intravenous injection of living human bacilli, is not applicable to man. Smith points out, however, that the high percentage of latent or arrested tuberculosis in human beings indicates that man normally possesses considerable resistance, which probably may be augmented specifically by some form of inoculation. On theoretical grounds he recommends for this purpose early cultures of tubercle bacilli, grown on media resembling as nearly as possible living human tissues, in order to maintain the virulence of the organisms, and killed by heating to 60° C. It may be recalled that A. E. Wright for the same purpose employs ground and crushed bacilli (tuberculin TR) in small doses, measuring the result for guidance as to dosage and proper intervals between the injections by determination of the opsonic index of the patients. The therapeutic results obtained by Wright have awakened great enthusiasm and certainly demand that the method be given a fair and exhaustive trial. In the meantime Theobald Smith's suggestions as to the possible advantages of the killed bacilli should be subjected to experimental test.

In concluding Smith points out that in the case of the tubercle bacillus partial immunization, i. e., increased resistance, can not eradicate tuberculosis, because it would lead to the survival of especially virulent races of bacilli, that in the unprotected probably would cause severe manifestations. Careful isolation of the sources of infection, namely, the sick, so that the actual spread of infection be prevented, combined with protective inoculation, would seem to be the weapons with which to attempt to drive back tuberculosis.

LIFE INSURANCE EXAMINATION FEES.

Whether it is because gold has depreciated in value, owing to the increase in its production, or whether it is because of good times resulting from good crops and other good things that tend to prosperity, we do not know, and it does not matter; but, whatever the cause, the prices of all the necessities and luxuries of life—except a few articles whose cost of production has lessened by improved machinery—have enormously increased during the last few years. This is common knowledge. Likewise it is well known that the shoemaker, the bricklayer, the carpenter and artisans of all kinds, as well as the hod-carrier and the day laborer, are receiving from 25 to 100 per cent. higher wages than they did ten or fifteen years ago. The lawyer is not hesitating to charge for preparing a brief double what he charged ten years ago—and he gets it. Even the preachers' salaries are better than they used to be. The doctor is the only breadwinner whose fees have remained

stationary. Where fifty cents for office consultation and a dollar for a visit were the average fees, say, fifteen years ago, the same high remuneration still prevails. This is especially true in the smaller towns. In the larger cities the better men and the specialists have not hesitated to charge more as the incomes of their patients increased, but the fees of average practitioners remain the same. Of course, no one is to blame but those who have been contented to put up with these absurd conditions; it is the doctor's, and not the patient's, fault. It is the same old story; if we do not look after our own interests we can not expect others to do it for us.

Our object now, however, is not to discuss the fee question in its general aspects, important though this question is, but to call attention to the subject as it relates to the examination for life insurance. As many of our readers know to their cost, some old-line companies have recently cut their fees from $5.00 to $3.00, and this without consulting those who did the work—at least not until after the cut had been made. And then the majority of those to whom the new terms were tendered meekly submitted. But what else could they do? They reasoned, undoubtedly, that if they refused to submit some other physician in the same town would accept, and, therefore, that it was better to have the reduced fee than none at all. But did they reason rightly when that reasoning forced them to the conclusion that another physician would take the pittance they were offered if they did not? This is the question to be considered. In the past, when the medical profession was poorly organized, probably they would have been right. Then each physician acted individually, for himself alone, without regard to the result of his action on the profession as a whole. It is different now.

In the greater portion of our country all the good men —and the old-line companies want no others—are in the organization and thus are in a position unitedly to demand their rights—justice. From the fact that these companies moved in the matter at the same time, took exactly the same action, and even used the same verbiage in their circular letters in some instances, it looks very much as though they were united and acted in conformity with a plan mutually agreed on. These wealthy organizations, without consulting those directly interested, said to their medical examiners: "We have reduced your fees 40 per cent.; accept this reduction or we will get some other physician to examine for us." They thought their proposition would be accepted, and we regret to say that they were right in too many instances.

The question arises: Are we now sufficiently united to resist successfully such arbitrary dictation on the part of a combination of wealthy corporations, or shall we continue to submit and to take the pittance that is offered? We certainly believe that we are sufficiently united; at least in most localities, and that we should not submit. As we have recorded from week to week in our news columns, several county societies have already taken action and have refused to accept this new rate. In some instances, every physician in the county has signed an agreement not to examine for the old-line companies for less than the fee received in the past. As one put it, "If we accept this 40 per cent. reduction now, how soon will there be another similar cut?"

We publish in our "Correspondence" columns a protest and a plea on this subject from Dr. J. N. McCormack. Having traveled over the country and having come in close touch with the medical profession, he knows the conditions and the sentiments of the profession, and he believes that a united resistance should be made everywhere. From the numerous letters we have received we believe that he is right and that action should be taken immediately in every county society in the country.

While we are giving attention to the question as it relates to the old-line companies, we should not forget that the prevailing conditions as they relate to the industrial companies and fraternal insurance orders are still worse, one dollar and even less being the usual examination fee for this work. It is absurd, and a reflection on the good common sense of the members of our profession, that we should have put up with this for so long, and, while we are discussing the question as it relates to the old-line companies, let us not forget to take in the industrial and fraternal phase of the question.

The time has come to act.

URIC ACID SOLVENTS.

If we analyze the various remedies that are recommended as uric acid eliminators or solvents, we find that nearly all of them contain two chief ingredients, i. e., alkali and water; the idea being presumably to alkalinize the blood stream, thereby rendering the uric acid more soluble and hence promoting its excretion. This in itself is not a bad idea, although it is an exceedingly difficult matter more than temporarily to change the reaction of the blood by the administration of alkalies by mouth, because the kidneys at once eliminate any excess of alkali. The idea, however, that alkalies given by mouth can in any way aid in dissolving uric acid concretions after they have once formed is, of course, preposterous. One might as well give ether to dissolve the fat of the body in obesity or acids to dissolve the calcium out of osteophytes, on the ground that ether or acids can dissolve fat or calcium salts in the test-tube; in other words, the fact that alkalies are a uric acid solvent *in vitro* does not mean that they can accomplish the same *in vivo*. The amount of ingested alkali, moreover, that could reach uric acid deposits in the circulation would be so infinitesimally small that a solvent effect could impossibly be accomplished.

This criticism applies with particular emphasis to lithium preparations that are so popular in the treatment of uric acid diseases. In the first place so-called

lithia waters[1] contain only a few decigrams of lithium carbonate to the liter; as they always also contain large quantities of other alkalies, only a very minimal amount of uric acid (according to Berthollet's law) would combine with the lithia, the bulk with the sodium and potassium salts, while at the same time most of the lithium would be promptly excreted as chlorid, phosphate and sulphate. Finally, lithium carbonate, which actually does readily dissolve uric acid in the test-tube, is immediately converted in the stomach into lithium chlorid, a salt that possesses only slight uric acid dissolving properties.

Whatever virtues, therefore, the innumerable uric acid remedies and lithia waters may possess, they owe to the alkali that they contain, but this alkali acts only mildly as a uric acid eliminator and not at all as a solvent of urate concretions; it acts chiefly as an antacid in acidosis and possibly as a stimulant to the liver function. The water is probably the most efficacious ingredient of these uric acid remedies, because abundant water drinking combined with a rational diet, the details of which can not be enumerated here, undoubtedly acts beneficially in most disorders in which metabolism is retarded and in which incompletely oxidized waste products accumulate.

Until we understand the real cause of gout and allied conditions, until we know what produces the symptoms that are popularly considered to be manifestations of a hypothetical uric acid diathesis, we can do no better than to treat the gastrointestinal tract and the liver, to promote elimination and give the patient the benefit of certain symptomatic and local treatment.

If alkali and water are to be used, and we know empirically that they are of some benefit, why not order our patients to drink a few quarts of water a day, to which may be advantageously added a teaspoonful or so of baking soda and a pinch or two of precipitated chalk? This would accomplish all that can possibly be claimed for their goods by promoters of a host of expensive mineral waters and the manufacturers of most of our well advertised so-called uric acid remedies.

1. The following quotation from an advertisement of Londonderry Lithia Water is taken from a daily paper:

> There are several Elements produced from Food that in sufficient quantities will eventually destroy your Body the chief one is called by learned scientists Uric Acid
>
> Now Uric Acid is just a Poison—
>
> And when Uric Acid gets into the System from the Food you eat, it usually goes straight for the Blood—the great highway of Health and Disease in the Body.
>
> Now Uric Acid is one of the hardest things in the world to dissolve
>
> Some metals are easier to dissolve than Uric Acid—
>
> And the Blood, which can usually dissolve almost everything, has no effect on it whatever—
>
> Consequently the Uric Acid remains in the Blood as Uric Acid—and clogs or impedes the circulation of the Blood just as Ashes clog your Stove draughts.
>
> Now Uric Acid clogs the circulation because primarily it makes the Arteries smaller—that it does this is an acknowledged scientific fact.

In this connection, it may be interesting to know that an analysis of [illegible] water showed that it contained only a trace of lithia.

THE BOSTON SESSION.

Considerable space is given this week to Boston and the coming session of the American Medical Association. But we make no apologies, for, if we mistake not, the session, in a month from now in the chief city of the old Bay State, will be the largest gathering of medical men ever held in this or in any other country. And not only will it be the largest, but it will bring together the leading men of our profession from the United States, as well as many from abroad. The preliminary programs of the Sections printed in this issue indicate in part what will be the character of the scientific work; but only in part. Aside from the scientific exhibit, which promises to be unusually attractive and instructive, there will be demonstrations of the application of scientific methods in practice that will be appreciated both by those who already have, as well as by those who have not, a good knowledge of such methods. But, aside from the scientific work and attractions, the social entertainments promise a season of enjoyable relaxation that will make the gathering one of pleasure as well as of profit. Under the indefatigable leadership of Dr. H. L. Burrell, Chairman of the local Committee of Arrangements, the physicians and surgeons of Boston have been working for months to make the visit of their professional brethren one of enjoyment. The whole Boston profession has been, and is, working unitedly and unselfishly to make the session a memorable one. Provisions have been made for seeing the historic spots in and around Boston, and excursions to other New England points undoubtedly will be arranged. While there will be a very large attendance, the committee promises to find good comfortable accommodations for all. But we suggest that those who expect to go should write to the hotel committee in advance, and not wait until their arrival and then expect a large corner room with bath prepared for them.

THE CALIFORNIA FUND.

Reports received from San Francisco show that there will be abundant need for the money which physicians are contributing to the fund for the California physicians. A large number—how many is not known—lost all their property, including house and office furniture, instruments, etc., and, in addition to this, their practice—at least for some time to come. They are true to their professional instincts, however, for they are working without compensation among the sick and injured, overseeing sanitation and aiding in the prophylactic measures which are so necessary under the present circumstances. While it is gratifying to note the response to the appeal to physicians in behalf of their suffering brethren, it is hoped that all who have not yet done so and are able to contribute will feel it a privilege to make some contribution, however small. The opportunity is a rare one, and no one will have cause to regret the philanthropy shown. We publish on another page the list of contributions thus far received, and we trust that still further and more generous response is forthcoming from the more fortunate brothers of those in distress.

THE REGENERATION OF LIMBS.

The anticipation of Dr. Morgan, in his article[1] in this issue of THE JOURNAL, seems almost as extreme as the alleged prophecy of a distinguished foreign surgeon, that synthetic chemistry would yet produce living, sentient and thinking beings. There is a great deal of faith in scientific men—some might call it credulity—as to the results of their labors. The suggestion of Dr. Morgan, however, has a better basis than have some of the others. It merely asserts the probability in the highest vertebrates of a process that is well known in the lower vertebrates and is still more frequent throughout the invertebrate kingdom. Nearly all the tissues in vertebrates, including even the bones, tend, when destroyed, to reproduce themselves to a greater or less extent, and the suggestion of Tornier (quoted by Dr. Morgan) that the double limbs sometimes found in human embryos may have their origin in injuries to the fetal periosteum is perhaps not unworthy of consideration. It would seem at first sight still more probable that some of the abortive limbs or parts (for example, fingers growing out of the shoulder joint) might be the result of some such process attempting to make up for a lost member. We should expect such things more in the cartilaginous fetus than in the further advanced organism, and this is supported by the facts observed in the embryonal stage of the frog. We can not even say that mammals do not have this tendency to reproduce lost parts. A recent observation by Oldfield Thomas[2] of the tendency to regeneration of the tail of the dormouse is a case in point. The facts of paraffin prothesis are also suggestive, indicating, as they do, that very extensive bone lesions can be compensated for if we only give a proper support on which the soft tissues can reproduce themselves. A prominent Belgian physician visiting this country is quoted as saying that among his colleagues at home amputation is almost ignored as a surgical necessity unless the joints are involved. It may be a very long time before we see the realization of Dr. Morgan's prediction, and it seems improbable enough, but it can not be said to be an altogether impossible thing.

Medical News

CALIFORNIA.

Accident.—Drs. Charles Sexton and Charles Freedman, Los Angeles, were thrown from their carriage in a runaway accident, April 11, and rendered unconscious.

Plague at Oakland.—Dr. N. K. Foster, secretary of the State Board of Health, reports that there is no doubt of the diagnosis of the case of bubonic plague recently discovered at Oakland.

Personal.—Dr. Henry J. Kreutzmann and family, San Francisco, have returned from a European trip.——Dr. Francis L. Newton, Woodland, has been made president of the local board of health.——Dr. Charles E. Parent, San Francisco, sailed for Europe, April 6.——Dr. Louis C. Deane, San Francisco, has returned from Europe.——Dr. William J. Caesar, San José, has been appointed member of the local board of health, vice Dr. E. D. Moffit, resigned.

CONNECTICUT.

New Internes.—As a result of the examination for internes at Hartford Hospital, the successful applicants out of the 13 who took the examination were Drs. J. D. Blake, A. C. Rowley, R. S. Risley and C. J. Griswold.

Communicable Diseases.—During March 25 cases of smallpox were reported in one town, Putnam; 686 cases of measles in 63 towns; 193 cases of scarlet fever in 46 towns; 17 cases of cerebrospinal meningitis in 9 towns; 148 cases of diphtheria in 32 towns; 112 cases of whooping cough in 20 towns; 30 cases of typhoid fever in 19 towns, and 56 cases of tuberculosis in 17 towns.

Personal.—Dr. W. Matthew Kenna, police surgeon of New Haven, has resigned.——At the meeting of the New Haven County Medical Society, April 19, the following were appointed delegates to the Connecticut Medical Society: Drs. Gustavus Eliot, Frederick N. Sperry, E. Herman Arnold and Henry C. Swain, New Haven; Thomas M. Bull, Naugatuck, and Henry G. Anderson and Frederick G. Graves, Waterbury. Dr. Charles J. Foote, New Haven, was re-elected councilor.——Dr. Frank E. Beckwith, New Haven, expects to start for Switzerland, July 1.

ILLINOIS.

Fever Closes School.—On account of the prevalence of scarlet fever in Deer Creek, and to prevent further spread of the disease, the public school in that village has been closed.

Personal.—Dr. Albert M. Beal, Moline, has been elected president of the board of education.——Dr. Harry R. Lemen, Alton, left for San Francisco, April 22.

Hospital Internes Named.—The names of the successful candidates for interneship in the Cook County Hospital were certified April 26 by the civil service commissioners. The following are the names of the successful applicants and their marks: Lawrence W. Smith, 90.8; R. L. Burns, 90.7; Fred Epplen, 90.5; C. A. Katherman, 90.5; E. P. Oldham, 90.5; Eagan N. Fishinam, 89.9; James T. Churchill, 87.6; Evan S. Evans, 87.6; M. J. Moes, 85.5; M. T. Easton, 85.4.

Chicago.

Personal.—Dr. Marie W. Walker sailed for Europe on the *Deutschland*, April 28.——Dr. and Mrs. Alexander Hugh Ferguson have returned from a southern trip.

Hospital Appeals for Help.—The directors of the Chicago Charity Hospital have made an appeal for $5,000 in aid of the institution which, so far as its capacity of 30 beds will allow, is free to the poor.

Hospital for Ravenswood.—The trustees of the Ravenswood Hospital have purchased a tract of land at Winchester and Wilson avenues, 192x152 feet, on which a modern hospital building will be erected.

Ask for Ambulance Physicians.—The health commissioner and the chief of police have asked the finance committee to recommend to the city council the transfer of the ambulance service from the police to the health department and to authorize an appointment of a police surgeon to have charge of each ambulance.

Examination of Candidate Medical Officers.—An examination of candidate medical officers for the National Guard will be held at Senn Hall, Rush Medical College, May 5. The examining board consists of Lieutenant-Colonel George Paull Marquis, assistant surgeon general; Major and Surgeon Charles Adams; Captain and Assistant Surgeon Samuel C. Stanton; First Lieutenant and Assistant Surgeon Truman W. Brophy.

Deaths of the Week.—The total deaths from all causes for the week ended April 28 was 621, 24 less than for the preceding week and 94 more than for the corresponding week of 1905. The mortality of the week is equivalent to an annual death rate of 15.80 per 1,000. Pneumonia still heads the list of death causes with 117, followed by consumption with 81; heart disease, with 48; nephritis, with 47; suicide, including violence, with 43; cancer, with 33; acute intestinal diseases, with 28, and nervous diseases, with 22. Scarlet fever caused 11 deaths; typhoid fever, 9; measles, 5; diphtheria, 4, and whooping cough, 2.

INDIANA.

The Afflicted.—Dr. James A. Comstock, Greenfield, has been compelled to abandon practice on account of illness.——Dr. Ernest R. Sisson, Maxwell, has been ill for a year, but is now improving.

Personal.—Dr. Patrick Jameson, Indianapolis, more than 57 years in practice, celebrated his eighty-second birthday anniversary April 18.——Dr. Benjamin L. W. Floyd, Evansville, sailed for England on the *St. Paul*, April 21.——Dr. Marion Thrasher of San Francisco, Cal., formerly of Fayette County, reports himself and family safe, but that everything in the way of property was lost.

1. This issue of THE JOURNAL, page 1327.
2. Zool. Soc. London Nature, Jan. 11, 1906.

IOWA.

Restore Meeting Date.—The officers of the Iowa State Medical Society, who changed the date of meeting from May 16-18 to May 9-10, have announced that the meeting will be held on the dates originally fixed, namely, May 16, 17 and 18.

Protest Against Abolition of Registrars. The physicians of the state have received with great disfavor the recent act of the legislature abolishing registers of births and deaths, and doing away with the issuance of burial permits after July 1.

Personal.—Dr. Theodore Engle, State Center, has been elected delegate from the Marshall County Medical Society to the Iowa State Medical Society, and Dr. Winfield S. Devine, Marshalltown, has been chosen as alternate.——Dr. Newton J. Rice has been appointed city physician of Council Bluffs.——Dr. and Mrs. James E. Conn, Ida Grove, will spend a portion of the summer on the Atlantic seaboard.——Dr. P. Alfred Bendixon, Davenport, sailed from New York, April 24, for Naples.

KENTUCKY.

Druggists May Sell Liquor.—An ordinance to prohibit the granting of retail liquor licenses to retail druggists of Louisville was defeated at a meeting of the general council, April 25. The ordinance specified that no druggist in Louisville should sell whisky or alcohol except on the prescription of a practicing physician.

Prohibit Medicine Sample Distribution.—The Louisville board of aldermen has adopted an ordinance prohibiting the distribution of the samples of "patent medicines," preventing the promiscuous throwing of samples of medicine into yards, and stipulates that whenever samples are distributed they must be given to some responsible person of the household.

MARYLAND.

Tuberculosis Commission.—The governor has appointed the following on the state tuberculosis commission: Drs. Lillian Welsh and William Sidney Thayer, Baltimore, and Messrs. John M. Glen and Daniel W. Hopper.

Milk Exhibit.—The State Board of Health, encouraged by the success of the tuberculosis exhibit two years ago, is preparing to hold a public milk exhibit at McCoy Hall, Johns Hopkins University, Baltimore, May 7 to 14. This is the culmination of the course of lectures recently delivered on the same subject and in the same hall. In arranging this exhibit the board has called to its aid many other boards and societies. The exhibit will embrace the following: Chemistry of milk; pathology and bacteriology of milk and milk products; statistics of milk; morbific, infectious and anomalous milk; medical milk commissions and milk dispensaries; modified milk; model dairies; dairy utensils and dairy rations; sophistications and adulterations of milk; manufactured milks and milk foods; technical uses of milk; dairy customs of foreign countries; the culinary uses of milk; literature of milk and dairy products. The contributors to the exhibit will include the United States Department of Agriculture, state food and dairy departments, sanitary live stock boards, agricultural experiment stations, boards of health, medical milk commissions, charitable agencies, research laboratories, and a selected list of commercial concerns.

Baltimore.

Hospital Report.—The report of the dispensary physician, University of Maryland Hospital, shows 28,028 cases treated during the year ended April 1, namely, 7,163 new and 20,865 old cases.

Smallpox has been discovered in the southwestern part of the city. Two white women and two white children are now at quarantine and it is expected that others will follow. Five or six other cases have been discovered in the western suburbs, and a general diffusion of the disease seems imminent there, as from the mildness of the disease its nature was not suspected and there was no attempt at isolation.

MASSACHUSETTS.

Personal.—Dr. William T. Councilman of Harvard University Medical School has been elected president of the Southern Society of Boston.

Emergency Hospital Closed. The Emergency Hospital, Springfield, which was started five years ago on the certificate principle of $1 a year for treatment, has surrendered its lease and its affairs are being closed.

New French Medical Society. A medical society has been organized at Fall River, known as the "L'Union Medicale de Fall River, Mass.," with 20 members and the following officers: President, Dr. Samuel J. Kelly, and treasurer, Dr. F. de Borgia Bergeron.

Bradford in Cleveland.—Dr. Edward H. Bradford, Boston, was the guest of honor at a complimentary dinner at the Hollenden, Cleveland, April 20, and later addressed the Academy of Medicine on "Muscle and Tendon Transference and the Relation of General to Orthopedic Surgery."

Hospital Debt Liquidated.—The liquidation of the $22,000 debt of the Springfield Hospital has been assured by the receipt of $2,460 from a benefit concert and three additional contributions of $1,000 each. The amount now pledged is $23,300, which will free the hospital from debt and leave a good nucleus for a surplus fund.

District Society Meeting.—The Hampden District Medical Society held its annual meeting in Springfield, April 17. The following officers were elected: President, Dr. Edgar M. Guild, Springfield; vice-president, Dr. Daniel F. Donoghue, Holyoke, and secretary-treasurer, Dr. Frederick S. Ward, Springfield. Drs. Daniel E. Keefe, Springfield; Arthur L. Damon, North Wilbraham, and Walter R. Weiser, Harvey W. Van Allen and James E. Marsh, Springfield, were appointed censors; Drs. Daniel E. Keefe, Walter A. Smith, Theodore S. Bacon, Everett A. Bates, Robert P. M. Ames, Frederick W. Chapin, Frederick B. Sweet, Harry C. Martin and Charles F. Lynch, Springfield; J. Philip Schneider, Palmer; Charles W. Jackson, Thorndyke; George H. Janes, Westfield, and Locero J. Gibbs, Chicopee Falls, were chosen as councilors, and Dr. James W. Hannum, Ludlow, was appointed commissioner of trials.

MICHIGAN.

Personal.—Dr. J. F. Munson, who has been assistant to Dr. Victor C. Vaughan, Ann Arbor, for the past two years, has been appointed resident pathologist at the Craig Colony for Epileptics, Sonyea, New York.——Dr. Willit J. Herrington, Bad Axe, who has been suffering from septicemia, due to an operation wound, was operated on a few days ago and is now improving.——The medical section of the Wayne County Medical Society has elected Dr. F. L. Newman, chairman, and Dr. Walter J. Wilson, secretary.——Dr. Alexander H. Scott, St. Joseph, is seriously ill with heart disease.——Dr. George W. Orr, Lake Linden, has been appointed township health officer. ——Dr. Elliott K. Herdman, Ann Arbor, has been re-elected city physician.——Dr. Charles G. Jennings, Detroit, has been elected president of the board of health.——Dr. Walter T. Parker, Fowlerville, has returned after a year in Germany.

MISSOURI.

Will Not Grant Pardon.—The governor has declined to interfere in the case of Dr. Jefferson Goddard, who is serving a ten years' sentence in the penitentiary for the murder of Fred Jackson, a laundryman of Kansas City.

Commencement.—The Ensworth-Central Medical College, St. Joseph, held its twenty-ninth annual commencement exercises, April 21, when a class of 37 received diplomas. The faculty address was delivered by Dr. O. Beverly Campbell, and Dr. James W. Heddens conferred the degrees.

Fined for Illegal Practice. "Dr." J. M. Davis, Shelbyville, who was arrested, tried and found guilty of practicing medicine without a license in Scotland County, Mo., and who appealed to the Supreme Court, has had judgment rendered against him, the decision confirming the decision of the lower court. He was fined $50.

Board of Health Sustained.—The Supreme Court on March 30 decided that the State Board of Health has the right to revoke the license of a physician for unprofessional conduct and to order a physician before it for trial. The case in point was that of Dr. S. M. McAnnally, Marble Hill, against Dr. Robert H. Goodier, Hannibal, and other representatives of the State Board of Health. Dr. McAnnally was charged by the citizens of Marble Hill with selling liquor in quantity, and also with selling liquor to minors.

Personal. Dr. Paul Y. Tupper, St. Louis, has resigned as a member of the State Board of Health.——Dr. R. M. James, Joplin, has been elected secretary of the Jasper County Medical Society.——Dr. J. Thomas Pittam, Kansas City, has been commissioned lieutenant in the medical department of the state and assigned to Battery B, Kansas City Light Artillery. ——Dr. John Young Brown, superintendent of the City Hospital, St. Louis, has returned from a trip to Texas and Mexico. ——Dr. Anselm C. Robinson, St. Louis, police physician, has been appointed police surgeon at a salary of $2,000 a year. ——Dr. H. Wheeler Bond has been appointed health commissioner of St. Louis, succeeding the late Dr. Snodgrass.——Dr. J. N. Barger, Darlington, has been elected delegate to the State Medical Association from the Gentry County Medical Association. ——Dr. A. J. Campbell, Sedalia, has been appointed

local surgeon for the Missouri Pacific Railway.——Dr. Richard L. Sutton, United States Navy, retired, and Mrs. Sutton, who have been abroad for several months, have gone to Northern Germany for the summer.

NEW HAMPSHIRE.

Appropriation for Hospital.—The Nashua city council, at its meeting March 27, appropriated $2,500 to the Nashua Hospital.

Compromises Claim.—The city government of Nashua has compromised for $911 the claim of Dr. Charles E. Congdon of about $1,800 for services during the smallpox epidemic in 1902 and 1903.

Personal.—Dr. Eugene F. McQuesten, Nashua, on March 26, completed 40 years of practice in medicine.——Dr. Timothy G. Herrick, formerly of Manchester, is reported to be critically ill in Aiken, S. C.

Consumption.—The State Board of Health has issued for gratuitons distribution a pamphlet entitled "Consumption, Its Prevalence, Cause, Restrictions and Prevention," in which it gives statistics of deaths from tuberculosis in the state.

Graduation Exercises.—The graduation exercises of the Dartmouth Medical School were held in the auditorium of Dartmouth Hall, Hanover, March 31. Dr. William T. Smith, dean of the faculty, presided. The doctorate address was delivered by Dr. Ira J. Prouty, Keene, and a class of 10 was graduated.

NEW YORK.

Personal.—Dr. Albert Van der Veer, Albany, has been made a member of the board of regents of the State University.

New Head of Lunacy Commission.—Dr. Charles W. Pilgrim, superintendent of the Hudson River State Hospital, Poughkeepsie, has been appointed president of the state lunacy commission to fill the vacancy created by the resignation of Dr. William Mabon, appointed superintendent of the Manhattan State Hospital.

Examiners of Alien Insane.—Governor Higgins has permitted to become a law without his signature, Senator Raines' bill defining the powers of the board of three examiners of alien insane at the port of New York, and increasing the salaries of two of the examiners so as to make the salaries of each of the three $5,000 a year.

To Vote on Medical Ethics.—The Medical Society of the State of New York is taking a vote by mail as to whether "The Principles of Medical Ethics of the American Medical Association, being suggestive and advisory, shall be the guide of members in their relation to each other and to the public." The polls will be closed at the expiration of ten days after the submission of the question, which occurred April 27.

Bills Passed.—A bill has been passed by the senate making it a misdemeanor for anyone in authority in any city hospital to refuse admittance to any patient brought by ambulance, or to order his removal to another hospital while he is in a dangerously sick condition.——Assemblyman Hackett's bill has been passed appropriating $1,000,000 for an additional public hospital on Manhattan Island between Twentieth and Seventieth Streets.——Assemblyman Agnew's bill has been passed providing for a commission to consider means for protecting the waters of New York Bay against pollution.

"Patent-Medicine" Bill Passed Senate.—Senator Stevens' bill, providing for the proper labeling of medicinal preparations containing alcoholic, narcotic or other potent drugs and for their inspection, analysis and regulation of manufacture, passed the senate April 27 by a vote of 30 to 15. In making his plea for the passage of the measure Senator Stevens produced a letter containing the astounding statement that "patent-medicine" interests had sent $100,000 to Albany to defeat a similar measure last year, and had succeeded. In discussing the opposition to the measure, Senator Stevens said:

> There are three distinct forces against this measure: the manufacturer of "patent medicine," the retail druggist and the country newspaper. The manufacturer whose "patent medicine" contains alcohol or some potent drug in such percentage as to result ultimately in creating a drug habit is afraid his medicine will not be in demand; the retail druggist has opposed the measure because it applied to stock on hand, but his opposition has been largely withdrawn as the result of an amendment. Finally, the small newspapers are opposed and have flooded me, and I dare say every other member of this body, with circulars urging me to defeat the measure. The proprietors of these papers admit that if the measure is passed their profits will be greatly curtailed, for probably the greatest fraction of the revenue of country newspapers comes from this source. Nearly all the contracts for advertising of this sort, I am informed, have been made containing a clause specifying they shall be binding so long as no adverse legislation is passed by the State Legislature. This is, of course, only a species of blackmail by which the newspapers are permitted to retain the patronage so long as they prevent adverse legislation.

New York City.

Personal.—Dr. Minas S. B. Gregory sailed for Europe, April 26.——Dr. Thomas Darlington will make the address at the graduation exercises of the Training School for Nurses of St. Mark's Hospital.

Seaside Hospital.—The seaside hospital and park bill was signed by Mayor McClellan. This enables the city to spend $2,500,000 for land near the seashore, and it is likely that the site will be purchased at Far Rockaway, where there are four miles of beach front.

OHIO.

Forgot the Appropriation.—The legislature passed a bill creating a commission of six to secure a site for a State Hospital for Criminal Insane at Lima, but failed to make an appropriation for the erection of the building.

Found Guilty of Criminal Malpractice.—Dr. David P. Maxwell, Cleveland, charged with having caused the death of Celia Ritzer by a criminal operation, was found guilty, April 19. The penalty for the crime is imprisonment for from one to seven years.

Personal.—Dr. C. E. Sawyer, Marion, has associated with him in business his son, Dr. Carl W. Sawyer.——Dr. Floyd Swimley, Forrest, who was injured in the blowing up of an acetylene machine, has gone to Columbus for treatment of his eyes.——Dr. A. Per Lee Pease, Massillon, returned from Europe on the *Minneapolis*, April 22.——Dr. A. S. Rochester, Columbus, has been offered an appointment as surgeon in the army of Guatemala.——Dr. Sterling B. Taylor, Columbus, is suffering from septicemia, due to an operation wound, and may lose the middle finger of his right hand.——Dr. Frank Graham, Lisbon, is seriously ill with pneumonia.

PENNSYLVANIA.

Crusade Against Typhoid.—The state commisioner of health has issued a statement urging local boards of health throughout the state, and physicians, nurses and attendants on persons afflicted with typhoid fever to use the greatest care in disinfection and other means of prophylaxis.

Staff Appointments.—The following appointments have been made on the staff of the Taylor Hospital: Surgeons, Drs. John L. Griffith, Taylor, and Stephen S. Watson, Moosic, and John W. Houser, Taylor; physicians, Drs. James S. Porteous, William H. Olmstead, John J. Timlin and W. W. Myers, and consulting surgeon, Dr. Addison W. Smith, Scranton.

New Medical Inspectors.—Dr. Samuel G. Dixon, state commissioner of health, has appointed Dr. Andrew A. Cairns, chief medical inspector of the Philadelphia bureau of health, and Drs. Charles B. Penrose, Norton Downs and Alfred C. Wood, special medical inspectors for Montgomery County. The duties of the special inspectors will be to investigate all cases of contagious disease reported in the county and to inspect the streams of the county with a view to preventing pollution.

Endorse Council on Pharmacy.—At the April executive meeting of the Allegheny County Medical Society the following resolutions were unanimously adopted:

> Whereas, It appears that at the present time there is a greater and more widespread awakening than ever before on the part of the profession and the public generally through the land to a realization of the danger and impropriety of using secret or "patent medicines;" therefore be it
>
> *Resolved*, By the Allegheny County Medical Society, that:
>
> 1. It highly commends the action of the American Medical Association for the comprehensive and well-planned campaign which, by means of its JOURNAL and Council on Pharmacy and Chemistry, it is conducting against non-ethical pharmaceutical preparations.
>
> 2. It commends the *Ladies' Home Journal* and *Colliers' Weekly* for the clear, intelligent and persistent way in which they are setting forth to the public the dangers which attend the use of "patent medicines" for purging their own columns, from "patent medicine" advertisements and for exposing the shameless and utterly selfish and mendacious manner in which these nostrums are exploited.
>
> 3. It recognizes in its honored member, Dr. Adolph Koenig, the great merit which belongs to him in that, as editor of the *Pittsburg Medical Review* and later of the *Pennsylvania Medical Journal*, he steadily and persistently refused to admit to their advertising columns any unethical preparation whatsoever, a position which was for many years higher than that taken by any other medical journal in the United States; that it felicitates Dr. Koenig on the fact that THE JOURNAL of the American Medical Association has finally come to adopt the position regarding its advertising columns which he, with his co-editors, adopted for the *Pittsburg Medical Review* many years ago; at the same time it commends THE JOURNAL of the American Medical Association for this righteous, if somewhat tardy, stand which it is now taking; finally, Dr. Koenig's course with regard to advertising in the *Pennsylvania State Medical Journal* is commended to the present editor of that journal.

4. It is considered by the Allegheny County Medical Society to be highly unethical and improper for a physician to prescribe for internal use or external application any preparation of a secret character or to recommend any sanitarium or hospital where it is known that such preparations are employed.

5. It directs the committee on public policy and legislation to report to the society at the regular January meeting of each year a list of such unethical preparations advertised to the profession as shall have come to its notice.

6. The committee on legislation of the Pennsylvania State Medical Society is requested to endeavor to secure the enactment by the legislature of this state of a law providing that all manufacturers of "proprietary" or "patent" medicines shall be compelled to print on each bottle or package an exact formula of the contents; that the commonwealth shall provide for the analysis of all such medicines sold within its borders, and that a heavy fine be imposed for the publication of a fraudulent formula.

7. It directs its secretary to send a copy of these resolutions to the Editor of THE JOURNAL of the American Medical Association and to the editor of the *Pennsylvania State Medical Journal;* to send a copy of section 2 of these resolutions to the editors of the *Ladies' Home Journal* and *Collier's Weekly,* and that until otherwise directed it is ordered that section 4 of these resolutions be printed on every notice of the regular meetings of this society.

Philadelphia.

Society Entertained.—Dr. L. Webster Fox entertained the Ophthalmological Society of the Medico-Chirurgical College, named in his honor, at the University Club, April 28.

New Branch Society Organized.—The petition for a Northwest branch of the Philadelphia County Medical Society, which was signed by a large number of representative physicians residing north of Huntington Park Way and east of Old York Road, was favorably acted on at the business meeting of the society, April 18.

Personal.—Dr. and Mrs. Harry K. Carey have sailed for England.——Dr. Charles Mitchell sailed for Europe, April 28. ——Dr. John H. Musser addressed the graduating class of nurses of the Harrisburg Hospital, April 17.——The home of Dr. T. Mellor Tyson in Rosemont was destroyed by fire April 23.——Dr. DeForest Willard, professor of orthopedic surgery in the University of Pennsylvania, is seriously ill at his home with pneumonia.——Dr. Ross V. Patterson, assistant chief resident physician of the Philadelphia General Hospital, has resigned.

To Aid San Francisco Physicians.—The Philadelphia County Medical Society held a special meeting, April 25, and formulated plans for the relief of San Francisco physicians, and appropriated $200 to the relief fund and appointed the following committee to further the movement: Drs. James M. Anders, J. F. Schamberg, William S. Wray, John H. Musser, Hobart A. Hare, Albert M. Eaton, John B. Turner, Thomas H. Fenton and C. L. Bower.——The Philadelphia Homeopathic Medical Society took similar steps and appointed a committee to further the movement.——The Alumni Society of the University of Pennsylvania and Jefferson Medical College have also taken steps to help their destitute brothers in the stricken city.

Health Report.—The total number of deaths reported for the week reached 587. This is an increase of 9 over the number reported last week, and an increase of 35 over the number reported in the corresponding week of last year. The principal causes of death were: Typhoid fever, 27; measles, 8; pertussis, 6; diphtheria, 17; meningitis, 5; consumption, 76; cancer, 26; apoplexy, 14; heart disease, 57; acute respiratory disease, 79; enteritis, 34; Bright's disease, 50; accidents, 28, and marasmus, 4. There were 332 cases of contagious disease reported, with 48 deaths, as compared with 357 cases and 27 deaths in the preceding week. There were 216 new cases of typhoid fever reported, with 27 deaths, as compared with 222 cases and 20 deaths reported in the previous week.

RHODE ISLAND.

Smallpox. Two cases of smallpox have been discovered in pupils of the Darlington school, Pawtucket.

Isolation Hospital Burns.—Fire, which destroyed the Isolation Hospital, Woonsocket, April 8, caused a loss of about $4,700.

Sixty Years of Practice. Dr. James W. C. Ely, dean of the medical profession of Providence, was the guest of honor at a dinner given by his fellow practitioners, April 27, in honor of the sixtieth anniversary of his entry into the practice of medicine.

Hospital Staff Changes.—Dr. Joseph C. Maranda has been appointed physician to the Woonsocket Hospital, vice Dr. Joseph Hils, deceased. Drs. William F. Barry, Elisha D. Clarke, J. Edgar Tanguay and Joseph T. Roswell have been appointed members of the staff of the hospital.

SOUTH CAROLINA.

Alumni Election.—The Alumni Association of the Medical College of the State of South Carolina, Charleston, held its annual meeting April 11, at which the following officers were elected: Dr. Robert S. Cathcart, Charleston, president; Drs. T. H. Tuten, Crockettsville; J. R. Bell, Due West; Henry Horlbeck, Columbia, and Arthur F. Doty, Sumter, vice-presidents, and Dr. C. Bunting Colson, Charleston, secretary and treasurer.

Insurance Fees.—Dr. William Weston, Columbia, S. C., sends us a copy of the following resolutions, which were adopted at the meeting of the State Medical Association, held in Columbia, April 17:

WHEREAS, Many of the life insurance companies have notified their medical examiners of a reduction of the examining fee from $5 to $3; and

WHEREAS, We, as physicians, realizing the responsibility incident to proper examination of the individual, believe such reduction to be unjust; therefore be it

Resolved, That in the House of Delegates, in session assembled, we do hereby declare such reduction to be unjust and respectfully request that no physician legally authorized to practice medicine in South Carolina accept such reduction of fee; and further that any physician accepting such reduction be guilty of a breach of professional courtesy.

Resolved, That it is the sense of the House of Delegates that hereafter in each examination for life insurance in which urine analysis is required the minimum fee shall be $5 and that when no such analysis is required the minimum fee shall be $3.

Resolved, That the several component societies forming this state association be requested to adopt these resolutions.

VIRGINIA.

Established Club Rooms.—The Newport News Medical Society has established headquarters in the Coleman Building, which will be open at all times, and where the current issue of medical journals, books of reference and other literature of value to the profession will be found on file.

SAN FRANCISCO CATASTROPHE.

Present Conditions in California—Needs of Physicians—The Work of Relief and Aid—List of Uninjured Physicians.

Report largely by telegraph from Dr. Philip Mills Jones.

The sanitary condition of the city is excellent considering the very limited water supply and the fact that all house toilets are ordered closed. Latrines and closets over sewers and manholes are generally used, and the latrines are covered with lime daily. No new cases of communicable diseases have been reported since the fire, and the deaths have been only 352, or about double the normal number. No cases of typhoid have yet been reported, although every preparation has been made to treat the disease should it occur. A typhoid hospital capable of holding 1,200 patients has been erected in Golden Gate Park. There are at present 47 cases of contagious disease in the city, mostly measles and scarlet fever. All are in quarantine and all were ill prior to April 18. All cases of tuberculosis have been sent to the San Francisco City and County Hospital, and all other cases to the contagious ward of the Children's Hospital or to the Emergency Contagious Disease Hospital at Harbor View.

The city has been divided into three sanitary districts in charge respectively of Drs. J. Henry Barbat, John M. Williamson and Charles E. Jones. Each of these districts is divided into eight subdistricts with from 15 to 20 physicians assigned to each. House-to-house inspection is made almost daily. Instructions are given to boil all water and milk, to cook all vegetables, and not to use the house closets, and the military authorities see that the orders of the sanitary inspectors are carried out.

Dr. E. C. Dalton, Salem, Ore., was one of the first to come to the city with supplies and established an emergency hospital which is doing most excellent work. Among others who came early to the assistance of the city are Dr. J. F. Shiels, New York City, and Dr. P. J. H. Farrell, Chicago, with about 30 other physicians. The health authorities report that there is now no necessity for outside medical aid, but that there is urgent need of medical supplies, drugs, medicines and minor surgical instruments.

Dr. Jones also says: "Please announce that it is almost impossible to get private telegrams from San Francisco east, as the press is monopolizing all lines. Also announce that there will be destitution among San Francisco physicians, and that as county officers can not be found, remittances should be sent to Dr. Frank Adams, ex-president of the Medical Society of the State of California, 1230 Telegraph Avenue, Oakland, or to myself, at the same address, and all funds will be turned over by us to the officers of the county society as soon as possible.

"The *California State Medical Journal* for May, of four pages only, is now on the press.

"No one not here can have the faintest idea of the situation. Please publish my thanks for many telegrams as regards my personal safety and for many offers of help."

Dr. D. W. Montgomery has notified THE JOURNAL that the following physicians and their families are saved and uninjured: Drs. William C. Riley, Joseph Bayer, E. F. Donnelly, George H. Powers, A. Barkan, Philip Collischonn, Dr. Barndt, Dr. Hadely, S. Cleary, A. B. Grosse, René Bine, A. P. O'Brien, H. M. Sherman, S. J. Hunkin, W. H. Barbat, W. W. Kerr, John Gallwey, Douglass W Montgomery, W. B. Lewitt, Morris Herzstein, W. S. Thorne, W. Thorne, Lucia M. Lane, Virginia Smiley, Emma Sutro Merritt, Edna Field, George W. Merritt, and Victor Vecki. Dr. J. N. Williamson received a scalp wound from a falling brick, but was otherwise uninjured. Dr. Rether's family is safe.

The St. Louis Medical Society to May 1 had collected $464 for the physicians of California who need aid as a result of the earthquake and fire.

The Norfolk District (Mass.) Medical Society, at a special meeting, April 24, voted to omit the usual dinner on the occasion of the annual meeting, and instead, to contribute $300 for the medical fraternity of California.——The Suffolk District Medical Society has appropriated $500 for the same purpose.

A benefit for the women physicians of San Francisco will be given by the women physicians of Philadelphia in the Broad Street Theater, May 29.

THE CALIFORNIA FUND.

Subscription List Opened for Relief of Physicians in Need.

As announced last week, the Board of Trustees has authorized that the columns of THE JOURNAL be opened for subscriptions to a fund for the relief of those physicians who have been left in destitute circumstances through the California earthquake and fire. The local committee in Chicago to have supervision of the fund in behalf of the American Medical Association consists of: Dr. Frank Billings, Treasurer of the American Medical Association, Chairman; Dr. M. L. Harris, Resident Trustee of the American Medical Association; Dr. C. S. Bacon, Chairman of the Section on Obstetrics and Diseases of Women, and President of the Chicago Medical Society; Dr. R. B. Preble, Chairman of the Chicago Medical Society Committee, and Dr. George H. Simmons, Editor of THE JOURNAL of the American Medical Association.

Subscriptions are solicited from those who feel able to give. Make checks payable to the American Medical Association, marking the check "California Fund." Send to the American Medical Association, 103 Dearborn Avenue, Chicago, marking the envelope in lower left-hand corner, "California Fund." An acknowledgment will be made in THE JOURNAL of each contribution. Local or county societies that wish to make a contribution as a body and prefer to send it through the American Medical Association Fund, may do so and credit will be given to the society and the names of the individual contributors will also be printed.

The question regarding the acceptance of contributions from those not members of the medical profession was discussed by the committee representing the American Medical Association, and it was agreed that such contributions already made he accepted with thanks. The committee decided, however, that as this fund is for physicians only and intended as a donation by the profession to its brethren in need, that outside contributions hereafter be declined.

The following contributions, not acknowledged last week, have been received up to 9 o'clock Wednesday morning:

INDIVIDUAL CONTRIBUTIONS.

J. F. Jenkins, Tecumseh, Mich.	$ 5.00
Frank C. Todd, Minneapolis	10.00
C. H. Vinton, Wernersville, Pa.	5.00
N. H. Kern, Thawville, Ill.	2.00
G. L. Greenawalt, Fort Wayne, Ind.	10.00
W. C. Wightman, Wayne, Neb.	5.00
J. F. Burnham, Lawrence, Mass.	2.00
Henry Belt, New York	5.00
W. Q. Spilling, Lonaconing, Md.	2.00
R. J. Curdy, Kansas City	5.00
W. C. Kelley, Morgantown, W. Va.	5.00
Frederick Peterson, New York	25.00
D. D. Monroe, Hillrose, Colo.	2.00
C. A. Kirkley, Toledo, Ohio	15.00
F. B. Harrington, Boston	25.00
R. G. Cook, Rochester, N. Y.	5.00
C. B. Turner, Bluemont, Va.	1.00
Physicians' Defense Co., Fort Wayne, Ind.	200.00
T. J. Happel, Trenton, Tenn. (additional)	5.00
W. A. Chamberlin, Waseca, Minn	5.00
C. C. Stephenson, Little Rock, Ark.	5.00
S. W. Woodyard, Greeneville, Tenn.	2.00
W. J. Judy, Dunlevie, W. Va.	1.00
Wm. Jacobsohn, New York	1.00
O. S. Werner, Lindstrom, Minn	$ 1.00
B. W. Hale, Tallula, Ill.	5.00
E. F. Cushing, Cleveland, Ohio	50.00
T. E. Holland, Hot Springs, Ark.	25.00
J. N. and A. T. McCormack, Bowling Green, Ky	100.00
	529.00
Acknowledged last week	342.00
Total	$871.00

CHICAGO MEDICAL SOCIETY CONTRIBUTIONS.

The following amounts have been received through the committee appointed by the Chicago Medical Society since the list of last week:

Abt, A. I.	$25.00
Abt, J. I.	5.00
Alcorn, S. J.	5.00
Allport, W. H.	10.00
Anderson, J. A.	5.00
Anonymous	1.00
Armstrong, J. B.	5.00
Babcock, Robert	25.00
Baker, W. E.	2.00
Bannister, H. M.	4.00
Barnes, Walter S.	10.00
Barrett, C. W.	10.00
Bass, G. E.	10.00
Banmann, E. S.	4.00
Baumrucker, O.	1.00
Beck, E. G.	5.00
Benz, F. A.	5.00
Best, John E.	3.00
Bettman, Boerne	5.00
Betz, H. E.	2.00
Bevan, A. D.	50.00
Blankinl, A.	5.00
Bieringer, W. A.	5.00
Billig, G. W.	5.00
Boehm, P.	10.00
Borucki, F. M.	1.00
Bray, H. T.	3.00
Braylon, S. H.	5.00
Brinckerhoff, C. E.	5.00

GENERAL.

No Longer Members of the Proprietary Association.—The Purdue Frederick Company asks us to announce that the firm is no longer a member of the Proprietary Association of America.

National Tuberculosis Association.—The second annual meeting of the National Association for the Study and Prevention of Tuberculosis will be held at the New Willard Hotel, Washington, D. C., May 16-18. Among the papers to be read are: "Immunity in Tuberculosis," Dr. Simon Flexner, New York; "Tuberculosis Nostrums," Samuel Hopkins Adams, New York; "Industrial Sickness Relief Associations and Tuberculosis," Dr. Arnold C. Klebs, Chicago; "The Kidneys in Tuberculosis," Dr. Joseph Walsh, Philadelphia; "Common Errors in the Technic of Examining Sputum for Tubercle Bacilli," Dr. Charles L. Minor, Asheville; "Therapeutic Use of Tuberculin Combined with Sanatorium Treatment of Tuberculosis," Dr. Edward L. Trudeau, Saranac Lake. Others speakers will be Drs. Frank Billings, John S. Fulton, J. W. Irwin, M. P. Ravenel, Vincent Y. Bowditch, Karl von Ruck, L. Hektoen, Theobald Smith, Norman Bridge, Sherman J. Bonney, S. A. Knopf, Robert G. Le Conte, Charles H. Mayo, Joseph Bloodgood, W. P. Northrup, A. Jacobi, John Lovett Morse, J. P. Crozer Griffith, etc. A round-trip rate of one and one-third fares on the certificate plan has been granted by the Trunk Line Association, and other associations are expected to do the same.

FOREIGN.

Increase of Pulmonary Tuberculosis Among School Teachers in Great Britain.—It is stated on reliable authority that phthisis is greatly on the increase among school teachers in Great Britain. It has been shown that by far the greater number of such cases occurred among those who had entered the teaching profession within the past few years. It is also said that the habits of the teachers have had much to do with this condition of things, as they stayed in the vitiated atmosphere of the schools too long.

Organization of the Profession in Austria.—It is regarded as remarkable that the 900 country practitioners of lower Austria have so solidly united in their attempt to obtain more just remuneration from the authorities for vaccinating the poor and similar official duties. Their "passive resistance," as they call it, the first effort at organization of the profession in Austria has presented a solid front without a single backslider. The physicians in Vienna not only officially endorsed their stand, by resolutions and appropriations voted in the medical societies, but a personal canvass has been made to obtain the signed statement of individual physicians that they would not interfere or take the place of any of the resisting physicians under any circumstances. An unexpected but welcome result of this concerted action is that the numerous warring factions of physicians, representing various political parties, etc., have all been brought together and fused into one general committee for sustaining the organized action of their colleagues in lower Austria. The "passive resistance" was described in these columns on page 970. All signs point to a speedy and satisfactory outcome of the struggle.

Correspondence

INSURANCE EXAMINATION FEES.

A Protest from Dr. McCormack, and a Plea That Physicians Stand Together in Opposition to a Gross and Unnecessary Injustice.

Bowling Green, Ky., April 30, 1906.

To the Editor:—The simultaneous and uniform reduction of fees for medical examinations recently made by the Mutual Life of New York, the Equitable and several other old line life and accident insurance companies, and the other information bearing on the same point, leaves little room for doubt that this was done as the result of a carefully prearranged and concerted understanding. Sprung on us midway between the meetings of our national and state associations, without even the courtesy of a notice, or an opportunity for conference or protest, as employers would not now attempt to do in dealing with miners or bricklayers, the profession was taken completely by surprise. Expecting some official action by their organizations, many quietly put the formal acceptance of the reduction requested by the companies in the waste-basket, while many others, without advisors, and not knowing what their competitors would do, reluctantly and resentfully signed and returned the agreement. It was all an adroit and well devised plan of the companies to deal with the isolated and individual physician instead of with the organized profession.

And there were abundant reasons for believing that it would succeed. Eleven years before the New York Life, the original and arch sinner against the best interests alike of their policyholders and the profession in this regard, had cut its fee in the same unceremonious and discourteous way, and probably a majority of leading physicians in all sections of the country failed to resent the recognized indignity. At that time we

had no real organization anywhere, the profession was living in more or less suspicion and discord in most communities, and many felt that it would be useless to offer single-handed resistance to this then respected and powerful corporation. But it is far different now. We already have societies in over 2,400 of the 2,830 counties in the United States, with a total of 60,000 members, embracing nearly all of the more progressive and intelligent elements of the profession, and our organization is fresh in its infancy. The counties not yet organized are in the sparsely settled regions, and most of those outside of the membership where societies exist want to come in and co-operate with us for the promotion of their own and the common welfare.

In most states many individual county societies have acted promptly in this matter, even without the leadership and concert of action so much needed, while in several states steps have been taken to secure uniform resistance to the injustice. The society of Pike County, Illinois, pledged its members to make no examinations for old line companies for less than $5, or for industrial or fraternal orders for less than $2 or $3, and has requested every other county society in the state to join in the movement. I have been present at meetings almost daily for four weeks where this request met with a most cordial response. A similar policy has been inaugurated in Kentucky and other states and can easily be made general, as the feeling is widespread, not only that the profession was most unjustly and unkindly treated in this matter, but that it was done in such a disdainful and discourteous manner that we can not submit to it without loss of prestige and dignity.

The requirements of medical examiners have always been exacting. It is now necessary that they should have had four years of special training and several years of practical experience before they are permitted to undertake this important duty. Their selection has always been made with care and from the highest class of the profession. This is eminently proper. Cheap and incompetent doctors are likely to prove as dangerous to the best interests of policy-holders in mutual insurance affairs as they have always been as family physicians. And now this large class of specially trained, selected and loyal men, without the common courtesy of notice or even so much as a "By your leave," are asked to submit to a uniform reduction of fees amounting practically to 40 per cent., as most examinations are for small policies. All this is done, too, under the specious and misleading plea of economy, under the leadership of such eminently worthy men as Mr. Paul Morton, who, without a day of training for his duties, was taken from a position of high honor, with a salary of $8,000, and put at the head of the Equitable on a salary of $80,000, and Messrs. Peabody and Orr, similarly lacking in special training, who have been made presidents respectively of the Mutual and New York Life on salaries of $50,000 each, the latter being equal to that paid to the President of the United States. These gentlemen succeeded to offices of which they are no doubt in every way worthy because of the scandal and popular outcry, never before equaled in the financial history of this country, at least partly due to the inordinate and disproportionate salaries paid their predecessors. On the false assumptions that their own compensation had been largely reduced, these still high salaried officials had scarcely warmed their new seats before they began to institute reforms at the expense of their medical subordinates, a popular and long-favored pastime with lay officials of almost every class. It is true that a reduction was made in other departments, in many of which there had been more or less scandal, of 20 per cent., but the medical department, against which, to the honor of our profession be it said, there has never come even a breath of suspicion, having no friends at court to make a plea for it, was summarily reduced 40 per cent. This would have been bad enough if our officials had been given a hearing in our behalf, but I submit that the manner in which it was all done was far more humiliating and hurtful than the financial loss and that it should provoke a manly and dignified resentment at the hands of every lover of his profession.

It is suggested that examiners who have not agreed to accept the reduction go on making examinations whenever requested to do, charging full fees in every instance, and bringing suit when not paid wherever legal service can be had on agents. It is advised that others who have formally accepted the reduction, under the impression that there would be no uniform resistance, write at once, recalling the same. Our friends are advised not to resign, but simply to "stand pat." In addition, it is urged that every medical man in this country begin at once, actively and persistently, to throw his influence to the Northwestern, Mutual Benefit, Massachusetts Mutual and other well-known and stable companies which have been more honestly and economically managed, and which have also refrained from this unkindness to our already underpaid profession.

If our friends are willing to give the time and trouble to this work which its importance demands, we can easily control the situation in several states and in a majority of counties in a few months, can demonstrate what organized medicine stands for in a small field, where no charity or sentiment is involved, and at the same time protect ourselves from injustice from other sources, and encouraged by what seemed would be our tame submission to this great wrong. It is almost equally important, while engaged in this work, to free our members once for all from the large and almost gratuitous work done for industrial and fraternal orders. This has been in the hands largely of the poorest and humblest in the profession, those least able to protect themselves, and for concerns which relatively sell insurance at the highest price. Their examination requirements are tedious and exacting, and we should insist that their fees be so regulated as to give our less fortunate brethren reasonable compensation.

It has been in my mind to suggest that examiners in every county in the United States secure the proxies of all policy-holders in their respective jurisdictions, in the name of the president, secretary or some designated representative of the Association, but it does not seem advisable to do this at present, if at all. It would be easy for the profession to become an important if not a determining factor in the reorganization of most of the companies. Our best interests and those of the policy-holders are mutual and inseparable. Old examiners have the names of all policy-holders in their respective jurisdictions on their ledgers, they know them personally, and on assurance that our representative will co-operate with the state insurance commissioners and others who are conservatively striving to free these corporations from the evils so long involving them, there should be no great difficulty in securing nearly every proxy in most counties. This would be greatly assisted by the fact that the legislature of New York has recently canceled all outstanding proxies and postponed the election of new directors until October. This is only a tentative suggestion which came into my mind, and it will not be pressed without the official sanction of the House of Delegates at Boston. It is important that all matters of grave concern like this should be managed in the broad, conservative and statesman-like way which will commend itself to all right-thinking people in and out of the profession.

State and independent journals are respectfully requested to give this a place in their columns, with such editorial comment as may be deemed proper. It is the duty of our organization, and especially of its official organs, intelligently and conservatively to guard every interest of the rank and file of the profession. The chief agency in doing this, and the source of all power for doing it, is in our system of county societies. Most of them have all the machinery ready at all times; they can be called together on short notice, and it is urged that they take such action everywhere as will best safeguard the rights and dignity of their members.

Speaking two or three times every day, and being on the road most of the time when not speaking, this communication has been prepared under great difficulties, and is very imperfect. I am not engaged in practice, will probably never make another insurance examination, and consequently have no personal interest in the matter. My reason for taking up the work was that I found our friends at sea about it, indignant and resentful, but without a plan for securing the concert of action so manifest in the policy of those who had visited this unnecessary and unmerited injustice on us, and after all, it

seemed to come more naturally to my department than any other. I found also that many of those to whom we are accustomed to look for guidance are busy men in other fields, not even indirectly connected with this interest, and hence it is difficult for them to appreciate its importance to the rank and file of the profession.

Since this was written it has been suggested by one of my best personal friends, who is equally interested in one of the great life insurance companies and our profession, that we ought to be estopped from resistance in this matter because we so long submitted to the same injustice from some of the other old line and all of the industrial and fraternal orders. As I have said, we were unorganized then and could only act as individuals. Whether old or new, acute or chronic the complaint is the same, and my suggestion is that the same remedy is indicated for all of the companies which have adopted this policy at any time, and that it be uniformly applied.

J. N. McCORMACK.

Marriages

WALTER W. HULL, M.D., to Miss Ruth Jones, both of Kearney, Neb., April 19.

LUCIAN DEMENT LEE, M.D., to Miss Nora Lawrence, both of Centre, Ala., May 1.

RALPH RAYBURN COBLE, M.D., to Miss Lucile Bowman, both of Spencer, Ind., April 23.

CHARLES L. RESONER, M.D., to Miss Marie Anderson, both of Hartford City, Ind., May 1.

HARRY K. CAREY, M.D., Philadelphia, to Miss Constance M. Beddoe of Bedford, Ind., April 26.

ALBERT SETTLE, M.D., Kansas City, Mo., to Miss Beatrice Norman of Lawton, Okla., April 25.

CHESTER HARLAN CLARK, M.D., Beloit, Wis., to LENNA EMELINE JONES, M.D., of Chicago, April 27.

GEORGE S. ARMSTRONG, M.D., Spokane, Wash., to Miss Mary Agnes Meeds of Zanesville, Ohio, April 25.

STEPHEN B. SIMS, M.D., to Mrs. Sarah Guernsey, both of Frankfort, Ind., at Los Angeles, Cal., April 21.

H. M. IMBODEN, M.D., Clifton Springs, N. Y., to Miss Edith Sprecher Grabill of Lancaster, Pa., April 20.

DAVID GALEN MCCAA, M.D., Lancaster, Pa., to Miss May Estella Yeiser of Meyerstown, Pa., April 25.

MARTIN F. M. HARMANN, M.D., St. Louis, to Miss Margaret Elizabeth Johnson of Charleston, Mo., April 17.

MAURICE OSTHEIMER, M.D., Philadelphia, to Miss Martha Gibson McIlvain of Downingtown, Pa., April 18.

ALBERT S. THOMPSON, M.D., Mount Horeb, Wis., to Miss Marie Anderson of Minneapolis, Minn., April 18.

DARWIN E. BROWN, M.D., Diamondville, Wyo., to Miss Margaret Anneta Greer of Fort Madison, Iowa, April 10.

JOSEPH GOLDBERGER, M.D., assistant surgeon, United States Public Health and Marine-Hospital Service, Washington, D. C., to Miss Mary Farrar of New Orleans, April 19.

Deaths

Rhoades Stansbury Sutton, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1865; surgeon to Terrace Bank Hospital for Women, Allegheny, from 1883 to the present date; chief surgeon of the Second Brigade, Third Division of the First Army Corps in the Spanish-American War; ex-president of the American Academy of Medicine, Mississippi Valley Medical Association, and Pittsburg Obstetrical and Gynecological Society; in 1884 chairman of the Section on Obstetrics and Gynecology of the American Medical Association; for many years vice-president of the American Gynecological Society and president of the Pittsburg Gynecological Society; member of the British Medical Association; British Gynecological Society, and International Gynecological Society; for a long time proprietor of a hospital in Allegheny, known by his name; eminent as a gynecologist and abdominal surgeon, and a frequent contributor to the medical journals, especially those connected with surgery and gynecology, died suddenly from heart disease on a street car in Pittsburg, April 21, aged 65.

John C. Pegram, Jr., M.D. Harvard University Medical School, Boston, 1897; of Providence, R. I.; a member of the American Medical Association, American Academy of Medicine, Massachusetts Medical Society, Rhode Island Medical Society, Amos Troop Medical Club, Providence Medical Association and Friday Evening Medical Club; medical examiner for the city of Providence; visiting surgeon to the Rhode Island Hospital; orthopedic surgeon to St. Joseph's Hospital and the Rhode Island Catholic Orphan Asylum; demonstrator of anatomy in Brown University; consulting surgeon to Butler Hospital for the Insane; assistant surgeon of the First Rhode Island Light Infantry, died at the Corey Hospital, Brookline, Mass., April 26, from complications following an operation for appendicitis, a week before, aged 34.

George W. Beggs, M.D. Rush Medical College, Chicago, 1862; major and surgeon of the One Hundred and Sixth Illinois Volunteer Infantry during the Civil War; a member of the Iowa State Medical Society, Woodbury County Medical Society, and Association of Military Surgeons of the United States; for many years local surgeon to the Illinois Central and Chicago, Milwaukee & St. Paul railways, and for ten years president of the Sioux City College of Medicine, died at his home in Sioux City, April 10, from kidney disease, after an illness of two years, aged 68.

David B. Devendorf, M.D. Geneva (N. Y.) Medical College, 1845; for fifty years a practitioner of Walworth County, Wis.; assistant surgeon of the First Wisconsin Volunteer Infantry; later surgeon of the Nineteenth Wisconsin Volunteer Infantry, then chief surgeon of the Fourth Brigade, Eighteenth Army Corps; medical inspector under General Smith, and finally medical purveyor of the Army of the James under General B. F. Butler; physician for the Deaf and Dumb School at Delavan, died at his home in that city, April 24, from senile debility, aged 86.

Daniel David Quillian, M.D. Atlanta (Ga.) Medical College, 1889; a member of the American Medical Association and the Medical Association of Georgia; for seven years sanitary inspector and attending physician to the Georgia State Normal School, Athens; one of the most prominent physicians of Clark County, Ga., died at his home in Athens, April 17, from pneumonia, after an illness of one week.

Charles Fred Moulton, M.D. Dartmouth Medical School, Hanover, N. H., 1890; assistant ophthalmic surgeon to the Boston City Hospital; member of the American Academy of Medicine and Massachusetts Medical Society; a member of the medical staff of the Massachusetts Eye and Ear Infirmary, died at his home in West Roxbury, Boston, from tubercular meningitis, April 24, aged 40.

Thomas Jacob Garrigan, M.D. New York University, Medical Department, 1879; a member of the Massachusetts Medical Society and one of the founders of the Brookfield Medical Club; for many years a selectman and member of the board of trade of North Brookfield, Mass., died at his home in that city, April 20, from valvular heart disease, aged 51.

Frank L. Tozier, M.D. Bellevue Hospital Medical College, New York City, 1896, of Batavia, N. Y.; formerly of Washburn, Maine; surgeon to the New York State School for the Blind, Batavia, and member of the Genesee County Medical Society, died at the German Deaconess' Hospital, Buffalo, April 21, after an operation for appendicitis.

Thomas T. Beveridge, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1862, for many years a member of the staff of St. Elizabeth Hospital, Appleton, Wis., of which he was one of the founders, died at his home in Appleton, April 20, from catarrhal pneumonia, after an illness of three weeks, aged 63.

William R. Marsden, M.D. New York University, Medical Department, New York City, 1881; a member of the Medical Society of New York, the Oneida County Medical Society, Utica Medical Library Association and Utica Medical Club, died at his home in Utica, April 25, from acute nephritis, aged 52.

Benjamin Henry Burrell, M.D. Eclectic Medical Institute, Cincinnati, 1878; of Boston; from 1882 to 1884 professor of anatomy and physiology in Bates College, Lewiston, Maine; a member of the Massachusetts Medical Society, died suddenly at the home of his daughter in Denver, Colo., April 23, aged 53.

Hallet W. Thompson, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1900, a member of the American Medical Association, and a young practitioner of great promise, died at his home in Plantersville, La., March 5, it is supposed, from poison, accidentally administered.

Lorenzo Dow Glazebrook, M.D. Rush Medical College, Chicago, 1857; deputy revenue collector for the Ninth district of

Indiana for three years; in 1872 and 1885 representative in the General Assembly, died at his home in Knox, Ind., after an illness of six months, from senile debility, aged 76.

Benjamin Pennebaker, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1872; for 13 years physician-in-chief of the House of Correction; physician to the County Prison, Holmesburg, and to the Frankford Arsenal, died at his home in Philadelphia, April 25, aged 66.

William N. Cline, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, for many years a practitioner of Illinois, died at his home in Rialto, Cal., Nov. 29, 1905, from prostatic hypertrophy and resultant kidney complications, after an illness of seven years, aged 84.

Edward W. Lane, M.D. Oglethorpe Medical College, Savannah, Ga., 1857; University of Louisville, Medical Department, 1859, of Butts, Ga.; once president of the Georgia Medical Association, and in 1890 and 1891 a state senator, died at the home of his son in Millen, Ga., April 15, aged 82.

Louis C. Blitz, M.D. University of Louisville, Medical Department, 1897, a member of the faculty of his alma mater and a member of the Louisville Academy of Medicine, died at the Jewish Hospital, Louisville, April 25, from meningitis following an operation for mastoiditis, aged 34.

John Fruit, M.D. Jefferson Medical College, Philadelphia, 1881, physician in charge of the Hazelton (Pa.) Hospital during the smallpox epidemic, 1891, died at his home in Hazelton, April 16, from carcinoma of the stomach, after an illness of eight months, aged 46.

Jacob C. Spohn, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1868, for forty years a practitioner of Rochester, Ind., but for the last ten years in St. Louis, died in a hospital in that city, April 19, after a surgical operation, aged 66.

Hugh W. McReynolds, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1848, for many years a prominent physician of Bloomsburg, Pa., and for one term treasurer of Columbia County, died at his home in Bloomsburg, April 25, aged 84.

Mauricio Flores y Fernandez, M.D. Howard University, Medical Department, Washington, D. C., 1903; a native of Havana, Cuba; a member of the Dauphin County Medical Society, died at his home in Harrisburg, Pa., February 2, from heart disease, aged 40.

Aaron J. Bates, M.D. Indiana Medical College, Indianapolis, 1873, a veteran of the Civil War, and for several years a member of the pension board of Kokomo, Ind., died at his home in that city, April 24, from pneumonia, after an illness of two days, aged 59.

Charles H. Tilghman, M.D. University of Maryland School of Medicine, Baltimore, 1866, a surgeon in the service of the Red Cross Society during the Franco-German War, died suddenly at his home in Baltimore, April 25, from angina pectoris, aged 60.

T. L. H. Cook, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1880, of Artesia, Miss., who was brought to Columbus, Miss., April 14, suffering from alcoholic insanity, died suddenly in the Columbus jail, April 17.

Charles Bradley, M.D. Jefferson Medical College, Philadelphia, 1875, formerly president of the Norristown board of health and coroner's physician of Montgomery County, Pa., died at his home in Norristown, April 25, aged 58.

Orrin F. Burroughs, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1869, a practitioner of Galesburg, Mich., for nearly fifty years, died at his home in that place, April 16, from senile debility, aged 79.

Joseph Hedges, M.D. College of Physicians and Surgeons in the City of New York, 1853, a member of the Medical Society of the State of New Jersey, died at his home in Newton, N. J., April 14, after a protracted illness, aged 76.

Charles W. Hilton, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1887, a member of the Tri-State Medical Society, died at his home in Monroe, La., April 20, after an illness of three weeks, aged 44.

Frank Donaldson, M.D. University of Maryland School of Medicine, Baltimore, 1883, of Los Angeles, Cal., for a time acting assistant surgeon, United States Army, died at San Francisco, April 12, from consumption, aged 49.

James M. Young, M.D. University of Louisville, Medical Department, 1860, surgeon in the Confederate service throughout the Civil War, died at his home in Bloomfield, Ky., April 19, after a lingering illness, aged 69.

Isaac Farrar, M.D. University of Vermont, Medical Department, Burlington, 1862, for thirty-five years a well-known lecturer, died at his home in Dorchester, Boston, April 23, after a lingering illness, aged 76.

Charles Miller Booth, M.D. Vermont Medical College, Woodstock, 1851, a noted expert on microscopy and botany, of Rochester, N. Y., died at his home in that city, January 8, from senile debility, aged 75.

Samuel L. Marston, M.D. Rush Medical College, Chicago, 1863, assistant surgeon of the Twelfth Wisconsin Volunteer Infantry during the Civil War, died at his home in Hartford, Wis., April 22, aged 78.

James Lindsay Trader, M.D. Jefferson Medical College, Philadelphia, 1871, twice coroner of Fayette County, Pa., died at his home in Connellsville, April 23, from cerebral hemorrhage, aged 59.

Israel T. Buckbee, M.D. Albany (N. Y.) Medical College, 1841, a member of the New York State Medical Society for 45 years, died at his home in Fonda, N. Y., April 25, aged 86.

Daniel B. Wise, M.D. Cleveland College of Physicians and Surgeons, 1874, died suddenly at his home in Mount Eaton, Ohio, April 16, from valvular heart disease, aged 55.

Emil Hertel, M.D. Jefferson Medical College, Philadelphia, 1883, died at his home in Wilmington, Del., from chronic fibroid pneumonia, after an illness of two years, aged 50.

George Owen Willis, M.D. Royal College of Physicians, Edinburgh, Scotland, 1876, died suddenly in his apartment, in Grass Valley, Cal., April 14, from cirrhosis of the liver.

Samuel C. Allaband, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1865, died at his home in Philadelphia, Sept. 18, 1905, aged 63.

Caroline M. Niemann, M.D. Hering Medical College and Hospital, Chicago, 1900, died at her home in Chicago, Aug. 22, 1905, from pulmonary tuberculosis, aged 37.

Robert S. Peyton, M.D. Jefferson Medical College, Philadelphia, 1852, died at his home in Pinckneyville, Ill., Jan. 16, 1905, from cancer of the stomach, aged 75.

William W. Pierce, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1876, died at his home in Findlay, Ill., Aug. 17, 1905, from hepatic colic, aged 71.

Preston Minor, M.D. University Medical College of Kansas City, 1900, died at his home in Sheridan, Wyo., April 20, from typhoid fever, aged 34.

Thomas H. Johnson, M.D. Cincinnati College of Medicine and Surgery, 1854, died at his home in Clarksburg, Ind., April 22, after an illness of several weeks, aged 79.

Amos G. Driver, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1899, died at his home in Carrollton, Ill., January 30, aged 29.

Ida Dole Nicholson, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1899, died at her home in Los Angeles, Cal., Jan. 1, 1905, aged 42.

Charles M. Shiltneck, M.D. College of Physicians and Surgeons, Baltimore, 1880, died at Burkittsville, Md., April 24, from internal hemorrhage, aged 46.

J. G. Porter, M.D. Chicago Homeopathic Medical College, 1899, of Clinton, Ill., died in Hahnemann Hospital, Chicago, April 24, after a surgical operation.

William T. Roberts, M.D. Harvey Medical College, Chicago, 1905, died at his home in that city from rupture of an aortic aneurism, Sept. 17, 1905, aged 30.

Granville, I. Smart, M.D. Dartmouth Medical College, Hanover, N. H., 1880, formerly of Blue Earth, Minn., died recently at his home in Ontario, Cal.

Herman Kirschstein, M.D. University of Breslau, Germany, 1862, one of the oldest German physicians of Chicago, died at his home, April 29, aged 77.

John E. Coyle, M.D. University of Tennessee, Medical Department, Nashville, 1892, formerly of Paducah, Ky., died recently at Wewaka, I. T.

Thomas P. Lark, M.D. Rush Medical College, Chicago, 1871, died at his home in Ruma, Ill., Aug. 8, 1905, from valvular heart disease, aged 63.

Elkanah Alonzo Thoman, M.D. Eclectic Medical Institute, Cincinnati, 1875, of Bucyrus, Ohio, died at his home in Los Angeles Cal., April 25.

Edwin J. Bertenshaw, M.D. Miami Medical College, Cincinnati, 1893, of Elk City, Kan., died recently at Bartelsville, Kan., aged 37.

E. Collins Blaisdell, M.D. Albany (N. Y.) Medical College, 1858, died at his home in Quincy, Ill., Dec. 22, 1905, from paralysis.

Daniel P. Dailey, M.D. Hospital College of Medicine, Louisville, 1890, died at his home in Birds, Ill., Aug. 16, 1905, aged 48.

Colmore Harris, M.D. (Years of Practice, Illinois), 1878, died at his home in Boos Station, Ill., May 7, 1905, from tumor, aged 77.

Franz Baeumer, M.D. American Medical College, St. Louis, 1875, died at his home in New Athens, Ill., in January, aged 64.

Frank W. Gross, M.D. Eclectic Medical Institute, Cincinnati, 1860, died at his home in Chrisman, Ill., Jan. 28, 1905, aged 69.

George W. Hyde, M.D. Eclectic Medical Institute, Cincinnati, 1876, died at his home in Clinton, Ill., Sept. 5, 1905, aged 76.

John W. Rawlins, M.D. Medical College of Indiana, Indianapolis, 1888, died at his home in Jewett, Ill., February 4.

D. M. Stewart, M.D. Iowa Medical College, Keokuk, 1869, died at his home in Denton, Texas, April 19, aged 81.

William H. Phillips, M.D. (Years of Practice, Pennsylvania), died at his home in California, Pa., April 22, aged 67.

George Shamhart, M.D. (Years of Practice, Illinois), 1877, died at his home in Latona, Ill., January 24, aged 84.

Job Sweet, M.D. (Years of Practice, Massachusetts), died at his home in New Bedford, Mass., April 22, aged 78.

Francis McGuire, M.D. Rush Medical College, Chicago, 1868, died recently at his home in St. Cloud, Minn.

Jacob F. Stough, M.D. (Examination, Ohio), died at his home in Warren, Ohio, April 14, aged 73.

Death Abroad.

Lionel Smith Beale, M.B. London, 1851; M.R.C.P. London, 1856; F.R.C.P. London, 1859; Baly Medal R.C.P. 1871 Croonian Lecturer, Royal Society, 1865; Lumleian Lecturer, R.C.P., 1875, has died in London from pontine hemorrhage, aged 78. In 1896 he had a slight attack of cerebral hemorrhage or thrombosis. Born in London, the son of a doctor, he was educated at King's College. His career was remarkable. A year after taking his degree he established a private chemical and microscopic laboratory for teaching and original research. In 1853, though only 25 years of age, he was appointed professor of physiology and general and morbid anatomy at King's College, a post for which the late Professor Huxley was a candidate. He soon established a reputation as a learned and lucid teacher. He was a great worker and incessantly wrote papers for the Royal Society on original microscopic investigations. At the age of 25 he published the first edition of his most successful book, "How to Work with the Microscope." He afterward published a work, "The Microscope in Medicine." He was constantly engaged in controversies with those who sought to give a purely physical explanation of the phenomena of life, and in his book on "Protoplasm of Life, Matter and Mind," strenuously maintained that vital action transcended physical and chemical phenomena. In 1876 he was appointed professor of principles and practice of medicine and was made consulting physician to King's College Hospital. He soon established a reputation as a practical physician and his powers are shown in his most useful work, "Slight Ailments: Their Nature and Treatment." He possessed an extraordinary power of diagnosis by facies. At the age of 29 he received the great distinction of fellowship in the Royal Society. Of the many papers he read at the society perhaps the most important was on "The Ultimate Nerve Fibers Distributed to the Muscles and to Some Other Tissues." His publications on clinical medicine were numerous. They included books on "The Liver," "Kidney Diseases, Urinary Deposits and Calculi," "The Mystery of Life," "Our Morality and the Moral Question."

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

THE AUTOMOBILE FOR THE PHYSICIAN'S USE

DR. I. J. KERR, Cleveland, O., writes: "I have read your articles on 'Automobiles for Physicians,' and find them very valuable, giving the opinions of so many men from their various standpoints and in their different locations. I think you have conferred a great favor on the physicians of the United States in collecting and publishing these series of opinions. I am especially interested now in the subject of purchasing an automobile."

DR. ROBERT ALGIE, Lima, Kan., writes: "I have had a good deal of trouble, especially with tires. I notice that Dr. Collins speaks of four-inch solid tires. Now I want something of that kind. All of the solid tires I have seen listed are smaller than pneumatics, and as my wheels are very low, I want something that will, if possible, make them higher."

DR. J. D. SOUTHARD, Fort Smith, Ark., says: "I predict that this issue of THE JOURNAL will increase the sale of autos more than any other one thing that has ever happened. Thank you for taking the matter up in the splendid way you did."

DR. E. P. STIMSON, Tiverton, R. I., writes: "Since your announcement that you would issue an automobile number I have been looking forward to it to learn whether I should purchase an auto or not. There is one point which was not, as I noticed, touched on: If business slacks up and you do not have full draft on your horses, the expense goes on just about the same for food, while if the auto is idle, it costs only interest on investment."

DR. AUGUSTUS A. ESHNER, Philadelphia, writes: "I want to congratulate you on your automobile number. I am sure it will be instructive to many who are undecided or are novices. I shall try to interest the agent for the sale of the machine I have, with the hope of securing special interest for cars for medical men You should now be able to obtain a generous amount of advertising from automobile manufacturers, for physicians are good patrons, and the market is a constant one for a good and needed article."

DR. A. G. COUMBE, Vienna, Va., writes: "I congratulate you on the issue of April 21, as the motive power for physicians is of the greatest importance to us all, and the auto must receive our consideration. I have used a car for two years with more or less unsatisfactory results—not so much the car refusing to work, but the dirt and grease which I am compelled to get on my hands when I get caught, which has prevented me from operating frequently."

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending April 28, 1906:

Powell, Wm. A., asst.-surgeon, left Jefferson Barracks, Mo., for St. Louis, to accompany medical supplies to, and for temporary duty at San Francisco.

Butcher, B. H., asst.-surgeon, reported for temporary duty at Army General Hospital, Washington Barracks, D. C.

Gilchrist, H. L., and Davis, Wm. T., asst. surgeons, left General Hospital, Washington Barracks, D. C., with Co. A, Hospital Corps, en route to San Francisco, for temporary duty.

Chidester, W. C., asst. surgeon, leave of absence extended to June 5, 1906.

Hathaway, L. M., asst.-surgeon, left Fort Thomas, Ky., en route to St. Louis, for duty with medical supplies to and for temporary duty at San Francisco.

Hoff, John Van R., asst.-surgeon-general, and Johnson, R. W., surgeon, appointed members of an Army retiring board, to meet at the call of the president of the board, for the examination of such officers as may be ordered before it.

Bevans, James L., asst. surgeon, granted ten days' leave of absence to take effect on the completion of his examination for advancement.

Byars, Caspar R., contract surgeon, relieved from duty at Fort Sam Houston, Texas, and ordered to Jefferson Barracks, Mo., for duty.

Newton, Ralph W., contract surgeon, ordered to duty with troops in the Yosemite National Park.

Wing, Franklin F., dental surgeon, left Fort Omaha, Neb., and arrived at Fort Washakie, Wyo., for duty; is ordered thence to Fort Robinson, Neb., and Fort Meade, S. D., and thence will return to Fort Riley, Kan.

Koyle, Fred T., contract surgeon, returned to Fort Bliss, Texas, from leave of absence.

McMillan, Clemens W., contract surgeon, left Fort Michie, N. Y., and arrived at Fort Crook, Neb., for duty.

Porter, Elias H., Grieger, Hubert, Hogan, David D., contract surgeon, arrived at San Francisco, April 26, on transport *Sherman*, for leave of absence from the Philippines Division.

Tuttle, George B., contract surgeon, arrived at San Francisco, April 26, on transport *Sherman*, for station in the United States.

Springwater, Samuel A., contract surgeon, arrived at San Francisco, April 26, on transport *Sherman*, for annulment of contract.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending April 28, 1906.

Old, E. H. H., asst.-surgeon, detached from the Naval Medical School, Washington, D. C., and ordered to the Naval Training Station, San Francisco.

Cordeiro, F. J. B., surgeon, discharged from treatment at the Naval Hospital, New York, and ordered to Washington, D. C., May 2, for examination in conformity with Title 15, Chapter 3, Revised Statutes, and thence home to wait orders.

Hoyt, R. E., P. A. surgeon, detached from the Naval Academy and ordered to the *Newark*.

Reed, E. C., asst surgeon, ordered to the *Charleston*, May 1.

Dessez, P. T., asst. surgeon, detached from the *Charleston* and ordered to the *Severn*.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending April 25, 1906:

Nydegger, J. A., P. A. surgeon, granted seven days' leave of absence, from April 23, under the provisions of Paragraph 191 of the Regulations.

Blue, Rupert, P. A. surgeon, relieved from special temporary duty at Reedy Island Quarantine, and directed to report in Washington, D. C.

Blue, Rupert, P. A. surgeon, temporarily relieved from duty at Norfolk, Va., and from temporary duty in the Hygienic Laboratory in Washington, and directed to proceed to San Francisco for special temporary duty, on completion of which to rejoin temporary station at Washington, D. C.

Oakley, J. H., P. A. surgeon, directed to proceed from Port Townsend Quarantine Station, Port Townsend, Wash., to San Francisco, Cal., reporting to the medical officer in command for temporary duty.

King, W. W., P. A. surgeon, directed to proceed to Missoula, Mont., for special temporary duty, on completion of which to rejoin station in Washington, D. C.

McCoy, G. W., P. A. surgeon, relieved from duty in the Philippine Islands, and directed to return to the United States, reporting arrival in San Francisco by wire.

Burkhalter, J. T., P. A. surgeon, granted leave of absence for seven days under Paragraph 191 of the Regulations.

Burkhalter, J. T., P. A. surgeon, granted seven days' extension of leave of absence under Paragraph 191 of the Regulation.

Ebert, H. G., asst.-surgeon, directed to proceed from Seattle, Wash., to San Francisco, reporting to the medical officer in command for temporary duty.

Steger, E. M., asst.-surgeon, granted leave of absence for one month and twenty-three days, from May 17, 1906.

Goldsborough, B. W., acting assistant surgeon, granted leave of absence for three days, from April 24, 1906.

Hamilton, H. J., acting asst.-surgeon, granted leave of absence for five days, from April 25, 1906.

Nute, A. J., acting asst.-surgeon, transferred from Port Huron, Mich., to Ellis Island, N. Y.

Schug, F. J., acting asst.-surgeon, granted leave of absence for 15 days, from May 3, 1906.

Watters, M. H., pharmacist, directed to proceed to San Francisco, Cal., reporting to the medical officer in command for temporary duty.

McBride, Charles R., pharmacist, relieved from duty at Manila, P. I., and directed to proceed to Cebu Quarantine Station, reporting to the medical officer in command for duty and assignment to quarters.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended April 27, 1906:

SMALLPOX—UNITED STATES.

Arkansas: Fort Smith, April 7-14, 2 cases.
California: Los Angeles, April 7-14, 5 cases.
Delaware: Wilmington, April 7-14, 2 cases.
Georgia: Augusta, April 9-23, 6 cases.
Illinois: Chicago, April 14-21, 2 cases.
Indiana: Indianapolis, April 15-22, 6 cases.
Louisiana: New Orleans, April 7-14, 21 cases (8 imported).
Maryland: Baltimore, April 14-21, 2 cases.
Michigan: Detroit, April 14-21, 2 cases.
New Jersey: Jersey City, April 15-22, 1 case; Passaic County, to April 10, 75 cases.
New York: Middletown, April 24, 4 cases; New York, April 14-21, 2 cases.
Ohio: Cincinnati, April 13-20, 17 cases.
Oregon: General, March 1-31, 23 cases.
Pennsylvania: Pittsburg, April 7-14, 1 death.
Tennessee: Memphis, April 7-14, 16 cases.
Texas: Houston, April 14-21, 4 cases.
Utah: General, March 1-31, 157 cases.
West Virginia: Wheeling, April 14-21, 3 cases.
Wisconsin: Appleton, April 14-21, 3 cases; Marinette, April 7-14, 4 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, March 3-10, 4 cases, 1 death.

SMALLPOX—FOREIGN.

Africa: Cape Town, March 3-17, 18 cases.
Brazil: Bahia, March 3-24, 20 cases, 3 deaths; Pernambuco, March 1-15, 11 deaths.
Canada: Toronto, March 24-April 14, 10 cases.
Chile: Antofagasta, April 10, 14 cases, 6 deaths; Coquimbo, 12 cases, 4 deaths; Iquique, March 17-24, 8 cases, 4 deaths.
China: Hongkong: March 3-10, 13 cases, 11 deaths; Shanghai, 2 deaths.
Ecuador: Guayaquil: March 31-April 7, 5 deaths.
Germany: Stettin, March 30, 3 cases, 1 death.
Gibraltar: April 1-8, 2 cases.
Great Britain: Bristol, March 31-April 7, 2 cases; Liverpool, 1 case.
Greece: Athens, March 23-30, 1 death.
India: Bombay, March 20-27, 22 cases; Calcutta, March 10-17, 140 deaths; Karachi, March 18-25, 42 cases, 18 deaths; Madras, March 17-23, 40 deaths; Rangoon, March 10-17, 69 deaths.
Mexico: Tuxpam, April 4-11, 1 death.
Russia: Moscow, March 17-31, 49 cases, 4 deaths; St. Petersburg, March 24-31, 3 cases, 2 deaths.
Straits Settlements: Singapore, March 14, epidemic.
Turkey: Alexandretta, March 24-31, 1 case, 1 death.

YELLOW FEVER—FOREIGN.

Ecuador: Guayaquil, March 31-April 7, 23 deaths.

CHOLERA—INSULAR.

Philippine Islands: Provinces, Feb. 24-March 10, 139 cases, 113 deaths.

CHOLERA—FOREIGN.

India: Bombay, March 20-27, 802 deaths; Calcutta, March 10-17, 32 deaths.

PLAGUE—FOREIGN.

Australia: Brisbane, March 10, 1 case.
Chile: Antofagasta, March 19-April 2, 5 cases.
China: Hongkong, March 3-10, 15 cases, 10 deaths.
India: Bombay, March 20-27, 802 deaths; Calcutta, March 10-17, 134 deaths; Karachi, March 18-25, 68 cases, 59 deaths; Madras, March 17-23, 1 death; Rangoon, March 10-17, 65 deaths.
Peru: Callao, March 6-April 1, 2 cases, 1 death; Chiclayo, 4 cases, 3 deaths; Eten, 2 cases, 2 deaths; Lambayeque, 1 case, 2 deaths; Mansefu, 2 cases; Mollendo, 5 cases, 1 death; Paita, 10 cases; Pisco, 1 case, 2 deaths; Reque, 11 cases, 5 deaths; Trugillo, 49 cases, 17 deaths.

Society Proceedings

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, Boston, June 5-8.

Oklahoma Medical Association, Oklahoma City, May 8.
Indian Territory Medical Association, Oklahoma City, May 8.
Utah State Medical Association, Salt Lake City, May 8-9.
Nevada State Medical Society, Reno, May 8-9.
Louisiana State Medical Society, New Orleans, May 8-10.
Arkansas Medical Society, Hot Springs, May 8-10.
Montana State Medical Association, Butte, May 9-10.
Kansas Medical Society, Topeka, May 9-11.
Ohio State Medical Association, Canton, Ohio, May 9-11.
American Climatological Assn., Atlantic City, N. J., May 12-14.
American Assn. of Physicians, Washington, D. C., May 15-16.
Missouri State Medical Association, Jefferson City, May 15-17.
Iowa State Medical Society, Des Moines, May 16-18.
North Dakota State Medical Association, Fargo, May 16-17.
New Hampshire Medical Society, Concord, May 17-18.
Amer. Assn. of Path. and Bacteriologists, Baltimore, May 18-19.
American Gynecological Society, Hot Springs, Va., May 22.
Illinois State Medical Society, Springfield, May 15-17. (Note change of time back to date originally planned.)
Connecticut State Medical Society, New Haven, May 23-24.
Indiana State Medical Association, Winona Lake, May 23-25.
Michigan State Medical Society, Jackson, May 23-25.
Med. Soc. of State of North Carolina, Charlotte, May 29-31.
Rhode Island Medical Society, Providence, May 31.
American Dermatological Assn., Cleveland, May 30-June 1.
American Pediatric Society, Atlantic City, May 30-June 1
American Surgical Association, Cleveland, May 30-June 1.
American Laryngological Assn., Niagara Falls, May 31-June 2.
American Assn. of Genito-Urinary Surgeons, New York, June 1-2.
American Academy of Medicine, Boston, June 2-4.
Amer. Assn. of Life Insurance Exam. Surgeons, Boston, June 4.
American Gastro-Enterological Assn., Boston, June 4.
American Urological Assn., Boston, June 4-5.
American Proctologic Society, Boston, June 5-6.
American Medico-Psychological Society, Boston, June 12-15.
Massachusetts Medical Society, Boston, June 12-13.
Maine Medical Association, Portland, June 13-15.
Minnesota State Medical Association, Minneapolis, June 20.
West Virginia State Medical Assn., Webster Springs, June 20-22.

MEDICAL AND CHIRURGICAL FACULTY OF MARYLAND.

The 108th Annual Meeting, held at Johns Hopkins University, Baltimore, April 24-26, 1906.

The President, DR. SAMUEL T. EARLE, in the Chair.

Society in Good Condition.

The reports showed that the society is in a flourishing condition financially. It possesses a library of 15,275 volumes, valued at $45,000, and portraits worth $5,000. Funds for the purchase of new books are provided by the Frick fund, the Baker fund, and the Book and Journal club. The library was used by a large number of people during the year and many duplicate volumes were given away to help other libraries. There are at present 921 members, of whom 434 are country members and 495 Baltimore members. During the year there were 8 deaths. The fund for the relief of widows and orphans of deceased members now amounts to $918.56; during the year one appropriation was made in the case of an aged widow whose only support was a son who was ill with typhoid fever.

Advocate Improved Medical Laws.

The secretary of the State Board of Medical Examiners reported that the answers to questions asked at the state board

examination showed a lack of proper training in the candidates. Resolutions were passed approving the minimum standard of requirements adopted by the American Medical Association, in July, 1905, and directing the committee on legislation to arrange for such changes in the medical laws of the state, to be presented at the next meeting of the legislature, as shall bring the laws into full conformity with these requirements. A committee was appointed to investigate the dispensary abuse and to devise ways of correcting it.

Approve Movement for Pharmaceutic Reform.

A resolution was also passed endorsing the action of the American Medical Association in establishing a Council on Pharmacy and Chemistry for the investigation of non-official drugs, endorsing the plan of action proposed by the council, and approving the change in the advertising columns of THE JOURNAL of the American Medical Association, and expressing the hope that THE JOURNAL will soon be free of all advertisements which may in any sense be considered objectionable.

Message of the President.

In his presidential address, Dr. Earle spoke of the imperative need of organization, and said that only a beginning has been made. He said that efforts should be made to have every physician in the state in the organization, and that the conditions of entrance should not be too rigid, but that every honorable and upright physician should be welcome, no matter what his sentiments. Dr. Earle urged allegiance to the profession and care in the selection of officers generally.

The Role of Pure Cow's Milk in Infant Feeding.

The annual oration was delivered by Dr. Jacobi. He stated that cow's milk is not a proper substitute for mother's milk, and no matter how it is modified it can never become so. He called attention to the fact that there was no artificial feeding in antiquity; artificial feeding of infants was first practiced, so far as we know, in 1500 A. D. It is only, he said, when a woman has no milk that the use of modified cow's milk is permissible, and only then when the more appropriate asses' milk is not obtainable. He mentioned in some detail the various disorders arising from a diet of cow's milk in young infants and the sequels to be expected such as rickets and allied conditions. He spoke of the advantages of buttermilk and said that too great uniformity in food is not to be desired. He urged the use of cane sugar in preference to milk sugar in the preparation of the cow's milk mixtures and dwelt strongly on the importance of copious dilution of the food, stating that this is best effected by the addition of cereal decoctions in place of mere water. He also referred to methods of preparing infant foods.

(To be continued.)

AMERICAN CONFEDERATION OF RECIPROCATING, EXAMINING AND LICENSING BOARDS.

Meeting held at Columbus, Ohio, April 25, 1906.

The President, DR. W. A. SPURGEON, in the Chair.

Report of Secretary.

The secretary, Dr. B. D. Harison, reported that the following states are members of the confederation: Ohio, South Carolina, New Mexico, District of Columbia, Wisconsin, Iowa, Kentucky, Indiana, Nebraska, Michigan, Georgia, Illinois, Kansas, Maryland, Oklahoma, Nevada and North Dakota.

The following states reciprocate under Qualification I: Illinois, Ohio, New Jersey, North Dakota, Virginia, Wyoming, South Carolina. Under Qualification II: Michigan, Wisconsin, Indiana, Iowa, Kansas, Nebraska, Maryland, Minnesota, Vermont, Missouri, Nevada, Maine, Georgia, District of Columbia. A number of these states are not members of the confederation, but have adopted its basis of reciprocal registration.

During the past year 699 reciprocal registrations were made by 12 of the states from which a report was obtained. Of this number 147 were issued under Qualification II and 452 under Qualification I. No report was received from 10 other reciprocating states.

Report of Committee on Modifications in Reciprocal Qualifications.

The committee recommended the substitution of the following for the requirements now in force:

PREREQUISITE CREDENTIALS.

As a prerequisite to reciprocal registration the applicant therefor shall file, in the offices of the boards of the state of which he is a licentiate and of the state where reciprocal registration is sought, such evidence of good moral and professional character as may be demanded by said boards, and such evidence, at the discretion of either board, may include proof of membership in a recognized medical society, and such membership may be considered in connection with the other evidences of character presented.

QUALIFICATION I.

A certificate of registration showing that an examination was less than that prescribed by the state in which an average grade of not less than 75 per cent. was awarded, the holder thereof having been at the time of said examination the legal possessor of a diploma from a medical college in good standing in the state where reciprocal registration is sought, may be accepted, in lieu of examination, as evidence of qualification. Provided, that in case the scope of the said examination was less than that prescribed by the state in which registration is sought, the applicant may be required to submit to a supplemental examination by the board thereof in such subjects as have not been covered.

QUALIFICATION II.

A certificate of registration, or license issued by the proper board of any state, may be accepted as evidence of qualification for reciprocal registration in any other state. Provided, the holder of such certificate had been engaged in the reputable practice of medicine in such state at least one year, and also provided that the holder thereof was, at the time of such registration, the legal possessor of a diploma issued by a medical college in good standing in the state in which reciprocal registration is sought, and that the date of such diploma was prior to the legal requirement of the examination test in such state.

The report was adopted.

Report of Committee on Uniform Entrance and Graduation Requirements.

The committee recommended as a substitute for the requirements adopted at Indianapolis, April 17, 1905, that, after July 1, 1906, the minimum requirement for registration in a medical college shall be a recognized diploma for a four-year high-school, college, academy or university, or a recognized equivalent certificate, such diploma or certificate having the following minimum standard: Academic work and examinations, 60 counts (a count represents one recitation a week for the school year). Required, 30 counts (after 1906, 35 counts), as follows: English, 10 counts; mathematics, 10 counts; Latin, 5 counts (10 counts after 1906); physics, 5 counts. Elective, 30 counts (after 1906, 25 counts), be chosen from the following: English, 10 counts; French, 10 counts; German, 10 counts; Spanish, 10 counts; Greek, 10 counts; drawing, 3 counts; history, including civics, 10 counts; botany, 5 counts; zoology, 5 counts; biology, 5 counts; chemistry, 5 counts; trigonometry, 2 counts; physical geography, 5 counts; physiology and hygiene, 5 counts. Conditions may be allowed not to exceed a total of 15 counts.

The report was adopted.

Report of Committee on Advanced Standing.

The committee suggested that the first clause of the present requirements be amended to read as follows:

Graduates holding degrees of A.B., B.S., or equivalent qualifications from a reputable college or university may be given credits not exceeding one year. Provided that the applicant for such credit shall produce evidence which will satisfy the state board of medical examiners of the state in which such credit is asked that he has done within 10 per cent. of all the work embraced in the minimum standard of requirements of the confederation in the following subjects: Histology, embryology, osteology, anatomy, physiology, chemistry and toxicology and bacteriology; and provided that any literary college which shall undertake this work shall in its catalogue announce the fact that it will give this first year of the medical course.

The report was adopted.

Primary Examination.

The following resolution was offered by the Ohio Board:

Resolved, That a certificate issued by a board covering credits received in a primary or junior examination held by said board may be received and given credit by the board of another state; provided that the primary examination shall only include the following subjects which must have been completed to the end of the second year, at least, in a recognized medical college in accordance with the standard medical curriculum of the confederation: Anatomy, physiology, chemistry and toxicology, histology, embryology and bacteriology.

The resolution was adopted.

Report of Committee on Uniformity of Forms.

The committee recommended a uniformity in reciprocal license applications blanks, and that the following require-

ments at least be considered essential: (a) A question which will reveal the past conduct and proposed attitude toward engaging in itinerant practice or objectionable advertising business. (b) A comprehensive physical description sworn to by the applicant and endorsed by those who make affidavits, as to his moral and professional standing; affidavits by applicant to be positive instead of "to the best of his knowledge and belief." Intended residence not necessarily required. (c) A certified copy of license which is used as a basis for reciprocity. (d) A detailed statement of preliminary and medical college education.

The report was adopted.

President's Address.

The president, in his closing address, emphasized the point that the work of the confederation was purely educational, and its resulting standards, qualifications and regulations were merely suggestive and intended as a guide and in the interest of uniformity rather than mandatory on boards who held membership in the confederation. The boards, however, were naturally expected to live up to the ideals of the confederation in as far as their laws and local conditions permitted. He acknowledged the indebtedness of the confederation to the very valuable assistance rendered by the Ohio State Medical Board, the Faculty of the Ohio State Medical University, and the visiting deans of other medical colleges throughout the country in contributing to the success of the meeting by their presence and advice. He also especially referred to the great assistance rendered the confederation by Prof. Charles F. Wheelock, representing the New York Board of Regents, and Dr. Fred C. Zapffe, Secretary Association American Medical Colleges.

Officers Elected.

The present officers were re-elected for the ensuing year: President, Dr. W. A. Spurgeon, Muncie, Ind.; secretary, Dr. B. D. Harison, Detroit.

MEDICAL ASSOCIATION OF GEORGIA.

Fifty-seventh Annual Meeting, held at Augusta, April 18-20, 1906.

The President, DR. W. Z. HOLLIDAY, Augusta, in the Chair.

(*Continued from Page 1292.*)

Is There a Continued Fever Other than Malarial or Typhoid?

DR. J. W. PALMER, Ailey, said that from a clinical standpoint he believes all questionable cases of continued fever are a variety of mild, uncomplicated cases of typhoid fever, except occasionally they may be malarial.

The General Practitioner as a Factor in Surgery.

DR. R. R. KIME, Atlanta, said the physician bears a threefold relation to surgery. The first, and most important, is the prevention of the necessity for surgery. Second, the physician may be a causative factor in developing directly or indirectly conditions that require operative procedures. Third, the physician is often called on to use his judgment and advise his patient either for or against operative procedures. To secure the best results and place surgery and medicine on a higher scientific basis, the work of the physician and surgeon should be more closely associated and combined with that of the anatomist, the physiologist, and the pathologist.

Suprarenal Tuberculosis.

DR. WILLIAM CLIFTON LYLE, Augusta, reported a case of Addison's disease which came to postmortem. The special points were the freedom of the sclerotics and roots of the nails from pigment; the dark lines at the juncture of the skin and mucous membrane of the lips and in the creases of the palms. The hemophilia, acetonuria, the atrophy of the suprarenals, uncommon in persons of that age (55), and the decided improvement consequent to the administration of suprarenal substance. In this disease, even when marked improvement takes place, the patient's life, owing to the abolished function of the suprarenal glands, is extremely precarious, and all patients who have greatly improved or apparently recovered, should lead inactive lives. They should be warned that they are not cured; that the morbid conditions are still present, and that any overexertion or undue exposure liable to depress the heart may be attended with grave danger.

Intussusception.

DR. MARION M. HULL, Atlanta, believes that early operation is the only rational treatment. High irrigation may be used with advantage to aid in reducing the intussusception.

Appendicitis.

DR. FLOYD W. MCRAE, Atlanta, presented some general observations and statistics up to date regarding this disease. He emphasized the point that appendicitis is first, last and all the time a surgical disease, though not always under all conditions an operative one. Early diagnosis and prompt surgical intervention in all cases will reduce the mortality to less than 2 per cent.

Needed Legislation on Pure Food Laws for Georgia.

DR. O. H. BUFORD, Cartersville, said that it devolves on the medical profession to educate the masses to see the importance of having wholesome food to build strong bodies, so that they may withstand the inroads of disease. The medical profession of the state can wield great power for good if they would realize that they are the watchmen on the towers. The author made an eloquent plea for more stringent laws with regard to pure food.

DR. O. L. HOLMES, Covington, reported a case of vaginal sarcoma in an infant, seven months of age. He presented a study of all similar cases found in the literature.

DR. C. R. ANDREWS, Atlanta, described a method of staining *Spirochæta pallida*.

DR. J. E. SOMMERFIELD, Atlanta, reported a case of typhoid fever followed by an abscess of the liver. On aspiration, pus was found. Recovery followed operation.

(*To be continued.*)

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Tuberculosis.

In speaking of the dietetic and medicinal treatment of tuberculosis, Bjorkman, in *Merck's Archives*, states that the condition of the stomach and intestinal canal must be carefully watched, even more carefully than the lungs, because if failure of these organs takes place the case will be lost. The patient, consequently, should never eat heartily at any time, nor should liquid foods be taken in too large quantities. Small meals and of the highest caloric value, he states, should be partaken of frequently. The patient should be allowed, as a rule, to choose the articles of food he relishes most, and no food that does not meet with his approval should be served.

Fats in the form of butter and cream are important articles of diet. Cod-liver oil is of value when it agrees with the patient. Whenever fever is present the patient should be put to bed in the open air and should remain at rest as long as the fever continues; at the same time he should be fed to the maximum.

Raw eggs in increasing amounts are recommended, also milk and whisky in small amounts and oft repeated. If the patient can bear wine or beer in small quantities at meal times they are permissible, but should never be given in doses large enough to irritate the stomach.

Excellent results may be expected from change of climate if the case is not too far advanced, and providing that the patient remains long enough at an altitude where he can enjoy pure air and out-of-door life.

In advanced cases Bjorkman condemns any change of climate which would take the patient away from his friends.

Individuals with weak heart, arteriosclerosis, diabetes and emphysema should not be sent to high altitudes, but rather

to a low, dry, sunny climate, where the air is pure and the fluctuations of temperature not great.

In the medicinal treatment, it should be the aim to raise the physiologic activity of the cells as nearly to normal as possible, in this way facilitating the destruction of tubercle bacilli and assisting in eventual cicatrization. While Bjorkman places no specific value in the following medicinal combinations, they are recommended according to the certain requirements and value in correcting digestive, bronchial and nutritive disturbances:

℞ Creosoti ..... m. lxxv 5
Mucil. acaciæ ..... ʒiiss 10
Pulv. althææ rad. q. s.

M. Ft. pil. No. c. Sig.: Two pills after each meal, gradually increasing the dose to five pills after each meal.

The foregoing may be continued for several months. Or:

℞ Creosoti ..... ʒi 4
Tinct. nucis vomicæ ..... ʒii 8
Mucil. acaciæ ..... ʒi 30
Syrupi hypophos. q. s. ad ..... ʒiv 120

M. Sig.: One teaspoonful after each meal.

Guaiacol is recommended as follows:

℞ Guaiacol. carb. ..... gr. iii-viii |20-.50

M. Ft. chart. No. i. Sig.: One such powder morning and night, gradually increasing the amount to 75 grains (5.00) a day. Or:

℞ Guaiacoli ..... gr. xxx 2
Olei amygd. dulcis ..... ʒv 20
Pulv. acaciæ ..... ʒiiss 10
Ft. emulsio et adde
Aquæ dest. q. s. ad ..... Oii 1000

M. Sig.: Eight ounces to be injected by the bowel once daily.

If digestive disturbances arise creosote may be administered by the bowels as follows:

℞ Creosoti ..... ʒss-i 2-4
Olei amygdalæ dulcis ..... ʒiiss 75
Vitelli ovi ..... No. i
Aquæ dest. ..... ʒviss 195

M. Ft. emulsio. Sig.: The entire amount to be introduced into the rectum through a high rectal tube.

As an inhalation the following is recommended:

℞ Iodoformi ..... gr. xv 1
Creosoti ..... m. iv |25
Olei eucalypti ..... m. viii |50
Spts. chloroformi ..... ʒss 2
Spts. vini rect.
Spts. etheris, ää ..... ʒss 15

M. To be used as an inhalation. Or:

℞ Resorcini resublim. ..... gr. viii-xvi |50-1
Aquæ dest q. s. ad ..... ʒiv 120

M. Sig.: To be used in a steam inhaler.

In the treatment of the cough the sweet cough syrups and elixirs should be avoided, as they tend to quickly disturb the digestion. For the relief of the cough the following is recommended:

℞ Apomorphinæ hydrochlor ..... gr. ss |03
Acidi hydrochlor. dil ..... m. viii |50
Aquæ dest. ..... ʒiv 120
Syr. althææ ..... ʒi 30

M. Sig.: One tablespoonful every two hours.

In extreme cases in which other agencies have failed the following combination is recommended:

℞ Ext. hyoscyami ..... gr. iv |25
Morphinæ hydrochlor. ..... gr. iss |09
Aquæ amygdalæ amari ..... ʒss 15

M. Sig.: From twelve to fifteen drops in water several times a day.

In the treatment of diarrhea the following combinations are recommended:

℞ Pulv. plumbi acetatis
Pulv. althææ rad., ää ..... gr. lxxv 75
Syrupi simplicis q. s. ad massam

M. Ft. pil No. l. Sig.: One pill four or five times a day. Or:

℞ Pulv. opii ..... gr. ss |03
Acidi tannici ..... gr. i |06
Saccheri lactis ..... gr. xii |50

M. Ft. chart. No. x. Sig.: One powder three times a day.

Acute Conjunctivitis.

In conjunctivitis the following outline of treatment is recommended by the *Med. News:*

As an antiseptic lotion the following:

℞ Hydrargyri cyanidi ..... gr. ii |125
Aquæ ..... Oi 500

M. Sig.: To be used as an eye lotion, alternating with the following combination:

℞ Zinci sulphatis ..... gr. v |30
Aquæ ..... ʒiiss 10

M. Sig.: To be instilled into the eye once daily.

When the conjunctivitis is purulent and due to the gonococcus a solution of silver nitrate should be employed locally:

℞ Argenti nitratis ..... gr. v |30
Aquæ ..... ʒiiss 10

M. Ft. lotio. Sig.: To be applied locally to the conjunctivæ, and followed immediately by a saline solution as follows:

℞ Natrii chloridi ..... gr. xxx 2
Aquæ ..... ʒiiss 10

M. Sig.: Apply locally to the conjunctivæ to counteract the effect of the silver nitrate solution.

In keratitis the same outline of treatment may be carried out as in conjunctivitis and the following ointment inserted into the eye as an antiseptic:

℞ Iodoformi ..... gr. v-x |30-.65
Lanolini ..... ʒiiss 10

M. Ft. unguentum. Sig.: A small piece to be placed on the conjunctivæ and massage given to the eyeball. Or:

℞ Hydrarg. oxidi flavi ..... gr. i-v |06-.30
Lanolini ..... ʒiiss 10

M. Ft. unguentum. Sig.: A small piece to be inserted into the eye once daily, followed by massage of the eyeball.

In cases of iritis in which the condition is acute and the pain intense, it is recommended that from four to six leeches be applied to the temporal region and the following ointment applied locally:

℞ Ext. belladonnæ ..... gr. xv 1
Ung. hydrargyri ..... ʒiiss 10

M. Ft. unguentum. Sig.: Apply locally to the region above the eye.

If the condition is very acute the following is recommended:

℞ Atropinæ sulphatis ..... gr. i |06
Cocainæ hydrochlor ..... gr. iv |25
Sol. adrenalini (1-1,000) ..... m. xxx 2
Aquæ ..... ʒiiss 10

M. Sig.: One drop into the eye every three hours.

In cases of glaucoma the following is recommended after iridectomy is performed:

℞ Pilocarpinæ hydrochlor. ..... gr. ii |12
Physostigminæ sulphatis ..... gr. 1 5 |012
Solutio adrenalis (1-1,000) ..... ʒi 4
Aquæ ..... ʒi 4

M. Sig.: As an instillation into the eye four or five times daily.

In cases of granular conjunctivitis the following is recommended:

℞ Cupri sulphatis ..... gr. i |06
Acidi salicylici
Cocainæ hydrochlor., ää ..... gr. ii |12
Lanolini ..... ʒiiss 10

M. Sig.: Apply locally to the conjunctivæ at night, and wash it off in the morning with a warm boric acid solution.

Rheumatism.

In the treatment of rheumatism or tonsillitis the following combination is recommended by Dr. E. S. McKee in *Merck's Archives:*

℞ Codeinæ sulph. ..... gr. iv |25
Acetanilidi ..... gr. xlv 3
Sodii salicylatis ..... ʒiiss 10
Alcoholis ..... ʒss 15
Syrupi rubi ..... ʒi 30
Glycerini ..... ʒss 15

M. Sig.: One teaspoonful every three hours in water.

The alcohol is used to dissolve the acetanilid, and the raspberry syrup and glycerin aid in rendering the mixture more palatable.

Medicolegal

Members of State Board of Health Can Not Sue.

The Supreme Court of Georgia holds, in Woodward vs. Westmoreland, that the act of that state of 1903 creating the state board of health, not declaring that board to be a corporation and not conferring on the board as such, nor its members, the right to sue, no suit can be brought, in the names of the members of the board, in alleged representative capacity, relating to matters within the jurisdiction of the board. It says that the board is created simply as an agency of the state government, to have supervision and control over all matters relating to the public health. There are always a number of these agencies for the control of certain matters relating to public affairs, and the authority of such agencies, or of the individuals composing the same, to bring suit in behalf of the public, depends upon the terms of the act creating the agencies and defining their limits and powers. If the act creating the board does not declare it to be a corporation, and does not in terms authorize a suit to be brought by it or its members, then suits cannot be brought by the members in their individual capacity.

No Damages for Physical Injury from Mental Anxiety.

The Appellate Court of Indiana, Division No. 1, says, in the case of Kagy vs. Western Union Telegraph Co., that it is now the rule of law in Indiana, in harmony with the weight of authority elsewhere, that damages can not be recovered for mental anguish alone, caused through the negligent failure of a telegraph company to deliver a telegraphic message. But the question presented here was: In a case where the direct effect of the defendant's negligence is mental anxiety and distress, for which alone no damages are recoverable, however real and manifest the mental disturbance be, may there be recovery for physical consequence of such mental hurt? The court, however, is unable to find any reason for allowing a recovery of damages for physical injury resulting from mental anxiety and suffering, occasioned by negligence, which would not require it to hold the defendant to liability where the consequence of such negligence is mental suffering alone. Every serious mental shock or tension has physical sequence of varying severity and duration, which is immediately connected with, and naturally dependent on, the mental disturbance as the cause thereof. If mental injury of such character is so obscure and incapable of satisfactory investigation in a court of justice that it is wise policy not to submit the matter to a jury, the physical depression or irregularity reasonably to be expected therefrom is ordinarily not less difficult of being intelligently apprehended as a matter of damages. Moreover, in this case the alleged consequence was the rupture of an intestine by the plaintiff, who was sick with typhoid fever, and the court follows the statement of that fact with the declaration that even where damages are allowed in such cases, as in some jurisdictions, for mere mental suffering, it is said that they "ought not to be enhanced by evidence of any circumstances which could not reasonably have been anticipated as probable from the notice received by the telegrapher."

Standard for Village Physician.

The Supreme Court of Iowa says, in the malpractice case of Ferrell vs. Ellis, that the defendant was a physician residing in the village of Powersville, Mo. He was called to attend the plaintiff, who lived about three and one-half miles distant, and who had fallen from a ladder and dislocated the radius of his arm at the elbow. Whether it was a forward or a backward dislocation was in dispute. The defendant testified that it was a backward dislocation; that he brought the head of the radius in opposition with the external condyle and dressed the arm extended; that it healed as well as usual in such cases. The arm was examined by other physicians some months afterward, and about seven months after the accident was operated on by a physician of Centerville, assisted by two other physicians. According to their testimony the head of the radius had slipped forward, and after breaking the adhesions they set the arm and dressed it, flexed, or at right angles. The trial court instructed the jury that: "The standard of skill and learning required in any case is that reasonable degree of skill and learning ordinarily exercised by the members of the profession at the time of the treatment in question, having regard to the advanced state of the profession at the time." This, the Supreme Court holds, was erroneous in not limiting the degree of skill and learning to that ordinarily possessed by physicians and surgeons practicing in similar localities. The presumption that prejudice resulted was in no way obviated by the record. No physician other than the defendant, residing at Powersville, testified. Surgeons of more or less experience from Lineville, Corydon, Allerton and Centerville, places varying in population, according to the last federal census, from 690 to more than 5,000 inhabitants, testified; while the village of Powersville was too small to find place in the enumeration. Judicial notice is taken of the population of towns and cities. The Supreme Court has here done so, not to sustain an error, but in order to ascertain if possible, that an error committed might not have been without prejudice. No other debatable question was raised by the record. For the error pointed out a judgment in favor of the plaintiff must be and is reversed.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

Medical Record, New York.

April 21.

1 Condition of the Air of the New York Rapid Transit Subway. G. A. Soper, New York.
2 Explosion of a Radium Tube. R. Abbe, New York.
3 *X-Ray Therapy. A. D. Rockwell, New York.
4 Memoranda Anent the Treatment of Gangrene in the Diabetic. H. Stern, New York.
5 *Laryngeal Edema. H. Smith, New York.
6 *The Three-Glass Catheter Test of Urethral and Bladder Detritus in Urethritis. A. L. Wolbarst, New York.

3. **X-Ray Therapy.**—Rockwell reports the history of a number of cases and gives a summary of his results. There is one case of melanotic sarcoma in which 32 exposures were made with no benefit; one case of osteosarcoma with 40 exposures and no benefit; two cases of epithelioma with 45 and 47 exposures respectively, with recovery in both cases; one case of Basedow's disease, with no benefit from 16 exposures; one case of carcinoma of the tongue with 16 exposures but no benefit; one case of carcinoma of the mouth in which 24 exposures were given with no benefit; two cases of carcinoma of the neck, with 24 and 25 exposures respectively, followed by no benefit; on the contrary, both were stimulated to increased activity of growth; one case of alopecia areata subjected to 22 exposures with no benefit; one case of lupus vulgaris, with 45 exposures, terminating in recovery; one case of lupus erythematosus, with 36 exposures, but no benefit; one case of tuberculous glands in which there was decided benefit, but the treatment was abandoned because of sudden and severe dermatitis; one case of scirrus of the breast, treated by 24 postoperative exposures, in which there was no evidence of return after three years; one case of rheumatoid arthritis with 24 exposures but no benefit; one case of nevus with 36 exposures followed by recovery.

5. **Laryngeal Edema.**—Smith's treatment of these cases is as follows: In the acute stage the external measures consist of cold compresses to the throat, and leeches. Internally a brisk purgative, or even emesis, will abstract some of the accumulating serum. Bits of ice, benzoin vapor, adrenalin by spray to the larynx, and 10 drops of the same solution every hour internally are important therapeutic agents. Venesection is also of value in these cases. Scarification or puncture, whenever feasible, is valuable. If all local measures fail, tracheotomy is the one most effective measure. When edema is secondary to a neighboring abscess, evacuation of pus will generally relieve it.

6. **Three-Glass Catheter Test of Urethral and Bladder Detritus.**—Wolbarst advocates the use of the following test: The anterior urethra is washed out carefully until the washings

come out clear into glass No. 1; this shows the condition of the anterior urethra. A soft, sterile catheter of small caliber is now passel into the bladder, and the bladder contents are drawn off into glass No. 2; this shows the bladder urine plus any possible drippings from the posterior urethra, or any possible urethral detritus carried in by the catheter; with the catheter *in situ*, the bladder is washed out thoroughly, until the washings come out clear; this shows that the bladder is empty of all pus or shreds. About eight ounces of clear fluid are now injected into the bladder, and the catheter is withdrawn; the anterior urethra and the bladder have been thoroughly washed out. The patient now passes two ounces of the fluid into glass No. 3; this shows the condition of the posterior urethra. The separate urines from the three parts of the urinary tract have, therefore, been mechanically obtained. If the physician decides to go into further detail he may massage the prostate and have two ounces of fluid passed into glass No. 4; this will show the prostatic condition after massage.

New York Medical Journal.

April 21.

7 Clinical and Microscopic Variations of Chorioepithelioma from a Practical Standpoint. (To be concluded.) R. T. Frank, New York.
8 Renal Calculus; Symptoms and Treatment. E. Eliot, Jr., New York.
9 *Bile Acids as a Remedy. A. C. Croftan, Chicago.
10 *Brow Ague; Frontal Sinus Congestion with Periodic Headaches. F. Woodbury, Philadelphia.
11 Chemistry of Toxemias in Pregnancy. C. G. I. Wolf, New York.
12 Association of Adenoids and Beginning Deafness in Young Children. P. D. Kerrison, New York.
13 Medical Society of Kingdom Come. W. C. Gardner, New York.
14 Case of Melena Neonatorum. B. E. Helprin, Brooklyn.

9. **Bile Acids as a Remedy.**—According to Croftan, bile acids may be employed with propriety chiefly in three conditions that are causally related to each other, namely, intestinal putrefaction, hepatic insufficiency, gallstone disease, and the various syndromes known to be consecutive to these states. Croftan employs glycocholic acid, in the form of the sodium salt, because it is more readily procurable and cheaper than taurocholic acid. The dose varies according to the exigencies of the case. Croftan has been in the habit of giving half-grain doses at frequent intervals until the desired effect is produced. He says that there is never any danger of giving too much because the sodium glycocholate in no way deranges the stomach, and, if given in very large doses, merely occasionally produces a little diarrhea which promptly carries off the surplus. Aside from the clinical results obtained there are three chemical indices that enough is being given: 1, The disappearance of sulphids from the stools; 2, the disappearance or great reduction of the aromatic sulphates (of which indican is the prototype) from the urine, and 3, the appearance of bile acids in the urine.

10. **Brow Ague.**—The practical feature of Woodbury's paper consists in calling attention to the importance of careful local examination in cases of frontal periodic headache instead of simply dismissing them with prescriptions without such examination. In cases of brow ague the discovery of the local tumefaction directly leads to its removal by methods in common use and the prompt relief of the symptoms. Woodbury says that it has happened in cases of frontal headache that after a course of unsuccessful treatment the patient spontaneously expelled some foreign body or living larvæ which caused the local pain and which would have been recognized at the beginning if a proper examination had been made.

20 *Visit to the Mayos at Rochester, Minn. A. C. Bernays, St Louis.

20. **Visit to the Mayos.**—Bernays states that a visit to the Mayos at Rochester, Minn., will convince any one that the home treatment of disease, acute or chronic, is unsatisfactory, and that its results are in every way inferior to hospital or institutional treatment. This being granted, the example set by the Mayos will be followed. Hospitals will be built by aggregations of specialists financially backed by capitalists. The money invested will earn legitimate dividends, and the physicians and surgeons, as well as the men conducting the special departments, will be paid. He can thus see the easy solution of many questions that now perplex and retard professional aims and ends. There will be united effort, and the miserable, petty, personal interests will yield to the greater interests and exalted rivalry between fully equipped scientific institutions. The medical profession, as well as the public, will be better served; both will be elevated and benefited by the division of labor among men trained for the special lines of research; and the business management may perhaps be left to a large extent in clerical hands.

28 *Primary Tumors of the Urinary Bladder. L. Davis, Boston.
29 Ischemic Muscular Atrophy, Contractures and Paralysis. A. H. Ferguson, Chicago.

21. **Value of Differential Leucocyte Count.**—Gibson claims that the differential blood count and its relation to the total leucocytosis is to-day the most valuable diagnostic and prognostic aid in acute surgical diseases that is furnished by any of the methods of blood examination. It is of value chiefly in indicating fairly consistently the existence of suppuration or gangrene, as evidenced by an increase of the polynuclear cells disproportionately high as compared to the total leucocytosis. The greater the disproportion the more sure are the findings, and in extreme disproportions the method has proved itself practically infallible. As the relative disproportion between the leucocytosis and the percentage of polynuclear cells is of so much more value than the findings based on a leucocyte count alone, this latter method should be abandoned in favor of the newer and more reliable procedure. The negative findings showing no relative increase or even an actual decrease of the proportion of the polynuclear cells while of less value, shows with rare exceptions the absence of the severer forms of inflammation. In its practical applications the method is of more frequent value in the interpretation of the severity of the lesions of appendicitis and their sequel. In order to have some standard to measure disproportion of the polynuclear percentage, it is suggested that a trial be made of a chart which is tentatively recommended under the arbitrary designation of standard.

23. **Discission of Pleura in Chronic Empyema.**—Ransohoff urges that every operation on the thorax for pleuritic effusions of any kind should be done with the patient on his back or slightly resting on the sound side. An incision should be made above the fistulous opening and a piece of one or two ribs removed in order that the cavity may be subjected to inspection and to touch. According to the size of the cavity thus determined, multiple subperiosteal rib resections are to be made either through a number of parallel incisions, through the U-shaped Schede incision, or through a trapdoor incision, a method favored by the French surgeons. It matters little which of these methods be practiced, provided that the resections be ample and that the thickened parietal pleura be excised. Attention should then be given to the diaphragm and to the pulmonary pleura. If the thickened pleura can be removed easily by decortication, it is, perhaps, preferable. If ample expansion of the lung does not ensue an incision in the groove of reflection of the costal and pulmonary pleura must

be made. The condition of the patient should be carefully watched lest too much be done at one sitting. When the cavities are large, repeated operations are necessary for the safety of the patient.

26. **Cecostomy and Appendostomy in Amebic Dysentery.**—In intermediate cases in which treatment is not controlling the dysentery, but in which the patients still have a reasonable amount of strength, Curl claims that the operation of cecostomy, with irrigation of the colon with quinin solution, is indicated. Cecostomy is preferred to appendostomy because of less sloughing and an easier closure of the fistula. The appendix should be removed at the time of fastening the cecum in the abdominal wound. A rapid improvement usually follows the beginning of irrigation, but convalescence is slow, and at times difficulty is experienced in closing the fistula. The after-treatment,—irrigation, etc.,—is tedious, and the patients are offensive cases to have in a ward. And in all, it is the lesser of two evils, it saves lives in selected cases.

27. **Silver Wire for Cure of Large Hernia.**—Wiener believes that it can be safely said that if the silver-wire filigree be correctly made and correctly introduced according to the method devised by Bartlett, it will seldom be necessary subsequently to remove it. If, furthermore, the precaution be taken of introducing two separate filigrees in different planes, then the large majority of otherwise inoperable herniæ will be cured radically. He says that with careful attention to a few technical details we have in the use of the filigree a rapid, safe, and efficient method of curing large herniæ, and one that deserves, in properly-selected cases, the hearty approval of every surgeon.

28. **Primary Tumors of Urinary Bladder.**—From a clinical and histological study of 41 cases of tumor of the bladder, Davis draws the following conclusions: 1. Stone in the bladder is not an etiologic factor of importance in the causation of these tumors. 2. The condition of the underlying bladder-wall in regard to epithelial infiltration, is the more satisfactory and reliable guide in the determination of the benign or malignant character of papillary epithelial tumors of the bladder. 3. If the foregoing condition is accepted as the differential test of these growths then will the benign forms commonly called papillomata, be found to at least equal if not outnumber the malignant, the papillary carcinomata. 4. Recurrent epithelial tumors are not necessarily malignant. 5. Papillary tumors of the bladder, proved to be histologically benign, may rapidly lead to a fatal result if left alone. 6. Surgical intervention at the proper time in the case of pedunculated papillary tumors of the bladder offers a very fair chance of long immunity, if not of permanent cure. 7. The method of surgical intervention to be preferred in these cases, is excision of the tumor in toto, with a margin of bladder wall at its base, including mucosa, sub-mucosa, and muscularis in part; the section need not penetrate the entire thickness of the wall. In this way, a beginning epithelial infiltration of the base, if present, may be circumvented; or if it is not present, the knowledge of the fact is of general value in the important matters of diagnosis and prognosis. The defect in the bladder wall should be closed with sutures, which will at the same time control hemorrhage. The gravity of the operation is not appreciably increased by this procedure.

April.

30 *Care of the Insane and the Study of Psychiatry in Germany. S. Paton.
31 Dispensary Work in Nervous and Mental Diseases. S. E. Jelliffe, New York.
32 *Tuberculous Meningitis. J. N. Hall and S. D. Hopkins, Denver, Colo.
33 *Leprosy Simulating Syringomyelia. H. C. Moffitt, San Francisco.
34 Types in Mental Diseases. W. A. White, Washington.
35 Importance of the Early Diagnosis of Mental Diseases. G. Stockton, Columbus, Ohio.

30. **Study of Psychiatry in Germany.**—Paton says that although the German methods of organization may occasionally reflect the disadvantages of constitutional monarchy, the American methods may, if eternal vigilance is not exercised, assume the form of absolutism. If common-sense business methods, a sense of patriotism and a true feeling of democracy are guiding principles of those whose duties it shall be to organize the first university psychiatrical clinic in America, the future of psychiatry will be bright. To one who seriously considers the national importance of these clinics, there can be little doubt that state authorities as well as private benefactors will soon make it possible to establish in the United States, under university control, a number of institutions whose purposes may be briefly summarized as follows: 1. The cure of many patients who now become hopelessly insane. 2. The instruction of medical students as well as practicing physicians in psychiatry, so that eventually there may be found in the community a greater number of men who are competent to advise whether an individual is capable of standing the mental strain imposed by special forms of education or is liable to endure the nervous strain of the enviroment in which the individual lives. 3. The possibility of keeping under observation a large number of individuals whose nervous system may, if occasion presents itself, become sources of danger to the individuals themselves or to the community. 4. The examination of cases in which the question of mental responsibility is under debate and a submission to courts of formal reports based on observation to supersede the hypothetical expert evidence that so frequently is a parody of justice. 5. The study of all problems whose ultimate solution will tend to a more comprehensive understanding of the functions of the brain, with a view to determining the most efficient methods of increasing the number of individuals in the nation who are capable of rational thought and action.

32. **Tuberculosis and Meningitis.**—Hall and Hopkins report fifty-two cases, forty of which occurred in male subjects. Twenty-nine of the cases occurred after twenty years of age; only fourteen were in the first decade of life; nine of these were in children under the school age. In eleven cases there was a history of at least one death in the family from tuberculosis. In three instances two of the family had died of tuberculosis, in two instances three, and in one instance six. There was a positive history of preceding tuberculosis in twenty-five cases. Abdominal tuberculosis was also present in one of the cases. One of the children who died had had a tuberculous nurse during the previous summer. In another child, a tuberculous meningitis followed shortly after a severe attack of whooping-cough. The duration of the disease was ten days or less in about half the cases, while but twelve cases lasted over fifteen days. Cheyne-Stokes respiration was noted in 14 cases. Unconsciousness was noted in forty-four of the cases, and in one it is said to have been absent until death approached. The pupils were noted as unequal and responding to light in nine cases. Optic neuritis was noted in the majority of the cases. Divergence of the eyes was noted in eight cases, convergence in two, divergence to the right in three cases, to the left in one case. In one case each blindness, hippus and ptosis are noted. Rigidity of the neck was noticed in 24 cases. Muscular twitching was noted in the right arm twice, both arms three times, left leg once, all over three times, and general convulsions occurred in three cases. The reflexes were noted as increased in fourteen cases, as decreased in five, and absent in fourteen cases. The superficial reflexes were absent in seventeen cases, slight in one case, and increased in but a single case. The Babinski reflex was noted on the left side only once, on both sides once. Kernig's sign was frequently present, but the authors have no exact statistics on it. Paralysis was absent in six cases. Among the complications noted were the following: Erysipelas, tuberculous peritonitis, erythema of great extent, alcoholism, melancholia, myelitis, acute pneumonia, phlebitis, uremia, acute bedsores, ulcer of edge of cornea with inflamed conjunctiva and enlarged glands in neck.

33. **Leprosy Simulating Syringomyelia.**—Moffitt reports the case of a boy, 11 years of age, who presented symptoms pointing strongly toward syringomyelia, except for the following: 1. The absence of sympathetic eye signs in presence of the involvement of the small muscles of the hand supplied by the first dorsal segment; 2, the absence of scoliosis; 3, the absence of rigidity and of increased reflexes, especially the absence of these signs in the lower extremities; 4, the distribution of the palsies left hand and right foot, and the limitation of palsies

and atrophies to the distal parts of the extremities; 5, the absence of ataxia and sphincter involvement; 6, the loss of temperature sense in the left ear, and the limitation of sensory changes in the right arm to the areas supplied by the ulnar nerve; 7, the absence of the Babinski sign and the abolition of the plantar reflex; 8, the widespread involvement of sensation in the lower extremities; 9, the thickening of the peripheral nerves.

Buffalo Medical Journal.

April.

36 Some Minor Rectal Lesions. D. H. Murray, Syracuse, N. Y.
37 *Posterior Gastroenterostomy; An Unusual Postoperative Complication. J. Burke, Buffalo, N. Y.
38 Operation for Strangulated Femoral Hernia. F. H. Flaherty, Syracuse.
39 *Constipation in Childhood. E. S. McKee, Cincinnati.

37. **Gastroenterostomy.**—The patient whose case is reported by Burke was operated on for an acute perforation of a gastric ulcer. A posterior gastroenterostomy by Connell suture with button enteroenterostomy was made, and the abdominal wound closed. After four months of absolute relief from gastric disturbance symptoms which indicated a return of the original trouble appeared suddenly, beginning with vomiting. The vomiting became so persistent that even liquids were rejected as soon as taken. A second operation was done and it revealed the following condition: The union of bowel and stomach as well as the enteroenterostomy was perfect. At a point half an inch away from the stomach, coming from the transverse mesocolon, was a tough band of adhesion one-eighth inch wide attached to and constricting the efferent jejunal loop; the gastrointestinal anastomosis opening would hardly admit the tip of the little finger; evidently the partial obstruction of the circulation of intestinal contents from the stomach to and through the efferent bowel put the new opening proportionately out of function, in consequence of which corresponding contraction took place. The anterior line of gastrointestinal union was incised, some encapsulated celluloid was removed, the interior of the stomach and bowel being exposed. The opening was made larger and the anastomosis completed as usual. One year after the second operation the patient reports perfect health.

39. **Constipation in Childhood.**—The treatment employed by McKee consists of the usual remedies used for the relief of this condition and massage of the abdomen from eight to ten minutes, morning and evening. This massage should be a circular motion commencing in the lower right quadrant of the abdomen and extending up, across and down the abdomen, following the course of the colon.

The Journal of Infectious Diseases, Chicago.

April 6.

40 Significance of Streptococci in Milk. P. G. Heinemann, Chicago.
41 *Method of Isolating the Pneumococcus in Mixed Cultures, Such as Throat Cultures. G. F. Ruediger, Chicago.
42 Common Mosquitoes of Bihe and Ballundo Districts, Portuguese West Africa. (Concluded.) F. C. Wellman.
43 *Toxins and Antitoxins of Poisonous Mushrooms (*Amanita Phalloides*). W. W. Ford, Baltimore.
44 Auxilysins. W. H. Manwaring.
45 New Species of Trypanosome Occurring in the Mouse Mus Musculus. A. I. Kendall.

41. **Method of Isolating the Pneumococcus.**—With the object of making the isolation of pneumococci easier, Ruediger has prepared a blue litmus inulin-agar medium, in which pneumococci form red colonies. This medium is simply a sugar-free agar, with the addition of inulin and litmus, and is made as fololws:

(a) Peptone (Witte)	10
Agar-agar	15
Sugar-free beef broth (neutral)	1,000

Ruediger's directions are to dissolve the mixture by boiling one hour, adding water from time to time to make up the loss from evaporation. Heat in the autoclav for from 15 to 20 minutes (to prevent subsequent precipitation while sterilizing), clarify with egg, filter through cotton, and make the volume up to 800 c.c. with distilled water. (b) Dissolve 15 grams of pure inulin in 200 c.c. of distilled water, mix this solution with (a), add 20 c.c. of a 5 per cent. solution of litmus, put in tubes, and sterilize in the autoclav under 10 pounds' pressure for 15 minutes. Each tube should contain 7 or 8 c.c. of medium. Some pneumococci do not grow well in this medium, hence it is necessary to add 1 c.c. of heated (65 C.) ascites fluid to each tube of melted agar (which has been cooled to 45 C.) immediately before using. In this mixture the pneumococci grow very well, and in from 24 to 96 hours the inulin fermenters form red colonies (acid production), which stand out very prominently on the blue background. The surface colonies do not produce so much acid as the deep colonies, and it is for this reason that each tube should contain a rather large amount of medium. In this way a thick plate is formed, with relatively few surface colonies.

43.—See editorial in The Journal, April 21, 1906, page 1209.

The Journal of the Michigan State Medical Society, Detroit.

April.

46 *Sporadic Cretinism. H. H. Sanderson, Windsor, Canada.
47 Why Not Be Frank with the Public? E. H. Flynn, Marquette.
48 Operative Treatment of Recent Closed Fractures. C. S. Oakman, Detroit.
49 *Treatment of Chronic Constipation Without Cathartics. L. J Hirschman, Detroit.
50 Health Officers, Their Duties and Responsibilities in Contagious Diseases. F. W. Shumway, Lansing.

46. **Sporadic Cretinism.**—The three cases reported by Sanderson occurred in three sisters, aged 21, 11 and 8 years respectively. The father was perfectly well and gave no history of goiter or any hereditary disease. The mother gave a history of having had a thick neck when young, and also an abscess in the neck. All the patients presented the characteristic signs of cretinism. They were treated with thyroid extract, 5 grains, three times daily, with very satisfactory results.

49. **Treatment of Chronic Constipation.**—The treatment outlined by Hirschman consists in strict observance of all hygienic measures tending toward improving the tone of the intestinal muscle, of the abolition of dietetic errors and of internal massage and dilation of the sphincter, the latter a method which has been attended by uniform success. It consists in the introduction into the rectum and sigmoid of sausage-shaped pneumatic dilators. These are dilated to conform to the shape of the rectum or sigmoid by means of low compressed air pressure. This dilatation is carried to a point where the patient feels a fullness and the dilator is alternately inflated and deflated and manipulated so that the mucous lining of the bowel is stimulated and the circular muscular fibers contract and gradually regain their tone. Cases of chronic constipation of years' standing have been successfully treated and cured in from one week to two months' treatment, the most obstinate case not requiring over 25 treatments to establish a perfect cure. Normal defecation usually follows within a few hours after the first treatment. These pneumatic dilators the author has made from a rubber bag shaped like a condom and they are mounted on a Wales bougie, sizes 5 to 7. These are attached by means of a cutoff valve to the compressed-air apparatus, at a low pressure, and are slowly expanded and allowed to empty themselves. These treatments do not last over five minutes at a time and are followed by good expulsive efforts.

Denver Medical Times.

April.

51 Acute Coryza. D. S. Neuman, Denver.
52 *Treatment of Acute Coryza. T. E. Carmody, Denver.
53 Prevention and Treatment of Coryza. W. C. Bane, Denver.
54 *Coryza (Acute Rhinitis, Cold in the Head, the Snuffles). F. E. Waxham, Denver.
55 Prevention and Treatment of Simple Acute Coryza. J. M. Foster, Denver.
56 Treatment and Prevention of Acute Coryza. J. H. Allen, Denver.
57 Early Diagnosis of Tuberculosis. G. R. Pogue, Denver.
58 Laboratory Diagnosis for the Practitioner. J. C. Todd, Denver.
59 Vomiting. D. S. Neuman, Denver.

52. **Treatment of Acute Coryza.**—Carmody outlines his treatment of all forms of acute coryza, including the preventive treatment. In the early stages he makes use of hot alkaline douches, purgatives, hot footbath, hot lemonade and Dover's powders, and 1 to 10,000 adrenalin solution, the latter to be followed by an oil spray as a protective. In the second stage hot alkaline solutions are used, and if necessary an astringent spray composed of:

R. Ext. hamamelidis	ʒi	30
Ext. hydrastis	ʒiv	15
Aquæ dest. q. s.	ʒii	60

Internally he uses 1/200 grain of atropin, repeated in from four to six hours, or the following may be used:

℞. Ammonii mur.
Camphoræ, āā.....gr. 1/2 |03
Ext. belladonnæ
Opii pulv., āā.....gr. 1/15 |004

54. Id.—Waxham has found the following combination very effective:

℞. Quininæ salicylatis.....gr. 1½ |10
Acidi arsenious.....gr. 1/120 |00055
Ext. belladonnæ.....gr. 1/20 |003
Capsicum.....gr. ¼ |015

Two of these capsules may be given every hour for three hours, and subsequently one every three hours. Waxham claims that when commenced early this combination acts almost as a specific.

2. **Surgical Treatment of Gastroptosis.**—Eve says that if possible the stomach should be raised into its normal position by means of its natural suspensory ligaments, the gastrophrenic and the gastrohepatic omentum. This is carried out by Beyea's operation, but in three of Eve's cases this procedure was absolutely impracticable on account of the extreme tenuity of the gastrohepatic omentum. The operation performed on these three patients was very similar in each instance, and may be described as follows: A sand bag was placed beneath the back, and the liver raised and held upward as in performing operations on the gall bladder. Five silk sutures were then passed through the lesser curvature of the stomach, ranging from the pylorus to the cardiac orifice, and above they were carried through the attachment of the lesser omentum to the liver, and forward, somewhat deeply, through the liver substance itself, in order to obtain a better hold. When these sutures were tied the lesser curvature was effectually raised and the greater curvature was roughly two inches above the umbilicus. There being a tendency to displacement of the liver downward, a series of interrupted sutures were carried through the anterior surface of the left lobe of the liver, and then through the margins of the costal cartilages.

3. **Complicated Case of Appendicitis.**—Stevenson's patient had had ill-health for several months and was suffering from some vague abdominal pains and from an offensive vaginal discharge. She presented all the classical symptoms of a true appendicitis. Two days later, the symptoms getting worse, she was operated on. Inside the peritoneal cavity coils of small intestines were seen glued together, and a sac was opened containing a good deal of pus; on a higher level another cavity was entered and more offensive pus let out. As the appendix could not be felt, the cecum firmly anchored down, and the patient's condition septic, nothing further was done; the sacs were cleaned with gauze and drained with split tubes. The immediate results were satisfactory. On the fifteenth day the temperature began to rise and the abdomen to swell, but there were no special pains. This condition lasted a fortnight, and the woman was then operated on again. The new incision was made outside the former one so as to enable the surgeon to work from without inward. The cecum was fixed and adherent to the lateral wall and not covered by peritoneum. Carefully dissecting always inward, a grooved cavity was reached, and in it a fecal concretion the size of a hazelnut was found. No appendix could be seen, but low down in the pelvis the end of the appendix was felt adhering to the right tube or to the uterus. From the terminal end to its origin the appendix was pocketed in a mass of adhesions. The appendix was then dissected upward, leaving in some places its peritoneal covering behind. The pocket was cleaned out and the external wound sewn up without drainage. The appendix was large and ruptured in two places—at its end and a little higher up where the adhesion had taken place and where the concretion had escaped. A week after this last operation the patient developed all the symptoms and signs of pneumothorax on the right side. She was again operated on, and following this operation made a complete recovery.

6. **Sarsaparilla in Syphilis.** Cullingworth reports 10 cases to show the excellent results obtained in the treatment of syphilis with a decoction of sarsaparilla, given three times a day in four ounce doses. Three pounds of sarsaparilla were placed in two gallons of water. After boiling this down to one gallon the decoction was strained, two gallons of water were added; boiled down to one gallon and strained, two more gallons of water added and again boiled down to one gallon and strained. Two pounds of sugar were then added, and the resulting liquid was used.

12 *Results of Operation for Radical Cure of Hernia. J. Hutchinson.
13 *Treatment of Cancer by Therapeutic Inoculations of a Bacterial Vaccine. C. Jacobs and V. Geets.

10. **Doyen's Serum in Malignant Disease.**—Paine and Morgan investigated the value of this serum in nine cases. The injections had no influence on the course of the disease in four cases. In two cases of carcinoma of the breast the injections were followed by severe constitutional disturbances characterized by cardiac failure. In none of the cases was there any improvement. Doyen's *Micrococcus neoformans* was often found present in 44 cases of tumor, in common with other micrococci, but the authors are of the opinion that it is not present in sufficient numbers or with reasonable constancy to be regarded as the etiologic factor in the evolution of these growths. They were unable to produce a neoplasm in animals inoculated with this germ.

12. **Results of Radical Cure of Hernia.**—A careful study of the results obtained by operation for hernia on 500 patients led Hutchison to draw the following conclusions: 1, In all but the simplest cases in children it is best to open up the canal and to narrow it by deep sutures; 2, suturing the conjoined tendon to Poupart's ligament behind the cord by a series of interrupted sutures is probably the best method of narrowing the canal; 3, when the conjoined tendon is deficient, in all recurrent cases, and in inguinal hernia in women the canal should be obliterated; 4, kangaroo tendon is admirably adapted for the suture material, silver wire being probably the worst; 5, recurrence of the hernia *in situ* may possibly take place at any length of time after the operation, but if two years be adopted as the limit it should not occur in more than from 5 to 8 per cent.; and 6, the development of a hernia at another site after operation may be expected in a proportion of cases at least as large as that just given.

13. **Serum Treatment of Cancer.**—In marked contrast to the results obtained by Paine and Morgan are those obtained by Jacobs and Geets. Their researches have convinced them: 1, That we have in cancerous cachexia a specific micro-organism, the *Micrococcus neoformans* of Doyen; 2, that the anti-cancerous sera of Doyen are wholly useless; and 3, that it is practicable to immunize the human organism by means of a series of inoculations of the *Micrococcus neoformans* vaccine, provided that these are properly controlled by examinations of the opsonic power of the blood. In all the patients treated according to their method, the authors noticed real and definite improvement. They succeeded in cultivating the *Micrococcus neoformans* from 90 per cent. of the tumors examined, and succeeded in producing localized or generalized neoplastic lesions in 30 per cent. of the cases by inoculating young and vigorous cultures of the micro-organism into mice and white rats. The reader is referred to the original paper for a complete description of the methods employed by the authors.

22 Miner's Disease at Bendigo. W. F. S. Bottomley.

18. **Congenital Heart Malformations.**—The cases observed by Simmons are arranged in several groups. 1. In this group cases of patent foramen ovale are included. This group is subdivided into three classes: (a) Those patients which exhibited no cardiac symptoms, and no signs on physical examination, but died in infancy. On autopsy a patent foramen ovale was found. (b) Those which exhibit no symptoms, but on physical examination definite signs may be detected. (c) This class of cases presents well-marked physical signs, and also symptoms of varying intensity. 2. Cases of pulmonary stenosis. 3. Patients with deficient ventricular septum. 4. Aortic stenosis, with patent ductus arteriosus. 5. Patients with a patent ductus arteriosus (a) alone, and (b) associated with another deformity. 6. Cases which present many of the signs of congenital heart malformation, signs and symptoms being present from birth, but in which the postmortem examination indicates that the trouble is a valvulitis, originating, probably, before birth. 7. Patients with some mild heart abnormality, which, after an attack of acute rheumatism, develop a valvulitis or pericarditis, the mixed lesion proving fatal, whereas either lesion alone need not necessarily prove so.

38. **Five Years of Antityphoid Serotherapy.**—Chantemesse gives a table showing the mortality from typhoid fever in the various hospitals of Paris during the last five years, the average being 17.3 per cent. in 3,595 cases. At the hospital known as Bastion 29, there have been 712 typhoid patients, and all have been treated with antityphoid serum, with a mortality of only 3.7 per cent. This treatment has not yet been introduced in the other hospitals. In the 27 fatal cases death was due to perforation in 9, to pneumonia in 3, to gangrene of the mouth in 1, to rupture of an aneurism in 1, to cancer of the kidney in 1, and to gangrenous pleurisy in 1. None of the patients succumbed to hemorrhage. Chantemesse makes a practice of giving calcium chlorid in the severe cases not treated until late. A little calcium chlorid is given as a preventive of hemorrhage about the middle or end of the second week. This is about the only drug used aside from the serum. Perforation occurred in only 9 cases, and in these treatment had not been instituted until late. It was never observed in any patient whose treatment had been commenced during the first week; all the patients treated during the first week recovered without exception. In 2 other patients perforation occurred, but was successfully sutured. This is a total of 11 perforations in 712 cases, or 1.5 per cent. In various statistics cited the proportion was 2.6 per cent. in 8,160 cases. Chantemesse ascribes the action of the serum to its stimulating influence on the lymphoid system. If the disease is advanced and the lymphoid system gravely affected, it is wise to inject only a small amount of the serum.

41. **Bottles for Poisons.**—Several new designs for bottles are illustrated which would attract attention to the fact that they contain poisons. One is of ordinary shape and size, but is thickly studded with spike-like projections. Another has two necks and stoppers. The contents will not flow out of one neck unless the stopper is taken out of the other neck also. A third form of bottle is bullet-shaped, the point upward; the opening and stopper are at the bottom. A fourth form has the neck of the flat bottle at one corner and turned back horizontally. The contents can be poured out only when the bottle is tipped in a certain direction.

46. **Kefir in Cancer of Stomach and Pancreas.**—Martinet describes without comment the case of a man of 55 with an inoperable cancer in the stomach involving the pancreas, causing continuous pain and vomiting. What he calls "Bulgarian clotted milk, prepared with Maia" was given the patient and at once all pain and vomiting ceased. On a Sunday, when the store was closed and it was impossible to obtain the milk, the pains and vomiting reappeared at once, but vanished again when it was resumed. After an exploratory laparotomy the curdled milk was stopped and again the pains and vomiting reappeared. They vanished when the clotted milk was taken again, and the patient was free from these symptoms on this diet until he succumbed to cachexia. He ingested from 500 c.c. to 2 liters a day.

47 (XXVI, No. 11.) Ictère chronique et coliques hépatiques symptomatiques de kyste hydatique du lobe de Spiegel. T. Tuffier.
48 *Le diagnostic précoce de la tuberculose pulmonaire par la recherche des points de submatité des sommets (of apices). M. Landolfi (Naples).

48. **Early Diagnosis of Pulmonary Tuberculosis.**—Landolfi has been studying in the clinic, with subsequent postmortem examinations, the points where resonance is impaired in case of an incipient tuberculous process at the apex. He has located six points where percussion is liable to reveal impairment of resonance, and this finding at even one of these points is extremely suspicious. Point 1 is 1 cm. below the clavicle, at the junction of the inner third and outer two-thirds. Point 2 is the same distance above the clavicle on the same vertical line. Point 3 is at the intersection of the acromio-mastoid line with a line uniting point 1 with point 4. The latter point is in the center of a line drawn from the acromion to the spinous process of the second dorsal vertebra, and is the only point on the back. Point 5 is 1 cm. below the center of the clavicle, and point 6 is just inside the acromion and above the acromio-cervical line. They are numbered in the order of their importance. Percussion should be with the middle finger on the nail of the index finger applied horizontally, the patient seated or standing, the arms pendant. The percussion should be light and then heavy, and should be applied at symmetrical points on each side. The less the difference between the results of light and strong percussion at point 6, the greater the probability of a lesion of the apex. He diagnosed one case from this finding alone, and the autopsy confirmed the diagnosis. It is necessary to be skilled in the physiologic findings at these points, but this comparative percussion, combined with light topographic percussion of the apex, will early reveal not only a lesion at the apex, but also the pathologic anatomic condition of the parenchyma of the lung.

55 *Die Malignität der Blasen-Mole (hydatidiform mole). Schickele.

49. **Operative Treatment of Puerperal Peritonitis and Pyemia.**—Leopold reviews his experience with operative treatment of puerperal peritonitis. He regards it as a promising field on condition that the incisions and drainage tubes are protected so carefully that no possibility of secondary infection is permitted. In 5 cases of acute, generalized peritonitis 3 of the patients recovered. They were all operated on by the second or third day of the peritonitis, while 2 others, not operated on until the fifth day, succumbed, the intervention having come too late. The abdominal cavity was filled with pus or a dirty reddish fluid, the intestines were congested and covered with deposits of fibrin, the lymph spaces in the right wall of the uterus were distended with pus, and streptococci were cultivated from small abscesses in the left corner of the uterus. These findings emphasize the importance of prompt interference, not allowing the proper moment for intervention to pass. This, he thinks, is when high fever, increasing and smaller pulse and increasing distension and tenderness of the abdomen become accompanied by hiccough and vomiting, while the complexion and expression indicate severe infection, and an area of dullness develops and spreads in the hypochondrium on both sides. A laparotomy under such conditions in commencing peritonitis can do only good. It is necessary under all circumstances to open and drain the Douglas pouch into the vagina, and it is also wise to drain the region of the hypochondrium. In Leopold's experience daily rinsing out of the abdominal cavity afterward seemed to be unmistakably beneficial. The 5 patients with circumscribed peritonitis all recovered after an operation performed between the nineteenth and fiftieth days. The search for the focus causing the protracted sickness may prove long and difficult. If the inflamed and possibly suppurating adnexa on one side are included in the circumscribed intraperitoneal pus focus, they must be released from adhesions and removed after ligature. The most complicated conditions can be straightened out by calm, cautious technic. Whether or not to remove the adnexa depends on the individual conditions. In 3 cases he merely opened and drained the focus, an abscess in the uterus. These cases show that several operations may be necessary before the primary focus is discovered. It is generally found in or near the uterus, and the experiences related indicate that even earlier intervention might have been still better. In one of the cases reported and tabulated, abdominal section was undertaken on the twenty-fourth day of the severe illness. After exposing the adherent organs the pus focus was finally found in the uterus, and the circumscribed peritonitis rapidly healed after this focus had been drained.

53. **Dermoid Cysts of the Ovary.**—Schottlaender's article is a histologic study of 4 cases of dermoid cysts in the ovaries. He states that the assumption that dermoid cysts are innocent growths requires some modification. The similarity to endothelioma is too striking.

54. **Childbirths with Fetid Amniotic Fluid.**—Lehmann has encountered 59 cases of this kind in 9,500 childbirths at Breslau. There was temperature in all but 3 cases. Five of the mothers died, and 32 of the children. The walls of the uterus are protected by the membrane against infection from the fetid fluid, and it does no harm to the external parts so long as they are intact. Rinsing with an antiseptic before, during or after the birth did not seem to influence the further course of the cases. Expectant treatment at first, with cautious rinsing out of the vagina after delivery, not allowing the fluid to enter the uterus, he states, seems to be the most promising treatment.

55. **Malignancy of Hydatidiform Mole.**—Schickele discusses whether the uterus should be removed as a matter of course in case of a hydatidiform mole. He thinks that the danger of malignancy should always be borne in mind, and that after removal of the mole the uterus should be curetted and the scrapings examined. If a chorioepithelioma exists outside of the uterus it should be removed and the uterus should be curetted and palpated. If the findings are negative the examination should be repeated in four weeks, or in two if there is the slightest suspicion of positive findings. The presence of a chorioepithelioma outside of the uterus should not influence the decision as to the removal of the uterus unless the findings suggest the probability of malignancy. He replies to the possible objection that the hysterectomy might come too late by saying that this could occur only in cases with very early metastasis, and in such cases the physician is powerless whether there is a neoplasm in the uterus or not.

56. **Treatment of Acute Peritonitis.**—Lennander insists on the importance of an early and exact diagnosis and on an early operation, if possible before the intestines become paralyzed. The cause of the acute peritonitis must be sought for and removed in every case. When the intestines are paralyzed three measures should be considered: 1. Enterotomy (single or multiple), emptying the intestine during the operation. 2. An oblique fistula into the intestine. 3. In desperate cases, resection of from 0.5 to 1 or even 2 yards of the paralyzed bowel. In case of peritonitis from appendicitis with paresis in the cecum and adjacent part of the ileum, an oblique fistula must be made in the cecum during the operation, or the wall of the cecum can be sutured to the incision in the abdominal wall so that it will be ready to have an oblique fistula made without the necessity for general anesthesia in case symptoms of paralysis of the intestines develop after the operation. In case of recent suppurative peritonitis in the center of the abdominal cavity (that is, around the mesentery of the small intestine), the most harmless and effectual measure for removing the pus is to rinse with 0.9 per cent. salt solution at a temperature of 40 C. (104 F.), under very slight pressure and with free outlet. He declares that no one is justified in rinsing the sound peritoneal surfaces at the same time. Only when it has been established that the rinsing of sound peritoneal surfaces with a 0.9 per cent. salt solution induces leucocytosis which will protect against the danger of infection, will we be justified in rinsing out the intact parts of the peritoneum; as for example, in case of suppurative peritonitis in the small pelvis, rinsing out the center of the abdominal cavity, or in case of suppurative peritonitis below the transverse colon, allowing the rinsing fluid to find its way above this part of the bowel. Infected and acutely inflamed peritoneal surfaces must be drained. He thinks the best technic for this is to wall off the infected area from the sound regions of the peritoneal cavity. He uses tamponade drainage, with very coarse cotton yarn (wicking) with drain tubes between the strands of yarn and rubber tissue. He tampons only in the peripheral regions of the abdomen, around the stump of the appendix, of the gall bladder, etc., when it is a question of separating a certain part of the serosa from the rest. The best rubber stuff for draining he has found to be long rubber operating gloves that have outlived their usefulness as gloves. Instead of large tubes he prefers a bundle of from four to eight small tubes, not more than from 1 to 1.5 mm. in diameter. He sometimes inserts a pair of these tubes through a glove. Adhesions do not form around the rubber as around gauze. He begins to remove the tubes about the twelfth hour, and the rubber drainage is usually all removed from the thirty-sixth to the seventy-second hour. In the after treatment everything must be done to favor the resumption of normal functions by the stomach and intestines at the earliest possible moment. Lavage of rectum, colon and stomach and enterostomy are good and tried measures. An efficient subcutaneous purgative is greatly needed. Too little is known of the action of strychnin, physos-

tigmin or atropin on the intestines for any definite rules for their use. Lennander has used strychnin for a heart tonic, and imagines that benefit has been derived from physostigmin in doses of from 0.5 to 1 mg. once or twice a day, from fifteen to thirty minutes before lavage of the intestines in case of intestinal paresis, or when the symptoms of intestinal paralysis were commencing to subside. Mechanical measures to empty the intestines and stomach are the most important in combating intestinal paralysis. Typhlostomy is an excellent measure in case of appendicitis peritonitis with commencing intestinal paralysis. It is important, he adds, to supply the water lost in the course of the affection. From 1,200 to 2,000 c.c. of water must be supplied to the adult organism in the course of twenty-four hours. If it can be given through the rectum or through an oblique fistula into the cecum, this is better than by the subcutaneous or intravenous routes. Whether or not larger amounts of water are desirable is a matter for discussion. More can be given if the general appearance and the heart action are improved and the diuresis and peritoneal secretion are increased in direct proportion to the supply of water. If convinced that paresis in the vascular domain of the splanchnic nerve is the most important factor in the trouble, artificial serum must be infused, from 1 to 2.5 quarts, once or twice in the twenty-four hours. Nothing in the way of food except grape sugar, he states, can be given to advantage through the rectum, but large amounts of peptonized nourishment can be administered through a fistula into the cecum. A patient can be fed for a few days by subcutaneous injection of 100 or 200 gm. olive oil, 160 gm. grape sugar and 40 gm. alcohol (2 liters salt solution containing 8 per cent. grape sugar and 2 per cent. alcohol). In all cases of suppurative peritonitis the after treatment should always reckon with adhesions and kinking of the intestine at sharp angles. It is important not to allow food by the mouth too soon. If food hard to digest or too large quantities of fluids are allowed, the intestines are not able to force them along past all these obstacles. Easily digested food, and drinks in small amounts at a time, the intestine is able to handle, and the adhesions, he declares, will become gradually detached in time. After every operation for acute peritonitis the patient must be impressed with the necessity for regular evacuation of the bowels and avoidance of indigestible articles of food. This article by Lennander was read to introduce the subject of acute peritonitis at the recent International Surgical Congress.

57. **Results of Slitting the Kidney.**—Wildbolz reports experiments with 9 rabbits and 5 large dogs. In every instance when one of the large arteries in the kidney was severed, an infarct formed at the spot.

58. **Intubation Through Mouth for Anesthesia and for Over-Pressure in Lungs.**—Kuhn gives an illustrated description of his apparatus for "peroral" intubation, that is, intubation with the tube extending out through the mouth. He has adapted it to induce over-pressure in the lungs to allow operations in the thorax.

60. **Displacement of Large Intestine in Case of Distension.**—Lessing remarks that the topography of the intestines has been based on the findings with the normal or relaxed intestines of the cadaver. He has been studying on 50 cadavers the positions assumed by the large intestine when inflated.

62. **Importance of Anesthesia in Treatment of Inflammation.**—Spiess is convinced that inflammations are favorably influenced when the pain is reduced by artificially induced anesthesia. He believes that it is possible to prevent inflammation by preventing the development of painfulness in a wound. By the use of local anesthetics, he states, it is possible to abolish the pain, and wounds heal without inflammation, or if there is already inflammation, it rapidly subsides. By abolishing the reflexes emanating from the focus of inflammation through the centripetal sensory nerves it is possible to prevent the development of inflammation or to cure it if already existent. The anesthetization should affect only the sensory nerves, and should not disturb the normal play of the vasomotor nerves. As irritation of sensory nerves induces hyperemia by reflex action, so suppression of such irritation (by local anesthesia) prevents the development of the hyperemia or abolishes it if already present. He gives a number of experiences and arguments to sustain this view, suggesting that the beneficial action of passive congestion may be due to its anesthetizing properties. All writers on the subject mention the prompt relief from pain as its most constant feature. In treatment of inflammation the focus must be kept thoroughly and permanently under the influence of the local anesthetic which must come into intimate contact with the focus throughout its extent. Repeated insufflation of a local anesthetic, every five minutes, will abort incipient sore throat or coryza, and by injection will abort furuncles and styes. The criterion is the subjective relief from all disagreeable sensation from the focus. When this is accomplished and kept up the inflammation rapidly subsides.

63. **Suture of the Patella.**—Witzel has been using for years a method of suturing the patella without the necessity for opening up the joint, and it has proved extremely satisfactory in his hands. He uses stout silver wire and two slightly curved trocars. He passes one trocar through the tendon of the quadriceps, just above the patella, and the second trocar through the ligamentum patellæ, just below the patella. The concave curve of the trocars is turned toward the patella, and the needles are removed. A piece of wire is then passed through each trocar, the ends being tied together with considerable traction in the center over a tampon, the ends of the wire forming an X over the fractured patella, which is thus held immovably in place. A plaster cast is then applied and massage of the muscles commenced the second week; the cast is removed once daily for the purpose. Passive and then active movements are commenced at the beginning of the third week; the wires and trocars are not removed until the fourth or fifth week has passed. The same technic has been successfully applied in treatment of fracture of the olecranon. Schäfer states in conclusion that the simplicity and the excellence of the results have fully established the superiority of the method.

71. **Orthopedics of the Abdomen.**—Bracco gives illustrations of a model supporting bandage for the abdomen. A bandage wound around the abdomen, passing from the center of the abdomen around the thigh, forms a figure 8 on each side, which bring the pressure and support on suitable regions. The bandage is made of ten or more narrow bands, each wound separately, with narrow spaces between them and cross bands to hold them in place. The whole opens in front and can be easily removed and put on. The general aspect is like a pair of bathing trunks. He claims that its use cured cases of obstinate constipation, of albuminuria of many years' standing, and other effects of ptosis, and that in cases of threatening eventration it has enabled the tissues to regain firmness and strength. He has found it very useful also during and after pregnancy; the energy otherwise devoted to holding up the weight of the pregnant uterus could be diverted to other purposes.

73. **Microphotography with Ultra-Violet Light.**—The method of microphotography with ultra-violet light proposed by A. Köhler of Jena is regarded by von Schrötter as a great advance in progress, on a par with the ultra-microscope of Siedentopf and Zsigmondy. It opens a new field for investigation. The process differs from ordinary microscopic technic only in the fact that it is not possible to observe directly with the eye. The eye is substituted by the sensitized plate on which the invisible rays act. He uses magnesium or cadmium one-colored light with a wave length of 280 or 275, a numerical aperture of 1.25, and exposure of about a second. An artificial eye or finder, on which the invisible rays cause fluorescence, enables the image to be centered. Nineteen views are given by von Schrötter of bacteria and tissues of various kinds photographed with this technic, which brings out the details as clearly as if they had been stained by the best technic. Until the technic is further perfected the results of ultra-violet photography are not superior to those of staining so far as bacteria and trypanosomes are concerned, but examination of blood from malarial and leukemic patients revealed details hitherto unsuspected, which establish the great value of this new mode of investigation. With it, von Schrötter says, we can inspect the finest structural elements down to 0.25 micron. It also enables us to study the permeability of various tissues and their elements for the ultra-violet light, and, in combination with the findings of the spectrograph (Freund, Hertel and others), to learn new optical characteristics in regard to them. The behavior of structures in regard to their permeability for the short wave rays after having been stained or acted on by chemical agents, is also a promising field for research. Each simple tissue element should be studied separately before we can appreciate the findings in pathologic tissues. The action of autolytic processes and the influence of ferments can also be traced with the ultra-violet photography. Ordinary staining methods fail to help us in this. New details of histopathology will be revealed by the new technic, and possibly the causal agents of certain infectious diseases, as of scarlet fever, may be run to earth with its aid. Another advantage of this new technic is its use as a control for our previous technical procedures. It is a fortunate coincidence that ultra-violet photography allows the use of physiologic salt solution as a vehicle for the objects, and in this vehicle living elements can be photographed and vital processes can thus be studied. The dynamogenic action of electricity and the resulting changes in tissues can perhaps be studied with the ultra-violet rays. Especially important in this line would be the examination of the nervous systems of animals after these had been killed by electricity. Another interesting line of research would be the photographic reproduction of the processes involved in hemolysis and agglutination, and in the action of normal and antitoxic sera on bacteria and on the cell protoplasm from a morphologic point of view. Köhler's original article was published in the *Zeitschrift f. wissenschaftliche Mikroskopie und mikrophotographische Technik*, XXI, pp. 129 and 273, 1901, but the apparatus is fully described in the Zeiss catalogues. Grawitz and Grüneberg have just published a work on the blood studied by ultra-violet light, which contains also some views of leukemic blood.

74. **Death from Extensive Burns.**—The conclusions of the experimental research reported are to the effect that death from extensive burns may be due to paralysis of the heart, the result of the overheating of the blood. Likewise to the formation of substances in the skin under the influence of the heat, which, when taken into the blood, have a fatal toxic action. Burning of muscle tissue does not cause the formation of such toxic substances as in the skin. A deep burn of limited extent is borne much better than a shallower burn over a larger area.

81. **Myoma and Cancer of the Uterus.**—Winter discusses the question of malignant and innocent degeneration of uterine myomas. The testimony to date indicates that a simple myoma can be regarded as an essentially benign growth. He found a carcinoma in the corpus in 12 cases. It had been previously diagnosed in only 4. If symptoms occur in the course of a myoma, such as are seldom observed with myoma but are frequent with cancer (cohabitation bleedings, hemorrhage in the menopause, a blood-stained discharge, pains independent of menstruation), a careful search must be made for evidences of carcinoma in corpus or cervix. He has been able to find only 16 cases on record in which a carcinoma developed in the stump left from supravaginal amputation on account of myoma. Study of these cases shows that the malignant disease had probably been installed before the operation in a number of them, and that in others the cancer developing later had no connection with the preceding operation. There is no reason, therefore, for abandoning supravaginal amputation for total extirpation from fear of development of cancer in the stump. The myoma evidently is liable in some cases to create a predisposition to carcinoma, especially in the corpus. Its relations with sarcoma are on a different basis, as sarcomatous degeneration is not so very rare. He encountered it in 17 out of 753 cases, that is, in 3.6 per cent., and believes that it occurs in about 4 per cent. of all cases of myoma. Submucous myomas are the most liable to sarcomatous degeneration, in his experience nearly 9 per cent. (11 out of 126 submucous myomas; 10 in 237 insterstitial, and 6 in 299 subserous and subperitoneal myomas). In his 27 cases the diagnosis of sarcomatous degeneration had been made in only one instance. The entire tumor should be examined under the microscope, especially the stem of every polyp. Operative removal of the myoma on account of fear of sarcomatous degeneration is scarcely justified, he thinks, unless there are grounds for suspicion. The diagnosis is generally difficult, and is rendered positive only by anatomic investigation. This should never be neglected with submucous myoma, so that it may be followed with a prompt radical operation if necessary. Total necrosis of interstitial myoma occurred in 17 out of his total of 753 cases of myoma, presenting a syndrome including irregular, frequently severe, hemorrhages, with labor-like pains and phenomena of autointoxication. There were no characteristic objective findings until the necrosis was in its last stage and had broken through into the interior of the uterus. Total necrosis must be regarded as a very serious and rather dangerous complication of myoma. Prolonged irregular bleeding from the uterus, especially when accompanied by pains suggesting labor, should always arouse suspicion. The finding of acetone may be a valuable differentiating sign, but it was lacking in 2 of his cases. Most important of all is a history of a just preceding childbirth or abortion. The radical operation was performed in his 17 cases by supravaginal amputation in all but one, and recovery was uneventful. Poorly nourished myomas, the subserous, the intraligamentary and those with a thin pedicle, are most liable to become affected with cystic degeneration, and the age of the patient and consequently of the growth enhances this tendency. Congestion in the venous system is liable to entail edema of a myoma. Primary softening of an interstitial myoma is accompanied by considerable bleeding, as a rule, but otherwise causes no local or general symptoms. Treatment of myoma, on the whole must be guided by the symptoms.

PHAGOCYTOSIS AND OPSONINS *

LUDVIG HEKTOEN, M.D.

CHICAGO.

INTRODUCTION.

Phagocytosis in its relations to healing and immunity has been discussed most actively from various points of view, and it is to some of the results of the most recent investigations in this field that I not without hesitation ask your attention.

The demonstration by Wright and Douglas[1] of the presence in blood and other fluids of certain substances called by them opsonins,[2] which render various bacteria susceptible to the phagocytic action of leucocytes, has given a fresh interest to the study of phagocytosis. At present we may accept as an established fact that phagocytosis of many bacterial and other cells by the leucocytes, in the first instance, is dependent on special substances, normal and immune, which become attached to the cells in question and in some manner so change them that they are taken up readily by polynuclear leucocytes *in vitro*. Leucocytes freed from serum do not take up to any great extent bacteria or red corpuscles suspended in salt solution. The quantitative effect of serum on phagocytosis is illustrated by Table 1.

TABLE 1.—QUANTITATIVE EFFECT OF SERUM ON PHAGOCYTOSIS.[3]

Quantity of serum.	Number of cocci taken up.
0.2 c.c.	23.4
0.1 c.c.	19.2
0.05 c.c.	14.0
0.025 c.c.	7.5
0.0125 c.c.	2.2
0.006 c.c.	1.5
0.003 c.c.	0.7
0.000 c.c.	0.0

This table shows the influence of serum on phagocytosis. In this experiment each tube contained 0.3 c.c. of suspension of washed guinea-pig leucocytes and falling quantities of guinea-pig serum, enough 0.85 per cent. NaCl solution being added to make 0.6 c.c. in each case, and 0.5 c.c. of a streptococcal suspension.

By means of experiments giving comparable results, it has been found that the variable factor in a series of bloods is the serum and not the leucocytes.[4]

Bacterial and other cells treated with opsonic serum and then freed from serum by repeated washing in salt solution are taken up by washed leucocytes. Indeed, all the opsonin may be removed from the serum by adding a sufficient number of suitable corpuscles or bacteria, as the case may be, which now become susceptible to phagocytosis. Bacteria and red corpuscles so treated may be said to be sensitized for phagocytosis or "opsonized," but such cells are not necessarily obviously altered either in form or function, and many bacteria, e. g., staphylococci, streptococci, pneumococci, anthrax bacilli, multiply freely in sera that contain opsonin. Leucocytes treated with opsonic serum and then washed, on the contrary, are not able to take up unsensitized bacteria or corpuscles. We see at once that a means has been given us for a better analysis than heretofore possible of the mechanism of phagocytosis, at least up to a certain point.

The technic required to study phagocytosis *in vitro* is quite simple.

Leishmann's method,[5] which is used in a modified form by the English workers, consists in placing blood or other fluid containing leucocytes and suitable homogenous bacterial suspensions at 37° C. (from 15 to 60 minutes) when smears are made and stained with Leishmann's stain. Counts are now made of the bacteria in a certain number of leucocytes and in this way is obtained the average number of bacteria taken up. In comparison of different bacterial emulsions these must contain an equal number of bacteria and Wright[6] has devised a method of counting bacteria and diluting as necessary for that purpose.

In order to free the leucocytes from serum it is necessary to wash small quantities of defibrinated or citrated blood or exudate at least three or four times in many times their volume of salt solution by means of centrifugalization. In our work at the Memorial Institute for Infectious Diseases it has been the experience that serum-free streptococci, staphylococci, pneumococci, typhoid bacilli, diphtheria bacilli and pseudo-diphtheria bacilli, meningococci and anthrax bacilli are not taken up to any appreciable extent by leucocytes so washed.

In case of anthrax bacilli, on account of the long threads, it sometimes may be difficult to determine whether a given leucocyte is or is not engaged in phagocytosis, but the difference in the relation of the leucocytes to the bacilli in smears from mixtures with and without serum is so striking that I am convinced of the dominant influence of the serum on phagocytosis of this organism also. Löhlein's[7] conclusions to the contrary notwithstanding.

While there can be no question of the essential rôle of substances in the serum in phagocytosis of the bacteria mentioned, as well as of others, there undoubtedly will be found bacteria that are taken up with almost equal readiness by washed leucocytes without and with serum. Thus Miss Tunnicliff finds that certain fusiform bacilli and spirilla are taken up with great readiness by carefully washed human leucocytes, and Dr. D. J. Davis concludes that this is probably also true of the influenza-like bacilli that occur in whooping cough and other conditions, because six typical strains of these bacilli, isolated from various sources, and grown on blood media free from opsonin, were taken up not only by leucocytes in serum, but also, though to a less degree, by washed leucocytes in salt solution. This is true for both human and dog leucocytes.

It is probable, too, that bacteria will be found, phago-

cytosis of which by certain leucocytes, but not by others, requires the aid of serum.

I. THE OPSONINS IN THE SERA OF NORMAL ANIMALS.

The sera of the higher animals normally contain opsonin for many different bacteria. Thus normal human serum contains opsonin for staphylococci, streptococci, pneumococci (of feeble or medium virulence), meningococci, gonococci, influenza bacilli, diphtheria and pseudodiphtheria bacilli, anthrax bacilli, tubercle bacilli, typhoid and colon bacilli, the comma bacillus, the pest bacillus, and probably many other pathogenic and non-pathogenic bacteria. Whether this wide range of opsonic action is dependent wholly on a common opsonin or on several more or less specific opsonins has not been determined. Bulloch and Western[8] found that human serum contains different opsonins for tubercle bacillus and staphylococcus.

In the case of many bacteria strains of reduced virulence are highly sensitive to opsonic influences and the opsonin in the blood of one species may sensitize such bacteria for phagocytosis by washed leucocytes of different species (Hektoen and Ruediger, Bulloch and Atkin). In the case of bacterial strains of high virulence for a given animal, it seems, however, that neither homologous nor heterologous normal serum has the amount or kind of opsonin necessary to subject the organism in question to phagocytosis by the leucocytes of the susceptible animal. The relation of virulence to opsonification is a most interesting one that requires separate consideration.

The serum of normal animals may contain opsonins for other cells than bacteria. I have found that blastomycetes from human lesions become surrounded by masses of leucocytes in the presence of normal human and dog serum, whereas in the absence of serum the leucocytes do not seem to be attracted to the organisms. Preliminary observations indicate that phagocytosis of trypanosomes also is dependent on opsonification.

Barratt[9] noted the presence of opsonins in small amounts for erythrocytes in the serum of normal animals. In my own experiments I have observed that normal rabbit serum may contain substances that subject human and guinea-pig corpuscles to some phagocytosis by dog leucocytes; traces of analogous substances have been noted also in one or two other sera. Clearly the amount of erythrocytic opsonin in normal serum is quite minute and limited in its occurrence as compared with that of bacterio-opsonin.

II. IMMUNE OPSONINS.

Numerous illustrations may be cited of the faculty of the animal organism to react to the introduction of foreign cellular material by the production of special opsonins. It seems that the mechanism concerned is quite analogous to that involved in the formation of other and at present more familiar antibodies. Several years ago (1895) Denys and his co-workers observed that rabbit leucocytes in normal rabbit serum ingested the avirulent strain of a streptococcus, but not the strain made virulent by repeated passages through rabbits. In the serum of rabbits and horses immunized against this streptococcus, the leucocytes, on the contrary, had marked phagocytic power over the virulent cocci.[10] Others also noted the greatly increased phagocytosis of streptococci in the presence of antistreptococcus serum both *in vivo* and *in vitro,* notably Bordet, Aronson and v. Lingelsheim. Strictly analogous phenomena were described by Mennes,[11] in 1897, with respect to pneumococci, and later by others in regard to other bacteria.

Metchnikoff and his adherents ascribed the power of immune serum to cause phagocytosis of virulent bacteria to a special and direct stimulation of the leucocytes. Issaef,[13] as the result of an investigation inspired by Metchnikoff, concluded that antipneumococcic serum owed its protective action to so stimulating leucocytes that they destroyed pneumococci by phagocytosis. Later the same view was advanced by Bordet, Denys, Mesnil, Besredka and others in regard to the action of antistreptococcus serum, and the special substances concerned, were sometimes designated as stimulines.

By others the function of immune serum in the promotion of phagocytosis was conceived to be exercised by a special fixator (*substance sensibilisatrice*) corresponding to Ehrlich's amboceptor or immune body, which by union either with the leucocytes or the microbes changed, so it was thought, the negative chemotaxis of virulent microbes with respect to leucocytes and other phagocytic cells. Savtchenko and Melkich[14] so explained the phagocytosis of the spirilla of recurrent fever in the serum of immune persons and Savtchenko[15] the phagocytosis of red corpuscles under the influence of immune serum.

Wright and Douglas[16] in 1904 noted a marked increase in the opsonic power of patients suffering with chronic staphylococcus infections of the skin (acne, sycosis, furunculosis), in response to the injection of 0.25 to 1 cc. of heated broth cultures of staphylococci. These investigators[17] also found the opsonic power of human serum with respect to tubercle bacilli greatly increased in consequence of minute doses of tuberculin, and Wright has developed on this basis a method of treatment of localized tuberculosis and other infections by vaccines prepared with the corresponding bacteria to which further consideration is given in the latter part of this article. Wright and Douglas were able to show that the newly formed immune opsonins, like normal opsonins, act on the bacteria and not directly on the leucocytes.

Apparently quite independently of Wright and Douglas' work Neufeld and Rimpau[18] found that leucocytes digested in antistreptococcus serum and then suspended in normal serum do not take up virulent streptococci, but that virulent streptococci, treated with antistreptococcus serum, then washed and mixed with leucocytes are taken up freely. Analogous observations were reported with reference to pneumococci. These authors conclude that active antistreptococcus and antipneumococcus sera owe their immunizing effect primarily to their power so to act on the respective virulent organisms as to subject them to phagocytosis, and that these and other similar sera consequently do not fall in the same group as the antitoxic nor as the bacteriolytic but constitute a distinct class.

A little later Neufeld and Töpfer[19] demonstrated that

the blood of rabbits immunized with goat blood contains a substance that by acting on goat corpuscles renders them subject to phagocytosis by guinea-pig leucocytes.

Hence immune opsonins may be regarded as acting primarily on the bodies against which the animals have been immunized, as would be expected in accord with the fundamental idea of Ehrlich's theory, and not directly on the leucocytes.

It has been proposed by Neufeld and Rimpau to designate the substances in immune serum that render bacteria and corpuscles susceptible to phagocytosis as bacteriotropic and hemotropic substances. The term "tropic," however, has been applied to other antibodies as well. Wright and Douglas suggested the name opsonin in 1903, and in view of the priority of their suggestion as well as on account of the appropriateness and adaptability of the term, it, in my opinion, should be applied, as is rapidly coming to be the case, to opsonic substances that arise in consequence of immunization as well as to those present in normal animals. In accordance with the current usage in the case of agglutinins and other terms employed in immunology we may speak of opsonins for bacteria and for red corpuscles as bacteriopsonins and hemopsonins, respectively, normal and immune, as the case may be.

The following experiment is given by way of further illustration of the production of opsonins in response to injections of bacterial substances: A healthy man received under the skin of the arm two 24-hour blood-agar cultures of a virulent streptococcus (381 P.), suspended in salt solution and heated to 60 C. for 30 minutes. This was followed within six hours by a leucocytosis of 12,000, persisting for 48 hours, during which there was a slight fever, a little headache and loss of appetite. An erysipelatous flush spread over the skin about the injection and faded away gradually except over a small indurated area that eventually softened into a small abscess with sterile contents. Now this injection was followed by a fall, succeeded by a sharp rise in the opsonic power of the serum with respect to the streptococcus injected, as shown by the subjacent curve:

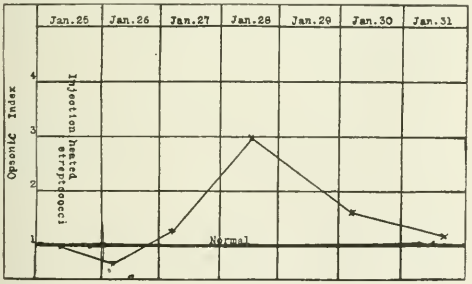

Chart showing increase of streptococco-opsonic index in a healthy man in response to injection of heated streptococci.

The train of events outlined in this instance[20] corresponds to the changes in the antibacterial powers of the blood shown by Wright to supervene on the inoculation of bacterial vaccines in general.[21] At first there was a fall in the opsonin—Wright's "negative phase"—followed by a marked rise, the "positive phase."

The presence of specific opsonin in the serum of immune animals is shown in Table 2 which I have taken from Miss Hamilton and Miss Horton's work on the pseudodiphtheria bacilli.

In this case the presence of specific opsonin is in full

TABLE 2.—PHAGOCYTOSIS OF VARIOUS BACTERIA UNDER THE INFLUENCE OF THE SERUM OF NORMAL RABBITS AND OF RABBITS IMMUNIZED WITH SO-CALLED VIRULENT PSEUDODIPHTHERIA BACILLI.

Washed Corpuscles in NaCl sol., 0.25 c.c. Serum or NaCl sol. 0.25 c.c. Bacterial suspension 0.5 c.c.	Phagocytosis (Average in 40 Leucocytes).			
	NaCl Sol.	Homologous Serum.	Normal Rabbit Serum	Immune Rabbit Serum.
VIRULENT PSEUDODIPHTHERIA BACILLI:

* Leucocytes so crowded with bacilli that no accurate count could be made.

harmony with the protective and curative powers of the immune serum which, however, is also specifically bactericidal.[22]

In accord with the results of experimental immunization we naturally expect increase in opsonin in consequence of certain spontaneous infections, especially of course as convalescence becomes established. The observations at hand indicate such to be the case although this matter has not been systematically investigated. I have referred to the prononnced phagocytosis of the spirilla of recurrent fever observed by Savtchenko and Melkich under the influence of the serum of convalescent patients. Dr. Ruediger[23] notes an increase in the streptococco-opsonic index of erysipelas serum, and in convalescent typhoids there is a well-marked increase in the opsonin for typhoid bacilli, the index in some cases reaching as high as 4. Careful measurements by Dr. Rosenow indicate, as his work now stands, that during the course of pneumonia up to and shortly after crisis there is probably no increase in the pneumococco-opsonic index. Systematic observations have not yet been made in convalescents from pneumonia, but last winter Dr. Ruediger and I noted a well-marked increase in certain cases with localized metapneumonic processes.

The lack of clinical evidence of marked active immunity after streptococcus and other infections of this class would seem to indicate that postinfectious opsonic increase is only of brief duration.

Reference has been made to the development of opsonins for red corpuscles on immunization with blood. The immune hemopsonins are of interest from various points of view especially because their study will help us to understand better the bacterio-opsonins.

Phagocytosis of red corpuscles *in vitro* may be studied in the following manner: The serum of an animal injected several

20. Dr. Ruediger has immunized rabbits with the streptococcus used in this experiment, and as a result of several tests the serum of the immune rabbits have given an average opsonic index of 2.4

21. Medico-chirurgical Transactions, 1905, vol. xxx; Lancet, 1905, vol. ii, p. 1598.

22. Park and Williams (Jour. Exp. Med., 1905, vol. vii, p. 403) noted a slight specific increase in phagocytic power *in vitro* in serum of sheep immunized against pneumococci. This increase, however, was not always in harmony with the protective power of the serum against pneumococcic infection of mice. Cler (Centbl. f. Bakt., part I, 1905, Orig., vol. xl, p. 241) has shown that Sclavo's antianthrax serum contains an opsonic substance for anthrax bacilli; he used washed guinea-pig corpuscles as phagocytes.

23. THE JOURNAL A. M. A., 1906, vol. xlvi, p. 108.

times with increasing quantities of alien blood is heated to 60° C. for 30 minutes in order to destroy the hemolytic complement present and prevent laking. A small quantity of this serum, e. g., .1 c.c., is mixed with, say, .2 c.c. of a 5 per cent. suspension of washed red corpuscles, and to this is added a quantity of washed leucocytes, obtainable from fresh aleuronat exudates, and the whole placed at 37° C. for 30 to 60 minutes or longer, when smears are made and stained. Smears from other mixtures, made in the same way, in which the equivalent amount of normal serum replaces the immune, are used for controls.

When the immune serum is active and the leucocytes well preserved many of them will be found packed with unchanged red corpuscles. Laking in the ordinary sense does not occur, but in a few hours the intraleucocytic corpuscles may swell up or coalesce to form large globules.

Barratt as well as Neufeld and Töpfer have shown that the opsonin is absorbed by the red corpuscles, which now remain susceptible of phagocytosis even after being washed. Leucocytes, on the other hand, are not stimulated to phagocytosis by direct treatment with the serum. I can corroborate this observation and also the fact that leucocytes of various species may be used as phagocytes so that one is not limited for this purpose to the leucocytes of the animal furnishing the serum.

The extent to which immune serum of this kind is specific in its hemopsonic powers has not been determined accurately. An immune serum may have a fairly wide range of activity in case dog leucocytes are used as phagocytes, and, on the other hand, may appear limited in a quite specific way when guinea-pig leucocytes are used as phagocytes. The opsonin just as the hemolytic amboceptor finds suitable receptors in other corpuscles than the particular kind used for immunization, but, so far as my experiments go, immune sera, as a general rule, have the most marked and the earliest opsonic effect on the corpuscles used for immunization; of course, there may be exceptions here.

In various infectious, toxic and anemic processes an extensive phagocytosis of red corpuscles and of other cells takes place in various parts of the body, especially in the spleen, the marrow, the lymph and hemolymph nodes. This process has been studied morphologically by Mallory[24] as it occurs in typhoid fever, and by Warthin[25] as it is seen in the hemolymph glands. Mallory has suggested that bacterial toxins stimulate the phagocytes so that they for a certain length of time acquire "malignant properties." Now the demonstration of erythrocytic opsonins naturally carries with it the suggestion that in certain diseased conditions, infectious and otherwise, substances are produced that render red corpuscles and other cells susceptible to phagocytosis by mobile cells in the same individual. It has been shown experimentally by Savtchenko[26] and others that if serum of a rabbit immunized with guinea-pig corpuscles be introduced into the abdominal cavity of guinea-pigs, then the red corpuscles are promptly taken up by their fellow leucocytes, especially those in the peritoneum and the spleen; Levaditi observed phagocytosis of red cells in the circulating blood also. Ruziczka (quoted by Gruber, loc. cit.) observed this phagocytosis *in vitro*. And Portis[27] found that in dogs injected with the serum of goats, immunized with dog thyroid material, there occurred an extensive phagocytosis of the red corpuscles by hyaline and endothelial cells. In the test tube, dog leucocytes and human leucocytes readily take up the corresponding red corpuscles if these have been influenced by an immune serum of the proper kind. Whether abnormal phagocytosis of red corpuscles occurs in the body of animals immunized with foreign blood has not been determined.

The agglutination of red corpuscles occasionally seen in the organs in typhoid fever and other diseases[28] is held to be the result of the action of hemagglutinins of bacterial origin. Indeed Pearce and Winne[29] were able to demonstrate the presence of hemagglutinins in cultures of typhoid bacilli. Hence it is not unreasonable to expect that hemopsonins also may be developed as the result of infections. Indeed, I have found recently that the serum of convalescents from various infectious diseases (typhoid fever especially, but also pneumonia and scarlet fever) may contain not only agglutinins, but also opsonins for human erythrocytes, which, when acted on by such serum, are subjected to phagocytosis by homologous leucocytes. This demonstration may serve in time to explain to some extent the anemia of many infections.*

III. THE EFFECT OF HEAT ON OPSONINS.

Many normal opsonins are destroyed or rendered inactive by heating at 54 to 60° C. for 30 minutes, some being more resistant than others. Thus normal human serum contains an opsonin for typhoid bacilli that resists heating above 60, and there is an opsonin for anthrax bacilli in the serum of white rats that resists heating to 70. Dean[30] holds that in heating sera to 60 only a fractional destruction of the opsonin occurs, and that on account of the brief time that the opsonin is allowed to act on the bacteria according to the original method of Wright and Douglas (15 minutes) only fairly high concentrations are indicated. On longer treatment of bacteria with serum heated even for a longer time, Dean obtained evidence of the persistence of considerable opsonin. Normal serum kept at about 2° C. may preserve its opsonins for several days, but at 37° C. they seem to deteriorate rapidly.[31] Dean, however, found normal horse serum to contain opsonin even after several years.

Immune opsonins appear more resistant to heat than the normal. Rimpau and Neufeld found that the opsonin in their immune antistreptococcus serum resisted heating to 59° C. for 30 minutes. Dean found that the bacteriopsonins in various immune sera are thermostable, resisting heating at 60° for several hours; he believes that the "fixateurs" of the French and the normal opsonins of Wright and Douglas in reality are indentical in a general way with these thermostable substances, and he recommends the use of the word opsonin in order to designate the particular property indicated by it. On the other hand it is quite possible that normal and immune opsonin may not be wholly identical bodies but differ somewhat, as Landsteiner and Reich[32] conclude is the case with normal and immune hemagglutinins.

The specific opsonin present in the serum of rabbits and goats immunized against so-called virulent pseudodiphtheria bacilli is destroyed on heating at 70° C. for two hours.[33]

Leishmann and his associates[34] found that the serum of persons vaccinated against typhoid fever, after heating to 56° C.,

still contains a substance that promotes phagocytosis of typhoid bacilli, and I have determined on several occasions that the serum of typhoid convalescents contains a typho-opsonin that is not completely destroyed on heating at 70° C. for 30 minutes.

Immune hemopsonins are also thermostable. Barratt found the opsonic power to be reduced by heating at 69, and destroyed after heating at 100° C. for 30 minutes. I have found that the hemopsonin in the serum of rabbits immunized with goat corpuscles persists to some extent after heating at 70° C. for one hour.

Efforts to determine something of the chemical nature of opsonic substances do not seem to have been made as yet.

IV. NON-SPECIFIC ANTIOPSONINS.

The production of specific antiopsonins does not seem to have received much attention as yet, but in mixtures of bacteria, leucocytes and normal serum phagocytosis may be diminished or inhibited by a number of different substances, such as solutions, isotonic with serum, of $CaCl_2$, $BaCl_2$, $SrCl_2$, $MgCl_2$ K_2SO_4, $NaHCO_3$, $Na_3H_3C_6O_7$, $Na_2C_2O_4$, $KFe(CN)_6$, formalin, lactic acid, chloroform, alcohol.

The question of how these substances hinder phagocytosis, whether by acting on the leucocytes, the bacteria or the serum, is an interesting one. The results of experiments by Dr. Ruediger and myself indicate that the substances mentioned act essentially on the opsonin which they prevent from acting on the bacteria. Lactic acid, for instance, in doses of from 0.003 to 0.0015 c.c. of a solution containing 77.14 per cent. of lactic acid ($C_3H_6O_3$) by weight prevents phagocytosis of anthrax bacilli and staphylococci by the leucocytes in 0.5 c.c. of defibrinated blood, human and dog. The antiphagocytic action of lactic acid is also illustrated in its neutralization of the anthracidal effect of normal dog blood as shown in Table 3.

TABLE 3.—THE SUSPENSION BY LACTIC ACID OF THE ANTHRACIDAL ACTION OF DOG BLOOD.

Defibrinated Dog Blood 0.5 c.c. + Lactic Acid + NaCl sol. to Make 1 c.c.	Number of Bacilli in Total Quantity.		
	At once.	3 hours.	6 hours.
Lactic acid .003	5880	0	0
Lactic acid .0015	5880	800	4270
Lactic acid .00075	5880	6370	3080
Lactic acid .000375	5880	600	88
NaCl only + blood	5880	548	22

That this effect of lactic acid is due to action on the opsonin is shown in this way: 0.2 c.c. of serum are mixed with 0.0015 c.c. lactic acid in 0.5 c.c. of NaCl solution and placed at 36° C. for one hour; anthrax bacilli are now added and the mixture returned to the incubator for 30 minutes, when the bacilli are washed twice and suspended in salt solution 0.5 c.c., to which are added washed leucocytes. The control mixtures are made in the same way except that the bacilli are treated with serum free from lactic acid. Counting the leucocytes in each case with reference to phagocytosis shows that the acid prevents the sensitization of the bacilli, and inasmuch as the treatment of the bacteria with lactic acid does not render them insensitive to the opsonic action of fresh normal serum, the action of the acid is primarily on the opsonin.

TABLE 4.—THE ANTIOPSONIC ACTION OF LACTIC ACID.

	Phagocytosis.	
	+	0
Bacilli sensitized in dog serum + lactic acid	0	50
Bacilli sensitized in dog serum + NaCl only	45	5
Bacilli sensitized in human serum + lactic acid	0	50
Bacilli sensitized in human serum + NaCl only	38	12

Neither lactic acid nor any of the other antiphagocytic substances employed in our earlier experiments has any appreciable detrimental effect, in the concentrations tested, on the phagocytic action of leucocytes[35] with respect to previously sensitized bacteria. It is probable, therefore, that certain so-called negatively chemotactic substances, of which lactic acid is a good example, owe their effect to neutralization or destruction of the opsonin. The diminution of resistance to various infections produced by lactic acid[36] and ascribed to its direct repulsion of phagocytes is therefore perhaps dependent primarily on its antiopsonic action.

Non-specific antiopsonins may be important factors in the establishment and spread of various infections. It is quite possible that substances with antiopsonic action arise in consequence of local and general metabolic disturbances. Perhaps it is in this direction that we should seek a better understanding of the so-called lessened vital resistance that we believe permits the development of the primary and secondary infections in which phagocytosis is an essential means of defense. It certainly would seem unwise in such infections to inject into the tissues and vessels agents that, like formalin, possess antiopsonic properties. Of course the condition of the leucocytes themselves must not be left wholly out of consideration inasmuch as it is possible that various agents may reduce not only the property to react to stimuli leading to phagocytosis but also their power to destroy the ingested microbes. Thus Ruediger noted that leucocytes from a case of acute nephritis were less effective in destroying streptococci than those from normal individuals. The decrease of resistance to certain experimental infections by antileucocytic serum[37] is of interest in connection with this question.

V. THE NATURE, STRUCTURE, AND FUNCTION OF OPSONINS.

Are opsonins distinct from other antibodies?—I do not propose at this time to discuss in detail the evidence in favor of the view that opsonins are distinct from lytic amboceptors and agglutinins.[38] The reasons why opsonic action of normal and immune serum are to be regarded for the present as connected with distinct bodies may be summarily stated as follows:

1. Normal serum may possess lytic power, but not opsonic, and *vice versa*.

2. Immunization may give rise to opsonic substances, but not to lytic or agglutinating.

3. Heat may destroy opsonic power, while the lytic amboceptors remain intact, and *vice versa*.

The Structure of Opsonins.—Opsonins like other antibodies occur in normal serum and are produced anew in response to immunization with suitable foreign cellular receptors or antigens. As in the case of other antibodies the production and structure of opsonins are explainable in the general terms of Ehrlich's lateral chain theory. They may be regarded as a product of the reaction of cells in the body to certain receptors or molecules ("opsogens") in bacteria, red corpuscles and possibly other cells for which they in turn have a special affinity. In the case of bacteria it would seem, as pointed out by Neufeld and Rimpau, that it concerns especially those receptors on which virulence depends. Like agglutinins and precipitins opsonins may be conceived

35. Probably true also of alcohol and chloroform in certain concentrations

36. Himmel, for instance (Ann. de l'Inst. Pasteur, 1901, vol. xv, p. 928), produced an artificial susceptibility toward the bacillus of soft chancre by means of injection of lactic acid in a guinea pig. Vaillard and Vincent observed that the addition of lactic acid to pyocyaneus culture in the proportion of 1 to 500 served to repel the leucocytes which otherwise crowd rapidly into the tubes filled with pyocyaneus cultures. Increasing the dilution to 1 to 1,000 leucocytes are no longer repelled. This has been confirmed by Massart and Bordet.

37. Ricketts: Trans. Chicago Path. Soc., 1903, vol. v, p. 173.

38. See Neufeld and Töpfer; Barratt: loc. cit.

to possess two molecular groups, a haptophore, whereby they attach themselves to corresponding receptors in bacteria and other cells, and a functional group which may be called the opsoniferous, whereby is effected in the cell to which they are attached some change, physical or chemical, that is necessary for phagocytosis. Whether it is possible to destroy or inactivate the opsoniferous group and thus to change an opsonin into an inactive opsonoid, comparable to the "oid" modifications of other antibodies, remains to be seen.[39]

The Opsonic Action.—We may regard a leucocyte as a drop of viscid fluid, largely colloid in nature, suspended in a medium in which it is nearly or quite insoluble. Within the drop the particles are subject to the same pressure from all sides, but at the surface the pressure is unequal because of the difference in the cohesion pressures of the two fluids, and as the result of the surface tension a delicate permeable membrane is formed.

The tangible reactions of motile cells like leucocytes to various stimuli are generally interpreted as results of changes of surface tension. When the surface tension is lessened at any part of a leucocyte the wall at this point bulges, and as the contents of the cell flow in here the whole cell moves toward the point of lessened tension. On the other hand, increase of tension at any one point causes bulging elsewhere and the result is that the whole cell tends to move away from the point of increased tension.

Now the stimuli that may cause these changes may come from within the cell and be the result of metabolic activities and chemical or physical in nature. They may give rise to spontaneous motion. Or stimuli may come from without and be chemical, electrical, thermal or mechanical in character. At present the external forces concerned in the motion of leucocytes are regarded as essentially chemical in nature and we speak of the manifestations of these forces as chemotaxis, the term applied by Pfeiffer in 1888 to the attraction that the malic acid in the female sperm cell exercises on the spermatozoids of certain ferns.

Phagocytosis is essentially ameboid motion, continuing until the object is enclosed within the phagocyte, or, in the case of large objects, partly so enclosed. Viewed in the light of the foregoing considerations, the action of opsonins may be defined in all brevity to consist in so changing bacteria and other cells that these by chemical or electrical (possibly also mechanical) means diminish the surface tension of leucocytes and thus bring about phagocytosis or, as stated in terms more familiar, substitute positive for negative chemotaxis.

Manifestly leucocytes from different species may react differently to the same stimulus. Thus the stimulus that lessens the surface tension of human leucocytes may have no such effect upon rabbit leucocytes. In this way one may explain the difference in the behavior of different leucocytes under similar circumstances.[40]

VI. THE INTRAPHAGOCYTIC DESTRUCTION OF BACTERIA.

The demonstration that normal and immune opsonins subject various bacteria to phagocytosis does not prove that these substances are of any importance in infections. It must be shown that the streptococci, pneumococci, and other micro-organisms are destroyed within or by the phagocytes, that phagocytosis is essential for the destruction of certain bacteria by the blood and other fluids of the body. Valuable information in regard to these points, especially as concerns human beings, may be obtained from test tube experiments.

Years ago Denys demonstrated that in mixtures of normal rabbit serum and leucocytes there was little or no destruction of virulent streptococci, but that when immune serum was substituted prompt phagocytosis with complete destruction of the streptococci took place. G. F. Ruediger has shown that in man also the leucocytes play a cardinal rôle in combating streptococcus infections.[41] The serum of normal human beings and of patients suffering from streptococcic infections has no streptococcidal effect, but constitutes a good medium for streptococci. Normal defibrinated human blood, however, has some streptococcidal action and blood from patients with acute infections and leucocytosis has much greater effect, and the higher the leucocyte count the more marked this effect. He shows, too, that the opsonin in the serum must be present in the mixtures of blood and streptococci in order that the latter may be destroyed by leucocytes. "There is no phagocytosis and hence no destruction of unsensitized cocci by washed leucocytes." These facts are shown in Table 5, taken from Dr. Ruediger's article.

TABLE 5.—Streptococcal Action of Leucocytes.

Mixtures.	Colonies on Glucose Agar Plates.		
	Immediately.	2 hours.	24 hours.
Washed corpuscles + serum	1,500	7	21
Washed corpuscles + heated serum	1,400	5,000	Many
Washed corpuscles + NaCl solution	1,700	3,500	Many
Serum	1,200	1,400	Many

The manner in which the body rids itself of pneumococci as pneumonia with its pneumococcemia passes the crisis is of great interest. Recent and as yet unpublished work by Dr. E. C. Rosenow in our laboratory indicates clearly that the pneumococci are destroyed by the leucocytes in co-operation with the opsonin in the serum. In their behavior toward normal and pneumonic serum and toward the leucocytes the pneumococci appear to resemble streptococci as shown in Table 6 which also brings into prominence the numerical influence of leucocytes.[42]

39. Dr. Ruediger and I believed that by heating opsonified bacteria to destroy the opsonic effect, but Bulloch and Atkin (*loc. cit.*) appear to have reached contrary results.

40. Human and dog leucocytes lose the power of phagocytosis of bacteria when heated to 45 C for 30 minutes. After heating at 42 C. there is still good phagocytosis. When mixtures of leucocytes heated at 45 C., with bacteria and normal serum are placed in a shaking machine and gently agitated for an hour or so, the smears commonly show a neat accumulation in more or less perfect circles of bacteria immediately around leucocytes. This interesting phenomenon was first observed by Dr. Rosenow in mixtures of pneumococci, heated human leucocytes and human serum, but is observable in other mixtures of the same general nature. Omitting the serum, heating the serum to 58 C., or heating the leucocytes to 50 C. eliminates in each case some factor or factors essential for the development of this perileucocytic arrangement. Vlassow and Sepp found that motility of leucocytes is increased at 40 C and that temperatures of 42 to 46 C. cause irregular and feeble movements. It is possible that the perileucocytic disposition of the bacteria about the leucocytes heated at 45 C. are the results of movements on the part of the heated cells toward sensitized bacteria, but it also would seem to be necessary to look for some mechanism that holds the bacteria together about the leucocytes. Under the circumstances there must be assumed to exist a mutual attraction between the bacteria and the cells.

41. The Journal A. M. A., 1905, vol. xliv, p. 198, and 1906, vol. xlvi, p. 108.

42. As regards staphylococci I have found that their destruction in human and dog blood is roughly proportionate to the number of leucocytes; that washed blood permits of multiplication and that the destructive action of serum alone falls short of that of defibrinated blood. Furthermore, normal serum heated to 58 C. for thirty minutes mixed with washed homologous leucocytes is a good medium for these bacteria. Hence it may be concluded that here also leucocytes and opsonin are essential for the greatest destructive effect of blood on staphylococci *in vitro*.

TABLE 6.—PNEUMOCOCCIDAL ACTION OF HUMAN LEUCOCYTES.

Mixtures.	Number of Leucocytes per c.mm.	Extent of Phagocytosis in 1 hour.	Number of Colonies on Plates.			
			At once.	1½ hrs.	10 hrs.	24 hrs.

Washed corpuscles, 0.5 + fresh serum 0.5	9500	0*	45	1200	5000	∞
Washed corpuscles, + NaCl sol. 0.5	5500	0	1450	1500	∞	∞
Washed corpuscles, 0.5 + serum heated to 60° C. for ½ hour 0.5	5500	8	1450	1200	1850	1600
Washed corpuscles, (heated to 50° C. for 30 min. 0.5 + fresh serum 0.5	11100	0	1250	1300	∞	∞
Fresh serum 1			480	800	1400	4500

(∞ stands for innumerable.)

* In this case a highly virulent pneumococcal strain, resistant to phagocytosis, was used.

It is generally accepted as extremely probable that the relative natural immunity of the dog to anthrax is due to phagocytosis. Virulent anthrax bacilli grow freely in normal dog serum and in suspensions of washed dog blood. They are destroyed, however, in defibrinated dog blood and the destruction is associated with marked phagocytosis, the bacilli within the phagocytes undergoing the well-known changes described by Metchnikoff in his early, classical experiments on phagocytosis. Destruction also takes place when normal serum is added to washed corpuscles and when bacilli, sensitized in normal serum, then washed, are added to the washed blood or leucocytic exudate. In serum-free mixtures the leucocytes remain scattered, while they gather in clumps about opsonized bacilli.

TABLE 7.—ANTHRACIDAL ACTION OF DOG BLOOD.

Mixtures; total quantity 1 c.c.	No. of Bacilli in Total Quantity.		
	At once	2 hrs.	5 hrs.

Broth 0.5 + NaCl sol. 0.5 + bacilli treated with normal serum	3076	9860	∞

The essential rôle of the intraleucocytic destruction of the bacilli is well shown in plates made with decreasing quantities of blood, a fixed quantity of bacilli, the total quantity being kept at 1 c.c. in all cases by addition of normal dog serum. The destruction decreases as the leucocytes decrease in number.[43]

TABLE 8.—DIMINISHING DESTRUCTION OF ANTHRAX BACILLI WITH DECREASING QUANTITIES OF DOG CORPUSCLES (LEUCOCYTES) AND INCREASING QUANTITIES OF DOG SERUM.

43. Dr. Davis has observed that meningococci undergo rapid disintegration in the cytoplasm of the leucocytes (in serum) as shown by failure to stain.

The prompt and pronounced phagocytosis observed by numerous investigators of different bacteria in the peritoneal cavity in the presence of specific immune serum indicates that opsonins play an analogous rôle *in vivo* as *in vitro*, and we must conclude that in opsonins we have a new form of antibody that plays an essential part in the explanation of immunity to and healing of those infections that are caused by bacteria like streptococci, pneumococci, and staphylococci and others, the destruction of which is not at all or at least not readily accomplished by free lysins and in infections with which there is so pronounced a leucocytosis.

On the whole it seems to me that these recent studies of opsonins and phagocytosis place Metchnikoff's general theory, hitherto perhaps generalized too much, on a very substantial basis.

I shall not attempt to discuss in detail the manner in which the intraphagocytic destruction of certain bacteria takes place and shall leave untouched the question as to the part played by cytase and other bodies. It is interesting to note, however, that, on autolysis or extraction with water, washed dog leucocytes yield soluble, thermostable and filterable anthracidal substances. Whether human leucocytes contain similar substances remains to be determined. Neufeld and Rimpau were unable to extract streptococcidal or pneumococcidal substances from the washed leucocytes of rabbits and guinea-pigs.

Of course it does not necessarily follow that phagocytosis of bacteria is always synonymous with their destruction. The phagocyte may be killed by the toxic products of the bacteria taken up, which in the mean time perhaps have grown in virulence. In this case phagocytosis might be the means of spreading rather than limiting infection. Unquestionably agglutination renders easy the taking up of large numbers of bacteria, but the phagococytes may suffer the more in consequence of the concentration of toxic products. Undoubtedly the power of intraphagocytic destruction varies with respect to different bacteria.

VII. VIRULENCE AND RESISTANCE TO PHAGOCYTOSIS.

A fundamental tenet in Metchnikoff's doctrine of phagocytosis in infections teaches that as a microbe increases in virulence its resistance to phagocytosis increases. Experiments outside the body give results in full harmony with this view.

I have referred to the interesting observations by Denys on the insusceptibility of virulent streptococci to phagocytosis by rabbit leucocytes in normal rabbit serum. Dr. Ruediger and I have found that normal rabbit or guinea-pig serum has no appreciable effect on streptococci in a state of animal virulence (using rabbit, guinea-pig or human leucocytes as phagocytes), but when grown for from two to four weeks on glucose and other media the streptococci become readily susceptible to the opsonic action of the sera mentioned. It has been found also that those media best conserve virulence and resistance to phagocytosis that approach closest in composition to the natural fluids of the body, e. g. blood-agar, serum media.

With the aid of Miss Horton I have made analogous observations with the same general results as to anthrax bacillus and staphylococcus pyogenes. As the strain of anthrax bacillus increases in virulence on passage through guinea-pig to guinea-pig, it resists phagocytosis by guinea-pig leucocytes in guinea-pig serum more and more until it no longer is taken up. In a particular instance the bacillus now killed medium-sized guinea-pigs in doses of 0.00625 c.c. of a 24-hour broth culture. Similarly a strain of staphylococcus, whose virulence for rabbits was raised by successive inoculations soon became insusceptible to phagocytosis by rabbit leucocytes in

rabbit serum. A few days' growth outside the body, however, was sufficient to lower both virulence and resistance to opsonin.

The figures in Table 9 are not strictly comparable for the reason that the suspensions of the different strains, though made of as nearly the same bacterial content as possible, nevertheless may have varied considerably in respect to the actual number present in each. The differences in the degree of phagocytosis, however, are so marked as to leave no doubt of the close relation between virulence and resistance to opsonin.[44]

TABLE 9.—PHAGOCYTOSIS OF ATTENUATED AND VIRULENT BACTERIA.

Organism.	Leucocytes	Serum.	Phagocytosis.	
			Attenuated Strain.	Virulent Strain.
Streptococcus B 104	Rabbit	Rabbit	10	0
Streptococcus B 104	Guinea pig	Guinea-pig	16	1
Streptococcus B 104	Human	Human	10	10.5
Streptococcus B 104	Human	Rabbit	10.5	0
Streptococcus B 104	Human	Guinea-pig	40	0
Staphylococcus	Rabbit	Rabbit	36	0
Anthrax bacillus	Guinea-pig	Guinea-pig	15	0
Pneumococcus*	Human	Human	33	0
Pneumococcus*	Human	Human	33	3.1

* When first isolated by Dr. Rosenow this pneumococcus was virulent for rabbits and was not taken up by human leucocytes. After cultivation for one month on plain agar it had lost its virulence and also its resistance to phagocytosis. After passage through seven rabbits its virulence was restored to some extent and also its resistance to phagocytosis.

It seems, then, that the relative susceptibility of various bacteria to phagocytosis under the influence of normal serum is a very accurate index of virulence of which practical and possibly prognostic use might be made.

The question of the manner in which the bacteria when virulent protect themselves from phagocytosis is of great interest. Marchand[45] reached the conclusion that the resistance of virulent streptococci to phagocytosis depended on the physical state of the cocci because neither living nor dead cocci were taken up and because there was no phagocytosis of virulent cocci freed by washing from all soluble products and placed in filtrates of the non-virulent strain, while non-virulent cocci placed in filtrates of the virulent were taken up freely. My own experiments also show that virulent organisms, freed from antiopsonic substances by washing, on being heated at 55° C. for 30 minutes, are not opsonified when treated with normal serum. Similar treatment of the avirulent strains has no effect on their phagocytability. Now virulent streptococci that are not rendered phagocytable for rabbit and guinea-pig leucocytes by normal serum (rabbit, guinea-pig, human) are taken up to some extent by human leucocytes after treatment with human serum. We know also that virulent cocci are subjected to phagocytosis under the influence of immune serum and, further, that immunization of animals with virulent cocci increases the opsonin in the serum. Consequently, the insusceptibility of virulent cocci to phagocytosis probably does not depend on any lack of suitable receptors or affinity for opsonin, but rather, it would seem, on an increased resistance to its peculiar action, namely, so to modify the cocci that they lower the surface tension of the leucocytes in their neighborhood and thus lead to phagocytosis. The chemical and physical factors, e. g., a possible capsule formation, that protect virulent bacteria against opsonification are subjects for further investigation.

So far as our observations have extended centrifugated culture fluids of virulent streptococci, staphylococci and anthrax bacilli reduce phagocytosis of the corresponding non-virulent strains, principally, I believe, through direct action on the leucocytes because the fluids in question have but a comparatively slight inhibitive or destructive effect on the opsonin in normal serum, but reduce greatly by one hour's contact the phagocytic power of leucocytes with respect to previously sensitized bacteria. In full harmony with this loss in phagocytic power are the marked functional and morphologic disturbances in the leucocytes placed in fluids containing the products of the growth of virulent bacteria. Thus, when leucocytes are placed in the culture fluids of a virulent streptococcus and examined from time to time on the warm stage, they are seen to lose ameboid movement and to swell greatly in from 30 to 60 minutes, whereas the leucocytes in control experiments remain normal in form and motion several times as long.

Dr. Ruediger[46] has shown that the filtrates of virulent streptococcus cultures may suspend the destruction of non-virulent streptococci by leucocytes.

According to Dr. Rosenow's observations suspensions of virulent pneumococci do not prevent phagocytosis of other bacteria, and he has not been able so far to secure any evidence of a pneumococcal leucotoxin.

In serum-broth cultures of rabbit-virulent streptococcus (streptococcus M. 1 and B. 104) Dr. Ruediger finds that leucocytes undergo marked morphologic changes after from one to one and a half hours at 37° C. There is no phagocytosis or very little; the cytoplasm appears more or less homogeneous with indistinct margins and the nuclei may swell up into large masses with irregular outlines; many cells appear indistinct, the nuclei only faintly stained, and disintegration seems to be taking place. These changes are still more profound after three hours in the incubator. They take place to about the same degree in the culture fluid from which most of the streptococci have been removed by centrifugalization, but not nearly to so marked a degree in Berkefeld filtrates. Heating the centrifugated fluid at 56 and 62° C. for 30 minutes does not destroy its leucocidal powers. In 24-hour cultures of a non-virulent streptococcus there is good phagocytosis and only a few cells show any changes. In control specimens from sterile ascites broth the cells appear quite normal with definite deeply stained nuclei. Changes occur also in guinea-pig leucocytes treated with centrifugates of broth cultures of virulent anthrax bacilli and in rabbit leucocytes treated with centrifugates of cultures of virulent staphylococci.[47]

In some of our experiments Dr. Ruediger and I have obtained evidence that the serum of animals immunized with virulent streptococci may neutralize the leucocidal and antiphagocytic actions of virulent streptococcus filtrates, but much further work is necessary to secure definite results of general value.

It would seem, then, that as certain bacteria under the influence of stimuli from the host increase in virulence they become better able to defend themselves against phagocytosis in at least two ways, namely, by producing

44. Dr. Rosenow finds that pneumococci which have been recently isolated from pneumonic patients, as well as those that are virulent for rabbits, as a rule are relatively resistant to phagocytosis in normal human serum. The rapidity with which virulence and resistance to phagocytosis are lost on artificial cultivation vary greatly, and both properties are best conserved in media containing blood. While difficult, yet Dr. Rosenow, by prompt reinoculation of organisms obtained from the blood during the life of inoculated rabbits, has been able to restore lost virulence and with it relative insusceptibility to phagocytosis.

45. Arch. de Med. exp., 1898, vol. x, p. 253.

46. THE JOURNAL, A. M. A., 1905, vol. xliv, p. 198.

47. The leucotoxic power of staphylococci was first studied by van de Velde (La Cellule, vol. x, Ann. de l'Inst. Pasteur 1896, vol. x, p. 580), and by Denys and van de Velde (La Cellule, vol. xi), who showed that the leucocidin, as the particular substance concerned in leucocidal action is called, on immunization gives rise to a specific antileucocidin. The toxins produced by staphylococci have been studied also by Neisser and Wechsberg (Zeitschr. f. Hyg. u. Infektionskr., 1902, vol. xxxvi, p. 299).

substances that are harmful to the phagocytes and by an increased resistance to opsonification. Conversely we may think of the host as defending himself against certain infection by the production of opsonins and of anti-leucocidal substances.

VIII. GENERAL CONSIDERATIONS OF THE PRACTICAL AND THERAPEUTIC IMPORTANCE OF THE INVESTIGATIONS CONCERNING OPSONINS.

The Opsonic Value of Antistreptococcus Serum.—The usefulness of specific sera in the curative treatment of established streptococcemia and like diseases may be a limited one in so far as essential symptoms perhaps are due not solely to bacterial intoxication but in large measure to substances derived from abnormal changes in the constituent elements of the host. The fact, however, that in progressive infections of this kind there seems to be an unabated multiplication of bacteria in the blood and the tissues lend strong support to the view that the functional disturbances are dependent on the growth and activity of the bacteria.

If the conclusion already indicated be correct, namely, that certain virulent bacteria, so to speak, guard themselves against phagocytic destruction by means of substances that are harmful to the phagocytes and by resistance to opsonification, then one would expect potent antibacterial sera for organisms in this class to contain at least two kinds of substances, namely, antileucocidal substances and opsonic substances, powerful enough to subject the virulent strains to phagocytosis. Neufeld and Rimpau explain the action of their antistreptococcus and antipneumococcus sera as due to occupation of the bacterial receptors on which virulence depends and which give rise to the production of immune bodies.

At present the principal serum used in infections in the healing of which phagocytic immunity may be regarded as an essential phenomenon is antistreptococcus serum. Tests made a year ago by Dr. Ruediger and myself showed that the antistreptococcus sera then in general use in this country all possessed a lower opsonic index for various streptococci than normal horse serum, many samples being without any opsonic power presumably on account of their age. It would seem that a careful study of the streptococco-opsonic index of the different sera at different times might prove of interest for the purpose of determining not only the degree and duration but also the range of their opsonic activity with reference to different strains of streptococci of differing virulence, thus securing valuable indications of the content of specific antibodies in sera that have hitherto been insusceptible of adequate control.

Perhaps sera of increased opsonic potency might be obtained if opsonic receptors of virulent streptococci freed beforehand from other constituents of the bacterial cells could be used in the immunization of animals. The study of antistreptococcus sera with reference to antileucocidal, antistreptolytic and other antibodies may also yield valuable information. These remarks would seem to be equally applicable to antipneumococcus serum.

Considerations Relating to Leucocytosis.—The study of opsonins has given us a clearer conception of the relative importance of local and general leucocytosis. The use in the treatment of septic infections, so-called, of agents that increase the general leucocytosis (collargol, nucleinic acid, etc.) may be of benefit and quite rational if the increased leucocytosis be produced at times when the opsonic index is high and, further, if the agents used do not in themselves reduce or neutralize the opsonin.[48] In many of these conditions and in pneumonia, for instance, in which there is commonly a very high leucocytosis, it would seem that the opsonin is at fault as much as if not more than the leucocytes, and we need detailed investigations on this point.

The efforts of Mikulicz and others to enhance the resisting power of the peritoneum and of the body in general by the production of leucocytosis preliminary to abdominal operations associated with grave dangers of infection—"the summons of leucocytes as advance guards"—would seem to be a rational procedure in favor of which we have considerable experimental evidence. In this case also, care must be taken that the leucocytotic agents employed do not depress the opsonic index. The suggestion lies near at hand that the chances of the patient would be raised still further if the operation could be made during the positive phase of Wright, the period of increased bacteriotropic content of the blood, following inoculations with vaccines, properly dosed, of dead cultures of the bacteria most likely to cause infection, namely, streptococcus, colon bacillus, staphylococcus.

Considerations Concerning the Treatment of Various Local Infections.—There are various procedures employed, many of them more or less empirically, in the treatment of local infections, all of which serve in some way or other to increase the flow of blood and lymph through the area involved. Here belong hot applications of different kinds, rubefacients and irritants, massage, Bier's method of artificial hyperemia, the exposure to *x*-ray and radium, and also, in a measure at least, the Finsen treatment. Wright[49] has pointed out that the blind empirical use of some of these methods may not always be without danger when the blood possesses only inferior antibacterial power and that their effectiveness may be increased in various ways, but particularly when the antibacterial power of the blood, as measured by its opsonic index, is high either as a result of reactions to autoinoculations or to artificial inoculations of the proper bacterial vaccine. By the measurement of the opsonic index, then, valuable information may be obtained to guide in the treatment of local infections. Considering the practical impossibility in many cases of local tuberculosis of removing completely all infected tissue, it certainly would seem more desirable to undertake operation, if considered necessary, at a time when the tuberculo-opsonic index is high rather than when it is low and the general resistance of the patient to the bacilli that remain and may enter the opened lymph spaces consequently relatively reduced. The work of Wright and his followers on the antituberculo-opsonin in the blood of tuberculous patients also offers new points of view for the explanation of the healing of tuberculous peritonitis after laparotomy, long the subject of much discussion.

Brief Reference to the Therapeutic Inoculation of Vaccines.—Finally, I come to the most important practical part of this whole matter, namely, the value of the opsonic index in the successful treatment of infections, especially chronic and local and, above all, tuberculous, by means of the inoculation of bacterial vaccines, i. e., sterilized and standardized suspensions of bacterial cul-

48. Bulloch and Ledingham (Bulloch: Lancet, 1905, vol. ii, p. 1603) found that certain agents—"betol," tallianine increase the leucocytosis but not the opsonin content, while nuclein from yeast increases the opsonin (for what bacteria is not stated), and also the number of leucocytes, but the latter effect was inconstant.

49. Medico-Chirurgical Trans., 1905, vol. lxxxix.

tures. It is the merit of A. E. Wright, of London, who, since 1902, has been carrying out the underlying investigations to which I have referred so frequently, that this method of treatment has been placed on a firm and promising basis.[50]

According to Wright, many local infections persist, for the reason that the causative bacteria or their elements are not permitted to pass into the circulation in such numbers as to stimulate the machinery of immunization to form adequate quantities of antibodies at the proper time, and because the bacteria, in a measure, are protected from the action of such antibodies as may be present normally in the body or form in the course of the infection. Numerous tests by Bulloch and others show that in the tuberculous the tuberculo-opsonic index is subnormal. In lupus the average is 0.75 (Bulloch).

By measuring the resistance to the infective germ by comparison of the opsonic power of the patient's serum with that of the serum of normal persons, Wright and his followers have shown that in all infections there are times when the resistance of the patient is rising and times when it is falling. In the latter instance the repeated introduction of the corresponding bacterial vaccines serves to depress still further the opsonic index, i. e., to lower the patient's general resistance. The vaccines should be administered when the opsonic index is high—this is the fundamental principle of Wright's method—and by "properly adjusted and interspaced" doses; in other words, by controlling the effects by means of the opsonic index aim to maintain the antibacterial power of the blood at a high level. By numerous tests Wright has shown that in tuberculosis much smaller doses of new tuberculin than commonly employed give maxima' immunizing responses without any constitutional disturbances. For this he employs new tuberculin in doses corresponding to from 1/1000 to 1/600 mg. tubercle powder.

As pointed out already, Wright, in addition to the use of "properly adjusted and interspaced" doses of vaccine in the treatment of local infections, especially tuberculous, also employs means to increase the flow of blood and lymph through the infected area in order to favor as much as possible the action of the antibodies on the bacteria.

This, briefly, is Wright's method of treatment of infections by inoculations of the corresponding vaccines. Remarkable results have been achieved in intractable cases of bone, lymph node and subcutaneous tuberculosis. The application of the general method to pulmonary tuberculosis, in which Lawson and Stewart[51] and others have shown that tuberculin when properly given also increases the tuberculo-opsonic index, promises well and it is hoped that Wright's treatment may be given a thorough trial.

50. For the references to Wright's publications on this subject see his address "On the General Principles of the Therapeutic Inoculations of Bacterial Vaccines as Applied to the Treatment of Tuberculous Infection," Medico-Chirurgical Transactions, 1905, vol. lxxxix, and Lancet, 1905, vol. II, p. 1598. See also Bulloch, Practitioner, 1905, and Lancet, 1905, vol. II, p. 1603.

51. Lancet, 1905, vol. II, p. 1697.

Massage of Inflamed Tonsils.—Molinié of Marseilles is quoted by the *Gazette Méd. Belge* as having been very successful in treating tonsillitis by squeezing out of the tonsils the concretions and septic relics which keep up the trouble. He introduces his forefinger and compresses each tonsil in turn from below upward. The procedure makes the tonsil bleed a little, and this local bleeding also aids in the cure.

MALARIA IN THE TROPICS.*

WILLIAM C. GORGAS, M.D.

Colonel and Assistant Surgeon-General, U. S. Army; Chief Sanitary Officer, Canal Zone.

ISTHMUS OF PANAMA.

Since 1898 I have served almost continuously in the tropics—four years in Cuba and two years at Panama—part of the time with troops, but most of this time being connected with municipal sanitation.

At Santiago, Cuba, I was with the army at the Base Hospital at Siboney, where all the seriously sick were sent during the entire campaign against Santiago until the army returned home.

In Havana I had charge of the yellow-fever wards at Las Animas Hospital. Las Animas was the hospital for contagious diseases for the Sanitary Department of Havana, and, while a large majority of the patients treated by me there had yellow fever, a considerable number of malarial cases were also received, being mistaken for yellow fever.

Here at Panama I am in charge of the yellow-fever ward. All non-immunes with fever from any cause coming into Ancon Hospital are sent to these wards, and much the larger proportion of these cases are malaria. We treat something like two hundred cases of malaria each month in these wards.

I give here my experience in some detail so as to indicate what my opportunities for observing malaria in the tropics have been. This experience has impressed on me the fact that malaria in the tropics is by far the most important disease to which tropical populations are subject, either military or civil. While the percentage of fatalities is not nearly so great as from some other tropical diseases, the amount of incapacity caused by malaria is very much greater than that due to all other diseases combined. I was very much impressed with this at Santiago. While we had more deaths from yellow fever and typhoid fever than from malaria, the latter was the disease that prostrated our splendid little army. About the beginning of August there were very few individuals that were not suffering from fever, and the army, as a whole, was scarcely able to move. The mental depression caused by this general sickness can hardly be appreciated by any one who did not see it, and against a fresh enemy of greatly inferior strength our army at that time would have been entirely helpless. This campaign was a good illustration of what might occur to an army operating in the tropics and subjected to unchecked malaria. I have not at hand the statistics to which I can refer concerning the mortality from malaria during this campaign, but my recollection is that it was not very fatal. I recollect very few cases of pernicious malaria or black-water fever.

In a tropical city like Havana, where I spent the four years succeeding the Santiago campaign, malaria was by no means so general as one would expect. The anopheles have very little opportunity of breeding about a city except in the suburbs, but even at Havana a greater number of persons died from malaria every year than from yellow fever. In Havana all our efforts and attention were given to the eradication of yellow fever, and very little emphasis was laid in our reports on the effect which the mosquito work had on malaria. This, however, was very marked. The average number of deaths reported in Havana from malaria for many years had been about 350; in 1901, our first year of mosquito

* Read at the Annual Meeting of the American Society of Tropical Medicine, in Philadelphia, March 24, 1906.

work, it was 151; in 1902, 77; in 1903, about 50, and it has remained since that date at about 40. I conside· that for a city the size of Havana this means the practical extermination of the disease, as that number of cases in the ordinary course of events would be brought in from the outside, or be due to mistakes in diagnosis.

Panama, I suppose, is as favorable a place for the development of malaria as could be found. The towns of Colon and Panama, at the termini of the canal, are not large enough to do away with the breeding of anopheles; that is, anopheles breeding in the suburbs can very well travel to the centers of these towns, and the population living along the canal in little villages a mile or two apart, between Colon and Panama, are ideally situated for the development of malaria. About one-third of the canal runs through a low alluvial and marshy plain, and the other two-thirds pass through a hilly and mountainous country. Along the banks of the little rivulets, which run in every direction, the anopheles breed just about as well as in the marshy level country, and the very general infection of the population by malaria causes most of the anopheles near human habitations to become infected.

We knew from the experience of our predecessors on the Isthmus that malaria would be our greatest trouble, and we did what we could toward correcting the conditions. Our greatest endeavor has been toward draining the localities near all towns and dwellings, so as to make the ground as dry as possible, and in order to leave as few breeding places as possible for the mosquitoes. In places that could not be drained, oil was used very freely.

With a large body of laborers such as we have here, I think an equally important measure is the giving of prophylactic doses of quinin. We also screened as many of the houses as possible and influenced all inhabitants to use mosquito-bars. These measures followed up persistently have had a great effect in reducing the malaria.

With a force of 22,000 men on the pay rolls during February, we had only twenty-two per thousand incapacitated every day on account of sickness. As I said before, fully three-fourths of this sickness was due to malaria, but the total would not be a large sick rate in a healthy locality in the United States. In my wards at Ancon I have personally treated 1,055 cases of malaria in the last six months. In each of these cases a blood examination was made and the character of parasite recorded. The estivo-autumnal variety largely predominated, but the attacks in general were mild and yielded easily to treatment. Among these 1,055 cases we have had only five deaths. So far as personal care for malarial fever is concerned, I believe that the most important thing the individual can do is to take a small dose of quinin daily. While this will not always prevent attacks, in a given body of men it will enormously reduce the number, and I think will prevent a severe type of the disease when it comes. The good results we have had in hemoglobinuric fever have surprised me most. In these wards we have had twenty cases of hemoglobinuric fever in the past eight months, and of these we have lost three.

The treatment has been the persistent use of quinin as soon as we could get hold of the patient. For the first three or four days the quinin is given hypodermically, but as soon as the patient ceases to vomit it is given by mouth; twenty grains in the twenty-four hours hypodermically and thirty by mouth has been the ordinary course. I have seen no evil results that could fairly be attributed to the administration of quinin, and I have often wondered if it could be the same disease which the English have on the west coast of Africa and in which so many of their leading practitioners think that quinin does harm.

The malaria we have here at present among the whites seems to me about as grave, and no graver, than the malaria which I treated in the garrisons along the gulf coast in the United States.

I look forward very hopefully to a diminution in the prevalence of malaria down here. It seems to me that by the continuance of our present measures we ought still further to decrease malaria. Year by year the ditching will decrease the number of anopheles near the habitations along the Canal Zone, and the treatment of the patients in hospital and the constant giving of prophylactic quinin will decrease the number of people who are liable to spread the infection, and I believe that these two forces will act and react as time goes on. Our conditions have been as trying in the past year as they are likely to be. We have had a larger force of men than the French had. The population was very generally infected with malaria, and the ditching and draining had just been completed. All these conditions ought to improve steadily as time goes on, and it seems to me a perfectly rational hope that malaria will decrease in the same ratio. Even if we can not decrease malaria below what it is at present, we will have succeeded in building the canal with no greater number of days lost from disease than if we were building it at home. I hope to do better than this.

A COMPARISON OF THE PHARMACOLOGIC ACTIVITY OF THE FLUID EXTRACT OF SQUILL PREPARED ACCORDING TO THE UNITED STATES PHARMACOPEIA 1890 AND 1900.

E. M. HOUGHTON, Ph.C., M.D.
DETROIT, MICH.

Quite a number of more or less important changes in the method of making some of our important standard pharmaceutical preparations have been introduced in the new eighth edition of the United States Pharmacopeia. One of the most radical of these changes is the substitution of acetic acid (10 per cent. absolute acid) in place of alcohol (95 per cent.) as the menstruum for making fluid extract of squill. During the past eight years it has been my privilege to examine personally, or to check the results obtained by an assistant, many samples representing thousands of pounds of fluid extract of squill and other heart tonics for physiologic activity. The method of assay has been substantially that given in an article published in The Journal[1] for making quantitative pharmacological assays of the heart tonics.[2] For the sake of clearness it may be explained that the strength of the given preparation is determined by a comparison of the minimum fatal dose per gram body weight of frog of the unknown and the known standard, the minimum fatal dose of each being determined at the same time by injecting the properly diluted preparations into the abdominal lymph sacs of frogs of the same size and species and kept under the same conditions. The standard adopted for squill

1. The Journal A. M. A., Oct. 22, 1898.
2. Further details of this method of assay will be found in the 1905 edition of the National Dispensatory, page 1728.

has been a fluid extract prepared according to the seventh edition of the United States Pharmacopeia from first-class drug, and possesses the average physiologic activity of several fluid extracts produced from different lots of drug, made by the same formula.

Records for the past two years show that the strength of fluid extract of squill (U. S. P., 1890), as it is obtained from the manufacturer, fluctuates between 30 and 140 per cent. of the standard. Usually the activity of the percolate has been found to approximate the strength of the standard within 10 per cent., in this respect being much more uniform in activity than similar preparations of digitalis, which have been found to fluctuate between 50 and 300 per cent. standard.

Immediately after the issuance of the eighth edition of the United States Pharmacopeia, a commercial lot of fluid extract of squill was made according to the new formula which differs so radically from that previously employed. Some difficulty was experienced in making the percolate, and the final product when physiologically assayed was found to possess about 30 per cent. of the activity of the standard. At first it was thought that the drug was not completely exhausted and repercolation was resorted to, but subsequent tests showed that the physiologic action of the second percolate was not materially more active than the first (Table 1).

5	5	27 gms.	.0016	Died.

Table 1.—Minimum fatal dose of standard .0015; minimum fatal dose of fluid extract being assayed between .0005 and .0055. The dose was not closely determined as the product was much below strength, and it was deemed advisable to fortify it by continuing percolation.

It seemed desirable as a check to examine the product of several reputable firms. Accordingly there was obtained on the open market the fluid extract of squill from three different houses made according to the new and the old formulæ. These were assayed as above, except that the end results were checked more closely (Table 2).

The names of these manufacturers are not given for obvious reasons, being designated simply by the letters A, B and C.

TABLE 2.—Comparative Strength of Fluid Extract of Squill Bought on the Open Market.

	U. S. P., 1890. Menstruum 75 per cent. alcohol.	U. S. P., 1900. Menstruum about 10 per cent acetic acid by weight
A	25 p. c. as active as standard.	44 p. c. as active as standard.
B	100 p. c. as active as standard.	53 p. c. as active as standard.
C	135 p. c. as active as standard.	50 p. c. as active as standard.

Sample A, United States Pharmacopeia, 1890, for some reason, probably owing to poor drug or imperfect extraction, is the least active alcoholic fluid extract of squill that has ever come to my attention. It is of therapeutic interest likewise to note the great variation in the activity of both the 1890 and 1900 preparations.

In order to be more certain of the results obtained from the use of the menstrua, four experimental lots of fluid extract of squill were made, two according to the United States Pharmacopeia, 1890, and two according to the United States Pharmacopeia, 1900, all from the same drug, extreme care being taken that the directions given be followed exactly so far as possible. No special difficulty was experienced in employing the alcoholic menstruum, but in the case of the acetic acid, after repeated trials, it was found absolutely impossible to percolate the drug according to the directions given, suction being finally resorted to in order completely to exhaust the drug (Table 3).

TABLE 3.—Comparative Strength of Fluid Extract of Squill Prepared from the Same Lot of Daug According to the United States Pharmacopeia of 1890 and 1900.

1, U. S. P. 1890, 140 per cent. as active as standard fluid extract.
2, U. S. P. 1890, 140 per cent. as active as standard fluid extract.
3, U. S. P. 1900, 60 per cent. as active as standard fluid extract.
4, U. S. P. 1900, 60 per cent. as active as standard fluid extract.

It may be observed that activity of both products is high as compared with the results given in Table 2. This probably is due to the great care exercised completely to exhaust the drug and to the high quality of the drug.

In order to meet any objections that might be offered against the results as shown by the special method of assay employed, the work was checked by experiments on dogs showing the comparative activity of the two products in producing changes in the blood pressure, which is perhaps the most characteristic physiologic action of the members of the digitalis series (Tables 4 and 5 and Figs. 1 and 2).

Experiment No. 8, Nov. 22, 1905 (Charts 1 and 2).

Dog, weighing 14 kilos, was anesthetized with chloretone and morphin. A manometer tube was connected with the right carotid; the time-marker recorded seconds.

At 10:45 a. m. the pulse rate was 100, blood pressure 46 mm., mercury, respiration 8.5 a minute. At 10:45.5 a. m., 0.3 c.c. of fluid extract of squill (U. S. P., 1890), diluted to 5 c.c. with physiologic salt solution, was slowly injected into the femoral vein.

At 10:46.5 a. m. pulse rate was 102 blood pressure 54 mm., mercury, respiration 8.

At 10:51.5 a. m. pulse rate was 96, blood pressure 55mm., mercury, respiration 7. The dog was kept quietly in place on the table until 2:40 p. m., when the experiment was repeated.

At 2:40 p. m. pulse rate was 116, blood pressure 48 mm., mercury, respiration 5.5 a minute.

At 2:41 p. m. 0.3 c.c. of fluid extract of squill (U. S. P., 1900), diluted to 5 c.c. with physiologic salt solution, were injected into the femoral vein.

At 2:41.5 p. m. pulse rate was 124, blood pressure 50 mm., mercury, respiration 8.

At 2:46.5 p. m. pulse rate was 138, blood pressure 45 mm., mercury, and respiration 11.

In this experiment particular notice should be given to the tracing (Fig. 1), which shows more strongly than words that the 1900 preparation produces very slight digitalis action. It may be objected that this animal was kept on the table until it was exhausted before the second part of the experiment was continued. Table 5 gives similar results, but is not open to this objection, as the animal received an injection of the 1900 product when first put on the table.

Experiment No. 10, Nov. 23, 1905 (Charts 3 and 4).

Dog, weighing 12 kilos, was anesthetized with chloretone and

morphin; a canula was inserted in the right carotid; no attention was paid to respiration.

At 8 46 a. m. pulse rate was 102, blood pressure 47 mm., mercury.

At 8:46.5 a. m. 0.3 c.c. of the fluid extract of squill (U. S. P., 1900), diluted to 5 c.c. with normal salt solution, were injected into the femoral vein. It at once produced a transient fluctuating rise in blood pressure, which subsided very quickly to normal.

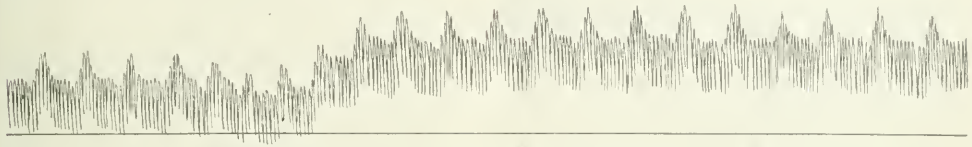
At 8:48 a. m. pulse rate was 104, blood pressure 46 mm., mercury.

At 9:15 a. m. pulse rate was 98, blood pressure still 46 mm.

At 9:20 a. m. pulse rate and blood pressure were the same as at 9:15. Fluid extract of squill (U. S. P., 1900), 0.3 c.c., was injected as before.

At 9:22 a. m. pulse rate was 100, blood pressure 52 mm., mercury.

At 9:27 a. m. pulse was 94, blood pressure 50 mm., mercury.



Pulse rate 100
Blood pressure 46 mm.

CONCLUSIONS

From these results we may conclude that acetic acid is not so satisfactory a menstruum as alcohol for making a fluid extract of squill. The therapeutic results obtained from the use of fluid extract of squill (United States Pharmacopeia, 1900.) will be variable and considerably less than would be expected from the use of the 1890 preparation. It would seem desirable that physicians in prescribing squill should indicate that they desire the preparation of the United States Pharmacopeia. 1890, when they wish to obtain the usual therapeutic action of squill.

A CASE OF HEMORRHAGE FROM THE STOMACH, DUE TO CIRRHOSIS OF THE LIVER, IN WHICH GASTROENTEROSTOMY WAS DONE ON THE SUPPOSITION THAT THERE WAS GASTRIC OR DUODENAL ULCER.*

WILLIAM J. TAYLOR, M.D.

Attending Surgeon to the Orthopedic Hospital and Infirmary for Nervous Diseases, and to St. Agnes' Hospital; Consulting Surgeon to the West Philadelphia Hospital for Women.

PHILADELPHIA.

NARRATIVE OF CASE.

Patient.—A man of 40 years of age, of rather medium height and weight, family history negative.

Previous History.—There was no tendency to tuberculous or other constitutional disease, and he had never had syphilis. He had always enjoyed good health, was a steady, hard worker in an office where he had large business responsibilities, and he took unusually good care of his health. He lived in the country, where he walked, and rode a bicycle. He ate plain food and never touched liquor or tobacco. About thirteen years previously he had had a severe attack of typhoid fever with very high temperature, but from this he made a complete recovery. His wife said that he had never been ill, and had never taken any medicine beyond an occasional dose of calomel for his liver, which at times had been torpid. He was a dark brunette with rather sallow skin, but his three children have about the same color and appearance.

History of Present Illness.—During the past summer he had great anxieties and business cares involving much additional care and responsibility, and for this reason, he told me, he had been particularly careful of his own health, lived on the simplest kind of food, had special bottled milk brought to his office which he drank between meals, as a precaution against letting his health run down. He could not recollect having had the slightest indigestion or any symptoms referable to his stomach.

Hemorrhage.—On Sept. 21 he reached his home in the country at 10:30 p. m., having been hard at work in his office in the city until late, and went out to the toilet in the yard. He strained quite hard at stool and then came in through the kitchen, which had been closed up and was very hot. He felt nauseated, picked up a basin, and vomited a large amount of blood, which, by actual measurement, was a quart and a pint.

Treatment.—His wife, hearing him come into the house but not in from the kitchen, went to look for him, and got to him just at the end of the vomiting attack. He was so weak that she put him down flat on the kitchen floor, and his pulse disappeared entirely from the wrist. His wife, who is a physician, gave him strychnin and ergot hypodermically. His little daughter had been ill with typhoid fever and there was in the house and ready a sterile salt solution with apparatus for intracellular infusion. This his wife got at once and pumped into him one quart of the solution, aided by a trained nurse who was in the house, and then she summoned other assistance. Undoubtedly the man would have died from the loss of blood if this plan of treatment had not been instituted so promptly. Some of the saline solution was also injected into the bowel, and after its use brownish-red blood came away.

Subsequent History.—Conditions improved, and in about two hours he was lifted by two men and carried into the next room and laid flat on his back on a mattress on the floor. In less than half an hour he had another severe hemorrhage from the stomach, vomiting without effort one quart and half a pint of blood. His collapse was most profound, and Dr. T. Branson, who had been hastily summoned, and Dr. McCollin gave him strychnin and ergot hypodermically, and thirty drops of adrenalin (repeated in an hour) was given by the mouth. Morphin was also administered. His condition was so bad and his weakness so profound that they could not remove his outer clothing, and he was kept flat on the floor for five days. He was seen at this time also by Dr. Musser, who agreed in the diagnosis of ulcer and advised that a gastroenterostomy be done. This was also urged by Dr. Branson, but Dr. John H. Gibbons, who saw him at the same time, was opposed to immediate operation.

At the end of five days the man was taken to the Bryn Mawr Hospital and kept under observation for two weeks. Nothing whatever was given him by the mouth and he was nourished entirely by the rectum. The bowel was irrigated daily with normal salt solution, and tarry evacuations persisted until about the twelfth day. Peptonized broth and other peptonized preparations were given every six hours. Malted milk enemata were tried, but were always expelled. For two weeks the man had no food by the stomach, and, while the rectum retained the nourishment introduced into it, he became cross, irritable and slightly delirious as the result of extreme hunger. He was taken back to his home on October 7, where I saw him for the first time on October 9.

On this date an enema was given, and after some straining he complained of distress and gas in the stomach and bowel. On inserting a rectal tube to carry off the gas the end became covered with tarry material and on irrigation more was found. No food was given by the mouth for twenty-four hours. The irrigations were dark-colored for five days.

The patient reacted well from this setback, but the anemia was much more marked. With cautious use of food by the mouth and rectal feeding his general condition improved very much and his color showed he was making blood fast.

On the morning of October 15 he awakened his wife, who was lying asleep on the foot of his bed, to tell her that he felt very uncomfortable in his stomach—he had a feeling of distension and nausea. Almost immediately he vomited a considerable quantity of blood, and during the day he passed tarry material from the bowel. This day he was brought in an ambulance to the city, where, after his arrival, he again vomited a little blood and had black, tarry stools.

Consultation.—Dr. M. J. Lewis saw him with Dr. McCollin and me in consultation. He was extremely pale, showing evidences of internal hemorrhage, although his pulse was fairly good. He had edema of the feet and fluid in the abdomen; but this we thought to be confined to the large bowel and was probably a collection of fluid blood. The heart's action, considering the profound anemia, was good. The kidneys were acting well and the spleen and liver did not seem to be altered in size from the normal. His temperature was slightly above normal. He had vomited some little blood the day before, and had passed, and was passing, dark, tarry material from the bowel. His condition was so extremely grave that we deemed it best to wait, if possible, for a few days before deciding on operation, to enable him to regain the ground lost from this additional hemorrhage. He was given adrenalin chlorid, strychnin and nourishment by the bowel.

Examination of Blood and Urine.—On this date the following examinations were made of the urine and blood:

Urine: Light amber, clear, no sediment, acid reaction; sp.

* Read before the College fo Physicians of Philadelphia, Feb. 7, 1906.

gr., 1023; no albumin; no sugar; centrifugated specimen contained only a few leucocytes.

Blood:

	Per cent.
Polymorphonuclear	58
Small erythrocytes	32
Large erythrocytes	4
Transitional	4
Basophiles	2
	100

Macrocytes and microcytes present.
Hemoglobin, 45 per cent.
Coagulation time, 3 1/3 minutes.
Microscopic:
Leucocytes, 2,400.
Erythrocytes, 1,280,000.
No malarial organisms.
Widal, negative.

Course of Disease.—The next day his general condition had decidedly improved. There had been no more vomiting of blood and no bloody stools. He did not appear so completely exsanguinated, although still very pale, and on October 19 Dr. Lewis again saw him with me in consultation, when we found his color better. He had also gained in strength, but there was still some general edema. For twenty-four hours he had taken some Valentine's meat juice by the mouth in addition to the rectal feeding.[1] There was little or no change in the physical condition since the last consultation, two days before, and not quite so much liquid in the ascending and transverse colon.

Operation.—Dr. Lewis again saw him with me early, October 21, and his condition had improved so much that we decided on immediate operation, and for this purpose he was taken to the Orthopedic Hospital and carried directly into the operating room. His condition was such that it was not deemed advisable even to take him in the elevator upstairs to a bedroom. Ether was given him by Dr. George W. Spencer, and the skin of the abdomen was shaved and prepared after he was on the operating table.

An incision was made through the right rectus muscle, and as soon as the peritoneum was opened there gushed out a large quantity of perfectly clear, straw-colored fluid. This escape of fluid was so marked that every one present who saw it immediately thought of the possibility of malignant disease and spoke of the necessity of a more careful examination of the abdominal cavity than a simple operation for gastric ulcer would ordinarily require. It was almost impossible to relax the belly wall without danger to his life from the anesthetic.

The vessels of the stomach and omentum were much engorged and resembled a colored diagram of an injected subject. The stomach was examined over its anterior surface, but no ulcer or induration could be detected. It was not dilated; indeed, it was smaller than normal. On the anterior or free border of the duodenum, about one and a half inches from the pylorus, was found a thickening of the gut wall about three quarters of an inch in its longest diameter, almond-shaped, not circular, and much unlike the surrounding surface. It was distinct in outline, but not hard or indurated, as would be the case in chronic ulceration, and this I took to be an acute ulcer, probably the site of the hemorrhage. There were numerous, very recent, easily separated adhesions about the duodenum, liver and mesentery. The edge of the liver was examined by the finger and by sight, but nothing abnormal was distinguished, and the gall-bladder seemed normal. There was nothing unusual in the portal space, and the pancreas seemed to be of normal size and consistency.

The omentum and colon were lifted up, a slit was torn in the mesocolon and with the finger, and the whole of the posterior surface of the stomach wall examined without finding any induration or evidence of ulceration. A posterior gastro-enterostomy with a short loop was then rapidly performed by Moynihan's method by clamps. Pagenstecher thread was used for both hemostatic and peritoneal sutures. The mucous membrane in the incision in the stomach and intestines was cut out with scissors. Owing to his weak condition and the profound shock caused by the operation no effort was made to suture the slit in the mesocolon to the stomach wall, although this was quite large.

There was nothing unusual in the technic of the operation, other than difficulty was experienced in pulling out the stomach sufficiently far to clamp it. A pint of normal salt solution was introduced into a vein in his left arm, and he was given strychnin and atropin hypodermically.

He reacted nicely from the shock of the operation and did not vomit. Nothing was given by the mouth for seventy-two hours, but during this time he was nourished by the rectum. Salt solution was also given by the bowel.

Postoperative History.—On the morning of the third day he had three small stools, the fecal matter coming out through a rectal tube; the first and second contained some few dark and very old bloodclots, mixed with the fecal matter, but from that time on there was no evidence of blood in the stools. There was no distension of the intestines nor disturbance of the stomach, and he was given first water and then Valentine's meat juice, and for some days was nourished in addition by the bowel.

On October 27, the sixth day, as his pulse, temperature and respiration were normal, he was given some scraped beef, a soft-boiled egg and toast by the mouth, without any discomfort following.

His color steadily improved and his strength increased, and on October 28, or just one week after the date of operation, his blood showed 52 per cent. of hemoglobin, 2,170,000 red cells and 2,800 white cells.

By the end of another week he was feeling perfectly well and was digesting all food most satisfactorily. Indeed, the only articles of food which showed any appearance in the stools were two grapes which he had swallowed apparently without chewing, and these had slipped from the stomach into the bowel. He had some edema of the feet and ankles.

On November 7, or three weeks after the operation, he was again seen by Dr. Lewis in consultation, when there was very marked edema over the whole of the body—the feet, ankles, genitalia, chest wall and even the forehead and cheeks. He was passing only a limited amount of water, although the urine showed no evidence of disease of the kidneys.

Urinalysis.—November 8.

Macroscopic: Light yellow, cloudy, slight flocculent sediment, acid reaction, sp. gr. 1017. No bile. No sugar. Faint trace of albumin.

Microscopic: Centrifugated specimen contains a great quantity of calcium oxalate crystals and leucocytes, with a number of epithelial cells.

Physical condition.—The abdomen was distended by fluid, so much, indeed, that his abdominal binder had to be let out several inches, and on a careful physical examination by Dr. Lewis free fluid was found in the pleural cavities, particularly so on the right side. At this time his blood count had improved. The spleen did not appear to be enlarged, neither did the liver seem to be contracted, although on this one point I have not a note made at the time; but the impressions of Dr. Lewis and Dr. McCollin, as well as my own recollection, all go to show there was no apparent diminution in the size of the liver. As the edema was very marked, we were fearful of some form of obstruction to the portal circulation.

Treatment.—We agreed that diuretics in the shape of Basham's mixture, with strychnin and careful feeding, would be the best plan of treatment, and considered that the edema might be accounted for by the extreme poverty of his blood. The amount of urine, which had been scant, increased under this plan of treatment by leaps and bounds until he was passing from 80 to 90 ounces of urine in twenty-four hours. The edema rapidly disappeared, the fluid apparently left the abdominal cavity, and he steadily improved in health and strength.

At the end of three weeks he was allowed to sit up in bed and to go out and about in a little over four weeks.

Blood Examination.—By November 22, or at the end of four weeks, an examination of the blood showed: hemoglobin, 55

1. On October 18, 1905, Dr. L. Webster Fox found considerable thinning of the choroid coat and retina. The remains of a hemorrhage between the optic nerve and macula were visible. The blood vessels in the neighborhood of the hemorrhage were enlarged. He had, also, high degree of myopia, for which Dr. Fox had refracted him in 1898.

per cent.; red cells, 2,810,000; leucocytes, 4,800. Cells were of good size and shape.

General Condition.—All this time his color was improving; he was eating and sleeping well, digesting his food perfectly, and his stools were normal in appearance and color. He became so well and strong that it was impossible to keep him away from his office, to which, at the end of seven weeks, he insisted on going with regularity, but keeping short hours and doing only a small amount of work.

PERIOD OF APPARENT RECOVERY.

On December 27, or at the end of nine weeks, he came to my office and reported that he had gained in weight, which was now 151½ pounds, or about his normal weight. All edema had been gone for weeks, and he had gained in strength. He was going to his office each day for a few hours and simply assuming direction of the work without doing any hard work himself. His digestion was perfect. A careful examination of the abdomen showed the scar to be in good condition. There was no distension of the abdomen and I did not detect any marked diminution in the size of the liver nor enlargement of the spleen, or did the superficial abdominal veins seem unduly prominent. He told me he had eaten a somewhat hearty and injudicious Christmas dinner, but that he had felt no ill effects from it. He did tell me, however, that he had had some dark stools, not the black stools seen so commonly in persons who are taking iron as he was doing, but brownish-black. Several of the stools were not homogenous as to color, but were partly dark and partly light. These dark and partly colored stools had somewhat alarmed his wife, and he came to see me largely to tell me about them and to relieve her anxiety. His general condition was so satisfactory that I did not attach very much importance to this symptom, and advised him merely to take food between his meals, to be careful as to the amount which he ate at any one time, and suggested that he eat only a few articles at each meal.

RELAPSE.

He did not feel well on January 1 and his wife noticed that he was paler than usual, and complained of discomfort in the stomach. He went into town after eating a simple breakfast, however, and went to his office where he remained until 2 p. m. He spent the remainder of the day at the house of a relative, but ate little and slept most of the afternoon, and then returned to his home in the country. He walked from the station to the house—about half a mile—and went to bed about 9:30 p. m.

Hemorrhage.—A little after midnight January 2 he awakened his wife, saying that he felt nauseated, and started for the bathroom but fell at the bedroom door, unconscious and pulseless. Almost immediately he passed by the bowel a large amount of blood, which was dark and contained numerous clots. In a few minutes he regained consciousness, called for a basin, and vomited a large quantity of dark blood and some few clots, showing that the bleeding must have been going on for some hours. The total amount of blood lost by the bowel and from the stomach must have been even greater than at the time of his first hemorrhage in September.

Subsequent History.—I saw him in about 4 hours, when his pulse was 96, full, quite strong, and of good volume. He was perfectly conscious but extremely blanched in appearance and was sweating profusely. He had no more hemorrhages that day and passed a very good night, but about 11 a. m. January 3 he had another hemorrhage which was bright red in color and contained also a few old currant-jelly like clots. He was still further blanched in consequence of this hemorrhage but reacted very well from it, and his pulse, while rapid, had a good volume.

On Jan. 3 his pulse was very fair but he was terribly blanched; his abdomen was scaphoid with no distension whatever; there was no enlargement that could be detected of the spleen; but the liver dullness was greatly diminished—so much so that it did not come anywhere near the edge of the ribs. There was no distension of the abdomen nor any possibility of intestine floating over the edge of the liver and thus obscuring its outline. Certainly there was some condition present producing portal congestion and Dr. Gibbons and I both believed him to be suffering from an acute cirrhosis of the liver.

On January 4 Dr. Lewis saw him with us again in consultation and now the diminished size of the liver was very apparent, but not so easily demonstrated as the day before, for the large bowel was filled with blood from further hemorrhage. Early on the morning of January 5 he steadily grew worse, had another hemorrhage and bleeding constantly from the bowel until he died on the night of January 6.

On this day a blood count showed: Hemoglobin, 14 per cent.; red cells, 1,300,000; white cells, 16,000.

AUTOPSY.

A postmortem was performed Jan. 7, 1906, by Dr. Longcope.

Anatomic Diagnosis.—Atrophic cirrhosis of liver; enormous dilatation of veins along the greater curvature of stomach near the cardia, with erosion of mucous membrane of stomach, and hemorrhage. Gastroduodenostomy; adhesions between omentum and anterior parietes; slight ascites and rightsided hydrothorax; edema and congestion of the lungs.

General Appearance of Body.—The body was 168 cm. in length with marked rigor mortis. There was very slight postmortem lividity over dependent parts. The mucous membranes and skin surfaces were exceedingly pale, and there was slight edema of the forehead and a suspicion of edema of the ankles. On the right side of the abdomen there was a linear scar 12 cm. in length, extending up from the umbilicus; it was completely healed. On incision the subcuticular fat was found present in fair amount and light yellow in color. The muscles of the thorax were red; those of the abdomen much paler. On opening the abdominal cavity the omentum was found to be adherent to the anterior parietes immediately beneath the abdominal wound and for some distance to the right of it. The adhesions were fat and contained a number of blood vessels, some of which were almost as large as a match stick. The area of parietal peritoneum covered by adhesions measured 7.5 cm. in length by 6 cm. in width. The liver was just visible to the right of the xiphoid cartilage. The urinary bladder was greatly distended. The abdominal cavity contained a small quantity of almost colorless, clear fluid. The intestines were bluish-gray in color, distended, and the serous surfaces were everywhere moist, smooth, and glistening.

Thorax.—The lungs were voluminous and met in the middle line. The left lung was bound to the chest wall by numerous delicate fibrinous adhesions. There was no fluid in the left pleural cavity; the right pleural cavity contained about 200 c.c. of very pale, clear fluid. The pericardial cavity contained a slight excess of clear fluid. The serous surfaces were smooth and glistening.

Heart.—The epicardium was smooth; there was a moderate amount of fat; the cavities contained pale firm clots and fluid blood; the muscle was exceedingly pale and yellowish in color, rather soft. The left ventricle was found to be 10 to 12 cm. in thickness. The valves were normal with faint thickening at the base of the aortics. The coronary arteries were delicate and patulous. The aorta was smooth and rather narrow.

Lungs.—The left lung was very large and heavy. The pleura was covered with fibrous tags, and there were small hemorrhages over the pleura. On section the cut surface oozed quantities of frothy fluid. The surface was smooth and pale pink; air was present throughout. Bronchi at the root of the lung contained frothy fluid; the vessels were clear. The right lung was exactly like the left except that the pleura was free from fibrous adhesions.

Spleen.—The spleen measured 17x11.5x6.5 cm. and was much enlarged, very soft, exceedingly pale, pinkish mottled with purple. It was regular in outline. The capsule was much thickened but free from adhesions. The pulp was exceedingly pale and very soft, with extensive coarse reticulation. Between the reticular bands the pulp was depressed and the space seemed only partially filled. There were adhesions between the gall-bladder and hepatic flexure of the colon, so that the gall-bladder and hepatic flexure were covered by a continuous coat of peritoneum. All the vessels were normal in the portal space.

Liver.—Weight, 1070 gm.; size, 23x14x9 cm.

The liver was quite small, slightly irregular and very firm. The capsule showed some irregular thickening and through it injected blood vessels were seen. There were no adhesions. The surface was finely granular. The inferior surface was much more coarsely granular and in places there were deep pittings. The color was a tawny yellow. On section the cut surface was seen to be rough and presented a very irregular, coarsely granular appearance, producing an artificial lobulation. Between the lobules there were tiny depressed lines, pinkish in color. The portal connective tissue was much increased and filled with small injected blood vessels. Many of the bile ducts were also injected with bile. The gall-bladder was fairly large and covered posteriorly with adhesions. It contained thick, dark green bile. The bile ducts were patent.

Kidney.—Size of the left kidney was 11x5.1 cm. The kidney was of medium size, regular and decreased in consistency. The capsule stripped well, leaving a smooth pale yellowish gray surface. On section the cut surface showed great pallor. The cortex and medulla were in good proportion. The medullary pyramids were regular and pale pink. The cortex was regular and pale yellowish, the striæ were very poorly seen, but when visible appeared to be regular. The glomeruli were invisible. The cortex varied from 5 to 7 mm. in thickness. The pelvis appeared to be normal.

Pelvic Organs.—The urinary bladder, prostate, testes and seminal vesicles were not examined.

Stomach.—The stomach was fairly large. At a distance of 8 cm. from the pylorus, an anastomosis was found between the stomach and the loop of duodenum a few cm. from where it entered the peritoneal cavity. The point of anastomosis was on the posterior wall just posterior to the attachment of the omentum to the greater curvature. All about the line of anastomosis there was much fat which was attached to the wall of the stomach and duodenum and hid the line of anastomosis. On opening the stomach much dark brownish-black grumous fluid escaped, together with some blackish blood clots. The mucous membrane was pale, thin, and showed toward the fundus some mammillation. The opening between the stomach and the duodenum was beautifully smooth, the edges were round, and one could scarcely tell where stomach mucosa stopped and mucosa of duodenum began. A suture still hung free from the line of anastomosis. There was a loop of tough black string 6 cm. in length. The ends of the loop emerged from exactly opposite sides of the wound and hung free in the stomach. Attached to the dependent part of the loop there was a mass of soft greenish-black material about the size of an almond, but with stringy margins looking something like a bunch of seaweed. On the peritoneal surface of the stomach along the greater curvature and about 5 cm. from the cardia there was a bunch of tortuous enormously dilated veins, which covered an area about 7 cm. in diameter. They were collapsed, but some of them seemed as large as a thumb. The mucous membrane and wall of the stomach covering them was exceedingly thin and the tortuous vessels showed through the mucous membrane and appeared to run in a ring 5 cm. in diameter. At one point over the veins there was a tiny erosion in the mucous membrane about 2 mm. in diameter. On injecting the veins with Berlin blue the coloring matter escaped from this tiny erosion, but from nowhere else in the mucous membrane. About the cardiac end of the esophagus there was another small varix. The largest single veins there were about the size of a slate pencil. Fluid injected into these veins did not escape through the mucous membrane. The veins anastomosed with the vessels along the lesser curvature of the stomach. The splenic and mesenteric veins were enormously dilated and showed many anastomoses.

Other Abdominal Organs.—The duodenum was apparently normal. The mucous membrane of the first portion of duodenum was delicate. There were no scars or ulcers. The pancreas was apparently normal. The other organs were not examined.

HISTOLOGIC EXAMINATION.

Heart.—Sections of this organ show a good deal of fat in the pericardium. The myocardium is edematous; in patches the fibers show a fine fatty degeneration. The striæ are not well-marked and there is much fragmentation.

Spleen.—Sections of the spleen show chronic interstitial splenitis. The capsule is thickened. The pulp spaces are empty and collapsed. There is marked general increase in connective tissue with great thickening of the trabeculæ and thickening of both media and intima of blood vessels. The Malpighian bodies are very small and in them, too, there is an increase of connective tissue.

Liver.—Sections of the liver show interlobular cirrhosis. There is marked increase of connective tissue of the portal spaces, cutting the section into coarse lobules. This is very slightly cellular and there is slight, if any, increase in bile ducts. The liver cells are generally granular and show some fatty degeneration. In certain localized areas the liver cells are very large, pale, finely granular, and contain sometimes two or three nuclei. The capillaries about the central veins are large but empty.

Kidney.—Sections of the kidney show extensive degeneration of the epithelium, and some slight increase in connective tissue of cortex. The tubular epithelium shows the most extreme grade of degeneration in patches. The cells are granular, frayed, often desquamated, and the nuclei refuse to stain. Some tubules contain large fat droplets. The ascending loops of Henle are particularly affected. There is no cellular infiltration.

DISCUSSION OF CASE.

The great interest in this case centers, of course, in the diagnosis and in the probable cause of the development of cirrhosis of the liver.

Here was a man, 40 years of age, who had lived a most simple and exemplary life, and who had never taken alcohol in any form, had never had syphilis, nor any tendency, either inherited or acquired, to tuberculosis or other constitutional disease. At the time of operation, as soon as the peritoneum was opened and the clear serum gushed out, doubt as to the accuracy of the diagnosis of acute ulcer of the stomach was at once entertained by all present, and for this reason a more careful, although very rapid, examination was made, by sight and touch, of all of the organs within easy reach. The edge of the liver was seen, and it did not present any gross changes such as would have suggested cirrhosis, and the finger, passing over its anterior surface, did not detect any roughness. The other organs were normal in size and consistence, but I thought, and, indeed, those present believed with me, that there was a distinct ulcer on the free border of the duodenum about one and one-half inches from the pylorus. Here was a spot a little less than an inch in diameter and rather oblong in shape, which was different in color from the surrounding gut; it was indurated, and in grasping it with the fingers gave the sensation of thickening of the intestinal wall, such as is noticed in the very early stages of ulceration of the intestines in typhoid fever. There was, however, no marked induration, such as would have been present if there had been an ulceration of long standing, and not only my assistant, Dr. Macy Brooks, but also Dr. Morris J. Lewis, agreed with me in thinking that this was probably the site of the hemorrhage.

The examination of this place in the gut after death did not disclose any true ulceration; all induration and thickening had disappeared, but at this point the mucous membrane seemed somewhat less thick and its surface had a slight difference in appearance from the surrounding mucous membrane. This was certainly not a healed ulcer. Indeed, it could not have been an ulcer at all; but it must have been an area of hyperemia which, if the gastroenterostomy had not been performed, might have become an ulcer. It is possible, however, that this might simply have been a muscular spasm of a limited portion of a wall of the gut.

The operation of gastroenterostomy was of the most signal benefit by providing drainage for the stomach, thus greatly lessening the local congestion and consequent hemorrhage. The patient was able almost immediately to digest freely a variety of foods in normal amount, and all hemorrhage, both by mouth and bowels, ceased at once. The omentum attached to the parietal peritoneum directly beneath the scar in the belly wall was most happy in its effects; the large blood vessels in it permitted the portal stasis to be greatly relieved, thus accomplishing by accident that which is attempted in Talma's operation.

Our error in diagnosis was very great, but the results accomplished in respect to comfort to the patient—ten weeks of perfect relief from all hemorrhage—somewhat atoned for our mistake.

The details of differential diagnosis between this and other forms of portal congestion and the various forms of ulceration of the stomach and intestines must be left largely to the medical diagnostician in consultation in the case; but I did not give sufficient prominence, in forming my diagnosis, to the sudden and violent hemorrhage occurring without any antecedent symptoms of disorders of digestion, and without there being any pain either before or after its occurrence. While the absence of pain and the sudden overwhelming hemorrhage are all in favor of portal obstruction rather than definite ulceration, yet many cases of acute ulceration are reported by Moynihan and other writers of large experience where all other symptoms referable to the stomach have been wanting.

This somewhat lengthy report is made in the hope that much may be gained in the discussion of the details of this extremely interesting case, and because we have been most fortunate in having had an autopsy made by such an expert pathologist as Dr. W. T. Longcope. I wish to thank him again for the most careful and painstaking manner in which this examination was made.

REVIEW OF LITERATURE.

Dr. R. B. Preble,[2] Chicago, has collected reports of sixty cases of fatal gastrointestinal hemorrhage due to cirrhosis of the liver, all that had been reported in literature up to that date. The most common cause was varices of the esophagus. In the great majority of the cases the cirrhosis was atrophic. In one-third of the cases the first hemorrhage was fatal, and in the other two-thirds the hemorrhages continued at intervals over a period varying from a few months to several years, the maximum time being eleven years. His conclusion is that in one-third of these cases the diagnosis can be made at or before the time of the first hemorrhage; in the other two-thirds the diagnosis can not be made at all, or only after months or years, during which time other symptoms of cirrhosis have developed.

Esophageal varices were present in 80 per cent. of the cases. In only 6 per cent. in these cases which showed esophageal varices was the cirrhosis typical.

One death was due to erosion of veins in the stomach near the cardia. He states that these veins in the cardiac end of the stomach are part of the portal system, while those of the esophagus are part of the systemic system; that they connect by anastomotic branches, which, as a rule, are too small or two few to contribute much to the formation of a collateral circulation when the portal system is obstructed; when, however, the anastomosis is free they become an important factor, and their dilatation may so completely compensate for the veins obstructed in the liver that the clinical course of the case is altered and obscured.

The compensation may be so complete that all the clinical symptoms on which a diagnosis of cirrhosis of the liver must depend, namely, the splenic tumor, the ascites and the subcutaneous abdominal varices, are wanting, and the patient, while apparently in good health, dies suddenly from hemorrhage from the stomach. Hemorrhage was the first and only symptom in ten out of thirty-five of these cases. Two patients whom he mentions, a man of 45 and a woman of 22, were both perfectly temperate in their habits, with no previous history of any predisposition toward cirrhosis, and in both a diagnosis was made of ulcer of the stomach, but the autopsy demonstrated that the stomach and intestines contained no lesions whatever.

THE ULTIMATE RESULTS OF KIDNEY FIXATION.*

J. H. CARSTENS, M.D.
DETROIT, MICH.

As a more or less movable kidney seldom occurs without other morbid conditions of the body, it is often very difficult to tell which of the various symptoms found in a case are produced by the movable kidney and which are produced by the other pathologic condition; therefore, the controversy about the symptomatology and the relief obtained in fixing movable kidneys.

My object in writing this paper is to help clear up some of the points at issue, and I have taken my own experience as a basis from which to draw conclusions. I have gone back five years—to July 1, 1900—and selected all those cases operated on in which the kidney was apparently the only trouble and in which there were no other serious complications or only such other light operations required as curettage, hemorrhoids and catarrhal appendicitis, etc. Cases in which complicated operations were required, such as gall-bladder operations, abdominal hysterectomies, etc., have been excluded as not proper for this inquiry. All other conditions not requiring surgical interference, such as the digestive symptoms, nervous symptoms, pain in the back in the region of the kidney, were considered and taken note of. The patients that came to me sometimes knew they had a movable kidney, sometimes they did not, but in either case they were suffering from the following symptoms:

A feeling of distress and pain was experienced on the afflicted side, in every case the right except one. There was more or less distress. When standing or when lifting anything they would often have a severe colicky pain, which they had generally learned to relieve by forced expiration of the air from their lungs, by bending forward and twisting their body in a peculiar manner, each finding his or her own way of being relieved. Perhaps they would have no trouble for days and weeks at a time. Some of the patients would notice a swelling or lump in the side that would disappear when lying on their back. They would consult their physician and the diagnosis was made.

In nearly every case there was a disturbance of digestion, especially of the intestinal variety, accompanied by bloating; in fact, many patients complained only of that, and on investigation a loose kidney was found.

* Read before the Tri-state Medical Society, Michigan, Indiana, Ohio, Jan. 9, 1905.

Nearly all patients lost flesh, whether they knew what the trouble was or not. The nervous disturbances were well marked in nearly every case. They can be probably best described by calling the condition neurasthenia, which, of course, varies so much in symptoms, more or less severe as hysteria. In general I may say these patients suffered from that indescribable nervousness and restlessness which we find in irritation and disturbances of the sympathetic system of nerves, often accompanied by hypochondriasis and despondency. There was no severe pain or distress in any cases except in those in which I assumed there was a kinking or twisting of the ureter.

In order to get at the ultimate result I wrote out a circular, which I sent to the patient and also to the family physician, expecting thus to hear from one or the other, if not from both, and get the report of the largest number of cases. As already stated, I carefully selected those cases in which I thought the kidney was at the bottom of the trouble. For the five years mentioned the patients number thirty-two, and I received answers from fourteen patients and eighteen answers from the physicians. There were some duplicates. In six instances personal examination was made. The facts in each form the basis of this article.

In the circular letter I asked the following questions:

1. *Has the kidney remained in place?*
2. *Has the pain and distress been relieved?*
3. *Have the stomach and digestive symptoms improved?*
4. *Have any other symptoms of pain or distress been relieved?*

The object of the first question was to find out whether my present technic was perfect. Apparently there has been only one failure which required a second operation. I shall take up the question of technic at some future time. The object of the second question was to find out whether the pain and distress caused by the kidney itself has been relieved. The object of the third was, "Did a floating or movable kidney really produce digestive disturbances?" The fourth was simply put in to get the general results.

CONDENSED REPORT OF CASES.

CASE 1.—Miss A. C., aged 24. Operation Feb. 24, 1900. Family physician wrote: "Yes, is married and has a baby; moved away."

CASE 2.—Mr. F. Operation Sept. 3, 1900. All questions answered "Yes" by family physician. "Works hard."

CASE 3.—Dr. C., aged 28. Operation Nov. 10, 1900. Seen one year later; feeling good.

CASE 4.—Mrs. W. D. J., aged 30. Operation April 15, 1901. First question answered "Yes"; second, "Not entirely; never had digestive trouble; still has dysmenorrhea."

CASE 5.—Mrs. E., aged 26. Operation May 7, 1901. Reported by her physician, who answers all questions with "Yes" and adds: "Her health is better now than it has been for the last ten years."

CASE 6.—Mrs. J., aged 25. Operation July 26, 1901. There was a small ovarian cyst which I removed through the vagina and fixed the kidney in place. Her doctor answers all questions "Yes" and adds: "She has been in good health ever since."

CASE 7.—Mrs. S., aged 25. Operation Oct. 1, 1901. Patient had floating kidney, result of a fall apparently. Her doctor answers all questions "Yes" and adds: "Delivered her of a child two years after operation."

CASE 8.—Mr. G., aged 25. Operation Jan. 27, 1902. I operated on in August, 1901, with an *en masse* suture through the kidney of silkworm gut. When he went to work it came down again, and this time I sewed the resected capsule to the muscle. He has worked hard at farming ever since and writes: "Digestion very much better."

CASE 9.—Miss M., aged 17. Operated Oct. 29, 1902. When lifting a very heavy trunk she noticed something giving way and I found the kidney the only trouble. Stitched in place and her family physician reports by answering all question "Yes."

CASE 10.—Miss M. G., aged 21. Operation March 7, 1903. Physician answers: "Kidney not in proper place, but fixed a great deal better than before." To third question: "A great deal; she can do a good deal of work."

CASE 11.—Mrs. M., aged 29. Operation Jan. 8, 1903. Only trouble floating kidney. All questions were answered "Yes."

CASE 12.—Miss L., aged 16. Operation Feb. 21, 1903. Both kidneys floating. All questions answered "Yes" by her family physician, who adds: "Recovery was slow, but progressive. The girl is now comparatively strong and healthy. It took about a year for complete recovery." She writes: "The kidney has remained in place and I am real well and working every day."

CASE 13.—Mrs. H., aged 27. Operation April 15, 1903. Curetted for endometritis and floating kidney fixation. Report from family physician answers all questions "Yes," which she repeats, but complains of bladder.

CASE 14.—Miss J. K., aged 17. Operation April 30, 1903. Had appendicular colic and floating kidney; could not tell which was most distressing. Removed appendix and stitched kidney in place. She has been perfectly well since.

CASE 15.—Mrs. C. Operation June 30, 1903. Floating kidney with torsion and attacks of severe pain. Kidney fixed in the usual manner. I found liver large and made a small exploratory opening, looking for gallstones, but found none; fixed the coronary ligament to the lower angle of the wound. Family physician answers all questions "Yes" and adds: "She has had no more severe attacks of pain and is much improved."

CASE 16.—Miss D., aged 24. Operation Feb. 14, 1904. A very hysterical patient. Kidney fixation only. Excepting the last she answers all questions "Yes."

CASE 17.—Mrs. G., aged 27. Operation Feb. 27, 1904. Fixed right kidney and double decapsulation for albuminuria. Kidney in place and much improved for six months. Left the city and address not known.

CASE 18.—Mr. S., aged 27. Operation March 23, 1904. Double kidney fixation. All questions answered "Yes." Personal examination.

CASE 19.—Mrs. C., aged 36. Operation Dec. 15, 1904. All questions answered "Yes."

CASE 20.—Mrs. W., aged 45. Operation Aug. 1, 1904. First case of left kidney fixed in place. Her family physician answers all questions "Yes" and adds: "Some distress and nervous symptoms have been relieved." She also answers herself in the same way.

CASE 21.—Miss C., aged 35. Operation Aug. 30, 1904. Patient was suffering from severe dysmenorrhea, for which I inserted a stem pessary and fixed the kidney. The stem pessary dropped out soon after. Her family physician reinserted one lately. He reports kidney still in place. To the second question he answers: "Not entirely." To the third question, "No," and adds: "There was considerable improvement for two or three months and then relapse." Her present condition evidently due to the dysmenorrhea.

CASE 22.—Mrs. G., aged 31. Operation Dec. 15, 1904. Neurotic patient. She answers: "Yes, the kidney is in place; has been relieved of pain and distress, but gradually had return of her headache." To the third question she answers: "Yes, but suffering from constipation." To the fourth question, "Yes."

CASE 23.—Miss T., aged 30. General ptosis. Operation April 25, 1905. The right kidney seemed to cause much trouble; both kidneys fixed. Answers first and second questions "Yes" and adds: "Must still wear abdominal belt. Stomach does perfect work; bowels still give trouble."

CASE 24.—Mrs. B., aged 47. Operation June 10, 1905. Kidney in place. She is the first patient who complains of pain in the region of the incision; perhaps it was pulled up a little too tight. She had other troubles and really does not belong here, but is mentioned on account of pain in the incision.

CASE 25.—Miss P., aged 28. Operation May 28, 1905. Neurotic. When examined four months later kidney was in place and patient had gained five pounds. She walks four to five miles a day. She is not relieved of general abdominal ptosis.

Since reading this paper I saw a patient on whom I operated

five years before and who had not received my letter. She had been perfectly well and worked hard during this time until three months ago, when she again had pain in the right side, which increased. I found the kidney movable, evidently caused by very hard work.

DISCUSSION OF RESULTS.

These condensed reports are more than three-fourths of the total number of cases selected and ought to give the general average ultimate results. To the first question, Has the kidney remained in place? the answers are all "Yes." (One early case was operated on the second time.) Has the pain and distress been relieved? is also answered with "Yes," except by one, who complains of pain in the incision of the back. To the third, Have the stomach and digestive symptoms improved? most answered "Yes," except a few, who evidently expected also relief from headache or chronic constipation The fourth question, Have any other symptoms, pain or distress been relieved? is answered "Yes" by nearly all patients, while a few still have other troubles.

I have always claimed that the whole question was one of correct diagnosis. I have any number of cases of movable kidney which I do not operate on when they produce no serious symptoms. I have always operated on cases in which I did not know if the kidney or the other pathologic conditions produced the trouble. In nearly every operative case which also has a loose kidney I fix the latter in order to be sure that I cure my case, otherwise the patient will not be relieved and blame me for not doing so. In case of general abdominal ptosis, fixation of the kidney will be of little benefit, although it may relieve one symptom, viz., the distress caused by the kidney, and I always refuse to operate on those cases except the patient has a clear understanding of the doubtful benefit. Still, some of those cases receive a great deal more benefit than they or I expect. I never make any promises. If, however, there is kinking and twisting of the ureter, or albumin makes its appearance in the urine, then I operate, as I have found that fixing a loose kidney and decapsulating it pretty thoroughly relieves, or I might say, cures the early stages of so-called Bright's disease.

At the same time, fixing a floating kidney does not mean that you get it in the exact position where it was or should be, but by fixing it high up as near to the original site as possible you prevent it pulling on or irritating other organs or the solar plexus of nerves; you prevent congestion, and kinking or twisting of the ureter. You simply fix it so that it stays in that locality subject only to that mobility which is required in respiration. You get it as near as possible in its normal position, but that will not cure smallpox nor fracture of the arm nor ingrowing toe nails. It will cure neither piles nor whooping cough. It will not relieve the headache caused by astigmatism. It will not relieve nervous affectations of syphilis nor elevate moral impulses.

As far as the mortality is concerned, I myself have never lost any case, neither in this series nor in other cases of fixation of the kidney. The mortality should be absolutely nil, although an unavoidable death may take place from some accident, chloroform, etc. In a few cases there was a superficial stitch abscess, but this does not interfere with complete recovery. I keep them in bed fifteen or sixteen days and in three weeks they can return home. It seems to me that I am perfectly justified in making these conclusions:

1. Movable kidneys can be permanently fixed by a proper technic.

2. Undoubtedly many disturbances of digestion are caused by movable kidneys, probably by causing irritation of the sympathetic nervous system, perhaps of the solar plexus.

3. Fixation of a loose kidney will relieve some digestive disturbances.

4. Many of the nervous symptoms in this condition are relieved after a short time.

5. A proper diagnosis must be made before operating and the kidney found to be the cause of the trouble beyond any reasonable doubt.

6. The fixation of a floating kidney can not cure cancer of the stomach, remove gall-stones, subdue an inflamed appendix, nor dilate a constricted bowel.

CESAREAN SECTION IN THE TREATMENT OF PLACENTA PRÆVIA.*

W. A. BRIGGS, M.D.

SACRAMENTO, CAL.

Placenta prævia in its manifestations and in its combined mortality of mother and child is the most appalling complication of pregnancy. In its management the courage, judgment and knowledge of the obstetrician will be taxed to their uttermost. It behooves him, therefore, to be prepared for every contingency of this multifarious condition. To paraphrase a paraphrase of Addison, she who has a hesitating physician is lost.

Within the brief period of three months I have seen four cases of total placenta prævia.

CASE REPORTS.

Case 1.—This case occurred in the practice of Dr. S. E. Simmons and formed the basis of a paper read by him before the Sacramento Society for Medical Improvement. In this paper he laid particular emphasis on the importance of early diagnosis, insisting that every pregnant woman should be carefully examined with special reference to this condition as early as the sixth or seventh month. This is an important point universally neglected.

Patient.—The patient, a multipara, in the ninth month, was practically moribund from hemorrhage when the physician reached her. He delivered with forceps within fifteen minutes, and maintained the circulation with hypodermoclysis and hourly hypodermics of adrenalin for twenty-eight hours, when death took place from circulatory failure.

Remarks.—Nothing, I believe, could have saved this woman. Completely exsanguinated by a sudden and enormous hemorrhage, when Dr. Simmons reached her she was in a state of vasomotor paralysis from which, notwithstanding vigorous and well-directed measures, she never rallied. This case, with any respect whatever for the canons of surgery, certainly was not suitable for Cesarean section.

Case 2.—This was one of total placenta prævia in the seventh month; there was rather sharp hemorrhage. Dr. Sutliff made a diagnosis of total placenta prævia, in which I concurred. Fetal heart sounds were inaudible, and, as bleeding had ceased, it was thought best to leave the case to Nature. Three days later labor set in and was completed without further hemorrhage.

Case 3.—Mrs. S., a multipara, in the ninth month of pregnancy, was taken with hemorrhage and attended by Dr. Sutliff, who packed. Hemorrhage was repeated and profuse, and in Dr. Sutliff's absence the husband packed the vagina at least once. The patient was sent to a hospital where I saw her at 10 p. m., Feb. 4, 1905. She was extremely anemic; the cervix was undilated and undilatable; the lower segment was boggy in entire circumference as far as finger could reach; the sac was ruptured and largely emptied; the head was at superior straight, but unengaged; hemorrhage was profuse; the child was alive, but feeble.

In the opinion of both Dr. Sutliff and myself Cesarian sec-

* Read before the Nevada State Medical Society, May 10, 1905.

tion offered the only hope for the child, and practically the only hope for the mother. It was accordingly proposed and accepted.

Operation.—I operated, with the assistance of Drs. Sutliff and Parkinson at 11 p. m., following the plan prescribed. The child was delivered alive in two minutes; the shock and loss of blood were slight; the uterine contraction was prompt and efficient.

Postoperative History.—Uterine infection, suspected at the time of operation, was quite evident the day following. Fearing some accident, however, I delayed intrauterine treatment until the fifth day. From this time on an intrauterine douche, followed by an intrauterine injection of clove oil and glycerin, with the patient in the Sims' position, was given every six hours until her condition was greatly improved, and then every eight or twelve hours until convalescence was established. Within an hour after each injection the temperature dropped nearly or quite to normal, with a corresponding subjective improvement in the patient's condition. The patient left the hospital on the fifteenth day after operation, and both she and her child have done well since.

Case 4.—Mrs. T., primigravida, in the ninth month, was taken with severe uterine hemorrhage Feb. 8, 1905, at 7 p. m. On examination Dr. Sutliff found a total placenta prævia with long, undilated and undilatable cervix, and with the head presenting at upper straight. In consultation I confirmed the diagnosis and concurred in advising immediate Cesarean section.

Operation.—I operated at 10:30 p. m., with the assistance of Drs. Sutliff and S. E. Simmons. The extreme corpulence of the patient necessitated a freer incision, but without any effort the child was delivered within three minutes. The lower uterine segment was filled with blood, dammed back by the vaginal packing. The hypodermic of ergot was given late, and the uterus did not contract at all promptly or vigorously, but hemorrhage was kept fairly under control by compression of the aorta. The loss of blood, however, was considerably greater than in the previous case. The child could not be resuscitated, although Dr. Simmons thought he felt a few heart beats.

Postoperative History.—The uterus was also infected in this case and the same treatment was employed. The patient left the hospital on the tenth day, completely recovered. Examination May 27 showed uterus somewhat enlarged, but entirely free from abdominal wall.

DISCUSSION OF CASES.

The course pursued in these cases was justified, I believe, both by the conditions present and the results obtained. In the third case with total placenta prævia, undilated and rigid cervix, head presenting but unengaged, sac ruptured and largely emptied, any other procedure would have sacrificed the child inevitably, and probably the mother.

In the fourth case, with total placenta prævia and a long and rigid cervix, the same assumption is not unwarranted.

DIAGNOSIS AND TREATMENT.

Early diagnosis of placenta prævia is imperative. During the sixth month a thorough pelvic examination should be made in every case of pregnancy. The vaginal examination should be supplemented by a rectal one in order to determine the condition of the posterior and lower segment of the uterus, which it is sometimes difficult or impossible to reach by the usual method. Having made a positive diagnosis of total placenta prævia, I believe that serious hemorrhage and likelihood of infection consequent on repeated packing and manipulation should be prevented by early operation, prophylactic Cesarean section.

The difficulty with this dictum, it seems to me, will rather be with its application than its acceptance. To me it seems quite clear that taking time by the forelock and with due deference to the interests of both mother and child, selecting the opportune moment for surgical intervention, we may materially reduce the death rate, maternal no less than fetal.

But what is the opportune moment? The moment of maximum viability of fetus compatible with minimum danger to mother. In other words, the furthest point of pregnancy which does not materially compromise the safety of the mother—as a rule, probably, the last week of the eighth month or first week of the ninth month; earlier, of course, if hemorrhage has already occurred.

PLAN OF OPERATION.

Besides the avoidance of hemorrhage and infection, there is another important advantage in electing the time for operation—all preparations can be properly made.

In an emergency, preparation can be made in a few minutes: Shave abdomen, rub well with clove oil, scrub with sterile soap and water, wash off with alcohol, cover with sterile gauze, sheet or mackintosh with median slit, sterilize hands by same method and cover them with gloves.

Only a few instruments are absolutely necessary: Knife, scissors, needles and holder, hemostats, silk and silkworm sterilized by boiling; in fact, in case of necessity, one might do with sharp-pointed scissors, a hemostat or two, needles and thread.

Whenever time permits the most painstaking preparation should be made, and the most careful plan of operation should be laid out beforehand. Two lives are at stake, and each must be surrounded with every possible safeguard. These precautions consist of three days in bed preliminary to operation: a clear and aseptic digestive tract; free ingestion of water twenty-four hours before operation; thorough antiseptic preparation, and the strictest asepsis in every detail. Competent assistants should be provided in sufficient number; one, with every preparation for resuscitation, to take the infant immediately after delivery; one to compress the aorta after the uterus is emptied; one to compress the uterine arteries if need be, and two to hand instruments, to use hypodermoclysis or venous infusion and to render other necessary assistance. Each assistant should be thoroughly instructed in his special duties; sutures should all be threaded and ligatures cut; saline solution and apparatus for flooding abdomen, hypodermoclysis or venous infusion, ergot and adrenalin solution, Faradic battery, everything possible pertaining to the operation should be in readiness for immediate use, so that, from start to finish, there may not be the slightest hesitation, hitch or delay.

Anesthesia should be induced by a skilled anesthetist, beginning with ethyl chlorid and finishing with ether.

Ten minutes before the first incision a full dose of ergot should be administered hypodermically. Should arterial tension drop, adrenalin chlorid, 1/50 grain, may be given intravenously or hypodermically, but not mixed with ergot, as it might hinder the absorption of the latter and predispose to abscess or to necrosis.

With everything planned and prepared, a median incision from 15 to 20 cm. in length should be made over the most prominent part of the fundus, extending ordinarily about equally above and below the umbilicus, occasionally one-third above and two-thirds below. The abdominal incision should be made quickly, but not hurriedly, and should be completed before the uterine incision is made. While the assistant presses the edges of the abdominal wound against the uterus, the uterus and amnion are incised at either the lower or the upper

angle of the abdominal wound; either Kocher's director or two fingers of the left hand are introduced, and the uterine and amniotic incision is completed with angular scissors. The infant is seized by the feet, or, if the head presents, by the neck, and lifted carefully out of the womb and handed to the assistant selected for this purpose. The cord is clamped in two places with suitable hemostats and cut between.

No attempt at uterine hemostasis should be made until the child is delivered, when the second assistant, after cleansing the wound, should introduce the right hand behind the uterus and compress the aorta, in order to control uterine hemorrhage and to maintain the arterial tension of the central nervous system. If bleeding be not sufficiently controlled in this way, the third assistant should grasp the neck of the uterus with both hands, low down, and firmly compress the uterine arteries. Under the influence of the ergot, the uterus should now begin to contract; if not, it should be stimulated with a strong Faradic current conducted by aseptic cords and electrode; one pole should be applied to the fundus and the other to the back.

The placenta and membranes are removed in their entirety; if separated, by lifting and twisting; if not separated, either by the same process or by introducing the hand between the placenta and uterus and carefully peeling them off. The afterbirth must be examined thoroughly; if fragments remain and the condition of patient permits these should be found and removed. The uterine muscle should at once be stitched with No. 2 catgut alternately from the lower and the upper angle at intervals of one centimeter. A curved needle and holder should be used to carry the stitch into the muscularis just below the peritoneum and out of it just above the mucosa; the order is reversed on the opposite side. An assistant ties the stitch at one angle, while the operator introduces another at the other angle.

The wound is cleansed, and over the intramuscular suture the peritoneum is sutured with continuous Lembert catgut suture. The abdomen is cleansed, if necessary, and left full of physiologic salt solution, particularly in case of anemia or shock. The wound is closed by the tier method.

UTERINE INFECTION.

In consequence of repeated tamponing, uterine infection is a frequent and serious complication of placenta prævia; but with prompt, rational and energetic treatment it may be often aborted. The two cases of infection here reported were treated by the method to be outlined; the earlier one somewhat tardily, because of an exaggerated and probably groundless fear of preventing repair of the uterine wound, the later one promptly, and both patients recovered.

The method which I had previously used with excellent results in a number of cases of puerperal infection, and had described in the *Occidental Medical Times* and in *American Medicine*, is as follows:

> Immediately on evidence of probable uterine infection cleanse the vagina, and under strict antiseptic precautions, with the patient on the back, wash out the uterus thoroughly through a soft rubber uterine irrigator. This may be improvised with two soft rubber catheters—one No. 12, full length, the other No. 16, one inch longer than the depth of the uterine cavity, and fenestrated in several places so as to permit easy outflow—tacked together by two or three stitches. Then place the patient in Sims' position and inject from two to four ounces of 5 per cent. oil of cloves and glycerin. Leave the irrigator *in situ* and repeat the irrigation and injection from four to eight hours apart. Ordinarily I put the patient in Sims' position after washing out the uterus and before injecting the glycerin, and let her remain there as long as she can without particular discomfort. One of these patients bore the Sims' position very well; the other found it painful and had to discontinue it.

SUMMARY.

1. Every pregnant woman should be examined during the sixth month to determine the presence or absence and, if present, the degree of placenta prævia. The examination should be made bimanually both by vagina and by rectum and stethoscopically by the vagina and by the abdomen.

2. In case of central placenta prævia, elective Cesarean section of Sänger type should be done at the moment of greatest viability of fetus compatible with least danger to mother.

3. In case the fetus is dead and labor does not set in spontaneously, it should be induced after placental circulation is shut off.

4. In emergency cases, when the patient is not exsanguinated and a sufficiently experienced operator is at hand, the Sänger-Cesarean section with presumably clean or superficially infected uterus should be done, and the Porro-Cesarean operation if the uterus be positively and deeply infected. (A) In case of total placenta prævia with (1) undilated and undilatable cervix, (2) cancerous or fibroid cervix, pelvic tumors, pelvic contraction or other obstacle to the usual obstetric procedure; (3) ruptured sac with escape of amniotic fluid and presenting but undescended head. (B) In cases of lateral placenta prævia with living child, uncontrollable bleeding, and either (1) undilatable cervix or other obstacle to the indicated obstetric procedure, or (2) ruptured and emptied sac with presenting but undescended head.

5. In elective cases complete and thorough preparation should be made, and the operation systematically planned; distinct functions should be assigned to each assistant.

6. In imperative emergency cases, the surgeon must operate with what may be at hand—scissors, hemostats, needles, thread, antiseptic, ether.

7. Hemorrhage may be prevented by giving a full dose of ergot hypodermically ten minutes before beginning the operation, compressing the abdominal aorta as soon as the child is delivered, grasping the neck of the uterus low down with both hands and firmly compressing the uterine arteries and by Faradic stimulation of the uterine muscle.

8. Shock may be obviated and relieved by preventing hemorrhage; by rapid operation; by introducing physiologic salt solution into the colon, connective tissue, blood vessels and abdomen; by hypodermic or intravenous injection of adrenalin chlorid solution, and by compressing the abdominal aorta.

9. In the after-treatment, purgation should be avoided; colon injections of saline solution from eight to sixteen ounces, may be given at intervals of from three to eight hours; the bowels may be moved by enemata; epsom salts, two to four ounces; glycerin, three to six ounces, asafetida mixtures fifteen to thirty ounces.

10. On the first evidence of uterine infection prompt and energetic measures of local disinfection should be instituted by means of antiseptic exosmosis and drainage.

Normal Diet.—Dr. Harry Campbell, London, says that the minimum normal diet is the smallest quantity of food adequate to maintain a man at the lowest weight compatible with the highest attainable level of health.—*Clinical Journal.*

MORTALITY AFTER PROSTATECTOMY.*

BENJAMIN TENNEY, M.D.

Surgeon Boston Dispensary, formerly Instructor in Anatomy Harvard Medical School.

AND

HENRY MELVILLE CHASE, M.D.

Assistant Surgeon Boston Dispensary.

BOSTON.

Any operation whose mortality varies between 15 per cent. and 30 per cent. for institution work and 4.4 per cent. in the work of an individual does not seem to be based on uniform details.

We have had no deaths as yet in our own prostatectomies, but, with the expectation that later we shall have to report fatal cases and the hope of making them as few as possible, we have gathered from recent literature and personal communications of others interested in this line of work more than a thousand cases of prostatectomy with reference to the mortality and its causes.

We have accepted as possibly due to the operation every death reported as occurring within six weeks of the date of operation. This compels us to omit some extensive lists which only report mortalities occurring within a shorter period. If it be unfair to the operation, as it apparently is in some cases, it must include all cases about which there can be doubt in the mind of any one. A cerebral embolus following an enema given the day before a patient was to go home, and a fatal pneumonia beginning three weeks after operation and a satisfactory convalescence, seem to show the hand of Providence rather than of the surgeon. We have included all such cases and not attempted to edit or explain for the sake of more favorable statistics for the operation.

There is no question but that the reports still show a higher mortality for the transvesical than for the perineal operation, but the difference in mortality is much greater among operators of experience doing the same operation than between the gross results of the two operations. Whether there is any anatomic or physiologic factor which makes one operation more dangerous than the other under proper conditions, we doubt.

Our own cases have been operated suprapubically because the preliminary examinations have convinced us that these particular individuals could be operated more safely in that way. We expect to operate through the perineum when we find prostates which seem more readily approached from below, but with the wide variations in size and location of the obstructing masses or lobes an invariable route of approach seems to us too "consistent" to be the wisest course.

Our figures are taken from original reports which have been published within the past five years with one or two exceptions. The gross mortality compared with that found by other collectors of statistics is shown in Table 1.

TABLE 1.

	Perineal.	Mortality (per ct.).	Suprapubic.	Mortality (per ct.).
Proust[1]	813	7.13	244	12.0
Watson[2]	530	6.2	263	13.3
Escat[3]	382	11	164	18.0
Tenney and Chase	617	7.6	396	9.8

Reports from certain operators are included in Table 1 which lack the details necessary for further consideration according to our plan. Omitting these, we have 816 cases whose age and mortality appear in Table 2.

TABLE 2.

Cases.	Ages.	Mortality, per cent.	Decade mortality, per cent.
8	39-49	0	
31	50-54	10	5.8
89	55-59	4.5	
201	60-64	7	9.5
221	65-69	11.3	
175	70-74	13	15.
65	75-79	18.5	
24	80-84	8	
0	85-89	0	
2	90-94	50	

Most patients with prostatic obstruction present symptoms before 70, even if the catheter is not absolutely required, and these figures show better than any amount of argument the desirability of early operation. We have operated on three men aged 72, 77 and 78, and on one patient of 68, whose heart and arteries were at least ten years older. All recovered, but their convalescence was in marked contrast to that of our younger patients. The oldest surviving patient in this list was 92, operated suprapubically.

Age of itself is no argument against the operation, but conditions which often accompany and sometimes precede old age may increase the risk beyond the patient's wish to face it. No patient willing to face a moderate risk of death in order to escape the misery of such catheter existence as we sometimes see should be denied his chance of lightening his labor and sorrow because of his more than threescore years and ten. He has better than four chances of recovery to one of dying in any five-year period before ninety in the hands of the average operator.

In studying the seventy-three deaths, we first notice that there are fatal periods. There were twenty-three deaths, or more fatalities in the first forty-eight hours than in any other two days.

Another period of mortality includes the seventh, eighth and ninth days, which show twelve deaths. On the thirteenth and two following days there were six deaths, and on the twentieth to twenty-second days inclusive there were seven deaths. Two-thirds of all the deaths came during these fatal periods.

The table showing the time of death of the fatal cases is to us very interesting. First, the duration of life following the suprapubic and the perineal operations is almost identical. Of the 38 deaths in 384 suprapubic operations, 11 (or less than one-third) occurred during the first forty-eight hours, 19 (or one-half) during the first week and 25 (or two-thirds) during the first ten days.

Of the 35 deaths in 417 perineal operations there were 12 (or one-third) within the first forty-eight hours, 19 (or one-half) within the first week and 25 (or nearly three-quarters) within the first ten days. There were no deaths on the twelfth and thirteenth days. Contrast these results with one reported series of 51 patients with three fatal cases, only one of which occurred before the eighteenth day, and another series of 160 cases with one death before the thirteenth day in a total of seven mortalities!

These two series are included in our 617 perineal prostatectomies, with 7.6 per cent. mortality. Taking these out we find two men doing 211 operations with two deaths within twelve days, compared with "the field" doing 406 perineal operations and losing twenty-two patients within the same period. When we include the suprapubic operations we find a total of 45 fatalities in 790 operations within the same period, and these figures do not include the high institution mortality referred to at the beginning of this paper. It does not

* Read before the New England Urological Society, at Boston, May 3, 1906.

2. Watson: Annals of Surgery, June, 1904.
3. Escat: Annals des Malad. des Org., Genitourin., 1904, p. 1635.

seem as if rapidity of operation could account for the different results, for the two men referred to do not use the most expeditious method. Neither does it seem from published reports that their cases are specially selected. We have tried in various ways to account for this surprising difference—1 per cent. as against 6 per cent.

It has been stated by Moullin, Richardson and others that patients with stone in the bladder are more favorable subjects for operation than others. Our list contains 107 cases complicated by vesical calculus with a mortality of 13 or 12 per cent., as compared with 8.6 per cent. mortality among the cases without stone. If the presence of vesical calculus has any bearing on the mortality it is unfavorable.

The age of 23 patients dying within the first forty-eight hours gives a possible clue to the reason for the large number of early deaths. Three were in the fifties, out of seven dying in that decade, seven of the thirty-nine deaths in the sixties, thirteen of the thirty-five deaths in the seventies, none in the eighties and one patient of ninety-four.

The corresponding figures for forty-six patients dying within the first twelve days give us six deaths in the fifties, or 86 per cent. of all deaths in that decade, twenty deaths in the sixties, or 51 per cent. of the decade mortality, nineteen in the seventies, or 54 per cent. of the decade mortality, and one patient of 94. The number is too small for permanent conclusions. So far as it indicates anything it is that the older men are less likely to stand the shock and loss of blood in the operation, and that the younger men stand the sepsis, uremic complications and confinement less well than the elders. We have also tabulated the causes assigned for death in these 46 cases and have kept the perineal and suprapubic results separately.

TABLE 3.

Cause of Death.	Within 48 hours. Suprapubic.	Within 48 hours. Perineal.	Within 12 days. Suprapubic.	Within 12 days. Perineal.
Uremia	2	5	9	9
Shock and hemorrhage	4	1	4	2
Pulmonary	2	0	5	1
Sepsis	0	2	1	3
Cardiac	2	2	2	3
Collapse	0	0	1	2
Anesthesia	1	2	1	2
Unknown	0	0	0	1
Total	11	12	23	23

No man can tell how many of these deaths were inevitable, but we are convinced, in view of the experience of the two operators referred to, that some were unnecessary and that it is not entirely a problem of speed or technic in the operation. We believe that many of these disasters could have been prevented by the exercise of greater care before, during and after the operation.

Before operation the bladder must be made as clean as possible by irrigation or by drainage through a permanent catheter or a cystotomy tube. The heart and kidneys may require stimulation, the bowels may need attention for some days, and the skin is not to be forgotten when uremia is a possible complication.

During the operation the anesthetist has a great responsibility—only second to that of the surgeon, who must choose for himself the methods most desirable in each individual case. We believe that the after-care of these cases during the first few days is a more important matter than the special technic of any operation. Patients do not bleed to death on the table. A severe hemorrhage at the time of operation is located and controlled, but the bleeding into a limp bladder or the gauze dressing is easily overlooked in a busy hospital. Many of these cases deserve the cause of death given by one surgeon: "hemorrhage and neglect." The kidneys must be kept active and sometimes profuse sweating and purgation must be resorted to. Drains must be kept open, and we believe in frequent irrigation with mild antiseptics, though some men consider it unnecessary. Watering the patient during the first hours of his convalescence is more important than feeding him, which fact must be driven into the ordinary nurse against her will.

Last, but not least, he must be taken out of bed at the earliest possible moment and made to sit up, if only for a few minutes at a time. Our patients have been out of bed by the second or third day and regularly after that.

A prostatectomy is not a completed piece of handicraft, like most clean laparotomies or dissecting operations, after which the surgeon can wash his hands and leave the case to the care of the ordinary nurse or house officer. Each patient should have careful and intelligent attention almost constantly during the first forty-eight hours, and the same sort of attention later at frequent intervals until his convalescence is well established. The more feeble the patient the more necessary is this care.

Prepare the whole patient as well as the operative field for the ordeal; do not attempt too much at one sitting, and remember that the need of minute attention to the patient's condition has only begun when the anesthesia is over. These are the precautions which seem to us most essential to a low mortality after prostatectomy.

Note.—With the exception of cases tabulated in Proust's admirable book on Prostatectomy, we have taken all our cases from original reports. The references are much too numerous to be given here, comprising as they do, more than 150 different articles. We wish gratefully to acknowledge personal letters from Drs. Fuller, Young and Watson, which have been of material assistance in preparing this paper, and to express our appreciation of the great value of articles with full details of cases, convalescence and after results such as that published by Dr. Murphy in The Journal of the American Medical Association two years ago.

308 Marlborough Street.

THE ECONOMIC PRODUCTION AND DISTRIBUTION OF CLEAN MILK.

JOSEPH ROBY, M.D.
Deputy Health Officer.
ROCHESTER, N. Y.

An editorial in The Journal of the American Medical Association December 9 states: "The question as to whether milk is better food for children in a raw or Pasteurized state is easily answered in a few cities where supervision of dairies is properly carried out and the standard of dairy cleanliness high. Under such circumstances, there is no question that the raw material is the best in every way. . . . The conduct of a clean modern dairy requires a large outlay of buildings and apparatus and a much larger force of helpers than is to be found in the average dairy of the present. In order to procure clean milk in our cities, therefore, we must either raise the price of milk or resort to some artificial method of rendering it innocuous. Unfortunately, any increase in the price of milk would fall most heavily on the more prolific poorer classes, and for this reason is objectionable, though it might be possible to educate the general public up to the desirability of this step. Meanwhile the question of Pasteurization is of importance."

From an economic standpoint it would seem that

clean milk could be produced as easily as Pasteurized milk, for properly to Pasteurize milk and effectually to cool it after this process must require fully as expensive, if not more expensive, apparatus.

I desire to emphasize three points:

First.—Remarkably clean milk can be produced without an expensive plant.

Second.—The steps necessary to produce such a milk.

Third.—A scheme for improving the entire supply of cities.

Physicians who have devoted themselves more or less to the diseases of children have been responsible, as a rule, for certified milk, the certificate usually meaning a certain percentage of fat and total solids and a low bacteriologic count. What is said here will have to do only with milk of a low bacteriologic count or clean milk, because we are "firmly convinced from the results in Rochester that this is much more important than high fat percentages."

As Professor Conn of Wesleyan pointed out, it is not so much the number of bacteria in milk as it is the kind. Low counts, however, show how the milk is produced and handled, and if there are few of any kind, of course, there must be few injurious ones. von Behring and his pupils, by feeding young animals non-virulent cultures of anthrax bacilli, seem to have proved that the mucous membrane offers practically no resistance to the entrance of living bacteria into the blood, and the frightful mortality among young infants and the frequency with which they suffer from gastrointestinal infections would seem to prove this for the young of man. This has led von Behring to make the statement that an infant should not receive milk containing more than 1,000 bacteria to the c.c., or quarter of a teaspoonful.

Since the establishment of the Rochester municipal stations and a more efficient milk inspection the death rate in children under 5 has markedly decreased, not only relatively to increased population, but absolutely.

In 1904 the milk stations were unusually popular, and there were many protests against closing them, and we found ourselves with a considerable number of infants demanding clean milk, which they were unable to get for love or money. That is to say, there was no one in Rochester supplying a milk that could be depended on to run below 100,000 bacteria to the c.c. A great many men would occasionally have counts of 75,000, 50,000, or even 10,000, and the next month they would get over 500,000.

The average monthly counts in Rochester for the last six years vary from about 100,000 per c.c. in winter to about 500,000 per c.c. in summer.

Milk is supplied to Rochester very much, I imagine, as it is to other cities of the same size. There are several large dealers who get railroad milk and put out 1,000 or more quarts; small dealers getting railroad milk, and farmers who produce and peddle their own milk.

In spite of the continued object-lesson of these stations to milkmen (for the portable bottling and sterilizing plant has been located at a different farm almost every year), in spite of the opportunity for the milkmen to see how anxious the people are to get clean milk, and in spite of an invitation from the Academy of Medicine to milk dealers to get their milk certified, until this year no one has been found who would do it. In November, 1904, a bulletin containing about such advice as is given later in this paper, warning them about scarlet fever, diphtheria and typhoid and offering to give a rebate to assist in purchasing sterilizers, was sent to every milkman. Then, in order to get some milkman to produce a really clean milk, a letter was sent to about twenty men who had had rather low bacteriologic counts and who produced their own milk, for, of course, those who bought their milk could not control its production. This letter simply asked them to come into the health office, where it was explained to them what it was necessary for them to do, and on our part we said that we would try to get twenty people who would agree to take a quart of milk at the advanced price of nine cents a quart, six cents being the usual price in Rochester.

Much to our disappointment, we have never had a single order for the sterilizers, and we could only find one man who was willing to try to produce unusually clean milk, for we had at least hoped to be able to divide the city into quarters and have one man for each quarter, so that each man's route would not be too long.

The farmer who did qualify had not the advantages of a college education and his barn, although one of the best cow barns in Monroe County, is a very ordinary one. The main building is of two stories; the basement is of stone and partially underground on one side, and the upper part is of very rough boards, with a new, but inexpensive wooden cow barn attached so as to form a T. There are no cement floors. There is an inexpensive wooden milkroom, with wooden floor, situated about thirty feet from the barn. Fortunately the man had a steam boiler and had constructed a metallic-lined wooden tank for cooling the milk. This tank was converted into a sterilizer by making the cover fit tightly and running the steam pipe into it, so that a temperature of 212 degrees could be easily obtained and all the utensils sterilized. The cattle are ordinary grade cows, with a few Jerseys, but all tuberculin tested.

The directions embodied under Point 2 were given. The milk is poured from the milking pails into the bottle filler, the bottles filled, capped and sunk in ice water. No aërator is used. In well-equipped modern dairies these may work well, but we have been afraid to advise it, unless one could control the air in the milkroom rather better than seemed possible here, and it seemed to us one more chance for infection. We think we have also killed the dreaded animal, heat bugbear. We have not talked to a single milkman who has not held up his hands in holy horror at the idea of putting a tight cover on milk while it was still warm. And yet this can be done, and there will be no animal odor if the barn is clean. If milk produced in this way is kept cold at 45 degrees, it will keep sweet almost indefinitely. A quart of milk was opened every day to test it, and it kept sweet for sixteen days, and might have kept longer had there been any left.

The bacteriologic counts of this milk in 100 examinations have given an average of 3,853 cubic centimeter or ¼ teaspoonful, with 21 below 1,000, the lowest 240, and only one (29,000) above 20,000.

Thus our first point has been proved, for this man has certainly done without an expensive barn, what many another small farmer could do.

As to the second point, very long and complicated rules have been given to milkmen, and have been put down in such a way that the men have not attempted any of them, because they did not realize which was the most important. We think that the rules should be very few and arranged in the order of importance as follows:

First.—The protection of the milk from infection by scarlet fever, diphtheria and typhoid.

If one of these diseases develops on the farm, the patient must be immediately removed from the premises and must not come in contact with any one who has anything whatever to do with the milk. The milkroom, barn and cows should be thoroughly cleaned and every utensil must be sterilized by steam.

In case of diphtheria every one on the farm must have an immunizing dose of antitoxin.

These rules should be strictly enforced and the dairyman must be made to report these diseases to the health office; failure to do so, either wilfully or through ignorance, should mean a permanent revocation of the license. If no other place is available, patients with these diseases should be removed to a hospital, even at the expense of the municipality.

Second.—Cooling the milk and keeping it cold, or at least below 50 degrees. At first thought all might not agree to this being so important, but on reflection it will be self-evident. Practically, at least, sterile milk can not be drawn from the cow, so we start off with an excellent culture material already infected, and, if allowed to stay or to get warm, these bacteria multiply beyond comprehension, so that a milk containing 3,000 bacteria per c.c. in the beginning at the end of twenty-four hours would contain many millions, and be infinitely worse than one containing 30,000 at the start, that had been kept cold all the time. If kept very cold the bacteria would not increase much, and the number might be even less in twenty-four hours.

Third.—Keeping the utensils clean, or better, sterile, is about as important as keeping the milk cool. Milkmen must be made to understand that their "scalding" is not so efficacious as actually boiling water in the utensil, or submitting it to steam under pressure for some time, and that nothing like clean milk can ever be produced unless the vessels are comparatively sterile.

Fourth.—Milking directly through sterile cheese cloth into a pail with a small (five-inch) opening. On some thirty comparative counts, versus the open pail at the milk station during 1904, this cut the average count exactly in half. Cheese cloth covers must be changed at the time the pail is emptied.

Fifth.—Keeping milk tightly covered. These five points are absolutely necessary, and without following them milk with few bacteria can not be produced. Milk produced in this way will probably run about 10,000 to the c.c. Now every one of the subsequent points that are followed will reduce the count a certain amount, so that in perfectly equipped and managed dairies the count may run regularly at 1,000 or below. These points are:

Sixth.—Discarding the first draws from each teat.

Seventh.—Keeping the cow absolutely clean.

Eighth.—Keeping the milkers' hands and clothes clean.

Ninth.—Keeping the ceiling clean and free from dust; preferably it should be lathed and plastered.

Tenth.—Keeping the barn clean and using shavings for bedding instead of straw.

Eleventh.—Being careful not to stir up the dust just before or at time of milking.

Of course, in a barn constructed entirely of cement the last four requirements can be much more easily carried out.

Mrs. Cooke of the New York Commission assures us that just as good, if not better, milk can be produced in good dairies without the cheese-cloth strainers over the pail. We do not doubt but that this is so, but unless the last points can be closely followed the strainers seem necessary.

So much for the method of getting a certified milk plant started in cities where there is no such milk supply. But what are we to do for the great mass of people who can not afford to buy certified milk delivered in glass jars at an advanced price?

For the supply of cities we offer this scheme: There should be as many certified milk farms as possible, where the milk is to be put up in bottles at the farm and delivered in this way directly to the consumer. When the cities are small, like Rochester, so that the farmer can be within driving distance, the delivery wagons would start directly from the farm; in large cities they would have to start from railroad stations. For those who are not able to pay a considerably advanced price for this milk, we suggest that the city have a can-sterilizing plant—not a plant for sterilizing milk, dirt and bacteria together—located near the various railroad stations where milk comes in. After delivery the cans are returned to this sterilizing plant, washed by machinery, a cheese-cloth cover put over the can, then the metal cover, and over the entire top of the can a stout canvas cover with a purse-string arrangement so that no dust can get in. These cans are then slid into a sterilizer and sterilized by dry heat. The cans are then shipped back to the farms. The milkman receives his can, takes off the canvas cover, removes the metal cover and milks directly through the cheese cloth into the can. When the can is full, the cheese-cloth strainer is removed, put into a canvas bag, and subsequently returned to the city's sterilizing plant. The metallic cover is replaced on the can, and the can immediately sunk in ice water up to the neck. This can is then carried by rail to the city, and there the milk may be bottled, or the milk may be delivered directly from these cans. This milking, shipping and delivering pail or can should hold about fifteen quarts and have a small 5½-inch opening. The cooling tank should be made so that it overflows at a level just below the cover of this can. This scheme would necessitate the farmer having as his only apparatus a plain wooden tank or trough large enough to hold all his cans and enough ice properly to cool the milk. He would not have to handle the cans at all. In fact, he must be instructed not to handle them. He would not need an expensive milkroom.

This is the application of surgical principles to the milk business. Whenever surgical instruments or dressings are handled they become infected. The efficiency of this one-can scheme was tried in November, 1905, with the following result:

We had no special pail and no quart dipper, the can was opened, a quart poured off and a sample for bacterial examination taken each time.

Five hours after milking, 161; five minutes later, no growth (somewhere under 277); ten minutes later, 242; one and one-half hours later, 200.

The milk was on the wagon all this time.

Bottle milk, the same day, contained 13,000.

As in the dilutions made, only one colony grew; it it seems probable that 161 show some accidental contamination and that 200 would have been the right count with a heavier dilution.

TREATMENT OF THE BITES OF COPPERHEAD SNAKES

BY LOCAL FREEZING COMBINED WITH THE FREQUENT APPLICATION OF A POTASSIUM PERMANGANATE SOLUTION.

C. W. R. CRUM, M.D.
JEFFERSON, MD.

For several years I have averaged about two cases of bites of copperhead snakes a year, and finally hit on a plan of treatment which gives me such good results that it may be worth while to communicate it to others.

My earliest experience with the use of caustics locally and whisky and ammonia internally was unsatisfactory in many respects, although I had no deaths. During the past year I treated for two months a fearful ulcer of the finger and hand which was caused by cauterization with caustic potash for snake bite. The final result was a contracted palm and stiff fingers.

Several years ago Dr. Thomas R. Brown[1] published an account of some experiments with potassium permanganate as an antidote to the venom of snakes of the viper class, e. g., rattlesnakes, copperheads and vipers. Previously I had used this drug in a measure, but afterward I used it almost entirely, at first hypodermically. Being refused this method of administration on one occasion, I used permanganate solution locally on compresses and apparently with good effect. Shortly after I hit on the plan I now pursue which gives me results incomparably better than anything I have known of heretofore. My plan is to freeze the area around the bite with ethyl chlorid spray, incise through the wound, usually making two parallel incisions of almost an inch in length through the two little wounds made by the fangs. Then I soak the part for a few minutes in strong permanganate solution and apply dressings wet with this solution. The edge of this dressing is raised up every half-hour or hour and fresh solution poured over the surface. The incisions, which are trifling, usually heal in a day. Certainly, so far as my experience goes, an incision in an area poisoned by snake bite appears to heal with extraordinary rapidity even in the absence of any effort at asepsis.

This method I have now used successfully in eight cases. I am inclined to attribute some virtue to the freezing by ethyl chlorid over and above the mere anesthetic effect. If the patient is seen within one hour after the bite, he is usually all right in two or three hours, with the exception of trifling swelling. The extension of the poison seems to be checked very shortly after this application. Internally I usually employ a few doses of strychnin, but occasionally use whisky and ammonia as well, perhaps out of respect to local prejudice.

The three cases cited herewith are, respectively, one illustrating the happiest result of treatment, another the most serious case, and the third the most peculiar case of all the instances of poison bites that I have met with.

CASE HISTORIES.

CASE 1.—A boy, aged 8, visiting in the country, was bitten in the wrist by a huge copperhead. The snake was killed and was a typical specimen. It was during the month of August when snake bites are supposed to be most venomous.

I saw the boy within half an hour. Chloroform was employed to control the child, but ethyl chlorid was nevertheless used locally. The pain from the bite seemed to be intense. The arm was already much swollen and blue. The incisions were made. There was some bleeding, which was encouraged by immersion in warm water. The permanganate solutions were applied as usual.

It was 10:30 a. m. when I left the house. On my return at 4 p. m. the boy was out in the mountains playing, and the swelling was scarcely apparent. I did not see him afterward as he was considered well.

CASE 2.—The second patient was a young woman school teacher who with a party of young people was doing some mountain climbing on an August day. She trod on a copperhead of medium size, which stuck its fangs into her foot just in front of the ankle.

It was perhaps two hours before she reached our village, but she had already been sufficiently dosed with whiskey to insure of the good effects of such treatment—if it has any. In my absence a neighboring doctor prescribed onion poultices and more whiskey. Shortly after this she became nauseated and vomited, and could take no more whiskey. It was nearly four hours after the time of the bite when I first saw her. The leg was much swollen, the whole body was of a jaundiced hue, and over the leg were splotches of deeper copper color. The general condition was one of extreme prostration. The pulse was almost indistinguishable, the respiration shallow, but the mind was clear. I gave some aromatic spirits of ammonia and had turned to look after the local wound when the patient became unconscious and respiration stopped. She was given a hypodermic of strych. 1/30 and nitroglyc. 1/100, and artificial repirations were instituted. In a few minutes the injection was repeated. Respiration was re-established shortly afterward, the pulse returned with more force, and the patient revived.

Recovery was followed by a prolonged convalescence. There was marked anemia with a decided aortic murmur for some time. The mottling of the leg persisted for months.

I instance this case because of its gravity, the length of time from the bite until the extreme symptoms set in, and the evidence it afforded of the destruction of the red corpuscles of the blood.

About the time of the publication of the observations of Dr. Kelly and Dr. Brown another article appeared elsewhere in which were compared the relative effects of cobra viper venoms. The statement was made that both venoms contained two toxins, a poison destructive to red corpuscles and a nerve-destroying poison. It was also stated that the blood-destroying element was in excess of viper venom so that death occurred, if at all, some time after the bite, and with distinct evidences of destruction of red blood cells. Cobra bite, on the other hand, was said to be more rapidly fatal on account of the very large excess of the nerve-destroying poison in the cobra venom, the fatal result being accompanied by other evidences of implication of the nervous system.

From this article[1] also I received the impression that very young snakes—infant snakes—of the viper class were very poisonous and that this poison had a somewhat different action from the venom of the older snakes. By the way, it is the popular opinion among our mountain dwellers that large snakes are not more to be dreaded than smaller ones of the same species, and this certainly coincides with my observation. A very peculiar case came under my notice about six years ago, before I had used my present method of dealing with poisoned bites.

CASE 3.—A woman was walking barefoot in her garden on the mountain side. She was bitten on the side of the foot by something she did not see and could not find in the low vegetation that was there. She was a young woman of exceptionally fine physique and robust constitution.

Four or five hours later, when I first saw her, there were two very tiny spots at the side of her foot, and the leg was much swollen, but was white and edematous rather than blue or cop-

1. Johns Hopkins Hospital Bulletin, vol. x, 1899, p. 224.

per colored. She complained of a great deal of thirst, and the body was hot. The pulse was 120, and I was surprised to find a temperature of nearly 102 F. She declared that she had been perfectly well before. There was great pain in the foot and leg, which lasted for some days and required the use of opiates.

On the second day the temperature was 104 F. in the afternoon, and reached that point on several succeding days. An evening temperature of at least 102 F. persisted for three, or perhaps four, weeks. The woman became as much debilitated as from an attack of typhoid. Indeed the general conditions made one suspect typhoid,, and the blood was sent to the state health department on three or four occasions for a Widal test. One report was "suspicious," the others were uniformly "negative." The conditions in the leg persisted. It was pale and edematous. The dorsum of the foot gave a boggy sensation of fluctuation, and was incised deeply on three separate occasions. There was merely an exudation of watery fluid, and the incision did not cause any great pain. But the strangest thing to me was that the incisions healed in twenty-four hours.

Some very small snakes were seen in the garden the day after the woman was bitten. Could she have been bitten by a very small snake? This case has always been a matter of speculation to me, and I would like information on it. The woman has never quite recovered her former good health, and I understand that the affected leg is still different from the other.

Concerning the matter of the very poisonous nature of the bite of new-born snakes of the viper class, I remember a story from the Philadelphia Zoo. A rattlesnake and a boa-constrictor were separated by a fine-meshed wire screen. One night the rattlesnake hatched out young. The next morning some of her venomous brood were found about the dead body of the boa-constrictor.

REMARKS ON SAHLI'S DESMOID TEST OF THE STOMACH.

MAX EINHORN, M.D.
Professor of Medicine at the New York Postgraduate Medical School.
NEW YORK.

In the beginning of 1905 Sahli[1] published a new method of testing the functions of the stomach. It consists of placing methylene blue or iodoform in a little rubber bag and tying it tightly with thin raw catgut.

This "desmoid bag" is swallowed by the patient after a large meal (dinner) and the urine or saliva is tested for the presence of methylene blue or iodin. Methylene blue colors the urine green or blue; the iodin or the iodoform may be demonstrated in the saliva by means of starch paper and fuming nitric acid (violet color). The reaction appears in healthy persons usually from six to eight hours after swallowing the desmoid bag. Its occurrence at this time points to a proper function of the stomach; if the reaction occurs later or not at all, it points to insufficiency of the stomach. This test is based on the fact that raw connective tissue, including catgut, is digested only by the gastric juice, according to Schmidt,[2] and not by the pancreas.

Sahli prefers his method to the usual examination of the stomach contents. He says: "I believe that the desmoid reaction informs us not only how quickly the gastric juice is able to dissolve the connective tissue, but indirectly it shows how well the meal with which the bag has been given has been digested."

It is natural that such a method, if practicable, might be of considerable use. Investigations on the value of Sahli's method were made by Eichler,[3] Kühn[4] and Kaliski.[5] They were all favorable and Sahli's assertions were entirely confirmed. Kaliski even says that the various degrees of acidity can be determined from the strength and the time of occurrence of the reaction. He says in his conclusions:

"1. A deep blue color of urine after from four to seven hours speaks for hyperacidity. If the acidity is normal the reaction occurs after from seven to twelve hours; the first urine is light blue.

"2. In subacidity or motor insufficiency the reaction occurs only on the following day."

As already mentioned, the reaction is based on the solubility of raw connective tissue (catgut) in the gastric juice and not in the pancreatic secretion. Ogata and Schmidt have made these assertions regarding connective tissue. While I[6] was working on my method of testing the functions of the digestive apparatus by means of glass beads loaded with different food stuffs—I looked for a substance that would be soluble in the stomach and not in the bowel. Naturally I turned to catgut because it can be so easily handled. At first I was satisfied with the results obtained. Soon, however, it became evident that catgut was also soluble in the digestive apparatus of patients with marked achylia gastrica. This proves that catgut may be digested in the bowel. In order to establish this fact I made the following experiment: A catgut bead was placed in melted mutton fat and, after solidification of the fat which thus coated the bead entirely, it was given to healthy persons. These beads were then recovered in the stool and found without the catgut. The latter must have been digested in the bowel, as the stomach could not attack the fat.

Although these experiments seemed to show that catgut was hardly suitable as an indicator for gastric digestion, yet I decided to try the desmoid test on some patients. I selected several cases of achylia gastrica, simple and complicated, and tried the desmoid test on these patients. As there was no gastric juice present in these patients, the desmoid test, if it were to be really useful, ought to be negative, otherwise it could not be used for ascertaining the condition of stomach digestion.

REVIEW OF THE CASES.

CASE 1.—A. S., male, was suffering from achylia gastrica, took a desmoid bag filled with methylene blue. Five and one-half hours later the patient noticed that the urine was blue.

CASE 2.—G. N. W., male, suffering from achylia gastrica and subacute enteritis, was examined Feb. 13, 1906, one hour after a test breakfast, with the following result: HCl = 0; rennet = 0; T. A. = 8. He then received Sahli's desmoid bag with methylene blue. Seven hours later the urine was blue.

February 17: The stomach contents were again examined after a test breakfast: HCl = 0; rennet = 0; reaction, neutral. Shortly after this examination (at about 10 a. m.) the patient received a desmoid bag with methylene blue. At 12:30 he took his dinner consisting of a plate of soup, veg-

etables, two scrambled eggs, butter and bread. At 3:30 p. m., three hours after this meal, the stomach contents were removed; the chyme was yellowish from admixture of eggs, its reaction was neutral, and it did not contain rennet ferment. An hour later the patient emptied his bladder, the urine was blue.

February 18: The piece of rubber without the catgut was found in the stool.

February 21: The patient took another methylene desmoid bag. In the evening the urine was its natural color, also on the following day. The urine, therefore, did not turn blue.

February 24: The patient again received a desmoid bag.

February 25: The urine was of a normal color and did not turn blue.

Case 3.—L. L., male, suffering from cancer of the stomach, achylia gastrica and enteritis, took a methylene blue desmoid bag Feb. 20, 1906. On the following day (eighteen hours after taking), the urine was colored greenish as well as the stool. An examination of the stomach contents on February 21 showed entire absence of gastric juice.

Case 4.—C. P., male, suffering from achylia gastrica, was examined on Feb. 24, 1906, one hour after Ewald's test breakfast. *Result:* HCl = 0; rennet = 0; reaction, neutral. Shortly after this the patient received the methylene blue desmoid bag; four hours later the urine was blue.

REMARKS.

In these four cases in which there was a complete absence of gastric juice the desmoid reaction was positive. Only in Case 2, in which the desmoid test was applied four times, a varied condition was observed, the test being twice positive and twice negative. I usually examined these patients with the desmoid test on the days on which I tested their gastric secretion by means of the stomach tube, in order to be certain that no gastric juice was present. As the desmoid test was usually positive, I had to conclude that it was entirely unsuited for the examination of the stomach secretion, i. e., that it did not indicate whether gastric juice was present or not.

Sahli himself has been led to think that some error might be attached to the method, for he says: "On the one hand we have cases in which the test breakfast shows a lack of free HCl and yet the digestion appears to be sufficient according to the desmoid test; on the other hand, there are cases in which the digestion appears to be insufficient with the desmoid test, although after the test breakfast free HCl is found. I naturally thought at first that the desmoid test had some inherent fault. I was unable to discover it, however, and came to the conclusion that, on the contrary, these differences and apparent contradictions furnish a plain illustration of the value of the method and the defectiveness of previous procedures."

Sahli thinks that after a test dinner there is sufficient gastric juice even when the test breakfast shows an absence of free HCl. This would hardly correspond with the usual clinical experience. In order, however, to controvert even this objection of Sahli's I made the following experiment: In Case 2 I made a second desmoid test. Five hours after the patient had taken the methylene blue desmoid bag and three hours after a larger meal I again examined the stomach contents and found first, an entire absence of gastric juice and, second, no blue coloration of the stomach contents, although the urine voided shortly afterward was blue. In this case the reaction must have occurred in the bowel; otherwise the urine would not have been colored.

All in all, I must say that Sahli's desmoid reaction is unsuitable for the examination of the stomach functions because catgut is digested in the bowel as well as in the stomach.

SANITARIA AND TENT COLONIES.

DO THEY PREVENT AND CURE TUBERCULOSIS?*

DANIEL LICHTY, M.D.
ROCKFORD, ILL.

Whether sanitaria and tent colonies are the best means of treating and preventing tuberculosis is, it seems to me, a seasonable question. We easily recall how our old friend, the pendulum, is called on to picture for us a point. The proneness of a majority to assemble at either terminal of the arc is too true to be successfully refuted. The psychopathy of majorities must still be recognized.

It is not from a spirit of unkindly or adverse criticism or vicious iconoclasm that the subject is presented here in the form it is, but in order that a negative presentation may bring out the discussion the subject merits. It is realized that this exclusive and expert management as a form of treatment of tuberculosis has passed beyond the incubating period and is now in its maturity with abundant material for its defense. The potency and beneficence of pure air and sunlight has always been recognized. When the king asked Diogenes what greatest favor he could do for him, Diogenes asked the king to step out of his sunlight.

THE HOME THE UNIT.

As the home is the universally admitted unit of the state, its stability and integrity should be recognized as the first of all the agencies in the prophylaxis of disease, as well as in the prevention of crime. On the home foundation is built all that is good in state or individual, ethnically, ethically and sanitarially; here is the battle-field of bacteria, the vanquishing of which means the prevention as well as the cure of disease.

The ever-present and forever-enduring desire of the physician is to prevent disease, to alleviate suffering, to exalt mankind and to save and prolong human life; or, as Sir Thomas Browne, the quaint doctor-philosopher of the early seventeenth century, euphoniously expressed it, "It is better to appease pain than to invent pleasure." He who first and best does this, by word of mouth or touch of pen or hand, best serves his fellow-men; this endeavor, often arising to an aspiring, and may be some times erring ardor, has led men's minds to widely diverging views and ways.

In the zenith of his fame the eminent Louis Agassiz received urgent and complimentary invitations from numerous learned citizens and bodies across the seas to visit them, to aid some line of study or to direct some interesting research to a satisfactory conclusion; to all of which he replied that he had a field nearer home in which he wished to direct investigation. Immediately the scientific world was agog to know what great discovery was about to be made, and students and scientists began soliciting invitations and making inquiries as to his work. He replied that there were a great many things in his backyard strange to him and that needed investigation. So I am assured that in the investigation and study of the prevention and treatment of tuberculosis there are a great many things in our own vestibules as well as backyards that need investigation. We have not kept near enough home, in more senses than one; home study and homemaking is a neglected profession.

RESPIRATION.

The so-regarded simple, though most important, function of existence, respiration, hardly receives a

* Read at joint meeting of the Winnebago County Medical Society and the Central Wisconsin Medical Society, Jan. 30, 1906.

thought in our economy or training until deranged. The newly born babe is so wrapped in its swaddling clothes that it has to battle for its breath, and the numerous instances of "found dead in bed" are only cases of a babe smothered for want of air. Even the quality of air it gets is strained through many layers of soiled and not aseptic cloths. From this time on, no thought is given to the kind of air it breathes; it lives by sufferance and by suffering alone; but what it shall drink and later eat engages all attention. Food, food for the palate and not for the needs, is sought in every clime, in land and sea, and air, *but not of the air itself;* lowest fungi and highest thorough-bred alike are devoured; "balanced ration" and more often unbalanced are devised and consumed, and only the extreme limitations of the receiving viscus stops the intake. Then what medicines are sought to digest the incongruous mess? Every acid and every alkali, enzymes and peptones, natural and synthetic, are invoked to aid and digest the monstrous mass—for it is no longer food—remaining in the worn and wearied stomach.

The waters of Abana and Pharpar, of the mountains and valleys of Egypt, Europe and America, have been sought and urged for drink; they have been boiled and filtered of their organic salts and others added; they have been drunk boiling hot and ice cold; their gases driven off and others added at the ingenuity or option of the concocter. With the gastronome thought continues dominant for newer foods and more of them, for more capacity and more area, while the pneumogaster remains an unknown and faultily used territory.

Malnutrition from gastritis, apepsia, benign and malignant disease of stomach, if basically admitted, are as prevalent as tuberculosis and about as fatal, because more unamenable to managerial treatment; and from this polluted pool there is poured through the chyle duct into the vena cava descendens into the right auricle and into the lungs many of the diseases of the lungs. Chalmette, of the Pasteur Institute, announces, in his latest report, that, in the immense majority of cases, tuberculosis of the lungs is acquired through this channel from ingestion of bacillus-laden dust and food débris.

The literature on cooking is coexistent with civilization; enough recipes are written to fill a national library, and cooks, outdoing doctors in recompense, are the highest salaried of artisans. But who, with respiratory diseases causing more deaths than all other diseases combined, has heard as much written or said of the amount or quality of air to breathe or how to use it, or who teaches or studies pneumodynamics? From the proximal vestibule at the nose to the most distal cecа of the respiratory tract, who knows among the laymen, or cares among physicians, what becomes of the involuntary tidal air, to say nothing of the residuary air, or how to use the complemental or supplemental air we will know swarms with bacteria?

At early catechism, we were taught that "God breathed into man the breath of life," and most people go on as though the same beneficent Power was going to continue the pumping act for them. Complete inspiration and expiration is seldom called into use except by vocalists and professionals. If, after the indifferent use and wear of the brief period of adolescence, puberty is reached in the rocky road of life and there is a scratch a hacking cough and a "puncture" has taken place somewhere in the "inner tubing," and there is a hemorrhage or an emphysema, then alarming and immediate repair is demanded and the call is very imperious. Had the vestibule and anterior filters been kept clean, not to say aseptic, the areolar tissue of the lungs been systematically and persistently exercised, the alveoli expanded and, accustomed to use and good air, their capacity would have enlarged, their resiliency strengthened as exercise strengthens any part, resistance would have been increased, the invader vanquished and the abrasion, ulcer, puncture, would not have taken place.

The complete demands for oxygen in the economy are scarcely ever met; the adolescent boy goes about with stooped shoulders and a disfiguring acne, because his respiration does not stimulate his pleuritic or cutaneous capillaries and their accompanying lymphatics. His sister is flat-chested, has a pasty skin, cold hands and feet, a dislike for duty, an irritable temper and a lackadaisical manner, with often recurring amenorrhea, because of deficient respiration and lack of hematin and oxygen. She is the near and easy target for pulmonary tuberculosis, because no one taught her the importance of the life-saving function of complete respiration; she did always breathe, it will be said, but how much of the normal respiratory capacity of her lungs did she employ? She probably never knew the exhilaration of oxygen stimulation, the "compound oxygen" of God's laboratory? Her physician never called her attention to the necessity and quality of this food. He was derelict. He gave her an alluring preparation of iron with probably a label "made in Germany" on it (instead of made in Pittsburg). He may have recommended her to eat more and to walk in the air, but she did not know how to breathe or what for. If she ever had vocal lessons, it was to sing and never thought of it as to live; her lungs, her thorax, her physical heart, she knows nothing about; these organs and their functions are as ephemeral to her as are the nebulæ of the heavenly constellations which she will soon join in the primary class, unless she learns to breathe. Ask her to expand her chest, and she may reach an inch on the tape, scarcely over; put her at a spirometer and she may go beyond the one-hundred mark, more likely under; she retains in her lungs from day to day, may be from week to week, the residuary air of a germ-laden church, dance hall, theater, schoolroom, Pullman sleeper or dirty street car. The shallow tidal air is never supplemented by an inspiration or expiration that would replace the toxic compound; the autointoxication of residuary food is now well taught and acknowledged; but the autointoxication of vicious and residuary air, who teaches or knows about this? The girl's bronchioles and air cells had become constipated and needed a purge. She can not get refuge in the ubiquitous pill, but she must breathe, exhale, or be left pneumotoxemic, probably tuberculous, certainly listless.

Our pneumonias are no longer regarded as local infections, but systemic; and so is tuberculosis, with this distinction that one is acute and overwhelming, and the other insidious and usually chronic; both are residual air toxins; both are preventable diseases. No one taught this creature how to breathe or its necessity. She was waiting for germs lurking in that residuum to incubate; a more favorable soil, undisturbed, with warmth and moisture and rest could rarely have been prepared; she was waiting for the afternoon hectic and the delayed or missed menstruation before any one told her she ought to have air to breathe. Some one again derelict! Her lungs are atrophied to flabby appendages in her thin thorax from nothing but disuse; inability to inhale, less to exhale, non-resisting to disease from non-use. Non-resisting! This suggests the keyword to the preven-

tion of tuberculosis, which is breathe, breathe good air. The report of the National Bureau for the Prevention of Tuberculosis says, at the close of papers and discussions, that "the problem would soon disappear of itself if it were possible for everybody to breathe fairly pure air, to be clean with a reasonable effort, and to have enough of the right sort of food to eat." This is what called into existence the sanitaria where people get and are taught this; the isolated cottage, the lone tent and the open field. It should be taught in the home and practiced there first.

RESPONSIBILITY OF THE FAMILY PHYSICIAN.

When this health-breathing opportunity and period has passed and the sanitaria and the tents are reached, the golden apple has been stolen from the Hesperian garden of youth and the battle with the hydra-headed dragon of tuberculosis is begun. Can either or both defeat this foe? Again some one was derelict! Doctors as much as laymen have allowed themselves to be directed by the sugary sibillation of "specialist" and "expert"; the family physician, the most important factor in sanitary science and sanitary society, has been rendered by this presence too timid; he has not been persistent and positive enough; his innate modesty has influenced his dictum. The family physician is the agent to advise to prevent tuberculosis; the so-called "specialist" may be a medium to confirm the wisely-guarded suspicion and diagnosis of the family physician and convey the unpleasant intelligence to the subject or the family; but his affiliation with a teaching faculty of a medical college or a connection with a sanitarium or a tent colony has done and can do nothing to prevent tuberculosis in a family. Simon A. Knopf, the early interne in one of the first large sanitaria in Germany and the leader in urging states to provide infirmaries for the tuberculous poor, said,[1] at the Atlantic City session of the American Medical Association in June, 1904, "We must look to the family physician for the early curable cases." Further on he says, "The bacteriologic examination in individuals with early symptoms, even if repeatedly made, is but rarely positive, for there is not enough disintegration to show the presence of bacilli." In another paper he says, "No matter how many sanitaria and special hospitals for the consumptive poor we may have, we must look to the family physician for the bulk of the work in fighting the great white plague." Dr. Osler, who needs no introduction, said, "In the warfare against tuberculosis the man behind the gun is the general practitioner; the battle can not be won unless he takes an active, aggressive and accurate part."

STARTLING STATISTICS.

Applying statistical tests to this subject will not avail, because in its complexities are involved too many varied factors; all those of a complex body and of a complex disease, besides those of age, heredity, employment and environment; to detach a segment or fragment in this cycle and employ it in a consideration of the whole would be impossible and unreliable. Tuberculosis has domestic, filial, social and economic facets that must be adjusted to each other without friction in the management, and that means the treatment of tuberculosis.

Sociologists furnish the startling statistics[2] of four million families in the United States who subsist on four hundred dollars a year; employing the usual multiple of five to a family and there are over one-fourth of the inhabitants of the nation living on an income so close that there is no computation that would permit them to avail themselves of the alleged advantages of a sanitarium or a tent colony at present prices of management or supply them with the needed beef, eggs and milk at present trust prices. Should the bread winner himself be stricken, conditions would be still more deplorable. According to Robert Hunter's estimate, there are an equal number of willingly unemployed peripatetics, indigent by birth and training, disseminators of disease and vice, lawless in the moral code and utterly devoid of any appreciation of sanitation, on whom the law can apply no restrictions except vagrancy, which they court when winter time comes, polluting and inoculating fellow-prisoners in jails, almshouses and rural homes.

The question whether a patient should be told of his affliction is no longer a negative one; there is more safety in knowing and battling aright than in being deluded with ignorance of the disease and battling wrong. Then there is the aid through instruction that can be given to make a winning fight by one who, through study and training, knows, and that one is the family physician.

At the Tuberculosis Exposition in Philadelphia, Feb. 23 to March 1, 1906, of the dozen or more papers presented, not one dealt with *tuberculosis in the home*. The state, the municipality, the factory and the railroads were dealt with, but there was not a word about the home. And yet it is stated that the most attractive as well as graphic feature at the international congress at Paris last December was the little "model cottage bedroom, hygienically fitted up in the most modern and inexpensive way, showing not a speck of dust on the brightly varnished, lacquered or polished surfaces." An ideal object-lesson for a home and one practically attainable by any one anywhere. Even if statistics of sanitaria and tent colonies were admitted as to their real curative claims, they would be of little value. At the Philadelphia meeting of the Pennsylvania Society for the Prevention of Tuberculosis held last December in the Phipps Institute the statement was given out[3] that 90 per cent. of the people of this climate and country had implantations of tuberculosis some time or other; and with the familiar estimates variously furnished that from 8 to 11 per cent. of all deaths are from this disease, it must follow, if even the greater mortality per cent. is taken, that nearly 80 per cent. recover. Germany gives similar estimates, saying that "every one has had at some time a focus of tuberculosis," an estimate and claim no present sanitaria or tent colony has excelled or equalled.

Then, too, thus far in the crusade against tuberculosis, the inmates of all private and many public sanitaria have been volunteers of superior heredity and social environment; and even from these have been selected only those who on inspection and physical examination gave promise of successful management. Quoting Simon A. Knopf[4] again on sanitaria treatment, "Sanitaria are usually unwilling to receive cases that do not offer a favorable prognosis." Advanced cases are never taken. At the international congress held in Paris last autumn the statement was made and not refuted that "German sanitaria confessed that they accept only about three out of every ten presented them." Thus the presentation of figures from sanitaria as at present manipulated are of but little value until numbers and cases are admitted without regard to class or condition. Then,

4. New York Med. Record, November, 1905.

as to selection of applicants without bias, and on diagnosis only, another usually unadmitted difficulty is encountered. Dr. Bridge[5] says that "tuberculosis of the lungs always exists for a considerable time before it announces itself by signs or symptoms." Also Drs. Bradford and Seymour of Gouverneur Island Hospital, New York, in a paper read before the Hospital Alumni Association, at the Academy of Medicine, Jan. 13, 1905, say, "There are a not inconsiderable number of cases of such doubtful character that we keep them under observation many weeks or months before we can arrive at a diagnosis, if we are able to do so at all," and this in a dispensary where only "chest disease" patients are sent. One dispensary in Philadelphia last year passed on 900 patients of the poorer class without reporting a single case of tuberculosis. Still, in the face of such evidence, Dr. Trudeau of Saranac Lake Sanitarium says that "the average family physician can not make a diagnosis of tuberculosis." We all realize that to err is human, but to diagnose is divine. Those of us who have passed beyond the dogmas of the lecture room and the dicta of the so-called "expert," and have trained experience and historical data of cases and families extending through years, know that diagnoses have often been confirmed or defeated by the great arbiter Time, and that the family physician's early and guarded suspicions and directions as surely matured into a positive diagnosis and cure as those hastily culled by the college professor or the prolific and fluent author.

PLEA FOR HOME TREATMENT.

If, as Dr. Trudeau says, the family physician can not recognize tuberculosis until the physical symptoms have become well marked, then some one has been derelict; this doctor has the great five senses and the same gyra and convolutions; he has a diploma from the same college as his mentor, signed by the same faculty attesting his competency; he has access to the same text-books and reads the same journals; he is not distracted by the myriad subjects that divert his city confrère, and he studies his cases clinically as well as physically and can have bacteriologic examinations, and his diagnosis is to be relied on. The fast mail and rural free delivery keeps the remotest doctor in touch with the latest and the best at all times. He can become as faultless in technic and diagnosis and as familiar with management and direction of tuberculosis cases as the sanitaria director or employé. Knowledge is not confined to the few, but is the common heritage of all. The institutionalizing of a community is to be guarded against; the rightly cultivated independence of the average American citizen is to be encouraged and his dependence to be deplored. It is the initiative of the American that has marked his successful progress in civil, military and industrial life, and it is this that is to make him the efficient helpmeet of the family physician in the conflict with the great white plague. The dependence, servility and stoicism of the peasant on the other side of the pond is not to be taken as a guide for the citizen on this side; let us avoid institutionalizing him. The social and economic question, the first to be considered, can be best met domiciliarily; of these the family physician knows more for the family's sake and for society's sake than any one else can possibly know. The depression that domestic or rural isolation burdens the tuberculous child or adult with will deter its progress in an institution; ennui and nostalgia, the concomitants of a strange environment, both great depressants, would not have to be contended with in the home, besides the psychic stimulus of the family doctor's visits and his helpful words to the family would certainly be more inspiring than the words and presence of the indifferent patrol or nurse of an institution. The educational advantages of such a nucleus in a neighborhood would also be of incalculable advantage, because each would be an object-lesson carried on in the identical environment that the restored subject must spend the remainder of his or her days in.

Already S. A. Knopf, whose name I have freely used because of his close identity with sanitaria work, is modifying his views to adjust them to the home and has suggested the elevated house recess, the porch-lodge and window canopy inside the house to protect the patient and still be really in the open air, but under the care of parent or family, thus favoring domiciliary treatment. Numerous other devices, resourceful parents and an ingenious doctor will invent and adjust to the cottage, the tenement as well as to the mansion.

In a recent address before the Civic Betterment Association of Philadelphia, in the Civic Club's rooms, Dr. Walsh said:[6] "If consumptive patients are curable at all, they can be cured at home," an indication of the trend of thought among those engaged in research work. This is also the highly commendable sentiment and spirit prevailing in the Visiting Nurses' Associations of the various cities and states[7] which provide home treatment, nursing, care and, most and best of all, instruction and adjustment among thousands of consumptive poor with their own facilities in their own environment. It is this education of common people along common lines of wholesome living, the nutritive values of foods and their economics; above all else, the value of pure air and the means of obtaining it, that will vanquish this common foe of mankind. That this was the sentiment of the Paris international congress last October was brought out by Cheinisse in the *Semaine Medicale* October, 1905. Cheinisse remarks that "the first enthusiasm for the sanatoria as the sole means of salvation from tuberculosis has subsided. The recent international congress showed this declining tendency in a marked degree. The sanitaria for the well-to-do person who can modify his mode of life afterward so as to maintain the benefit derived is still the great benefit claimed at first. Members of the working classes, however, return from the public sanitarium to their old poverty-stricken environment. Their zeal and conviction will gradually be modified, and they will refrain from using their pocket cuspidors for fear of the prejudices of the proprietors and fellow-workmen, as it stamps them as dangerous. The rôle of the sanitarium in prophylaxis is thus illusory; its therapeutic rôle, evidenced by the restoration of the working capacity, is more than dubious, as it is subordinate to the natural progress of the disease and to the occupation of the individual. On the other hand, the expense of the public sanitarium as conducted in Europe (who would expect them to be any more economically conducted in profligate America) is out of all proportion to its purely palliative effect among the laboring classes." Cheinisse cites Beco to the effect that the sanitarium has been too long regarded as the pivot of the antituberculosis campaign, when in reality it is only a secondary element. He adds that experience in Europe has also shown that, "besides the true scientific and useful dispensaries,

5. Bridge "Tuberculosis."

6. Philadelphia American, Dec. 8, 1905.

7. The Journal A. M. A., Dec. 2, 1905.

pseudodispensaries spring up for advertising purposes, which, under the guise of benevolence, are in reality but centers of competing interests to advertise politicians connected with the inception and promotion of the dispensary. Thus patients find themselves at the mercy of regrettable practices where séances of electrization or ozonation, or exploitation of pharmaceutic specialties substitute real hygienic regulations." One need but look about in our own country to see where yankee enterprise would very soon lead to in such schemes.

The congress adopted a resolution to the effect that the sanitarium and the dispensary are neither exclusive nor predominant in the campaign against tuberculosis, but that the problem of healthy homes will always dominate its prophylaxis. Its control belongs to the individual and to the family and its prevention to the tutelage of the family physician.

The original unit of society remains the family, and through it the factor to prevent tuberculosis is the family doctor. There are, and will be only a few sanatoria, but there are and will be many family physicians.

The errors of our homes and home lives are so inconsistent and palpable that it is a wonder we have passed them by. Against constant knowledge and teaching, homes are made as hermetically tight as mechanical skill can make them. We chide the poor for listing their windows and stuffing the keyhole; but the well-to-do have impervious walls, double storm windows and double air-locks or pneumatic caissons at their doors; air is reheated from gilded radiators and pallor is the stigma of its inmates, and non-resistance to disease is their fate. Sunny days are the claim and boast of regions seeking recognition as health resorts and the preachment of the sanitarian; yet the architect is ignoring all this and designing houses and porches to shut out all the sun possible; porches that throw the house "in the shade" are in vogue. As if this were not enough, they erect a massive quartet of twenty-ton pillars to support a two-ton roof, and shade all the area possible. In the home the sunny window is taken up with a few straggling plants set in stable compost, while the baby or the invalid is hid in a shady and darkened corner behind the stove or over the radiator.

It has been asserted without contradiction that the demise of the North American Indian by the tuberculous route is due to his exchange of the tepee for the modern house. But the lesson and application is lost; for we triplicate their errors and invite the disease, and then with an atavism fought through many generations promptly relinquish our boasted civilization and again seek the tepee and the bush for relief without inurement to the storm or the relentless sun, and expect immediate relief from our woes.

Let us be sensibly consistent, and consistently sensible in this struggle against a self-invited foe; teaching that it is every one's duty to be enrolled in the defensive warfare, that the home is the fortress from which the battle must be fought in both its prevention and its cure; that the family doctor is the commanding general and must be prepared to do his duty to all, and the victory is ours.

Uncinariasis.—G. Peri (*Atti dei Lincei*), discusses how far *Ankylostoma duodenale* is parasitic in other animals than man. Peri has been able to infect dogs both by way of the mouth and through the skin, and there are good reasons for believing that horses are also susceptible to the infection. The practical importance of the liability of the domestic animals is obvious.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN.

CHAPTER XX.

ALTERATIVES.

Alteratives are tonics, which, in some unknown way, favorably influence the processes of nutrition which have been disturbed by disease. They include the hematinics, which were discussed in the preceding chapter, the various preparations of mercury, and many, if not all of the preparations containing iodin, either free or in combination.

A number of drugs of vegetable origin, such as sarsaparilla, were formerly classed as alteratives, but these are, for the most part, merely purgatives, or else devoid of therapeutic interest.

The use of the thyroid gland in thyroid disease and in obesity, and of the newly discovered serum of Beebe in exophthalmic goiter, have a scientific basis, but the employment of the iodids in rheumatism and in syphilis, and of the mercurials in the latter disease is empirical, and in this connection the pharmacology of these agents is of minor importance since it throws little light on their therapeutic applications.

While the attempts to investigate the action of these agents have not led to satisfactory results, we may refer to the conclusions of J. Levi, who sought to compare the effect of mercurials and of potassium iodid on the metabolism and on the blood of syphilitics. He used potassium iodid and various organic and inorganic preparations of mercury in the second stage of the disease on 252 patients.

Levi found that the mercurials increase organic combustion and hasten metabolism in this condition. With the gradual disappearance of the disease the processes of nutrition improve, but relapses are frequent. He found no evidence, however, of a specific influence on the micro-organism of syphilis, but according to the most recent view mercury is antagonistic to this micro-organism.

If the use of mercurials be too greatly prolonged the number of red blood corpuscles is diminished. Levi found that potassium iodid had a similar general influence on the nutrition o syphilitics. While it causes an increase in the body weight, improves the blood, and adds to the muscular strength, it retards combustion and lessens metabolism. He explains its uses in tertiary syphilis by supposing that it neutralizes the disease products without increasing organic combustion.

Nearly all observers are agreed that the action of mercurials is almost wholly independent of the preparation chosen, the only essential for its action being that it shall be absorbed. Mercury probably circulates as an albuminate, which is soluble in the blood because of the excess of proteids and chlorids which it encounters there.

Owing to the obscurity of many of the symptoms of syphilis, and also to the fact that a comparatively large number of people are not willing to have it known to their physician that they suffer with so loathsome a disease, the condition is peculiarly favorable for the practices of charlatans. While there is no disease that more urgently demands the skill and judgment of the specialist, there is none, perhaps, that is so frequently treated by incompetents and even by patients themselves.

While we have always with us the humiliating spectacle of numerous nostrums ostensibly advertised only to the medical profession, some of them of vegetable origin and wholly worthless in syphilis, others consisting of one form or another of mercury and possessing few or no advantages over the older and better known official mercurials, we are also daily confronted with advertisements which disgrace our boasted civilization in that they seek to persuade the deluded victims to palter with the useless nostrums in the vain effort to treat themselves.

Mercury and the Mercurials.

HYDRARGYRUM.—U. S.—Mercury, or quicksilver, has been known from remote antiquity, and from the earliest times has played an important part, not alone in the industries, arts and superstitions, but also in the medical practices of the people who are acquainted with it.

Even at present, this substance, in the form of preparations produced by mechanical subdivision of the mercury, is widely used for external application as well as for internal administration. Several of the preparations of mercury have been mentioned under other headings, and we shall content ourselves, therefore, with recounting a few of the salient features of these several substances.

HYDRARGYRUM CUM CRETA.—U. S.—Mercury with chalk, also known as gray powder, represents 38 per cent. of metallic mercury, with clarified honey and prepared chalk.

Average dose: 0.25 gm. (4 grains).

MASSA HYDRARGYRI.—U. S.—Mass of mercury, better known as blue mass, contains 33 per cent. of metallic mercury, with glycyrrhiza, althæa, glycerin and honey of roses. An analogous preparation without the glycerin is frequently found in the shops under the somewhat incongruous title, "Powdered Blue Mass."

Average dose: 0.25 gm. (4 grains).

The mass of mercury and the mercury with chalk are widely used as mild mercurials and are especially popular for use with children.

Probably the most widely used as well as the most popular of all the preparations of mercury as an antisyphilitic is:

HYDRARGYRI IODIDUM FLAVUM.—U. S.—Yellow mercurous iodid occurs as a bright yellow, amorphous powder, without odor or taste, and is practically insoluble in water and in alcohol.

Average dose: 0.01 gm. (10 mg. 1/5 grain).

HYDRARGYRI IODIDUM RUBRUM.—U. S.—Red mercuric iodid occurs as a scarlet-red, amorphous powder that is nearly insoluble in water, but soluble in 116 parts of alcohol; it is also soluble in solutions of the soluble iodids and in solution of mercuric chlorid.

Average dose: 0.003 gm. (3 mg. 1/20 grain).

HYDRARGYRI CHLORIDUM CORROSIVUM.—U. S.—Corrosive mercuric chlorid, more popularly known as corrosive sublimate, has been used by the Chinese from a very early period. It was used by the early Arabian physicians, and a process for its production was described by Geber in the eighth century.

Mercuric chlorid occurs as colorless, rhombic crystals or crystalline masses, or, more frequently, as a white powder, and is odorless, but has an acrid and persistent metallic taste. It is soluble in about thirteen parts of water and in five parts of alcohol, more freely soluble in solutions of the alkaline chlorids.

Average dose: 0.003 gm. (3mg. 1/20 grain).

HYDRARGYRI CHLORIDUM MITE.—U. S.—Mild mercurous chlorid, better known as calomel, has been known to some of the Eastern people from a very early period. It appears to have been introduced in Europe about the beginning of the seventeenth century. It occurs as a heavy white powder, without odor and practically without taste, and is insoluble in water and in alcohol.

Average dose as an alterative: 0.05 gm. (1 grain).

There are several additional compounds of mercury, but as they are not used for internal administration they need not be enumerated in this connection.

Uses of Mercurials.

Since the use of mercury as an alterative is largely limited to those conditions resulting from syphilis, either acquired or congenital, we shall at present confine ourselves to discussing its employment in this way.

The pathology of syphilis is very often so obscure that it should be treated by the specialist when possible, and the following is intended for the general practitioner who finds himself compelled to undertake the treatment of such cases.

There are many distinct symptoms that are manifested by patients with a syphilitic history which fail to respond to the sons otherwise healthy), but which at once disappear when mercury is given.

Many authorities are opposed to any form of constitutional treatment for the first stage of syphilis because we have no specific, and the treatment may mask or even prevent the appearance of those symptoms which render the diagnosis absolutely positive, without preventing the ultimate effects of the disease, thus condemning the patient to the hardships of a long and painful course of treatment without positive knowledge of its necessity. Others rely on their ability to diagnose syphilis by the chancre and the history of the case, and proceed at once to the use of mercury.

Inasmuch as it is supposed that mercury has comparatively little immediate influence on the course of the disease at this time, we should be very sure of the correctness of our diagnosis before beginning a course of treatment which, to be effective, must be continued for many months, and is in itself not free from danger to the patient's health.

When the history of the case, together with the chancre, renders an immediate diagnosis certain, treatment should be instituted at once.

All mercurials are irritant when dissolved and there are serious objections to all the different available methods of administration. Chief among these objections is the disturbance of digestion, which is not wholly obviated even when the mercury is injected hypodermically or applied by inunction.

Diarrhea is often a troublesome result, for which opium is advised, but the evils attending its use are obvious and its presence should always be suspected in nostrums containing well-known mercurials that are advertised as being guaranteed not to cause diarrhea or other gastric disturbances. Mercury is eliminated by all the channels of excretion and the kidneys not infrequently suffer serious injury. It follows that we must try to find the method best suited to the individual case, and attention is directed to the following means of administration with some of the objections to be guarded against or at least kept in mind:

It is generally agreed that since there is no essential difference between the action of the various organic and inorganic salts of mercury in syphilitic conditions, we should be guided in our choice of agent by the method of administration which experience teaches us to be best suited to the individual case. If the digestion suffers from internal administration of mercurials, intramuscular injections may be tried; if these are too painful, inunction may be resorted to; but whatever method is followed we must be alert for the appearance of untoward effects and the diet must be the object of especial attention, one being selected which is nutritious while it is easily digested.

The mercurials are to be avoided or used only with great caution in cachexia due to other causes than syphilis, as their tendency to disturb digestion may increase the trouble.

They must be used only with the greatest caution in acute nephritis, but they seem to be less deleterious in the chronic form, though here, too, their action must be carefully observed.

Mercury is particularly potent for harm in pregnancy, especially in the latter months; abortion may occur or the child may suffer from mercurial poisoning.

For internal use either mercurous or mercuric iodid is usually preferred. The combination of mercuric chlorid with potassium iodid merely means the giving of mercuric and potassium iodids, as the reaction occurs as soon as the two substances are brought into contact. When the mercuric chlorid is used it is best given alone, in dilute solution, as it is incompatible with a great many substances.

Mercuric iodid may be given as follows:

R.	Hydrargyri chloridi cor.....gr. iii	20
	Potassii iodidi.....gr. x	60
	Aquæ dest., q. s. ad.....f.℥iii	100

M. Sig.: Ten drops in water after each meal. Increase each dose daily by one drop until symptoms of mercurialism are noted, then reduce to one-half.

This is not given as an example of the so-called mixed treatment, the dose of potassium iodid being entirely too small to be effective.

An example of a prescription for mixed treatment would be as follows:

R.	Hydrargyri chloridi cor.....gr. i	06
	Potassii iodidi.....℥ii	8
	Aquæ dest., q. s. ad.....f.℥iii	100

M. Sig.: One teaspoonful after each meal.

The object of giving the mercurials after meals is to insure the protection of the stomach, which the presence of food affords, against the irritant action of the metal.

The menstruum or diluent for the prescription for mixed treatment may be varied in a number of ways. The water may be substituted by any one of the medicated waters by elixir adjuvans, aromatic elixir, compound tincture of gentian, compound syrup of sarsaparilla, or by a mixture of one or more of these vehicles; the most important point to be guarded against is the attempt to combine the potassium and mercuric iodid with alkaloids in solution, as the mixture of potassium and mercuric iodids is one of the most effective of precipitants for alkaloids.

The characteristic effects of mercury are to be carefully watched for and when the gums become slightly tender the dose is to be reduced somewhat in amount and given but twice a day—after the morning and evening meals. It would be well to wash down the dose with milk, the proteid of which will serve to protect the stomach against the irritant action of the mercury.

Mercurous iodid is not so corrosive as the mercuric, or red iodid, and it is often given in pill form with some colloidal substance, such as extract of gentian.

The following is an example of the method of giving it in this way:

℞. Hydrargyri iodidi flav.....gr. vi |40
Extracti gentianæ.....gr. lx 4|

M. Fiat pilulæ No. lx. Sig.: One pill after eating.

This dose may be gradually increased by giving two pills after the mid-day meal, then two twice and finally three times a day until the symptoms of mercurialism mentioned above are seen. The dose is then reduced, as in the case of mercuric iodid, and given after the principal meals.

The mild mercurous chlorid, or calomel, may be used, but it is so insoluble that it is impossible to regulate the amount that is absorbed. Next to the administration by the mouth, the intramuscular injection is to be preferred, but it causes great pain and may result in abscess unless caution is observed. The addition of cocain hydrochlorid has been recommended by some authorities, but we should bear in mind the danger of forming a habit which is, if anything, even more terrible than syphilis.

The injection should be made by the physician, as the patient can not be trusted to do it satisfactorily.

Eight milligrams (one-eighth of a grain) of mercuric chlorid, or of the unofficial mercuric salicylate,[1] is dissolved in about ten minims of normal saline solution and injected deeply into the gluteal muscle, care being taken to avoid the spot which supports the body when the patient is seated. The part should then be massaged gently and an icebag or cold compress applied to relieve pain.

The injections may be repeated two or three times a week. The inunction method is very commonly employed in the establishments at Hot Springs, Ark., where many syphilities are treated.

The inunction may be done as follows: After inducing diaphoresis, 3 grams (about 45 grains) of mercurial ointment are rubbed into the skin, not on it, daily. As this must be applied to a rather large extent of surface it is customary to select six regions which are utilized on successive days, returning on the seventh day to the first region. These are the adductor surfaces of the thighs (the most convenient when the patient is to rub the ointment into his person), the armpits and the regions just below, extending anteriorly, and the subscapular regions of each side.

The ointments of the oxids of mercury and the oleate of mercury are more irritant than the mercurial ointment or the blue ointment, as the diluted mercurial ointment is now called.

Too much stress can not be placed on the necessity of giving close attention to the various bodily functions during the mercurial treatment to maintain the appetite and digestion unimpaired, to regulate the bowels and to secure scrupulous cleanliness of the body. The mouth should be the object of especial attention; carious teeth should be filled and the mouth and teeth kept thoroughly cleansed.

1. Six grains (0.4 gms.) of mercuric chlorid to the fluid ounce (30 c.c.) will equal ¼ grain (8 milligrams) in ten minims.

The Iodids.

The use of the iodids, like that of mercury, is well established on clinical evidence and we can only speculate as to the way in which it produces its effects in syphilis, chronic rheumatism and asthma.

OFFICIAL PREPARATIONS.

Iodum.—U. S.—Iodin occurs as bluish-black rhombic plates that have a metallic luster, a distinctive odor and a sharp and acrid taste. It is only slightly soluble (1/5,000) in water, but is readily soluble in ten parts of alcohol. It is also soluble in an aqueous solution of potassium or of sodium iodid.

Iodin was discovered about 1812 by Courtois, a French manufacturing chemist, but it was not used in medicine until after 1820, when its medicinal virtues were first made known by Dr. Coindet, Sr., of Geneva.

Average dose: 0.005 gm. (5 mg. 1/10 grain).

Liquor Iodi Compositus.—U. S.—Compound solution of iodin contains 5 per cent. of iodin and 10 per cent. of potassium iodid in distilled water.

Average dose: 0.20 c.c. (3 minims).

Tinctura Iodi.—U. S.—Tincture of iodin, as now official, represents an alcoholic solution of 7 per cent. of iodin and 5 per cent. of potassium iodid. The resulting tincture is freely miscible with water and with alcohol.

Average dose: 0.10 c.c. (1½ minims).

Acidum Hydriodicum Dilutum.—U. S.—This is a new addition to the Pharmacopeia and is intended primarily for the preparation of the syrup of hydriodic acid. It should contain not less than 10 per cent. by weight of the absolute acid.

Average dose: 0.50 c.c. (8 minims).

Syrupus Acidi Hydriodici.—U. S.—This is a clear, colorless, syrupy liquid that contains about 1 per cent. of absolute hydriodic acid.

Average dose: 4 c.c. (1 fluidram).

Attention may here be called to the fact that some of the manufacturers of so-called permanent syrup of hydriodic acid have taken advantage of the fact that glycerin is less susceptible to chemic change with hydriodic acid than syrup, and are, therefore, offering a glycerite of hydriodic acid under the name of syrup. While it can not be definitely proved that this substitution is a dangerous practice, it is, nevertheless, one of the little dishonesties that are so frequent in other lines of trade and should not be countenanced in connection with the production or the use of medicinal substances.

Syrupus Ferri Iodidi.—U. S.—This syrup, in harmony with the Brussels conference agreement, now contains about 5 per cent., by weight, of ferrous iodid.

Average dose: 1 c.c. (15 minims).

The official salts of iodin are all freely soluble in water and are also soluble in alcohol and alcoholic liquids. They are, in the order of their popularity and use:

Potassii Iodidum.—U. S.

Sodii Iodidum.—U. S.

Strontii Iodidum.—U. S.

Average dose of any of the above: 0.50 gm. (7½ grains).

Ammonii Iodidum.—U. S.

Average dose: 0.25 gm. (4 grains).

While mercury is employed in all stages of syphilis, but is most useful in the second stage, the iodids are employed in the second and third stages, but find their greatest field of usefulness in the third. The iodids enjoy a peculiar reputation in the treatment of those symptoms of tertiary syphilis, such as periostitis, which are manifested in connection with the bones.

Bronchitis, in those who suffer with a rheumatic or gouty diathesis, often shows greater improvement under the influence of this drug than with any other treatment.

The iodids are rarely used alone in the second stage of syphilis, but in combination with mercury, known as the mixed treatment, already referred to, they appear to be of value.

There can be no doubt of the usefulness of the iodids in relieving the symptoms occurring in the third stage of syphilis, and we have few therapeutic facts which are better attested.

The saturated solution of potassium iodid is, perhaps, the most commonly used form of administration.

The preparation of this may be entrusted to the pharmacist or it may be ordered as follows:

℞. Potassii iodidi 3i 30
Aquæ dest., q. s. ad. ..f. 3i 30

M. Ft. solut. Sig.: Five drops after each meal, the dose to be increased by one drop each day.

The increase in the amount to be taken may be continued until the symptoms of iodism arise or until sixty or more drops are taken daily.

The patient is to be instructed as to the symptoms to be expected, such as pain in the region of the parotid gland, etc.

We are as far from being able to explain the action of the iodids in chronic rheumatism and asthma as in syphilis, but their usefulness is indisputable and unquestioned.

It is of little consequence whether we choose potassium or one of the other inorganic iodids or an organic preparation. Potassium iodid has long been the most popular of all of the available preparations and will probably continue to be the most useful or, at least, the most frequently used.

Thyroid Gland.

When it was found that the feeding of thyroid substances would obviate the symptoms which ordinarily follow the removal of that gland, the suggestion was made that it might be effective in combating the symptoms associated with disease of the gland. This was found to be true, and the fact that the substance is effective when given by the stomach at once suggested that there must be some active principle formed in the gland. This principle, called iodothyrin, containing 9.3 per cent of iodin, possesses the same therapeutic properties as the gland substance; under its uses a great increase in metabolism occurs, superfluous fat disappears and an increased combustion of proteid takes place, explaining its use in obesity and the necessity for a diet rich in proteid when this substance is used for such conditions as myxedema.

GLANDULÆ THYROIDEÆ SICCÆ.—U. S.—Dessicated thyroid gland is officially described as "the cleaned, dried and powdered thyroid glands of the sheep, freed from fat." It occurs as a yellowish amorphous powder, having a peculiar odor; it contains the active ingredients of the thyroid tissue. It is partially soluble in water.

Average dose: 0.25 gm. (4 grains).

Thyroid gland or iodothyrin is indicated in obesity and after removal of the thyroid or when the latter, through disease, fails to function properly, as in myxedema and in hypoplastic follicular goiter.

NOTE.—In THE JOURNAL, April 14, page 1107, in Chapter 16 of the special article on "The Pharmacopœia and the Physician," the average dose of aqua camphoræ was given as 1 c.c. instead of 8 c.c. (2 fluidrams).

Clinical Note

EMPYEMA DUE TO THE INFLUENZA BACILLUS.*

HEBERDEN BEALL, M.D.
Medical House Officer, The Johns Hopkins Hospital.
BALTIMORE.

Empyema due to the influenza bacillus is probably of more common occurrence than is generally believed. Last year Boggs[1] reported from this clinic the only case found in the literature in which this organism has been demonstrated. I give below an abstract of this case and report a second case, in which I obtained the influenza bacillus in pure culture from the pus from the pleural cavity.

CASE 1.—(Bogg's case). A. B., male, white, aged 60, a tailor, was admitted to the hospital March 1, 1905. None of his family had had tuberculosis.

History.—The patient had always been well, except for a chronic cough. His present illness began about one year before admission, with a severe attack of bronchitis; at this time the expectoration was very profuse and he spat a little blood; occasionally he had fever and sweats. He had not been quite well since this attack and four weeks before admission his condition became much worse. The chief complaints on entering the hospital were pain in the side and night sweats.

Examination.—On examination he was found to have a diffuse bronchitis and a small amount of fluid in the left pleural cavity. This fluid, removed by aspiration, was clear and yielded no growth or ordinary media. The patient at this time had an irregular fever and sweats. His sputum was abundant, tenacious, mucopurulent and blood-streaked, and from it was grown *Bacillus influenza* in pure culture. The patient was discharged on request, not much improved. He was re-admitted eighteen days later, feebler and with more fever and drenching sweats. There were signs of a pleural effusion and small amounts of bloody fluid were withdrawn on several occasions; this was not saved for cultures. He had at this time a moderate leucocytosis. Two weeks after his admission pus was obtained from the pleural cavity and from this influenza bacilli grew in pure culture.

Treatment.—The patient was transferred to the surgical side. At operation the pleura was found much thickened and a considerable amount of grayish, odorless pus was evacuated. There was rapid improvement.

CASE 2.—L. H., male, white, aged 23, a saw-mill hand, was admitted to the hospital Nov. 14, 1905, complaining of "pain in right side, cough and night sweats."

History.—There was no tuberculosis in his family and he had always been healthy. As a child he had had measles, chickenpox and whooping cough; he had not had pneumonia, had never had a chronic cough or an hemoptysis. So far as he knew, he had never suffered from any cardiovascular or gastrointestinal disease. His work was moderately heavy and in a saw mill, where he was much exposed to the weather.

Present Illness.—The patient had been perfectly well up to March 1, 1905. On March 2, eight months before admission, he caught cold after exposure and had "grip" for five days; he was then up and around for eleven days, but did not feel well enough to return to his work. On March 13, he was awakened by a sharp pain in the right side of his chest; the pain became very severe and required morphin. He grew rapidly worse, became delirious, and remained so for two weeks. About four weeks after the onset he began to have cough, which was worse on lying down; he became short of breath and had to sleep in a sitting posture. About this time also he began to have drenching night sweats. After being ill for two months his right chest was aspirated and a pint of thick creamy fluid was obtained. This relieved the dyspnea and cough for a short time. Three weeks later paracentesis was tried again, but unsuccessfully. The cough, which was worse at night, gradually grew better. He had no hemoptysis at any time. On admission the chief complaint was of night sweats.

Examination.—Aside from the thorax no abnormality was made out. Examination of the chest showed signs of a moderate effusion into the right pleural cavity. The heart was not displaced. There was no anemia; the leucocytes were 9000. His pulse was 72 and the temperature ranged from 96 to 98.2 F. An exploratory needle was introduced and 15 cc. of a thick yellowish green pus obtained.

Treatment.—The man was transferred to the surgical side for immediate operation. The eighth, ninth and tenth ribs were resected and about 600 cc. of greenish pus evacuated. The cavity showed but slight tendency to collapse and on leaving the hospital he had rather a deep sinus, which discharged freely.

Microscopic Examination.—The report of the microscopic examination of the tissue removed is as follows: "Pleura lined with a hemorrhagic granulation tissue; no evidence of tuberculosis."

Bacteriologic Examination.—In stained smears of the pus obtained by aspiration were seen pus cells, much granular detritus and a few influenza-like forms. From this pus, agar plates, bouillon, glycerin agar and human blood agar slants were inoculated. No growth was obtained except on the blood agar. After twenty-four hours there appeared on this medium fairly numerous, clear, dewy, discrete pinpoint colonies, which were just visible. Transfers were made repeatedly to all the

* From the Medical Clinic of the Johns Hopkins Hospital.

usual media, but no growth was ever obtained except on blood agar. On this, the organism grew fairly well and was kept growing for two months. The organism was a very minute bacillus with a tendency to polar staining; it often seemed constricted at its middle and often looked like a small diplococcus. It was non-motile. Involution forms appeared after several days' growth, long chains, resembling streptococci, and long thread-like filaments. This bacillus was best stained with dilute carbol fuchsin; it stained but feebly with methylen blue; it was Gram-negative. It corresponded in every particular, therefore, with the influenza bacillus described by Pfeiffer.[2]

These two cases are strong proof that Pfeiffer's bacillus may cause an empyema, and were cultures made systematically on the proper medium it is likely that this organism would be found to be the cause of not a few cases of "sterile pus" in the pleural cavity.

New Appliance

A CONVENIENT BURETTE APPARATUS

FOR USE IN THE CHEMICAL EXAMINATION OF THE GASTRIC CONTENTS.

WARREN P. ELMER, M.D.
Instructor in Medicine, St. Louis University.
ST. LOUIS.

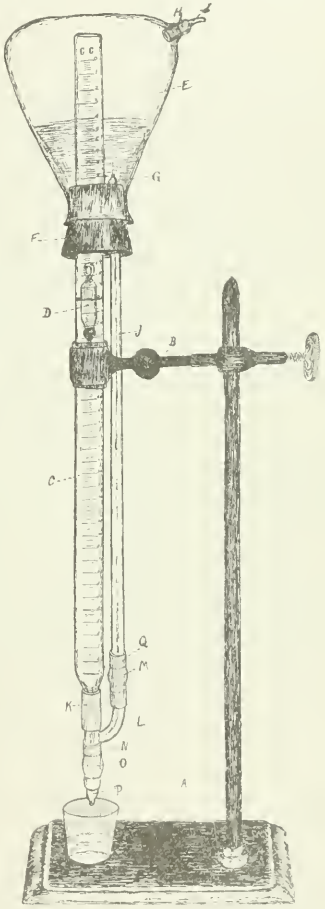
The growing importance of the chemical examination of the gastric contents as an aid to diagnosis renders it important that the up-to-date physician have such appliances at his command that this may be accomplished with the least possible waste of time and at the least possible expense.

With this fact in view I present the following description of a burette apparatus for decinormal sodium hydrate which I have found convenient for the titration of gastric contents:

The device consists of an ordinary burette stand (A), a burette clamp the jaws of which are covered by cork or rubber (B), a 50 c.c. burette (C) graduated in tenths, and fitted with a float (D). Through one of the openings of a two-hole soft rubber stopper No. 4 (F) is thrust the upper end of the burette in such a manner that the top of the burette projects above the stopper about four or five inches and the small end of the stopper is toward the top of the burette. Through the other opening in the stopper is thrust the end of a plain glass tube about one-fourth inch in diameter (J) drawn out by heating in a flame to a point (G), the opening of which is about a millimeter in diameter. The length of the tube should be that of the burette from this point to the bottom. The stopper thus equipped is placed in the neck of a 250 c.c. wide-mouthed Erlenmeyer flask (E), through one side of the bottom of which a hole (H) has been blown by heating it in the flame of a Bunsen burner until red and blowing vigorously, then heating again until the edges are smooth, and cooling slowly to prevent the glass becoming too brittle. In this opening, which is to serve as a vent and also as an opening for filling, is placed a small one-hole rubber stopper, through the opening of which is placed a small glass tube, drawn out so that the opening does not exceed one millimeter in diameter. This will allow sufficient air to enter and, if one wishes, it could be made to contain a little soda lime, thus freeing the air entering the flask from carbon dioxid and keeping the decinormal sodium hydrate absolutely accurate.

The bottom of the burette (C) and the free end of the glass tube (J) are connected by means of pieces of rubber tubing (Q-K) to a glass "T" tube (L), the stem of which is bent by heating in a Bunsen flame until it is parallel with one of the arms. The diameter of this tube is the same as the tube (J). Such a tube can be purchased for a small sum, but is rather difficult to make. Between the end of the long tube (J) and the T-tube (L) a space (M) is left about one-fourth inch long, in which a small piece of glass rod or a glass ball is placed to act as a valve. This can be made by heating a piece of glass rod one-fourth inch long and the diameter of the tubing until the edges are smooth.

To the free arm of the T-tube is attached by means of another piece of rubber tubing (N) a piece of glass tubing (P) three-fourths inch long and the same diameter as the T-tube and drawn out to a diameter of about two millimeters at the point. Between this tube (P) and the end of the T-tube a space (O) is left similar to that between the end of the long tube and the bent arm of the T-tube and similarly filled with a piece of glass rod or ball. By squeezing the rubber over the point (M) fluid flows from the flask into the burette and



can be stopped at any desired height, so that titration may always begin at the same point on the burette and by squeezing the rubber over the point (O) fluid is allowed to flow out of the burette in a very fine stream, which can be instantly shut off by releasing the rubber.

My idea of going so minutely into the description is that by following the directions any physician can make a similar apparatus, or at least have it made at a comparatively small expense. The decinormal sodium hydrate keeps very well in the reservoir (E) and is ready for use at a moment's notice, thus making the chemical analysis of gastric contents the work of a very few moments.

LEUCOCYTES AND OPSONINS IN THE DEFENSE OF THE BODY.

In certain infections the chief means of defense of the body seems to lie in the production of antitoxic substances that neutralize the poisons of the invading organisms. In a second class of infections no distinct soluble toxins are produced, hence no antitoxins are formed, and the resistance of the host seems to depend on the development of bactericidal substances that destroy the bacteria. There remains, however, a large and important group of infections, including especially tuberculosis and infections with the pus cocci, in which neither antitoxic nor bactericidal substances seem to be produced to defend the invaded host, and with these the chief source of resistance seems to lie in the action of the leucocytes. Until recently the exact significance of the leucocytes in the defense of the body against these infectious agents was a matter of uncertainty, and the source of much dispute. As one of the first on the field, Metchnikoff's view that the leucocytes were essential in the combat against the bacteria met wide favor and for a time almost universal acceptance. After a time it was found that the blood serum contained substances that injured or destroyed the bacteria, and it was urged that the leucocyte was more a scavenger than a defender, picking up only bacteria that had been injured by the serum and not attacking bacteria possessed of their full virulence. Between the upholders of these two views had been waged active combat for some years, with the production of many pieces of evidence speaking for one view or for the other, when the observation that the serum contains certain specific substances that prepare bacteria to be engulfed by leucocytes, showed the way to a harmonization of the existing differences.

These substances have been particularly studied by A. E. Wright, of London, who gave to them the name "opsonins" by which they are generally known; and in this country by Dr. Ludvig Hektoen and his associates. In this issue we publish Dr. Hektoen's review of the subject as given by him in the Middleton-Goldsmith lecture of the New York Pathological Society, and wish in this place to call attention to a few of the salient features of the article. Opsonins seem to be of very essential importance in the defense of the body, for without their presence leucocytes can not take up bacteria (with a very few exceptions). They act on the bacteria, rather than on the leucocytes, and seem to alter the physical or chemical properties of the bacteria in such a manner that it becomes possible for leucocytes to surround and to engulf them. Opsonins exist in normal serum to a certain extent, but are increased by immunizing against the bacteria in question, and they may also be important in the phagocytosis of red corpuscles by leucocytes and other cells. The increased power of phagocytosis observed in immunized animals is, therefore, not due to a stimulation of the leucocytes, as Metchnikoff believed, but to an effect of the serum on the bacteria. This opsonic power of the serum, however, is not the same as its bactericidal power, for bacteria may live and grow well in serum rich in opsonins; but if to such a mixture of bacteria and serum a sufficient number of leucocytes be added the bacteria are soon engulfed and destroyed, so that the mixture produces no growth on culture media and no infection when injected into animals.

This leaves little room for doubt that we must answer in the affirmative the long contested question: Can leucocytes take up and destroy living, virulent bacteria, i. e., are they actually an important agent in the defense of the body against infection? The power of the leucocyte in this direction is limited, however, for if the bacteria possess a certain degree of virulence they then successfully resist phagocytosis through two processes: one being the neutralization of the opsonins, the other a direct injury of the leucocytes by toxic substances.

Many points of great practical importance have been brought forward through the study of the opsonins. Thus, as Hektoen points out, the artificial production of leucocytosis can not be expected to accomplish much effect if there is a deficiency in opsonins, and the use of substances that injure opsonin (i. e., are negatively chemotactic) should be avoided. Wright has shown the variations of the opsonic power of the blood under various conditions and has given us simple means for determining this power. Furthermore, he has aroused new hopes of success in the treatment of disease by vaccination with minute quantities of bacterial substance. By carefully observing the opsonic power of the patient's blood and by modifying the vaccination process accordingly, it seems to be possible to keep this power at a maximum, with a corresponding increase of resistance to the infectious organism. Encouraging results have been obtained in tuberculosis and pus infections, and there exist good reasons for hoping that the usefulness of this method may be found to be both real and large.

SHOCK AS A CURATIVE AGENT.

One of the most interesting of the later developments of the unfortunate catastrophe at San Francisco has been the announcement that a certain number of persons who had been for some time confined strictly to their beds and who were considered, at least by themselves and their friends, to be suffering from incurable paralysis, as

a consequence of the shock have been restored to strength enough to walk and in some cases to apparently perfect health. In one case, the patient is reported to have been absolutely bedridden for over fifteen years, yet was so completely cured that he was able to help very shortly after the earthquake in the work of relief. The newspapers have made much of these cures and yet they will probably not appear so surprising to physicians. It is not an unusual thing in medical experience to have a patient who is suffering from hysterical paralysis frightened into activity by the occurrence of a fire or by a visit from burglars or some act of violence in his or more often her immediate neighborhood. The cure of hysterical mutism in the same way is an old-time tradition in medicine, of which Hippocrates has made mention.

What these cases illustrate is the wonderful power that the mind has over the body for good and ill. The original paralytic condition is due to the loss of control by the central nervous system over the muscles of locomotion. The restoration of control is brought about by the overpowering impulse of the will which reasserts co-ordination in spite of the inhibition of the neurotic condition. The earnest therapeutist can scarcely fail to be envious of Nature's methods and success in such cases. The great power for good that mental influence may have is thoroughly recognized, but sufficient efforts, as a rule, are not made to make use of it in such a degree as would place it among the important therapeutic agents. In recent years a definite effort has been made to systematize the influence of suggestion so as to bring mental sway into play, at least as an auxiliary in the treatment of many affections which, even though they are not entirely due to nervous conditions, have many neurotic elements.

As the result of the modern introspection, coupled with the half knowledge of things medical that has been rendered possible by a perverted activity of the printing press, there are but few serious ailments which are not complicated to some degree by neurotic symptoms. Even so serious an organic condition as apoplexy, during the course of improvement after the effects of the first shock have passed, may present definite neurotic or hysterical symptoms that are sure to delay convalescence. In woman particularly, bedriddenness may result and may continue for years, because apparently the hysterical condition will not allow the patient to gather enough courage to attempt ordinary movements. Even in such cases fright has been followed by a reflex response that made locomotion possible. Other intense emotional stresses, as religious feelings or maternal solicitude, produce similar results. Suggestion may play a like rôle. It would seem to be of first importance, then, that the medical lesson emphasized by so serious a calamity should not be lost, and that mental influences should come to have a more systematic place in our modern therapeutics.

If employed with proper confidence and with systematized individualization, this branch of therapeutics, as we perfectly pointed out,[1] has proved eminently helpful in the hands of experts and will undoubtedly accomplish much for the general practitioner who avails himself of it in the right spirit.

OLD-TIME MEDICAL AND SURGICAL ANTICIPATIONS.

It is so generally the custom to consider that medicine, as we know it at the present time, is entirely the result of nineteenth century investigation, that it is often forgotten that for many centuries intellectual men were at work in the European medical schools investigating and teaching truths in medicine and surgery. How many of our modern discoveries are really the refinding of forgotten truths may perhaps be most easily realized from a reading of Professor Allbutt's[2] address on the "Relations of Medicine and Surgery to the End of the Sixteenth Century," which was delivered at the St. Louis Congress of Arts and Science, in 1904, and which has recently been published. This book is a treasure house of the wonders of old-time medicine with definite reference to the works in which further details of information may be obtained.

It is not a little surprising for the modern, rather self-complacent student of medicine to learn that even in the thirteenth century there were original and independent observers in medicine and surgery who made discoveries of great importance. At that time there was no distinction between the physician and the surgeon and these great medical scholars were distinguished in both departments. Of one of the best known of these early writers on medicine, Guglielmo Salicetti, of Piacenza, Dr. Allbutt says:

"William Salicet fully recognized that surgery can not be learned from books alone. His surgery contains many case histories, for he rightly opined that good notes of cases are the soundest foundation of good practice; and in this opinion and method Lanfranc followed him. Salicet discovered that dropsy may be due to a 'durities renum'; he substituted the knife for the Arabist abuse of the cautery; he investigated the causes of the failure of healing by first intention; he described the danger of wounds of the neck; he sutured divided nerves; he forwarded the diagnosis of suppurative disease of the hip; and he referred chancre and phagedena to *coitus cum meretrice.*"

These are indeed some surprising anticipations of things often said to be quite typically modern. Usually the first hint of the connection between kidney disease and dropsy is thought to be less than a century old and as for union by first intention that is ordinarily considered a matter of scarcely more than the last quarter of a century. At least one of Salicet's pupils went

2. "The Historical Relations of Medicine and Surgery to the end of the Sixteenth Century," T. Clifford Allbutt, Regis Professor of Physic in the University of Cambridge. London and New York: Macmillan & Co. 1905.

even farther and added new ideas of the greatest significance to practical surgery in a book of which Allbutt says:

"Lanfranc's 'Chirurgia Magna' was a great work, written by a reverent but independent follower of Salicet. He distinguished between venous and arterial hemorrhage and used styptics (rabbit's fur, aloes, and white of egg, which was a popular styptic in elder surgery), digital compression for an hour, or in severe cases ligature. His chapter on injuries of the head is one of the classics of medieval surgery. Clerk as he was, Lanfranc, nevertheless, saw but the more clearly the danger of separating surgery from medicine."

It is one of the favorite ideas of Allbutt often emphasized and recently taken up and favorably commented by Osler, that medicine should not be separated from surgery and that the internist should take every opportunity that offered to see the condition of organs within the body during life as it can be obtained only during surgical operations. Such a view is quite different from the one obtained at autopsies and is likely to prove supremely helpful for diagnostic purposes. Most of these distinguished physicians of the middle ages emphasize just this necessity for the physician taking surgical opportunities to obtain surer and more definite knowledge.

The teaching of at least one other distinguished member of the medical profession in those early times deserves notice. Henry Mondeville, who taught at Paris, was a student of Lanfranc and introduced new methods of wound treatment. Briefly summarized, they were as follows: "Wash the wound scrupulously from all foreign matter, use no probes, no tents except under special circumstances, apply no oily or irritant materials; avoid the formation of pus, which is not a stage of healing, but of complication." "Wounds dry much better before suppuration," to use his exact words, "than after it." It seems unfortunate that such clear-headed results of investigation should have been lost to mankind for nearly seven centuries and the fact is a warning of the instability of even our modern scientific progress, unless care is exercised not to let theory replace observation in the domain of medicine.

THE CALIFORNIA CATACLYSM; AN APPEAL

Naturally, as time passes, the newspapers are devoting less and less space to the California cataclysm, and the emotional phase of the public mind is disappearing—the public is already forgetting. So also the excitement of those on the spot is supplanted by a grim realization of the terrible conditions that have resulted from the combination of earthquake and fire; to a realization of the hardships, the ordeals and the problems before them. While we who are away are forgetting, those who are there are realizing more and more the magnitude of the calamity. They are realizing, too, the deprivation of all of the luxuries and many of the things that had been heretofore considered necessaries of life. As Dr. Philip Mills Jones says, in a letter just received, "San Francisco seems more horrible to me every time I see it."

As more definite information reaches us it becomes more evident that the worst has not been told; that the actual needs of many physicians in San Francisco are such that they must have help to put them on their feet. This applies to many who were in good circumstances, who had well-furnished homes and offices and good practices. All are gone, even the practices that they had built up. But the sufferers are men who are not asking for aid, and will not ask; they are not of that kind. Yet others, who are there temporarily and who know the conditions, are asking in their behalf. An army surgeon, who prefers that his name be not mentioned, says: "Use your influence to get the doctors all over the country to aid the men here to get started; the condition of hundreds of physicians here is truly pitiful, but they don't complain." Dr. Kenneth A. J. Mackenzie, of Portland, Oregon, who has been in San Francisco since the earthquake, in a telegram, says: "Please appeal through THE JOURNAL columns to best traditions of our profession to aid brethren stripped of all property and means of revenue and support."

We again, therefore, appeal to our readers and to the profession of the country for contributions to the relief of our brethren in San Francisco and other California points. There is hardly a physician who can not contribute at least one dollar. The various churches, lodges, etc., are raising special funds for their own particular people: let us not allow our brethren to suffer more than is necessary. As is noted in another column, instruments, books, etc., are needed. Books especially will be welcome. The libraries of the San Francisco and the Sonoma County medical societies are destroyed. In the near future we must undertake to help them get another, but there is plenty of time for this. Meanwhile, we repeat that the Board of Trustees of the American Medical Association authorized THE JOURNAL to solicit subscriptions for this cause to accommodate those who might not know how to send their contributions. Some individuals and societies may find it more convenient or more satisfactory to send their contributions direct. All that is desired is that every physician who is able shall contribute something for the California profession in need.

SODIUM CITRATE AS AN ADDITION TO MILK MIXTURES FOR NURSING INFANTS.

It will not be denied that a great advance has been made in recent years in the successful hand-feeding of infants deprived, for one reason or another, of their natural nourishment, mother's milk. While the milk from some other animals approaches more nearly in composition that of nursing women, still, for practical purposes, cow's milk, variously modified, is the most serviceable substitute. By the method of percentage feeding

it has become possible to determine and to adjust the proportions of the constituents in milk mixtures for nursing infants in such a manner that the amounts of water, proteid, fat, sugar and mineral matter shall closely approximate the proportions of these in healthy mother's milk. Two facts, however, need to be borne in mind in this connection. The first is that there are differences in the quality as well as in the quantity of the ingredients of cow's and mother's milk, respectively, and, second, that the digestive power and capacity differ somewhat in different children, and that within certain limits the healthy child is capable of adapting itself to variations in the constitution of the milk supplied to it as food, whether from its mother or elsewhere.

As is well known, cow's milk as compared with mother's milk contains too much proteid and too little sugar, and in adding water for the purpose of diluting the former the fat strength also is reduced, so that cream is added to restore the proper proportion. Of the proteids of mother's milk, albumin and casein are present in approximately equal proportions, while in cow's milk the proportion is about one to six. Moreover, the casein of cow's milk forms a denser and larger curd, and is accordingly more difficult of digestion than the casein of human milk. Further, the latter has an acid reaction, while cow's milk has an alkaline reaction. Lime-water is commonly used for the double purpose of neutralizing the acidity of cow's milk and making a finer subdivision of the curd, but the best diluent is whey, which contains many desirable chemical constituents.

Within recent years the use of sodium citrate has been recommended for the purpose of lessening the size and the density of the curd yielded by the casein of cow's milk and thereby increasing its digestibility. A working formula consists in the addition of one grain of sodium citrate to each ounce of milk diluted with an equal amount of water. In a recent communication Dr. W. H. Wynn[1] reports highly satisfactory results in 69 cases from the mode of procedure described. Most of the infants suffered from milk-dyspepsia. In others the nutrition was impaired from the use of dilute milk mixtures. Four infants with scurvy were subjected to the treatment, and it was employed in nine cases in which it became necessary to wean healthy infants. It is suggested that the method may prove applicable also in the cases of adults requiring a milk diet from one cause or other. Results of a similarly favorable character were reported at the last meeting of the American Pediatric Society by Dr. Harry L. K. Shaw,[2] who employed sodium citrate as an addition to milk mixtures in 22 cases.

SURGERY FOR CRIMINALITY.

One or two stories have been recently circulated in the newspaper press of cases of marked moral reformation following operative procedures on the brain, and the usual tendency to generalization from such has been very much in evidence. Some of the newspaper writers see a prospect ahead, and not in the very distant future, when criminality will be considered a surgical disease and reform methods take this direction more or less exclusively. There is no doubt that if surgery was carried sufficiently far a good deal of crime could be prevented. Amputation of a pickpocket's fingers, for example, would check his operations at least for a while, and it is easy to imagine other reforms of the same character. It is safe to say, also, that any very extensive application of brain surgery on the criminal class would be likely to diminish their number, but the old-fashioned methods of reform by moral suasion and measures based on the theory of human responsibility will probably be the ones to be relied on in the future as in the past.

THE PROGNOSIS OF PULMONARY TUBERCULOSIS.

While both clinical and pathologic evidence are not wanting in support of the curability of tuberculosis of the lungs, it is difficult to foresee the outcome in any given case. It were even better, perhaps, to speak of recovery rather than cure under such circumstances. All that the physician can do—apart, of course, from removing sources of infection and preventing dissemination of infective material—is to provide conditions favorable to subsidence of the tuberculous process and involution of the tuberculous lesions. The result after all, will be determined by certain qualities inherent in the individual, and these are beyond the range of clinical estimation, but that such defensive mechanisms can be fortified there is no doubt. The main factors contributing to this end are comprised in an abundance of pure, fresh air and a generous supply of easily digestible, nutritious food, in conjunction with rest and exercise in proper apportionment. By the adoption of these means, the disease can often be arrested, in fact it not rarely undergoes spontaneous arrest, even in the absence of special attention to these matters, and with the observance of proper precautions the arrest can be made permanent. In a discussion of the prognosis of pulmonary tuberculosis, in the course of a paper read recently before the Bristol Medico-Chirurgical Society, Dr. J. J. S Lucas[1] wisely emphasizes the fact that a tuberculous patient should never consider himself sound, at least not for some years, even after the disappearance of all symptoms. The appearance of the patient, the shape of his chest and the family history are of the greatest importance in prognosis. Of early symptoms hemoptysis by itself is rather a good sign, while dyspepsia is a bad one. The presence of fever at a single examination does not, as a rule, have any bearing on the prognosis, but persistent elevation of evening temperature for some time is of unfavorable significance. A rapid pulse is one of the worst omens. Of laryngeal complications, ulceration of the vocal bands alone is of little significance; swelling in the larynx is of much more serious import. Under these conditions the physical signs referable to the lungs are often deceptive. The effect of treatment can be gauged only by the condition of the patient several months after he has been dismissed from the treatment and has taken up duties he intends to pursue for the remainder of his life.

Medical News

ALABAMA.

Commencement.—The Alabama Medical College held its forty-first annual commencement at the Mobile Theater, April 9, at which Dr. J. W. Abercrombie, president of the University of Alabama, conferred the degrees, and Dr. William H. Sanders, state health officer, delivered the charge to the graduating class. Dr. George A. Ketchum, the dean, made his annual report, and Dr. J. H. Penniman of Philadelphia, dean of the University of Pennsylvania, delivered the doctorate address.

ARIZONA.

Certificate Issued.—E. A. Hall, Prescott, whose certificate to practice was withheld by the Territorial Board of Medical Examiners last summer, and who began mandamus proceedings against the board to compel the issuance of the certificate, has been issued a certificate by the board, the cause for which it was withheld not having been confirmed.

Personal.—Dr. Claude Thompson has been elected chairman, and Dr. O. C. Ciass, secretary, of the Phoenix board of health. —— Dr. William H. Ward, superintendent of the Territorial Asylum for the Insane, Phoenix, has resigned, and Dr. Ray Ferguson, Nogales, has succeeded to the position.——Dr. Henry Dietrich and family, Morenci, have started for a prolonged European trip.

ARKANSAS.

License Revoked.—For violation of the anti-drumming ordinance Dr. R. O. Williams, Hot Springs, was fined $100 and his license to practice medicine in the state was revoked, March 31.

Wins Appeal.—Dr. T. B. Rider, Hot Springs, who was recently fined $100 and whose license was revoked on account of alleged violation of the city anti-drumming ordinance, and who appealed his case to the circuit court, won the appeal and will continue to practice.

Emergency Hospital.—It has been announced that on and after May 1 the Emergency Hospital of the Iron Mountain Railway for the Arkansas Central and Valley divisions, for the Little Rock and Argenta terminals, and for the Baring Cross shops, will be located at Little Rock and will be under the charge of Dr. S. S. Stewart.

Commencement.—The twenty-seventh annual commencement of the University of Arkansas, Medical Department, Little Rock, was held April 12. Degrees were conferred on a class of 26 by the governor of Arkansas, and the annual address was delivered by the Hon. J. N. Tillman, Fayetteville, president of the university. The doctorate address was delivered by Dr. John R. Dibrell.

CONNECTICUT.

Ely Will Found.—The will of the late Dr. John S. Ely, New Haven, has been found and offered for probate. Dr. Ely left an estate appraised at about $150,000.

March Deaths.—During March, 1,477 deaths were reported to the State Board of Health, 244 more than in February, 100 less than in March of last year, and 37 more than the average mortality for the month of the five preceding years. The death rate for the month was equivalent to an annual death rate of 18 per 1,000. Infectious diseases caused 258 deaths, or 17.4 per cent. of the total mortality. Nervous diseases caused 210 deaths; pneumonia, 207; heart diseases, 136; tuberculosis, 126; accidents and violence, 82; bronchitis, 61; influenza, 28; diphtheria, 27; measles, 22; whooping cough, 17, and cerebrospinal meningitis, 15.

DISTRICT OF COLUMBIA.

Hospital Opened.—The Potomac Hospital and Training School was opened with proper exercises April 23. Dr. John P. Green delivered the principal address. Dr. Albert R. Collins is vice-president of the institution, and Dr. Harry J. Williams, secretary and medical director.

Wants Prescriptions in English.—A bill has been introduced into the House of Representatives by Representative Brownlow of Tennessee to require physicians in the District of Columbia and the territories to write prescriptions in English as well as in Latin, in order to avoid the mistakes said to be made by druggists.

Disease Prevention. The commissioners of the district have forwarded to Congress, with a favorable recommendation, a bill for the prevention of scarlet fever, diphtheria, measles, whooping cough, chickenpox, cerebrospinal meningitis and typhoid fever. This bill calls for the compulsory report of all cases of the diseases mentioned and provides a severe penalty for violation.

Medical Association Officers.—At the annual meeting of the Medical Association of the District of Columbia, April 3, the following officers were elected: President, Dr. D. Olin Leech; vice-presidents, Drs. A. Barnes Hooe and Presley C. Hunt; secretary, Dr. Daniel W. Prentiss; treasurer, Dr. Frank Leach; censors, Drs. Louis Mackall, Sothoron Key and James A. Watson; delegate to the American Medical Association, Dr. George N. Acker, and alternate, Dr. George M. Kober.

GEORGIA.

Alumni Reorganized.—The alumni of the Medical Department of the University of Georgia, Augusta, reorganized April 19 with the following officers: President, Dr. J. Lawton Hiers, Savannah; vice-presidents, Drs. Sterling R. Gibson, Thomson, and W. W. Pilcher, Warrenton, and secretary and treasurer, Dr. Charles W. Crane, Augusta.

Personal.—Dr. J. T. Plunket has been elected a member of the board of trustees of the Medical College of Georgia, Augusta, vice Dr. De Saussure Ford, deceased.——Dr. Levi P. Hammond, Rome, has been elected physician of Floyd County, vice Dr. William A. Johnson, resigned.——Dr. J. Scott Todd, Atlanta, sustained a fracture of the collar bone by being thrown from his horse, April 12.

Wanted for Contempt of Court.—Dr. Millard B. MacAfee, Atlanta, who was arrested March 20 on a charge of violating the city ordinance by selling cocain, and who failed to appear for trial March 24, as ordered, was declared in contempt of court and a warrant was issued for his arrest. He was charged with selling cocain without a prescription, and also with prescribing cocain for certain of his customers and then filling the prescriptions himself.

College Commencements.—The annual commencement exercises of the Medical College of Georgia were held April 2, when a class of 31 was graduated. The addresses of the evening were given by Prof. David C. Barrow, acting chancellor of the university; the Right-Rev. Charles K. Nelson, bishop of Georgia, and Dr. T. D. Gunter.——The Atlanta School of Medicine on April 2 graduated a class of 21. Hon. Hooper Alexander was orator of the occasion, and diplomas were conferred by ex-Governor Norton.——The Atlanta College of Physicians and Surgeons held its fifty-second annual commencement, April 2, when a class of 52 was graduated. In the annual report made by Dr. William S. Elkin, dean of the faculty, it was announced that Andrew Carnegie had given $10,000 toward the erection of the new building, the cornerstone of which was laid April 6 and which is to cost $100,000.

ILLINOIS.

Fined for Misusing Mails.—Dr. Charles A. Nichols, Urbana, was convicted by a jury of using the mails for a scheme to defraud, and on April 27 was sentenced by United States District Judge Humphrey to pay a fine of $250 and costs, bringing the total up to $700, with imprisonment in jail until paid.

Coroner's Work for April.—During April the coroner of Cook County investigated 315 deaths, 137 of which were found to be from natural causes, 33 from railway accidents, 26 from suicide, 22 from falls, 18 from asphyxiation, 12 from drowning and 10 from burns and scalds. Nine homicides were reported during the month.

Special Train for State Society Meeting.—A special train for Springfield will leave Chicago via the Illinois Central Railroad Monday evening, May 14. A rate of one fare for the round trip will be made provided 150 can be secured. The names of those who intend to go should be sent to Dr. James H. Stowell, 103 State Street, at as early a date as possible that arrangements may be perfected.

Society Meetings.—Knox County Medical Society held its annual meeting in Galesburg, April 26, at which the following officers were elected: President, Dr. J. H. Brown, Rio; vice-president, Dr. George S. Chalmers, Galesburg; secretary and treasurer, Dr. George S. Bower, Galesburg; censor, Dr. William O'R. Bradley, Galesburg, and delegate to the State Medical Society, Dr. William H. Maley, Galesburg. The presidential address by Dr. Lawrence R. Ryan, Galesburg, was on the "Field of the Specialist," and Dr. J. F. Percy presented a paper on the "Borderland of Insanity." The meeting came to a fitting close with a banquet attended by both the medical and legal professions.——At the annual meeting of the Central Illinois Medical Society in Pana, April 24, the following officers

were elected: Dr. Frederick J. Eberspacher, Pana, president; Drs. Frank P. Auld, Shelbyville, and Wilbur C. Wood, Decatur, vice-presidents; Dr. Roscoe C. Danford, Pana, secretary, and Dr. John N. Nelms, Taylorville, treasurer.

Civil-Service Examinations.—Examinations for the medical staff of the Illinois Charitable Eye and Ear Infirmary, 227 West Adams Street, Chicago, will be held the latter part of this month by the Illinois Civil-Service Commission. There are now the following vacancies: One assistant ear surgeon, one assistant eye surgeon, one assistant pathologist, three internes.——Examinations for attendants in the hospitals for the insane will be held by the Illinois Civil-Service Commission the latter part of this month in various parts of the state. Male applicants must be between the ages of 21 and 45 years and must weigh not less than 155 pounds. Women should be between the ages of 18 and 45 years and weigh not less than 125 pounds. Men start at $25 per month, with board, lodging and laundry, and women at $18 per month. The communities producing the largest number of applicants will get the examinations. All applications should be addressed to Joseph C. Mason, chief examiner, Springfield, Ill.

Chicago.

Sentenced to Imprisonment.—Dr. A. Judson Booth, charged with mistreating young girls, was found guilty May 2 and sentenced to imprisonment for 18 years in the penitentiary.

Hospital License Revoked.—The governor, acting on the recommendation of the state home visitor for children, has revoked the license of Dr. George H. How, in charge of the Irene How Sanitarium.

Personal.—Prof. Dr. Trendelenburg, Leipzig, visited Chicago, May 11.——Dr. John T. Binkley has sailed for Italy.——Dr. J. A. Jerger, formerly interne in the Alexian Brothers' Hospital, has located in Waterloo, Iowa.

Cheaper Antitoxin.—The Memorial Institute for Infectious Diseases is said to be supplying the city with antitoxin at $1.50 per 3,000 units as against $5.25 for 3,000 units, the sum charged by the alleged antitoxin trust.

April Mortality.—The mortality for April was 2,770, equivalent to an annual death rate of 16.44 per 1,000. Pneumonia caused 548 deaths; consumption, 336; heart diseases, 211; Bright's disease, 194, and violence, including suicide, 170.

Farewell Dinner to Findley.—A faculty farewell dinner was given to Dr. Palmer Findley, assistant professor of gynecology and obstetrics, Rush Medical College, on April 26, at the Auditorium Annex, on the occasion of his departure from Chicago to take the chair of gynecology in the Medical Department of the University of Nebraska, Omaha.

Site for Hospital Secured.—Arrangements have been completed for the purchase of ground on Michigan Avenue, immediately north of the present site of St. Luke's Hospital, for the erection of the new building which is to cost $500,000. The site was secured for $145,000. The new building is to be six stories high and of fireproof brick construction throughout.

Communicable Diseases.—During April, 1,082 cases of communicable diseases were reported, as against 480 in April, 1905. The chief increases were in diphtheria, 273, or 80 more than the previous year; scarlet fever, 527, or 442 more than 1905, and measles, 196, an increase of 92. Two cases of imported smallpox were removed to the isolation Hospital during last week.

Deaths of the Week.—The total deaths from all causes for the week ended May 5, were 593, or 28 less than the preceding week. The mortality is equal to an annual death rate of 15.09 per 1,000. Pneumonia still leads the death causes with 115 deaths, and is followed by consumption, with 75; Bright's disease, with 42; violence, including suicide, with 34; acute intestinal diseases, with 30; cancer, with 27; nervous diseases, with 21; bronchitis, with 20, and scarlet fever, with 17.

The First Four Months of the Year.—During the first four months of 1906 there were 229 more deaths reported than during the corresponding period of 1905, although the death rate is almost the same. Pneumonia caused during this period in 1905, 1,857 deaths, and in the corresponding period of 1906 only one less. Tuberculosis was responsible for 466 fewer deaths in 1906 than in 1905. There were also 11 fewer deaths from apoplexy; 143 from bronchitis; 41 from convulsions; 57 from influenza; 38 from smallpox; 29 from measles, and 131 from whooping cough less than in the corresponding period of 1905. There were, on the other hand, increases in death as follows: Nephritis, 37; cancer, 60; heart diseases, 60; nervous diseases, 54; diphtheria, 27; acute intestinal diseases, 71; scarlet fever, 134; typhoid fever, 21; violence other than suicide, 79, as compared with 1905.

Home for Destitute Crippled Children.—The Home for Destitute Crippled Children, of which Dr. John Ridlon is surgeon-in-charge, has outgrown its original quarters and has completed a new building, the total cost of which was about $40,000. Of this amount $25,000 was donated by Mrs. R. H. McElwee for the erection of the outpatient department, which is to be a memorial to her daughter. At a recent meeting of the board of trustees Dr. Frederick W. Belknap was appointed consulting pediatrician; Dr. Gilbert Bailey, assistant orthopedic surgeon, and Dr. Coleman G. Buford, attending surgeon. A resolution was adopted to the effect that ruptured children are to be considered crippled children, and that as soon as proper facilities have been added to the home for handling such cases, those needing operation will be admitted as house patients. An out-patient department for ruptured children was opened May 1 under the direction of Dr. Buford. A dispensary for orthopedic patients is open on Monday, Wednesday and Friday from 1 to 4 p. m., and for hernia cases on Tuesday and Friday from 9 to 10 a. m. The object of the latter department is to supply trusses to destitute ruptured children, and to educate parents in the proper application and maintenance of the trusses. It is estimated that under proper management about 75 per cent. of the patients under 4 years of age will recover from rupture without operation.

INDIANA.

Election of Officers.—The Ninth Councilor District Medical Society met at Frankfort May 1 and elected Dr. Charles Chittick, Frankfort, President; Dr. George F. Keiper, Lafayette, secretary, and Dr. Edgar Cox, Kokomo, treasurer.

Personal.—Dr. Arthur E. Vinton, Muncie, has started East and will spend the summer in Germany.——Dr. Charles P. Davis, Galena, who was operated on recently in Louisville, has resumed practice.——Dr. John T. Anderson, Swayzee, was seriously injured in a runaway accident, May 2, near his home. He was thrown out of his buggy and fractured several ribs.

Asks Postponement of Trial.—Dr. Charles L. Landfair, formerly a practitioner of Bluffton, who is serving a term in the state penitentiary in Michigan City on account of illegal medical practice, has written to the State Board of Medical Examination and Registration, asking that his trial by that body be postponed until after the expiration of his term of imprisonment.

District Society Meeting.—At the annual meeting of the Second District Medical Society, held in Vincennes, April 24, Dr. George Knapp of that city was elected president, and Dr. A. B. Knapp, secretary. Dr. H. M. Smith gave a historical talk on the Medical Association of Knox County, showing that more than 90 years ago there was a medical society in the county. The next meeting of the society will be held in Washington.

New College Incorporated.—The articles of incorporation for the State College of Physicians and Surgeons, a new school to be established in connection with the Indiana University, Bloomington, were filed with the secretary of the state, May 2. The trustees named in the incorporation papers are Judge Vinson Carter, Dr. Allison Maxwell, Dr. John F. Barnhill and W. C. Bobbs, Indianapolis; Dr. M. V. B. Newcomer, Tipton; Dr. Charles Stoltz, South Bend; Dr. Charles F. C. Hancock, Jeffersonville; Dr. John C. Sexton, Rushville, and Messrs. James D. Showers, Fred Matthews and Henry B. Gentry, Bloomington.

Approves of Medical College.—At a meeting of the Third Councilor District Society at West Baden, April 21, the following resolutions, introduced by Dr. David C. Peyton, Jeffersonville, relative to the recent merger of Indiana medical schools into the medical department of Purdue University, were adopted:

Resolved, That the Third District Medical Society cordially approves the union of these schools and hereby expresses its desire that the legislature shall ratify the same and thereby secure a permanent school of medicine under the control of Purdue and located at Indianapolis, where ample clinical and other facilities can be obtained; also

Resolved, That we approve the wisdom and self-sacrifice of the faculties of these three schools in uniting in donating to the state their combined efforts and their valuable property, which consists of a magnificent college building, thoroughly equipped and out of debt, and has an excellently organized, experienced and capable faculty.

March Diseases and Deaths.—During March tonsillitis was the most prevalent disease reported. Pneumonia was less prevalent than in the preceding month, and bronchitis stood third, followed by influenza, rheumatism, pleurisy, whooping cough, scarlet fever, typhoid fever, intermittent and remittent

fever, diarrhea, erysipelas, measles, diphtheria, smallpox, puerperal fever, peritonitis, typho-malarial fever, cerebrospinal meningitis, dysentery, cholera morbus and cholera infantum. Smallpox was reported epidemic in Allen County, where 38 cases occurred. In all 124 cases of smallpox were reported from 16 counties, with no deaths. Typhoid fever was reported present in 46 counties, 258 cases and 37 deaths. Pneumonia caused 469 deaths or 115 less than occurred in the corresponding month of 1905. Deaths by violence numbered 112, of which 7 were homicides and 20 suicides. The mortality for the month was at the annual rate of 17.3 per 1,000.

IOWA.

Chiropractic Pays Fine.—D. D. Palmer, Davenport, who was sentenced to pay a fine of $350 for practicing medicine without a certificate, after 24 days in the county jail, was released April 21 on payment of the fine.

Case Against Physician Dismissed.—In the case of the State of Iowa vs. "Dr." J. G. Shipley, Madrid, charged with practicing medicine without a license, as no witnesses against the physician appeared, the case was dismissed and the defendant discharged.

KENTUCKY.

Personal.—Dr. Sylvester J. Wedding, Hartford, is seriously ill with heart disease at his home.——Dr. W. Albert Berry, Ashland, who was operated on for appendicitis at the Charles S. Gray Deaconess Hospital, Ironton, Ohio, four weeks ago, has recovered sufficiently to return home.

Damage Suit Dismissed.—On April 14 Judge Field, Louisville, dismissed on demurrer the $25,000 damage suit of Dr. Jesse L. Melton against the Kentucky State Board of Health, which was brought to hold the members of that body individually liable because of the refusal of the board to approve the application of the plaintiff for license to practice medicine in the state.

MARYLAND.

Cecil County Society Officers.—Dr. S. Groome Fisher, Port Deposit, has been elected president, and Dr. Howard Bratton, Elkton, secretary and treasurer, of the Cecil County Medical Society.

Personal.—Dr. Joseph R. Owens has been nominated for mayor of Hyattsville.——The President has renominated Dr. Robert A. Ravenscroft of Garret County as surveyor of customs of Baltimore.

Smallpox.—An outbreak of smallpox among the colored people in Crisfield, an oyster town in the southern part of the eastern shore, is reported. Fifteen cases were discovered there by Dr. Marshall L. Price, Baltimore, of the State Board of Health.

Cocain Seller Convicted.—A young negro was convicted of selling cocain among the negroes at Hagerstown, April 18, and was sentenced to one year in jail and a fine of $500 and costs. This evil has grown to alarming proportions there and a crusade has been inaugurated by the police against it. The maximum penalty was inflicted in this case.

Annual Meeting of Society.—The annual meeting of the Montgomery County Medical Society was held at Rockville, April 17. Dr Edward Anderson, Rockville, was elected president; Dr. James E. Deets, Clarksburg, vice-president, and Dr. John L. Lewis, Bethesda, secretary-treasurer. Dr. Roger Brooke, Sandy Spring, was chosen as delegate to the state society, with Dr. James E. Deets, Clarksburg, alternate. Drs. W. French Greene, Brookeville, and Otis M. Linthicum, Rockville, were chosen censors. It was decided to hold the fall meeting at Germantown.

Baltimore.

Personal.—Dr. A. R. L. Dohme sailed for Europe, May 5.——Drs. Henry Lee Smith, Wirt A. Duvall, Andrew H. Whitridge and Jacob D. Norris have been reappointed police surgeons.

Bequest.—Mrs. Margaret A. Snyder died April 16, leaving by her will $2,000 to the Union Protestant Infirmary, the income of which is to be used for the support of free beds for the sick poor.

Will Study Mosquitoes.—Dr. George H. Dieffenbacher arrived in Baltimore May 4 from Bremen. He has been delegated by the grand duke of Baden to study malarial germs and mosquitoes in North and Central America.

College News.—Maryland Medical College graduated a class of 29 at its eighth annual commencement, May 3.——The Baltimore University School of Medicine intends to build a hospital on the site recently purchased in the northern section of the city.

Portrait Presented.—A handsome oil portrait of the late Dr. Richard McSherry, professor of principles and practice of medicine for many years in the University of Maryland, has been presented to the Medical and Chirurgical Faculty of Maryland by his sons.

Church Home Report.—The Church Home and Infirmary reports for the year an income of $67,236 and expenses of $55,556. Bequests, etc., received amounted to $12,259. During the year 353 operations were performed, with 8 deaths. An annex has been built at an expense of $50,000, which provides a home for nurses and rooms for special diseases.

Additional Smallpox Appropriation.—The board of estimates has voted an additional $1,000 to the health department to be used in the fight against smallpox. Since the original appropriation of $5,000 was made there have been 83 cases of smallpox, each of which has cost the city $62.55. There were 9 cases of smallpox reported during April.

MICHIGAN.

Found Guilty.—Dr. William C. Kitchen, Detroit, convicted of an attempt to perform a criminal operation, was sentenced on April 17 to pay a fine of $250 or to be imprisoned for six months in the house of correction.

Secures Tuberculosis Sanitarium.—The board of trustees of the Michigan State Sanitarium for the Treatment of Incipient Tuberculosis has selected a site for the institution at Howell, containing about 190 acres at an altitude of 1,100 feet above sea level.

Hospital for Ann Arbor.—The announcement is made that a large Roman Catholic Hospital will be built on a site purchased on the brow of a hill overlooking the Huron River. It is to be known as St. Thomas Sanitarium and is expected to cost about $100,000.

Graduating Exercises.—A class of 12 was graduated from the Grand Rapids Medical College, May 3. Dr. William Fuller delivered the president's address. Dr. Francis J. Lee presented the diplomas and Martin H. Carmody delivered the address of the evening.

German Clinic Opened.—A new free clinic, to be known as the German Polyclinic, was opened at Grace Hospital, Detroit, April 2. The staff of the polyclinic is composed exclusively of German physicians. Dr. Hermann Kiefer is president, and Dr. Ernest W. Haas, secretary, of the staff.

Personal.—Dr. Joseph Foster, in attempting to alight from a buggy in front of his office in Lansing, fell and sustained a fracture of the right humerus.——Dr. A. Douglass Lake, Kalamazoo, who has been under hospital treatment for several months, has recovered, and will soon resume practice.

Crusade Against Itinerants.—Physicians of Marshall and surrounding cities assembled in the office of Dr. G. B. Gesner, Marshall, April 20, and by resolution decided to continue the crusade inaugurated some time ago against itinerant and other physicians practicing medicine in Calhoun County without having been properly registered as required by law.

March Mortality.—During March 3,236 deaths were reported, corresponding to an annual rate of 14.8 per 1,000, which compares favorably with the rate of 15.5 per 1,000 for March, 1905. Pneumonia caused 368 deaths; tuberculosis, 233; accident and violence, 140; cancer, 138; whooping cough and influenza, each 60; diarrheal diseases of infants, 47; meningitis, 44; diphtheria, 38; measles, 28; scarlet fever, 27, and typhoid fever, 26.

MISSOURI.

Southwestern Physicians Meet.—The Southwestern Missouri Medical Association met at Springfield, April 19 and 20. The following officers were elected: Dr. Thomas R. Loer, Billings, president; Drs. Finis L. Anderson, Joplin, and O. N. Carter, Brookline, vice-presidents; Dr. Herbert S. Hill, Springfield, secretary, and Dr. William B. Patterson, Springfield, treasurer.

Snodgrass Memorial.—Memorial resolutions on the death of Dr. Charles A. Snodgrass were adopted by the St. Louis board of health, April 19, which extended sympathy to his family and authorized that a memorial stone in his honor be placed on the wall of the new pathologic building at the State Hospital. The resolution also names the building the Snodgrass Laboratory of Pathology and Bacteriology.

NEW JERSEY.

Personal.—Dr. E. L. B. Godfrey, Camden, was given a complimentary dinner by physicians of Camden and Philadelphia at Washington Park, May 3.

Mosquito Bill Signed.—The mosquito bill of Prof. John B.

Smith, state entomologist, was signed by Governor Stokes, April 22. The bill provides for an appropriation of $350,000 for the drainage of mosquito marshes throughout the state, and for the removal of other breeding places of the mosquito. The work is expected to take a period of five years, and the legislature has decided that no more than $70,000 shall be expended in any one year. Municipalities are expected to contribute a share of the expense, and state money is to be allowed in proportion to the amount of local assistance given.

Medical Society Meets.—At the regular meeting of the Camden County District Medical Society, April 25, a resolution was adopted urging the United States senators and representatives from New Jersey to bring about the passage, without amendment, of the Pure Food and Drug bill as passed in the senate. They also endorsed the action of the Medical Council to secure passage of a bill providing for a department of public health with representation in the cabinet. The following officers were elected: President, Joel W. Fithian; vice-president, Dr. Sylvan G. Bushey; secretary, Dr. Paul M. Mecray; treasurer, Dr. A. Haines Lippincott; historian, Alfred Cramer; committee of arrangements, Drs. Daniel Strock, H. F. Palm and Edward A. Y. Schellenger, and delegates to the Medical Society of New Jersey, Drs. Paul M. Mecray, Dowling Benjamin, all of Camden, and William A. Westcott, Berlin.

NEW YORK.

Personal.—Dr. Charles W. Pilgrim, superintendent of the Hudson River State Hospital, Poughkeepsie, has been appointed president of the state commission on lunacy, to succeed Dr. William Mason, resigned.

From Buffalo to Europe.—Dr. A. W. Hurd, superintendent of the Buffalo State Hospital, sails for Europe.——Dr. Leonard Wacker will sail for Europe.——Dr. E. Rampacher sails for Europe.——Dr. F. Park Lewis sails for Europe.

Bills Passed.—The Wedemyer bill, which was designed to prevent New York City from building a consumptive hospital in Staten Island, passed the assembly but got no further.—— The Tully bill, prohibiting a druggist from selling narcotic or patent drugs except on prescription of a physician, passed the senate.

Commencement.—The seventy-fifth annual commencement exercises of Albany Medical College were held May 1, when degrees were conferred on a class of 32 by Rev. Andrew Van Vranken Raymond, D.D., chancellor of the university. The address to the graduating class was delivered by the Hon. Andrew S. Draper, and Dr. Lemon D. Washburn delivered the valedictory address.

Alumni Meeting.—The annual meeting of the Alumni Association of Albany Medical College was held May 1, at which the following officers were elected: President, Dr. Thomas Wilson, Hudson; vice-presidents, Drs. Frederick L. Classen, Albany; James A. Clyne, Joliet, Ill.; Charles P. McCabe, Greenville, N. Y.; Robert W. Andrews, Poughkeepsie, N. Y., and James W. King, Stottville, N. Y.; recording secretary, Dr. J. Montgomery Mosher, Albany, (re-elected); corresponding secretary, Dr. Andrew McFarlane, Albany; treasurer, Dr. Robert Babcock, Albany, and historian, Eugene E. Hinman, Albany (re-elected).

Physicians for Board of Regents.—The following appointments have been made to the State Board of Medical Examiners: Dr. William Warren Potter, Buffalo; Dr. William S. Ely, Rochester, and Dr. Maurice J. Lewi, New York City, have been reappointed, and Dr. Arthur W. Booth, Elmira, has been appointed to fill the unexpired term of the late Dr. George Ryerson Fowler, Brooklyn.——From the Homeopathic Medical Society, Drs. John M. Lee, Rochester; J. Willis Candee, Syracuse, and George E. Gorham, Albany, were reappointed, and from the State Eclectic Society, Drs. H. L. Smith, Buffalo; Orlando W. Sutton, Bath, and M. H. Nichols, Worcester.

Defeat of Stevens-Wainwright Bill.—The defeat of the Stevens-Wainwright "patent-medicine" bill in the assembly, May 3, was accomplished by the adoption of four amendments offered by four members, none of whom was opposed to legislation curbing the "patent-medicine" trust and each of whom believed that in some respects the measure was too radical. The New York *Times* says:

> Tompkins of New York stated that he favored such legislation and contemplated introducing similar legislation. He then asked that three certain poisons be exempted from the provisions of the measure, on the ground that they were not "habit forming." The amendment was adopted by an overwhelming rising vote. Three other amendments were adopted in rapid succession, and the fate of the measure was sealed then and there.
>
> Hooker of Genesee spoke of certain "patent medicines" that contained "one good drunk." He doubted if it would be advisable to compel the printing of the formula on "patent medicine" packages, as in many instances it would certainly instruct people how an intoxicant could be obtained in a genteel way.
>
> Some members held that "patent medicine" business was largely fraudulent, but their convictions did not cause them to vote against the amendments. The retail drug merchants had been deluging the members with protests against the bill. These protests had much weight. Another factor against the measure was the influence of the country newspapers, which derive considerable revenue from "patent medicine" advertisements.

New York City.

Bequest.—According to the will of Edgar V. Lawrence, the Brooklyn Home for Consumptives is to receive $1,000, and the Home for Crippled Children in Manhattan, $1,000.

Quarantine Season Begins.—The quarantine season for vessels arriving from coastwise ports has begun and will continue until November 1. All vessels from ports south of Cape Henlopen will be inspected at quarantine.

More Impure Milk Sold.—Six dealers were arraigned before the Westchester police court for selling impure milk. Five were held in $100 bail each for trial at special sessions. In the Court of Special Sessions six dealers were fined, the fines ranging from $50 to $15.

Rockefeller Institute for Medical Research.—This institution, which has been occupying temporary quarters during the past two years, has moved into its new laboratories at Avenue A and Sixty-sixth Street. It is announced that the formal opening, which has been delayed for several months, will take place on May 11.

Cerebrospinal Meningitis at Quarantine.—The Italian liner *Il Pcimonte* has been released after being held up for two days on account of the illness of five passengers. The ship's surgeon reported five deaths at sea. The sick passengers showed symptoms of cerebrospinal meningitis and the autopsy on one woman who died at quarantine confirmed this diagnosis.

Low Mortality.—The number of deaths in Greater New York for the week ended April 28 was 1,523, as compared with 1,636 for the corresponding week of last year. The mortality from measles and bronchopneumonia has been three times as great as last year. There has been a decrease in the number of deaths from tuberculosis, heart disease and cerebrospinal meningitis.

Monument to Dr. Skene.—This monument was unveiled on Saturday, May 5, by Mr. Hirsch in behalf of the Skene Monument Association and presented to the city. Dr. Abraham Jacobi delivered the address. It was erected by private subscription and was the work of J. Massey Rhind. It occupies one of the mounds near the plaza at the main entrance to Prospect park, Brooklyn.

Experimentation with Embalming Fluids.—Coroner's Physician Dr. Edward T. Weston is being examined before District Attorney Jerome on the charge of having experimented without any authority on the corpses in his charge with embalming fluids, and that this was done before the cause of death had been ascertained. In these experiments, which were made at the morgue, 20 bodies were used, and Dr. Weston claimed that the cases had all been reported to the coroner's office.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended April 28, 1,454 cases of measles, with 39 deaths; 475 cases of tuberculosis, with 175 deaths; 475 cases of cerebrospinal meningitis, with 175 deaths; 337 cases of diphtheria, with 40 deaths; 237 cases of scarlet fever, with 13 deaths; 26 cases of whooping cough, with 5 deaths; 22 cases of typhoid fever, with 8 deaths; 2 cases of smallpox, with 1 death, and 97 cases of varicella, a totality of 3,125 cases, with 456 deaths.

PENNSYLVANIA.

Philadelphia.

Entertainments.—Dr. Emery Marvel of Atlantic City, N. J., entertained the members of the executive committee of the Philadelphia Medical Club at dinner May 5, at the Hotel Chelsea, in Atlantic City.

Hospital Opened.—The new addition to the Samaritan Hospital was dedicated with appropriate ceremonies, April 30. The building was thrown open for inspection from 3 to 10 p. m., and supper was served by the Woman's Samaritan Club from 6 to 8.

Hospital Examination.—The examination of applicants for resident interneships in the Philadelphia General Hospital will be held by the civil-service commission in City Hall, May 12. There are 24 vacancies, but Dr. Coplin, director of the department of public health and charities, it is said, will increase the number to 32.

Trendelenburg Here.—Dr. Trendelenburg, the eminent surgeon of Leipzig, who comes to America to be the guest of the American Medical Association at Boston, arrived in Philadelphia, May 4, and was entertained by Dr. William W. Keen. He visited Jefferson Medical College and its hospital, and the University of Pennsylvania, May 5. He went from Philadelphia to Chicago and Baltimore, and will attend the meeting of the American Surgical Association at Washington, and will go to Cleveland, May 30.

Hospital Reports.—The report of the Presbyterian Hospital for the month of April shows that 233 patients were admitted to the wards and that 1,724 were treated in the different dispensaries. The ambulance made 170 calls.——The report of the Charity Hospital for the month of April shows that 313 medical, 239 surgical, 20 ophthalmologic, 23 otologic and 105 laryngologic patients were treated in the clinics.——The report of the Polyclinic Hospital shows that 7,915 patients visited the different dispensaries, 608 patients were treated in the accident wards, and 116 were admitted to the main building.

Street Cars Reported Clean.—Inspectors attached to the bureau of health continued their examinations of street cars, and reported May 2 that the inspection of 249 cars revealed that only four were unclean. These four exceptions showed evidences of expectoration only. Complaints have been received by Dr. Abbott of the health bureau, by the public of the odor arising from the disinfection of cars with carbolic acid. It is possible, therefore, that disinfection may be abandoned and that the official director will endeavor to secure sanitary cars by keeping the cars scrupulously clean of dirt and dust.

Bequests.—By the will of the late Rebecca White the Women's Medical College of Philadelphia receives $5,000, the income of which is to be applied to a beneficiary fund for the gratuitous education and training of worthy, well selected students who are in need; especially for those who feel called for the Christian missionary service; to the West Philadelphia Hospital for Women, $1,000; to the Women's Hospital of Philadelphia, a valuable property in trust, the income of which is to be used for furnishing and supplying its diet kitchen, and to the Women's Hospital of Philadelphia, $5,000 in cash.——By the will of the late Caroline Steppacher a bequest of $100 is made to the Jewish Hospital.——By the will of the late Leonard Zeller the German Lutheran Home receives $500.

Health Report.—The total number of deaths reported from all causes during the week reached 502. This is a decrease of 85 over the number reported last week and an increase of 21 over the number reported in the corresponding week of last year. The principal causes of death were: Typhoid fever, 14; measles, 6; pertussis, 7; consumption, 70; cancer, 22; apoplexy, 18; heart disease, 45; acute respiratory disease, 82; enteritis, 17; hepatic cirrhosis, 6; appendicitis, 6; Bright's disease, 37; suicide, 7, and accidents, 28. There were 264 cases of contagious disease reported, with 26 deaths, as compared with 332 cases and 48 deaths reported in the preceding week. Typhoid fever is present throughout the city, only three wards being exempt from the disease. Statistics show an increase of 37 over the number reported last week. Measles is on the decrease, the cases reported numbering 390, as compared with 411 reported in the preceding seven days. One case of smallpox was reported.

CANADA.

French Medical Society in Manitoba.—A medical association has been organized in Manitoba with a charter membership of 15, to be known as L'Association Médicale Française du Manitoba. The president is Dr. J. U. O. Lambert of St. Boniface.

Personal.—Dr. Charles O'Reilly, for nearly thirty years superintendent of the Toronto General Hospital, has returned to Toronto from a year's sojourn abroad, and has commenced practice there, confining himself to consultation work. His son, Dr. Brefmey O'Reilly, who has been in Japan, will join him in the autumn.——Dr. Walter B. Geikie, one of the prominent medical educationalists of Ontario for the past forty years and for many years dean of Trinity Medical College, was presented with a gold-headed ebony cane by the class of '06, which was the last to register with old Trinity before its amalgamation with Toronto University.——Dr. Charles A. Peters has been appointed attending physician to the Montreal Contagious Diseases Hospital; Dr. John McCrae, attending physician in diphtheria, and Dr. A. H. Gordon for scarlet fever.——Dr. Colin A. Campbell, late senior house surgeon at Moorfields, where he had been for three years, has commenced practice in Toronto. Dr. Campbell is one of five Canadian physicians who held this position.

THE CALIFORNIA SITUATION.

List of Physicians and Addresses—Medical Aspects of the San Francisco Calamity.

Dr. George Blumer, under date of May 2, writes:

"Probably no one, unless he has been on the spot under similar circumstances, can appreciate the magnitude and the effects of a disaster like that which befell San Francisco on April 18. The earthquake, in itself sufficient to cause an immense amount of damage and loss of life and property, was followed in a few hours by the fire which, on account of the lack of water, could only be imperfectly combated. The earthquake came, as a matter of fact, at an unusually favorable time of day, for, though it was already light, the number of people on the streets was very small, and many doubtless owe their lives to this fact. The loss of life from the fire also was very slight, considering its magnitude, for those in the residence portions of the city had, as a rule, plenty of warning.

"On the day of the disaster the efforts of the medical men were confined mainly to attending to those hurt by falling buildings or burned. The great majority of the injured were suffering from contusions, abrasions, or fractures of the skull or limbs. The regular emergency hospitals at the City Hall and at the Golden Gate Park were so severely damaged that they were useless, but the Harbor Emergency Hospital on the water front was practically unharmed. The Mechanics' Pavilion, a large wooden structure, was converted into a temporary emergency hospital, and here the regular emergency surgeons, aided by numerous volunteers, had under treatment some 250 patients, who were placed on mattresses on the floor of the main pavilion. Unfortunately, this building had to be abandoned on account of fire early in the afternoon of the 18th, but the patients were rapidly removed without a single mishap, and were transferred to the Army General Hospital at the Presidio, the German Hospital and the California Women's Hospital. At the same time the uninjured Harbor Emergency had been doing good work, and was transferring serious cases to the Naval Hospital on Goat Island.

"As a result of the fire thousands of people were rendered homeless, and these were compelled to escape across the bay on ferries, or to camp out in the various parks and open squares of the city. The main medical problem then resolved itself into one of sanitation. The sick and injured being cared for in those hospitals which escaped the flames, it became necessary to protect the well from the dangers of their own excreta, and from the ravages of epidemic diseases. This work has been, even now, so well organized that all danger from these sources is practically nil. In each public square there is organized a sanitary committee, partly laymen and partly physicians; under the committee are relief men who keep the squares clean, inspect the latrines, and keep the inhabitants informed as to the sanitary regulations. The scarcity of water is now being remedied, food is abundant and wholesome, blankets and mattresses have been forthcoming, and the prospects from a medical standpoint are encouraging.

"It seems certain that for some time the conditions will remain the same as those described so far as living conditions are concerned. In an eastern climate the campers might suffer much from exposure; here, with the rains practically over till next October, this is not to be anticipated. It is safe to say that many of the poorer class will be in better physical condition than they have been for years. The plain food, the outdoor living, and the withdrawal of alcoholic stimulants will all aid in producing physical betterment. From a medical standpoint San Francisco is now in excellent condition, and likely to stay so. The profession in this, as in previous catastrophes, has shouldered its share of the burden without shirking and without grumbling."

From the President of the County Society.

Dr. Wallace I. Terry, president of the San Francisco County Medical Society, writes:

"I hasten to express sincere thanks for your kindness in our misfortune, which I am sure will be voiced by every member of the medical profession in the city. . . . I have announced that I should call a meeting of the San Francisco County Medical Society next Thursday evening, May 3, 1906, at which time we will take up the question of ways and means to assist physicians of this city.

"Outside of San Francisco but few physicians suffered any loss, but I estimate that 1,000 of our physicians were burned out, at least so far as their offices were concerned. . . .

"The president of the New York Academy of Medicine has tendered us aid as well as medical bodies of Portland, Ore., Salt Lake City and Los Angeles, and there may be other offers

with which I am as yet unacquainted, owing to the confusion and scattering of the medical men. . . .

"We lost our county society library of about 6,000 volumes and many individual medical libraries which will be hard to replace and later I shall request you to aid us in securing duplicates from many other libraries in the United States. We have a small fund of money which has been placed at our disposal and is sufficient to meet our immediate necessities. In the meantime I wish you would announce how grateful we are for the aid tendered us and the sympathy which has poured in from all quarters."

The Situation in Santa Rosa.

"SANTA ROSA, CAL., May 2, 1906.

"*To the Editor:*—We notice with great pleasure that a fund is being raised to aid the doctors of the Pacific Coast who have suffered so severely in the recent great disaster. The earthquake did comparatively little damage in San Francisco, but the fire which followed spread ruin over a great area, and made desolate many a home.

"In Santa Rosa, Sonoma County, Cal., a most beautiful town of about 12,000 inhabitants, the earthquake did great damage; all the business blocks were thrown down, also many dwellings, and scarcely a chimney remained standing in town. Fire followed and burned about half of the business section before it was conquered. Many of our doctors lost everything in this conflagration, and are now in need of assistance.

"Santa Rosa suffered heavily both in loss of life and loss of property, more so in proportion than San Francisco. The calamity in San Francisco is so great that it has taken notice from us. We have a flourishing county medical society of 45 members, but we have lost all of our books, etc.

"We respectfully ask that any donation intended for our unfortunate members be sent to us, in Santa Rosa, where it will be most thankfully received and properly distributed by the county society.

"We wish you godspeed in your work of aiding the deserving. Fraternally,

"A. MCG. STUART, M.D., President.
"G. W. MALLORY, M.D., Secretary."

White Cross Contingent.

The following report, dated April 29, has been received of the physicians and nurses sent to San Francisco, April 23, under the auspices of the American White Cross First Aid Society, in charge of Major P. J. H. Farrell:

The first section arrived six hours late and was taken to the Hearst camp in Oakland. Surgeon Joseph B. Greene, in command, reported to Captain Kennedy, representative of Colonel Torney, who stated that he had been instructed to quarter the detachment in the Presidio adjoining the General Hospital. The following are the assignments:

To the Smallpox Hospital, Oakland, 6 nurses.
To the W. R. Hearst Maternity Hospital, Oakland, 8 nurses.
To the California City Hospital, one surgeon and one nurse.
To Logan Square, Harbor View Camp, seven surgeons.
As health examiners, on the ferries plying between Oakland and San Francisco, 14 surgeons, under charge of Surgeon Greene.
To the W. R. Hearst Camp, Adams Point, Oakland, 17 nurses.
To the Model Government Hospital Camp, 15 nurses.

Several nurses have also been assigned to duty at the United States General Hospital at the Presidio.

The health of all is reported excellent, and all are working earnestly and well.

Dr. Joseph B. Greene writes that it is difficult to trace refugees, as transportation is so difficult and the refugees are so scattered. The physicians and nurses sent out by the society are scattered over the entire city, doing various and sundry duties. Dr. Greene is in charge of inspection on ferry boats searching for smallpox.

The laundry at the United States Army General Hospital, Presidio, of San Francisco, just in the rear of the main hospital building, caught fire April 29, but owing to a favorable wind and prompt work, the fire was confined to this building and did not spread to the hospital.

Present Addresses of San Francisco Physicians.

The following list of present addresses of San Francisco physicians is taken from San Francisco papers and other sources:

Adams, Frank L., 1230 Telegraph Ave., Oakland.
Bailey, Thomas E., 1917 Fillmore St.
Belmont, Francis, Oakville, Napa Co.
Blake, Selden L., Irving Sanatorium, 906 Eddy St.
Bucknell, George J., 1121 Laguna St.
Burke, Isaac, Twelfth and Clay St., Oakland.
Burke, William P., Twelfth and Clay Sts., Oakland.
Cross, Charles V., 2007 Devisadero St.
Day-Bew, Lolita B., 2264 California St.
Dessau, H. F., Twelfth and Clay Sts., Oakland.
Dozier, Charles A., 827 Du Boce Ave.
Farnum, Charles E., 513 Devisadero St.
Forster, William M., Irving Sanatorium, 906 Eddy St.
Franklin, W. Scott, 2470 Bush St.
French, Charles E., 2715 Hillegas St., Berkeley.
Fredrick, M. W., 2015 Fillmore St.
Friedlander, David, 2897 Jackson St.
Griswold, William H., 894 Eddy St.
Goss, Alice M., 1800 Buchanan St.
Johansen, Erneste A., 1309 Oak St.
Jones, Philip Mills, 1230 Telegraph Ave.
Juilly, Georges H., Franco-American Hosp., 21st and Howard Sts.
Kenyon, C. G., 2355 Pacific Ave.
Lamb, Frank T., 1064 Bush St.
Lamb, Lottie A., 1964 Bush St.
Maclean, Daniel, Irving Sanatorium, 906 Eddy St.
McMurdo, John R., 2026 Steiner St.
Mercer, Ernest H., 3810 Mission St.
Minaker, Andrew J., 224 San Jose Ave.
Mish, Solomon C., 1075 Gough St.
Morrison, Joseph G., Haight and Masonic Ave.
Nelson, Arthur B., Irving Sanatorium, 906 Eddy St.
Orella, F. R., 872 Chestnut St.
Philip, John H., Irving Sanatorium, 906 Eddy St.
Preston, Walton, 1823 Franklin St.
Read, William P., 2105 Pine St.
Riley, William C. 1796 Post St.
Rosenthal, Adolph G., German Hospital.
Scott, Catherine V. C., 1386 Haight St.
Stafford, David E., Sacred Heart Church.
Terry, W. L., Presidio Sanitary Division.
Thelle, Emil, 472 Eighth St., Oakland.
Thomas, Frank, 810 Turk St.
Thompson, John E., 200 Fourth Ave., Richmond District
Thrasher, Marion, 881 Fulton St.
Tuchler, Alexander S., 703 Van Ness Ave.
Wakefield, W. Francis B., 2161 Sutter St.
Whitman, Charles H., 1007 Fillmore St.

Additional List of the Safe.

Dr. Douglas W. Montgomery sends us, under date of April 27, the following additional list of physicians who are safe and well: John M. Macdonald, Frederick J. Hund, Vincent P. Buel ley, George P. Purlenky, Alfred Newman, George H. Borkowitz, D. E. Barger, Edward G. Frisbie, Gerald J. Fitzgibbon, Frank T. Fitzgibbon, Alexander T. Leonard, Michael J. Fottrell.

St. Louis Sends Relief.

St. Louis physicians, through the St. Louis Medical Society, have contributed $650 for the California physicians' relief. The names of the individual contributors are as follows:

Alt, A.	Gettys, S. L.	Moeller, C. E.
Amerland, J. H.	Goodwin, E. J.	Neuhoff, F.
Ambruster, A. C.	Graul, R. E.	Nietert, H. L.
Ament, C. M.	Green, John, Jr.	Ogle, O. E.
Anderson, C. E.	Greer, E. O.	Orth, Carl.
Avars, T. R.	Grindon, J.	Porter, Wm.
Bader, G. W.	Gross, J. H.	Price, J. M.
Ball, James M.	Hardy, J. A.	Reder, F.
Ball, O. F.	Haverstick, G. W.	Ring, Frank.
Bartscher, H. W.	Hansneck, F. A.	Rothman, P. M.
Baumgarten, G.	Hempel, Max.	Rothstein, H.
Bedal, A. C.	Henderson, F. L.	Sauls, J. A.
Blair, V. P.	Hill, Roland.	Schmidt, Aug.
Becker, E. F.	Hirschl, W. T.	Schlossstein, A. G.
Brookes, H. S.	Hoffmann, Phil.	Scott, C. W.
Bryan, W. M. C.	Hoge, M. W.	Sensenv, E. T.
Buchwalter, J. C.	Homan, George.	Shattinger, C.
Bunford, C. E.	Hopkins, T. A.	Shelman, A. P.
Caplan, L.	Jennings, J. E.	Shields, W. B.
Cawood, J. H.	Johnson, H. McC.	Skrainka, P.
Claasen, H. W.	Jullan, H. M.	Slader, G.
Coughlin, W. T.	Kennedy, A. F.	Smith, Elsworth.
Crandall, G. C.	Kern, J. H.	Spitzig, F.
Curtis, A. N.	Kolbenhever, F.	Steger, W. T.
Dalton, H. C.	Kollme, Otto.	Steedman, I. G. W.
Dorsett, W. B.	Konzelmann, P. R.	Steele, A. J.
Dudley, C. R.	Lightner, C. R.	Streutker, C. E. F.
Faber, J. E.	Lutz, F. J.	Stockwell, B. E.
Ehrenfest, H.	Magoon, E.	Sturhahn, F. O.
Fisch, C.	Mansfield, T. B.	Terry, R. J.
Fries, W. A.	Martens, E. J.	Thumser, L.
Everett, A. E.	Mathews, M. H.	Tupper, P. Y.
Fulton, A.	Mares, J. F.	Upshaw, H. A.
Galloway, W. L.	Meng, E. R.	Ware, C. A.
Gamble, D. C.	Merwin, G. M. D.	Wichmann, H. L.
Garstang, D. B.	McLean, M. H.	Wolf, A. S.
Gebrung, E. C.	Mickel, R.	Zahorsky, John.
Gellhorn, G.	Millican, K. W.	

The contributions were in sums as follows: Five individuals contributed $25 each; one, $15; twenty, $10; one, $8; forty-nine, $5; two, $3; sixteen, $2; seventeen, $1; four, $0.50.

Appeal to Pennsylvania Physicians.

A copy of the following circular letter has been mailed by the secretary of the Philadelphia County Society, Dr. William S. Wray, to every regular physician in the state of Pennsylvania:

PHILADELPHIA, April, 1906.

Dear Sir:—I enclose herewith a copy of the resolutions passed by the Philadelphia County Medical Society, April 25, 1906. You will note in the matter therein contained that it is desired to create a fund for the relief of California physicians who are in financial distress by reason of the recent disaster. Will you kindly bring

this matter to the attention of your County Medical Society at the earliest possible moment. The treasurer of our committee will be glad to receive from your society or from the individual members thereof any contribution which they may feel inclined to make. The fund when collected will be placed in the hands of some responsible representative physician of California who will see that the money is expended judiciously and where it is most needed. The fund will be sent out as the contribution of the physicians of the State of Pennsylvania.

Any contribution, from one dollar up, will be gladly received.

WILLIAM S. WRAY.
Secretary of the Philadelphia County Medical Society.

Cincinnati to Aid.

The president of the Cincinnati Academy of Medicine has appointed Drs. C. L. Bonifield, E. O. Smith and Magnus Tate as a committee on subscription to help the profession of San Francisco.

THE CALIFORNIA FUND.

It is not necessary to repeat what has already been printed in these columns regarding the fund to aid physicians in California. The object of the Board of Trustees in authorizing THE JOURNAL to receive subscriptions for the purpose was to give all an opportunity to contribute who otherwise might not know through what channels they could send their contributions. As has been stated, in addition to the Board of Trustees of the American Medical Association, under whose direction this fund is being collected and will be distributed, a local committee, which could be quickly gotten together in an emergency, was appointed to act in an advisory capacity. As we go to press we have no definite information regarding who will constitute the committee appointed by the California profession. A meeting of the San Francisco County Medical Society was called for May 3 to appoint a local committee for the distribution of this and other funds. Next week we hope to give full details in regard to this committee.

The following contributions, not acknowledged last week, have been received up to 9 o'clock, Wednesday morning, May 9:

INDIVIDUAL CONTRIBUTIONS.

Allen, Frank H., Shelby, Iowa	$ 2.00
Anderson, Edw. T., Platte, S. D.	2.00
Arnold, B. A., Freeport, Ill.	20.00
Atwood, F. C., Daytona, Fla.	10.00
Campbell, W. J., La Plata, Macon Co., Mo.	1.00
Cunningham, H. K., La Plata, Macon Co., Mo.	0.50
Deaderick, Wm. H., Marianna, Ark.	1.00
Donnellan, P. S., Redlands, Cal.	5.00
Ellis, S. L., La Plata, Macon Co., Mo.	1.00
Friedenwald, Harry, Baltimore	5.00
Gage-Day, Mary, Klogston-on-Hudson, N. Y.	5.00
Gates, J., La Plata Macon Co., Mo.	1.00
Graham, W. A., Fayette, Ala.	1.00
Grant, W. W., Denver, Colo.	10.00
Hicks, L. E., Dunn, N. C.	2.50
Hirshfelder, Arthur D., Baltimore	25.00
Hodson, F. A., Sheridan, Wyo.	5.00

Grand total	$5,735.05

GENERAL.

Mare Island Navy Yard.—It is reported from Washington that the Senate Committee on Naval Affairs has ordered a favorable report on a bill authorizing the expenditure of $300,000 at the Mare Island Navy Yard, San Francisco. The object is to give work to the earthquake and fire sufferers.

Railway Surgeons Meet.—At the annual session of the Central of Georgia Railway Association, held in Birmingham, Ala., April 15, the following officers were elected: President, Dr. George R. West, Chattanooga, Tenn.; vice-president, Dr. Robert H. Taylor, Griffin, Ga., and secretary, Dr. J. R. Burdette, Tennille, Ga.

Cholera in the Philippines.—Chief Quarantine Officer Heiser reports that there has been a great decrease in the number of plague cases in the provinces; from an average of about 50 a day the number has dropped to about 5. The improvement is attributed to the very vigorous measures which the health department recently put in operation. In one town alone several thousand persons were vaccinated with anticholera vaccine.

Health Report of the Isthmus for March.—Colonel Gorgas in his monthly report states that the health conditions of the Isthmus continue excellent. No case of smallpox has occurred within the last year. The last case of plague occurred seven months ago, and the last case of yellow fever over three months ago. During March, among the 25,000 employés there were 28 deaths, 10 among whites and 68 among negroes. Of the 10 whites 5 were from the United States. Of these 5, only 3 died from disease, 1 from pneumonia and 2 from dysen-

tery. The principal causes of death were malaria and dysentery. The disease causing the next highest death rate was dysentery, which caused 8 deaths, and after that accidental traumatism, which caused 4 deaths.

The Journal of Abnormal Psychology.—The first number of this journal has been received. According to the announcement it is intended for the publication of articles embodying clinical and laboratory researches in abnormal mental phenomena. The data supplied by such researches are of fundamental importance to neurology, psychiatry and psychology. "The field of investigation includes, for instance, such subjects as hysteria, hallucinations, delusions, amnesias, abulias, aphasias, fixed ideas, obsessions, delirums, perversions, emotions and their influence, exaltations, depressions, habit neuroses and psychoses, phenomena of hypnosis, sleep, dreams, automatisms, alterations of personality, multiple personality, dissociation of consciousness, subconscious phenomena, relation of the mind to physiologic processes, neurasthenic and psychasthenic states." The first number contains the following articles: "The Pathogenesis of Some Impulsions," Dr. Pierre Janet; "What Is Hypnosis?" Prof. W. v. Bechterew; "Recent Experiences in the Study and Treatment of Hysteria at the Massachusetts General Hospital, with Remarks on Freud's Method of Treatment by 'Psycho-Analysis'," Dr. James J. Putnam; "The Psychology of Sudden Religious Conversion," Dr. Morton Prince. The price is $3 a year and the editor is Dr. Morton Prince, 458 Beacon Street, Boston.

FOREIGN.

Australian Hospital Damaged by Storm.—The hospital at Longreach, Queensland, was recently damaged to the extent of $1,000 by a thunderstorm accompanied by heavy winds. The morgue was completely demolished.

Strike of Printers in Paris.—We have received a notice from Masson et Cie, publishers of the *Presse Médicale*, stating that the present strike among the printers will interfere with the further issuing of the journal until satisfactory arrangements can be concluded.

In Russia.—The *St. Petersburg. med. Wochft.* for April 7 gives the names of several physicians who have been released from custody on the payment of forfeit sums ranging from $50 to $2,000. They had been arrested for alleged participation in the revolutionary movement.

Plague in India.—A serious outbreak of plague is reported to have occurred at Jummoo, in Kashmir, northern India. A native ruler, the maharajah of Jummoo, has his palace there, and many deaths are reported among the palace attendants and the troops. Two hundred and eighty-five deaths are said to have occurred during the week ending April 21.

Multi-Centennials of the German Universities.—The University of Giessen completes in 1907 the three-hundredth year of its existence. The University of Leipsic is arranging a celebration for 1909 of its five-hundredth anniversary. We learn that the University of Leipsic was founded by secession of several thousand students, Dec. 14, 1409, from the flourishing university at Prague.

Suit for Damages Against German Surgeon.—A surgeon at Graz had occasion to take a skin flap of 2 sq. cm. from the thigh of a housemaid for transplantation. Some time afterward she instituted suit for damages, claiming $10,000 for the pain and lessening of her chances to get married, and $200 more for loss of time and expense of treatment. The surgeon was able to prove that the girl had given her formal consent beforehand, and the suit was dismissed.

Regional Bacteriologic Institutes in Belgium.—According to an article in the *Progrès Médical* for April 7, Belgium is the best provided with official laboratories for bacteriologic investigation of any country in the world to date. Each province has one or more, and the number of specimens sent for examination is constantly increasing every year. Since its foundation in 1896 to 1905 the laboratory at Liège has made about 35,000 analyses. Of this number 14,045 were made during the year 1904.

Beco Appointed Governor of Brabant.—Dr. E. Beco of Brussels, Belgium, has for some time been secretary-general of the department of agriculture and has had charge of the medical and sanitary matters connected with this department of the administration. He has recently been appointed governor of the province of Brabant. While congratulating him on his promotion, the *Gaz. Méd. Belge* mourns the loss of his able and devoted services for the welfare of the profession at large and the public health in general in his previous official capacity.

Vaccinated Scotland.—The report on vaccination in Scotland, in 1904, puts the argument in support of the operation in a somewhat striking manner. It states that the deaths from smallpox in 1903 numbered 41; of these persons 20 had been vaccinated, 12 had not, while the remaining 9 were doubtful. The report remarks: "Inferring from the average number of children vaccinated that about 94 per cent. of the population is vaccinated, these figures may be taken as indicating that the death rate among the unvaccinated is nearly fourteen times as great as it is among the vaccinated."

Medical Excursions for Medical Students.—A society has been formed in France to promote medical study trips of medical students. A large excursion of this kind was planned for April 18, a party of English medical students going to Paris for two or three days, and then on to Angers and Nantes, and home by way of Rouen and Havre. The medical students at each place visited welcomed the party and escorted them to the local medical institutions. The party returned after an instructive and enjoyable ten days' trip. The expense of the ocean trip debars American medical students from participating in the simple and inexpensive object lessons of such outings in other lands.

The Apathy of Londoners Toward Their Hospitals.—The duke of Fife, by some remarks regarding the apathetic attitude of Londoners toward their hospitals, has raised a storm of discussion in the lay press of the British metropolis. The duke of Fife, as acting president of the King of England Hospital Fund, said: "The great majority of Londoners do not subscribe to the hospitals at all, and the plain truth is that the London hospitals are maintained by a small number of charitable people." The consensus of opinion on the point raised by the duke of Fife is that Londoners are apathetic toward their hospitals, and that the total number of the London subscribers to the metropolitan hospitals does not exceed 20,000. It is stated that it is the well-to-do middle classes who are to blame.

Petition for Restriction of Experimental Research.—A committee in the German Senate recently reported on two petitions which asked for restrictions on laboratory research with animals. The spokesman remarked that one petition was "of the sentimental type, signed by society ladies, by a foreign diplomat accredited to the court of Berlin, by 'nature healers' and others, but not by a single person to whom the world owes any scientific progress. Many of the signatures were evidently given 'merely to oblige,' and the signers would be much surprised if their physicians were to refuse to make an injection of antidiphtheria serum in case of need in their families." The *Deutsche med. Wochft.* states that in his virgin speech, von Bergmann endorsed the condemnatory report of the committee with cutting sarcasm.

Exhibition of Appliances for Care of the Sick.—An exhibition of this kind was held at Berlin in 1899 and proved so popular that a credit of nearly $4,000 was left after its closure. A committee was recently formed to urge the appropriation of this sum for the foundation of a permanent educational exhibit of everything connected with the care of the sick. The committee has accomplished its purpose, and the exhibit was recently thrown open to the public in the new "Empress Frederick House," which was described in these columns on page 894. A model sick room and nursery are part of the exhibit. Owing to the comparatively small space, the committee aimed to exhibit only the most practicable and approved appliances, but even of these there is a bewildering array. Means to entertain, occupy and divert the patients are also shown, and garments for the very sick and for convalescents. The exhibition is described in detail in the *Zeitft. für aerztliche Fortbildung* for April 15.

Immunization with Bacteria Killed with Sugar.—Levy and Blumenthal of Strasburg announce that solutions of sugar have a marked bactericidal action, proportional to their concentration. They describe in the *Med. Klinik* for April 22 a number of experiments in which a single subcutaneous injection of typhoid bacteria treated with sugar rendered guinea-pigs immune to five to ten times the fatal intraperitoneal dose of virulent bacilli. They used galactose as the most convenient form of sugar, applying 1 to 4 mg. in a dry powder or dissolved in physiologic salt solution, to typhoid bacilli whose virulence had been tested and found to be one-tenth of the standard loop. The sugar and bacilli were then shaken up well at 37 C. and injected unfiltered. Rabbits injected with 2 mg. were also protected against fatal intraperitoneal infection. They conclude from their research that the prospects are encouraging for similar immunization of man with this simple, convenient and harmless technic. The sugar does not have a destructive action on the bodies of the bacteria and consequently interferes less with the generation of antibodies.

A 25 per cent. solution of galactose killed cholera vibrios in one to two hours, streptococci and diphtheria bacilli in six hours, tubercle bacilli in four or five days, and typhoid bacilli in less than seventy-two hours.

Disease Among Alien Emigrants in Glasgow.—Dr. A. K. Chalmers, medical health officer for Glasgow, in a report to the city council calls attention to grave defects in the housing and inspection of aliens detained in Glasgow while waiting for the steamer to convey them to America. He referred particularly to the case of a Russian Jew, who was admitted to the isolation hospital suffering from smallpox. The man arrived from Russia via Rotterdam and Grangemouth on March 22, and with four others was acommodated in one of the hotels of the city. On the same evening he visited the shop of a fellow-countryman who, observing an eruption on his face, took him to another hotel which is also used by emigrants and at once communicated with the medical officer of the shipping company concerned. In this latter hotel the patient was detained in a room by himself, but in the previous hotel he occupied two rooms in succession and had opportunities for mixing with between 400 and 500 people who were accommodated in the hotel. The aliens act of 1905 holds the shipping companies responsible for the completion of transit of such persons as they have introduced into this country, but while in Glasgow, as this case illustrates, infection from a smallpox patient may reach a considerable section of the resident population before its presence is recognized. The *Lancet* states that it would seem desirable that so long as this traffic continues these emigrants should be housed by themselves and regularly inspected so that the public may have a reasonable degree of protection against imported disease. There is no daily medical inspection of emigrants, although the interpreters employed are expected to report at once any case of sickness coming under their notice.

Fifth German Congress for Orthopedic Surgery.—One of the features of this congress, which was held at Berlin in the first week of April, was the application of water power in orthopedics. The apparatus constructed for the purpose by Machol of Garré's clinic, Breslau, was briefly described in THE JOURNAL recently, on page 839. In his report of the congress in the *Deutsche med. Wochft.* for April 19, Muskat refers to it as an ingenious application of valve pumps which allows the use of a new source of power for active and passive movements, surpassing in simplicity and cheapness all other methods to date. Another interesting feature of the congress was the presentation by Finck of Charkow, in Russia, of 3 patients cured of Pott's disease and hump by prolonged lying in a plaster bed with gradual over-correction of the hump. He has thus treated 66 patients, and 52 are completely cured with no trace left of the hump. The others are cured, with 2 exceptions, but he does not call these cases entirely successful. Muskat refers to his work and technic as indicating important progress in conservative orthopedic surgery. It is the result of many years' experience. Finck assumes that the hump is the result of contraction of ligaments more than of muscles, and that reduction can not be realized by traction, but only by gradual action of dorsoventral pressure. This reduces the hump by retracing the steps that produced it. This he accomplishes by means of a pad of folded compresses, forming a cross, placed in the plaster bed beneath the hump. The spine is more amenable to reduction when horizontal. Very slowly, not until after several months to a year, the hump thus becomes reduced, and then a celluloid corset is applied, retaining the pressure on the hump. The patient is not allowed at first to be up more than half an hour, to a maximum of six hours. The entire treatment requires three or four years before the patient is finally dismissed, but the results are brilliant.

Thirty-fifth German Congress of Surgery.—This congress convened at Berlin April 4; the surgical experiences gathered during the Russo-Japanese war opened the proceedings. Among the points emphasized by the Russian surgeon, Zoege von Manteuffel, was that the battles are mostly in the night, and that the wounded always leave the field by the route they took in going. He trephines at once all tangential skull wounds, but not the diametral. Bergman of Berlin commented on the little progress that has been made in military surgery since the Russo Turkish war. All agreed on the value of immobilization of wounds in the joints and restriction of primary operations. Sauerbruch reported that hemorrhage could be prevented in experimental operations on the skull by arranging the skull part of the head in his air cabinet, under over-pressure, with the rest of the head outside. Rehn and König advocated partial resection of the thymus if it interferes with respiration, the latter presenting a child whose thymus had been removed in infancy for thymic asthma, and rickets developed. Krönig reported excellent results from a combination of spinal anesthesia with the scopolamin-morphin technic for gynecologic operations. The greatest interest, perhaps, centered in the experiences reported in regard to passive congestion in the treatment of acute inflammatory processes. Bier stated that he had applied it in 1,500 cases. Before adopting this treatment he had never been able to save a tendon bathed in pus, while under the artificial hyperemia he had now a record of 17 complete recoveries in 25 cases of suppurative processes in the tendon sheaths. Küster styled the method the greatest progress in surgery since Lister's discovery. Bardenheuer remarked that he had not been successful with the method until he sent for one of Bier's assistants to show him the correct technic. Since then his results had been fine. He had been able to save 5 out of 7 cases of phlegmon of the tendon sheaths. Thole of Dantsic asserted that we have no means of dosing this method, and that it has no scientific basis, but he was interrupted by murmurs of disapproval to such an extent that the president of the congress, Körte, of Berlin, had to call the meeting to order. The *Semaine Médicale* for April 11 and 18 has a full report of the congress, and our German exchanges are publishing reports in lengthy installments.

Organization of the Profession in Italy.—A most remarkable congress was recently held at Rome, which signifies much for the progress of the profession and its organization in Italy, as also for the public health in general. The group of physicians in the national legislature, the famous "Fascio Medico Parlamentare," arranged what they called a sanitary congress, and summoned all the district doctors, veterinarians and pharmacists throughout the country to a conference. The Italian laws require that each community or group of very small communities must have a salaried physician and midwife. The physician is appointed and discharged by the local authorities, and the overcrowding of the profession and sharp competition have reduced the salaries below the living point among other abuses. The conference was summoned to discuss these and other matters and suggest legislation. In his opening address Baccelli described the peculiarly favored position of the physician in ancient Rome. He was exempt from military and civic duties; his property could not be seized for debt, and any one who injured or defamed him had to pay a large fine. The number of physicians in a place was regulated by law, and the rulers of the city were responsible for keeping the number within the legal limit. Four thousand sunburned and weatherbeaten district physicians from all parts of the country to the remotest hamlets gathered at Rome in March in response to the official summons, and the proceedings, although not strictly parliamentary, yet amply accomplished the aims of the organizers. One resolution voted was for legislation which would give a legal, official standing to associations of physicians. The minimal salary to be paid by a community was also voted as 200 lire a month (about $40). Another resolution was for the adoption of uniform conditions for applicants for the position of district physician. Heretofore the communities were free to make any exactions and conditions they chose. A plea for Sunday rest was also made. This great convocation enabled the medical men in parliament to come into closer touch with medical conditions throughout the country and with the needs of the populace and their physicians than could have been obtained in any other way. It was also a great event for the district doctors. The membership fee of $1 (60 cents for members of the family) entitled to a reduction of 75 per cent. on all lines of transportation throughout the country for forty days.

Baccelli and the Great Policlinico at Rome.—The *Gazzetta degli Ospedali* for April 15 is devoted entirely to an illustrated description of the great public hospital and clinical school, the Policlinico, which owes its inception to Guido Baccelli and was formally inaugurated on the fiftieth anniversary of his entry into the practice of his profession. The occasion was celebrated as an opportunity for homage to Baccelli, and a gold tablet, bronze laurel wreath, doctoral diamond ring, etc., were presented to him with ceremonies of a national and international character. The king of Italy presided, and addresses were made by Riehl on behalf of Austria, by De Mayer for Belgium, Bouchard for France, Livierato for Greece, MacAlister for Great Britain, De Bildt for Sweden, and Koranyi for Hungary. Congratulations were also wired from the United States and Germany. The *Gazzetta* states that the Policlinico is the largest single clinical school in Europe, and that only some of those in the United States can be compared with it. The grounds cover an area of 160,000 square meters, and are out-

side the city proper, on an eminence. The various clinics are separate, but with a connecting corridor, each a two-story building with amphitheater in the central part, corridors each side and two wards in the pavilions at each end. The buildings are heated by steam, which is also used for disinfecting the operating rooms, etc. Besides Baccelli's contributions to medical science, mentioned recently in these columns on page 1044, the addresses emphasized his important work as senator and then as minister of public instruction, minister of agriculture, delegate to international congresses, etc. He introduced elective courses into the universities and dispensed with examinations for the students standing highest in their classes, allowing them to complete their courses with regular study instead of the tumult of examination days. To him Rome owes the recent excavations in the Forum and at Pompeii, and the establishment of the Gallery of Modern Arts and the Historical Institute. He founded the first chair of agrarian bacteriology, and it was during his term as minister of agriculture that the antimalaria legislation was framed and adopted. The Policlinico is regarded as his greatest triumph, as it embodies advanced ideas in many respects. The cornerstone was laid in 1888 and it is not yet entirely completed. The *Gazzetta* gives illustrations of the Boston City Hospital and of some other American institutions for comparison, remarking that the arrangement of the Johns Hopkins Hospital is most like that of the Policlinico. It refers to Boston as "the Athens or rather the Edinburgh of the United States, whose medical school enjoys a reputation surpassing that of its rival cities, New York and Philadelphia."

The German Day Health Resorts.—Germany now has 30 of the fresh-air daytime sanitariums, for men or for women, first introduced in 1900. The patients sleep at home, but spend nearly all their waking hours at the resort, which is in some accessible forest glade near the town, on some trolley or suburban road, which usually grants reduced rates to the bearers of the sanitarium admission ticket. A lunch is given free in the forenoon and afternoon, and a good dinner at noon; other food can be obtained at any time at minimal rates. There are few regulations except that all must keep still in the reclining chairs for two hours after dinner, and that smoking is prohibited. At first the resorts were kept open only in summer, but the success of keeping one near Berlin open all the year around has been so marked that the others will probably follow suit. The persons taking advantage of these resorts are mostly tuberculous and are either waiting to be admitted to a sanatorium or recently dismissed from one, or do not wish to go to a sanatorium. These resorts are probably one of the manifold results of the compulsory insurance of wage-earners in Germany. The insurance companies find it cheaper to bend their energies to cure their policyholders than to pay indemnities for disability. Some of the German cities have placed one of the public schools in some outlying woodland location, and children who are found to be candidates for or already affected with tuberculosis, rickets or scrofula are allowed to attend this school. The school work is kept up regularly, but much of it is done out of doors. The lesson hours are short, with frequent long recesses for play, out of doors or in open pavilions, and nourishing meals are given the children. The success of the school at Charlottenburg has surpassed all anticipations. It has encouraged the authorities to establish another, which was formally opened April 17, principally designed for children with rickets. This school has dormitories where the children sleep at night, so as to give them the benefit of the country air both night and day. An article in the *Lancet* for April 14 gives the impressions of a visitor to some of these day health resorts. They are erected by the Red Cross Society, but the expenses for maintenance are met by private subscriptions and by the sums paid *per capita* by the insurance companies which send the majority of the patients. The Germans call these day health resorts *Walderholungsstütte*, whose syllables allow a glimpse of woodland wilds, recovering health, taking recreation and amusement and retrieving damage. The article in the *Lancet* discusses the advisability of the introduction of the system into Great Britain, remarking that the local trades unions, sick clubs and lodges may in time also find it to their pecuniary interest to help cure their policy-holders instead of paying sick benefits. If they undertake the task they will soon find that true economy means the greatest thoroughness in this case.

LONDON LETTER.

Death of an Englishman from Sleeping Sickness.

One of the first English victims of sleeping sickness is Mr. John Mahon, who has just died at University College Hospital. About three years ago he was superintendent of the botanic gardens at Entebbe, Uganda, when he was bitten by a tsetse fly. He was invalided home for an undefined complaint which proved after some months' residence in England to be sleeping sickness. For the first 18 months after his return he performed some light duties at the Colonial Institute. After that the torpor of the disease seized him. He wasted to a skeleton. Another victim to the disease is Lieutenant Forbes Tulloch, who has been invalided home from Entebbe.

Rat Fleas and Plague.

Some very striking experiments have been conducted at Bombay to prove that rat fleas carry plague, not only from rat to rat, but from rat to man. In a room in which a rat dead from plague had been found animals were placed in cages. Some of the cages were protected by fine metallic gauze to keep away the fleas. The unprotected animals sickened and died of plague and rat fleas infected with plague were found on them. The protected animals escaped. The health authorities of Bombay are taking active measures with regard to rats found in the streets and houses. Where plague rats are found the houses are marked and disinfected and the occupants are warned.

Sir Thomas Browne's Skull.

At Norwich the question of the reinterment of the skull of Sir Thomas Browne, the author of the "Religio Medici," which has long been preserved at the Norfolk and Norwich Hospital, was discussed at the annual meeting of the governors of that charity. Sir Thomas Browne, who lived at Norwich in the middle of the seventeenth century, was buried in the Church of St. Peter, Mancroft. During the early part of the last century when an interment was taking place in the adjoining vault his grave was accidentally broken into. It is alleged that the skull was abstracted, and after passing through various hands became the property of the hospital authorities, who latterly have preserved it in a handsome reliquary presented for the purpose by Professor Osler, who is one of Browne's most devoted admirers. Recently there has been a considerable expression of opinion at Norwich, backed up by the vicar and church wardens of St. Peter, Mancroft, that the skull ought to be returned to the tomb whence it was taken. The hospital governors unanimously passed a resolution agreeing to this course on condition that the tomb should be opened in the presence of representatives of the hospital with a view to satisfying them that the remains therein are without a skull.

Action by a Midwife Against a Physician.

An action has been brought in Ireland against a physician by a midwife under peculiar circumstances. She attended a woman in her confinement, which was quite normal. A few days later she attended another case, in which the mother died of sepsis. For several days she attended both cases, and after she had ceased attendance on the first case the infant developed suppurative omphalitis, from which it died. Two days before death it was taken to the physician in a dying state. He prescribed one-half grain doses of gray powder. He certified the cause of death to be "spreading cellulitis." The parents asked what this meant and he said blood poisoning. The father immediately connected the death of the child with that of the other patient of the midwife, who had died of sepsis, and said that she had communicated the disease and that he would take action against her. He reported the case to the public health authorities, who sent for the nurse's clothes in order to have them sterilized. The midwife considered that this was detrimental to her practice and brought an action for damages against the parents of the child, two relatives and the physician. The cases were very protracted. The chief point relied on by the plaintiff was that the physician first diagnosed syphilis and that he altered this diagnosis out of spite against the midwife because she advised patients of his to seek advice elsewhere. The midwife contended that the administration of mercury showed that the child suffered from syphilis. This notion was, of course, easily refuted. A verdict for the defendant was returned.

The Prevention of Sleeping Sickness.

Dr. J. L. Todd, who has been several years on the west coast of Africa investigating sleeping sickness and other tropical diseases on behalf of the Liverpool School of Tropical Medicine, delivered an address before the members of the African trade section of the Liverpool chamber of commerce on "The Danger of the Spread of Sleeping Sickness Through Africa and the Necessary Measures for Its Prevention." He said that from 400,000 to 600,000 natives have died from the disease during the last ten years. In the opening up of the

country sleeping sickness took a great extension. It is along the much used routes that the disease has spread and is spreading. The way in which it has been recommended that the disease might be combated in the Congo Free State is by the establishment of medical posts of inspection along the most traveled trade routes and the transportation of infected persons at present living in uninfected districts to localities already infected. In the Congo it was found that enlargement of the cervical glands without obvious cause in natives might be taken as a sign of sleeping sickness and, therefore, every employer of labor should be informed of the significance of this symptom. It was decided at the meeting to send a resolution to the colonial secretary calling the attention of the secretary of state for the colonies to the alarming spread of sleeping sickness in British and foreign areas in Africa, and to the desire of the African trade section of the Liverpool chamber of commerce that steps should at once be taken in conjunction with other African powers to investigate and, as far as possible, arrest the progress of the disease.

The Health of the City of London.

The report of the health officer for the city of London for 1905 has just been issued and contains much interesting information. The night population of the famous "square mile" at the middle of that year was 22,425, although the day population was estimated at 369,380. It is unsatisfactory to find that 23 per cent. of the samples of milk examined were found unclean, and that a further 9 per cent. were tuberculous. The principal railway companies with one exception have recast their by-laws during the year and made spitting on platforms, booking offices, etc., or in railway carriages, a punitive offense. The penalty is a fine not exceeding $8 for a first offense and not exceeding $40 for any subsequent offense. Many hair dressers have availed themselves of the decision of the corporation to grant voluntary certificates of the sanitary condition of their premises, and those who first opposed the movement now recognize the advantage of falling into line with those who have been placed on the register. The production of ice creams—a trade almost entirely in the hands of Italians—has been controlled, and no case of illness attributed to eating ice cream has occurred. The report contains a good deal about the sophistication of butter. Certain traders sell an article containing as much as 25 per cent. of water, which has been ingeniously incorporated with genuine butter, and is sold as "milk-blended butter." The makers protect themselves from prosecution by disclosing the fact that the article is a mixture, but the ordinary buyer is not likely to know that the milk added contains from 86 to 88 per cent. of water. The buyer is deceived, and thinks that he is buying cheap butter, but the quantity of water present makes it dear. Another disadvantage is that the keeping properties of the butter are diminished by the addition of the water, especially during warm weather. The sale of this stuff has opened the door to another sophistication—the admixture with butter of skimmed milk and cocoanut oil.

The Government and Vaccination; the Jenner Society's Suggestion.

The report of the executive committee of the Jenner Society for 1905 is of special interest, in view of the fact that with the advent to power of the liberal government there is renewed activity in antivaccination circles. Established in 1896, the society has done much to demonstrate the value of vaccination. Among the honorary vice-presidents are Lord Lister, Sir W. Huggins, Sir W. Turner and Dr. Ferguson (ex-president of the B.M.A.). The vaccination act of 1898 was avowedly an experiment, and was therefore enacted for only five years. It would have ceased to operate last year, but was kept alive for another year by the expiring laws act. The government must take action during the ensuing session, but as the time is already mortgaged for more pressing questions there will be no time to discuss a vaccination bill. It may be concluded, therefore, that the act will be kept alive for another year, but with an explicit promise of legislation in 1907. During the interval the government will have ample opportunity for gaining information of the weak points of the act and of other matters involved in the administration of vaccination with which the act did not deal. The Jenner Society suggests that preliminary to such legislation the government will do well to institute a formal inquiry, preferably by a special commission, into the whole subject of vaccination administration, for it is much more to the defects of its administration than to any disbelief in the protective value of vaccination itself that the practice owes any unpopularity it may have acquired. The necessity of meeting the agitation against vaccination is emphasized: "That the country which gave birth to this great discovery should be left a prey to the unchallenged vituperation of Jenner and to the mischievous deprecation of his work would be as grave a discredit to it as it would be a deplorable abnegation of duty."

The Lowest Birth Rate on Record.

The decline of the birth rate which has been evident in recent years continues to be shown by the most recent statistics. The report of the registrar general for 1904 has just been issued. In the middle of that year the estimated population of England and Wales was 33,763,434, of whom 16,316,647 were males and 17,446,787 females. The marriage rate was 15.2 per 1,000—.04 below the rate of 1903 and .06 below the average of the ten years 1894-1903. The birth rate was 27.9 per 1,000—the lowest on record. This was .05 below the rate of 1903 and 1.3 below the average of the last 10 years. Since 1895, when the birth rate was 30.3, it has gradually declined. The death rate was 16.2, which was 1 per 1,000 below the mean rate of the 10 years 1894-1903. The deaths of infants under one year were in the proportion of 145 per 1,000 births, as compared with 132 in 1903 and 150 in the 10 years 1894-1903. The proportion in 1904 was higher than in 1902 and 1903, but lower than in any other years since 1894. Among the deaths were 59 reputed centenarians—17 males and 42 females. Deaths from smallpox numbered 507—a rate of 15 per 1,000,000 of the population. Chickenpox is said to have caused 104 deaths, but it is thought that most of these were due to smallpox; 28 deaths were due to cowpox or other effects of vaccination. Deaths from tuberculosis numbered 60,205—3,526 less than the average of the previous 10 years. The deaths from cancer showed an increase; they numbered 29,682 and exceeded by 2,461 the average of the last 10 years. The deaths of 2,523 men and 822 women were attributed to suicide, the figures in both cases exceeding the average.

Award of Prizes by Royal College of Physicians and Surgeons.

The Council of the Royal College of Surgeons has awarded the Walker prize of $500, instituted to encourage investigation into the pathology and therapeutics of cancer, to Professor Jensen of Copenhagen. The committee appointed to advise the council in reference to the award reported that after receiving valuable advice and assistance from eminent American, Belgian, Danish, French, German, Italian, Swedish, Swiss and British surgeons and pathologists regarding the work in their respective countries, and after carefully examining papers on the pathology and treatment of cancer published in various languages during the last five years, they found that in any report presented to the council much important work could not be considered because it had not been done within the prescribed time limit; because it had no direct bearing on the treatment of cancer; because it was still being pursued and the prize could scarcely be awarded to it at this stage of its progress. In recommending Professor Jensen, the committee quoted the description of his work from a letter of Professor Salomonsen of the State Serum Institute of Copenhagen: "The inoculation of cancer from animal to animal had been made in comparatively few cases, and therefore afforded no decisive material for the study of cancer. Professor Jensen first succeeded in discovering a tumor in the mouse which made the experimental investigation of cancer on a large scale possible. He first carried out a large series of inoculations through 35 generations, comprehending about 1,000 mice, and thus gave the impulse to certain experimental investigations which are now being carried out in different parts of the world. He thus made it possible to investigate, and was the first to investigate systematically, the effect of different factors (heat, light, chemical agents, radium, etc.) on the cancer cells. He further demonstrated the possibility of producing an anticancer serum for mice by the injection of the crushed tumor into rabbits. The serum of rabbits thus prepared has been injected into mice suffering from cancer, with the result that the cancer tumors in many of them disappeared permanently." The Jacksonian prize for 1905 was awarded to Reginald Cheyne Elmsley, M.S., F.R.C.S., for his essay on "The Pathology and Treatment of Deformities of the Long Bones Due to Disease Occurring During and After Adolescence." The subject for 1907 will be "The Operative Surgery of the Heart and Lungs, Including the Pericardium and the Pleura." The subject selected for Cartwright prize for 1906-10 is "The Prevention of Dental Caries." Dr. Lucas Championnière of the Hotel Dieu, Paris, was elected as honorary fellow of the college. The honorary medal of the college was awarded to Lieut. Col. Sir Havelock Charles, I.M.S., in appreciative recognition of his gift of anthropologic specimens—an addition to the museum of special value not only on the account of the number and variety of the specimens, but also on account of the authentic particulars attached to them.

Pharmacology

The Physician and the Pharmacist.

As has been emphasized repeatedly, the true function of the pharmacist has been sadly curtailed by physicians prescribing ready-made proprietary mixtures. In too many localities the pharmacist has found that the work for which he had been educated, that of compounding physicians' prescriptions, was not called for; that the filling of prescriptions too often had become merely the handing over the counter of some ready-prepared nostrum, which he well knew was, if not a fraud, at least no better than he could have easily compounded. He not only lost respect for, and confidence in, physicians, therefore, but naturally turned his attention to something else. And so the ordinary drug store has become almost everything except a place for compounding physicians' prescriptions; and the pharmacist instead of being the assistant of the physician has become in too many instances his competitor. As the movement has progressed for more sane prescribing by physicians, the pharmacists have become interested and are moving for reform in their ranks. We have noted the organization of local branches of the American Pharmaceutical Association in Chicago and Philadelphia, and last week a similar organization was started in Washington, D. C. Our correspondent tells us that 23 out of the 39 Washington members of the American Pharmaceutical Association were present and that much interest was manifested. A temporary organization was effected, and a committee was appointed to draw up a constitution and by-laws and to communicate with the officers of the national and other branch associations.

The meeting of the Philadelphia Branch of the American Pharmaceutical Association, held April 24, at the College of Physicians, was largely devoted to a discussion of the relations existing between physicians and pharmacists with a view of bringing the latter in closer touch with and more in harmony with the ideas, ideals and present requirements of members of the medical profession. Among the subjects discussed were: "The Discontinuance of the Indiscriminate Renewal of Prescriptions," "Discouraging the Sale and Use of 'Patent Medicines' or Nostrums," and "The Desirability of Endorsing and Assisting the Council on Pharmacy and Chemistry of the American Medical Association." In speaking on the last subject, Henry Kraemer, professor of pharmacognosy in the Philadelphia College of Pharmacy, said:

> The importance of endorsing and assisting the Council on Pharmacy and Chemistry is such that I feel that it should be given due consideration at this time, and that this branch should go on record, at a very early date, as being in favor of the principles that are evolved. As is well known, the American Medical Association has instituted a Council on Pharmacy and Chemistry, whose object it is to inquire into and to report on the composition, claims and reliability of the proprietary preparations that are now being exploited through the medical profession. That some regulation of the present traffic in proprietary preparations is necessary, and desirable, is apparent when we remember that from a small and quite unostentatious beginning, less than three decades ago, the traffic in these so-called ethical proprietaries has increased and developed until to-day they rival "patent medicines" in number, and, if anything, excel them in the number and the variety of exorbitant claims and misleading statements.
>
> The object of this council is not to commend or to condemn proprietary medicines, but simply to point out the shortcomings and the errors in connection with the more objectionable articles and to enumerate, in a proposed book or pamphlet, such of the new and non-official remedies as meet with the several provisions of the rules that have been adopted for the guidance of the council. These rules, it may be added, are thoroughly in harmony with the constitution and the principles of the American Pharmaceutical Association, and it will not be necessary, therefore, to discuss them in detail at this time. Suffice it to say, that all that is required is the elimination of false and misleading statements from the labels and advertising matter and the publication, in place thereof, of demonstrable facts as to the composition, uses and limitations of the several preparations.
>
> That secrecy is not an absolute necessity for commercial success is evidenced by a large number of really excellent proprietary preparations, but is perhaps best illustrated by the successful and, at the same time, eminently honorable career of the late Dr. E. R. Squibb, who was for many years one of the most active and most highly respected members of the American Pharmaceutical Association.
>
> From his first venture in business, for himself, Dr. Squibb gave the fullest and most complete publicity not alone to his formulas, but also to the most minute details of his processes, and despite this liberality, or perhaps because of it, he was enabled to develop a huge and profitable business, that, in all of its various phases, was successful beyond the question of a doubt.
>
> It may, of course, be suggested that conditions have changed and that to-day it would be practically impossible to establish a successful enterprise on the lines followed by Dr. Squibb. This suggestion is best controverted by the fact that the American Medical Association has found it to be desirable to institute this advisory council to inquire into the status of several proprietary remedies that are now being offered with a view of eliminating, or at least restricting the sale of, such of the articles as do not meet with the requirements of the adopted rules.

Dr. Miles Medical Company vs. The May Drug Company.

The Pittsburg *Legal Journal*, April 11, 1906, gives the text of an important decision by Judge Macfarlane in the above case. The Miles Medical Company, to enforce its rule that its remedies should not be sold under a certain price, fixed by contract with certain retailers, brought suit in equity against the May Drug Company, proprietors of a cut-rate drug store in Pittsburg, who had obtained these remedies at reduced rate of Louis Hoechstetter, of Sehring, Ohio, thus causing him to break his contract and to injure the plaintiff. It appears that the Miles Medical Company manufactures and advertises certain remedies which it claims will cure affections of the heart and of the nervous system generally recognized as incurable, that it had spent about $2,000,000 in advertising, that its sales amount to over $500,000 each year and that it maintained a bureau of free medical advice, by which it pretended to make diagnoses of heart disease without physical examination and without seeing the patient. The plaintiff's representations that its remedies are a cure for heart disease, epilepsy and rheumatism are regarded by the court as untrue and calculated to deceive the public.

In regard to the law the opinion of Judge Macfarlane holds that the contract made with Hoechstetter is not in restraint of trade, and it seems that the defendants should be enjoined, but for other facts and conclusions of law. The false statements of the plaintiff, however, bar its action and its business as against public policy. Its advertisement of a cure for secret or venereal disease and for the cure of diseases peculiarly appertaining to females is contrary to Pennsylvania statutes and prevents it from obtaining relief in a court of equity.

The judge says:

> On the argument the position was taken generally that the vendor or manufacturer of a proprietary medicine whose ingredients were secret had no standing in a court of equity. When this suggestion was made on the preliminary hearing we had no evidence as to the plaintiff's products and mode of business other than the general testimony of its witnesses.
>
> The courts have frequently supported bills of such plaintiffs, but in many cases, no doubt, the question was not raised. On further consideration it is our opinion that the public health requires protection against these preparations and that the vendor of remedies of unknown ingredients advertised and sold as remedies for diseases should not be aided by courts of equity. If he sees fit to keep them a "trade secret" and to persuade the public to "dose" with his mysteries, let him not come into chancery.
>
> We take judicial notice of the facts of medical science which are known to intelligent persons, although not educated as physicians, but we need not go even so far in finding that the plaintiff can not cure incurable cases. Were it necessary for the disposition of this case we might go even further than we have in the fifth finding. The averment of the bill that their preparations "are intended to be and are a consistent comprehensive system of remedies and medicines," and "each of said remedies being indicated as a specific for certain kindred ills and diseases," may bear different constructions, but in its ordinary meaning is startling and needs something more than its statement to carry conviction.
>
> Although these defenses were not set up in the answer, when it appears that the plaintiff's business is based on misrepresentations or when it appears, as we find on examining the pamphlet sent out with its medicines, that it is violating a criminal statute and is conducting a business contrary to public policy, it needs no authority that it is the duty of the court to deny relief. . . .
>
> Its "medical experts" are attempting to prescribe at long range. The attempt to diagnose cases of heart disease, for example, without a physical examination can not be too severely reprobated. We do not need to be told by medical authority, our own knowledge informs us, that not only a careful examination but great skill is needed to detect the numerous valvular and other diseases of the heart. Further, any intelligent, thoughtful person knows that many of the symptoms listed by the plaintiff are caused by other diseases or disorders. For one sick to diagnose his own case is the

height of folly, yet this plaintiff advises the poor deluded victim to pass on subjects often baffling to the highest medical skill, to settle the disease and then to take "Dr. Miles' Nervine or Heart Cure" or some other high-sounding preparation of unknown ingredients, recommended in glowing "testimonials." . . .

The enormous business done by the proprietors of medicines and the serious menace which it is to the health and lives of the public require us to scrutinize carefully the ground on which the plaintiff stands, and as it has been shown that it belongs to a reprehensible class we decline to grant it a decree.

Societies Take Action.

At its regular monthly meeting, held April 11, 1906, the Warren County (Ky.) Medical Society passed the following resolution:

WHEREAS, Through the carelessness, negligence and ignorance of the doctors and people of this country and the criminal cupidity of certain low-grade drug manufacturing establishments the country has been flooded with nostrums, many of which are highly dangerous to innocent users, and many others entirely useless and inert, thereby causing harm to persons using them by delaying the proper treatment of their diseases; and,

WHEREAS, The American Medical Association has established a Council on Pharmacy and Chemistry, composed of eminent, disinterested pharmacists, whose duty is to analyze drugs and pharmaceuticals from reputable manufacturers, so that the profession may be properly advised of the constituents of such preparations. Now, therefore, be it

Resolved, By the Warren County Medical Association that we hereby endorse the creation of the Council on Pharmacy and Chemistry by the American Medical Association and its plans, rules and purposes, and that we pledge the people of Warren County that its physicians will not administer or prescribe any nostrum or medicament the exact contents of which are not known to all men.

A. T. MCCORMACK,
J. H. BLACKBURN,
E. RAU,
Committee.

At a meeting of the McLeod County (Minn.) Medical Society, held at Glencoe, April 12, a resolution was adopted expressing satisfaction with the work of the Council on Pharmacy and Chemistry on the nostrum evil and a desire for its continuance.

The Rutherford County (Tenn.) Medical Society, at its regular monthly meeting, held May 2, adopted the following resolutions:

WHEREAS, The Council on Pharmacy and Chemistry of the American Medical Association, acting by the authority of that organization, is carrying on a campaign of education regarding the use of nostrums by physicians, and is investigating the various products offered to physicians as remedial agents, the purpose of which is to defend the decency and dignity of the medical profession for the benefit of all the people against nostrum prescribing, advertising and selling. Be it therefore

Resolved, That the Rutherford County Medical Society heartily commends the work undertaken by the Council on Pharmacy and Chemistry of the American Medical Association; Be It Further,

Resolved, That the society condemns the practice of prescribing and advertising secret remedies of any kind, and be it

Resolved, That a copy of these resolutions be forwarded to THE JOURNAL of the American Medical Association.

At a meeting of the Waterbury (Conn.) Medical Association, held April 9, the following resolutions proposed by Dr. W. L. Barber were unanimously adopted:

Resolved, 1. That the members of the Waterbury Medical Association hereby agree to support with cordiality the efforts of the New Haven Medical Association in its campaign against the sale of all nostrums, and that we approve heartily the action of the American Medical Association in establishing the Council on Pharmacy and Chemistry for the purpose of investigating and reporting on all non-official drugs. 2. That we heartily commend the action of these journals, medical or secular, and will in every way help them in the educational campaign now being carried on against the manufacturing of all secret medicines or mixtures with unknown formulas.

The Auglaize County (Ohio) Medical Society, at a meeting held April 12, adopted the following resolution:

Resolved, That the Auglaize County Medical Society heartily endorses the stand taken by *Collier's Weekly* and the *Ladies' Home Journal* on the "patent medicine" fraud, and that we give them our support in the self-sacrificing fight that they are making to enlighten the public as to frauds as practiced by "patent-medicine" concerns, also that every member of this society should show his appreciation by becoming a subscriber to these two journals.

At a meeting of the San Luis Valley (Colo.) Medical Society, held April 20, resolutions were passed heartily endorsing the good work of the Council on Pharmacy and Chemistry in its fight against the nostrum and proprietary-medicine evil.

Similar resolutions were adopted by the Fifth District (Wis.) Medical Society at a meeting held at Brillon, April 12, and by the Dallas (Texas) Medical and Surgical Association.

Letters of Endorsement.

Dr. R. J. Owens, Will Spring, Mo., writes:

"I am heartily in sympathy with the Association in the war on the nostrum evil and am willing to contribute my energies in fighting it."

Dr. W. H. Woodworth, Delaware, Ohio, writes:

"We are pleased with your work and the crusade against frauds, although we have shown the fact poorly."

Dr. C. F. Engels, Ballard, Wash., writes:

"With full and cordial sympathy for THE JOURNAL'S efforts to enlighten the profession regarding the nostrum evil."

Dr. Calvin N. Weidner, Manchester, Conn., writes:

"I am very much pleased with the stand THE JOURNAL has taken on the "patent medicine" and proprietary drug business. I think your articles on "The Physician and the Pharmacopeia" are excellent and very helpful, as they contain the kind of knowledge none of us can have too much of. If we as practitioners understand our pharmacopeia as we should, the proprietary firms with their wonderful mixtures and free samples would find a barren field in which to labor. It is to our everlasting shame that we let them teach us our materia medica."

Dr. W. J. Wilson, Jr., Detroit, writes:

I wish to compliment the Association on the work it has done and is doing anent "patent" and proprietary medicines. It seems to me that at this juncture no greater service can be done for the rank and file of the profession. Some mud-slinging was to have been expected, but it will only serve to besmirch the hands of those who throw, and at the same time will display the position of the enemy. The Association is as much to be congratulated on its foes as on its friends. I am sure that the Association will win in this contest and will secure great additions to its membership as outsiders see evidences of its practical value in this way.

Insurance Examination Fees

The Minimum Fee.

At the annual meeting of the Montgomery County (Md.) Medical Society, April 17, a resolution was adopted fixing $5 as the minimum fee to be charged for examining an applicant for life insurance, when a full examination is required.

The Fee Problem in 1870.

It may be of interest at this time to quote from the minutes the following preambles and resolutions adopted by the American Medical Association at its meeting held in 1870 at Washington, D. C.:

"On motion of Dr. C. T. Collins, of Massachusetts, the following was unanimously adopted:

"WHEREAS, The business of life insurance has already become one of great magnitude in the United States, and is daily increasing in importance, affording large profits to those interested; and

"WHEREAS, The responsibility assumed by the medical examiners does not seem to have been heretofore properly appreciated by the different companies; therefore,

"*Resolved*, That this association recommend that the sum of five dollars should be the lowest amount charged for every such examination." (Tr., vol. xxi, 1870, p. 34.)

Fees for Life Insurance Examinations.

BROOKINGS, S. D., March 31, 1906.

To the Editor:—I enclose a letter from the medical director of the Mutual Life Insurance Company of New York, and a copy of my answer. It seems to me that it is high time that the profession should take some concerted action in matters of this kind. Therefore, I wish, through the columns of THE JOURNAL, to appeal to the medical profession of the United States to refuse to be dictated to in any such manner. An opportunity is before us to demonstrate that skilled medical service is not to be bought in the open market like pork.

J. G. PARSONS.

THE MUTUAL LIFE INSURANCE COMPANY OF NEW YORK.

NEW YORK, March 27, 1906.

Dr. J. G. Parsons, President E. D. Medical Society, Brookings, S. D.

Dear Doctor:—Your favor of recent date replying to one which I wrote Dr. F. B. McGarvey, of Cavour, S. D., is at hand.

I enclose copy of the fee schedule which has just been put into effect in this company.

The practical significance of the new fee schedule lies in the fact that it reduces the average fee for a medical examination from $5 to something over $3; how much over three dollars the average fee will be, can not be stated now, for it depends on the number of applications in the larger amounts and also on the extra allowance of $1 for each additional specimen of urine obtained by order of the company. Under the old flat fee of $5 no extra allowance was made. This retrenchment looks like a small matter, but owing to the large number of examinations now made for this company, it will effect a substantial saving to the policy-holders. That statement is a sufficient reason for the company's desire to establish this new schedule.

Rigid economizing is now being done in all departments of the company, so that this retrenchment is only one of many. The medical examiner must bear in mind that his fee is paid by the policy-holders, even though his bill is presented to the company, for this company is not an impersonal corporation, but is a partnership in which every policy-holder participates, both in earnings and expenses. Do not think that the medical departent is practicing economy any more than all the other departments of the company. The heaviest reduction of expenses has occurred among the executive officers, where the president's salary has been reduced two-thirds, from $150,000 to $50,000, and the salaries of the other executive and administrative officers have also been reduced so that the saving effected in this one branch alone amounts to over $200,000. The allowance for advertising has been cut down from over $300,000 to $100,000. The cost of supplies has been reduced over $300,000. The agency expenses have also been materially reduced. The economies that have been and are being made in every department will represent a saving of over one million dollars this year.

The claim was made and substantiated during the recent investigation that too high a price was paid for new business. The company is endeavoring in every way and in every department to reduce this cost of new business, and the medical examiner must not feel that he is being singled out for economy, for such is not the case. Each department sympathizes with its own work and working force, but we are all loyally striving to put the company on such a basis that the charges of extravagance which were made during the late investigation will have no foundation hereafter.

This matter of the medical examiner's fee resolves itself into two questions:

First: Is the fee adequate compensation for the service rendered? It seems to be adequate when measured by the customary fees of competent physicians. This is certainly true of the physicians in country villages and smaller cities. In the larger cities, on the other hand, some physicians may get larger fees than these, and to them the compensation would be inadequate. We can not, however, discriminate among our examiners and pay a larger fee to the city examiner than we pay to the country practitioner, for this would be manifestly unfair to the latter. That the medical profession in this country regard the new fee schedule as adequate is shown by the fact that thus far we have had only 900 refusals as against over 12,000 signed acceptances.

Second: Will the company get satisfactory services for these fees? We have no doubt of this from the experience of other companies which have a graded fee schedule similar to this. This company was rather late in adopting a graded fee schedule. Other companies have had one in force for years.

In the early days of the company, the flat fee of $5 was a small extravagance which did not show owing to the limited number of examinations. Even ten years ago, the burden had become noticeable, though not to a marked degree, owing to the larger size of the application at that time. The medical department of this company resisted any modification of the flat fee of $5 until it was proven beyond question that it was extravagant, and that good service could be obtained for less.

I have written you thus fully to show you the justice of the company's position. Do you think it fair to discriminate against us by charging us $5 for an examination, while you charge considerably less for examinations for fraternal and assessment associations? Is this fair to a company like the Mutual Life, which is fraternal in the highest sense of the term? You surely do not give a less thorough examination for one of these organizations than you do for us? If you are going to be entirely fair in this matter, why do you not charge $5 for all insurance examinations?

I shall be very glad to hear from you further in this matter.

BRANDRETH SYMONDS, M.D.
Medical Director.

BROOKINGS, S. D., March 31, 1906.

Dr. Brandreth Symonds, Medical Director, Mutual Life Ins. Co., New York:

Dear Doctor: I have your letter of the 27th inst. at hand. I note the position you take in regard to the matter, and while it does not concern me personally, I think I voice the sentiment of the physicians in this part of the country when I make reply to the following statements:

The matter of economy in the expenses of your company is not exactly a good matter to discuss here. The relative value of the services actually rendered by Mr. McCurdy and your medical examiners considering the remuneration received, is better discussed elsewhere. The value of medical services rendered is the only thing we have to discuss.

A carefully made life insurance examination is worth $5 if it is worth a penny. It is the safeguard which stands between the company and a possible loss of thousands. The company can not afford to take even a thousand dollar chance in debating over five. Compared with examinations made in practice generally, you must admit that there is here no opportunity for repeated observations. The examination must be made with the greatest care, and time taken to gather all the desired information at once. The report calls for the exercise of professional judgment and greatest accuracy in detailed statements. All these things are of unquestioned value, and are worth, as stated before, $5 if worth a penny.

I do not believe you will get as satisfactory service when you cut your fee from $5 to $3. I make this statement with all respect to medical men everywhere; but I know them to be human, and not necessarily disposed to become altruistic to the extent of two dollars' worth when a business institution like the Mutual Life cuts off two dollars from a reasonable fee under the pretext of "saving." I have a somewhat exteaded medical acquaintance, most of whom are men whom I highly respect as men and physicians. I think nearly all of them would admit to me in private conversation (as many have) that the services rendered for an inadequate fee do not compare favorably with those rendered for a reasonable compensation, pure charity, of course, excepted.

That this feeling is prevalent among medical men the country over may be inferred from their attitude toward lodge and contract practice. As regards fraternal examinations, I am surprised that an old line company should consider itself in the same class as a fraternal. We are usually given to understand that they are nosafe concerns. I believe that physicians generally give fraternal companies their money's worth, and no more. The bulk of the work done for fraternals is done in "classes," and practically all the writing is done by the "deputy" before the examiner sees the applicants. The actual work done by the examiner is small, and usually very superficial at that. A "deputy" of one fraternal society told me a "good joke" on one of their examiners who had forwarded to the medical director a bunch of twenty-five examinations of a "class." These reports were all returned to the examiner for reconsideration because the specific gravity of the urine in every case was 1020. A rather abnormally normal class! This illustrates the disposition on the part of the examiner to give the *money's worth.* Failure to be careful in details may mean overlooking a vital point in an examination.

You practically admit that you expect greater care in examination when greater fees are paid. You pay $7.50 for examination when the application is for $25,000. You expect just as careful examination for $3.00 when the application is for only $1,000. This extra fee is surely not a gratuity. In five hundred examinations you would save $1,000, but you would run the risk of letting in several poor risks which would make your loss far greater than your saving, by getting only three dollars' worth of examination in cases that needed five dollars' worth.

You mention the fact that under your new schedule of fees the average of fees received would be raised by examining applicants for larger amounts. This would hardly affect the country doctors. They have few opportunities to examine applicants for large amounts. It is largely the fault of the profession that they have not been sufficiently organized to demand higher standards of work and fair fees.

In the case of this society you have an example of an effort to bring about this result. Accordingly, we have made an item in our fee bill placing the minimum fee for life insurance examination at $5. I believe that the physicians of the whole country feel about this matter as we do, but, owing to lack of proper organization have not met the proposition as we have. If the reputable physicians of the United States stood together it would not be possible for any insurance company to take advantage of the curtailing of expenses enforced by recent exposures, to compel their examiners to accept two dollars less than a reasonable fee for their work.

J. G. PARSONS,
President Eastern Dakota Medical Society.

Medical Legislation

Favor Army Medical Reorganization Bill.

At the recent bi-monthly meeting of the Blair County (Pa.) Medical Society at Altoona the following resolutions were adopted:

Resolved, That the Blair County Medical Society believes it is the duty of our government to establish a national health organization and that congress be urged to aid such organization in every proper way in the prosecution of its duties in improving and protecting the public health.

We further trust, by the union of all now existing public health services, soon to have a department of public health with representation in the president's cabinet.

Resolved, That a copy of these resolutions be furnished our United States senators, Hon. Boies Penrose and Hon. Philander C. Knox and Hon. John M. Reynolds, our representative in Congress, with the request that they use every honorable effort to secure the passage of all laws favorable to this subject.

The second resolution was adopted as follows:

WHEREAS, We believe that the present Medical Corps of the Army is entirely inadaquate to look after the health and welfare of our Army in time of war, and that it should be increased to furnish our Army with an adequate number of physicians and surgeons, trained in the care of large bodies of men in camp life and on the march; therefore be it

Resolved, That we urge on our United States senators, Hon. Boies Penrose and Hon. Philander C. Knox and our congressman, Hon. J. M. Reynolds, at Washington, the importance of upholding the army medical reorganization bill and request that they do all in their power to secure the passage of the same.

This resolution was also adopted:

Resolved, That we urge on our United State senators, Hon. Boies Penrose and Philander C. Knox, and congressman, Hon. J. M. Reynolds, that they use all honorable efforts to secure the passage of such laws as will tend to establish institutions for the separate care and treatment of indigent consumptives.

Urge Passage of Pure-Food Bill.

The Elbert County (Ga.) Medical Society, at its regular meeting, March 3, 1906, adopted the following resolutions. A copy has been sent to each member of the House from Georgia:

WHEREAS, There is now pending before the House of Representatives, an act for preventing the adulteration or misbranding of foods, or drugs, and for regulating traffic therein, and for other purposes; and as we believe that such an act is absolutely necessary for the public health; therefore be it

Resolved, By the Elbert County (Ga.) Medical Society, that our representatives in Congress from Georgia are hereby respectfully requested to vote for said bill.

Resolved further, That a copy of these resolutions be sent to each representative from Georgia in Congress.

Correspondence

A Further Note on the Antiseptic Properties of Sodium Aurate.

BOSTON, April 30, 1906.

To the Editor:—In THE JOURNAL, Jan. 27, 1906, I described a non-irritating antiseptic solution, the active constituent of which was believed to be sodium aurate. I showed that this solution possessed strong bactericidal power and that its action was not appreciably affected by the presence of albumin. At that time the antiseptic had been used clinically in only a limited number of cases, but had given most encouraging results. Since then, it has been used in a larger number of cases, and I find that while it is effective in case of acute catarrhal conjunctivitis, its action in severe cases of gonorrheal ophthalmia is disappointing. The cases of the latter affection on which it was first tried were probably of a mild type, and no doubt would have done equally well under the usual methods of treatment. In several of the later cases, even after frequent and prolonged use of the antiseptic, the secretion showed an abundance of gonococci, both in pus cells and in desquamated epithelial cells. It seemed evident, therefore, that the antiseptic either did not penetrate the tissues or that its action was inhibited by the tissue fluids. I find that the latter is the correct explanation. When the 1 per cent. solution is mixed with an equal quantity of human serum (hydrocele fluid) its bactericidal power is immediately and completely destroyed, although no visible reaction takes place. This fact no doubt also explains the non-irritating property of the antiseptic. The test was not previously made because similar tests with egg albumin seemed to render it unnecessary.

The unsatisfactory results attending the treatment of gonorrheal ophthalmia with protargol and argyrol are no doubt to be attributed to a similar cause. I have already shown that argyrol is rendered ineffective by egg albumin; in fact, is precipitated by it when the latter is added in sufficient amount. I have since found that protargol, although not precipitated by albumin, is likewise rendered ineffective by it. Hydrocele fluid does not precipitate solutions of either of these preparations, but nevertheless inhibits their action when added in sufficient amount to satisfy them.

It seems unlikely, therefore, that sodium aurate can be of much real value in the treatment of gonorrheal ophthalmia or gonorrheal urethritis. It is possible that it might reduce the frequency of corneal infection, but this would require a large series of cases to determine. There is no doubt, however, that it is effective in other forms of conjunctivitis, probably because it prevents constant reinfection of the tissues. Whether or not it is more effective than protargol for this purpose I am not yet convinced. It would seem to be a satisfactory antiseptic for the conjunctival sac to be used preliminary to operations, for which purpose I now employ it.

F. H. VERHOEFF.

Colloidal Silver.

NEW YORK, March 26, 1906.

To the Editor:—The article on "The Pharmacopeia and the Physician," in THE JOURNAL, March 24, 1906, contains the following surprising passage:

"Credé some years ago introduced a soluble form of metallic silver, for which certain manufacturers make the fabulous claim that it is an efficient disinfectant of blood and tissue. So long as septic diseases resist all treatment, it seems strange that reputable manufacturers will make such obvious misstatements."

In the same issue (page 909) you print an abstract of a report by Prof. Solis-Cohen, recording striking results from colloidal silver in endocardites and associated sepses, bronchopneumonia with pronounced meningeal symptoms, etc. That the claim of efficacy for colloidal silver is by no means "fabulous" is shown by a literature of more than 250 publications, with contributions by such men as Profs. Roswell Park, Warren Coleman, G. T. Harrison, D. L. Edsall, H. N. Vineberg, Edward Speidel, A. Jacobi, Frank Allport, C. S. Bacon, N. S. Davis, F. Forchheimer and many others. That colloidal silver produces profound physiologic effects is shown by such researches as those of Bamberger, Beyer, Schade, Rodsewicz and Robin. The last-named writes in International Clinics, 1905, volume III, that the colloid metals exert a powerful catalytic action like that of the organic diastases and are destined to take a prominent place in functional therapeutics.

While colloidal silver is no such powerful bactericide as the salts of silver, it most assuredly does accomplish blood and tissue disinfection by an inhibitory effect on germ growth, by its electro-catalytic properties, and by its leucocytogenetic action, if it is not used too late.

In view of these facts, the assertion that our claims for colloidal silver are "fabulous" and "obvious misstatements," is unjustified.

SCHERING & GLATZ.

The Association Button.

NEW ORLEANS, April 26, 1906.

To the Editor:—I hope that you will again and again urge the advisability of every member wearing the button, for by this means the public will soon learn to distinguish us from the many irregulars who infest every large city and call themselves doctors. Besides, the constant sight of these buttons will give the wearers power and influence in the public eye.

T. S. DABNEY, M.D.

CINCINNATI, April 24, 1906.

To the Editor:—The letter of Dr. Fletcher Ingals in THE JOURNAL meets with my hearty approval. There certainly should be a spirit of fraternity among physicians both at home and abroad, and especially so among members of the American Medical Association. I am surprised that the button is not more worn at other times than at the annual sessions.

E. S. McKEE, M.D.

What's the Difference?

CHICAGO, ILL., April 26, 1906.

To the Editor:—The following advertisement, which has appeared in various papers, was taken from *Life* for April 5, 1906, where it appeared along with advertisements of corsets, Scotch whisky and other such things:

WILL YOU TRY THE BATTLE CREEK LIFE FOR 30 DAYS?
WILL YOU EAT THE FOODS AND LIVE THE LIFE OUR EXPERTS RECOMMEND?

Do You Really Want to Be Perfectly Well?

Tell us, then, if you are ailing, or if in good health that you wish to remain so. Let us send you our book. It is very interesting. The life it recommends you can live in your own *home*. You ought to read about it. Nowhere else are so many specialists studying this one thing alone: how to get well and how to *stay* well. No organization anywhere has been so successful. None other is so near the truth. And the basis of all this is right food, right living, keeping the stomach right. All this we can explain in our book—explain clearly, logically, interestingly, so that you may *understand*. Isn't it worth the mere effort of writing us simply to know? Won't you ask for our book to-day? Address the Battle Creek Sanitarium Co., Ltd., Dept. A 191, Battle Creek, Mich.

Suppose you or I should insert in *Life:*

WILL YOU TRY MY TREATMENT FOR THIRTY DAYS?

Tell me if you are ailing or if (preposterous question)* you want to remain in good health.

Let me send you my book. The life it recommends you can live in your own home (by buying my things).

Nobody else is studying so thoroughly or has been so successful in solving the problems of how to get well and how to keep well. None other (than my earnest self) is so near the truth. (And doesn't this have the old familiar sound of the

* As the critics would say the parentheses are mine.—W. A. P.

letter-press that accompanies the picture of the gentleman in the orator's attitude in the advertisements we see in the daily papers?)

All this I explain in my little book, clearly, logically (and plausibly). Isn't it worth the effort of writing to know? (And isn't that like the gentleman with cures for this, that and the other who beseeches you to write him and wants to know if it isn't worth a postal card to get well?) Won't you write to-day (for if you put it off you are apt to forget it and I may be the loser, if you are not.) Address (so that I can keep track of my ads), Dept. X.

Suppose you or I perpetrated that sort of stuff on the community? What would be thought of us?

W. A. Pusey.

Warning Against Fraudulent Insurance Agent.

Summerville, S. C., April 27, 1906.

To the Editor:—If you will give publicity to the following you will do our profession a great service and aid in placing in the penitentiary one of the nerviest thieves in America. A man, six feet in height, with stubby, iron-gray moustache, large gray eyes with a decided outward and downward slant, rather prominent eyeballs, hair slightly curly, iron gray and rather thin over the forehead and on top of the head, weighing 260 pounds and about 60 years of age is traveling the country over, purporting to be an agent of the Columbian National Life Insurance Company. He has swindled a number of physicians in Charleston by the following scheme: He shows credentials as agent of the company and offers to appoint his intended victim a medical examiner and sell him stock of the company at a reduced price, representing that the stock is salable only to policy-holders and examining physicians, who can each purchase as many as four shares if they like, without being obliged to take a policy with the company. The unwary physician gives his check or $30 in cash, for which he receives a receipt agreeing to deliver stock of the American Investment Securities Company. The Columbian National Life Insurance Company repudiates him and asks for his arrest if seen again. He left Charleston, giving Asheville, N. C., as his destination.

A. H. Hayden.

Association News

THE BOSTON SESSION.

Railroad Rates—Limits of Tickets—Stop-over Privileges—Hotels—Other Announcements.

The last issue of The Journal was the Boston number, containing some twenty pages of pictures and descriptive matter of interest to those who will attend the fifty-seventh annual session of the American Medical Association at Boston, June 5-8, 1906. Some additional information is given below, and if any other announcements are received later they will appear in subsequent issues of The Journal.

Hotels.

The chairman of the Committee on Hotels, Dr. Charles Harrington, 8 The Fenway, Boston, calls attention again to the announcement of hotels which appeared in The Journal last week. It will be to the advantage of all who wish accommodations in Boston to write at once, giving particulars, so that reservations may be made for them. The committee announces that in addition to the hotels specified there are many others of excellent quality, as well as many boarding houses, where members will find pleasant accommodations. The committee will assign rooms in accordance with the wishes of those who write to them.

Loan Exhibit of Portraits of Ophthalmologists.

It has been decided to hold a loan exhibit of portraits of ophthalmologists in a hall adjacent to the amphitheater in which the Section on Ophthalmology is to meet. Members of the section, and others, are requested to co-operate in making this exhibition as large and representative as possible by forwarding by mail or express, to the Williams & Everett Company, 190 Boylston Street, Boston, any portraits (etchings, photographs, line engravings, paintings, etc.) of deceased ophthalmologists (especially Americans) that they may possess or can borrow for this purpose. The Williams & Everett Company will receive, unpack, care for and reship, without expense, any portrait so loaned. Credit will be given the lender, whose name should appear on or be attached to each portrait. When possible portraits should be forwarded without frames. From the pictures thus loaned it is expected to choose those that will best serve the purpose of the exhibit and to issue a catalogue to be distributed the first day of the session.

Pacific Coast August Return Limit Canceled.

The Transcontinental Passenger Association has withdrawn its proposed final return limit of August 31. The limit of all tickets will, therefore, be July 15.

Return Limit Extended.

As announced in The Journal last week, the final return limit of the Boston tickets, instead of June 30, will be July 15. Ordinarily the ticket will require the holder to leave Boston by June 18 after having had the ticket validated by the joint agent. To have the ticket extended it must be deposited with the agent not later than June 18, and it can be obtained just before departure.

Stop-over at New York.

Stop-over at New York may be obtained on the return trip on tickets reading via New York on these conditions:

1. The ticket must be validated by the joint agent at Boston.

2. The ticket must be deposited by the original purchaser in person with the joint agent at New York not later than one day after validation at Boston. (A fee of $1 is required.)

3. The passenger will call at the New York validating office for the ticket not more than two hours before the departure of the train out of New York (except that if trains leave after 6 p. m. and before 9 a. m. ticket will be delivered before 6 p. m.).

Note.—Ticket will not be good leaving New York later than the day following the date of leaving Boston unless stop-over certificate is secured. For example, one who leaves Boston on Friday, reaching New York Saturday morning, could stop off in New York until the evening of Saturday, but no longer without securing a stop-over certificate.

Those who wish to stop off at New York and whose tickets do not read via New York should consult the agents of their railroads or the railroad officials at Boston for arrangements for this privilege.

Validating Agencies.

The Boston validating agent is Mr. P. H. Gallaher, 63 Federal Street, corner of Franklin. Office hours, 8 a. m. to 6 p. m. daily up to July 15 inclusive, except Sunday, when office hours will be from 12 noon to 5 p. m.

The New York joint agent is Mr. W. F. Holwill, 182 Fifth avenue, New York. His office hours are 8 a. m. to 6 p. m. daily.

Rates and Dates of Sale.

The rate to Boston is one fare plus $1 for the round trip from territory east of the Mississippi River. Tickets will be on sale from May 31 or June 1 to June 9 in Central Passenger Association territory, but purchaser must not reach the gateways of the New England Passenger Association earlier than June 2 and must not arrive in Boston later than noon of June 12. Date of leaving Boston will not be earlier than June 2. (The return limit has been detailed above.)

Any One May Purchase Tickets.

Inquiries are received as to who may purchase tickets. These rates are open to any one, whether a physician or not.

An Ocean Trip to Boston.

Special excursion tickets are offered on boats of the Merchants' and Miners' Transportation Company, of Baltimore, between Boston, New York, Baltimore, Norfolk, Old Point Comfort, etc. A special round-trip from Baltimore to Boston is offered, going by way of Albany, Hudson River day line to New York and thence by rail to Baltimore at a rate of $24.55.

For further information address Mr. W. P. Turner, general passenger agent at Baltimore; also see below under the Baltimore & Ohio Railway.

Trains and Routes.

THE JOURNAL last week gave in brief the advantages of several special trains to Boston. The New York Central lines run a special train, with the finest possible equipment, from Chicago at 10:30 a. m., Sunday, June 3, to arrive at Boston at 2 p. m., Monday, June 4. Particulars of this train may be secured from Mr. L. F. Vosburgh, general western passenger agent, room 529 La Salle Street Station, Chicago. The committee on transportation of Chicago Medical Society has selected this train and this insures an enjoyable party. On tickets reading via this line stop-over of ten days at New York may be secured on the return trip, and these tickets will be accepted on the Hudson River day line steamers between Albany and New York in either or both directions, also on the steamers of the Cleveland and Buffalo Transit Company between Buffalo and Cleveland on return trip.

The Canadian Pacific offers a beautiful trip through the Thousand Islands, Canada, Quebec, the White and the Green Mountains. Further particulars may be had from Mr. A. C. Shaw, general passenger agent Canadian Pacific Railroad, Chicago.

The Wabash Railroad special train leaves Chicago, Sunday, June 3, at 10:30 p. m., and will reach Boston, Tuesday, June 5, at 7 a. m. For particulars address Mr. F. H. Tristram, assistant general passenger agent, 97 Adams street, Chicago.

The Baltimore & Ohio Railroad announces its regular trains through Philadelphia, Washington and New York, with stop-over privileges. Arrangements are made for a steamboat ride from Baltimore to Boston on the Merchants' and Miners' steamers, mentioned above, for $20 from Chicago to Boston and return. A neat booklet, which gives full details as to rates, routes, etc., has been issued by the Baltimore & Ohio Railroad, which can be had on application to W. W. Picking, district passenger agent, 244 Clark Street, Chicago.

Our wideawake Missouri Valley doctors expect to have a special train in two sections to run through the beautiful Grand Trunk Railway scenery, including the St. Lawrence River by boat. Through cars for this train will leave Missouri River points on the evening of May 31. The special trains will be formed in Chicago, leaving June 1 at 3 p. m. The arrival in Boston will be June 4. Further particulars of these trains may be had from Mr. George W. Vaux, assistant general passenger agent, 135 Adams Street, Chicago, or Dr. Charles Wood Fassett, St. Joseph. The latter emphasizes the advantage of this train in its early arrival in Boston.

The Commercial Exhibit at Boston.

The Committee of Arrangements expects to have a Commercial Exhibit at the Boston Session which will be one of the features of the gathering. Special pains have been taken to have this an assemblage of exhibits not only by firms which have sought the privilege, but by firms representing all the lines of manufacture and sale in which physicians would be at all interested. Quantity and mere display are to be disregarded and quality and representative character have been secured. According to the announcement of the committee in the *Boston Transcript*, the medical book display is to have a historical side as in addition to the usual elaborate display of books, a great collection of pictures, rare books, historical documents, etc., will be exhibited. In the drug line, manufacturing chemists will not content themselves with showing the preparations alone, but will exhibit methods of manufacture and use. The surgical instrument department will, it is said, outdo in interest all of its predecessors.

"Another extremely important exhibit, important especially to physicians, will be the automobile show, and it is expected that a special exhibit of physicians' carriages will stand opposite by way of comparison."

"Those having the arrangements of the exhibit in charge are making every effort to have it as practical, suggestive, useful and advantageous as possible to all concerned. A determined effort also is being made to attract only responsible firms."

NEW MEMBERS.

List of new members of the American Medical Association for the month of April, 1906:

ALABAMA.

Ballard, I. C., Gadsden.
Battle, J. K., Eufaula.
Beard, J. S., Troy.
Bowman, J. L., Union Springs.
Copeland, B. G., Birmingham.
Craddock, F. H., Sylacauga.
Fitts, Alston, Tuscaloosa.
Ison, H. L., Gadsden.
Killian, A. D., Holt.
McGeehee, H. T., Morris.
Moore, L. H., Orrville.
Morland, H. C. Birmingham.
Pornell, J. K., Reform.
Quin, W. E., Ft. Payne.
Robinson, E. M., Birmingham.
Wilkinson, J. E., Jr., Prattville.

ARIZONA.

Graham, R. W., Prescott.
McDonnell, J. K., Crown King.

ARKANSAS.

Cowger, Robert, Danville.
Fletcher, B. A., Augusta.
Greene, L. O., Pea Ridge.
Logan, B. C., Morrilton.
Reiser, G. F., Thornton.
Robinson, F. C., Henzen.
White, R. L., Little Rock.

CALIFORNIA.

Austin, S. A., Los Angeles.
Carlson, C. H., San Francisco.
Cornish, E. J., La Moine.
Culver, J. T., Oak Park.
Dickson, C. S., Riverside.
Farnum, C. E., San Francisco.
Frasse, I. N., San José.
Jackson, W. J., San Francisco.
Johnson, A. W., San Francisco.
Johnson, W. S., San Francisco.
Kizer, W. H., Ocean Park.
Lorini, R., Coronado.
Newton, J. C., San Francisco.
Ponge, C. A., Colusa.
Potts, R. D., Oxnard.
Putnam, H. A., Inglewood.
Royal, A. B., Pasadena.
Saylor, B. F., French Gulch.
Whitman, C. H., San Francisco.

COLORADO.

Barrett, G. W., Greeley.
Buchanan, F. G., Denver.
Dowling, J. T., Sopris.
Gilmore, G. B., Colorado City.
Hutchinson, A. F., Durango.
Jones, N. W., Kersey.
Leisenring, P. S., San Diego.
McKinnie, L. H., Colorado Springs.
Nordlander, A. G. E., Leadville.
Ray, J. C. B., Denver.
Reed, W. W., La Junta
Wood, Lucy M., Boulder.

CONNECTICUT.

Driscoll, D. M., Bridgeport.
Downs, F. B., Bridgeport.
Sanford, W. H., New Haven
Smith, Charles, Riverside.

DISTRICT OF COLUMBIA.

Copeland, E. P., Washington.
Gleason, J. K. P., Washington.
Hull, T. Y., Washington.
Jones, T. G., Washington.

William H. Weir, M.D. (Examination, Ohio), died at his home in Edinboro, Ohio, April 27, aged 68.

Book Notices

BODILY DEFORMITIES. The Nature, Causes, Variety and Treatment. A Series of Lectures. By E. J. Chance, F.R.C.S. Edited by J. Poland, F.R.C.S. Second Edition, in two volumes. Vol. I. Cloth. Pp. 315. Price, 6s. net. London: Smith, Elder & Co., 1905.

The appearance of a second edition of a medical work over 50 years after the publication of the first edition is in some respects a rather noteworthy event in medicine, but in the present instance it will probably be welcomed by orthopedic specialists and others. These lectures are certainly interesting reading and Chance's views, if not always altogether modern, were generally original and sensible considering the time of their announcement. One of the notions which he combated is not yet as extinct as it probably ought to be, namely, that of the specific effect of maternal impressions on the fetus. Even his 1905 edition calls it "still *sub judice*." If for nothing else, the book is valuable as the statement of the views of an old authority whom no specialist ought to ignore. The editor has reproduced the peculiar capitalization in some of the lectures; he has not attempted to change the characteristic style, but has simply omitted obsolete tables and notes and added such modern comments as seemed to him appropriate.

THE MODERN MATERIA MEDICA. The Source, Chemical and Physical Properties, Therapeutic Action, Dosage, Etc. Cloth. Pp. 306. Price, $1.50. New York: The Druggists' Circular, 1906.

With a view of affording the pharmacist some information concerning the many new remedies constantly brought to the attention of the medical profession the *Druggists' Circular* has published brief descriptions of these from time to time, which are now offered in book form. This list is arranged in alphabetic order and being a rather comprehensive one, will prove of interest to the pharmacist who is constantly called on to dispense medicines otherwise unknown to him; it will also interest the physician who attempts to keep informed of the new substances exploited to the medical profession. Unfortun-

ately, the book is, in the main, merely compiled from the literature furnished by the dealer and manufacturer: hence it does not give the information regarding certain remedies which one might expect from the introduction, which states that this publication was undertaken "with a view of affording a source of accurate and unbiased information."

State Boards of Registration

COMING EXAMINATIONS.

OREGON State Board of Medical Examiners, Portland, May 10-12. Secretary, Byron E. Miller, Portland.

KENTUCKY State Board of Health, Galt House, Louisville, begins May 15. Secretary, J. N. McCormack, Bowling Green.

INDIANA Board of Medical Registration and Examination, Indianapolis, May 22-24. Secretary, W. T. Gott, Indianapolis.

NEW YORK State Boards of Medical Examiners, Albany, May 22-25. Secretary, Charles F. Wheelock, Albany.

ILLINOIS State Board of Health, Coliseum Annex, Chicago, May 23-25. Secretary, J. A. Egan, Springfield.

NEBRASKA State Board of Health, State House, Lincoln, May 29-30. Secretary, George H. Brash, Beatrice.

Oklahoma March Report.—Dr. J. W. Baker, secretary of the Territorial Board of Medical Examiners, reports the written examination held at Guthrie, March 28, 1906. The number of subjects examined in was 12; total number of questions asked, 90; percentage required to pass, 66.6 in each branch. The total number of candidates examined was 22, of whom 16 passed and 6 failed. The following colleges were represented:

College.	PASSED. Year Grad.	Per Cent.
Rush Med. Coll.	(1882) 76.5; (1889)	73.2
Southern Med. Coll., Atlanta	(1891)	68.6
Medical School of Maine	(1899)	83.7
McGill University	(1902)	89.8
Albany Med. Coll.	(1900)	87.1
University of Iowa	(1891)	74.7
University of Louisville	(1903) 68.2; (1905)	70.4
Michigan College of Med. and Surg.	(1896)	76.1
Vanderbilt University	(1903) 76.2; (1905)	76.6
University of Buffalo	(1901)	82
Undergraduate*		
Ft. Worth University	(1900)	75
Hospital Coll. of Med., Louisville	(1890)	80

	FAILED.	
Meharry Med. Coll.	(1895)	67.4
University of Louisville	(1881)	59.5
Rush Med. Coll	(1874)	65.8
Marion-Sims Beaumont Med. Coll.	(1905)	64.7
Barnes Med. Coll.	(1901)	65
Grant University, Chattanooga, Tenn.	(1891)	20

* Has been engaged in practice for 21 years.

Rhode Island April Report.—Dr. Gardner T. Swarts, secretary of the Rhode Island State Board of Health, reports the written examination held at Providence, April 5, 1906. The number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 75. The total number of applicants examined was 18, of whom 8 passed and 10 failed, including one non-graduate. The following colleges were represented:

College.	PASSED. Year Grad.	Per Cent.
University of Naples, Italy	(1905)	75
Yale University	(1905)	80.1
College of P. and S., New York	(1902) 82.1; (1904)	82.6
Baltimore Med. Coll.	(1905)	81.8
Harvard University	(1904) 78.5,	90.1
Rush Med. Coll.	(1903)	80.6

	FAILED.	
Baltimore Med. Coll.	(1901)	65.9
College of P. & S., Boston	(1905) 68.1,	73.1
Kentucky School of Medicine	(1904)	62.6
Laval University	(1905) 55.6,	68.4
Tufts College Medical School	(1905)	71.6
University of Naples, Italy	(1890)	56.4
University of the South	(1905)	61.0
Non-graduate		55.4

Utah April Report.—Dr. R. W. Fisher, secretary of the Utah State Board of Medical Examiners, reports the written and oral examination held at Salt Lake City, April 2-3, 1906. The number of subjects examined in was 19; total number of questions asked, 85; percentage required to pass, 75. The total number of candidates examined was 8, of whom 5 passed and 3 failed. The following colleges were represented:

College.	PASSED Year Grad.	Per Cent.
Northwestern University	(1904) 85; (1905)	86
College of P. and S., Chicago	(1900)	87
University of Colorado	(1905)	81
Chiba Med. Coll., Japan	(1903)	75

	FAILED.	
Baltimore University	(1902)	*50
University of Kansas	(1904)	74
St. Louis University	(1905)	73

* Took only 9 subjects.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending May 5, 1906.

Flagg, Chas. E. B., asst.-surgeon, reports arrival at San Francisco, Cal., with 14th Infantry, for temporary duty, from Vancouver Barracks, Washington.

Allen, John H., asst.-surgeon, left Fort Sill, Oklahoma Territory, en route to San Francisco, Cal., for temporary duty.

Connor, C. H., asst.-surgeon, reported for temporary duty at Army Medical Supply Depot, General Hospital, Presidio of San Francisco, Cal., from leave of absence.

Kieffer, Charles F., surgeon, ordered to accompany 11th Infantry from Fort D. A. Russell, Wyoming, to San Francisco, Cal., for temporary duty.

Noble, R. E., asst.-surgeon, ordered to proceed immediately from Fort Casey, Washington, to San Francisco, Cal., for temporary duty.

Devereux, J. R., asst.-surgeon, left Fort Logan, Colo., en route to San Francisco, Cal., for temporary duty.

Banister, John M., deputy surgeon-general, ordered to proceed from Fort Riley, Kans., to General Hospital, Washington Barracks, D. C., for observation and treatment.

Whitcomb, C. C., asst.-surgeon, granted ten days' leave of absence on completion of examination for advancement.

Flagg, Chas. E. B., asst.-surgeon, ordered to report in person to Lieut.-Col. Geo. H. Torney, deputy surgeon-general, president, examining board, at the Presidio of San Francisco, Cal., for examination to determine his fitness for promotion.

Page, Henry, asst.-surgeon, reported at Army General Hospital, Presidio of San Francisco, Cal., for temporary duty, from Philippines Division.

Noble, R. E., asst.-surgeon, reported for temporary duty, Medical Supply Officer, Golden Gate Park, San Francisco, Cal.

Reno, Wm. W., asst.-surgeon, left Fort Riley, Kans., on ten days' leave.

Boyer, P. L., asst.-surgeon, left Fort Sam Houston, Texas, with Second Squadron, 1st Cavalry, en route to San Francisco, Cal., for temporary duty.

Woodbury, Frank T., asst.-surgeon, reports his arrival at San Francisco, Cal., for temporary duty, returning to Philippine Division from leave.

Lewis, William F., asst.-surgeon, in addition to his other duties will take charge of the office of the chief surgeon, headquarters Department of the Lakes, Chicago, Ill.

Mason, George L., dental surgeon, ordered from Fort Morgan, Ala., to Fort McPherson, Ga., for duty.

Whinnery, Jean C., dental surgeon, left Fort Lawton, Washington, and arrived at Vancouver Barracks, Washington, for duty.

Ware, William H., dental surgeon, left Fort Wingate, N. M., on leave of absence for one month.

Hogan, David D., and Springwater, Samuel A., contract surgeons, recently returned from Philippines Division, have been assigned to temporary sanitary duty at San Francisco, Cal.

Tuttle, George B., and Porter, Elias H., contract surgeons, recently returned from Philippine service, have been assigned to temporary duty at the Presidio of San Francisco, Cal.

Cass, William E., contract surgeon, ordered from Vancouver Barracks, Wash., with the 14th Infantry to San Francisco, Cal.

Kuhn, Charles F., contract surgeon, ordered from Fort Lawton, Wash., with Companies B and D, 10th Infantry, to San Francisco, Cal.

Felts, Robert L., contract surgeon, granted leave of absence for one month, with permission to apply for extension of one month ten days.

Kovle, Fred T., contract surgeon, left Fort Bliss, Texas, for duty at Fort McDowell, Cal.

Brown, Wilmont E., contract surgeon, left Fort Walla Walla, Wash., and arrived at Fort Stevens, Oregon, for temporary duty.

Pinguard, Joseph, contract surgeon, left Fort Leavenworth, Kans., to accompany troops marching from Fort Mackenzie, Wyo., to Fort D. A. Russell, Wyo.

Hayes, Melville A., contract surgeon, returned from temporary duty at Fort Wright, Wash., to his proper station, Vancouver Barracks, Wash.

Griswold, W. Church, contract surgeon, left Fort Delaware, Del., on leave of absence.

Whinnery, Jean C., dental surgeon, ordered from Vancouver Barracks, Wash., to Fort Walla Walla, Wash., and Boise Barracks, Idaho, for dental work.

Bernheim, Julien R., dental surgeon, left Plattsburg Barracks, N. Y., for duty at Fort Wadsworth, N. Y.

Lauderdale, Clarence E., dental surgeon, left Fort Sam Houston, Texas, for Seattle, Wash., to sail thence on the *Sherman* for Philippine service.

Wilcox, F. Homer, dental surgeon, left Fort Strong, Mass., for duty at Fort Warren, Mass.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending May 5, 1906:

Lowndes, C. H. T., surgeon, detached from the *Texas* and ordered to the *Virginia*.

Evans, S. G., surgeon, detached from the Naval Recruiting Station, Denver, and ordered to the *Louisiana*.

Morris, L., surgeon, detached from the *Iowa* and ordered home to wait orders.

Johnson, M. K., surgeon, detached from the *Maine* and ordered to the *Iowa*.

Williams, R. B., P. A. surgeon, detached from the *West Virginia* and ordered to the *Maine*.
Dykes, J. R., asst.-surgeon, ordered to the Navy Yard, New York.
Dean, F. W. S., asst.-surgeon, ordered to the Naval Recruiting Station, Denver.
Stalnaker, P. R., asst.-surgeon, ordered to the *West Virginia*.
Mears, J. B., asst.-surgeon, ordered to the *Minneapolis*.
Reeves, O. S. K., asst.-surgeon, detached from the *Minneapolis*, and ordered home to wait orders.
White, E. C., asst.-surgeon, ordered to the *Virginia*.
Haynes, J. P., asst.-surgeon, appointed asst.-surgeon, with rank of lieutenant, junior grade, from April 16, 1906.
Steadman, W. G., Jr., acting asst.-surgeon, appointed acting asst.-surgeon from April 27, 1906.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending May 2, 1906:

Kalloch, P. C., surgeon, granted leave of absence for one day, April 30, 1906.
Carrington, P. M., surgeon, granted leave of absence for three days, from April 30, 1906, under Paragraph 189 of the Service Regulations.
Nydegger, J. A., P. A. surgeon, leave of absence granted P. A. Surgeon Nydegger for seven days, from April 23, 1906, amended to read for five days only.
Lumsden, L. L., P. A. surgeon, granted leave of absence for two months, from June 1, 1906.
Stansfield, H. A., P. A. surgeon, granted leave of absence for five days under Paragraph 191 of the Regulations.
Stansfield, H. A., P. A. surgeon, granted leave of absence for fourteen days, from April 30, 1906.
Burkhalter, J. T., P. A. surgeon, granted extension of leave of absence for four days, from May 3.
Foster, A. D., asst.-surgeon, granted leave of absence for one month, from April 1, 1906, on account of sickness.
Robertson, H. McG., asst.-surgeon, granted leave of absence for one month and twenty-one days, from May 14, 1906.
Mason, W. C., acting assistant surgeon, granted leave of absence for three days, from April 30, 1906.
Stearns, H. H., acting asst.-surgeon, granted leave of absence for five days under the provisions of Paragraph 210 of the Service Regulations.
Tuttle, Jay, acting asst.-surgeon, granted leave of absence for thirty days, from May 1, 1906.
Ryder, L. W., pharmacist, granted leave of absence for two days, from April 30, 1906.
Bell, J. M., pharmacist, granted leave of absence for thirty days, from May 18, 1906.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended May 4, 1906.

SMALLPOX—UNITED STATES.

California: Los Angeles, April 14-21, 8 cases; Ukiah, March 26, 1 case, in State Insane Asylum.
Connecticut: Putnam, March 1-23, 30 cases.
Delaware: Wilmington, April 21-28, 1 case.
Florida: General, April 21-28, 8 cases; Jacksonville, April 14-21, 2 cases.
Illinois: Chicago, April 21-28, 1 case.
Missouri: St. Louis, April 14-28, 5 cases.
New York: New York, April 21-28, 2 cases, 1 death.
Maryland: Baltimore, April 21-28, 3 cases.
Ohio: Cincinnati, April 20-27, 2 cases.
Tennessee: Knoxville, April 20-28, 1 case, in county; Memphis, April 14-28, 27 cases.
Washington: General, March 1-31, 11 cases; Seattle, April 14-21, 1 case.
Wisconsin: Appleton, April 1-28, 1 case; La Crosse, April 14-28, 3 cases; Milwaukee, 8 cases.

SMALLPOX—INSULAR.

Hawaii: Honolulu, April 7-14, 1 case, 1 death.

SMALLPOX—FOREIGN.

Africa: Cape Town, March 17-24, 8 cases.
Argentina: Buenos Ayres, Jan. 1-31, 66 cases.
Canada: Toronto, April 14-21, 3 cases.
Chile: Iquique, March 24-31, 3 cases, 3 deaths.
China: Hongkong, March 10-17, 9 cases, 7 deaths; Nanking, March 24, 1 case.
France: Paris, March 31-April 7, 2 cases, 1 death.
Gibraltar: April 8-15, 1 case, 1 death.
Great Britain: Bristol, April 7-14, 2 cases; Glasgow, April 13-20, 1 case.
Greece: Athens, March 25-April 7, 4 deaths.
India: Bombay, March 27-April 3, 16 deaths; Calcutta, March 18-25, 276 cases; Karachi, March 25-April 1, 57 cases, 32 deaths; Madras, March 24-30, 33 cases; Rangoon, March 19-26, 66 deaths.

CHOLERA—FOREIGN.

India: Bombay, March 27-April 3, 13 deaths; Calcutta, March 17-24, 37 cases.

PLAGUE—INSULAR.

Hawaii: Honolulu, April 25-30, 3 cases.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, March 18-25, 7 cases, 1 death.
China: Hongkong, March 10-17, 7 cases, 7 deaths.
India: General, March 10-17, 13,325 cases, 10,782 deaths; Bombay, March 27-April 3, 821 deaths; Calcutta, March 17-24, 176 deaths; Karachi, March 31-April 1, 96 cases, 69 deaths; Rangoon, March 19-26, 99 deaths.

MEDICAL AND CHIRURGICAL FACULTY OF MARYLAND.

The 108th Annual Meeting, held at Baltimore, April 24-26, 1906.

(*Continued from page 1394.*)

Occult Hemorrhages in Diagnosis of Gastric Ulcer and Carcinoma.

DRS. J. FRIEDENWALD and L. J. ROSENTHAL have in many instances been able to rely on the constant absence of this sign as sufficient evidence to exclude the presence of ulcer and cancer of the stomach, and favoring the diagnosis of gastritis or some gastric neuroses. Thirty-five cases of ulcer of the stomach were examined and occult blood was found in the stools in 26 cases; not every examination, however, but usually some days before the patient had entered on the ulcer cure, which usually caused the disappearance of the blood. If, under this treatment, the blood does not disappear, the authors consider an operation indicated. Twenty-three cases of cancer of the stomach were also examined and in only a few instances was the sign found absent. It was always found present in 19 cases, and was noted occasionally in 4.

New Physical Sign of Aneurism of Aortic Arch.

DR. GORDON WILSON stated that on listening at the extreme right of the first interspace the voice sound is transmitted normally. Moving the stethoscope toward the sternal border there is reached a point at least half an inch from the sternal border, where the transmitted voice sounds suddenly change, becoming more distinct, higher pitch, and having a slightly nasal quality. In aneurism this area extends some 5 cm. on either side of the mid-sternal line in the first interspace. This sign was verified by the study of normal chests and of three cases of aneurism of the aorta arch and one case of aneurismal dilatation accompanying aortic insufficiency. In none of these cases was a tumor or pulsation visible.

Assault on Tropical Disease.

DR. LEWELLYS F. BARKER said that tropical pathology is rapidly becoming recognized as a special field in medicine, a field worthy of cultivation by itself for its own sake. Perhaps history does not afford a more striking impulse to medical research than that excited in recent times by the struggle of the nations for the control of the tropics. A great impetus has been given to American interest by our new relations to the West Indies and the Philippines and it has been greatly augmented by the construction of the Panama canal. The United States is far behind other countries in providing special institutes, hospitals and course of instruction in tropical diseases, but in Manila a biologic laboratory has been established with Dr. Richard P. Strong as director, which guarantees the thorough investigation of tropical pathology there. Germany has at Hamburg the Institute for Naval and Tropical Hygiene. England has its London School of Tropical Medicine and its Liverpool School and Special

Laboratory for Tropical Medicine and Parasitology. In France there is the Institute of Colonial Medicine. Portugal has a school of tropical medicine. Expeditions and commissions for the study of tropical diseases have been most fruitful.

A New Pyriform Organism.

DR. LEONARD K. HIRSHBERG reports the case of a man, aged 36, with elevated temperature, lasting eight weeks, which never rose above 102, with meningeal symptoms, photophobia, tremors, irritability, subsultus tendinum and joint involvement. The Widal reaction was constantly absent; leucocytosis, 14,000. Cultures taken from his blood revealed a lemon-yellow diplobacillus, pathogenic for guinea-pigs and rabbits, negative to Gram's stain, actively mobile, producing no indol, not liquefying gelatin until the seventh day and producing no gas or lactose, saccharin or glucose media, milk, manite litmus are acidified. The organism is killed at the exposure of 60 C. for ten minutes. At the suggestion of Prof. William H. Welch the organism was called *Bacillus pyriformis*.

Treatment of Prolapsed Ovaries.

DR. WILLIAM S. GARDNER recommended an operation which consists in shortening the elongated ovarian ligament by a couple of fine silk stitches. The first stitch takes a light but firm hold in the uterus near the lower border of the ovarian ligament; it is then continued through a portion of the ligament and is inserted firmly into the ligament near the ovary. The second stitch is placed in the same way, but near the upper border of the ligament. When these stitches are tied, the ovary is brought up close to the uterus, but still retains a limited mobility independent of the uterus and a complete mobility with the uterus. Retrodisplacement, if present, should be operated on at the same time.

General and Metastatic Gonococcus Infections.

DR. R. I. COLE said that it is not sufficiently realized that there are other primary infections besides these of the genital tract, and that these are of frequent occurrence, though often not recognized as such, rectal, for instance. In this rectal form there is danger of chronicity and stricture, stricture here probably being more frequent from gonorrhea than from syphilis. Gonorrheal stomatitis is also not rare. Wound infection also occurs and infection of the umbilical cord is known. The gonococci also enter the blood and set up septicemia and distant infections, the proof being first furnished by Thayer and Blumer in 1896, in a case of endocarditis. A number of cultures of the organism have been made from the blood. Cole had a case of septicemia which got well in which the organism was found in the blood, but there were no local lesions, and it may be that these cases are more frequent than is suspected. Gonorrheal infection is one of the causes of puerperal fever. The most frequent extragenital metastatic infections are those of the joints, from which the organisms have been obtained in a large number. It is not true that this joint involvement follows the chronic urethritis oftener than the acute. Cole's observations showed that the implication of the joints was nearly always a polyarthritis as often as in rheumatism. In one case there was tenderness and swelling over the thyroid and in one there was involvement of the nervous system. It has only recently been ascertained that gonorrheal peritonitis occurs in the male as well as the female. He saw one case of bilateral femoral phlebitis and one of plastic iritis.

(To be continued.)

THE PHYSICIANS' CLUB OF CHICAGO.

DR. C. S. BACON in the Chair.

The Relation of the Physician to Compulsory Sickness and Invalidity Insurance.

The Chairman said that physicians are interested in compulsory sickness and invalidity insurance, in that it has a broad bearing on the welfare of the state. It also affects the medical profession. Sickness and invalidity insurance require the co-operation of physicians; physicians must be employed, and if some system of insurance which requires the employment of physicians should come up, it would seem as if this kind of insurance would also meet with the approval of the present indemnity companies and others, whose efforts would be to secure a low or unfair rate of fees for physicians, so that physicians should have an intense interest in this subject.

PROF. C. R. HENDERSON of the University of Chicago discussed two aspects of workingmen's insurance. Intelligent men in America have not given insurance the thought and consideration it has received on the other side of the Atlantic. Countries like Denmark and Scandinavia are in advance of the United States in taking social care of the working classes. Insurance for the workingman is now being placed on a purely business basis; it has been taken out of its philanthropic and charitable sphere. Men in large cities are an occupational asset; their health, life and longevity are matters of national economic importance. The causes of diminution of industrial efficiency should be found out and measured, and in considering these the help of the medical profession is needed. It is an indispensable element in the progress of workingmen's insurance in America. It is necessary to get scientific and precise knowledge as to the facts in regard to the causes of sickness, especially of occupational diseases, which interfere with the public health, and also as to the causes of accidents. The methods of taking care of the health and wealth-producing power of the people depend on accurate knowledge.

He thinks that with medical supervision of factory inspection and legal arrangements made for it, many things might be found out in regard to the causes of accidents and sickness which are now deliberately concealed by business men because of the iniquities, because of the antiquated liability law which is cursing the nation. For the economic progress of the human race it is necessary that every cause of disease that is inherent in occupation or in the habits of the working people should be known. This information can be furnished by physicians. Sensible legislation can not be secured without it; and protective legislative measures must be obtained on strict, precise and comprehensive knowledge of the causes of both sickness and accident in connection with disease, and if actuaries can not furnish such facts without there being unfair litigation, then the manufacturers must be protected. There should exist a code of protection, and in the formation of it against disease and accident in connection with occupations, the medical profession should be in a commanding position and be the administrative authority.

What are some of the protective measures? If one will go through a German work shop he will see a red mark or shack painted red, which means that it is a dangerous place. The workingman is protected from accident, and if he is injured it will mean a financial loss to the company, because that workingman is an economic asset of the nation, and the protection of him is the protection of the public property and public welfare.

Speaking of the prevention of tuberculosis, he said that this disease is one of the most serious causes of invalidity. This disease is largely connected with occupation.

As to the policy of insurance, it means that every workingman is exposed to calamities which may befall anyone. As a matter of fact, they fall on a certain average number of persons varying with the different occupations. All of them are causes of economic loss and social distress, sickness, loss of time from sickness, loss of wages from accident, loss of income from invalidity, sometimes occurring before old age, and always with it. In Germany a part of the risk of sickness belongs to the community. For instance, one-third of the sickness from tuberculosis may be said to belong to the community, which can be prevented by that community in great part. Many causes of sickness can be partly prevented by the community. The workingman carries two-thirds of the premium and his employer pays the other third. But does the employer pay it? Primarily, he does, but a large part of it comes back on the working people, and often the workingmen have to carry it. In the case of invalidism, in old age, the workingmen pay half the premiums; the employers pay the other half. This comes to the point where the German empire pays $12.50 a year to old people or invalids who receive pensions. It is not claimed that such a system can be

introduced in the United States, but the principle is being introduced. In 1897, after having tried to amend, repair and tinker the common liability principle, Germany finally passed a law that in every case the employer should pay a certain indemnity for a certain time, or in case of death a certain lump sum for persons injured in his employ. This threw the burden on the employer, and the natural result was that employers banded together to form mutual insurance companies. Already railroad insurance companies have been organized in America.

If workingmen's insurance is established on a wide scale in America, the medical profession will at certain points have to bear their share of the public sacrifice. This problem ought not to go before the medical profession in an unintelligent way. It should be met frankly and candidly by the state, and the evils that have crept into the German administration should be guarded against in advance. Medical men in Germany are not properly paid for their services. There is general complaint there, and physicians are trying to remedy it. Under a proper system of insurance charity cases will be eliminated. They will be reduced in number. There is no profession which is so heavily burdened with charity cases as is the medical profession. There is no set of men giving away so much of their services to the poor as the doctors. Something will have to be done to dispose of charity cases which do not belong to insurance. Paupers can not be insured. They have to be cared for by charity or institutional relief. The only advantage of the insurance system among people to-day who ask for relief, who need the insurance system, is that they are able to pay a reasonable sum for it, because when they get sick they have nothing with which to buy the necessities of life; and they are earning nothing. So the doctor or the undertaker is the last man to get anything out of them. If there can be eliminated from the working class, all except the capable, those who have regular wages, and who can lay up something in times of accidents, invalidism, and old age, the medical profession is relieved of an actual burden and passes it over to the charity institutions or to insurance organizations, where it belongs. The medical profession derives most of its income from the well-to-do classes. In Germany physicians care for those who are willing and able to pay. They can buy their insurance from the company; they do not need sympathy or attention. This question concerns people who are earning for a family $350 a year, or less than $450 a year, up to $800 or $900.

It is a state problem to see that a physician gets his pay for services rendered, and whether he does or not, will depend on the influence he has with the committees or with the legislature. Physicians can not do their work well unless they are paid for it. The interests of the medical profession should be protected at every point. It will put the medical profession, so far as their practice among the working classes is concerned, in a more dignified, useful position than any method that has ever been tried where the social insurance principle has not been accepted. In social insurance, as applied to the industrial group, the medical profession have before them a new era. They will get paid for preventive medicine, and not merely for curing and mending. Physicians take a great step in advance when they are able to increase industrial longevity and industrial efficiency.

In closing, Professor Henderson solicited information from physicians in regard to the causes of sickness and accidents, saying that such information as was furnished him would be brought before the commission.

DR. FRANK BILLINGS spoke on the principles of administration of the law in Germany. He has talked with Germans in this country as to the benefit of insurance to the community as an economic principle, and also with reference to the systematic care of the sick without pauperizing them. It has been an unusual burden for the medical profession, particularly to those who have small incomes, in Germany, and this is due to some clause in the administration of the law in Germany which possibly would be overcome in America. The pauperizing effect in northwestern Germany among the medical profession was so great two years ago that at Leipsic the medical profession bound themselves not to visit any of these people. This was followed by practically the formation of a union among the physicians of Germany elsewhere, with the result that they petitioned the Reichstag to modify the law on account of receiving such small fees. The fees in some communities in Germany only amounted to 2½ cents.

The law, as administered in England, is better in the rural communities. The statement has been made that in England practitioners in the country receive as little as 2½ pence for visits. Not only has this a pauperizing effect, but it results in superficial treatment of the sick. A physician who receives no compensation under a contract which he is obliged to make gives superficial attention to his patient. Under the contract system the insured had no choice as to the doctor he would have, and this creates a competition for influence to get positions. In all probability many of these evils in the German law will be removed from the establishment of this insurance in America.

Insurance is bound to come. It does not make any difference what effect it will have on the medical profession, it is coming, and members of the medical profession should be willing to enter into an earnest investigation of the subject, and attempt by their knowledge and discussion to so modify the principles of its establishment that it will work as little hardship as possible, and at the same time be efficient in its performance. In many of the large corporations, like steel mills, iron mines, copper mines, lumber districts, planing mills, the rural contract systems exist. Reference was made to a practitioner who derives most of his income from attending employés at planing mills. This large corporation paid the physician 50 cents for each employé per month, but another physician secured the work by contracting to do it at one-half the sum, namely, 25 cents. That principle would be in a sense accentuated in this country, unless the principle can be modified in its working. In the country it will amount to something more than in the city. The individual or employé who has an income of $400 a year can not very well afford to pay a doctor very much. But the individual in the city, who earns more than the man in the country, who earns say $800 or $1,000, is able to pay his attending physician fair fees. The doctor who is receiving compensation for attendance on people will be more interested in keeping them well than in seeing them sick, because he will earn his money easier that way. And while it may work a hardship on the whole medical profession at the beginning, more particularly on rural than on city physicians, still the system of insurance will have an influence in preventing illnesses which every physician works for, and the wholesome effect of it on the community will be great.

DR. ARNOLD C. KLEBS said that he has talked to railroad men on the subject of sick-benefit insurance, and some interesting points were brought out. He said to some of them frankly, that their first idea in getting up a sick-benefit scheme was to advertise themselves as charitable men; then they soon realized that it paid to do it, because, first of all, by preventing accidents they saved sick benefits. They have determined scientifically what kind of accidents will happen in certain departments of the railroad, and they have to pay benefits to those who are injured. This has induced railroads to introduce safety appliances; the railroads save money by these appliances, which they can utilize for other purposes, so that the financial gain by this method of prevention of accidents is apparent.

Among the diseases that attack the laboring man, tuberculosis is the most important. The German sickness insurance law was passed in 1883; after that in 1889 the invalidity insurance law was passed. Sickness and invalidity insurance had to face a financial problem, in that it was found that one-half and more of those insured were tubercular. Tuberculosis is a most tremendous tax, not because it kills people, but because it disables them for such a long time. Invalidity insurance was recognized and utilized for the purpose of building sanatoria. It was proven by the first sanatoria established by Brehmer and Dettweiler that with thorough hygienic management of these cases, the insured could be brought back to earning capacity after a certain length of time. After an average treatment of three months these people were restored to an

earning capacity in fully 80 per cent. of the cases. But that means not only the restitution of men to their earning capacity, but that every one of these men has been educated in the principles of hygiene, and goes out as an apostle of this teaching. Prevention is the real and greatest task of the physician. He may prescribe medicines and he may operate, but where he really does good is in the matter of prevention. That is the highest task of medical men, and a scheme which will put the great mass of people, the workingmen, on a basis of self-defense against disease, making them able to pay by deducting small amounts from their wages in time of health, will remunerate the medical men for preventive work.

DR. FERNAND HENROTIN said that compulsory sickness and invalidity insurance is bound to come. It is a part of the development of our republican form of government. The government depends on its unit of citizens for the management of it. Each man has to do his share or the republic will not stand. Contract work is allied very closely to the work of the physician and to the subject of sickness insurance. There is no question but that a large number of sick people will have to be attended at low prices, and that means in one way or another a contract system. Physicians will apply themselves to the problem under discussion and eventually, he believes, find methods by which the contract system and the paying of low fees in caring for the sick and management of tuberculous people and all that class, can be brought about without either pauperizing the people or without lowering their estimation of physicians who attend them for this or that fee, or for a song. The solution of the contract system will eventually take some shape, but he is not prepared to say what it will be. He believes the profession will stand divided that it is wrong for a physician to do medical work on the contract plan. But as sick people must have medical attendance, he thinks it must take some such shape as this, that certain communities will be divided into certain districts; that contracts will be entered into between a city or a county, but not with any one physician or individual, by which certain districts will be taken care of by a group of doctors, who will look after the sanitation of the district, who will look after the preventive part of medicine, who will attend the sick, who will divide the work properly, who will compare notes, keep books, and decide upon the proper way to do things without pauperizing the patients or without pauperizing or humiliating doctors. An individual who earns $100 a year ought to pay his physician more than the man who earns $300. Each man should pay what he can, and each district or each group should have ratios in proportion to what they earn. The medical profession can not commit itself to any contract by which it is going to attend sick people for the lowest possible price. There is a certain remuneration in proportion to the ability of the individuals to pay, which must be paid; that this ratio must always exist; that we never give a lower price except for cause, and that it must be distinctly shown that in helping sick people we must do nothing either to pauperize them or degrade ourselves.

DR. M. L. HARRIS said that for several years past he has been physician of large corporations, and during this time he has had under his personal supervision thousands of accident cases, and has had a hand in distributing millions of dollars of indemnity. This money many times was not distributed in a just manner, for the reason that many of those injured did not receive what they were justly entitled to. On the other hand, a much larger number received many times the amount they were entitled to. The reasons for this are many, principally the law as it now exists, and largely because of dishonest lawyers and dishonest, ignorant doctors. He said he could mention a number of instances where people have gotten on cars for the express purpose of receiving an injury; had taken with them witnesses to see the accident, had people stationed at the corner to see the accident, and had a doctor waiting around the corner to take care of them as soon as the accident occurred, and then had the patients hustled to a particular doctor as though they were injured.

He did not agree with the statement that these companies started an indemnity plan as a matter of charity. Corporations are not known as eleemosynary institutions. They started these indemnity schemes as a matter of economy. There is little incentive for corporations to carry on these indemnity schemes under the present law. He has attempted to look after the indemnity plans of corporations, and while they can be carried out honestly, so that they will be an economic investment, so many times they are carried out dishonestly that there is little incentive to do it. An employé receives an injury; the company looks after him; they pay him his indemnity according to contract, and when they have done that and have fulfilled their part of the contract, the individual turns right around and sues the company for large damages, and many times he gets it. The company says: What is the use of us paying this man his indemnity to give him money to turn right around us and fight us, and win a large sum of money? The man may have signed a contract that he will accept the indemnity paid him by the company in lieu of damages, but the courts say that the contract is of no value, because the man has no right to sign away his rights in that way; that what the company has paid him in the way of indemnity he was entitled to. These are most important obstacles in the present law. Before companies will continue under the present law there must be some other law enacted of relieving these companies from further liability after they have once fulfilled their obligations of indemnity under contract. There must be some just way of arriving at a just estimate of what the damages are.

Physicians go into court; they testify before the jury; the average lawyer does not want a man to testify who knows anything about the case. He wants a medical man who is dishonest, and who will testify to what he wants him to. He wants a medical man who is ignorant, who does not know, and the man who is ignorant and does not know what he is talking about nearly always makes the best impression on the jury. He will testify that he believes anything to be so, because he is ignorant of anything himself. That is a sad state of affairs for the medical profession, but it is the truth. Until some way can be devised to determine the amount of liability and the extent of the damage done, companies will fight for their existence. They are not going to favor indemnity. Companies are anxious and willing to pay a just indemnity if it can be arrived at justly. If we can devise some insurance law which will do that, companies will gladly welcome it. He has studied the German laws, and while they have excellent and valuable points, he does not think they can be applied to American institutions at present.

DR. WILLIAM H. WILDER asked whether any consideration is to be taken of the relation that the different dispensaries in large cities bear to the insurance problem. The dispensary evil in large cities is an immense burden. It is not being handled in the broadest kind of way, as there is so much jealousy and rivalry on the part of physicians as to who shall do this work for nothing. Sometimes an almost unseemly scramble takes place for different positions on dispensary staffs. In many of the dispensaries in Chicago hundreds of patients are treated annually who can afford to pay something, but who are treated for nothing. The first step that should be taken is, whenever a patient comes to a medical clinic and asks for something for nothing, some means should be devised by which we may know what we are doing. In the New York Eye and Ear Infirmary they have an officer in attendance every day, who notices everyone who comes in. Patients are required to make a deposit of a quarter for a card of admission, and the revenue from this source alone amounts to $10,000 a year. This officer of charity notices if there is any individual who seems to be an impostor. He takes his address, and he is looked up. This is not done in Chicago. The medical profession ought to co-operate with the bureau of charities in this matter.

PROFESSOR HENDERSON, in closing the discussion, said with reference to the suggestion made by Dr. Wilder, that some of the people he described as seeking charity when they are able to pay ought to be passed over for perjury to the criminal arm of the law. There is, however, a charity aspect to the dispensary, and he hopes the medical profession will arrange with the bureau of charities to have certain cases investigated, so that those who can afford to pay should do so.

MEDICAL ASSOCIATION OF GEORGIA.

Fifty-seventh Annual Meeting, held at Augusta, April 18-20, 1906.

The President, Dr. W. Z. Holliday, in the Chair.

(*Continued from page 1395.*)

Some Remarks on Chronic Conditions.

Dr. H. McHatton, Macon, said that with the present relative positions so commonly held and the lack of correlation between the various medical attendants, a patient is in extreme danger. To illustrate, a patient with an active secondary syphilis, which had attacked two organs, consulted the most accessible authority on diseases of each organ. Each authority made a diagnosis of syphilis, and put the patient on the mixed treatment. As each of them had every reason to believe that he was the only attendant, and the patient was very good about taking his medicine, the result was most unpleasant. He stated that when a patient who is not directly under the observation of a general practitioner, whose general condition can not be fully and absolutely accounted for by the local lesion which he is treating, comes to the specialist, it is as much his duty to refer the patient to a competent general practitioner as it is for the general practitioner to refer him to the specialist, and even more so, because a life is often lost that otherwise can be saved. The innocent patient has every reason to believe that he is getting the full benefit that can be derived from medical science when he is not. Many errors in diagnosis are not due to lack of knowledge, but to incomplete examinations and insufficient time of observation of the case. One should not hesitate to tell a patient that he does not know what the disease is, and that it may take time and repeated examinations to make an accurate diagnosis.

Dementia Praecox.

Dr. J. W. Morley, Milledgeville, said that dementia præcox is a chronic progressive psychosis with a peculiar tendency toward dementia, and having its determining features represented in a peculiar chain of symptoms of excitement, delirium, stupor, mannerisms, negativism, verbigerations, stereotopy and cerea-flexibilitas.

Anterior Poliomyelitis.

Dr. J. Cheston King, Atlanta, said that an opinion can not be given as regards recovery from this condition until paralysis takes place. At the expiration of two weeks the muscles that react to faradism will recover, and those that do not react will either be permanently paralyzed or partially so. In the latter case, as long as the retention of reaction to the constant current remains, there is some hope that the faradic reaction may return and with it the power of the muscles.

At the onset of the attack, the patient should be kept quiet in bed and should lie on the face or one side, and hot applications should be made to the spine. He said that the destroyed cells can not be replaced, but recovery can be facilitated by maintaining the nutrition of the paralyzed parts. When the attack is due to cold, the limb should be kept warm from the first; diaphoretics, such as liquor ammoniæ acetatis and citrate of potash, should be given. He also recommends the use of ergot and belladonna. After the disease has assumed the stationary condition, cod-liver oil and tonics are used. Local treatment should not be used until at least a month has elapsed. The limb should then be bathed in hot salt water and rubbed with a rough towel, and especial care should be taken to keep the limb warm with thick stockings. The muscles should also be rubbed systematically every night and morning. The constant current should be used, both because it dilates the blood vessels of the part and because the muscles will contract under it and not under faradism.

Paramyoclonus Multiplex.

Dr. E. Bates Bloch, Atlanta, reported a case of this affection. The case was interesting, not only on account of the rarity of the affection, but because of the rapidity of the muscular contractions, which far exceeds those met with in any other case the author has ever heard of, in that the greatest number of muscular contractions reported heretofore has been 180. While many writers prefer to class this disease with hysteria, it seems very doubtful if this is the proper view to take of it, in that the motions are such as can not be imitated by any effort of the will, and also that not only individual muscles may be seized with these shock-like contractions, but even portions of muscles may be so affected, and the violent muscular contractions may take place even without locomotor effect. The disease is very commonly associated with epilepsy.

Recent Studies in Rabies.

Dr. James N. Brawner, Atlanta, called attention to the discovery of certain bodies in the central nervous system of animals dead of rabies by Negri, which Negri believes to be the specific germ of this disease. The value of these Negri bodies as a means of rapid diagnosis is now generally recognized. When the brain of an animal is examined and Negri bodies are found, the evidence is considered positive and a diagnosis of rabies is made. At the Georgia Pasteur Institute, within the last eighteen months, the author has demonstrated Negri bodies in forty-two dogs and three cats, and in every instance the rabbits inoculated died of typical rabies. In three cases where the inoculation test resulted positively, no bodies were found, though only the hippocampus major was examined and the animals were killed in the first stages of the disease. In fifteen dogs and two cats proved not to be rabid, no such structures could be demonstrated.

Proper Management of Chronic Suppurative Inflammation of the Middle Ear.

Dr. Dunbar Roy, Atlanta, said there are two kinds of chronic discharges: (1) A catarrhal, mucoid secretion, free from odor, except when the ear has not been cleansed for some time, coming from the middle ear through a perforation in the drum, associated with the same kind of catarrhal secretion in the nose and naso-pharynx. This condition can nearly always be cured by local therapeutic measures directed to both the ear and the nasal mucous membrane. This form of middle ear discharge is frequently seen in children, especially those having adenoids in the nasa-pharynx, and in those recovering from measles and scarlet fever. Proper and thorough treatment of this form will effect a cure. Frequently the only thing necessary is the removal of the adenoids. However, if the condition is not treated, it will pass into the next form. (2) Discharge from the middle ear of a whitish, desquamated epithelium, with purulent fetid secretion, destruction of the drum membrane, and in many cases erosion and liquefaction of the auditory canal at the point where the drum should exist. This is the form usually designated as chronic.

The treatment of chronic suppurative otitis was divided into two heads: (1) Conservative, and (2) radical. In the performance of the radical operation on the middle ear, the occurrence of the following results should be considered and intelligently placed before the patient or his parents before the same is undertaken: (1) Injury to the facial nerve, with a consequent facial paralysis for a more or less definite time. (2) A loss in the amount of hearing power in that ear, as compared to that which existed before the operation. (3) A possibility that the discharge may not be entirely cured. (4) Injury to the sigmoid sinus, an accident not likely to happen to the careful operator. The technic of the operation was described.

DISCUSSION.

Dr. C. L. Williams, Columbus, reported the case of a boy, 12 years of age, illustrating the fact that discharges from the ears ought not to be viewed lightly.

Dr. R. B. Ridley, Atlanta, said the longer he practices and sees cases of chronic ear trouble, the more thoroughly is he impressed with the fact that the radical operation is the only treatment for chronic suppuration of the middle ear.

Dr. L. Amster, Atlanta, said that often the physician should be censured for not paying early attention to these cases of ear discharge, which eventually develop into chronic middle ear trouble, especially after measles, scarlet fever, etc.

DR. J. L. HIERS, Savannah, denounced the insufflation of powders in these cases, as in his hands they have been more harmful than beneficial. The wet treatment, syringing with strong antiseptic solutions, is best suited to the individual case. He emphasized the importance of using the dry treatment and of packing the ear lightly with absorbent gauze, preferably bichlorid or iodoform gauze.

DR. HENRY R. SLACK, LaGrange, finds that the wet treatment is decidedly the best, especially if it has to be intrusted to a member of the family. In getting rid of granular conditions in the ear, he has frequently found nitrate of silver very efficacious.

Medicolegal

Physicians Prohibited Testifying to Paresis in Family.

The Court of Appeals of New York says that testimony was introduced *in re* Mary A. Myer's will tending to show that, at the time of the execution of the will, the testatrix was afflicted with paresis, which it was claimed deprived her of testamentary capacity. In order to supplement and support this evidence, two physicians were called as witnesses. One of them had been the medical adviser of the testatrix's brother, and the other of her mother. These witnesses testified that both the mother and brother of testatrix had been afflicted with what they termed "general paresis," that their knowledge of this condition was obtained while attending such persons in their professional capacity, and that such knowledge was necessary in order to treat them. The testimony was objected to as incompetent and privileged under section 834 of the New York Code of Civil Procedure, and the court holds that it was clearly within the provisions of said section, which prohibits a physician from disclosing "any information which he acquired in attending a patient, in a professional capacity, and which was necessary to enable him to act in that capacity."

By the express terms of section 836, the court goes on to say, the provisions of section 834 are made to apply to the "examination of any person as a witness." The fact that the testimony of these physicians related to patients who were not parties to the proceeding or interested therein, and who were, in fact, dead at that time, did not annul the prohibition of the statute. In Davis vs. Supreme Lodge, 165 N. Y. 159, the defense sought to prove the cause of death of two aunts of the deceased by the testimony of their attending physicians. The evidence was excluded, and this court upheld the ruling. Judge O'Brien, in writing for the court, said: "This court has held that the statements of the attending physician for the purpose of establishing the cause of death either of the insured himself or of his ancestors or their descendants, although not parties to nor beneficiaries under the contract, were not admissible. They are excluded, not only for the purpose of protecting parties from the disclosure of information imparted in the confidence that must necessarily exist between the physician and patient, but on grounds of public policy as well. The disclosure by a physician, whether voluntary or involuntary, of the secrets acquired by him while attending on a patient in his professional capacity, naturally shocks our sense of decency and propriety, and this is one reason why the law forbids it."

Besides, the court says that there was another equally potent reason why this evidence should not have been received. The case was barren of facts which tended to show that the paresis with which the mother and brother of the testatrix were said to have been afflicted was acquired by them under circumstances that would render it transmissible so as to taint the family blood. It is doubtless the general and well-established rule that, where the mental soundness of an individual is in question, the sanity of the blood relations in the ancestral line may be shown as tending to establish the fact in issue, but that rule does not permit indiscriminate and unexplained evidence of diseases afflicting such relations and affecting their mental faculties. There must be evidence tending to show at least that such diseases are hereditary or transmissible. It is a scientific fact of common knowledge that the transmissibility of the malady known as "general paresis" depends to a great extent on the conditions underlying the disease. The medical writers differ as to its cause or causes, but it seems to be conceded that the majority of cases result from syphilis, while in others it may be superinduced by various excesses or overexertions of the individuals afflicted. Whether the particular form of the disease from which the testatrix and her family suffered was of such a transmissible character that she might be said to have derived it from her ancestors could not be determined from the evidence in the record, and it was, therefore, difficult to see how the testimony of the physicians was really pertinent to the issue whether the testatrix was possessed of testamentary capacity.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Syphilis.

In speaking of the treatment of syphilis Campbell Williams, in the *Clinical Journal*, states that every method of administering mercury has its advantages and drawbacks.

The treatment of syphilis should not be made one of the rule-of-thumb order, as the dose required by one patient may be insufficient for another, and too much for a third person. Consequently the dose and preparation must be suitable to the patient in that it removes the symptoms and cures the patient. Irregularity in taking the mercury is one of the disadvantages of administration by the mouth. On the other hand, the overanxious patient may take more than double the dose prescribed and thus induce a stomatitis and diarrhea. In some instances, it matters not how small the dose may be nor the nature of the preparation, it can not be tolerated when taken by the mouth, as it produces griping and purging. In the majority of ordinary diarrheas the following combination is recommended:

R.	Hydrarg. tannatis.....gr. iss	09
	Pulv. opii.....gr. 1 4-1 2	015-.03
	Ext. hematoxylin	
	Ext. gentianæ, āā.....gr. ss	03

M. Ft. pillula No. i. Sig.: One such pill three times a day. Or:

R.	Hydrarg. gallatis.....gr. iss	09
	Pulv. opii.....gr. 1 4-1 2	015-.03
	Confectio, rosæ	
	Ext. hematoxylin, āā.....gr. 1 2	03

M. Ft. pil. No. i. Sig.: One such pill three times a day.

The astringency of the gallate in the foregoing combination not infrequently produces indigestion.

In a great many cases, according to Williams, all that may be necessary is to mask the gray powder as follows:

R.	Hydrarg. cum creta.....gr. i	06
	Bismuthi carb.....gr. ii	12
	Pulv. opii.....gr. 1 4-1 2	015-.03
	Ext. hematoxylin.....gr. 1 2	03

M. Ft. pil. No. i. Sig.: One such pill three times a day.

One of the simple remedies recommended for combating the mercurial diarrhea is the administration of a raw egg, as it probably forms a non-irritating albuminate of mercury, and two or three eggs in the twenty-four hours, together with a discontinuance of the drug, causes the enteritis rapidly to subside. The diarrhea most frequently develops following the administration of the biniodid, subchlorid, yellow mercurous iodid or the green iodid. The condition of the teeth should be carefully observed in order to keep the gums in a healthy condition. One of the best methods for hardening the gums is to paint them night and morning with alcohol (90 per cent.); mouth washes of alum or myrrh are also of value. Poor patients who can not afford to buy the medicine may be m

structed to rub a little alum into the gums once or twice daily. At any rate, the toothbrush must be used daily. The author recommends the following as a very efficacious mouth wash:

R. Plumbi acetatis	℥iiss	10
Pulv. alumin.	℥v	20
Aquæ	℥xvi	500

M. Dissolve the salts separately, mix, filter and add essence of peppermint one-half dram. Sig.: As a mouth wash four times a day.

In some cases chronic constipation may be present. In such instances it may be necessary to add extract of belladonna gr. 1/10 (.006), or aloin gr. 1/10 (.006), to each pill.

In patients who are run down or anemic and are in need of tonics, the following combination is recommended:

R. Hydrarg. cum cretæ		
Ferri reducti, āā	gr. i	06
Quin. sulph.	gr. ss	03
Ext. nucis vomicæ		
Pulv. opii, āā	gr. 1/6	01
Ext. gentianæ	gr. 1/2	03

M. Ft. pil. No. i. Sig.: One such pill three times a day.

When the treatment is meeting the requirements the patients increase in bodily weight, they experience no depressed feelings. It is the author's opinion that the iodids do not cure syphilis, but only clear up the symptoms, and unless mercury is administered in conjunction with the iodids or following them, relapses will surely occur. However, he recommends the following mixture in addition to the mercury in order to hasten the healing of the initial lesion and the reduction of enlarged lymphatic glands:

R. Liq. hydrarg. perchlor (B. P.)	℥i	4
Potassii iodidi	gr. v-x	30-.65
Syr. zingiberis	℥i	4
Aquæ chloroformi	℥i	30

M. Sig.: At one dose, to be taken at bedtime in a glassful of water.

Donovan's solution (liquor arseni et hydrargyri iodidi) is a valuable preparation in some cases, but its great drawback is the bad effect produced on the stomach. The amount of arsenious iodid which is contained in the usual dose in some cases is sufficient to produce arsenical pigmentation when administered for a great length of time. The most speedy reaction, according to Williams, follows an intramuscular injection. The patient, however, may object to such a method, in which event the inunction may be employed. The advantages of administration by the mouth are that it is cheaper, more convenient and can be carried out by the patient. An overdose or an underdose can be corrected at will, and the combination changed from time to time to avoid any disturbance of the stomach. Another great advantage of which the author speaks is that the treatment can be carried out in privacy. He rather favors the inunction method of treatment, however, when it can be satisfactorily carried out by employing a professional rubber, as the patient is too apt to be superficial when he attempts to do his own rubbing, as it is tiresome work. The time should occupy a space of from 20 to 30 minutes of energetic massage properly to rub in one dram (4.00) of the ointment. Consequently this in addition to a preparatory steaming or hot bath requires an hour's time each day. The keynote to success in the treatment of syphilis is continuity of treatment until a cure has been effected. The condition of the skin must be observed to avoid a mercurial erythema or suppuration of the hair follicles.

Rectal Feeding.

In an abstract in the *British Med. Jour.*, Drs. Francis Boyd and Jean Robertson conclude by observation on six cases that rectal feeding is of low value. In the opinion of the authors it is hopeless to expect that a patient who is suffering from esophageal or pyloric obstruction can be improved in a nutritional way. As albumin is absorbed in such small amounts, they recommend the abandonment of nitrogenous substances and the substitution for them of the fats and carbohydrates. The best form of fat is the yolk of egg. If prepared fat is used it should be in a state of fine emulsion and of low melting point. Pure olive oil is recommended, a small quantity being emulsified and used to emulsify the entire amount. As a good nutrient enema the following combination is recommended by them:

R. Yolk of eggs, two.		
Dextrose	℥ss	2
Sodii chloridi	gr. viii	50
Lactis (pancreatized)	℥x	300

M. Sig.: At one time as a nutrient enema one hour after cleansing the bowel by colonic flushing, by slowly siphoning it into the bowel by means of a soft rubber catheter.

An enema similar to the foregoing has an approximate caloric value of 300 heat units and thus, if given every six hours, the total heat units will reach 1,200, of which 500 heat units may be absorbed. They call attention to the fact that feeding by rectal enemata often causes pain in the stomach by exciting the flow of gastric juice, especially when gastric ulcer is present. In such instances, it is stated, the healing of the ulcer may be promoted by allowing the patient a small amount of milk by the mouth, which will combine with the acid thus secreted and protects the ulcer from its action. They arrive at the conclusions, therefore, that rectal feeding has a very limited field of usefulness and does not afford complete rest to the stomach.

Alkalies.

Brunton, in the *Practical Med. Series*, calls attention to the value of alkalies in the relief of pain, especially the pain of toothache. It is the presence of acid in the carious tooth that is the most potent factor in the production of toothache as demonstrated by the rapid disappearance of the pain almost immediately on the application of a solution of sodium bicarbonate. This method of treatment is also of value when there is general aching of the teeth due to retracted gums. He also calls attention to the benefit derived by the alkaline treatment in cases of furuncles accompanied by sharp, stinging pain. The theory is that the pain is due to diminished alkalinity of the blood, both in the general system and in the local area, consequently alkalies, both internally and externally, are advised. The same outline of treatment will hold good in some cases of neuralgia and other painful affections.

Cyclic Vomiting in Children.

In the treatment of cyclic or recurrent vomiting in children, LeRoy advises against the use of morphin. Lavage and colonic flushings have also been useless in his experience. He is of the opinion that the origin of the disease is in the small intestine and that therapeutic measures must be so directed. For this purpose he recommends the following outline of treatment:

R. Pulv. aloes et myrrh	℥ii	8
Pulv. guaiaci	℥iss	6
Pulv. capsici	℥i	4
Mix and triturate in porcelain mortar and add:		
Olei cinnamomi	m. xxv	1.65

Ft. cap. No. xxv. Sig.: One capsule every four hours until bowels act.

9 Muenster Am Stein. B. Fernow, New York.

1. Etiology of Relapses in Syphilis.—Neumann summarizes his paper as follows: The late syphilitic relapses, the relapse *in situ* as well as the metastatic relapse, have their origin in the microscopically demonstrable syphilitic products, including the syphilitic lymph glands, which persist after the dis-

appearance of the clinical manifestations. These may exist a very long time, even more than a decade. The complete elimination from the organism of all the germs of the disease as promptly as possible therefore follows as a fundamental indication in the treatment of syphilis.

4. **Common Form of Insanity.**—Drew discusses especially that type of insanity variously known as pubescent insanity, adolescent insanity, precocious dementia, primary dementia or dementia præcox. Drew believes in regard to treatment, that the only safe rule is to consider every case toxic, or due to some derangement of the physiologic functions of the body. The full confidence of the patient should be won, for then the troubled brain will be greatly relieved. Elimination should be encouraged. A brisk purge may be the best of all medicines at first. Home environment is often a great obstacle. Oxidation stands next in importance to elimination. All hypnotics should be avoided if possible. The treatment of each case must be considered separately, for its details will vary with each patient.

6. **Early Diagnosis and Treatment of Puerperal Septic Diseases.**—Marx maintains that practically all sepsis arising after labor gains its entrance from the so-called puerperal ulcers, whether they be situated at the vaginal outlet, their most frequent site, or on or within the cervix. Early recognition and treatment will cut short many a case of beginning sepsis that would otherwise develop into a dangerous and prolonged illness. All elevations of temperature, or an abnormally high pulse rate with or without fever, in the period of the puerperium should be considered with suspicion. In the case of evident ulcerative areas, which are limited to the lower genital tract, the interior of the uterus should under no condition be invaded by hand or instrument. Carbolic acid, in pure form, is the cauterant of choice because of its painlessness, its deep influence, and the ability to control its action with alcohol. In the case only of intrauterine sapremia is the exploration for retained products of conception justified.

7. **Determination of Absence of Hydrochloric Acid.**—Hess has found that by making use of the fact that connective tissue can be digested only by the gastric juice the lack of secretion of hydrochloric acid by the stomach can be determined by naked-eye inspection of the stools. The patient during three days is given a test diet, of which the chief requirement is that it shall contain one-fourth of a pound of chopped beef cooked so that it is still rare within. On carefully scrutinizing the finely divided stool under these conditions, if there is absence of hydrochloric acid secretion particles of undigested connective tissue will be recognizable. The author recommends the method of application in cases which the passage of the stomach tube would be inadvisable.

17 Roentgen Treatment of Some Non-malignant Superficial Lesions. C. L. Leonard, Philadelphia.

10. **The Over-Trained Nurse.**—Thompson claims that what ever shortcomings may be demonstrated in criticism of the present system of nurses training, the primary responsibility therefor belongs to the members of the medical profession, who, if they would devote as much time and thought to the problems of the training school curriculum, the relationship of the work of the nurses to that of the house staff in hospitals and similar matters, as they devote to other medical duties would soon produce ideal results in a system which, despite its serious shortcomings, has proved of the greatest possible benefit ever since it was established. The medical profession should define emphatically and clearly the limitations of the nurse's sphere of work and study. Physicians connected with institutions fostering training schools should insist on representation on their boards of school management, not merely in an advisory but in a governmental capacity. The curriculum of every training school should be submitted for approval and adoption by the physicians associated with the government of the school. The period of work for the trained nurse's ordinary diploma should be two years, but subsequent training for a year or more should entitle the graduate nurse to an additional certificate. Hospitals should admit for brief periods of study (say six months) a class of trained attendants, who should be exercised in the care of ordinary cases of illness not involving special technical skill or extended experience, and who could, in serious cases, aid the trained nurse in the work, and during convalescence supplant her at less expense to the patient. Provision should be made for the study of the nursing of private patients prior to graduation.

11. **The Trained Nurse and Surgery.**—Abbe contends that the value of a trained nurse in surgical work is much more dependent on her personal qualities, her conduct, discipline and experience than on the elaborate study of technical matter which had better be left to the physician.

12. **Training Schools.**—Ludlam insists that the organization of the training school should be as a department in the hospital to which it belongs. It should be conducted by one who has marked executive and administrative ability, and who, while free to discharge the duties of her office without interference should, at the same time, be distinctly subordinate and amenable to the general executive authority of the hospital. There should be a closer relation between the school and the attending staff of the hospital, and the wards of the hospital should be in charge of capable, permanent head nurses.

13. **What Nurses Should be Taught.**—Samuel says that it is not too much education that is the fault, but a want of more thoroughness and system in all that pertains to a nurse's work. Nurses should receive elementary instruction in anatomy, physiology, hygiene, bacteriology, materia medica, domestic science, and the principles and practice of nursing. The nurse should know something of normal and pathologic urine, and should be taught the simple tests for albumin and sugar. In order that the laws of asepsis may be intelligently and conscientiously obeyed, a clear knowledge of the fundamental principles of bacteriology is absolutely essential. The crusade against tuberculosis further illustrates the importance of a knowledge of bacteriology. Nurses should also know something of the preparation of antitoxins, the cost, how and when administered, with the results to be desired, and the effects that may be anticipated. Massage is another strong point for a nurse. During her course of training she should also be given an opportunity for the development of executive ability. The daily use of the *x* rays, for diagnosis or treatment, the wonderful revelations of the microscope and cystoscope, the very general use of intravenous saline infusion or hypodermoclysis, all make it very apparent that a nurse's education at present is a vastly different one from that received by her sister of ten or fifteen years ago.

25 Treatment of Autointoxication or Autoinfection When They Are the Cause of Mental Disturbance. (To be continued.) L. V. Briggs, Boston.

18. **Resistant Forward Shoulder.**—Fitz claims that the term round shoulders is misleading. Forward shoulders (postural resistance) is far more definite, but should be accompanied by a definite statement of the cause of resistance. Resistant forward shoulders are symptomatic of anatomic conditions. The commonly accepted statement that tight pectoral muscles

are the cause is not tenable. The most common factor in forward shoulders is the tightness of the serratus muscle. An occasional factor usually associated in extreme cases with the above is shortness of the coraco-clavicular and acromio-clavicular ligaments whereby the union of clavicle and scapula is made so rigid as to prevent full backward and downward movements of the shoulder. Systematic examination of forward shoulder cases is necessary in order to identify the definite causes of restriction of motion. The early recognition and treatment of pronounced cases is important since self-correction is unusual and the reflex moral effect is serious. When stretching and muscular development fail, it is possible to incise the tight coraco-clavicular ligaments, and thus to free the shoulder from rigid interference. The term "round shoulders" is misleading. Forward shoulders (postural or resistant) is far more definite, but should be accompanied by a definite statement of the cause of resistance.

23. **Operation for Cystocele.**—The operation described by Graves is an anterior colporrhaphy, and depends for its success on the presence of pubic attachments. Its essential principle is that of any anterior denudation which seeks support from the sides, but has in addition the purpose of gathering up all the slack tissue so as to avoid protrusions and to leave the anterior wall perfectly smooth. The most important protrusion to reduce is the somewhat loosely called urethrocele. Graves insists that this should always be reduced even in cases in which cystocele does not exist above it, as it is sure in time to stretch out the external portion of the repaired perineum. No particular originality is claimed in this operation as it combines and modifies principles long ago described by Dr. Emmet. [The operation is described in detail, but because of frequent references to diagrams and drawings which accompany the text it is impossible to abstract satisfactorily that portion of the paper.—ED.]

31 Hysteria Simulating Fracture of the Spine. F. H. Klaer, Philadelphia.

28. **Histologic Changes in Uterine Myomata.**—Allen thinks that in uterine myomata there is always a certain amount of elastic tissue, either in normal amounts and relations in the blood-vessel walls or sometimes in the tumor tissue, where it is distributed among the bundles of muscle along with fibrous tissue of such septa and muscular investments. Vascular changes of the type of fibrous and elastic hyperplasias are common in such tumors, leading to the thickening of their coats and to eventual obliteration of vessels, and to increase in the connective tissue framework of the tumor in the vicinity of the affected vessels. Probably as a result of nutritive disturbances brought about by such vascular changes this excess of the elastic tissue in the surrounding tissues does not maintain an integral condition, but deteriorates and eventually disappears. Probably dependent on the same nutritive disturbances the original muscular elements of the tumor also atrophy, degenerate and necrose, and finally disappear as muscle spindles, although there is some evidence that the cell wall (corresponding to the sarcolemma of the striated type of muscle) may remain and contribute in a passive manner to the fibrillar material of the final fibroid tissue. The character of the tissue and the relative paucity of fiber-forming young elements is consistent with the idea that the fibrillar tissue of the final uterine fibroid is in a large part not true fibrous connective tissue, and that the general process of transformation is not a progressive but a retrogressive one

39 Osteopathy. W. E. Blodgett, Detroit.
40 Progress of Internal Medicine. V. C. Vaughan, Detroit.

37. **Intermittent Claudication.**—For years Fintermann's patient complained of weakness and pain in the lower extremities, first in the left and then in the right. The pain and weakness were not constant, but were the most noticed after overexertion, either standing or walking. After rest, the pain and weakness would disappear for some time, always coming back after overexertion, and the intervals between those attacks would become shorter, so that finally, even when resting, the pain and weakness would not leave him. There were signs of imperfect nutrition of the parts, the foot would become stiff and cold, and signs of insufficient blood supply would manifest themselves. Impairment of motion and sensation would become very intense, finally developing to such a condition that nutrition became so insufficient that gangrene at the most peripheral parts developed, finally necessitating amputation below the knee. After years of suffering and insufficient nutrition, a condition developed showing a change in the tissue of the blood vessels, finally reaching such a state that pulsation could not be felt in some of the main arteries of the extremities. The examination of the blood vessels after the amputation showed an endarteritis obliterans.

50 Adrenalin and Chloretone in the Treatment of Chronic Rhinitis and Pharyngitis. J. C. Warbrick, Chicago.

45. **Pulmonary Edema.**—The multiplicity of affections with which pulmonary edema may be associated is well shown by the analysis of the 405 cases included in Coplin's report. There was a coexisting congestion of the lung in 235, tuberculosis in 69, croupous pneumonia in 38, atelectasis in 12, infarction in 12, gangrene in 5, bronchiectasis in 3, chronic pleurisy in 120, acute pleurisy in 23, and hydrothorax in 34. Bronchitis could be recognized in only 12 cases. In 350 of the cases associated cardiac lesions were also present; hypertrophy in 108, dilatation in 62, chronic endocarditis in 96, acute endocarditis in 7, myocarditis in 76, and in one the heart was malformed. In 35 cases there was a pericarditis, and in 6 a hydro-

pericardium. In 140 of the cases arteriosclerosis was sufficiently marked to attract attention. Renal lesions were present in 333 cases, chronic parenchymatous nephritis in 156, chronic interstitial nephritis in 126, acute diffuse nephritis in 42, and in 9 nephritis was observed, although the form is not stated. Hydronephrosis was found in 7 additional cases. The liver was congested in 150 cases and cirrhotic in 40. Although intracranial lesions are often named as important causes of pulmonary edema, the cases therein studied offer no convincing evidence of an intimate association between the pulmonary lesion and meningeal or cerebral disturbances. In 29 cases there was a cerebral edema, apparently due to the same causes as the pulmonary lesion. Meningitis was also present in 20 cases, and in most of these evidences of sepsis are recorded. Cerebral hemorrhage was found in 7 cases and meningeal hemorrhage in 6. In 50 patients colitis, either dysenteric or probably uremic, was observed. Ascites was a complication in but 25. With regard to the sex, 261 were males and 139 were females; in 5 cases the sex was not stated.

46. **Menopause in Fable and Fact.**—Reynolds claims that beyond slight disturbances there should be no symptoms in the normal menopause. Every definite symptom of pelvic origin which appears at the menopause has a given lesion to account for it; that is, with perfect pelvic organs the years of the menopause will pass pleasantly by, with little or nothing to direct the woman's attention to it save the cessation of the catamenia. He who has learned to search out the cause and effect is often horrified at the amount of unrelieved suffering which can be traced to the dogma so generally accepted by the laity, and by too many members of the profession, that any nervous or circulatory disturbance, or, indeed, any chronic ailment whatsoever that occurs between 35 and 50 may safely be attributed to the menopause. Reynolds urges that it must be insisted on that relatively slight lesions may at this period initiate processes of real importance, or may at least cause symptoms of importance, which usually take the form either of greatly increased nervousness, pelvic pressure or bearing-down sensations, actual pelvic pain, or irregular or increased flow. All these are abnormal, can in most cases be referred to a definite pelvic cause, and should always attract attention because usually they can be relieved by an intelligent understanding of the class of lesions to which each class of symptoms may be referred.

47. **Dietetic Management of Diabetes.**—Four points in particular as regarded by Croftan as of a special practical value as they may guide the practitioner away from the paths of routine and still enable him to remain within the limits of safety. The first of these points is the danger of too much meat. Meat actually leads to sugar excretion in diabetes, and excessive meat feeding favors the development of acidosis. Withdrawal or reduction of meat appreciably increases the tolerance for carbohydrates, even in mild cases. The second point is the danger of too little carbohydrate which results in acidosis and, finally, coma. It is important to determine the tolerance or the so-called boundary of assimilation for carbohydrates in each case of diabetes. Third, a diabetic should receive the largest amount of fat in his food that he can possibly stand. Not only does fat spare the tissue albumins, but its calorie value is so high that it aids most materially in maintaining nutritive equilibrium. Fourth, the value of the rice, potato, milk and oatmeal cures. Croftan's experience has been limited to the oatmeal cure. He claims that if the rule is observed to stop the oatmeal cure if good effects are not seen within three days, the number of bad results will be reduced to insignificant figures. The best results are obtained in juvenile diabetics, and he urges that no case of juvenile or adolescent diabetes should be deprived of the benefit of an oatmeal cure. The practical application of the quantitative method is described in full.

54. **Pathologic Calcification.**—Collecting the evidence obtained from both the literature and from experiments, Wells deduces therefrom the following facts: 1. The composition of the inorganic salts in calcified areas in the body seems to be practically the same, if not identical, whether the salts are laid down under normal conditions (ossification) or under pathologic conditions. (This is shown by a table giving the proportion of inorganic salts found by analysis in normal bone, and the proportion found in calcified materials.) 2. No evidence has been obtained by direct chemical analysis that calcium soaps form a constant and important stage in the process of calcification of tuberculous areas and thrombi. That the formation of calcium soaps is an essential process in pathologic calcification seems, however, highly improbable. 3. Cartilage, at least the epiphyseal cartilage of long bones, shows a striking tendency to accumulate calcium salts, even when the cells have been killed by heat. On the other hand, the presence of large amounts of nucleoproteids (spleen and thymus) seems to lead to no specially rapid impregnation with calcium, as compared with tissue poor in nucleoproteid (muscle). This agrees with the great tendency of degenerated connective tissue to calcify, in spite of its extreme paucity in nucleoproteid, an observation which speaks strongly against phosphoric acid, arising from decomposed nucleoproteids, as an important binder of calcium in pathologic calcification, attractive as this hypothesis is. Wells thinks that the facts at hand are not sufficient to warrant theorization, on the chemic and physiologic processes of calcification.

Titles marked with an asterisk (*) are abstracted below. Clinical lectures, single case reports and trials of new drugs and artificial foods are omitted unless of exceptional general interest.

British Medical Journal.
April 14.

1 *Treatment of Taenia. J. K. Fowler.
2 *Psoriasis and Its Treatment. P. S. Abraham.
3 Eye Accidents and Compensation. S. Snell.
4 Important Symptoms in Diseases of the Eye. A. M. Ramsay.
5 Tabes Dorsalis. D. Ferrier.

1. **Treatment of Taenia.**—The method of treatment employed by Fowler is described as follows: 1. The patient is kept in bed. 2. For two or three days the diet is restricted to beef tea, about two pints, two rusks, and four ounces of port wine daily. During this time the patient is given gr. ii of cascara sagrada three times daily. About 5 a. m. on the fourth day the patient is given ʒi of compound infusion of senna, and at 9 a. m. a capsule containing m. xv of extract of male fern. The dose of male fern is repeated at 9:15, 9:30 and 9:45. At 11 a. m. another ounce of the senna is given. If the worm has not been expelled with the head by 1 p. m. a second course of treatment is given with the male fern, followed in an hour by a purgative. If the head is not found a third course is administered. Fowler says it is not advisable to continue the treatment beyond this without an interval of a day, as the patient may be somewhat exhausted.

2. **Treatment of Psoriasis.**—Abraham does not believe that there is any one drug administered internally which can be regarded as a specific in psoriasis. In his experience magnesium sulphate with a little iron and some bitter tonic is often useful in regulating and in improving the general nutrition, and in every case in which there is the least suspicion of an excess of uric acid in the system he gives salicylates, salicin and alkalies. As regards external remedies, his usual plan is to order a thorough soaking, for at least ten minutes, in a weak tar bath every day, to be followed by a copious inunction with the following ointment:

℞. Creolini ..... ʒss 2
Acidi salicylici
Hydrarg. ammon., ää ..... gr. x 6
Lanolini et
Vasolini ad ..... ʒi 30

Abraham sometimes adds two or three drams of soft soap, and occasionally 15 grains of pure precipitated sulphur. Most cases yield to this treatment in a few weeks, but when progress is slow he adds to this ointment 10 or 20 grains of chrysarobin. For psoriasis of the scalp his routine ointment, for a few weeks, is:

R.	Hydrarg. ammon. 5i	4
	Saponis mollis	
	Vasolini 3i	30

With the addition sometimes of resorcin or some tarry oil.

The Lancet, London.

April 13.

6 Tabes Dorsalis. D. Ferrier.
7 *Appendicostomy and Appendicectomy as a Substitute for Cecal Colotomy, and in Treatment of Typhoid. C. B. Keetley.
8 Points in the Treatment of Chronic Bright's Disease. S. West.
9 *Management of the Third Stage of Labor. G. F. Blacker.
10 Influence of the Nervous System and External Temperature on Certain Circulatory Changes Concerned in the Etiology of Catarrh, Ulcer, and Simple Dilatation of the Stomach, with Suggestions as to Treatment. A. Mantle.
11 Case of Glioma of the Pons. G. Schorstein and A. J. Walton.
12 *Relationship Between Exophthalmic Goiter and Acute Rheumatism. W. E. Robinson.
13 Two Cases of Otitic Lateral Sinus Phlebitis, one Complicated with Cerebellar Abscess. D. Grant.
14 The Turk's and Caicos Islands as a Resort for Cases of Pulmonary Tuberculosis. G. S. S. Hirst.

7. **Appendicostomy.**—Keetley reports a case in which he used the appendix for giving egress to feces when it would otherwise have been necessary to perform a cecal colotomy. He also discusses whether or not typhoid patients should be operated on before perforation and bleeding occur. This could be done either by performing an enterostomy or appendicostomy which would permit of flushing the ileum with a warm weak saline or a silver solution.

9. **Management of Third Stage of Labor.**—Blacker summarizes his paper as follows:

1. The third stage of labor is best treated by the employment of the Dublin or Credé's method of expressing the placenta after a sufficient interval of time has been allowed to elapse for the placenta to become separated from the uterine wall. 2. The tendency to shorten this interval of time to much less than the thirty minutes recommended by Credé is attended with considerable risk to the mother. 3. It is, however, best to be guided by careful observation of the changes in the uterus indicating that separation of the placenta has or has not taken place rather than by any arbitrary period of time. 4. After the change in the level of the fundus of the uterus takes place, indicating that the separation of the placenta has occurred, from ten to fifteen minutes should still be allowed to elapse so as to diminish the risk of the retention of any portion of the placenta or membranes. 5. If there is reason to suppose that the placenta is adherent and a trial of expression fails no harm will result to the mother in the absence of any urgent indications if a period of from one and a half to two hours is spent in waiting for its spontaneous separation and expulsion. 6. Manual removal of the placenta should never be performed if it can be avoided, and it should not be practiced in the absence of severe hemorrhage or any other indication for its immediate performance until from one and a half to two hours have elapsed since the birth of the child, and then only if further attempts at expression fail. 7. Retained portions of placenta and membranes should be removed at once, unless in the case of the membranes they are of quite small size. 8. In performing this operation it is a wise precaution to wear sterilized rubber gloves.

12. **Exophthalmic Goiter and Rheumatism.**—The possible relationship between these two affections was brought to Robinson's attention by the occurrence in one of his patients of a definite attack of rheumatism about six months after the first signs of Grave's disease. The case proved somewhat intractable to treatment, but the acute rheumatism yielded very readily to salicylate of sodium, and at the same time there was very pronounced diminution of all the signs of the exophthalmic goiter, notably of the swelling of the thyroid gland, the exophthalmos and the tremors. The pulse rate continued to be higher than normal, but this also was considerably lessened.

28 *Diet in the Tropics. W. J. Simpson.
29 By-paths of Medicine; the Method of Cornaro.

16. **Therapeutic Uses of Diet.**—Hutchison sketches briefly the general uses and limitations of dietetic means in the cure of disease, and indicates the principles which guide their application. He lays down the following general rules which should be borne in mind when drawing up any plan of dietetic treatment: 1. When prescribing a diet in a case of local disease one must take care not to sacrifice the whole to the part. 2. No article of food should be forbidden unless there is a good reason for doing so. 3. In acute disease one should recommend; in chronic disease forbid. 4. Before recommending any article, find out whether the patient likes it, and whether it agrees with him. 5. If an article disagrees, it is generally better to reduce its amount in the diet than to cut it off altogether. 6. General and proposed changes of diet should be made gradually. 7. Always bear in mind the following aphorisms of three great physicians: "Such food as is the most grateful, though not so wholesome, is to be preferred to that which is better though distasteful."—Hippocrates. "More importance is to be attached to the desires and feelings of the patient than to doubtful and fallacious rules of medical art."—Sydenham. "Physicians appear to be too strict and particular in the rules of diet and regimen; too anxious attention to those rules hath often hurt those who were well, and added unnecessarily to the distress of the sick."—Heberden.

17. **Diet and Heart Disease.**—Duckworth states that plain food of all varieties, plainly cooked, taken in regular meals, without any overloading, or excess in solids or liquids, is to be enjoined. Gastric, or intestinal, dyspepsia is naturally inconsistent with favorable nutrition of the body generally, and of the myocardium in particular. In the young, so long as sufficient food is taken, there is no need to encourage excess, or to feed habitually between meals. Strong meat soups and essences are to be avoided, and tea sparingly taken by both young and older patients. As a rule, all alcoholic drinks are best omitted from the diet, and tobacco smoking is to be abjured, or very slightly indulged in, and then only after a meal. If tea or tobacco induces palpitation, neither must be used. If these measures are imperative in the case of simple myo-hypertrophy of the heart, they are even more so when failure of muscular efficiency shows itself by the well-recognized symptoms of dyspnea, palpitation and oppression of the chest.

If, as a result of this failure, there is dropsy, the diet has to be modified. It is necessary to feed such patients with small meals, and to limit the amount of fluids of all kinds. It is also desirable to make the principal meal soon after midday, and to enjoin a lighter one in the evening; to avoid giving, at any one time together, proteids and carbohydrates. The choice of food is hardly important so long as it is simply prepared and readily digested. Predigested food is not so necessary as is commonly believed, but it may be needed in some cases. Soups and milk, therefore, are unwisely recommended in most instances, as tending to flatulence and discomfort in bedridden or sedentary conditions. Coffee with an equal part of milk is often a good cardiac stimulant, and may be better digested than tea as commonly made. A small cupful of freshly made China tea, with cream, may be given in the morning, and as much cocoa with milk later in the day. Small amounts of water or unaërated, indifferent spa water, may be given between meals. In the later stages of progressive heart failure with tumidity of the liver and dropsy, predigested foods may be employed; milk and barley water with citrate of soda and Koumyss may prove sufficient nutriment till some measure of appetite returns. Small quantities of iced champagne may prove useful. The question of withholding all salt from the food is worthy of consideration as soon as dropsical symptoms appear, and this plan may be tried.

19. **Diet in Renal Disease.**—Bradford says that a rigid system of dieting is suitable neither for all kidney diseases nor for all stages of the same disease, and attention in determining the diet should not be directed exclusively to the condition of the urine, but other factors, such as the general nutrition of the patient, the presence or absence of dropsy, the degree

of cardiovascular degeneration present, and the presence or absence of uremia, are all factors that should be taken into consideration. In cases of true acute nephritis associated with considerable suppression of the urine, and in which the eliminating functions of the kidney are most seriously compromised, the diet should be reduced to the greatest extent possible, and in some cases of very acute nephritis it may be advisable to withhold all food for a few days. In most cases such starvation treatment is not necessary, but it is still essential to give as little food as possible, and it may be as well to restrict this to one or one and a half pints of milk, moderately diluted, in the twenty-four hours.

All meat extracts and soups should be avoided throughout the illness, as their nutritive value is low, and they contain numerous extractives and salts which can only act as irritants to the kidney. The amount of fluid given to these patients should also be strictly limited, especially if there is any tendency to dropsy or to the development of hydremic plethora, and the use of diluents as diuretics should be restricted to the later stage of the malady, where, no doubt, much good may be derived by the administration of moderate quantities of fluid in order to promote the removal of débris from the renal tubules. In chronic renal disease, if complications such as uremia and dropsy are present, the dietetic treatment must be somewhat similar to that applicable to cases of acute nephritis, but owing to the long continued character of the disease, restrictions can not be carried to the same length as those suitable to the treatment of the acute malady. In chronic renal disease associated with dropsy, and particularly with increasing dropsy, a milk diet is also advisable, but in very chronic cases, in which the dropsy is moderate in amount and persistent for weeks or for months, a pure milk diet for prolonged periods. Such patients may be put on a milk diet of some three pints per diem, and if improvement sets in such a diet may be continued for three weeks, but it is probable that no useful purpose is served by maintaining such a diet for months, and a more solid diet with a minimum of common salt may often produce more beneficial results.

The improvement under a milk diet in chronic renal disease is often more spurious than real, the quantity of urine is seen to be increased, and the albuminuria to be apparently diminished; these are looked on as signs of improvement, when really all that has happened is that the diuretic action of the milk has led to an increase in the flow of urine, and thus the loss of albumin, although really the same, has undergone a percentage reduction. Attention should never be directed solely to the state of the urine, the general appearance of the patient and the body weight should be carefully observed. An increase in dropsy frequently shows itself by a rapid increase in the body weight. The milk diet is not recommended as a routine measure for long-continued periods in chronic renal disease.

28. **Diet in the Tropics.**—Simpson claims that the majority of individuals who persist in high living in the tropics pay for it sooner or later in some form of intestinal disorder, colitis, disease of the liver or nervous affection. Apart from the excessive quantity of meat and alcohol which is partaken of in the tropics, but which is being gradually diminished, the principal defect in the present-day diet of the tropics are the soups and the rather frequent recourse to long iced drinks. The latter are often taken between meals, and are an active factor in the production of constipation. Both lead to dyspepsia and not infrequently to dilatation of the stomach, which is one of the more common affections from which residents in the tropics suffer. Dilated stomach, in those who have returned from the tropics, is a more common cause of indisposition than is generally recognized. It is always well to examine for this condition in a patient with yellowish conjunctiva and furred tongue, and who complains of nausea, dyspepsia, languor and palpitation. In such a case it is probably combined with enlargement of the liver. The effects of overindulgence in alcohol are very marked in the tropics. Neurasthenia, depression and incapacity for mental work in the tropics not uncommonly owe their origin to a consumption of alcohol which would be without any corresponding effect in a more temperate climate.

32. **Staining Reaction of Fat Acids.**—Jacobson has found that fat acids have an affinity for a weak solution of some basic anilin dye while the neutral fats repel it. His studies were made principally with the stools of nurslings. The fat acids took the diluted Ziehl stain while the neutral fats were unaffected by it and the soaps were only very slightly stained.

35. **Oral Teaching.**—Bonnier trains teachers to throw out their voice and to let the resonance of the hall speak for them with the minimum of effort on their part, instead of straining to emit a volume of sound sufficient for all to hear. He also describes means to test the hearing capacity of pupils. Relative deafness can be detected with what he calls "paracoustics at a distance," that is, the application on the leg of a tuning fork with 100 vibrations. The sound ear does not hear its vibrations, but they are transmitted through the bones to the paracoustic ear. Perception of them indicates relative deafness. In case of an affection of the labyrinth, the blindfolded child deviates to that side in walking, or the pupil on that side is sometimes dilated or reacts sluggishly to light. If the child is told to shut his eyes while the lids are held from closing, the eyeballs turn upward with dissociated binocular movements, possibly turning toward the side affected. These signs can be sought by the teacher, and will prove that many children whose inattention has annoyed the teacher are in reality subject to some unsuspected ear affection.

36. **Clinical Significance of the Lochia.**—As streptococcus puerperal infection is generally regarded as more serious than others, bacteriologic examination of the lochia may prove important for the prognosis and also for treatment. A fecal-like odor suggests that the infection is due to colon bacilli; such cases are usually in very constipated women. If the lochial discharge is blackish or like coffee grounds this does not necessarily mean infection, and nothing should be allowed which might cause infection. Undue persistence of the lochia should suggest relics of the placenta; if not promptly removed they may lead to the formation of a chorioepithelioma.

37. **Continuous Drainage of the Stomach in Acute Peritonitis.**—Jaboulay's prosector at Lyons describes some experiences with prompt gastrostomy and rubber-tube drainage of the stomach in cases of acute peritonitis with a predominance of gastric symptoms. This technic, he asserts, is superior in its results to enterostomy and lavage of the stomach, and it is simpler and easier than the latter in these conditions. Systematic drainage of the stomach should not supplant drainage of the peritoneum, but it is liable to prove an invaluable adjuvant. Even in the gravest cases it may be indicated as a palliative measure, freeing the patients from their distressing dyspnea, vomiting and hiccough. In a case thus treated the patient was a young man with symptoms of ileus and acute peritonitis. The distended stomach protruded and there was almost constant vomiting and hiccough. About 5 cm. of the stomach was drawn out and turned down over one side of the laparotomy wound. A sound 1 cm. in diameter

was introduced and fastened with a thread to the abdomen and a rubber tube for siphonage attached. Gases escaped at once and as much as a quart of bile; the abdomen subsided and the relief was great. Two more quarts of greenish fluid flowed through the tube during the next twenty-four hours, when the patient could be fed through the mouth. During the half-hour or hour after eating the drain tube was closed with a clamp. The pulse grew slower and the patient was entirely cured in a week. In a case of appendiceal peritonitis the distension of the stomach, the cardiorespiratory symptoms, the disturbances in the intestinal circulation and all the other symptoms yielded rapidly to gastrostomy and continuous drainage of the stomach. This procedure is also indicated in cases of postoperative dilatation of the stomach. The distension of the stomach hampers the adjacent organs and is the cause of many of the symptoms. When the accumulated gases and fluids are evacuated by continuous drainage, stools and flatus pass the anus by the second day without artificial aid, and the cure is soon complete.

39. **Diet in Case of Tendency to Gallstones.**—Dufourt enumerates the conditions for success in warding off gallstone trouble as: 1, To avoid or to attenuate infection of the biliary passages; 2, to keep the composition of the bile normal; 3, to maintain a copious secretion of bile, and, 4, to insure its constant excretion. The meals should be frequent and light, with a lunch in the afternoon. The extractives have the property of promoting the passage of the bile into the duodenum and consequently a glass of consommé or something of the kind should be taken just before retiring. A little milk might be sipped if one wakes in the night. By thus preventing the stomach being long empty at a time, the contraction of the gall bladder is promoted and the circulation of the bile kept active. In case of recurring colics, while waiting to decide the question of surgical interference, small amounts of milk, at short intervals, answer the indications and the result may decide against operative measures. The carbohydrates have little effect on the secretion of bile and should be reduced to the minimum. Fats favor its excretion and should be taken in the most digestible form, as cream, butter or yolks of eggs. Lard, oil and fat meats are too indigestible. Fruits and vegetables are advised. Condiments and stimulants should be avoided. The tolerance of the patient is the chief consideration in all these measures. The theoretical bases for them all are reviewed in detail.

41. **Reduction in Knee-Elbow Position of Retrodisplacement of Uterus.**—The thigh should be perpendicular to the resistant plane on which the patient kneels in the knee-elbow position. The vagina or rectum, or both, are then opened to admit air, which distends them and aids in mobilizing the uterus. Jayle gives eight illustrations showing the technic with which the uterus can then be swung into place with one or two fingers introduced into the vagina or rectum, the thumb braced against the pubic bone or buttocks. Pressure is applied gently five or six times, when the uterus generally slides into place.

42. **Methylene Blue Reaction of Typhoid Urine.**—This has been called the Russo test. Gandy and others write that the reaction is by no means a specific phenomenon. It occurs as an ordinary physical reaction in any urine.

43. **Schaudinn's Treponema Pallidum.**—Sézary's article reports positive findings, but is chiefly remarkable for the bibliography on the subject appended. It fills 16 inches of very fine type, printed solid, the oldest title being scarcely more than a year old; nearly all countries are represented. In his own research he was impressed with the great frequency of positive findings in contagious syphilitic lesions and the absence of treponema in ordinary lesions, also with its possible absence or at least its rarity with present methods of investigation in a certain number of specific manifestations. Schaudinn has never claimed that the *Treponema pallidum* is the causal agent of syphilis, but Metchnikoff and Fraenkel have not hesitated to affirm it. They base this conclusion on its almost constant presence in the primary and secondary accessible or inaccessible manifestations of syphilis, acquired and inherited. Another argument is that the *Treponema pallidum* has not been found in man or animals, well or sick, who are free from syphilitic infection. Positive findings confirm the existence of syphilis, but negative findings should not disprove it, as the parasite is not invariably encountered.

44. **Rubber Gloves.**—The special features of Chaput's gloves are the shortness and width of the fingers. He keeps always three sets on hand, one for aseptic work, one for septic and one for postmortem work. He boils each set in a separate box with perforated tray. The wrist of the glove is turned back an inch or so to take hold of the gloves in pulling them on. A strip of gauze dressing is wound around the forearm over the gauntlet and tucked in above the wrist. After the operation the gloves are washed on the hands and drawn off carefully by an assistant. They can be kept in boiled water, renewed every day, or in a weak solution of sodium borate which keeps indefinitely. During the operation the gloves can be washed on the hands.

45. **"False Gastropaths."**—The French speak often of false "urinaires," false "génitaux" and false "cardiaques," meaning persons who imagine they have some affection of the urinary or genital apparatus or of the heart. To this list Déjérine adds the false "gastropaths", the persons with purely psychic or nervous forms of stomach troubles. They range from simple dyspepsia in neurasthenics to phobias and pseudo-gastropathies. The stomach phobias are generally secondary to neurasthenia, but not always. Typical cases are described of this and of the false functional stomach disturbances, of which about 200 come under observation at the Salpêtrière dispensary during the year, out of the 1,500 patients, while an average of 40 severer cases requiring hospital treatment are received. In many instances these false gastropathies are the direct result of therapeutics; the physician treats some transient digestive disturbance and this attracts attention to the stomach. In a later article the diagnosis and treatment are to be described.

55. **Transplantation of Muscles.**—Hildebrandt's experimental and clinical experience has demonstrated that it is possible to transplant a muscle when it has been almost entirely excluded from the circulation. It will heal in place and retain its functions under the condition that its nerve, that is, its connection with its center, and the blood vessels supplying this nerve, are retained intact. Most of the muscle fibers die when cut off from their circulation, but the power of regeneration is retained and the muscle grows again. The importance of sparing the nerve or nerves of the muscle is emphasized by this work. The pure ischemia of the muscle, induced by transplantation under the circumstance described, caused remarkable laxness, instead of the contraction noticed when the ischemia was induced by constriction of the muscle.

61. **Trauma in Connection with Cancer Formation.**—Röpke reviews the surgical material at Jena, stating that he found 19 out of 800 cases of carcinoma in which there was a possible causal connection with a single trauma, while the connection with the chronic trauma was evident in a large number. In 189 cases of sarcoma he found 28 cases in which chronic trauma and 19 in which a single trauma might possibly have played a part in the etiology. The connection between the trauma and the neoplasm was unmistakable in all these cases, and such connection might easily have existed in other cases in which the details were not so well known. Chronic trauma seems to play a larger part in the origin of carcinoma, while single trauma is apparently responsible in more cases of sarcoma. In 44 cases in Röpke's experience carcinoma was known in other members of the family. In 5 cases a sarcoma developed in the descendants. In only 2 of the cases of neoplasms developing after a single trauma was there a history of family antecedents.

64. **Lung Complications After Abdominal Operations.**—Bibergeil's statistics include 3,909 abdominal operations, with 283 cases of consecutive lung complications. Pneumonia was observed in 135, that is, in 3.5 per cent. of the total number of cases; embolism of the lungs in 12, that is, 3 per cent. (all fatal); infarcts in 9, 2 per cent., with one death; bronchitis in 83, that is, in 2.1 per cent.; abscess in the lungs in 12; pleuritis in 15, and empyema in 13. Study of the conditions suggests that lobular pneumonia after a laparotomy is due to autoinfection (aspiration during the anesthesia). The principal factor in the postoperative pulmonary affection is the effort of the patient to spare himself pain in the sutured abdominal wound. To keep it from hurting he breathes as lightly as possible and refrains from expectorating. Supplementary factors are the debilitated condition of the organism as a whole and the depressing influence of the operation. Lobar pneumonia is due to infection from pneumococci, either present as saprophytes or aspirated with mucus from the mouth. In regard to prophylaxis, Bibergeil reiterates the advisability of curing any respiratory affection before attempting an abdominal operation. The mouth and throat must be carefully cleaned, and lavage of the stomach should precede any operation on the digestive tract. The head of the patient should be turned on the side so that mucus accumulating in the mouth can flow out readily. The patient should be carefully protected against getting chilled. If the abdominal cavity or parts thereof are rinsed, the fluid should be heated to 113 or 122 F. The exposed parts of the abdomen must be protected against loss of heat by hot compresses. After the operation the position of the patient should be frequently changed, and he should be instructed to breathe deep, regardless of any pain in the wound. Constricting bandages should be avoided, and the patient should be made to sit up and get out of bed at the earliest possible moment. The action of the heart should be carefully supervised. At the same time, he adds, the most scrupulous application of all these measures does not positively insure against the development of a postoperative lung affection.

68. **Mistaken Diagnoses of Appendicitis.**—In one of the 3 cases reported by Korach, diffuse miliary tuberculosis simulated the clinical picture of acute appendicitis. In another case the symptoms were due to a sarcoma in the mesentery which had perforated into the ileum. In the third patient nothing was found at the time of the operation or discovered later to explain the symptoms simulating acute appendicitis.

69. **Sound Palpation of Tuberculous Bronchial Glands.**—Neisser reports a second series of 34 patients who gave a decided positive reaction to tuberculin and had a number of mild subjective symptoms suggesting the possibility of tuberculosis, such as pains in the back and chest, "stitches" between the shoulders, and occasionally slight night sweats. The lungs seemed to be intact and actual tuberculosis has not developed in any of them, although under examination for two or three years or more. None of them had sanatorium treatment. He believes that the trouble in such cases is isolated tuberculous infection of the bronchial glands. It can be differentiated by the pain elicited by pressure or succussion on the spine, but a still more reliable and accurate measure is by palpation by means of a sound introduced into the esophagus. He uses a medium-sized pharyngeal catheter, the openings plugged with paraffin. About 10 cm. above the tip a long slit is made in the catheter. Another, very fine, stiff catheter, with a very small hole cut opposite the slit in the larger one, is slipped inside the large catheter, and a rubber condom drawn over both. A thread is tied around the whole above and another below the opening. Air is then blown into the catheters through an ear syringe; it inflates the rubber bag opposite the slit and hole in the catheters. The sound has been used on 250 individuals, the results showing that it causes no pain under ordinary conditions, while in the presence of a tuberculous process in the glands there is slight but characteristic painfulness when the rubber bag is inflated. The positive findings were almost invariably accompanied by pain on pressure of the spine. He remarks that if the term were not so hideous he would suggest calling this condition "tuberculosoid" to distinguish it from incipient tuberculosis. None of the patients to date have developed clinical tuberculosis. In his experience this condition was observed most frequently in families in which one member had typical tuberculosis.

70. **Hematuria as Initial Symptom of Primary Tuberculosis of the Kidneys.**—Askanazy has observed 5 cases in which profuse hematuria was the first symptom to call attention to a tuberculous process in the kidney. He has found a number of

such cases reported in the literature. The hematuria generally comes on suddenly in apparently healthy persons. In some cases it preceded the development of the clinical process by eight years, by 13 years in Newman's case, and by 16 years in one of his own cases. The hematuria recurred several times in the interval in some cases. In others the typical symptoms followed close on the hematuria. As spontaneous healing of a tuberculous process in the kidneys is generally possible, an early diagnosis does not necessarily call for immediate nephrectomy. Hygienic-dietetic measures and internal medication may arrest the process. The initial hematuria is thus of the greatest importance, as it allows an early and presumptive diagnosis and prompt treatment. He remarks in conclusion that in tuberculous affections the permanent integrity of the sound mate can never be guaranteed, so that nephrectomy should not be done without due consideration.

71. **Diagnosis of Displacement and Deformity of One Kidney.**—Cohn describes the various diagnostic means by whose aid he was able to differentiate a rudimentary dystopic kidney with obstructed ureter in a ii-para of 31, and a displaced and abnormally small kidney in a nullipara of 27.

72. **Beriberi and Scorbutus.**—Schubert argues that we must distinguish between sea scorbutus and land scorbutus and Barlow's disease. Sea scorbutus is a chronic meat poisoning, land scorbutus is an infectious disease. True tropical beriberi is an infectious disease, while the affection described under this name in England and elsewhere is a polyneuritis of unknown origin, possibly due to arsenic intoxication. Ship beriberi, he states, is an intoxication with rotten salt meat.

73. **Clinical Study of Cholelithiasis.**—Kuckein analyzes the primary symptoms and other features in 174 cases of gallstones. One patient had a serious recurrence after operative treatment. Kehr does not admit the possibility of recurrence after thorough operative treatment, but Körte has observed 6 cases of such recurrence among 313 patients on whom he had operated.

75. **Pathologic Anatomy of Congenital Deafmutism.**—Lindt had oportunity to examine the petrous portion of the temporal bone in a young woman who had been a deaf mute from infancy. The external and middle ear was normal, but both labyrinths showed anomalies evidently of embryonal origin, atrophy of the spiral ganglion, cochlear nerve, and ramus sacularis, with entire absence of the papilla basilaris on both sides, and with marked aplasia of the Corti organ and other findings similar to those of the 10 similar cases that have been examined histologically. The article is illustrated.

78. **Aneurism of the Basilar Arteries.**—Rindfleisch describes 3 cases and expatiates on the valuable information that may be obtained from study of the cerebrospinal fluid in various meningeal affections. The findings should be weighed with all the accompanying symptoms, but when this is done they may throw unexpected light into obscure places. The tint of the fluid is instructive. In case of hemorrhage into the subarachnoid space the red corpuscles rapidly disappear and are all gone by the end of a few weeks. The hemoglobin imparts a reddish-yellow or red tint to the fluid, which gradually turns brown in the course of a week or so. Hemoglobin can still be detected in the fluid at this stage, but later the findings are negative, the hemoglobin having become transformed, he states, into a brown derivate, probably hematoidin. The urine of the patient generally contains urobilin at this stage. Finally the hemoglobin entirely vanishes and the fluid becomes limpid once more. A large part of the blood pigment is deposited in the arachnoid as hemosiderin. He calls the tinting of the fluid "xanthochromia." Diffuse distribution of the blood throughout the subarachnoid space causes several characteristic symptoms, among them the signs of congestion in the fundus of the eye, explainable by an infarct in the sheath of the optic nerve. This "blood tamponing" of the sheath of the optic nerve was evident at the autopsy in his case. The diffusion of the blood through the subarachnoid space was the cause of the spinal irritation evidenced by the stiffness of the back and neck, the local and radiating pains, the Kernig sign etc. The vanishing of the knee jerks was probably the result of the stretching of the roots. In one of the cases described the spinal symptoms persisted for a long time and, in conjunction with oculomotor paralysis, aroused the suspicion of a diffuse chronic meningeal affection of an inflammatory or neoplastic nature. The symptoms were of a general cerebral nature, accompanied by focal symptoms pointing to the base of the brain, and diffuse spinal symptoms. The lesion proved to be an aneurism of the right posterior communicating artery.

79. **Tuberculosis of Stomach.**—Alexander describes a case in which the symptoms suggested cancer of the pylorus. The patient was a man of 40, who weighed 152 pounds. After an attack of "influenza" nine months before he began to experience pain on pressure and discomfort in the stomach region about 45 minutes after eating, especially after solid food, with eructations but no vomiting. There was constipation and much weakness. In the fasting stomach, after a test supper, a coffee-dregs residue was found containing lactic acid; traces of blood were revealed by the guaiac test, with lactic acid bacilli and fungi. The pylorus was found encircled with a flat granular ulceration. After the resection the patient had pneumonia, and died on the eighteenth day. No tubercle bacilli were found in the stomach lesion nor in the sputum, but the presence of giant cells in the pyloric tumor indicated a tuberculous origin. The process was isolated, as no other signs of tuberculosis could be detected elsewhere. This makes the fourth case of the kind on record. The patients in each instance had been operated on under the diagnosis of cancer.

81. **Lymphatism and Sudden Deaths.**—Hedinger reports the sudden death of five children in one family before they reached the age of 6. The autopsy of the last child, a girl nearly 6, showed marked hyperplasia of the lymphatic system, including the thymus, hyperplasia of Peyer's patches and of the solitary follicles in the digestive tract, enlarged tonsils and spleen and eccentric hypertrophy of the left ventricle. The little girl had had a sudden brief attack of loss of consciousness and extreme cyanosis six months before the fatal repetition of the same symptoms. The parents are closely related, and the father is an alcoholic. Other children in the family seem to be growing up in health, with less tendency to the lymphatic diathesis. Hedinger quotes from the literature, showing that sudden death in cases of hypertrophy of the thymus was recorded as early as 1614 by F. Plater, in respect to three children in one family. [An editorial in THE JOURNAL for February 10 discussed this subject, and Hedinger has recently published the details of the sudden death of 15 newborn infants with hypertrophic thymus. The *Presse Médicale* for February 3 describes the recent acquittal by the French courts of a woman named Weber who was accused of having caused the deaths of her three children and five of her nephews. The experts, Brouardel and Thoinot, reported that they had not been able to discover any evidences of poison nor of strangulation. Their opinion was that the eight deaths were due to natural causes. This opinion was sustained by the appearance of Hedinger's article about the same time calling attention to the occurence of series of such deaths in certain families. In Perrin's case, cited by Hedinger, the nine sons died between the ages of 3 and 9, after a few days of slight depression, with sudden coma and death in less than an hour. The two girls in this family are alive and in good health to date. Morquio has observed a similar case at Montevideo. Four boys in a family presented symptoms suggesting the Stokes-Adams' syndrome at about the fourth year, and died suddenly between the ages of 8 and 10. A fifth boy is now showing the same symptoms, but the girls in this family are healthy.—ED.]

90. **Reflux After Gastroenterostomy.**—Ferrari has observed reflux in 2 out of 11 cases after a gastroenterostomy, according to Roux's Y technic. He assumes that there must have been antiperistalsis as the amount of fluid in the stomach was so large. No method of gastroenterostomy absolutely prevents reflux as antiperistalsis is liable with all, and as the new pylorus has no sphincter to close and to prevent backward passage of the enteric juices into the stomach. The reflux ceased in his cases after lavage of the stomach, done twice, and setting the patient upright in bed. This changed the position of the loop of intestine from horizontal to vertical, which he thinks aided in suppressing the reflux and vomiting.

93. **Pulmonary Affection of Gastrointestinal Origin.**—Gugnoni describes the case of a healthy young soldier who had been indisposed for several days with slight headache, loss of appetite and constipation, with fever. He was given castor oil and in a day or so the fever subsided but the patient still felt sick and the tongue was much coated. He remained in bed and suddenly the fever lighted up again, this time accompanied by cough and expectoration. A focus of subcrepitant râles was discovered, but no bronchial souffle, and merely a slight dullness in the middle and lower lobe of one lung. Gugnoni reviews some similar cases on record in which a gastrointestinal affection became suddenly complicated with lung symptoms; the majority were in children. On the basis of gastrointestinal origin of the lung trouble he treated it exclusively with calomel and an intestinal disinfectant, with a strict milk diet and irrigation of the intestine with a 1 per 1,000 solution of salicylic acid. In less than four days the patient was entirely cured.

96. **Nervous Complications of Typhoid in Children.**—Allaria reports 2 cases of meningitic symptoms, aphasia and right spastic hemiplegia following typhoid in children of 6. Both soon recovered completely. In a third case, in a child of 8, bronchopneumonia followed typhoid, and this was followed by fatal meningo-typhoid. In the fourth case the typhoid and pneumonia were followed by tetany and recovery. The meningitic symptoms improved in the second case after lumbar puncture, but this did not prevent the focus symptoms from developing. Allaria's experience confirms the observation of others that when an epidemic of cerebrospinal meningitis is prevailing, typhoid in children is more liable to assume the meningitic type.

97. **Clinical Significance of Edema.**—Silvestri does not regard edema as merely a symptom. He accepts it as a defensive reaction on the part of the organism. The toxins are washed out by the edema, and in this Nature points the way for us to follow. The reaction may be out of all proportion to the inciting cause, and may need restriction. By evacuating the ascitic acid fluid and by intestinal catharsis we are able to remove a large quantity of toxins which Nature has conveniently collected for us in this form.

98. **Influence of Adrenalin on Course of Local Infections.**—Maragliano describes experiments on dogs and rabbits which demonstrated that injection of adrenalin with a culture of moderately virulent staphylococci enhanced the virulence of the germs. When injected in or near a phlegmon or other local inflammatory process, the latter was unmistakably aggravated. He used a 1 to 2,000 solution. This is stronger than used on man, and the drainage of local processes in the clinic also acts against this aggravating tendency of the adrenalin. In a dental case the injection of 1 c.c. of a solution of cocain and adrenalin for perialveolitis was followed by necrosis in the soft parts that had been injected, and fatal pyemia followed. Observation of a few similar cases, supplemented by the results of experimental research, have convinced him that the use of adrenalin should be limited to sound tissues, and that its effect on diseased or inflamed tissues is liable to be disastrous.

102. **Action of Radium on Virus of Rabies.**—Calabrese reviews the work done by Tizzoni and Relins in this line—recently summarized in these columns—and describes extensive research of his own. His results were negative.

104. **Tracheal Tugging, Etc., in Case of Aneurism.**—Pansini gives an illustrated report of 3 cases of aneurism of the thoracic aorta and 1 of innominate artery, with the postmortem findings. He discusses the cases from the standpoint of the diagnosis of adherence to the air passages, especially with reference to tracheal tugging and to the imminence of perforation into the air passages. In conclusion he remarks that any indications of compression of the air passages should suggest the possibility of an aneurism, and that every aneurism should be investigated for signs of adhesion to the air passages. When the signs suggest this, the patients should be supervised, kept quiet and coughing should be prevented at any cost. In case of hemoptysis the patients must stay in bed, be kept on a light diet and under the influence of morphin. By these means the physician may be able to ward off the fatal termination for days and weeks and, in any event, to make a correct diagnosis.

106. **Theory in Regard to Fever.**—Giuffré discusses whether or not the regulation of heat, its production, absorption and excretion, occur alike in health and in febrile conditions. He argues that the regulation of the heat is not the function of organs specially devoted to this task. It is a function secondary to the function of nutrition, and occurs independently of the nerves to some extent, the rest is exercised by all the nerves, not by any special thermoregulating center.

107. **Rectal Prolapse.**—Serafini reviews the history of treatment of severe rectal prolapse and reports a couple of cases in which he operated. His first patient was a child of 6, with long persisting, rebellious prolapse. Typical resection by Mikulicz' technic was followed by early recurrence of the prolapse and death in collapse nine days after the operation. The autopsy showed general ptosis of the viscera, relaxation of the tissues and abnormal length of the parts suspending the sigmoid flexure and descending colon. Death from exhaustion followed in some cases in Mikulicz' own experience with the operation. The second patient was a young man and the prolapse was less extensive. He was treated with ligature according to Weinlechner's technic and the results were eminently satisfactory, surpassing all expectations. The cure was rapid, complete and lasting.

108. **Invisible Hemorrhages in Typhoid.**—Romani relates in detail the results of hundreds of examinations of the stools in 50 cases of typhoid, with application of the Weber or Rossel test, for occult hemorrhage. His experience demonstrates that intestinal hemorrhage in the course of typhoid fever is always preceded by a few days during which traces of blood can be detected in the feces by these delicate tests. If symptoms of peritonitis develop during the course of typhoid fever, the presence of invisible traces of blood in the stools is a sign that the peritonitis is due to perforation rather than to propagation. Administration of a purgative to a constipated typhoid patient may be followed by the appearance of traces of blood in the stools, which may prove to be the prelude to

extensive intestinal hemorrhage. Systematic examination for traces of blood in typhoid stools may furnish a criterion for the progress of healing. The presence of blood indicates that the ulcerative process is not entirely healed. Serafini found traces of blood sometimes in the milder cases, while some of the severest ran their course without the appearance of blood in the stools. If the feces had been in contact with a metal vessel or tube, the typical reaction to the Weber test occurred at once, but it soon subsided, the feces later not showing the typical findings unless in case of the presence of blood. This phenomenon is due to the presence of iron. It causes the typical reaction at once, but as the iron then unites with the sulphuretted hydrogen in the feces to form an insoluble compound, the typical reaction to the test then vanishes as the iron is thus taken up. Experimental addition of traces of iron always induced this phenomenon. The Weber aloin test is more sensitive than the Rossel guaiac technic. The Weber test was found positive at a dilution of blood, 1 to 13,000, even when the spectroscope gave negative findings. The findings were positive in 16 out of his 50 patients. In 4 only for one day; in 2 on two days; in 3 on three days, and in the others from four to fifteen times. In 7 patients with negative findings the disease was exceptionally severe, in 3 moderate, and in 4 very mild. The traces of blood appeared in the stools 48 hours before an extensive hemorrhage in 1 case, and four days before in 3 other cases, including 1 in which the patient, a robust young man, was apparently convalescing at the nineteenth day of a very mild typhoid fever. Positive findings in regard to invisible blood in the stools were encountered generally in the third or fourth week, never in the first, but 7 times in the second week, 20 times in the third, 18 times in the fourth, 8 times in the fifth, and once in the seventh week. He ascribes the invisible hemorrhage to the dropping off of the scab. (For technic of tests see THE JOURNAL, page 1566, vol. xli, 1903.) z

109. Diazo Reaction and Indicanuria in Mental Affections.—The findings were negative in the majority of the large number of tests reported. Both the diazo reaction and the indicanuria are signs of profound organic intoxication, Pini remarks, and occur, generally speaking, in cases in which such might be expected. The article gives a historical summary of the subject, with bibliography.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

SCIENTIFIC MEMOIRS BY OFFICERS OF THE MEDICAL AND SANITARY DEPARTMENTS of the Government of India. Issued under the Authority of the Government of India by the Sanitary Commissioner with the Government of India, Simla. Calcutta: Office of the Superintendent of Government Printing, India, 1906. No. 22. Mediterranean Fever in India; Isolation of the Micrococcus Melitensis. By Capt. G. Lamb, M.D., I.M.S., and Assistant Surgeon M. Kesava Pal, M.B., C.M. Price, 10 annas or 1s.

MATERIA MEDICA AND THERAPEUTICS. An Introduction to the Rational Treatment of Disease by J. M. Bruce, M.A., LL.D., Fellow of the Royal College of Physicians of London, etc. New and Enlarged Edition. Revised Throughout, and Containing the Indian and Colonial Addendum to the British Pharmacopeia. Cloth. Pp. 632. Price, $4.75 net. Chicago: W. T. Keener & Co., 1906.

ANATOMY OF THE INGUINAL REGION.*

T. CASEY WITHERSPOON, M.D.

Professor of Operative and Clinical Surgery, St. Louis University.

ST. LOUIS.

This paper is limited to the region of the inguinal canal and enters into a description of such portions of the various structures as are directly included in this territory.

The observations are based on some fifty dissections. They have been compared with the descriptions in Toldt, Spalteholz, Morris, Gray, Deaver and Zukerkandel and found to be somewhat at variance with them. These textbooks were selected as representative of the anatomies usually referred to. A few monographs on the subject have been consulted with the same results. It would carry the paper to too great lengths to discuss these differences in connection with the findings here presented. This lack of uniformity of description has led to the publication of the present paper, in which are included such original drawings as are necessary to illustrate the text.

Fig. 1.—Abdominal wall face of a cast of the inner face of the inguinal region after removal of the peritoneal coat. (About 3/5 natural size.)

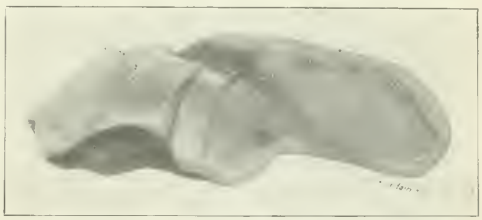

Fig. 2.—Pelvic wall face of cast, showing: A, Hesselbach's ligament and deep epigastric vessels; B, Superior ligament of the bladder; C, spermatic vessels; D, vas defereus. (About 3/5 natural size.)

The old nomenclature has been adhered to, although the terms often convey false ideas because of the anatomic misconceptions at the time they were adopted.

The structures which enter into the region under consideration are peritoneum, extraperitoneal fatty tissue, three muscles, four fascias and the so-called conjoined tendon.

The peritoneum had lost all evidence of the processus vaginalis in the adult subjects. Three full-term fetuses were dissected, in two of which it was widely patulous, in the third closed. Judging from statistics of inguinal hernia, it is safe to say that the processus vaginalis of the peritoneum closes in the very large majority of persons during the first four years of life.

The extraperitoneal fatty tissue is continued into the inguinal canal at all ages. It is a most important structure in its relationship to the inguinal canal. Surrounding the cord loosely attached to it, this tissue affords an easy passageway between the abdominal cavity and the scrotum, with but the thin layer of peritoneum acting as a barrier to a potentially open route. The large blood vessels and the spermatic cord are surrounded by this tissue in their course within the abdomen. In their immediate neighborhood the fatty tissue is thickened by bundles of rather dense connective tissue, which serves as a support. In the median direction from the internal abdominal opening it can be separated into three distinct layers; one passes posterior to the bladder, the other two anterior to it. These three layers encase the bladder in a fatty envelope of triangular outline, the base below and the apex above. In the fetus the hypogastric arteries and in the adult the remains of these arteries mark the lateral borders of this triangle. Lateral to this triangle the fatty tissue can not be divided into separate layers. Separation from the abdominal wall can be readily accomplished in this region except in the line of union of the iliac and transversalis fascias (Fig. 4, J). Immediately surrounding the deep epigastric arteries and lateral to them are a number of dense connective tissue bundles which are developed in the fatty tissue and which extend from the inner margin of the internal abdominal opening to the outer end of the semi-lunar fold of Douglas. The fatty tissue is closely connected with the outer-lying transversalis fascia in the route of these bundles, and together they give the appearance of a ligament which is known as Hesselbach's ligament (Fig. 3, B). This structure plays a most important part in rendering the inner end of the inguinal canal patulous during increased intra-abdominal tension. The resistance offered by it, in conjunction with the deep epigastric vessels, is well shown in Figures 1 and 2, reproduced from a cast made by taking an impression of the abdominal surface of the inguinal region with the peritoneum removed. The best quality of dental wax, made soft by heat, was tightly pressed against the region of the inguinal canal. The deep epigastric vessels and Hesselbach's ligament stand out well from the wall under

* From the Anatomical Laboratory of St. Louis University.

this pressure and make a depression in the wax (Fig. 1, A). The portion of the cast median to the depression (A), that is, in the direction toward B, corresponds with that area of the abdominal wall formed chiefly by the conjoined tendon. The portion of the cast lateral to the depression corresponds to the wall between the internal abdominal ring and the anterior superior spine of the ilium. This latter area is muscular. These two planes are seen to be anterior to Hesselbach's ligament, which stands out from the wall a centimeter or more when the wall is subjected to pressure. There is not much discrepancy between the outer and inner plane in the normal individual, but when the muscle area, which forms the wall represented by the outer plane, weakens through disease or age this discrepancy becomes marked. This difference in the two planes readily explains how hernias form, the bowel slipping anterior to Hesselbach's ligament and down the inguinal canal. Figure 2 represents the under side of the cast. The vas deferens (D) and spermatic vessels (C) are easily traced. The indenture in the cast between these two structures is made by the brim of the true pelvis.

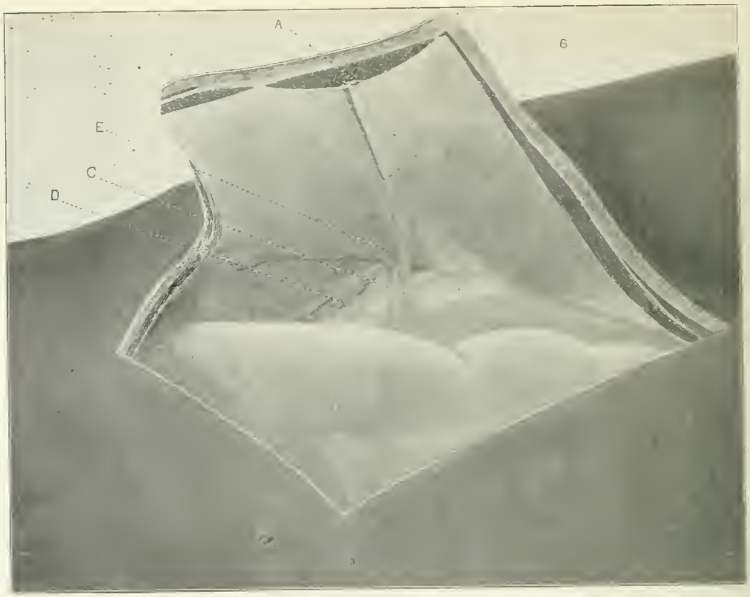

Fig. 3.—Dissection of the inner aspect of the inguinal region after removal of the peritoneum, showing: A, Deep epigastric vessels; B, Hesselbach's ligament; C, vas deferens; D, spermatic vessels; E, internal abdominal opening.

Fig. 4.—Dissection of the inner aspect of the inguinal region after removal of the fatty tissue, and portions of the iliac vessels and transversalis fascia, showing: F, Fibers out of the deep crural arch passing medianward; G, fibrous bundles which come out of the true pelvis and pass on to the abdominal wall; H, femoral opening; I, opening of the inguinal canal in the fascia transversalis; J, line of union of the iliac and the transversalis fascias; K, Cooper's ligament.

The inguinal canal has an oblique course through the abdominal wall from within outward, passing medianward and downward. The fatty tissue passes into and through the canal in an almost straight line from the lateral border of its inner end. From the median border it passes into the canal sharply flexed, giving to the median edge of the internal abdominal opening a falciform appearance. The internal abdominal opening of the inguinal canal, which is situated in this fatty tissue, is shown in Figure 3, E. It is found just above the junction of the anterior abdominal wall and the floor of the false pelvis.

The transversalis fascia is shown in Figure 4; from it a

window has been cut internal to the large vessels to show the outer-lying structures of that area. This fascia is not of uniform thickness, being quite thin in the region under the transversalis muscle, but thick enough in the region caudad of the arching lower fibers of that muscle to offer material support to the abdominal wall. Behind the rectus it is again thin and hard to distinguish from the fatty tissue. The transversalis fascia unites with the iliac fascia just internal to the origin of the transversalis muscle. It leaves the iliac fascia lateral to the iliac vessels and arches over them to the ilio-pectineal line median to the vessels. The intramuscular fascias between the transversalis muscle and internal oblique and between the internal and external obliques join the transversalis fascia in this arch to form the deep crural arch (Fig. 7, E). The transversalis fascia in this plate has been removed from the muscle and cut off along the edge of the arch to allow a view of other structures. Figure 4 gives the internal view of the arch. A number of dense fibers are developed in the deep crural arch which pass medianward across and internal to the lower portion of the conjoined tendon. These serve to hold the lower portion of the tendon in line with the abdominal wall. The transversalis fascia forms the second layer covering the spermatic cord. The description of the manner in which the fatty tissue enters the inguinal canal is applicable to this fascia.

External to the pelvic and iliac fascias and extending on to the abdominal wall to become

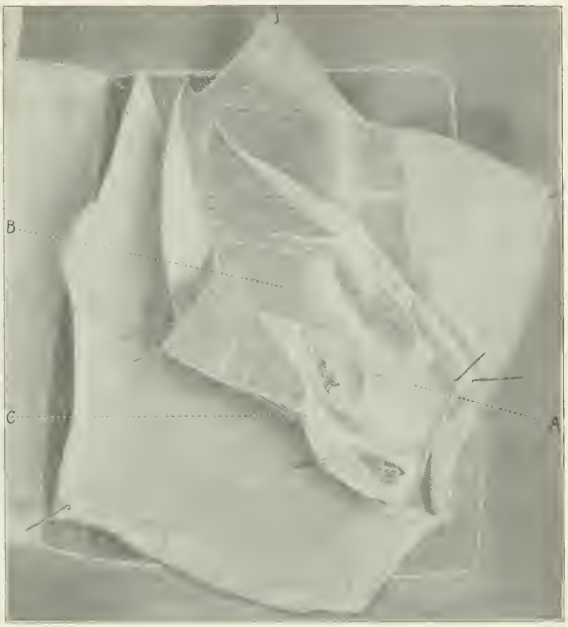

Fig. 5.—Dissection of right inguinal region showing: A, Fibers coming out of the pelvis in this subject constituting the whole of the so-called conjoined tendon; B, transversalis muscle; C, cremasteric muscle and fascia from the internal oblique.

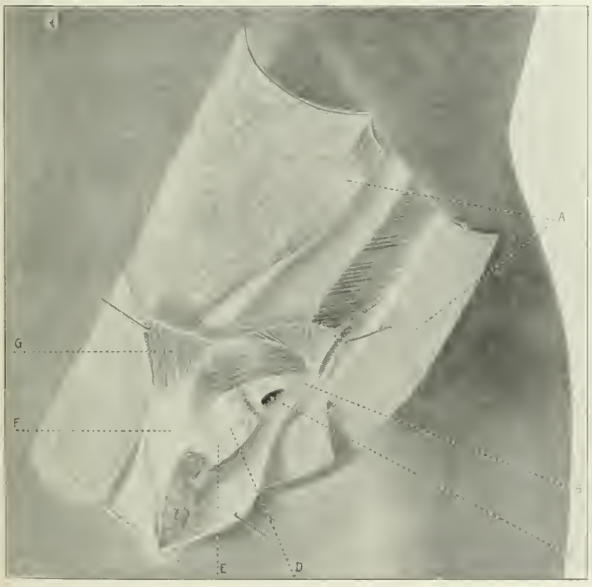

Fig. 6.—Dissection of left inguinal region, showing: A, External oblique muscle; B, cremasteric muscle from transversalis; C, internal opening of the inguinal canal through the transversalis fascia; D, transversalis fascia; E, fibers out of the pelvis which pass into the so-called conjoined tendon; F, aponeurosis of the transversalis muscle; G, internal oblique.

a part of the structure known as the conjoined tendon are a series of dense connective tissue fibers, quite ligamentous in appearance (Fig. 4, K, G). The lateral half of this structure (K), lying chiefly under and lateral to the iliac vessels, is known as Cooper's ligament. The fibers are lost below (caudad) under the femoral sheath posterior to the vessels as they pass into the thigh. The median half of this ligamentous structure is found beneath the pelvic fascia caudad of the ilio-pectineal line. It passes out of the pelvis over the ilio-pectineal line and on to the abdominal wall median to the iliac vessels (Fig. 4, G). In certain persons this structure constitutes the whole of the conjoined tendon, and in all more or less of the fibers enter it. Figure 5, A, represents the appearance of the area when the conjoined tendon is wholly formed by this structure. The median edge of the femoral opening is bordered by its lateral fibers (Fig. 4, H). In conjunction with the deep crural arch these cause constriction of the neck of a femoral hernia. In Figure 4 there is seen a triangular area lying between these ligamentous fibers (G), the deep crural arch (F) and the rectus muscle. This area is usually formed by the aponeurosis of the transversalis muscle, helping to form the conjoined tendon. Between G and Hesselbach's ligament the space is strengthened by the transversalis fascia. The median or lowermost fibers of

this structure course along the ilio-pectineal line to meet, behind the symphysis pubis, similar fibers from the other side.

The transversalis muscle takes origin from the continuation of the iliac fascia, caudad of the line of union of this fascia with the transversalis fascia. The extent of origin of the muscle from the iliac fascia varies, not only in different subjects, but also in the same subject on the two sides (Figs. 5 and 6). This may be stated to be under or within the outer half to one-third of Poupart's ligament. The lowermost fibers of this muscle take an inward and downward course over the internal abdominal ring to find insertion into the ilio-pectineal line for a variable extent. This insertion varies from a fraction of an inch to an inch and more. In some subjects, however, the muscle passes to the body of the pubis or even only to the linea alba, finding no bony insertion at all (Fig. 5). That portion of the muscle finding insertion into the ilio-pectineal line is usually described as forming with the internal oblique the conjoined tendon. This is never true. The transversalis (Fig. 6, F) becomes quite aponeurotic just before its insertion into the ilio-pectineal line and lies anterior to the ligamentous structure (Fig. 6, E). In Figure 6 the anatomic arrangement of the conjoined tendon is quite normal. The transversalis fascia is indicated by D, a window being cut out of it to show the relation of the deep epigastric vessels to this area. The ligamentous structure is indicated by E and the transversalis muscle by F. Figure 5 shows the other extreme of the relationship of the structures forming the conjoined tendon. It is here made up of only the ligamentous structure. Figure 7 shows an anatomic condition in which the transversalis muscle forms a distinct, compact aponeurotic lamina and finds insertion into the whole of the ilio-pectineal line median to the iliac vessels. Very few of the ligamentous fibers entered the conjoined tendon in this subject, but passed almost wholly behind the insertion of the rectus to unite with similar fibers from the opposite side.

Fig. 7.—Further dissection of the left inguinal region, showing: A, External oblique; B, internal oblique; C, transversalis; D, cremasteric muscle and fascia; E, deep crural arch; F, aponeurosis of the transversalis; G, rectus muscle; H, peritoneum covering the intestines.

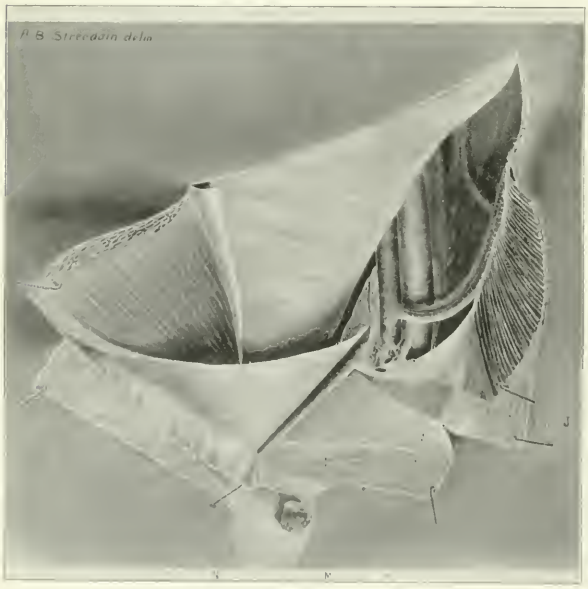

Fig. 8.—Further dissection of the left inguinal region with greater portion of cremasteric fascia, removed, showing: I, Femoral sheath; K, fascia lata; L, Gimbernat's ligament; M, cremasteric fascia; N, external oblique.

The cremaster muscle consists at times of a few of the lowest fibers of the transversalis having been carried into the scrotum by the descending testis (Fig. 6, B). Its fibers returning upward are inserted into the ilio-pectineal line just lateral to the insertion of the transversalis proper. The musculus interfovealaris consists of a few bundles derived from the posterior surface of the transversalis muscle and is inserted into the transversalis fascia just median to the internal abdominal opening. It is not constant.

The lower fibers of the internal oblique take origin from the iliac fascia parallel to and caudad of that of the transversalis muscle. The extent of this origin may be said

to be under the outer half of Poupart's ligament. The course of the fibers is from without inward and downward, but not quite so caudad in direction as that taken by the transversalis muscle. The internal oblique is, as a rule, quite closely connected with Poupart's ligament through its anterior fascia. Likewise some of the fibers of the internal oblique in many subjects become aponeurotic and enter Poupart's ligament near its middle. This secures a close union of the two muscles. The lowest fibers of the muscle are inserted into the pubic bone below and anterior to the transversalis muscle. These arch over the cord in front of the internal abdominal opening. The variableness of this feature has been repeatedly mentioned by different anatomists. From the lower edge of the internal oblique its fascias pass downward, cover the spermatic cord, surround the cremaster muscle and find insertion into the ilio-pectineal line. This fascia constitutes the cremasteric fascia and helps to form the deep crural arch anterior to the iliac vessels (Fig. 7, D, and Fig. 8, M).

The features to be mentioned in connection with the external oblique chiefly concern Poupart's-Gimbernat's ligament. Gimbernat's ligament (Fig. 8, L) is a most variable structure, consisting of those fibers of Poupart's ligament which turn posterior and medianward to be inserted into the ilio-pectineal line parallel with and external to the insertion of the cremaster fascia. These fibers are closely attached to the fascia lata of the thigh. Its inner border lies parallel with the deep crural arch, external to it. The intercolumnar fibers are derived from the lowest fibers of the external iliac aponeurosis. They cross the external abdominal opening at its apex and spread out in a fan-shape manner. Some of these aponeurotic fibers can be traced into the fascia lata below Poupart's ligament and are inserted into the ilio-pectineal line under Gimbernat's ligament. They lie within the falciform process of the fascia lata lateral to the cribriform fascia. The external abdominal opening in the external oblique is covered in by the peri-aponeurosis (deep fascia of the abdomen). This peri-aponeurosis is pushed forward as a covering of the cord, and the opening which the cord apparently makes is known as the external abdominal ring. This ring is strengthened by a number of dense fibers, which encircle its upper and outer border.

The ilio-inguinal nerve lies anterior to the cord as it passes out of the abdominal wall and the genito-crural posterior or internal to it. This latter nerve enters the canal median to the internal abdominal opening and passes through the canal anterior to the cremasteric fascia and posterior to the cord.

SUMMARY.

The internal abdominal opening is located in the extraperitoneal fatty tissue.

Hesselbach's ligament is formed by fibrous bundles which connect the outer end of the semi-lunar fold of Douglas with the inner margin of the internal abdominal opening. These bundles are developed chiefly in the extraperitoneal fatty tissue. Along the route of these bundles there exists between the fatty tissue and the transversalis fascia a close union. During intra-abdominal pressure, Hesselbach's ligament, due to its resistance, helps to increase the size of the internal abdominal opening.

In the inguinal area the internal surface of the abdominal wall is divided into two planes by Hesselbach's ligament. Normally, the plane lateral to this ligament is only slightly anterior to the plane median to the ligament. When the muscles of the lateral plane are weakened by disease or are enfeebled through advanced age intra-abdominal tension greatly exaggerates this difference. As the internal abdominal opening is situated at the junction of these two planes, the greater the difference the more patulous the opening and the greater the possibility of escape of a viscus through the opening.

The transversalis fascia does not join Poupart's ligament at any point.

The deep crural arch is formed by the junction of the transversalis and cremasteric fascias in the arch in front of the external iliac vessels as they pass into the thigh. The free (posterior) edge of Gimbernat's ligament is just external to and parallel with the deep crural arch.

The fibrous bundles which pass out of the pelvis into the so-called conjoined tendon give to the abdominal wall its chief strength internal (posterior) to the inguinal canal. The aponeurosis of the transversalis muscle strengthens the wall just internal (posterior) to the external abdominal ring.

The base of the so-called conjoined tendon, the lateral margin of which is formed by the fibrous bundles which enter the tendon from out of the pelvis, is the constricting agent in femoral hernia. A Spanish surgeon, Gimbernat, attributed this agency to the structure which has since been given his name.

The so-called conjoined tendon was in no instance formed by a union of fibers from the internal oblique and transversalis muscles in the subjects dissected. Judging from the usual anatomic arrangement this union seems quite impossible.

The external abdominal opening is situated between the dividing fibers of the aponeurosis of the external oblique muscle. The external abdominal ring is situated in the periaponeurosis which covers the external abdominal opening.

FATIGUE.*

FREDERIC S. LEE.

Professor of Physiology, Columbia University.

NEW YORK.

It is a striking principle of biology that the activity of living substance tends to inhibit its further activity. Carried to a moderate degree, this inhibition leads to the self-preservation of the living substance—to an extreme degree, to its self-destruction. The characteristics of this inhibition, its accompanying phenomena within the organism and the causes that lead to it form the subject of the present lecture. Fatigue is a comprehensive term, comprising, in its simple form, the functional state of the organism and its constituent parts after activity. Lying on the border zone where the physiologic and the pathologic meet, it reaches far into both and obscures the division lines between them. When present in slight or moderate degree, it limits achievement, but is easily recovered from; when excessive or an accompaniment of disease, it forms a serious condition, which, if in man, the medical practitioner must meet and combat.

Fatigue is a universal biologic phenomenon. The activity, however slight, of living substance, wherever found, reveals its beginnings. While it has been studied chiefly in the muscular and nervous tissues, it has been pointed out elsewhere, and our recognition of its signs

* Address delivered before the Harvey Society, New York, Feb. 3, 1906.

is certain of being extended by future study. The chief sign is, in a word, depression—depression of irritability, wherein a given stimulus calls forth a response of less intensity than before; and depression of the total capacity for work, whatever the intensity of the stimulus; its early stages may show, however, a temporary heightened irritability and an apparent, but not real, heightened capacity for work. There are many other signs, recognizable in individual cases.

Owing to the unequalled opportunity of applying to the study of muscular activity the exact methods of the physicist and the chemist, the phenomena of muscular fatigue are known more exactly than those of other tissues. Leaving aside for the present the chemical as causative of the physical phenomena, we may consider the latter first—and here the pioneer was Helmholtz,[1] to whom more than to any other in its long history scientific medicine is indebted for exactness in method. Let us assume a voluntary muscle, of either a cold-blooded or a warm-blooded animal, either a lower animal or man, either within the body with the circulation and nervous supply intact or (though this has not yet actually been proved for man) removed from the body. Let such a muscle be stimulated by a series of single artificial stimuli of equal intensity, regularly repeated and applied either directly to the muscle itself or indirectly through the mediation of the nerve, and let the muscle

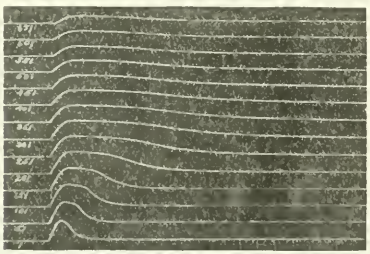

Fig. 1.—Record of fatigue of the frog's gastrocnemius muscle. The numbers signify contractions.

perform mechanical work, such as the lifting of a certain load. We may then observe the following phenomena (Fig. 1): The degree of shortening of the muscle during each contraction increases for a considerable time; hence the height to which the load is lifted or the amount of work that is performed is gradually increased. Later the reverse occurs—the shortening decreases, reaches its original amount, falls below it, and disappears slowly and very gradually, the muscle becoming incapable of performing further work unless a stronger stimulus or a lighter load be employed, or a period of rest be allowed to intervene, or the chemical composition of the muscle be artificially altered in a suitable manner. The irritability of the muscle at first increases and later decreases; its total capacity for performing work begins to decrease at the beginning of the experiment.

At the same time that the spatial changes are going on the time relations of the muscular action are also changing. Here, strangely enough, the muscle of the cold-blooded animal behaves differently from that of the warm-blooded one. In the former, almost from the first, the duration of each twitch begins to lengthen, the whole physiologic process slows, and this reaches large proportions even while the irritability is increasing. The slowing continues for a long time, and only when signs of exhaustion begin to appear does each twitch require a somewhat shortened time for its performance, although the duration is still far greater than at first. The slowing in activity is shared by both contraction and relaxation, but chiefly by the latter, although the degree in which each participates in the phenomenon differs in the muscles of different species. By reason of its existence, by reason of the continuance of the muscle in a contracted state, the organ is less capable of performing work, and, unless the successive stimulations occur at rather long intervals, it usually passes sooner or later into a pronounced and persistent contracture, from which it gives feeble twitches.

In warm-blooded animals, man included, there appears to be no analogous slowing of either contraction or relaxation, while in the later stages of the experiment, when the lifting power is feeble, there may even be a quickening. I have been able to show that this marked difference between the two groups of animals is independent of temperature; it persists even when the cold-blooded muscle is warmed to mammalian temperature, and the warm-blooded muscle is cooled, and it constitutes a real physiologic difference.[2] The cold-blooded or poikilothermal animal, which lacks a nervous mechanism that regulates its body temperature, represents the more primitive type, from which the homothermal condition has become evolved. It is not surprising that in the course of this evolution the muscle has dispensed with a process which distinctly hampers its activity, and has thus become a much more efficient machine.

Here a word of caution may be necessary. Do not jump to the conclusion, because of what I have said, that the voluntary contraction of a man's muscle, when fatigued, is fully as rapid as or more rapid than when in a fresh condition. We know from experience that this is not so, that we work more slowly when weary. I have been dealing so far with single contractions, not with voluntary contractions. The latter are always tetani, composed of single contractions fused together. The duration of the single contraction of the human muscle, which can be obtained only by an artificial stimulus, is not lengthened in fatigue; the voluntary contraction may be slowed. More than twenty years ago the Italian physiologist, Mosso,[3] devised the important apparatus called the ergograph, and by its means began the long series of studies of voluntary contractions in man, which has made the Turin school famous, and has immeasurably extended our knowledge of fatigue in living human beings. Treves,[4] one of Mosso's own pupils, Franz,[5] Hough,[6] Storey[7] and others have shown that the original form of the ergograph is defective, and have so perfected the instrument that it bids fair to become an important clinical aid in diagnosis. An ergographic record usually consists of a series of curves of momentary contractions, at regular intervals, of certain finger muscles, either one or more, a known weight being lifted or a spring of known tension being stretched. Such a record exhibits in fatigue a gradual diminution

of the lifting power of the muscle, the rate and regularity of the diminution varying with individuals. The single contractions of human muscle, induced by artificial stimuli, directly applied, may be recorded by the same instrument.

In the course of the experiments that I have quoted, it may justly be said that fatigue begins with the first contraction—the muscle is less capable of work by reason of this contraction. It is convenient to set apart the late stages as the period of exhaustion, although the beginning of such a period is not marked by distinctive physical phenomena. If at any stage the muscle be irrigated by a stream of fresh blood, by Ringer's solution, or even by an indifferent isotonic solution of sodium chlorid, or, what is less efficient, although in some degree effective, if it be allowed simply to rest, the physiologic pendulum tends to swing back, the irritability and the total capacity for work increase, and physiologically the organ is pushed back to an earlier stage of the fatigue process; in other words, the muscle is in some degree restored.

The term, muscular fatigue, requires a word of explanation, for it has been shown by various investigators, including Waller,[8] Abelous,[9] Santesson,[10] and Joteyko,[11] that when muscle in fatigue ceases to respond to stimuli sent to it through its nerve, it is still capable of contracting on direct stimulation. Their inference from this fact is that the motor nerve endings within the muscle are the first part of the mechanism to succumb. This inference is probably justified; the nerve endings are probably more susceptible to fatigue than the protoplasm of the muscle cells, and hence the muscle protoplasm itself within the organism probably never reaches the stage of profound exhaustion.

In the study of fatigue the nervous system has occupied a curious position. For while it has long been thought that the brain and spinal cord are, of all parts of the organism, the most susceptible to fatigue, it has been known for more than twenty years that the nerve fiber is extremely resistant. Although Bernstein,[12] in 1877, concluded that the nerve is less easily fatigued than the muscle, the Russian physiologist, Wedenskii,[13] was the first to suggest, in 1884, that the nerve may possibly perform its functions altogether without fatigue. Wedenskii stimulated the nerve at a distant point and blocked the passage of the nervous impulses before they reached the muscle by keeping an intermediate portion of the nerve in a constant state of anelectrotonus by means of a polarizing current. At the end of six hours he found the nerve still as active as at first. Maschek[14] obtained a similar result at the end of twelve hours, and, moreover, confirmed the general discovery by substituting ether for a polarizing current. Brodie and Halliburton[15] blocked the impulses by cooling the splanchnic. Bowditch[16] and Durig[17] by using curare with a motor nerve, Szana[18] by atropin with the cardiac vagus, Lambert[19] also by atropin with the secretory fibers of the chorda tympani, while Wedenskii,[13] Hering,[20] Maschek,[14] Edes[21] and Waller[8] studied the current of action during long periods of activity.

These investigators, working on both cold-blooded and warm-blooded animals, agree in maintaining the extreme resistance of the nerve to fatigue, their experiments continuing in some cases for fifteen hours. Objections have been brought against some of them, notably those in which the persistence of the negative variation is the indicator of indefatigability, it having been shown that negative variation persists even after other evidences of vital action have ceased; nevertheless, the main principle is well supported. Garten[22] seems, however, to have demonstrated some measure of fatigue in the non-medullated fibers of the olfactory nerve of the fish: by means of continued stimulation, the current of action, as measured by the capillary electrometer, becomes diminished in extent; after a pause it increases. Fröhlich,[23] too, believes that he has demonstrated fatigue in a frog's nerve when in partial asphyxiation. On the chemical side no decisive experimental evidence has been brought forward. While Funke[24] and Ranke[25] find acid in nerves after strong general tetanus, there is no proof that it is formed *in situ*. Waller's[26] inference of the production of carbon dioxid in tetanized nerves from the similarity of their electrical phenomena to those of nerves artificially placed under the influence of carbon dioxid seems hardly justified from such slight evidence. Our conclusion must, therefore, be, and with this we shall find general agreement, that, while nerve is probably not indefatigable, it is extremely resistant to fatigue in comparison with other peripheral tissues, and that, although nerve protoplasm is not an exception to the general biologic law according to which katabolic changes occur during activity, such changes here present are either minute or, more probably, are at once compensated for by adequate anabolism.

But the demonstrated resistance of nerve fibers could not easily shake the firm belief of physiologists in the extreme susceptibility to fatigue of the central portion of the nervous system. It has long gone without dispute that in prolonged activity the brain and spinal cord succumb first, and thus the exhaustion of the peripheral tissues is prevented. The nerve center has been compared to the fuse of an electric circuit, the burning out of which protects the muscle from grievous injury. By most upholders of the neuron theory central fatigue has been referred to the bodies of the nerve cells, in which Hodge,[27] Vas,[28] Mann,[29] Lugaro,[30] Eve,[31] and others have demonstrated histologic changes after activity. According to most of these observers, moderate activity

is accompanied by an increase in the bulk of both cytoplasm and nucleus, excessive activity by a decrease in bulk and the appearance of vacuoles in both, and a loss of the substance of the Nissl bodies. While these histologic changes after excessive activity have generally been interpreted as significant of fatigue, there does not exist general agreement as to their mode of origin.

Professor Sherrington,[32] a strenuous adherent of the neuron theory, a clear thinker and one of the ablest and most careful experimenters, whose investigations in recent years have widely extended our knowledge of the mode of action of the nervous system, doubts the inferences that have been drawn from the histologic observations and denies central fatigue to the bodies of the neurons. He ascribes great physiologic importance to the structure—if it can be called a structure—that is situated at the point where one neuron comes into functional relation with the next in the series, this structure being the synapse. The synapse is the surface of contact of the two neurons and is potentially a membrane.

One of Sherrington's experiments is as follows: Given a certain center within the spinal cord, which can be reached by several afferent tracts, and a common efferent tract to a given muscle, he stimulates one of the afferent tracts and records the reflex contractions of the muscle. In the course of time the motor response gives evidence of fatigue. He then turns to another afferent tract and stimulates it. The motor response now appears as strong as at first. Where is located the fatigue from the first stimulation? Not in the nerve fibers, says Sherrington, for they are practically incapable of fatigue; not in the muscle or the body of the motor neuron, for they are common to the two stimulations. Hence it must be at the synapse between the first afferent tract and the motor neuron. Sherrington likens the synaptic membrane to the motor end-plate, the former constituting the safety fuse within the central mechanism, the latter playing a similar rôle within the muscle; while of the two the synapse is the more susceptible.

Other experiments, however, indicate that there is less justification than has commonly been supposed for the idea that the central nervous system fatigues before the muscular system and lead us to suspect that the reverse is true. Woodworth,[33] for example, finds no perceptible difference in the rate of fatigue when one gastrocnemius is stimulated directly at the same time that the other is stimulated either through the medulla or through a sensory nerve, thus indicating that in such an experiment the nerve center contributes no appreciable amount of fatigue. Mlle. Jotcyko,[31] of Brussels, destroys the brain of a frog, thus rendering the animal a reflex machine, and exposes both sciatic nerves. On stimulating nerve A, she obtains direct contractions of its gastrocnemius muscle (A) and reflex contractions of the gastrocnemius (B) of the opposite side. She then blocks the passage of the impulses in nerve B by means of either a continuous polarizing current or ether, and continues to stimulate nerve A. When its muscle is exhausted the block is removed from the opposite nerve, and the muscle of that side responds nearly as well as at first to the reflex stimulations. The reflex centers thus remain active long after fatigue has placed the muscle *hors de combat*. Jotcyko concludes that, compared with the terminal organs, the reflex mechanism of the spinal cord is practically indefatigable.

If this conclusion be true, why may not the same be said of the brain centers? The common belief in the susceptibility of the brain to fatigue is based largely on the presence of sensations of fatigue. With such sensations as a daily experience we are all familiar. They are the psychologic concomitants of physiologic processes; and, since we know that the brain is the seat of the former, it is only natural to believe that the physiologic processes occur there also. We feel tired, and we infer that our brain is tired. For long a controversy has raged regarding the origin of the feeling of effort that accompanies muscular work. Is it central? Does the consciousness of the motor discharge precede actual movement? Does the sense of effort decrease as we continue to labor? In recent years we have learned much regarding the nervous relations of muscle, and the existence of the well-developed muscle sense has been established. Sensory end-organs have become recognized in muscles and tendons, and afferent fibers in muscle nerves; the muscles undoubtedly keep the brain informed of their general condition and of the intensity of their contractions. Along with this advance of our knowledge, it has become generally recognized with Wundt, James, Münsterberg and Baldwin that the feeling of the amount of effort required to make muscles contract is dependent on impulses reaching the psychic centers from the muscles, tendons and joints. The feeling of effort is of peripheral origin. The same is probably largely true of the feeling of fatigue. We are distinctly conscious of the fatigue of our muscles; their tone is diminished; their unusual tension gives us a feeling that they are heavy; it seems more difficult to make them respond to our will, and their response is often painful. Moreover, we are aware that our limbs are swollen, that blood vessels are dilated, and that lymph has accumulated in the intercellular spaces. These are but a few of the sensations. Other tissues add their share of stimuli, many of them obscure and difficult of analysis and location. The result of the flood of these impulses pouring into the brain is a large complex of sensations, which we call the feeling of fatigue. Experiment also appears to justify the peripheral location of the influences that lead to our feeling. Mosso,[3] by means of his ingenious instrument, the ponometer, demonstrates that during a series of voluntary muscular contractions resulting in fatigue the nervous effort to contract gradually increases; in other words, that the curve of nervous effort is the reverse of the curve of muscular performance. Evidence seemingly contradictory to the theory of the peripheral origin of fatigue sensations was contributed by Mosso,[3] Lombard[34] and Waller,[8] and for a time had wide acceptance. These investigators claim to have found that when a set of muscles, such as the flexors of the finger, stimulated by volition and lifting a given weight, became incapable of further voluntary contraction, they still responded readily to electrical stimuli applied directly to the muscles themselves. This supposed phenomenon, widely quoted, and at first thought decisive, has been examined critically by

Kraepelin,[35] G. E. Müller,[36] Henri,[37] R. Müller,[38] Hough,[6] Woodworth,[39] Storey[7] and Joteyko,[11] and the validity of its proof has been discredited. R. Müller shows, for example, that the muscles that were stimulated volitionally and those that were stimulated electrically were in reality not the same, the former being the interossei, the latter the flexors of the finger. Storey has repeated the work with an improved form of ergograph and with the abductor indicis alone, and clearly demonstrates the appearance of peripheral but not central fatigue. In view of these results and others, I am inclined to the belief that when we perform continued muscular work, our muscular system fatigues before our central nervous system. Moreover, the same results make it probable that the brain and the spinal cord are, like the nerve fiber, resistant, and they throw a certain measure of doubt on all supposed proofs of central fatigue.

With the general problem in this somewhat uncertain state, what can we say of mental fatigue? That it is a reality can not, of course, be denied. It is characterized pre-eminently by a weakening of the powers of attention and the reproductive phase of memory, and the psychophysical laboratories have shown us in innumerable ways how it manifests itself. To explain it on physiologic principles is not altogether possible in the present state of research. Our present theory interprets it as largely peripheral in origin, and Mosso's[3] school has demonstrated, though by imperfect methods, that intense mental work, long continued, such as in the oral examination of many students, diminishes the power of the muscles to respond to direct stimulation, the locus of the fatigue in this case being largely the muscles, as Mosso admits. But to what extent so-called mental fatigue is of peripheral origin we can speak only with caution. We can not deny fatigue to psychic centers, but the intimate relations of central and peripheral fatigue are much in need of exact experimental study.

It is customary to seek the causes of the physical phenomena of fatigue in the chemical changes undergone by the active living substance. Unfortunately, we know too little of these chemical changes. It has been pointed out by von Noorden[39] and Levene,[40] in their illuminating lectures before this Society, that, while the final products of protoplasmic activity are well known, we are sadly ignorant of the intermediate steps between income and outgo. In all tissues during activity substances of value to the organism are broken down and substances of little or no value are formed. When men began to speculate, in the light of the scientific chemistry of the nineteenth century, concerning the causes of fatigue, it was perceived that they might be of two kinds: the loss of valuable material essential to activity and the accumulation of waste products. Naturally the discussion centered on muscle, since many endeavors were being made to seek the source of muscular energy.

Without entering in detail into the interesting history of these endeavors, which are not yet ended, it is sufficient to say that it is now generally recognized that, under ordinary circumstances, the chief source of muscular energy is carbohydrate. Weiss,[41] a pupil of the Viennese physiologist, Brücke, definitely proved in 1871 that a marked diminution of glycogen accompanies muscular activity, and since then many others have demonstrated the same fact in a variety of ways. We might then expect muscular fatigue to be associated with loss of carbohydrate. So far as I am aware, but one research bearing directly on this subject has been made, namely, that of Harrold[42] and myself, performed several years ago and still unpublished in detail. We allowed cats to fast for several days and, during the latter portion of the period, administered hypodermically considerable doses of phlorhizin, which removes carbohydrate from the body. At the end of an adequate period, when, as the experiments of others have shown, the tissues were practically freed from this substance, the animals exhibited great muscular weakness. They were then killed and contraction records were made by selected muscles, artificially stimulated. It was found that under the influence of the drug the muscles were capable of making only from one-fifth to one-half of the number of contractions of which a normal muscle is capable. We proved that this diminution in working power was not due to a direct specific action of the drug on the muscle tissue. The result may, therefore, be explained in one or both of two ways: either by the loss of carbohydrate or by the accumulation of pathologic acids, which are now known to be formed both during fasting and under the influence of phlorhizin. That the former, however, was largely responsible for the fatigue seems probable from our further experiment, namely, that the administration of a quantity of dextrose to a phlorhizinised, and thus thoroughly fatigued, animal was followed within a few hours by a considerable return of muscular power. Our results are well supplemented by those of Mosso and Paoletti.[43] Harley,[44] Frey,[45] Schumburg,[46] and Hellsten,[47] all of whom working with the ergograph on human beings have observed an increase of working power and a diminution of fatigue after the ingestion of sugar.

A condition similar to that of our experiment is met constantly in disease. The physical weakness of fevers, of diabetes mellitus, and of many other pathologic states, in which a deranged metabolism exhausts the muscle cells of their proper store of available nutritive material, a physical weakness which is, physiologically, fatigue, is doubtless due in part to the lack of energy-yielding carbohydrate. Concerning a possible relation of the loss of other substances to fatigue, our present knowledge permits us to say nothing.

Ranke[25] was the first to investigate, from the standpoint of fatigue, the physiologic action of the products of protoplasmic activity. More than forty years ago he studied the action on frog's muscle of the supposed products of muscular action, namely, lactic acid, kreatin, kreatinin, sugar and carbon dioxid. He found that of all these substances only kreatin and lactic acid markedly depress muscular action, as measured by the strength of the induced current necessary to stimulate and also by the height to which the muscle is able to lift a given

load. He therefore designated these two substances as fatigue substances. Carbon dioxid was found to be slightly depressant, but not sufficiently so to be regarded as playing a distinctly fatiguing action. Both lactic acid and kreatin were found to augment nervous activity, and carbon dioxid slightly to depress it. Later Ranke rejected kreatin as a fatigue substance and accepted acid potassium phosphate. Little experimentation in this subject has been done since Ranke's time; but, partly from his results and partly from other considerations, it is now customary to recognize three distinct metabolic products as fatiguing, namely, sarcolactic acid, mono-potassium phosphate (KH_2PO_4) and carbon dioxid, all of which are acid in reaction. The action of these substances on the muscular and the nervous systems has never been fully investigated. My own experiments on muscle, which are not yet completed, have already yielded certain positive results. From the ready recognition of the phenomena of fatigue in frogs, I have worked so far with them only, but there is no reason to doubt that the results are equally applicable to mammals. I shall, however, extend the work to the latter. My method is to inject one gastrocnemius muscle with physiologic salt solution and the opposite gastrocnemius with similar solution containing a given quantity

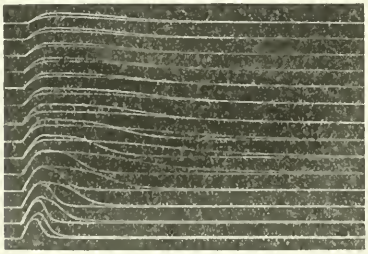

Fig. 2.—Record of fatigue of companion gastrocnemius muscles of the frog, one normal, the other under the influence of sarcolactic acid. The longer, or, in the later contractions, the lower curves, are those of the poisoned muscle. Every fiftieth contraction is recorded.

of the substance which is to be investigated. After a certain time the muscles are excised and stimulated at regular intervals, and comparative fatigue records of the two are made. In this manner I have studied the physiologic action on excised muscle of the three recognized fatigue substances.

Under the influence of a minute quantity of free sarcolactic acid the frog's gastrocnemius, regularly stimulated, presents a striking series of contractions (Fig. 2). The first contraction curve is usually higher and longer than that of the normal muscle. In successive curves this increased height is maintained for a certain time, but later gives place to the normal height and then to one still lower. From the first curve onward the length rapidly increases in proportion to the normal length until the increase has become very marked; later it slightly decreases. The curves show that in the poisoned muscle there is at first increased and then decreased lifting power, increased and then decreased duration of action in comparison with the unpoisoned muscle. At first sight the effect might be interpreted as due to a beneficial action of the acid. But such an interpretation is a superficial one. More careful observation shows that the fatigue series of the poisoned muscle is like that of the unpoisoned one, if the early contractions of the latter be left out of account. The first contraction curve of the poisoned muscle is not unlike the fiftieth or the seventy-fifth of the non-poisoned, the fiftieth of the former like the one-hundredth or the one-hundred-and-fiftieth of the latter, and so on. In other words, the acidified muscle is already fatigued at the beginning of the series, and with stronger doses of the acid the fatigue is more pronounced. Sarcolactic acid is truly named a fatigue substance. Whether, however, the acid in the free state exerts its depressant action is unknown. While it is conceivable that immediately on its formation it may act on the protoplasm of the cells in which it arises, it occurs in the blood not free but as a neutral salt, probably of potassium. I find the action of potassium sarcolactate to be indistinguishable, qualitatively, from that of the free acid, although a stronger solution of the former is required to produce the same quantitative effect.

After the injection of a few cubic centimeters of a one-fifteenth gram-molecular solution of mono-potassium phosphate, the poisoned gastrocnemius shows the following phenomena (Fig. 3): The first contraction of the series is usually closely similar to the first contraction of the normal muscle; very soon, however, the poisoned muscle shows signs of fatigue, and then rapidly

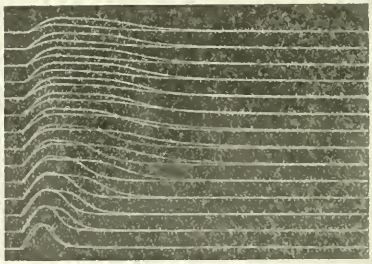

Fig. 3.—Record of fatigue of companion gastrocnemius muscles of the frog, one normal, the other under the influence of mono-potassium phosphate. The longer, or, in the later contractions, the lower curves, are those of the poisoned muscle. Every fiftieth contraction is recorded.

passes through the sequence of events which we have already recognized as characteristic of the gastrocnemius. The poisoned muscle becomes fatigued so rapidly that at last it is scarcely able to lift the weight, while its normal mate is still in excellent working condition. Mono-potassium phosphate, therefore, diminishes the working power and is distinctly fatiguing. I have made some attempt by means of parallel experiments with mono-sodium phosphate, which I find also fatiguing, to discover whether the action of the potassium salt is due to its potassium or to its hydrogen ions. So far as my experiments have gone they indicate that the two substances share in the general effect; the latter seems not to be an acid action solely. The depressant influence of the potassium ions on striated muscle is not unexpected in view of their inhibitory and relaxing effects on the heart, which have been observed by Howell[48] and will be discussed by him in a later lecture before this Society.

Carbon dioxid, when injected into the circulation, produces a result in general similar to that of sarcolactic acid or mono-potassium phosphate (Fig. 4). Like them, it is markedly fatiguing.

48. Howell: Amer. Jour. of Phys., 1898, vol. ii, p. 47; 1901, vol. vi, p. 181, 1906, vol. xv, p. 280.

My results seem to show a certain qualitative physiologic difference between mono-potassium phosphate on the one hand and sarcolactic acid and carbon dioxid on the other, though at present I would not assert this with positiveness. While the muscle under the influence of the salt seems at first not fatigued, but runs through its fatigue course rapidly, the muscle poisoned by sarcolactic acid or carbon dioxid appears fatigued at once, the first contraction being usually slower than the first normal contraction. Whether this apparent difference, which at best is only secondary, proves true or not, it is evident that sarcolactic acid, both free and combined, mono-potassium phosphate and carbon dioxid are fatiguing to muscle. Though I have not yet investigated their action on the central nervous system, the legitimacy of the term fatigue substance is abundantly proved. The organism produces normally in the course of its activity a number of acid substances which tend to inhibit further activity. Fatigue is due in great measure to the depressant action of these toxic products of metabolism on the body tissues, particularly on the muscular system, and the sensation of fatigue is in large part the psychic manifestation of the recognition of this depressant action.

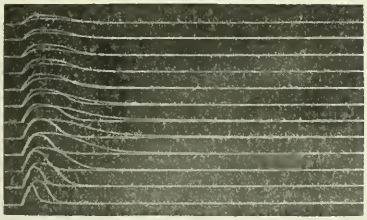

Fig. 4.—Record of fatigue of companion gastrocnemius muscles of the frog, one normal, the other under the influence of carbon dioxid. The longer, or, in the later contractions, the lower curves, are those of the poisoned muscle. Every fiftieth contraction is recorded.

My friend and colleague, Professor Curtis, whose invaluable studies of the early history of medicine often correct our false perspective and distorted judgments by showing us how our modern discoveries were foreshadowed long before, has called my attention to the following passage from the Hippocratic writings,[49] which I am permitted to quote in his own translation:

As to the varieties of fatigue which the body may experience, matters stand as follows: Untrained men are fatigued by every exertion, for no part of the body has been exercised at any kind of effort. Trained bodies are fatigued by unaccustomed forms of exertion and also by their accustomed exercises pushed to excess. Such are the forms of fatigue, and their potency takes effect as follows: The untrained have moist flesh, and when they exert themselves the body becomes heated and they yield the product of liquefaction in abundance. Of this, whatever is sweated out or purged away with the breath causes no trouble except to so much of the body as has undergone the unusual depletion, but whatever remains of the product of liquefaction causes trouble, not only to the unduly depleted part of the body, but also to whatever part receives the liquid in question, which is not akin to the body, but hostile. It does not so much affect the fleshless parts of the body, but rather the fleshy, causing trouble until it takes itself off. Inasmuch as it fails to move about, it keeps quiet and becomes heated, itself and what accrues to it; and if there come to be abundance of this separated stuff it may overpower the healthy parts so that the whole body becomes heated likewise and [the stuff in question] may cause severe fever.

These ideas, recorded twenty-three hundred years ago and in language to us quaint, are strangely prophetic. To Hippocrates and his contemporaries, as to us, excessive activity of a part of the body may cause general fatigue. To them the result is due to the "product of liquefaction" which is "hostile" to the body and affects chiefly the "fleshy" parts, there "causing trouble until it takes itself off." To us the result is due to "fatigue products," which are "toxic" to the body and affect chiefly the muscles, there "causing trouble" until they are either excreted or rendered innocuous by chemical change. Those same Greeks, however, whose speculations came so near the truth in one regard, knew not even the functions of the muscles or the other parts about which they were writing!

It is not improbable that future research will discover other fatigue substances besides those which I have named. Mention should here be made of the claim of Weichardt,[50] working in Zuntz's laboratory in Berlin, to have isolated from fatigued muscles a true toxin, of a chemical and physical nature like bacterial toxins, which, when introduced in minute quantity into the body, is capable of giving rise to the phenomena of fatigue. Weichardt further claims to have obtained by the usual methods of the bacteriologists an antitoxin endowed with the power of neutralizing the fatiguing properties of the toxin. So sweeping a discovery needs confirmation before it can be accepted. But it is hardly credible that the few substances which I have mentioned should prove to be, of all the links in the long metabolic chain, the only substances that are depressant to protoplasmic activity. It is the intermediate substances that we must watch especially. Autolysis opens up also a new field full of interest in this connection.

Concerning the production of fatigue substances by the central nervous system, very little is known. There is no certain evidence that sarcolactic or other organic acid is produced by nervous activity. In view of the striking fact which Macallum[51] has brought forward by means of his careful microchemical methods, namely, that potassium is not to be found in the neuron, we can not believe that potassium salts play any rôle in nervous fatigue. Carbon dioxid is, however, present, and to it has been ascribed by Verworn[52] an important share in the phenomenon in question. Yet Hill and Nebarro[53] have investigated the content in carbon dioxid of the venous blood which has passed through the muscles and that which has passed through the brain during both rest and activity, and find the systemic blood to contain between two and three times as much of this gas during rest as the cerebral venous blood contains, and from three to seven times as much during activity. They conclude that the metabolism of the muscles is, during rest, twice or three times as great as that of the brain, and that during activity muscular metabolism increases enormously in comparison with the metabolism of the brain—a further suggestion that the fatigue of the muscles is of pre-eminent importance relative to that of the central nervous system.

That intense mental activity is capable, however, of giving rise within the body to profound chemical changes

is proven by the not unfrequent occurrence of such cases as the following, this striking instance of which was recently related to me by its observer, a well-known medical authority: A nursing mother was subjected for a few minutes to intense fright. Her child, after taking the mother's milk some three or four hours later, was attacked by convulsions. But there is no evidence that the toxic substance in the mother's milk was produced in the brain cells. Indeed, the probability is that the deranged metabolism was localized elsewhere, an indirect result of the nervous shock.

The action of fatigue substances is not confined to the tissues in which they arise. The excessive activity of one tissue is capable of causing fatigue to appear in others. We all know that fatiguing muscular work diminishes our brain power, and I have already referred to the experiment by which Mosso's school has demonstrated that after intense mental labor the muscles are less capable of performing work on direct stimulation. Thus, localized activity is capable of producing general fatigue, a fact which is often overlooked in our daily life. The explanation of this is afforded by Mosso's[54] well-known experiment: A dog was fatigued by long continued running; his blood was then transfused into the vessels of a second dog, from which an equivalent amount of blood had been withdrawn, with the result that the second dog exhibited the usual phenomena of fatigue. The blood had evidently become charged with the fatigue substances produced in the muscles, and thus they were able to reach all parts of the body. Geppert and Zuntz[55] and others have demonstrated that in muscular work resulting in general fatigue the alkalinity of the blood, as determined by titration methods, is markedly diminished. Zuntz[56] has pointed out that in such a condition the circulatory and the respiratory organs are first affected, later the digestive and the urinary organs. Geppert and Zuntz[55] and Lehmann[57] have demonstrated that the increased action of the respiratory center in muscular work is probably caused by the stimulating action of the acid fatigue substances arising in the muscles. It seems to be a fact that in general fatigue the coagulation of the blood is hastened, while according to Manca[58] the red corpuscles break down less rapidly than before. Ceni[59] claims that the bactericidal power of the blood is diminished in brief and increased in prolonged muscular fatigue. Salvioli[60] finds the salivary and the gastric glands to secrete less during intense muscular fatigue, and the gastric juice to lose in acidity and in digestive power. Although exact researches are here needed, there are probably few physiologic functions that are not affected unfavorably by the prolonged and excessive activity of the muscular and the nervous systems. In such a condition the normal action of the tissues may easily give place to pathologic action, as is illustrated by the fever resulting from over-exertion. Fatigue undoubtedly diminishes the resistance of the tissues to bacteria and also predisposes the individual to attacks from diseases other than bacterial. Specific investigation in its relation to pathologic conditions is, however, sadly lacking.

Nevertheless there is one subject in pathology concerning which we can speak in more than general terms. The fact that certain acid substances are depressants has a far wider application than merely in the causation of physiologic fatigue. Pathologists have recognized in recent years as a widespread phenomenon the production in quantity of acids, which load the blood and the tissues and give rise to the condition known as acid intoxication. This condition has been demonstrated notably in diabetes mellitus, fevers, carcinoma, anemia, acute yellow atrophy of the liver, phosphorus and arsenic poisoning, arthritis deformans, various disorders of digestion, and inanition; and the acids which are involved are such as exist normally only in small quantities, if at all, and are intermediate products of metabolism, the results of incomplete oxidation. In nearly all, if not all, of the diseases mentioned, among the prominent symptoms are marked physical depression and ready fatigability. Zenoni[61] has made ergographic tracings from diabetics and finds advanced cases capable of a very small amount of muscular work, a limited number and a small amplitude of contractions, not rarely accompanied by contracture, and an early onset of fatigue. The facts of the toxic theory of fatigue suggest that we have in the pathologic acids and the depression and ready fatigability a relation of cause and effect.

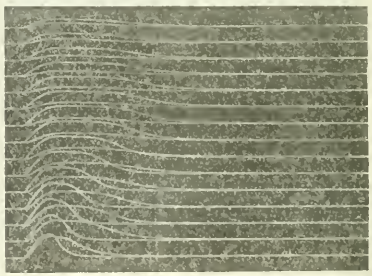

Fig. 5.—Record of fatigue of companion gastrocnemius muscles of the frog, one normal, the other under the influence of β-oxybutyric acid. The longer, or, in the later contractions, the lower curves, are those of the poisoned muscle. Every fiftieth contraction is recorded.

It is a well-known fact that the injection of these acids into living organisms is followed by the symptoms that follow their spontaneous formation within the body—artificial acid intoxication resembles spontaneous acid intoxication. I have been able to demonstrate on muscle the fatiguing action of one of the pathologic acids, namely, β-oxy-butyric acid, which is common in diabetes mellitus (Fig. 5). A frog's gastrocnemius under the influence of β-oxy-butyric acid reacts not unlike a muscle under the influence of sarcolactic acid or carbon dioxid. There is pronounced fatigue from the beginning, a curve of contraction that is high and long at first and becomes lower and longer as the experiment proceeds, and an early onset of exhaustion. Such a muscle is already in a fatigued condition, even before the series of stimulations has begun. Such a muscle within the body would undoubtedly give rise to fatigue sensations. To what extent within the body the free pathologic acid acts directly on the muscles is a problem like that presented by sarcolactic acid and is yet unsolved. It seems probable that the muscles are one of the places of origin

of the pathologic acid, and it is possible that the free acid exerts its depressant action on the cells in which it is formed. It seems to occur in the blood of diabetics, however, not free, except in the most extreme cases, but in combination with certain metals, such as sodium, potassium and ammonium. I have investigated the salts so formed, namely, sodium, potassium and ammonium oxy-butyrate, which, it should be emphasized, are not acid in reaction, and I find their action on muscle to be similar qualitatively to that of the free acid. Quantitatively they differ among themselves, the potassium salt being the most powerful. While, therefore, the free acid may possibly act as a fatigue substance to the cells in which it originates, its salts may act through the blood on distant cells and give rise to general fatigue, physical depression and ready fatigability. My results do not seem to require the acceptance of Minkowski's[62] hypothesis, based partly on his own observations and partly on those of Walter,[63] that the attachment of the sodium of the blood forces the carbon dioxid, continually produced, to remain in the tissues, and that the fatigue is then referable to it, rather than to the pathologic acid or its salts. My present inclination, however, is toward the belief that all these substances are causative. The salts certainly are so, and the beneficial effects which are known to follow the administration of alkalies, such as sodium bicarbonate, seem to demand free acid and perhaps carbon dioxid also as causative agents. However this may be, I wish to emphasize my main contention, namely, that in acid intoxication the tissues of the body are in a state wholly analogous to the state of fatigue, in so far as the latter is due to toxic substances. The facts that the fatigue products are produced in the one case normally and in the other pathologically and that they differ in composition in the two cases are altogether secondary. Their physiologic effects are the same. Heretofore attention has been directed chiefly to the extreme effects of the pathologic acids, as, for example, the production of diabetic coma. We should not, however, forget that long before these extreme effects are manifested the same causes are producing evil, if less obvious, phenomena and rendering the cells less capable of their proper functions.

Not all cases of fatigue accompanying pathologic conditions are, however, due to excessive production of acid. In diabetes itself we have an excellent example of the twofold cause. The body is not only intoxicated by acid, but carbohydrates are wanting, and I can cite no more typical instance of disease in which fatigue may be traced to its two recognized causes. The two causes are also present in fevers and inanition, and doubtless in other pathologic conditions, though here investigation is needed.

Several investigators, especially Abelous and Langlois[64] and Albanese,[65] have studied the relation of the suprarenal bodies to fatigue. They find that both in frogs and in mammals, after removal of these bodies, fatigue occurs very promptly on the performance of muscular work. The extract of the muscles of an animal dying as the result of removal of the bodies possesses a toxicity similar to that of the muscles of a normal animal tetanized to exhaustion. They infer that the muscular weakness following removal of the suprarenals is due to toxic substances of a similar nature to those producing physiologic fatigue, and that the function of the suprarenals is to supply antitoxic substances. In view of our present knowledge of the physiologic action of adrenalin in its various forms, it seems more probable that the weakness is to be explained by the absence of the normal tone-producing internal secretion of the bodies in question, and this is doubtless the true explanation of the muscular asthenia present in persons suffering from Addison's disease. Abelous, Charrin and Langlois[66] have published striking erographic tracings of such cases.

Future research will probably reveal much regarding the relation between perverted metabolism and fatigue in pathologic conditions. In diabetes, for example, the possible fatiguing action of diacetic acid and of acetone ought to be investigated. In poisoning by phosphorus and by arsenic, in anemia and in certain diseases of the liver, sarcolactic acid is eliminated in the urine, and the physiologic action of this substance, already discussed, is probably responsible, in part at least, for the physical weakness accompanying these conditions. Because of the interest connected with the formation of aromatic bodies in the intestines as a result of putrefaction, and the supposed toxic action of some of these bodies on the central nervous system, at the suggestion of Professor Herter I have recently made a preliminary study of the action on muscle of indol, skatol and methyl mercaptan, and find all to possess some degree of fatiguing power.

In view of the fact that fatigue occupies so prominent a place in our daily life in both health and disease, it is strange that outside of the nostrum vendors not more serious endeavors have been made to provide specific antidotes for it. That various chemical substances delay fatigue is well known. I may be permitted here to refer to the study of the action of ethyl alcohol on muscle by Salant and myself[67] several years ago, in which we found that in medium quantity this substance exerts a favorable action, which is characterized by a quickening of the contraction; a quickening of the relaxation; the power of making a larger number of contractions and of performing a larger amount of work in a given time: an increase in the working time, or, in other words, a delay of fatigue; and the power of making a larger number of contractions and of doing a larger amount of work before exhaustion sets in. This action is exerted directly on the muscle protoplasm itself, not on the intramuscular nerve endings. In large quantity alcohol exerts an unfavorable action which is, in general, the reverse of that caused by medium quantities. The favorable action seems to be followed by unfavorable after-effects. Alcohol can not, therefore, be considered as worthy of ranking among the valuable antidotes to fatigue. And the same may be said of other substances of similar physiologic properties. A true antidote must recognize the causes. Both scientific experience and the experience of unscientific mankind seem to have demonstrated the real value of sugar in its various forms as a partial restorer of working power, and the old wives' prescription of cooking soda for one's tired feeling is certainly justified by the administration of sodium bicarbonate in advanced diabetes, if indeed this substance is not of actual benefit in ordinary daily physiologic fatigue. But at best sugar and alkali are only in part efficacious, and mankind at

present can administer no food or drug that can push the wearied cells up the metabolic grade, either simultaneously with their descent or quickly after the descent has ceased. Only the assimilation and detoxication that normally come with rest—and, best, rest with sleep—are capable of adequate restoration of working power. Fatigue is a phenomenon of metabolism; recovery is a phenomenon of metabolism. To-day's research reveals only how much more complex is the body's metabolism than yesterday we thought it to be, and in the problem of fatigue there is probably much more before us than behind us.

SERO-PROGNOSIS OF TUBERCULOUS PLEURISIES.*

PAUL COURMONT, M.D.
LYONS, FRANCE.
[TRANSLATED BY MAZYCK P. RAVENEL, M.D.,
PHILADELPHIA.]

The general idea of sero-prognosis is personal with me.

In 1897[1] I showed in regard to typhoid fever that the intensity of the agglutinating power of the blood is in inverse proportion to the gravity of the infection and in direct proportion to the resistance of the patient. I established this by 112 observations on typhoid fever with studies of the agglutination curve and by numerous observations on animals. In like manner Griffon[2] has shown that the maximum agglutinating power of the blood in pneumonia is found at the moment of recovery, and that this agglutinant power is wanting in mortal cases. In tuberculosis, which is not a cyclical disease, the facts are less conclusive. However, in conjunction with Arloing[3] I have found, since 1898, that the agglutinant power of the blood is ordinarily greater in cases which are benign, or on the way to recovery, and that it is lacking often in the grave and fatal forms. Many authors (Bendix, Mongour, Descos) have confirmed these findings.

The study of the agglutinating power of the blood serum and of the pleural serosity in tuberculous pleurisies has given some very interesting facts from this point of view, and capable to a certain degree of practical application.

In 1898 and 1900[4] I studied the agglutination of homogeneous cultures of the tubercle bacillus by tuberculous serous effusions and my own conclusions, based on 16 cases of tuberculous pleurisy, were as follows:

1. The non-tuberculous serous fluids do not agglutinate the bacillus of Koch. 2. The greater part of the tuberculous serous fluids agglutinate the bacillus of Koch in the proportion of 1 to 5 up to 1 to 20. 3. A certain number of tuberculous serous fluids cannot give a positive reaction even in the proportion of 1 to 5. In general this is found in grave or fatal cases with lesions especially virulent or occurring in tuberculous people in the last stage. However, in certain benign tuberculous pleurisies the sero-reaction of the pleural effusion may be entirely absent at the beginning, and only become positive at the end of a certain time—in general, about the time of recovery. 4. The agglutinating power of the blood is not always equal to that of the serous fluids. It can be more or less elevated, or exist in the absence of that of the serous fluid, and *vice versa*. 5. In favorable cases the agglutinating power of the serosity, or of the blood, may rise progressively. 6. The study of effusions of the serous membranes brought about experimentally in animals confirms all of these findings. Consequently, in practice, (a) a clearly positive sero-reaction beginning at 1 to 5 with the serous liquid constitutes a sign of great value in favor of the tuberculous nature of the effusion; (b), a negative sero-reaction constitutes only a presumption against the diagnosis of tuberculosis. In such cases it will be necessary to repeat the examination by the sero-reaction; (c) the examination of the agglutinating power of the blood, and of its intensity, will give interesting facts for comparison with those of the pleural reaction.[5]

At this time I also stated:

As we have demonstrated experimentally with Arloing,[6] there is an inverse ratio on the one hand between the gravity of the tuberculous lesion, resulting from the virulence of the bacillus and from the receptivity of the soil, and on the other hand, the intensity of the agglutinating power of the blood. . . . Grave or mortal pleurisies, human or experimental, give only very feeble or oftener a negative reaction. On the contrary the benign or curable pleurisies in man or those produced in an animal by a very much attenuated tuberculous virus give almost always a positive sero-reaction, often elevated in proportion as the disease is less grave. Finally, in an animal already possessing an agglutinating power we have been able by inoculation with a highly virulent tuberculous virus to bring about a pleurisy the effusion from which presented an agglutinating power growing more and more feeble until death.

Since that time I have pursued my researches at the Hotel Dieu at Lyon, and have studied and followed in parallel lines the clinical evolution and the agglutinating power of sera (blood and pleural effusion) in 115 patients suffering with non-tuberculous pleurisy.

I have always made the study of the agglutinating power under the same conditions, following the technic pointed out by Arloing and myself in numerous publications. As far as possible I have multiplied the drawings of blood and of the pleural effusions, following as closely as possible the variations of the agglutination in the course of the disease; i. e., the agglutination curve. From a clinical point of view my patients have been minutely observed and followed during their stay in the hospital, and after going out as long as possible. The nature of the pleurisy was proven not only clinically, but by the inoculation of the pleural effusion into guinea-pigs, and by cytology.

In the future I purpose publishing the complete results of all of these findings. At present I give only that which concerns the relation between the agglutination and the evolution of the disease, between the clinical prognosis and the sero-prognosis. The clinical prognosis can be given only by the evolution of the disease in the hospital. In 1904-5 we made inquiries on our 115 patients after their discharge from the hospital. The record of a large number of these we have thus been able to trace, sometimes with great difficulty, and the results obtained are given in the theses of Grillot[7] and of Pallasse.[8]

Out of the 115 patients 35 died at the hospital, 12 died after their discharge, 42 recovered, and 25 we have

been unable to trace. As regards these last we have based their prognosis on their condition at the time of their discharge from the hospital. The conclusions at which we have arrived are not based then on superficial and hasty observation. Our results extend over a period of seven years and some of our patients have been followed during this entire time. Certain recoveries did not remain permanent during these years; in other cases a secondary tuberculous infection, more or less early, has come on to modify the impression of some prognostications which were too hasty. From this long and patient study, extending over seven years and taking in 115 cases, and several hundred sero-agglutination tests, certain striking conclusions are derived, confirming and strengthening my views expressed in 1898.

The Relations Between the Evolution of Tuberculous Pleurisies and the Agglutinating Power of the Pleural Effusion.—We will give at the present time only results as a whole—very striking by their clearness. Although in each case we have studied the agglutinating power of the blood at the same time as that of the pleural effusions, and although the comparative study of the two possesses a great interest, we will speak here only of the agglutinating power of the pleural effusion.

I have divided my cases into two series according as the pleural effusion agglutinated the homogeneous cultures, beginning in the proportion of 1 to 5, or did not possess the agglutinating power at least in the proportion of 1 to 5, and I have compared the number of deaths, exacerbations, and of recoveries in the two series.

1. *Pleurisies in which the effusion agglutinates.*

Of these there are 67 cases, in which the agglutinating power varied from 1 to 5 up to 1 to 20 and more. Of these 67 patients 50 recovered or improved very much. Many of the recoveries or improvements have been followed during some years. The remaining 17 died either in the hospital or during the years which followed.

It is interesting to note the proportion of agglutination in those who recovered and in those who died:

Among 67 patients, agglutinating power was demonstrated in 33; 1 to 10, 1 to 20 and above; of these, 28 recovered and 5 died; in 34 there was agglutinating power of 1 to 5 only; of these, 22 recovered and 12 died.

Out of a total of 67 cases with a positive reaction, we have 50 recoveries, that is to say, 75 per cent.; in 33 cases with a strong reaction, 28 recoveries, 79 per cent., and in 34 cases with a feeble agglutination, 22 recoveries, or only 65 per cent.

2. *Pleurisies in which the effusion does not agglutinate.*

It is not necessary to say that we are speaking always of tuberculous pleurisies, and in the absence of the positive sero-reaction the diagnosis was assured, as in the preceding cases, by inoculation, by the clinical history, and often by the cytology. We have 48 of these cases in which the sero-reaction was negative in the proportion 1 to 5, as many times as we examined them, often 4 to 5 times in the same subject during the course of the pleurisy. Out of these 48 cases we have 13 recoveries or permanent ameliorations, 27 per cent; 35 deaths or exacerbations, 73 per cent. Summing up, we have in cases with positive reaction, 75 per cent. recoveries, and 25 per cent. of deaths. In the cases with negative reaction 27 per cent. of recoveries, and 73 per cent. of deaths or exacerbations.

These figures speak for themselves. One can sum them up somewhat schematically in saying that the patient with pleurisy in whom the effusion agglutinates has about three chances out of four for recovery; the patient in whom the effusion is not agglutinant has about three chances out of four of dying. It appears clear then that the agglutination reaction may be the sign of a curative process, of the defense of the organism, or of a lack of virulence of the infection. Two other points support this theory. In the table of agglutinant pleurisies, those which are most strongly agglutinant have the best prognosis (79 per cent. of recoveries); and if one compares the percentages of recoveries in the pleurisies with high agglutination, feeble agglutination, or no agglutination, the result is as follows: In 33 cases of pleurisy in which there was a strong sero-reaction (1 to 10 and above), 75 per cent. terminated in recovery and 21 per cent. terminated fatally.

In 34 cases of pleurisy in which there was a feeble sero-reaction (1 to 5), 65 per cent. terminated in recovery, while 35 per cent. terminated fatally. In cases in which the sero-reaction was absent, recovery took place in only 27 per cent., while 73 per cent. terminated fatally.

We have here a very interesting scale of progression, which leads to the following conclusions: The prognosis of tuberculous pleurisy with effusion is favorable according to the intensity of the agglutinating power of the pleural liquid, and grows worse with the diminution or absence of this reaction.

On the other hand we have found very often that the agglutinating power of the effusion increases very sensibly as recovery progresses, but diminishes in mortal cases toward the approach of the fatal termination.

EXAMPLES.

Case 1.—G., aged 18, benign sero-fibrinous pleurisy, recovery.

Ninth day, lymphocytes in pleura, 67 per cent.; agglutination, 1 to 5.

Fourteenth day, lymphocytes in pleura, 89 per cent.; agglutination, 1 to 10.

Twenty-first day, lymphocytes in pleura, 96 per cent.; agglutination, 1 to 15.

Case 2.—M., aged 28, pregnant, double febrile pleurisy, galloping consumption.

Twentieth day, lymphocytes in pleura, 91 per cent.; agglutination—blood, 1 to 10; pleura, 1 to 5.

Fiftieth day, lymphocytes in pleura, 93 per cent.; agglutination—blood, 1 to 10; pleura, 0.

Eightieth day, lymphocytes in pleura, 71 per cent.; agglutination—blood, 0; pleura, 0.

Ninety-fifth day, lymphocytes in pleura, ?; agglutination—blood, 0; pleura, 0.

CONCLUSIONS.

From the study of 115 cases of tuberculous pleurisy with effusion, followed during seven years, and from the investigation of the mortality of these patients, the following conclusions may be drawn:

1. The mortality is about 25 per cent. in cases the pleural effusion of which has agglutinating power, and 75 per cent., on the contrary, in those in which the fluid has no agglutinating power.

2. Among patients with an agglutinating effusion the number of recoveries is large in proportion as the agglutinating power is high.

3. One can observe the agglutinating power of the effusion increase in proportion as the case progresses to recovery, and, on the contrary, diminish in those patients in whom the termination is near.

4. These facts are a new proof of what we have held concerning typhoid fever, viz., that the agglutinating reaction is a reaction of defense, or at least goes parallel

with the reaction of resistance of the organism. It is in general in inverse proportion to the gravity of the disease and in direct proportion with the intensity of the resistance.

5. The study of agglutination in tuberculous pleurisies leads to important prognostic conclusions.

THE TREATMENT OF TETANUS BY INTRASPINAL INJECTIONS OF MAGNESIUM SULPHATE FOR THE CONTROL OF CONVULSIONS.

REPORT OF TWO CASES, WITH A DISCUSSION OF THE METHOD.

SAMUEL LOGAN, M.D.

Assistant Demonstrator of Operative Surgery, Tulane University; Senior Chief of Clinic to Surgical Department, Tulane University.

NEW ORLEANS.

The extremely unfavorable prognosis which must be given in cases of tetanus and the doubtful value of the antitetanic serum save as a prophylactic remedy are of themselves sufficient justification for the trial of any new plan of treatment of this disease which may hold out even the faintest hope of obtaining better results.

With the object, therefore, of adding in a slight degree to the statistics of a newly-suggested method of treatment, I report two cases of tetanus which have been treated according to the method proposed by Dr. S. J. Meltzer.[1] While neither of the cases resulted in a cure, they are nevertheless reported, partly because of unusual features arising in each and partly because of my belief that the value of any new method of treatment can be obtained only from a study of its failures as well as of its successes. In one of the cases the method accomplished all that Dr. Meltzer claims for it, and the final result was due to other causes. In the other the negative result following the plan of treatment was due to inexperience as to the proper dose to be used rather than to the method of using it.

Dr. Meltzer[1] reports the cure of a case of tetanus at the Roosevelt Hospital by the use of an injection into the spinal canal of a 25 per cent. solution of magnesium sulphate in the proportion of 1 c.c. for every 25 pounds of body weight, for the control of the muscular spasms, after 115 c.c. of antitetanic serum had failed to produce any effect on the progress of the disease. The case is to be reported in detail by Dr. Blake, in whose service it occurred, but as yet I have not been able to get any exact information about it. On the theory that the violent muscular exertions during the convulsions cause a gradual wearing out of the patient's resisting powers, it seems reasonable to suppose that anything which tends to lessen the convulsions and to preserve the patient's strength will increase his chances of recovery. This theory forms the basis for the liberal use of such remedies as chloral and the bromids, and their general employment in these cases may be taken as an index of a belief that a cure of the convulsions will be followed by a cure of the disease. That this is not necessarily bound to follow is shown in one of the cases to be reported, in which the convulsions were completely controlled, but with no apparent effect on the further course of the disease.

A few days after the appearance of the article by Meltzer, a case of tetanus was admitted to the surgical service of Prof. Rudolph Matas at the Charity Hospital and was assigned to my ward. In the hope of duplicating the good result obtained by Dr. Blake, Professor Matas decided to try the use of the magnesium sulphate solution, and it is through his courtesy that I have been given the privilege of reporting the experiment. The history of the case is given in detail because of the several important facts which are brought out by a study of the clinical record of the course of the disease.

CASE 1.—E. Z., Mexican, aged 11, was admitted to hospital Jan. 9, 1906, at 9 p. m., and died Jan. 13, 1906, at 3:50 a. m. Time in hospital, three days and six hours. His previous and family history was not obtainable.

Present Illness.—On Jan. 1, 1906, while celebrating the arrival of the New Year, the patient accidentally shot himself in the palm of the right hand with an old toy pistol loaded with a blank cartridge. He was treated at the time by his family physician, the treatment being limited to the simple cleansing of the wound and the application of dry dressings. The physician refused to give antitetanic serum as a prophylactic, because he said he did not believe in it and never used it. The wound was cleansed and dressed every other day until January 9, when, the first symptoms of tetanus appearing, the family became alarmed and brought the boy to the hospital for treatment. This was on the ninth day after the injury.

Treatment.—The patient was admitted to the accident amphitheater at 7 p. m., and was found to be suffering with stiffness of the muscles of the neck and some muscular twitchings. A diagnosis of probable tetanus was made by the house surgeon, and under anesthesia the palmar wound was freely opened, cleansed and dressed. The boy was given 50 c.c. of antitetanic serum introduced into the spinal canal in the lumbar region before being admitted to Ward 1 of the surgical service, under the supervision of Professor Matas.

Course of Disease.—On admission to the ward, no distinct convulsions could be noted, but the patient complained of great stiffness of the neck and jaws and marked muscular twitchings were noticed all over the body. He was immediately put on the bromid and chloral treatment, gr. 30 of the former and gr. 15 of the latter being ordered every four hours. Stimulating nourishment was given freely during the night, which passed uneventfully, the patient resting well, with no convulsions, but some difficulty in swallowing when fed. Maximum pulse, 112 (at 4 a. m.); maximum temperature, 99.8 (at 1 a. m.).

January 10: During the day bromids and chloral were continued. Temperature ranged from 98.6 at 8 a. m. to 99 at 6 p. m.; the pulse ranged from 116 at 11 a. m. to 136 at 4 p. m.; respirations ranged from 28 at 8 a. m. to 36 at 2 p. m. The patient was quiet and dozing during the morning, but was very restless during the afternoon. Muscular twitchings were marked and increasing. He complained of severe pain in the chest and abdomen, the muscular walls of the latter being rigidly contracted. No distinct convulsions could be made out as yet. He could still open his mouth sufficiently to be fed, but had great difficulty in swallowing food.

During the night bromid and chloral were administered. Temperature fluctuated between 99 at 9 p. m. and 100, in the axilla, at 5 a. m.; pulse varied between 120 at 2 a. m. and 140 at 5 a. m.; respirations ranged between 24 at 9 p. m. and 36 at midnight. The patient was fairly quiet during the night, save for great muscular twitchings and severe abdominal pains at 9:30 p. m. There were no convulsions, but there was great difficulty in swallowing.

January 11: This was the eleventh day since the injury. Bromid and chloral were discontinued after one dose at 9:45 a. m. Up to that time the patient had been given gr. 450 of bromids and gr. 170 of chloral in thirty-six hours, with no apparent effect on the muscular twitchings.

At 9 a. m., thirty-eight hours after the appearance of the first symptoms of tetanus, the patient was given by mouth ℥ss of magnesium sulphate in an effort to clean out the bowels. The

1. Meltzer, S. J.: "Inhibitory and Anesthetic Properties of Magnesium Salts," Med. Rec., Dec. 16, 1905.

giving of this dose brought on the first noticeable convulsion, which was slight in character, and lasted only about ten seconds. After this, however, handling of the patient caused several slight convulsions. None of these lasted long, but each was distinct and fairly severe, the boy crying loudly from pain, and the head being drawn back in opisthotonos during them. This condition seemed to be getting rapidly worse.

At 10:30 a. m., on examination by Professor Matas, the patient was found in a marked tetanic state, with convulsions occurring every time he was handled or disturbed. These convulsions lasted only a few seconds, and the jaws during the intervals were only partially locked. The abdominal muscles were rigidly contracted at all times and very painful on palpation. After a thorough review of the case, and in view of the gloomy prognosis from the rapid setting in of the change for the worse, Professor Matas decided to try Dr. Meltzer's plan of injection of a solution of magnesium sulphate into the spinal canal in an effort to control the muscular spasms.

Injection of Magnesium Sulphate.—In order to avoid the causation of further convulsions from the unavoidable handling during moving of the patient, he was anesthetized in bed and then transferred to the operating room. After the most through preparation of the parts, 4 c.c. of a 25 per cent. solution of magnesium sulphate, previously sterilized by filtering and boiling, were introduced into the spinal canal by lumbar puncture. The estimated weight of the boy was 80 pounds, making the amount of solution 1 c.c. for every 20 pounds of weight, instead of for every 25 pounds, as suggested by Meltzer to be used for producing anesthesia. Dr. Matas experienced some slight difficulty in making the injection because the patient's muscles were not completely relaxed even under full anesthesia. A few drops of cerebrospinal fluid were allowed to escape, and the injection was made very slowly, ten minutes being taken to introduce it. It was hoped by this means to avoid trouble with the respiration, and as a further precaution against this the Fell-O'Dwyer apparatus was kept at hand in case it might be necessary to resort to artificial respiration.

While the patient was still under the anesthetic, the wound in the palm of the hand was examined, and several pieces of wadding were found, which were removed and sent to the pathologic department for examination. (The report from the department later showed an absence of tetanus bacilli in these.) In addition, 50 c.c. of antitetanic serum was given, 10 c.c. being injected into each sciatic nerve, 10 c.c. into each brachial plexus and 10 c.c. into the tissues around the wound. A fact noted at the time of injection was that even under complete anesthesia the abdominal muscles were never relaxed, the abdomen being rigid and board-like on palpation. The boy was returned to the ward after having been in the operating room forty minutes in all. His temperature at that time was 101 in the rectum; pulse, 120; respirations, 30.

Result.—At 12:15 p. m., forty minutes after the injection was made, all the muscles of the body were completely relaxed; the abdomen, heretofore the most persistently rigid part, was soft, and not in the least tender to the touch. The jaws were relaxed, and the mouth could be opened readily. Recovery from the anesthetic was complete and satisfactory save for a slight nausea. The patient was perfectly conscious, and said that he felt well, except for a sore feeling in the stomach, which was probably the after-results of the tonic spasms of the abdominal muscles.

At 4:15 p. m., four hours and forty minutes after the injection, the patient began to experience difficulty with respiration. A profuse bronchorrhea developed rapidly and the breathing grew rapid and shallow. The interne immediately administered gr. 1/150 of atropin sulphate by hypodermic, which, after a little while, seemed slowly to relieve the trouble, the bronchorrhea clearing up gradually, and the respiration getting slower and deeper.

At 4:30 p. m. I examined the boy. The respirations were still shallow, with a good deal of bronchorrhea and some cyanosis. The pulse was 140, weak and thready. Temperature, 102. All the muscles of the body were in a state of complete relaxation; handling of the patient and pinching of the skin of the legs and abdomen failed to produce the slightest muscular twitching. The abdomen was soft, and could be palpated without causing anything more than a feeling of soreness, which the patient referred to the pit of the stomach. The boy was fully conscious, could speak perfectly, could open his mouth wide and had no difficulty in swallowing water. He continued quiet during the afternoon, with no change save a slight improvement in the respirations; pulse ranged around 145.

During the night the patient was quiet and rested easily till midnight. At that time, twelve hours and forty-five minutes after the injection of the magnesium sulphate, the first symptoms of a return of the rigidity were noted in the right arm. The tonic spasms returned rapidly, and at 1:15 a. m. had extended to all the extremities and to the abdominal muscles. The boy screamed several times toward daybreak, but the nurse was unable to note any distinct convulsions. The temperature increased, going up to 101.5. Pulse and respiration about the same.

January 12: At 7 a. m. the temperature was 102; pulse, 144; respiration, 28. There was great difficulty in swallowing, and each effort to do so caused marked muscular twitchings, but no general convulsions could be noted as yet.

At 10 a. m. I examined the patient and the following facts were noted: Temperature, 102; pulse, 150 and thready; respirations, 30. The muscles of head, neck and abdomen were rigidly contracted. The head was bent slightly backward. There were no general convulsions, but there was distinct muscular twitching on handling. The patient responded to questions, but did not seem in full control of mental faculties. He complained constantly of pain, with groans and loud cries at intervals when the twitchings seemed greatest.

Second Injection.—As the first injection of the magnesium sulphate had relieved the patient's sufferings, and had afforded an interval of freedom from the muscular spasms with a certain amount of improvement, it was decided to repeat the injection in the hope that equally as good an effect might be obtained a second time. Accordingly, with the same precautions to avoid setting up convulsions during the transfer to the operating room, the boy was anesthetized in bed, and when fully under the anesthetic was removed to the operating room. Under strict aseptic precautions a second injection of a sterile 25 per cent. solution of magnesium sulphate (50 minims this time) was given into the lumbar spinal canal, the injection being made very slowly. Owing to the opisthotonos, which persisted under anesthesia, some difficulty was experienced in getting the needle into the canal; three trials had to be made before the cerebrospinal fluid was encountered. Four or five drops of this were allowed to escape in order to notice if any change had taken place, but it was found clear and normal in appearance.

Owing to the evident failure of the antitetanic serum to influence the course of the disease, no more of it was given. The rigid contraction of the abdominal walls under full anesthesia was noticed again this time. The patient was returned to the ward, having been in the amphitheatre forty minutes.

Result.—At 11:35 a. m., thirty-five minutes after the injection, all the muscles of the body were again completely relaxed, and the patient was resting easily, having recovered well from the anesthetic. The pulse was still high (158) and weak in character, and for this feature of the case digitalin, gr. 1/100, was ordered every three hours.

At 1:15 p. m., two hours and fifteen minutes after the injection, an attempt was made to nourish the boy by giving him a nutrient enema (℥2). While this was being given he was seized with a severe convulsion, lasting about fifteen seconds; during this attack the arms and legs became perfectly rigid, the jaws were tightly locked and the pulse was almost imperceptible. The convulsion passed away immediately on ceasing the enema, leaving the patient completely relaxed, save for the rigidity of the jaws, which lasted for about an hour.

At 2 p. m., three hours after the injection, trouble with the respiration set in, similar in character to that following after the first injection, and consisting of a profuse bronchorrhea with rapid and shallow breathing and some cyanosis. Atropin, gr. 1 150, was given, and the dose repeated in thirty minutes, which, with the application of external heat, relieved this con-

dition somewhat, but the patient was extremely weak. When I saw him at 3 p. m. the respirations were a trifle stronger and slower, and the muscular relaxation was complete. The pulse at this time was 168 and very weak. Nourishment by hypodermic, brandy m. xxx every hour, was added to the treatment.

A résumé of the clinical record for this day shows the following steady change for the worse in the boy's general condition, despite the fact that he had but one convulsion during the day:

Temperature ranged from 100.8 in the morning to 103 at 5 p. m.; the pulse ranged from 144 in the morning to 180 at 5 p. m.; respirations ranged from the same time from 26 in the morning to 36. The patient was unconscious from 3:50 p. m. After the convulsion following giving of enema there was complete muscular relaxation.

During the night the pulse steadily increased in frequency and weakened in force. Stimulation with brandy, m. xxx every hour, digitalin, gr. 1/100, every four hours, and atropin, gr. 1/150, every two hours, was of no avail, The pulse became weaker and weaker, reaching 192 at 10 p. m. The temperature gradually rose from 104 at 7 p. m. to 106 at 10 p. m. Respirations increased from 40 at 7 p. m. to 55 at 10 p. m.

The patient died at 3:50 a. m., January 13, forty hours and fifty minutes after the first injection of magnesium sulphate, without any convulsive attacks or muscular twitchings since the one caused by the giving of the nutrient enema fourteen hours previously. It was noted that the patient's heart failed before the respirations were affected, the pulse becoming imperceptible ten minutes before the last respiration was taken. Temperature postmortem was 108.2 by rectum. The body was claimed and no postmortem was allowed.

The second case occurred in the private practice of Professor Matas, who suggested the use of magnesium sulphate by Dr. Urban Maes, chief of clinic to the surgical department of Tulane University. The doctor has very kindly allowed me to report the facts, a courtesy which is greatly appreciated.

CASE 2.—Miss W., aged 24, gave negative personal and family history as regards present trouble.

Present Illness.—On Feb. 2, 1906, the patient was vaccinated under the strictest aseptic precautions by a dentist, and the wound sealed aseptically with sterile gauze held in place by adhesive strips. No trouble was experienced by the patient until February 19, seventeen days after the vaccination, when she noticed an inability to open the mouth freely. The dressing on the arm, which had not been touched so far, was immediately removed and the wound cleansed, a wet bichlorid dressing being applied. The vaccination was found to have taken well. An injection of 100 c.c. of antitetanic serum was given subcutaneously as soon as it could be obtained, but notwithstanding this the symptoms rapidly increased in severity.

Consultation.—When Dr. Maes saw the case in consultation, the following points were noticed: Temperature, 101; pulse, 120; respirations, irregular and about 30. The patient was suffering from marked convulsions, each one lasting from five to eight minutes, with from twelve to twenty minutes between each attack. The jaws were rigidly locked during the entire time. The general condition of the patient was fair.

Treatment.—In view of the fulminating character of the attack, and with a hope of obtaining some relief from the violent and frequent convulsions, it was determined to introduce the magnesium solution into the spinal canal. Accordingly, thirty hours after the first symptoms were noted, the patient was anesthetized locally, and 4 c.c. of a sterile 25 per cent. solution of magnesium sulphate was injected into the lumbar spinal canal, every precaution being taken to avoid infection. At the same time, wide excision of the wound was done under local anesthesia, and the wound saturated with powdered antitetanic serum. The patient's weight being estimated at 100 pounds, the amount of solution approximated 1 c.c. for every 25 pounds of weight. Slight difficulty was met in entering the spinal canal, and about ten minims of cerebrospinal fluid were allowed to escape.

Result.—On the next observation of the patient by Dr. Maes, seventeen hours after the injection, the following facts were noted: Temperature, 101; pulse, 160 and thready; respirations, spasmodic and irregular. Condition of muscles, tense, including the recti and digital muscles, the latter causing the characteristic *main en griffe*. The jaws were rigidly contracted. There was general cyanosis and the patient was comatose, with tetanic seizures, which were practically continuous, and involving the intercostal muscles and the muscles of the neck and diaphragm. No relief of convulsions had been noted to follow the injection.

Second Injection.—The condition of the patient being desperate and the family being anxious for the use of any means which might afford relief, a second attempt was made to control the convulsions, although Dr. Maes did not anticipate much good from the injection. With the patient in an almost moribund condition, a second injection of 4 c.c. of a 25 per cent. solution of magnesium sulphate was made seventeen and a half hours after the first. It proved of little value, and the patient shortly after succumbed to the disease, dying from respiratory failure, fifty hours after the appearance of the initial symptoms. The apex beat of the heart could be felt for three or four minutes after the last seizure involving the respiratory muscles. Cyanosis became marked, and the end came with eyes fixed and patient resting on head and heels in extreme opisthotonos.

Remarks.—At no time could it be noticed that any good had resulted from the use of the magnesium solution. Possibly the lengthening of the periods between each attack, which followed the first injection, might be attributed to this; the convulsions never ceased for a moment, however, and were equally as severe immediately after both injections as before.

COMMENTS.

So far as the use of the magnesium sulphate in these two cases is concerned, one showed a positive result in the control of the convulsions, while the other showed no change. This last failure, Dr. Macs and I both feel sure, was because of the use of too small a quantity of the solution in proportion to the severity of the attack, but on account of the limited experience we have had with the method Dr. Macs felt a natural hesitancy in exceeding the limits of dosage recommended by Meltzer. With a stronger solution or with a bigger dosage it is most probable that the spasms would have shown at least some slight abatement, and possibly might have been entirely controlled as in the first case. Further reference to the causes influencing the failure in this instance will be made later.

With the limited amount of data on hand it would be unfair to draw any conclusions in regard to the value of this line of treatment, but to our mind the simplicity of application is an appealing argument to its further trial, and we hope to be able to furnish more data as to its usefulness before long. As regards the two cases reported in this communication, the following points are deemed worthy of further emphasis:

1. Control of Convulsions by the Use of the Magnesium Sulphate Solution.—In Case 1 this was by far the most interesting feature, showing, as it did, the complete cessation of the muscular convulsions following the introduction of the magnesium solution into the spinal canal. At the time of both injections the rigid contraction of the abdominal muscles even under full anesthesia was especially notable, and the complete relaxation of these, as well as all the muscles of the body, forty minutes after the injection, verified to the fullest degree Meltzer's observations of the paralyzing effect of magnesium sulphate on the motor tracts of the spinal cord. The lasting effects of this paralysis were shown conclusively when four hours and a half later all attempts to induce muscular twitchings or convulsions, such as handling of patient, pinching of skin of legs and abdo-

men, failed to produce any result. The patient at that time was in a state of complete relaxation, could open the mouth wide and could swallow, and was conscious and talked freely to the attendants. The duration of the relaxed state for nearly thirteen hours before a return of the rigidity gave an interval of rest which could never have been obtained by any other mode of treatment, and during which the patient distinctly gained ground, only to fall back again on the renewal of the convulsive attacks. Had the second injection been given earlier, at the time of the first return of the rigidity, the interval of rest might have been lengthened indefinitely and a better final result might have been accomplished.

Case 2 was one of the fulminating type of the disease, with a rapid onset of severe symptoms and an immediate succumbing to the effects of the tetanus toxin. The long interval of time elapsing between the primary wound of vaccination and the appearance of the tetanic symptoms in all probability was not the true period of incubation, for, though the patient strenuously denied having touched the wound, it requires no great stretch of imagination to presume that the dressings were partially displaced at some time from a curiosity to see how the vaccination was "taking," and that at this time the tetanus germ gained entrance. In view of the extremely rigid aseptic precautions taken at the time of vaccination, and the long period of incubation before the onset of so severe an attack of tetanus, it is more reasonable to suspect an infection during the time in which the vaccination was taking than to imagine so unusually severe a fulminating case of tetanus following a seventeen-day period of incubation.

The failure of the magnesium sulphate to control the convulsions in this case is explainable in two ways: First, the fulminating type of the disease, with the rapid giving way of the patient's resisting powers, made it a hopeless case from the beginning; consequently the chances of a failure by any plan of treatment were largely increased. Second, the size of the dose of the magnesium was that ordinarily used by Meltzer for inducing spinal anesthesia for operative cases; consequently it was far too small for use in a pathologic condition whose main symptom consists of a hyperexcitation of the motor centers of the cord. We might just as well expect the same dose of chloral given to produce sleep to calm the ravings of delirium tremens as to expect the small amount of magnesium sulphate recommended for anesthetic purposes in a healthy person to have any calming effect on the hyperexcited spinal cord centers of tetanus. I firmly believe that if the quantity of magnesium sulphate given in this instance had been twice as much a marked influence on the convulsions would have been noted. Further experience with the use of the solution will bring a better knowledge of the dosage to be employed according to the severity of the attack. This was partly instanced in the first case, when, in an apparently mild case, a slightly stronger solution (1 c.c. to every 20 pounds) than the one recommended for anesthetic purposes (1 c.c. for every 25 pounds) proved sufficient to produce the desired effect.

2. Respiratory Disturbances Following the Injections.—The development of late respiratory difficulty following both injections of the magnesium in Case 1 was the only annoying feature of the treatment. Professor Matas had hoped that by the slow introduction of the solution into the spinal canal the unpleasant respiratory disturbances mentioned by Meltzer might be overcome. At the time of the injection everything was in readiness for the induction of artificial respiration in case it should be needed, but it was only after the lapse of several hours (4½ after the first injection, 3 after the second) that this trouble put in an appearance. The profuse bronchorrhea and rapid, shallow respiration which characterized it were very alarming, but administration of atropin, gr. 1/150, repeated in thirty minutes, checked it in a short while, only the two doses of atropin being given. The only explanation of the late appearance of the respiratory disturbance which we could suggest was an involvement of the respiratory center from the spreading of the paralyzing effect of the magnesium up to the medulla; this would explain the marked rise in the pulse rate which began about this time and which was due probably to a partial paralysis of the pneumogastrics, with a consequent rapidity and weakness of the heart action. In conjunction with the slow introduction of the solution into the canal, we would suggest propping up the patient in bed the moment muscular relaxation comes on, so as to limit by gravity the action of the drug to the cord proper. This procedure has been used to limit the action of the drug in intraspinal anesthesia with cocain. It is likely that in this way, with a better knowledge of the exactness of the dose required, the respiratory disturbances may be eliminated to a large degree.

In all cases to be treated by this plan it is advisable to have on hand some apparatus for producing artificial respiration, from the time the injection is made until the muscular relaxation is at its height. The injection should be made slowly, at least ten minutes being taken to introduce 4 c.c. of the solution into the canal. On the appearance of muscular relaxation the patient should be immediately propped up in bed to the semirecumbent position and kept in that position for several hours. If bronchorrhea, or rapid, shallow respirations with cyanosis appear, atropin, gr. 1/150, should be given and the dose repeated, if necessary, in from 30 to 40 minutes. If the condition becomes worse, artificial respiration should be used, and, as a last resort, withdrawal of cerebrospinal fluid and its substitution with an equal amount of sterile saline solution will be indicated to dilute the action of the drug. Meltzer has tried this with good results.[2]

That this respiratory disturbance is not permanent in character is shown by the fact that in Case 1, in which the trouble was experienced and relieved, the respiratory center was the last to fail, the heart apparently stopping fully eight minutes before the last gasp was taken. The absence of respiratory disturbances in Case 2 is another proof of the insufficiency of the dose used, as it is hard to imagine the development of signs of paralysis of the respiratory centers without some effect having been produced on the motor tracts of the cord. The respiratory failure at the end, in this instance before the heart stopped, was due to a mechanical interference with the muscles of respiration rather than to a failure of the centers in the medulla. Failure of the respiration during a convulsion is one of the usual causes of death in tetanus, but it has never been considered as being due to a failure of the respiratory center itself.

3. Death of Patient (Case 1) in a State of Complete Relaxation.—This fact, it seems to us, deserves particular emphasis, being, as it is, so out of the ordinary sequel of events in cases of tetanus ending fatally. We are so

2. Haubold and Meltzer: The Journal A. M. A., March 3, 1906.

accustomed to see the patient pass rapidly into a series of tonic convulsions, which increases in severity and frequency as the end comes, with death during an unusually severe one, that we are apt to attach a greater importance than they deserve to the muscular spasms as causes of a fatal result. It should always be borne in mind that the convulsions are but expressions of the action of the toxins which have been absorbed by the system, and that the result depends entirely on the quantity of these which have gained entrance to the body, provided, of course, that the patient does not die from mechanical interference with respiration by the convulsions. Case 1 bears out this observation of the majority of authorities on this point, for here we had an attack in which the convulsions were distinctly limited in number, mild and short in character, with two long intervals of complete muscular relaxation, and yet the pulse and temperature kept going up slowly and steadily, showing increasing effects of the toxins on the nervous system. Were it not for the lessened chances of respiratory failure during the convulsions, it would be a question whether any lasting good is accomplished in checking them any more than there would be in knocking out the temperature in typhoid in the hope of thereby curing the disease. It seems, therefore, that the value of this or of any other plan of treatment for tetanus which aims at a control of the muscular spasms is only palliative in nature, and that our efforts should rather be directed to the finding of some means of neutralizing the toxins of the disease once it has developed. When that has been accomplished the muscular convulsions will disappear of themselves. For the present, however, the use of the magnesium sulphate to control the spasms, and thereby to prevent death from respiratory disturbances, should be given further trial, on account of its ease of application and its comparative harmlessness when judiciously and cautiously used.

DIAGNOSTIC VALUE OF THE LEUCOCYTE FORMULA IN PERTUSSIS.*

FRANK SPOONER CHURCHILL, M.D.

Assistant Professor of Pediatrics, Rush Medical College (In affiliation with University of Chicago).

CHICAGO.

IMPORTANCE OF BLOOD EXAMINATION.

Whooping-cough is a far more serious disease than is generally supposed, and its diagnosis in the early stage is a matter of great importance, as it is at this time that the infection is most frequently spread. Any measure, therefore, which may help to its early recognition is worthy of careful study and investigation.

The examination of the blood in this disease, as in many other infections, has unexpectedly shown a condition which, in a certain number of cases, is abnormal and perhaps of diagnostic value. This condition consists of an increase, both relative and absolute, in the number of the lymphocytes—a lymphocytosis. Several series of cases have been reported showing this increase in these cells, but the number on record is still comparatively small. Therefore I have made some investigation on this subject with the object of determining how frequently this condition is found, how early in the course of the disease it occurs and hence of how much value blood examination may be in early diagnosis.

* Read at the Annual Meeting of The Mississippi Valley Medical Association, Indianapolis, Oct., 1904.

REVIEW OF LITERATURE.

The first investigation of this question was by Frohlich[1] in 1897. He studied the blood in 55 cases, total counts being made in all; differential in 15. He found a general leucocytosis in all but 2 cases, and a lymphocytosis in 8 of the 15 examined. He came to the conclusion that this increase in the lymphocytosis was of diagnostic value in atypical cases, but that its value in ordinary cases was lessened by its appearance. As 13 of his patients were examined during or after the third week, however, and only 2 in the first week, his opinion as to its significance in the early stages seems hardly justified.

Meunier[2] made total counts in 30 cases and differential in 10 of these. He found that a lymphocytosis occurred early in all cases and considered it of great diagnostic value and of practical importance in preventing the spread of the disease, e. g., in schools.

De Amici and Pacchioni[3] studied carefully 18 cases, 8 examinations being made in the catarrhal stage, 13 in the paroxysmal and 7 in the period of decline. A lymphocytosis was found in 15 of their 18 cases. They consider it of practical diagnostic value.

Stengel and White[4] reported 3 cases, all of which showed a lymphocytosis.

Wanstall[5] examined 19 children, all suspected of being in the catarrhal stage of whooping-cough. Later 15 of these proved to be pertussis. In 11 cases there was a lymphocytosis. He concludes that there are good grounds for the statement that an increased percentage of lymphocytes is of diagnostic value, occurring, as it does, before the onset of characteristic symptoms.

Muggia and Bertolotti[6] reported 35 cases in which they found a predominance of large mononuclear elements.

Isolated cases have been reported furthermore by Cabot,[7] Steven,[8] and others, which in general coincide with the above observations.

I now add to these reports 36 cases, 23 from my clinic at Rush Medical College and from private practice, and 13 from Dr. W. L. Baum's service at Cook County Hospital. The details of these cases briefly are as follows: The patients range in age from 6 months to 17 years. The total leucocyte count has been made in 29 cases and a general leucocytosis found in all but one. The counts range from 10,000 to 112,000. Differential counts have been made in all cases, 30 showing a lymphocytosis; 15 out of 16 patients examined in the catarrhal stage had a lymphocytosis. The percentages ranged from 34.3, in a 5 year old child, to 93 in a 4 year old. The latter was the one with a total of 112,000, was a severe case, and came to the clinic at the height of the disease. A count made 16 days later showed a total of 32,600 with 61 per cent. of lymphocytes, and great improvement in all the symptoms.

We have now for study 100 cases of whooping-cough in which differential counts of the blood have been made. There are also available total leucocyte counts from more than a hundred. I have grouped the reports on these

cases according to age, averaged the total leucocyte count, the percentage of lymphocytes and polymorphonuclears and constructed curves on these averages. I have averaged the percentage of these two types of cells also according to the time of examination, catarrhal stage and paroxysmal stage, and plotted their curves. For purposes of comparison I have introduced into the charts normal curves based on estimates for different ages given by Karniski[9] and by Carstagen.[10] The importance of taking into consideration the age of the child in making differential counts has not been sufficiently emphasized by the authors quoted. The necessity for so doing is evident from a glance at the normal curves,

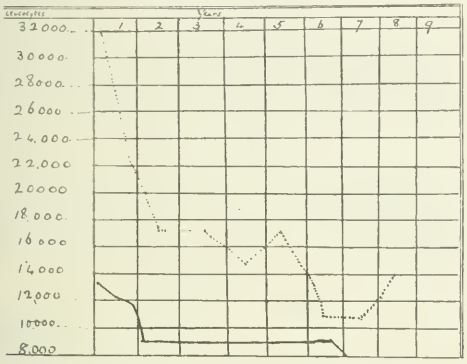

Chart 1.—Total leucocytes: —— normal; .... catarrhal stage.

which show the range of lymphocytes to be from 55 per cent. during the first year to 30 per cent. in the ninth year, and the neutrophiles for the same periods to range from 33 per cent. to 56 per cent. Thus a lymphocyte count of 50 per cent. at 6 years would be of considerable significance; at 1 year it would be of no significance. This variation in the leucocyte formula must be borne in mind in all blood work among children, especially in the present study.

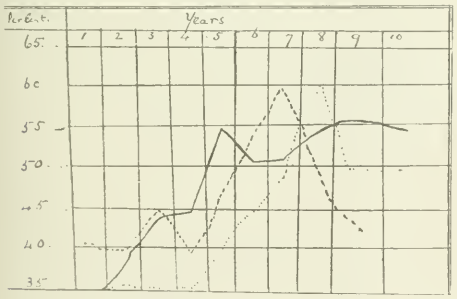

Chart 2.—Polymorphonuclear curve: —— normal; - - - - - paroxysmal stage; .... catarrhal stage.

Inspection of the total leucocyte chart (Chart 1) shows a general leucocytosis at all stages, most marked during infancy and early childhood. The comparatively high count during the first year is due to the occurrence of one count of 89,000.

The polymorphonuclear curve (Chart 2) during the catarrhal stage as a rule is relatively below the normal;

9. Karnizki: Archiv. f. Kind., 1903, vol. xxxvi, p. 42.
10. Carstangen: Jahrb. f Kindhlk., 1900, vol. lii, p. 215.

the total count, however, in some years is so high, e.g., in the second year, that absolutely there is an increase over the number of the cells normal to the age. During the paroxysmal stage the curve is above the normal except during the fourth, fifth and eighth years. Concerning this increase during the paroxysmal stage I will speak later.

The chief interest centers in the lymphocyte curve (Chart 3). It follows in a fairly close parallel the downward trend of the normal curve but always above it, the increase being greatest during the first 4 or 5 years. Furthermore the increase is greater during the catarrhal stage than during the paroxysmal stage. At first sight this seems somewhat unnatural; if the pertussis infection cause a lymphocytosis, one would expect this lymphocytosis to increase with the severity of the disease, whereas it apparently diminishes. I believe that among the cases examined during the paroxysmal stage are some with complications, e. g., bronchitis, perhaps lobular pneumonia, and that these complications caused an increase in the polymorphonuclears and a corresponding decrease in the lymphocytes at this period of the disease. The increase in the polymorphonuclears has already been mentioned. So far as possible, I have studied by themselves the cases with complications, but

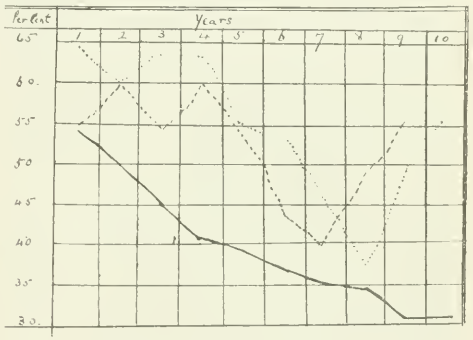

Chart 3.—Lymphocyte curve: —— normal; - - - - - paroxysmal stage; .... catarrhal stage.

the details are not always given with clearness and some complicated cases may have been included in the hundred cases regarded as uncomplicated. Whatever the cause, there appears to be a diminution in the lymphocytes and an increase in the polymorphonuclears during the paroxysmal stage.

While the average of the lymphocytes is thus above normal in each year, there are individual cases of course which show no increase. In actual figures, however, 87 of the 100 cases (87 per cent.) show a lymphocytosis at some time during the course of the disease. Analyzed as to time of appearance, we find that of 42 cases examined during the catarrhal stage 39, or 93 per cent., show the increase. As it is particularly in this stage that we wish accurate information it is gratifying to find such a large proportion of cases showing this characteristic condition of the blood at this time. How early the infection may cause this change is evident from the following: Eight cases examined in the first week all showed a lymphocytosis; one infant, aged 20 months, had a lymphocytosis of 65 per cent. after 5 days of cough; one child, aged 2 years, had a lymphocytosis of 60.3 per cent. after 3 days of cough. The last case was one of a family of 3, and the other 2 children already

had whooping-cough; hence the early date of the blood examination.

In view of these observations made by so many different workers, there can be no doubt of the frequent occurrence of a lymphocytosis in the early stages of whooping-cough. The infection apparently has no effect on the eosinophiles.

It remains to be asked whether or not we find this blood change in other conditions likely to be confused with pertussis. It must be remembered that in the blood as well as in the nervous system and indeed in all parts of the unstable infant organism slight causes produce more marked and irregular results than they do in the more stable adult organism. Thus the blood and especially the leucocyte formula is easily upset in early life. It shows a marked tendency to revert to the fetal type, especially in any prolonged wasting disease, e. g., hereditary syphilis. In such conditions, we frequently find an increase of lymphocytes above the standard normal to the age. In general glandular enlargement, e. g., I have repeatedly found a lymphocytosis. Stengel and White have found the condition in occasional cases of pneumonia, also in typhoid, though in the latter at certain periods of the disease a lymphocytosis is the rule, as has already been shown.[11] The same authors also found a predominance of lymphocytes over neutrophiles in occasional cases of varicella, of enteritis, in rickets, eczema, focal epilepsy, convulsions, spastic cerebral palsy and pleural effusion.

None of these conditions, however, are difficult to distinguish from whooping-cough. Furthermore, the increase in lymphocytes is only occasional. Lymphocytic leukemia alone has a constant and high percentage of lymphocytes, and this disease can be easily differentiated.

It is in children with a hard violent cough due to bronchitis, pharyngitis, laryngitis, especially of influenzal origin, that we are most often suspicious of whooping-cough. And it is in these very conditions that a blood examination is of value, for while we often find a leucocytosis, there is no lymphocytosis, as has been shown by the observations of various authors. Stengel and White[4] report in 6 cases of bronchitis with a hard cough the following averages: Total leucocytes, 12,911; lymphocytes, 29.9 per cent.; polymorphonuclears, 68 per cent.

Wanstall's 4 cases, which failed to develop into whooping-cough, had the following averages: Lymphocytes, 33 per cent.; large mononuclears, 7.8 per cent; polymorphonuclears, 56.5 per cent.; eosinophiles, 1.9 per cent.; mast cells, 0.3 per cent.

Meunier[2] found no such change in the blood in bronchitis or tracheitis.

The following cases in my practice are of interest in this connection:

Case 1.—A 5-year-old boy had been coughing hard for five days, after having been exposed to pertussis. His parents, making preparations for a European trip, were naturally anxious to know the nature of the cough. Physical examination showed considerable bronchitis. The blood was as follows: On April 5 the lymphocytes numbered 26 per cent. and the polymorphonuclears 73 per cent. On April 12 the lymphocytes were 31 per cent. and the polymorphonuclears 66 per cent. On April 19 the lymphocytes were 42 per cent. and the polymorphonuclears 55 per cent. The comparatively high polymorphonuclear count at the first examination with an active bronchitis will be noted, also the gradual resumption of the proportions normal to the age with the disappearance of the bronchitis. The child never developed pertussis.

Case 2.—Another case was that of a mother whose child was ill with whooping cough. She developed a severe paroxysmal cough without apparent cause. Her blood at the end of a week was as follows:

Total leucocytes	10,500
Lymphocytes	34.6 per cent.
Polymorphonuclears	63 per cent.
Eosinophiles	2.5 per cent.

Her cough subsided in about a week.

Case 3.—A child, aged 6, whose brother had pertussis began to cough slightly; after about a week her blood was as follows:

Lymphocytes	39 per cent.
Polymorphonuclears	55 per cent.
Eosinophiles	3 per cent.

She never developed pertussis.

Evidently the blood in those conditions most likely to be confused with whooping-cough, does not show a lymphocytosis. In the absence of the phenomenon in those conditions, and its almost constant presence in pertussis itself, the opinion seems warranted that its presence is a factor of great diagnostic value.

COMPLICATIONS.

The effect of complications such as pneumonia on the blood picture, has not been studied in sufficient detail to warrant conclusions. Fröhlich[1] is of the opinion that complications have no effect. DeAmici and Pacchioni[3] found pneumonia in 4 of their cases, the counts being as follows:

Age in years.	Percentage of Lymphocytes.	Percentage of Polymorph.	Stage of Disease.
2	42	56	Catarrhal
2	68	32	Paroxysmal
1	56	43	Catarrhal
	19	80	Stage of decline

The most significant case is the last with a reversal of the leucocyte formula in the stage of decline resulting in high neutrophile count.

My own cases with complications are only 4 in number, as follows:

Age.	Percentage of Lymphocytes.	Percentage of Polymorph.	Stage of disease.	Complication.
6 mos.	30	69	Late.	Varicella, pustules
8 mos.	38.5	62	"	Bronchopneumonia
3 yrs.	33	62.2	"	Gonococcus vaginitis
17 yrs.	33	66	"	Lobar pneumonia

The predominance of polymorphonuclears in all cases will be noted. Cabot[7] and Steven,[8] on the other hand, both report cases of undoubted pertussis with bronchopneumonia which show a high lymphocyte count. Evidently the effect of complications on the leucocyte formula must be left for future investigations.

It will be observed that in this study I have used the term lymphocyte and have not attempted to differentiate between large and small cells of this type. There can be no doubt that a difference between these does exist; but, as there has been no uniformity of classification among the authors quoted and as the personal equation enters so largely into what constitutes large and small, it has seemed to me simpler to group the two varieties under one head, combining the total percentages in those cases which authors have differentiated into large and small. *Apropos* of this general subject Cabot[7] discussing the terms "lymphocytes proper" (large or small) and the other "large mononuclears cells" says: "As no clinical importance has ever been attached to the so-called large mononuclear cells, and as they make up in the great majority of cases but a few per cent. of all the leucocytes, it seems to me best at the present time to include them for practical purposes within the lymphocyte group." So far as the cases in my own clinic and my private practice are concerned there was in all cases a marked predominance of undoubtedly small cells.

11. Churchill: Boston Med. and Surg. Jour., 1903, vol. cxlvii, p. 692.

TECHNIC.

The usual Thoma-Zeiss instrument has been used in my work in making total counts. In staining, Ehrlich's, Jenner's or Wright's stain has been used. I have been particularly fortunate with Wright's stain. No heating is required, the process takes but little time, is very simple, and can be done by one's office assistant. When the leucocytosis is very marked no total count is necessary for one who has had considerable experience in blood work, as he can tell from the dried specimens that a leucocytosis is present. This is of great advantage in working among children where it is often extremely difficult to fill the white counter exactly, as must be done if the count is to be of any value.

I do not wish to appear to advocate careless or inaccurate work in examining the blood of children. It is only when the leucocytosis is extreme that it is safe to dispense with the total count, and then only by one who has had much experience. The undergraduate and the graduate in medicine during the first years of actual practice must use his counter. By constant study of his dried specimens, however, he will gradually learn to measure approximately the degree of leucocytosis and furthermore will learn much more of the blood as a whole than he will from mere total counts either of erythrocytes or leucocytes.

CONCLUSIONS.

1. A general leucocytosis is present in almost all cases of whooping-cough.

2. A lymphocytosis, i. e., an increase in the number of lymphocytes is found in about 85 per cent. of cases at some time during the course of the disease.

3. A lymphocytosis is found even more constantly during the early or catarrhal stage, over 90 per cent. showing the phenomenon at this time.

4. A lymphocytosis is found usually in those conditions difficult to distinguish from whooping-cough.

5. Therefore, the presence of a lymphocytosis in a child with a hard persistent cough is a factor of great diagnostic value. It is also of prophylactic importance inasmuch as it can be utilized to prevent the spread of the disease by leading to the prompt isolation of the patient.

6. The child's age must be taken into account in estimating the importance of the lymphocyte percentage.

I wish to express to Dr. W. L. Baum my thanks for his courtesy in placing at my disposal the work done in his wards, and to my assistant, Dr. Alex. C. Soper, Jr., for much valuable help in the blood examinations.

HOW TO SUTURE THE WOUND IN EARLY OR INTERVAL OPERATIONS FOR APPENDICITIS, SO AS TO SHORTEN THE INDOOR CONFINEMENT TO ONE WEEK.

CLINICAL EXPERIENCE IN PROOF.*

J. E. SUMMERS, Jr., M.D.
OMAHA, NEB.

Besides the all-important question as to the dangers of an operation, the next in importance with the patient and friends is the necessary time of confinement in bed and of interference with business and every-day occupations. It is surprising how many people refuse absolutely, or put off from time to time, an advisable operation; although they know from common knowledge that the danger is exceedingly slight, yet they "can not afford the time." Having in many instances known of persons whose procrastination in this direction has cost them their lives, great jeopardy or much unnecessary suffering, I have been following the several recognized surgical procedures in the diseases of the appendix in order to choose for my own guidance the safest and shortest cut toward recovery and a return to customary duties.

Most of the professional grief I have suffered was during the growing period of knowledge by the medical profession and the laity in regard to the time for operation in acute appendicitis. The family physician either did not appreciate operative interference, except as a "last resort," or else did not recognize the meaning of certain ominous symptoms, even of the first few hours, until perhaps during the fatal lull an exploration demonstrated the true condition. The people, of course, had to be educated. The facts about appendicitis remind me forcibly of the treatment of laryngeal diphtheria in the preintubation-antitoxin days. I have tracheotomized more than sixty cases of this kind as a "last resort," this being called for by the physician and family, and the mortality was frightful. When I could get the chance to do an early tracheotomy, a fair percentage of the children recovered. So it has been with appendicitis. To-day with early operation in acute cases and timely operation in chronic and interval cases the disease is being robbed of its terrors; in fact, is rather joked about. Added to what has been referred to regarding a judicious time, an improved technic has done most to save life and shorten convalescence.

THE AUTHOR'S TECHNIC.

I will briefly describe what has been to me a most satisfactory technic in operating within the early hours of mild attacks of acute appendicitis, and in all cases between acute attacks, i. e., during quiescent periods, as well as in people, subjects of those indefinite, not always well-defined symptoms, sometimes simulating stomach trouble, indigestion and colic. It would be a waste of time to attempt a description of all of the different technics advocated for the operative treatment of the class of cases under consideration, as everybody is more or less familiar with them.

The Incision.—In the first place it should be distinctly understood that the abdominal wound must never be closed without providing for dependent drainage in any form of appendicitis, unless the operator knows that the inflammatory process has been confined within the appendix. I have been experimenting somewhat so as to determine for my own action what incision will best accomplish the desired end, i. e., removal of the appendix, and how to close this incision so as to admit of the earliest getting up and return to every-day habits. The incisions employed have been that through splitting the right rectus abdominalis muscle; the vertical incision behind the rectus advocated by Kammerer and others, and the McBurney incision, sometimes modified when more room was required, as recommended by Weir and Harrington.

Because this latter incision gives the nearest approach to the appendix and affords sufficient room for the intra-abdominal technic in about all cases which should be closed without drainage, and because this incision can be closed so that hernia is absolutely not to be expected, and the patients are up and out and in many cases at

* Read before the Sioux Valley Medical Association, Sioux City, Iowa, Jan. 19, 1906.

work after seven days, I now employ it and give it preference.

Suturing Material.—In order to simplify matters to this extent it is essential to use proper suturing material and so to introduce the sutures that at the end of the time specified your patient will surely be free from all complications. For this operation catgut is the only suturing material used. We are all prone to change our suturing materials too often, using perhaps within one year catgut prepared after several methods. When a catgut is found which, when prepared, is sterile, strong and easy to handle, the first essentials are at hand. When a wound requires anything greater than very slight tension in its closure, catgut is not the material for its closure. Some wounds, of course, require longer time than others in their repair, because of the different natures of the tissues brought into contact. An example of this is when in operations for the radical cure of inguinal hernia the internal oblique muscle is brought into close contact with Poupart's ligament, or again when heavy flaps are approximated and need strong support until Nature's repair has taken the weight off the supports. Catgut when used under such circumstances must be slower of absorption and, therefore, of large size or a chromatized material is employed. I use a cumolized gut and in the closure of a McBurney incision use two sizes, Nos. 1 and 2; No. 1 in children and in all reasonably thin adults; No. 2 in the heavier walled individuals.

Method of Suturing.—The wound is sutured from peritoneum to skin, inclusive, by a one-string continuous stitch. Commencing at the inner angle, the peritoneum is closed by a simple continuous or button-hole stitch. When the outer angle is reached, the needle (a full curved, round one, spear pointed) is passed from below upward through the transversalis and internal oblique muscles, the needle emerging one inch outside of and above the outer angle of the separation in these muscles. This manipulation pulls the closed and puckered wound in the peritoneum above and somewhat outside of the line of the cleft in the muscles. These muscles are now closed from without inward by a few deep (including all muscle) continuous stitches. Unless the suture brings the wound in the muscles nicely together, it is always better to approximate it more accurately by bringing the gut back to the outer angle as a superficial continuous stitch passed sufficiently deep to accomplish the object.

If the deep continuous stitch through the muscles has sufficed, the needle is passed from the inner angle of this closure superficially through the internal oblique muscle downward and brought out at the lower angle of the wound in the fascia of the external oblique muscle. This fascia is then closed either by a simple continuous stitch from below upward, which I prefer, or else the fascia may be made to overlap and in this way give firmer support. I think this overlapping of the fascia is unnecessary, but I sometimes employ it as a variation. If the superficial stitches in the internal oblique have been added to the deep stitches, the needle is passed superficially through the internal oblique muscle from the outer angle of the muscle wound to the upper angle of the wound in the external oblique, and this latter is closed from above down by the same methods as just given. I close the skin with either a compound button-hole stitch or else by a subcuticular stitch. For the former the needle is passed from within so as to come out opposite the angle of the wound and about ¼ to 1/3 in. away, and from this point the continuous suture which definitely closes the wound begins. For the subcuticular stitch the needle is brought out in the angle of the wound and the start made at this place; the final knot is tied within the opposite angle. The whole procedure from the commencement of the operation to the closure of the wound takes from eight to twenty minutes, according to the difficulties found within the abdomen and the thickness of the abdominal wall.

No. 1 plain catgut, Van Horn cumolized, can be brushed off the skin in five days; No. 2 in six or seven days. For years I had been sending my uncomplicated appendicitis cases home in ten to twelve days after operation, and have yet to see or hear of a hernia resulting. The active demand for beds emboldened me to look for a shorter confinement of my patients. After fixing on the technic briefly detailed as the most appropriate for the purpose, I have selected 61 cases as suitable, and except 5 who were detained several days because of complications independent of the operation, as bronchitis, diarrhea, etc., all have been discharged on the sixth or seventh days following operation, many being at home, perhaps fifty to one hundred and fifty or more miles away, one week from the day they left home. In cases of several farmers, I have known of their being at work on the farm on the seventh day.

RESULTS OF EXPERIENCE.

Put a well person in bed and keep him there and insist on his lying very quiet; keep this up for seven or eight days, and then tell him to get up, and see how he will wobble. My practice is to allow all of my simple appendicitis cases to suit their own comfort and desires as to the position in bed after the bowels have been made to move, i. e., forty-eight hours following the operation. There is no reason why these people may not leave the hospital on the fifth, sixth or seventh days, and it is my practice to send all such uncomplicated cases out of the hospitals on the seventh day.

I would not hesitate to allow a patient with an ordinary case of appendicitis operated on as described to travel to his home three days after operation were there any very important reason for such a course. The worst to be feared might be a little parting of the skin edges, and this can not happen if the wound is made secure from the bottom to top surface. And why not? The people for whom I would recommend the employment of the technic described are "walking cases." Many are not at all ill, but are suffering from somewhat debilitating or uncomfortable symptoms of a more or less chronic type or of a recurrent, sharper nature. If the symptoms of inflammation in the appendix are acute they must not be severe or of more than a few hours' duration if the McBurney incision is to be employed. If, after making this incision, evidences of infection outside of the appendix are found, the real and only safe work must be done through a vertical incision near the median line. Whenever the incision advocated is proper, the usual fair physical condition of the patient and the short anesthesia required make the affair, from a surgical standpoint, of little moment. The intra-abdominal repair is safe in forty-eight hours. I have done the McBurney incision in hundreds of patients, a few of these being pus cases, but it is a dangerous incision for this latter class even in the hands of the most experienced.

It would not be proper not to admonish against any one making light of a surgical operation. The safeties we are able to surround our patients with to-day are

rery different from those of years ago, and seemingly vonderful things are done, yet in spite of all our modern cience and art we still have the same old man to deal vith, and he may have idiosyncrasies and defects not easily, if at all, discoverable until the unexpected hapens.

No one who has not suffered from having one or more f what Sir James Paget called the "calamities of surery" occur in his professional experience can fully ppreciate the dangers he is apt to encounter. As a varning I would emphasize that many, if not all, of hese calamities follow sins of omission or commission n the part of the professional attendant.

TRANSMISSION OF BUBONIC PLAGUE BY SHIP RATS.

AUGUST STRAUCH.
CHICAGO.

I made a voyage from Austria to Brazil in 1901 on he steamer *Gundulic* under the worst conditions maginable. On the first night after leaving the Austrian harbor of Trieste the sight of numerous rats astonished me. A few days later we arrived at Alexandria, Egypt, which then was plague ridden. While there we were in quarantine, that is, without any direct communiation with the land in order to avoid troublesome measures in other ports. We took no merchandise, except ome provisions which were hauled on board with ropes n baskets and dirty sacks from barges.

After a stay of several days we left for Tangier Morocco), St. Vincent (Cape Verde Islands) and Pernambuco (Brazil). When we approached the warmer limate I noticed that the noise made every night by the ats grew less and finally ceased. After we left Pernamuco for Rio de Janeiro, our cook and the steward beame ill with foudroyant symptoms of fever, adynamia, eadache and vertigo, a syndrome which did not permit f a definite diagnosis. The next morning both patients resented very painful swellings of the right crural ymph glands.

In the cook the swelling increased very rapidly and pread to the iliac glands, which in four days were of he size of two fists. The surrounding tissues and the kin were hard, infiltrated and reddened, similar to rysipelas, so that the whole looked like an appendicitis umor ready for perforation. After six days the patient ied and was buried at sea. At a postmortem incision f the swelling a hemorrhagic gelatinous infiltration nd edema of the panniculus adiposus, the perglandular issues, with partly necrotic glands were found, but here was no suppuration within the reach of the section.

In the steward it was interesting to find the port of ntrance of the pest bacilli in the form of a small hemorhagic spot much like a flea bite on the second toe of the ight foot, which changed under my eyes in a few hours o a blood blister of the size of a lentil. Pest bacilli ould be found in its contents. The bubo was only of oderate size and contained numerous plague bacilli lmost in pure culture. This patient recovered.

From the occurrence of the primary bubo, as well as rom the plurality of the cases, I was able to recognize he character of the disease, especially as I had had an pportunity of studying it in the plague hospitals of Bombay in 1900 and 1901. I made further inquiry mong the crew, in order to determine the source of this utbreak which occurred fully one month after our leaving a pest-ridden harbor. This revealed the fact that as early as six or nine days, or may be longer, before the outbreak of the disease the sailors had noticed dead rats or sick rats in groups.

In spite of the numerous rodents on vessels, dead rats are rarely found, and then only in the remotest hiding places and always singly, never in groups, because the live ones eat them immediately. In our case evidently too many had died to be eaten by the surviving rats.

I learned that the cook repeatedly removed corpses of rats with his fingers and, holding them by the end of the tail, showed them in sport to the other men. About three days before he fell sick he had with his bare feet killed two rats that had been dying with convulsions.

My researches, therefore, fully explained the cessation of the nocturnal noises. Every day during our voyage from Pernambuco to Rio de Janeiro new dead rats in groups or singly were found and thrown overboard by means of long fire tongs or wooden sticks. Prophylactic measures were instituted. The places where dead rats were found were carefully disinfected. The patients were isolated. The daily routine work in the hull of the steamer was stopped altogether or reduced to the indispensable minimum necessary to manage the ship. Nobody was allowed to sleep in the magazines of the hull because of the many rats. As a result of these precautions no new case of plague occurred, not even at the period of greatest danger of infection, when the epizootic among the rats reached its highest point.

The most efficient and prompt measures were taken after our arrival in quarantine at Rio de Janeiro; the crew was immunized with Yersin's antiplague serum; the rats were exterminated by sulphuric vapors; the whole boat was repeatedly disinfected, almost with the accuracy employed in an operating room. Nevertheless, during the first days of our stay in that harbor, we continued to find rats which had died from plague and not from the effects of the sulphuric vapors.

It became evident that it would be difficult to eradicate all the rodents while the cargo was still on board.

After a while the crew became indifferent to the rules of personal prophylaxis and two more cases appeared twelve and thirteen days after the immunization with antiplague serum.

Among the cargo a number of more or less mummified rats were found again, and the fact that in both men the primary bubo developed in the axilla showed that they had become infected while handling the goods, which evidently were soiled with excretions of the sick rodents. The men did not wear gloves to protect themselves against infection, as they had been instructed to do.

The older patient had a number of lesions in his right palm, presumably the port of entrance of the plague bacilli; in the next five days a bubo of the size of almost a hen's egg developed in his right axilla. The fever, however, was not high, and after the second day of his illness he felt comparatively well. A microscopic specimen of the juice of the affected glands showed a few typical plague bacilli.

The second patient was under my observation only 48 hours. He had an extremely painful, somewhat swollen lymph gland in the right axilla many hours before the onset of fever or other general symptoms. A plague carbuncle developed very rapidly with a large, flat, partly hemorrhagic multilocular blister. Plague bacilli which showed numerous forms of degeneration were

found in the juice of tissue taken from the hard, infiltrated base of the carbuncle. Cultures as well as inoculations were positive.

The patients were taken to the plague hospital of Rio de Janeiro, where both recovered.

I am convinced that the peculiarly mild course which the disease took in the last two cases, notwithstanding the fact that cases are more fatal in which the buboes are located in the axilla near the center of circulation, must be ascribed to the use of the preventive serum.

There can be no doubt that the plague virus was carried to our steamer in Alexandria, although no direct communication with the land took place. The entrance of an infected harbor rat into the steamer, thereby transporting the virus to the numerous ship rats, I consider very improbable. I believe the provisions hauled to the ship in dirty sacks and baskets were the sole cause of the outbreak.

In case of plague the rats on board ship are a menace not only to the ship, but also to the ports at which it touches, because the pest-infected rodents soil the whole ship and the merchandise with their excretions, and in this way they are likely to transmit the bacilli to the rats of the harbor, for the harbor rats sniff at and gnaw the goods, especially eatable ones, and may eat the dead, plague-infected rats of the steamer.

HISTORICAL REVIEW.

That epidemics of pest are very often preceded by an enormous death rate among rats and mice laymen seem to have known for ages.

In Hindustan and Uganda and in other endemic plague foci, when rats come out of their hiding places and die in large numbers, a panic is created and the people leave their homes forthwith.

Rats may often have been the cause of single cases as well as of epidemics of plague, the origin of which could be explained in no other way. This applies particularly to cases occurring in harbors and especially in docks where the propagation by means of men or their baggage was excluded, but where navigation in some way played an important part in transmitting the disease. This method of transmission of plague may have been operative in many cases of outbreak of the plague on vessels long after leaving an infected port. Owing to the small power of resistance of the plague bacillus to dryness and heat, the direct importation of the pest through primarily infected merchandise is at present considered improbable, especially after a long voyage in tropical and subtropical latitudes. In such cases, therefore, the transportation of the bacilli must be assigned to an agent which can increase and preserve the virulence of the virus.

Pest affecting a limited number of rats having free communication among themselves would destroy them all in a short time on account of the great susceptibility of these animals to plague infection. On board ship, however, where the animals can not come in contact with each other so easily, especially when they are partitioned off in different separated parts of the hold, an epizootic may progress more slowly and last for weeks, finally transmitting the disease even after a long interval from one remote port to another. Since the discovery of the plague bacillus real proof of this fact has been established. For instance, the German government sent a commission to investigate the epidemic of plague which seized about 90 persons in Oporto in 1899. It was found that an epidemic of pest had killed many rats in the docks and their surroundings before the outbreak among the population occurred. The rats were either directly infected from the rats of a steamer or through merchandise which had become soiled with the excrement of plague-infected ship rats. A similar experience was reported by Kitasato in Kobe, Japan, in 1899, another in Sydney in 1900. Under favorable conditions the disease may remain confined to the rats. A number of dead rats, for instance, were found when the steamer *Rembrandt* returning from Smyrna in January, 1901, discharged its cargo in Bristol. The cadavers contained virulent plague bacilli; yet the disease was not communicated to men.

The steamer *Pergamon* returned to Hamburg January, 1901, from a cruise in the Mediterranean, and dead rats in groups of five or six were found between bales of merchandise. The number of rat corpses aroused suspicion. The bacteriologic examination which was ordered by the board of health showed that the rats died from bubonic plague. The merchandise was partly burned, the rest carefully disinfected, as was also the entire steamer; the rats were all exterminated, and in this way an infection of the rats in the dockyards and harbor and possibly among the inhabitants was prevented. No case of plague among the crew had occurred.

From such experiences it is evident that for international trade international quarantine rules ought to be made, demanding as one of their principal points systematic extermination of the rats on board with sulphur dioxid, carbon dioxid, carbon monoxid, traps, poison or a sufficiently virulent culture of Danysz's bacillus, while the ship lies empty at its terminus. The same should also be attempted with dock and harbor rats.

The Australian and Turkish governments have already included similar requirements in their quarantine regulations. Infected merchandise must be burned or very carefully disinfected; valuable goods which will not stand disinfection must be kept in an isolated place inaccessible to rats until the virus has entirely lost its activity.

1201 Irving Park Boulevard.

THE TREATMENT OF ARTHRITIS DEFORMANS WITH THE ROENTGEN RAYS.

A PRELIMINARY REPORT.*

J. M. ANDERS, M.D., JUDSON DALAND, M.D.
AND G. F. PFAHLER, M.D.
PHILADELPHIA.

We submit this preliminary report on the treatment of arthritis deformans with the Roentgen rays, and hope at a later date to make a more complete report on these and similar cases and then to be able to draw more definite conclusions.

CASE 1.—Mr. T. J., aged 47, a miner, was admitted to the wards of the Medico-Chirurgical Hospital under the care of Dr. Anders Oct. 26, 1905. The man's father died of miner's asthma, otherwise the family history is negative. His previous medical and social history have no bearing on the disease.

Present Illness.—This dates from July, 1902, when his feet, especially the joints of the toes, became swollen, tender and painful. This kept him from work one year; he then improved and was able to work four months. Since that time, which was fifteen months before admission to the hospital, he has

* Read before the Philadelphia County Medical Society, March 14, 1906.

not worked on account of the stiffness, swelling, tenderness and pain in his joints. Four months before admission his left wrist became swollen, tender and painful. Soon after this the left elbow and shoulder became similarly affected, and the joint movements became more and more restricted with the advancement of the disease. At the time of admission he could not, by his own power, raise his left arm from the side. It could, however, by passive motion, be raised half way to the level of the shoulder.

Physical Examination.—This showed the left shoulder to be larger than the right, and tender and painful when passive motion was attempted. The pain seemed to be confined to the joint. No crepitation could be elicited. The left elbow was tender, and somewhat stiff or partially ankylosed, but not swollen. The left wrist joint was tender, stiff, painful and swollen, and the periarticular tissues were infiltrated. The fingers of the left hand showed a tendency to bend backward and outward. The joints of the right upper extremity were normal. The feet were deformed, the toes were bent strongly outward, and the ankles were swollen and tender. The phalangeal and metatarso-phalangeal joints showed great restriction of movements. The knees showed a little joint rigidity, otherwise nothing abnormal.

The general examination showed some emaciation, an emphysematous chest, and more or less general atheroma of the arteries, otherwise there was nothing abnormal.

Radiographic Examination.—This was made Oct. 31, 1905. It showed particularly decalcification of the bones of the wrist joint, with erosion of some of the joint surfaces, and an exudate into the joint spaces. The elbow showed a similar decalcification, with some exudate into the joint space, and a roughening of the tip of the olecranon. The shoulder showed a similar condition.

Treatment.—In order to rule out any constitutional effect only the joints of the wrist, elbow and shoulder of the left side were selected for treatment. The arm was bent in such a way that all of these joints were brought into the field of exposure at one time. The man was treated three times a week, with a medium tube, at a distance of fifteen inches, with about one milliampere of current going through the tube. Each treatment lasted about fifteen minutes. Treatment was begun Nov. 14, 1905. After the first treatment he had less pain. After the third treatment there was distinctly less stiffness. The diminution in pain and stiffness continued progressively until at the end of about one month, and after sixteen treatments, the joints of the left upper extremity were practically well. While at first the patient could not raise his arm from his side he then could touch the ear on the opposite side of the head. He could raise his left arm to within two inches as high as the right, and he could reach around his back nearly as far with his left hand as with his right. The wrist improvements were normal.

Second Radiographic Examination.—This was made Dec. 11, 1905, less than one month after beginning *x*-ray treatment, and showed a decided approach to the normal.

Third Radiographic Examination.—This was made Feb. 27, 1906, nine weeks after discontinuing the treatment and showed only very slight difference in the joints of the two sides.

Internal Medication.—With the *x*-ray treatment sodium iodid was given internally, and massage and passive motion were given locally. While at the end of about a month the joints of the upper extremity had practically recovered, the joints of the lower extremities, which had not been treated with the *x*-ray, showed no change, which seems to indicate that it was neither the constitutional treatment nor the massage and passive motions in themselves that produced the results.

Treatment of Lower Extremities.—Since December 19 the joints of the lower extremities have been treated. There has been the same diminution in the amount of pain and stiffness, but the improvement has not been so well demonstrated as in the upper extremity, probably because of the marked deformity of the feet. At the end of a month, however, the man was able to sew up the cuts he had made in his shoes to make room for his feet nearly a year previously.

CASE 2.—Mr. O. G., aged 53, was admitted to the wards of the Medico-Chirurgical Hospital under the care of Dr. Daland. The family history is of no importance. Since 1890 he has had painful joint affections, short in duration, and with only one joint affected at a time, several months elapsing between attacks.

Present Illness.—This began in August, 1903, with pain, swelling and stiffness in the left ankle and instep. After four months the pain and swelling began to subside, but the soreness and stiffness remained. In June, the right knee, and in September, 1904, the left knee became similarly affected. The left knee continued to grow larger and more painful until admission to the hospital.

Physical Examination (Notes by Dr. Robertson).—This showed briefly a man older in appearance than his years; tendency to sweating; the right pupil a little larger than the left; the gums and teeth in bad condition; some wasting of the shoulder girdle and upper arm muscles. Both wrists, ankles and both knees more or less swollen and ankylosed. There was considerable synovitis of the left knee joint. The chest and lungs were emphysematous, and the heart showed a weak myocardium.

Radiographic Examination.—This was made Jan. 2, 1906, of both wrists, both knees, both ankles and showed in general the changes more or less characteristic of arthritis deformans, viz.: decalcification of the extremities of the bones, an exudate into the joint, erosions, or bony outgrowths of the bones, and actual deformities. In addition, this case showed marked atheroma of the arteries about the ankles.

The left knee, which gave the patient most concern, and which alone was treated, showed in particular distinct enlargement, an exudate into the periarticular tissues, an elevation of the patella by the fluid which was seen to fill the entire synovial sac. The patella showed a distinct exudate, which appeared to be beneath the periosteum on its anterior surface, and a more or less irregular exudate on its upper and posterior surface. The joint surfaces of both the femur and the tibia were eroded.

Treatment and Result.—The left joint alone was chosen for treatment because this was the one that most annoyed the patient. At the time of beginning treatment the knee was in a semiflexed position and could neither be extended nor flexed, and was very tender and painful.

The technic of the treatment was similar to that described in connection with the first case. After ten days and four treatments the pain had nearly subsided and the man could move the joint much more freely. After five weeks and fifteen treatments he was able to walk out of the hospital (at first he was bedfast). He has been able to go back and forth for treatment. There was an interval of three weeks in the treatment on account of a misunderstanding. During this time his pains slightly increased. In this case, as in the first one, massage and passive motion were given in conjunction with the *x*-ray treatment. A radiographic examination at this time showed a diminution in the periarticular exudate, and only about one-third of the exudate in the synovial sac.

We were led to investigate this treatment by the very excellent report made by Moser[1] on the treatment of gout and rheumatism with the Roentgen rays. His first case was reported in 1904.[2] This case began as an acute attack of gout, affecting the great toe. At the time of beginning treatment, however, seven years later, the patient presented the characteristics of general arthritis deformans. The disease had for a long time been at a standstill. A radiographic examination of one of the knees seemed to excite an acute attack, which subsided very promptly. This led Moser to repeat the exposures. At first each exposure was followed by acute pains; later the pains subsided; and then the joints became more mobile.

Moser's last report is based on the treatment of six cases of gout and six cases of rheumatism. In all good

1. Forts. auf dem Geb. der Röntgenstrahlen, vol. ix, No. 1, Aug 29, 1905.
2. Centbl. f. Chir., 1904, No. 23, p. 712.

results were obtained. Some of the cases of gout were treated during an acute attack with most prompt relief. In the cases of chronic rheumatism the pain, tenderness, swelling and stiffness either disappeared or were much diminished. As early as 1897 Sokolow[3] treated acute and chronic rheumatism in children's joints with the rays with marked improvement.

In 1900 Albers-Schonberg[4] observed marked improvement in cases of gout that had been exposed to the rays.

We believe that this method of treatment is a valuable adjunct in the treatment of these chronic joint affections, but that it is advisable to use massage and passive motion in conjunction with the Roentgen rays. We believe that the rays stimulate and increase the metabolism within the joint, and that this should be taken advantage of, and the massage and passive motion added to assist in the removal of the exudate.

THE COUNTRY DOCTOR.

JOHN G. WILSON, M.D.
MONTROSE, PA.

A country doctor ought to know what any trained physician ought to know. In order to make a success of his profession he must have a most thorough preliminary education, must avail himself of the advantages of his medical course to the utmost and be determined to improve himself at every opportunity.

His training when he enters on his life's work has simply laid open to his vision a glimpse of its possibilities. His future depends largely on his capacity for work. His savings for years must be reinvested in office equipment. He must embrace the opportunities freely given by the masters of the profession at their clinics to see their work and to learn to a certainty that their success has been by intense application for years along definite lines. Specialism is only a division of labor as practiced by all people as they have advanced through the various stages of development.

The discovery of ether by Morton in 1846 and the theory taught by Pasteur that micro-organisms caused fermentation, amplified by Lister in the treatment of wounds, greatly broadened the practice of medicine, and especially advanced and separated to some extent the practice of surgery from that of medicine.

The acceptance and perfection of antisepsis was of slow growth and gained almost no foothold in this country until Lister's visit to Philadelphia in 1876. Strange as it seems to us who never practiced any other method, the older members of the profession were loath to accept its truths and surgery was taken up by a few men and practiced as a specialty.

About this time Norris and Strawbridge returned from Germany, bringing with them the advances made in the treatment of diseases of the eye, and especially they had gained an inkling of the methods of refraction which were developed, and the oculist soon appeared. It is a fact that nearly all of the headaches just above and back of the eyes are caused by defective vision, and that large numbers of school children go to their physicians and are given headache remedies without end. This is to no purpose, and they finally have to give up school on account of becoming nervous wrecks, unless by chance they happen into some jewelry store and are given some kind of lenses to wear which may relieve the trouble to some extent.

The country physician, therefore, should take up refraction work. The great mass of working people simply can not pay the fee demanded by the oculists and are forced to put up with the indifferent work of the so-called opticians. Two or three hundred dollars will buy the necessary equipment and a month's work in some eye infirmary will give one a start, and one can do as well at once as any optician will ever be able to do.

A general knowledge of the diseases of the eye will be a help to one in many instances. After four or five years study and practice one will become very proficient and will be enabled to make many people more useful and add greatly to their happiness. Physicians as a class must give more attention to diseases of the eye, as a physician loses standing in a community if he fails to distinguish between a case of iritis and toothache, and a patient is apt to tell his neighbors if some country doctor treats a swollen and inflamed eye for weeks and then calls in a specialist who discovers a wheat-beard imbedded in the cornea.

Before the days of antiseptics, McDowell and The Atlees had boldly invaded the abdominal cavity and Marion Sims had given to the world the speculum. Soon after the advent of antisepsis the surgeon found that women could be mutilated almost with impunity and the era of the gynecologist began, but fortunately for suffering womankind it has passed away.

The great work of Howard Kelly in making plain to the profession at large the technic of plastic work, the advances made by McBurney in the operative treatment of appendicitis, the pathway blazed by the Mayo brothers in surgery of the gall bladder, have made it possible for any intelligent man to do good work and save his patients unnecessary suffering and, frequently, an untimely death.

The well-trained physician needs to recognize that the great question before the people now is this: Can my physician take care of me if I am sick and can he tell me how to keep well, or at least guard me from unnecessary sickness?

A physician that can make a diagnosis of appendicitis with certainty ought to be capable of operating and will give his patient a better chance of recovering than he would have if he waits a few hours longer to be sure of his diagnosis before putting the family to a useless expense of sending to the city for a great man and then waiting twenty-four hours more until he arrives, and perhaps by that time he finds the patient suffering with a general peritonitis.

At any rate a man that can not operate is not a safe person to leave a patient with after he has been operated on. If the case does not do well the great surgeon is far away and can not be had when again needed. If the patient wakes up in the night with every symptom of obstruction of the bowel something must be done and done at once, and it now requires more skill to give the patient the best chance than it did to do the primary operation, and if the country physician lacks experience or is deficient in equipment and does not dare to make the attempt to remove the obstruction, the patient will die.

The public at large would laugh at the physician that sent for the city man to reduce every dislocation or treat every case of fracture that came to him. Think of the worry, the anxiety that a bad fracture of the wrist or of the elbow entails.

Since few cases of fracture should be treated without careful *x*-ray examination, and in most instances must be reduced under an anesthetic, and not

3. Vratsch., 1897, No. 46
4. Munch. med. Wochft., 1900, No. 9, p. 284.

infrequently cut down on and wired, doing an ordinary abdominal section is child's play in comparison, and why should the country doctor be expected to do the one and not the other? If he without question accepts the case of the fracture, which entails, if done in the best manner possible, an expensive outfit, which every surgeon of wide experience dreads, which brings but little credit and almost no pecuniary reward, why not spend the time and learn to do the easy things that need to be done and at the same time bring their rewards with them?

A general practitioner, if he is as capable as he should be, can do almost the same work that any surgeon dare attempt, and his success will be as great and in most instances should be better, for he can give his personal attention to the case.

In too many instances the surgeon must give the after care of the patient almost wholly to some nurse or interne who has had but little opportunity and training. I do not believe, however, that the great operations should be attempted except in an emergency by any but men of the widest experience, as they will be able to do the work in a few minutes less time and by so doing save life. The exercise of their riper judgment would, in not a few instances, save organs that would be sacrificed by the less experienced.

The ordinary practitioner must become more competent or cease to exist. It is proper to be conservative, but that should not serve as a cloak to ignorance. We must be able to do the business that comes to our door, or in many instances it will not be done and the patients will suffer in consequence.

The "patent medicine" evil is no greater humbug than the fake attempted by many so-called specialists who write long articles in the journals on their special subjects, telling how very difficult it is to do their little special line of work—that it requires great skill to make a diagnosis—that a faulty diagnosis leads to faulty treatment and leaves you more in the dark than ever how to proceed; but somehow the impression is left in your mind that you had better send the patient to them, they alone know how to make a chemical analysis of the gastric contents. Don't do it. Just send for the carpenter who owes you for treating his daughter through a long sickness with typhoid and have him throw out a bay window on the side of the office. Equip a laboratory, buy some books and stop loafing. The $300 with which you thought of buying worthless mining stock will equip it nicely, and you will have the means at hand to tell whether your next patient has pernicious anemia or chlorosis, typhoid or malaria, and without these means you can not be absolutely certain. More is now required of the general practitioner than ever before and more is given. Each year people demand more accurate diagnosis and better treatment, and the question is, and it is a live one, where and how are they going to get it? Is the general practitioner going to become equal to the demand, or is the practice to be parceled out to a hundred specialists?

No one physician can do the best possible work in all lines of modern medical practice, but he may do better work in every field and the best work in almost every instance. Constant work in any specialty gives greater expertness along certain lines, and better results ought to be achieved by specialists in some cases.

As we find things to-day the great mass of work done by the specialists is work that should be done at home by the family physician and at far less expense and inconvenience to the patient. We need fewer so-called specialists but more thoroughly trained physicians. They must spend more money for equipment, be capable of making the most thorough examinations, and be prepared to carry out the various methods of treatment necessary to effect a cure.

All honor to the specialist, but hail to that type of practitioner that Carleton had in mind when he wrote these lines:

In the night-time or the day-time he would rally brave and well,
Though the summer lark was fifing or the frozen lances fell;
Knowing if he won the battle they would praise their Maker's name,
Knowing if he lost the battle, then the doctor was to blame.
'Twas the brave old virtuous doctor,
'Twas the good old faulty doctor,
'Twas the faithful country doctor—
Fighting stoutly all the same.

THE NASAL ACCESSORY SINUSES.*

EMIL MAYER, M.D.

Adjunct Attending Laryngologist to Mount Sinai Hospital; Chief of Clinic, Ear and Throat Department of the Mt. Sinai Hospital Dispensary.

NEW YORK.

While affections of the pneumatic sinuses of the skull have been recognized many years, it is only within the last 15 or 20 years that a fuller knowledge of their occurrence and their attendant treatment has become generally known, so that in mentioning the most important recent advances in rhinology the general consensus of opinion will be that diseases of the accessory sinuses, their diagnosis and treatment are the ones to be so considered.

Since those interested in special fields of rhinology have studied the question from every viewpoint, and voluminous essays have been presented which the general practician hardly finds time to read, a brief résumé of the advances made in this line may not be amiss.

The accessory sinuses of the nose, four in number, are the frontal, ethmoidal, sphenoidal and maxillary. These vary in size in different individuals, and anomalous conditions arise where there may be but a rudimentary sinus or even complete absence thereof. Some of these cavities are large single spaces, some have bony septa dividing them, while the ethmoidal sinus is always divided by partitions. All are lined with folds of mucous membrane which are so thin and so closely adherent to the periosteum that the bone is seen shining through. The mucous surface is coated with ciliated epithelium, the membrane is much thinner than that of the nose and there are few mucous glands. The functions of these cavities may be said to be those of resonating chambers for the voice.

The cavities all have natural openings into the nose, and, while these are so situated in some instances as to drain the cavity effectively into the nose, which is notably the case in the sphenoid and frontal sinuses and partially so in the ethmoid, the opening for the maxillary sinus is almost at its very top and hence drainage here can not be accomplished in the natural manner of a drain; that is, from its most dependent point. Some years ago when the treatment of chronic conditions of the maxillary sinuses was under discussion and it was claimed that washing out this cavity was all sufficient for its cure, I protested as to the possibility of an effective drain of a cavity whose opening was in the top. My views were stoutly contested, but since then those who objected make free openings in the dependent part to

* Read before the Metropolitan Medical Society, New York City, March 27, 1906.

cure their patients, and to-day we hear no more of those objections. The openings will be demonstrated in the description of the various sinuses.

ANATOMIC STRUCTURE OF THE SINUSES.

Taking the largest of the sinuses first, the maxillary, we find it somewhat pyramidal in shape, with its base formed by the floor of the orbit and apex over the roots of the molars. Its lateral wall is at the nasal chamber; its posterior wall is formed by the body of the superior maxilla. The anterior wall, over the canine fossa, is thinnest. The natural opening is near the roof of the cavity and opens into the middle meatus of the nose by the ostium maxillare at the posterior extremity of the hiatus semilunaris. Occasionally accessory openings are found also in the middle meatus. The maxillary sinus exists at birth and forms at about the seventh fetal month. It is well to have this in mind, as we shall revert to this later.

The frontal sinus lies between the two lamellæ into which the frontal bone separates in the region of the superciliary ridge. Its anterior wall is thickest and it is separated from the sinus on the opposite side by a bony septum which may be in the median line, but this is unusual. We frequently find the sinuses of one side encroaching far over on the opposite side, so that one sinus is much larger than the other. The cavity extends upward in the forehead often to a considerable distance, sometimes 1½ inches. Passing downward between the ethmoidal cells the sinus becomes narrow and at its most dependent part, in the middle meatus of the nose, opens into the hiatus semilunaris. The frontal sinus is seldom found before the seventh or eighth year of life.

The ethmoidal cells are in two groups, anterior and posterior, the former opening into the middle meatus, the latter into the superior meatus. They begin to develop about the fourth year of life.

The sphenoidal sinus lies in the body of the sphenoid bone, its anterior wall in part being the ethmoid bone. The orifice of the cavity is in the anterior wall and communicates with the superior meatus of the nose. The two sinuses are separated usually by a septum, but they have been known to communicate. The sphenoidal sinus appears about the seventh year of life.

ETIOLOGY OF SINUS AFFECTIONS.

The most frequent affections of these cavities are either acute or chronic inflammation. While frequently secondary to some nasal affection, they do occur primarily.

Among etiologic factors may be mentioned: Influenza, diphtheria, scarlatina, smallpox, measles, erysipelas and occasionally glanders and gonorrhea. Much has been written as to the etiologic relationship of ozena to accessory sinus disease, and the weight of opinion is that there is such relationship. Among the direct causes of purulent infection in the accessory sinuses may be mentioned galvano-cautery applications, probes and canulas and the misuse of the nasal douche. The practice of dentists of covering teeth with crowns of metal is one of the most frequent causes of sinus affection.

Most of the attacks of chronic suppuration occur as a result of an acute attack. The bacteria found are those that occur in inflammatory products and the pyogenic staphylococci and streptococci, the bacilli of Friedlander and of diphtheria.

The morbid anatomy of these affections is that of a chronic inflammation. There is a round-celled and serous infiltration, polypoid and cystic degeneration, periostitis, rarifying osteitis and caries. Caries may occur in the maxillary antrum. In the ethmoid it occurs frequently, as do also polypus formation and granulating osteitis. The secondary changes occur on the posterior wall in the frontal sinus. While polypi rarely occur in the sphenoid, erosions and necrosis of the anterior wall may occur.

Acute inflammation of these cavities is associated with inflammation of the nasal mucosa, and there may be an acute exacerbation associated with a chronic affection. Together with the symptoms referable to the acute rhinitis, there may be excessive temperature, but the chief complaint is that of pain. This is apt to be of a very severe character, in the brow if the frontal, about the eyes if ethmoidal, in the face if maxillary and in the back of the head if sphenoidal.

The mucous membrane is intensely congested, the middle turbinate swollen and pressing on the septum or there may be a single drop of pus at the site of the natural opening if the affection is anterior. If posterior, there is a congestion of the fornix and anterior sphenoidal wall and mucopus will be observed. Transillumination is so illusory that, while it establishes the presence of pus when a distinct dark spot is found, a negative find is by no means proof positive of its absence. The treatment is rest in bed, moist heat over the seat of pain, passing steam into the nose, washing out the accessory sinus where practicable with a warm antiseptic saline solution, after instilling a 1:5000 solution of adrenalin to which a small amount of salt has been added. It may become necessary to operate for this condition. This will be mentioned later.

Chronic suppuration of the accessory sinuses has perhaps, after all, the most interest to us, for the reason of its greater frequency, the difficulties in the matter of diagnosis, prognosis and the decision for operation and the skill and study required for its cure. The latent form of purulent condition has been fully studied but twenty years, though in 1875 Spencer Watson described it. Many of the members of the American Laryngological Association will recall the early papers by Bryan of Washington on chronic sinus affection and the silence that betokened an unfamiliarity with the subject that followed the reading thereof. To indicate how recent our knowledge is, I believe I was the first to operate on the frontal sinus at the New York Eye and Ear Infirmary, about 10 years ago. As to frequency, it may be said that the maxillary sinus is most frequently affected and the sphenoid least so.

DIAGNOSIS.

The one chief symptom is the presence of pus in one of the accessory sinuses, as indicated by its presence in the nose. More remote conditions exist that eventuate in the discovery of an empyema. Thus the pharynx, larynx, eyes and ears may be affected beside the nose. There may be pulmonary or gastric disturbance, or there may be the loss of general health, of weight and general malaise.

The symptoms most frequently elicited are pain, either a dull pain or severe lancinating one, nasal obstruction, one-sided usually, and a discharge of a purulent character on one side. Given a patient with these symptoms, locating the pain in the region of one or both of the sinuses and that pain constant in character, with the obstruction and discharge mentioned, the diagnosis of probable empyema of one or more sinuses may be readily made without rhinoscopic examination. If transillumination be practiced in a carefully darkened room and the dark spots be found in addition to the

linical evidence given, the diagnosis becomes still more ikely. If subsequent examination reveals pus or masses f polypi in the nose, the confirmation of the diagnosis s at hand.

In the more remote conditions associated with or aused by empyema, the diagnosis must often be made y exclusion, unless, indeed, we may be able to aid our iagnostic skill by examination of the blood. Sinus hrombosis has been so diagnosed, why not empyema ere? In children the diagnosis of empyema of the naxillary sinus, the only one actually present, is not ifficult in the pronounced cases. In severe forms of asal diphtheria the bacilli have been found post-ıortem. Pearce found them in 36 out of 39 cases. In ıost cases it clears up without any ill effects; in some a hronic empyema results. I have recorded my opinion n the question of empyema of the antrum of Highmore ı young infants and have taken the stand that it is not uberculosis nor caries, but as distinct an affection as it s later in life.

When chronic suppuration occurs the symptoms are he same in all recorded cases, of which there are about dozen, I having had one such. There is a fistula under he eye usually discharging pus, ectropion, one-sided urulent discharge from the nose with foul odor and roded bone.

The use of the *x*-ray is becoming more and more unerstood both for diagnostic purposes and also for the etermination of the exact size and position of the avities.

TREATMENT.

The diagnosis established, the important question of reatment arises, and here we may well pause, for, while hat is the natural sequence of all diagnoses, the many uestions that arise must be most seriously considered nd weighed. Is it a case for operation or local treatıent, and, if the former, how extensive shall it be?

A recent writer, lauding the galvano-cautery, considrs needle puncture to be all that may be required. He ays: "The needle puncture is not suggestive for clinial display, and hence, as the cosmetic condition is econdary, the external operation is quite naturally reorted to in the clinics and elsewhere as the quickest nd most spectacular means for immediate results." 'he same writer concludes that the negro must be of a ower race than the white man, for the reason that the ormer is said to have no accessory sinuses. Hence we ill not take him seriously.

In acute conditions of the maxillary antrum if the stium can be found, washing with tepid antiseptic olutions will be of much benefit and may effect a cure.)therwise a puncture with curved trocar beneath the nferior turbinate into the cavity, together with drainng and washing, may be required. In acute ethmoidal r sphenoidal disease the removal of the anterior end of he middle turbinate will permit free drainage. In cute frontal sinus affections it may become necessary o open the sinus from above, connecting with the nose hrough the infundibulum by a drainage tube.

In chronic maxillary antrum disease we may open he antrum through the canine fossa, then pack and inert a rubber tube which may be left as a constant drain. Ve may enter the antrum through a tooth cavity, or we ıay break down the nasal wall after opening the canine ossa. This is known as the Caldwell-Luc operation. 'he opening of the canine fossa must often be permaıent, and the annoyance of a constant taste of pus in he mouth and its commingling with the food is very great; but this may be obviated by making the nasal entrance into the antrum so large that the pus empties into the nose and has even better chance of complete cessation.

About one-half of the inferior turbinate is removed and then, by means of specially devised instruments, the antrum is broken into and the whole wall to the floor of the maxilla is removed. The canine fossa wound is curetted, the edges freshened and allowed to heal. In two severe cases in which I performed this operation the results were very satisfactory. The wound in the canine fossa closed permanently.

Ethmoidal disease is treated by the removal of the anterior half of the middle turbinate, the cells are curetted, and the septa broken down between them.

The sphenoid may be reached by the curette after the middle turbinate has been removed.

For the frontal sinus we have the Ogston-Luc method, which consists of opening the sinus from above and breaking through the infundibulum.

By the Kuhnt method the entire bony wall is cut away and the external parts therein are packed.

Killian's operation consists of making an incision below the eyebrow to the end of the nasal bone, separation of the periosteum, breaking down into the sinus from below and then from above, retaining a bridge of bone between for subsequent cosmetic effect. Entrance into the ethmoid cells through the wound becomes easy and also into the sphenoid.

Coakley operates from above downward and treats the wound by the open method, as in mastoid operations, with excellent results.

The radical operation as performed by Jansen does all this as to the frontal and ethmoidal. He next enters the maxillary antrum through the canine fossa, through the dependent and posterior ethmoids and into the sphenoid. Finally the nasal wall is broken into and the nasal mucosa used to line the cavity. This is sometimes done on both sides of the face. I have never attempted this radical procedure.

The prognosis as to complete recovery in all sinus cases must be very cautiously stated. We may succeed in eliminating the pain and even the discharge of pus, and in their place some new development arises, such as a neuritis over the incision resulting from injury to the exposed nerve at time of operation. At best it will take weeks and months before the last vestige of pus is seen.

Many of the maxillary antrum operations are done in physicians' offices and in public clinics, as are also the middle turbinate operations. As a matter of extra precaution, in a case of ethmoiditis and maxillary antrum disease and in which sphenoidal disease was suspected, I placed the patient in hospital. Under narcosis the antrum was opened after removal of one-half of the inferior turbinate and the middle turbinate was partially removed. The patient rallied well after the operation, but on the fourth day thereafter she developed coma and died, the cause of death being meningitis from a cavernous sinus thrombosis. This case illustrates the danger of considering such operations simple ones and the need of careful procedure, surrounding the patient with every precaution.

The method of removal of the middle turbinate in part, called uncapping, has for its object a free vent of the openings of the various sinuses which lie here.

Much is said of probing the sinuses through the nose. It is frequently impossible. For a successful performance it requires a non-resisting patient, thorough local anesthesia and a large roomy organ.

Some of the operations are followed by disagreeable cosmetic effects, and these are to be avoided if at all possible.

While the chronic cases take much time for their eventual recovery, requiring an infinity of patience on the part of both the physician and the sufferer, the ultimate end is often gained, a complete restoration to health.

OTHER AFFECTIONS OF THE ACCESSORY SINUSES.

While the acute and chronic affections of the accessory sinuses are by far the most frequent conditions here met with, we may have morbid growths, benign or malignant, foreign bodies, mucocele, caries of the bone, injuries, etc.

The morbid growths remain quiescent until forced into the nose, when either by hemorrhage or obstruction our attention is called to them. Malignant growths hereabouts form a chapter of fatalities sad to contemplate. Radical removal is rarely possible, and the recurrence which inevitably happens means most distressing fatality. Operation does give relief for the time and hence is not to be discouraged. The foreign bodies are mainly unerupted or ingrowing teeth.

Mucocele may exist, especially in the maxillary antrum. This may produce a rarefaction of bone so that the nasal wall, the facial wall and the floor over the superior maxilla may disappear, and only the mucous membrane may cover it. I have recently had such a case.

In the ordinary nasal polypi, pressure may interfere with the ethmoid cells and they may become absorbed into one large cavity. The bone-destroying power of this condition is remarkable. In a case recorded by me the vomer and superior maxilla were entirely absorbed from pressure of these mucous polypi.

Caries of the bone, especially of the facial surface of the superior maxilla, may occur usually from violence, and may simulate antral disease.

As illustrating the difficulties in the way of differentiating sinus disease from neuralgia, hysteria and the like, I relate the following:

In consultation with a prominent neurologist, I saw a young married woman from one of our southwestern states who gave the following history:

About two years previous to my seeing her she had pains in her face over the left antrum. These pains were very severe and practically constant. At night they were not severe enough to cause sleeplessness, but in the day they were always present, of a gnawing character, severe during mastication, and preventing her from attending any social duties by reason of their severity. Neuralgia was diagnosed and appropriate remedies were administered with no effect. A visit to a western city for the purpose of consulting a specialist resulted in the expression of an opinion that she had nothing the matter with her, that she should go home and behave herself. Her physical condition became so bad that she prevailed on her relatives to send her to New York to consult a neurologist, who, before expressing an opinion, asked me to see the patient.

She came to my office and required support while walking to the examining room. There was exquisite sensitiveness on the left side, dark spot on transillumination, without a sign of pus. I diagnosed some affection of the bone covering the antrum and advised operation. This was granted and after an incision from the center of the upper jaw to the maxillary ridge and removal of the periosteum, caries of the external portion of the maxillary antrum was found and the whole of this portion was then removed and the wound packed.

She was placed in a sanitarium on the fifth day, made an uninterrupted recovery after a rest cure of five weeks, and gained much in weight. She returned to her home in good spirits. Two years subsequently she remained well.

I feel confident that an early diagnosis and prompt operation would have saved the patient much suffering, to say nothing of the strained relations existing among the members of her family, who at one time believed her to be a malingerer and treated her accordingly.

25 East Seventy-seventh Street.

TROPICAL NEURASTHENIA.*

W. W. KING, M.D.

Passed Assistant Surgeon, Public Health and Marine Hospital Service.

WASHINGTON, D. C.

Tropical is used here in the sense of locality more than to characterize any special type of neurasthenia. My object primarily is to call attention to its frequency in warm countries, at the same time touching somewhat on the disease as I have observed it.

Writers on tropical diseases make little or no mention of it. Dana, in his work on "Nervous Diseases," states that it is not infrequent in tropical regions and that it is found in the West Indies. My experience extends over six years' residence in Porto Rico, but information derived from various sources has caused me to regard this condition as one quite general to the tropics, differing in degree through peculiar local influences. From what I have been told by medical men who have resided in the Philippine Islands I judge that it is even more prevalent and more severe there than in the West Indies.

The native of the tropics is not exempt, and in Porto Rico, where the percentage of neuroties is high and functional nervous disorders very common, it is not infrequently encountered associated with hysteria—hystero-neurasthenia. It is far more common, however, to find neurasthenics in the tropics among those who go there from colder countries, hence it becomes a very interesting question to American physicians, in view of the close relations recently established between the United States and Porto Rico, Cuba, the Philippines, etc. My remarks refer particularly to Americans living in the tropics, but the same considerations will undoubtedly be found true of other nationalities under like circumstances.

Comparatively few individuals entirely escape if they live in the tropics for any length of time. In many persons the manifestations are slight and are taken as a matter of course, due to climate. They do not consider themselves really ill, but commonly explain: "The climate is getting onto my nerves." Acute cases are not unusual. Grave ones are more rare, but do occur, and insanity has been known to follow. Some time ago considerable comment was made in both professional and lay press about the unusual number of American soldiers who became insane while serving in the Philippines. Making due allowance for malingerers who wished to be invalided home, it seems safe to assume that many of these men were victims of grave neurasthenia.

In proportion to the number of American women to men in Porto Rico, I have observed a relative greater frequency among the former. Several explanations may be offered. American women almost invariably menstruate more abundantly than in the States. The flow is prolonged and often so excessive as to require urgent treatment. The interval between periods is usually shortened during the first year or so of residence there. We can readily understand that to women accustomed

* Read by title at the annual meeting of the American Society of Tropical Medicine, Philadelphia, March 24, 1906.

) a regular monthly routine such conditions may be all ufficient to precipitate nervous exhaustion.

Housekeeping where customs and language are trange and where servants are inefficient and uncleanly as its thousand and one little difficulties and worries hat need to be seen to be appreciated, but which in the ggregate are often sufficient to cause housekeeping to e abandoned, the housewife sent to the States to re-uperate, and on return to live at a hotel or boarding ouse.

Another thing: life in most tropical countries is adically different from that in temperate climes. The ack of accustomed society, pleasures and diversions is nore keenly felt by women than men, who have more pportunity to make up the deficiency.

Without excluding the usual causes of neurasthenia, here are some which, in my opinion, deserve special ention when considering this as a tropical disease.

Climate is the favorite scapegoat and receives the ajor portion of the blame. I believe that its influence overestimated, though it undoubtedly causes a gen-ral atony of all the tissues of the body. Functional ctivity is decidedly lessened. The energetic American oes the pace according to his previous habit, and while is physical and mental capacities may be able to stand in the States, it is entirely too strenuous for his new nvironments. He either drops more or less into the ace of the country or breaks down. What may be nor-al work in one place is overwork in another. Add to is the mental exasperation and irritation which he eels at the slow, easy-going methods of those with whom e comes in contact.

The officials charged with the construction of the anama Canal have been suddenly confronted with the roblem of providing amusement for their employés. hey have come to realize that the need is imperative nd vital, and are now spending thousands of dollars to eet it. "All work and no play makes Jack a dull boy."

To our notion, the amusements of tropical peoples re limited and often of a character which does not ap-eal to us. Customs which are not understood and the ability to speak the language make it very difficult to ke an active part in whatever opportunities there may e for diversion. Theaters are few and seldom first-ass, except in large cities, and here again we meet e impediment of unfamiliar speech. The benefits of ublic parks and outdoor sports are rarely attainable. equaintances are limited to a small circle, the members which only too often tire of each other's society. In arch of something to relieve the monotony of life un-er such conditions, there is great liability of drifting to alcoholic or sexual excesses, thus further assisting ervous exhaustion.

As to diet, people from the north fare rather badly. he same articles of food (except in a limited number private houses) appear from day to day with almost ockwork regularity, while the methods of preparation o not result in dishes which appeal to the American alate. The sameness of it all becomes unbearable at mes, and a change is sought again and again. The gestive functions, especially that of the liver, become mpaired.

Moderate exercise is essential to health in the tropics. t, unfortunately, one's inclination is decidely averse it. Almost unconsciously everything is done with a inimum of physical exertion. On the other hand, too uch or too violent exercise may be more harmful than one at all.

The degree of neurasthenia is slight or moderate, exceptionally, severe. The patient first notices that he is less energetic. He feels fresh in the morning, but soon tires and at night feels worn out, apparently without sufficient cause. He becomes ill-natured, peevish and irritable, taking offense at small things which under ordinary circumstances would not be noticed. Mole-hills become mountains; proper attention can not be given to business; urgent matters are put off from morning till afternoon and from afternoon till next day. It becomes almost impossible to concentrate the thoughts on details or to plan for the future. Memory and the ability to reason may be at fault.

There is a decided tendency toward hypochondriasis, morbid introspection which distorts unimportant pains and ill feelings into supposed initial symptoms of some dreaded disease. The fear of impending disaster or death may render the patient's life miserable, even when he knows that there is no reason for such fear.

The appetite may fail and digestive disorders may arise or grow worse if already present. Loss of weight may result. During a moderate attack I lost about fifty pounds in three months. Sleep is troubled and unrefreshing. Dull, annoying headache is of almost daily occurrence, and, as a rule, is occipital, sometimes frontal if there are visual defects.

True anemia is not a prominent feature, although there is a very deceptive anemic appearance encountered, especially among women who are neurasthenic. I have repeatedly been asked to examine the blood of pale subjects without ever finding any marked reduction of the hemoglobin, unless due to some cause more than the nervous affection. Vasomotor disturbances most probably give rise to this pseudo-anemia.

Neurasthenia in the tropics presents the same great variety of symptoms as elsewhere, and I have only mentioned those which have struck me as specially marked. In slight cases improvement occurs readily or the patient recovers completely when the cause can be removed or its influence counteracted by change of scene or occupation. Proper and regular exercise, particularly if amusement can be combined with it, proves very beneficial, but it is easily overdone.

The symptoms may disappear gradually and the patient recover spontaneously as he becomes more accustomed to his new life and environment; we may say acclimated. The time necessary for this depends on the adaptability of the individual. It may be months or years. Some persons could never do so.

I have had little success with medicinal treatment, unless combined with hygienic measures. Prominent symptoms may require special medication, but the specific medication by drugs designed to act directly on the nervous system will too often prove disappointing.

ETIOLOGY OF DEMENTIA PRÆCOX.

WILLIAM A. WHITE, M.D.
Superintendent Government Hospital for the Insane.
WASHINGTON, D. C.

A number of articles on this subject have appeared lately in the medical press, setting forth the general proposition that dementia præcox is a disease due to autointoxication. The arguments of the writers have been backed up by the results of chemical analyses, which, in many instances, have been gone into in great detail and very exhaustively.

It seems to me that the chemists have gone to great lengths to find a cause which is right at hand and, further, that they have been singularly short-sighted

in their reasoning. Their results have been obtained from the examination of cases acknowledged to be dementia præcox, and because they have found changes in the blood and secretions from which they can argue the development in the body of autotoxins they have presumed these autotoxins to be the cause of the disease. If these chemical changes had been found before the development of the clinical picture, then there might be some good reason for considering the changes found as causes, but, being only found after the disease is established, it is incumbent on those who claim these to be causes to show why they may not be effects.

We find dementia præcox developing typically at the period of puberty and adolescence in persons preferably of marked hereditary taint and under all conditions of environment. It always has been regarded, and I see no reason why we should change our minds now, as a psychosis of the developmental period dependent on defective cerebral and corresponding mental evolution. It is certainly on its face, and is generally acknowledged to be, a mental disease, and the burden of proof, it would seem, should be on those who claim it to be a disease of tissue metabolism.

Now it seems to me that just what would most naturally be expected is true; that is, that these changes which are found in the secretions are the results of disturbed tissue metabolism due to the disease and not indicative of the presence of toxins which are to be regarded as causative factors.

The failure to consider this very manifest explanation of the conditions found is due perhaps to the lack of a profound appreciation of the intimate relations between the nervous system and the other organs of the body and the very common occurrence of bodily disorders associated with the psychoses and, very probably, due to the same underlying conditions—disease or disorder of the nervous system.

This is a subject which has been much written about even from early times, but perhaps because the physical changes are not relatively gross as in pneumonia, nephritis, valvular heart disease, it never seems to have been taken seriously, but to have been considered by many as largely academical. It seems to have been hard to conceive of any necessary bond between the physical organization and the mind. Recently, however, this connection is being more emphasized and we find Mercier,[1] in his latest work, speaking of insanity as a disorder "not of this or that organ, or tissue, or part of the body, as are the diseases which come under the purview of the general physician or surgeon, but of the whole individual who is the subject of the disorder."

The body is made up of a great number of organs, each one of which has a definite function: The kidneys to secrete urine, the lungs to carry on respiration, the heart to force blood through the vessels, the stomach and intestines to digest and to absorb nutrient. Definite as is the function of each one of these organs, its action must be timed in response to certain conditions and in relation to the other organs of the body, or it does not serve its purpose in the individual economy. The stomach must secrete its juices when food is introduced, the bladder must contract when there is urine to be expelled, the active brain must be supplied with an increased amount of blood, the kidneys and the skin must act harmoniously together to excrete certain substances, the respirations must increase on physical exertion, and so on indefinitely. Now it is the duty of the nervous system to see that the functions of the several organs are rightly timed and properly adjusted in relation to one another. This is the function of the lower nerve centers.

The highest nerve centers of the cerebral cortex that constitute the physical substratum of mind have quite a different function. Their duty is to initiate, to regulate, and to control the separate actions of the individual so as best to serve his interests in his relations with his environment, in other words to bring about an adjustment of the individual to his environment.

Referring to these, we may say, contrasted functions of the nerve centers, Mercier[1] sums up by saying (p. 83): "From the foregoing general account it appears that what is primarily disordered in insanity is believed to be the working of the highest regions of the brain; that the primary function of these regions is to determine and to actuate conduct; that a subsidiary function is to harmonize and to govern in a general way the bodily function of nutrition, or repair and waste of the tissues; and that the operations of mind are associated with the working of these regiona in such a way that, when the mind is disordered, the bodily functions also are deranged."

Tomlinson[2] takes the same position in a recent paper, which he writes to defend the thesis that: "There can not be special change in an organ without general disease in the rest of the organism, and in the study and treatment of the special condition, the general involvement and its extent are most important."

This paper of Tomlinson's was based on 2,366 cases admitted to the St. Peter State Hospital in Minnesota from Jan. 1, 1894, to Jan. 1, 1904. An analysis of the cases shows "practically all these patients were suffering from some kind of physical disease, most commonly malnutrition, perversions in the digestive processes and interference with the process of elimination."

These physical disturbances were manifested by disturbances of reflexes, tremors, impaired nutrition, constipation, renal inadequacy, changes in the urinary secretion and in many other ways. In the main, these physical disorders that were found associated with the mental diseases would be described as minor departures from the normal and many of them would undoubtedly have escaped discovery but for the systematic application of laboratory methods of clinical examination.

Now while physical disease, an attack of one of the acute infectious fevers for example, may be the determining cause of a psychosis, the character of physical disorder here referred to is such, at least in degree, as every one suffers from many times in the course of a lifetime. It could hardly be supposed, therefore, that physical disorders of such magnitude would produce insanity in ordinarily stable persons, although it may perhaps be conceivable that in very unstable individuals, the strongly predisposed, they might. Even granting this, the real cause after all would lie in the nervous system that was so unstable as to be disordered by so slight a cause, and the burden of proof, it seems to me, rests with those who claim the contrary.

What then is the explanation of these physical disturbances? They are the manifestations in the realm of the physical of the same disease which in the realm of the psychical is manifested as insanity and this disease is a disease of the nervous system.

Referring to the functions of the nervous system be-

1 "Criminal Responsibility," p. 79.

2. "The General Conditions Associated with Insanity," The Journal A. M. A., March 17, 1906.

ore described, viz., the adjustment of the individual to is environment by the higher centers and the harmonzing of the functions of the several organs by the lower enters, it can be seen that any disease of the nervous ystem which produce insanity must be very apt to prouce physical disorder and the nature and extent of that hysical disorder will depend on the depth of the disease n the hierarchy of the nervous centers.

Do the facts of clinical psychiatry support this view? think they do. Take for instance the classical type of aranoia, a disease which manifests itself at the height f the individual's mental development, at the crest of ie wave of cerebral and psychic evolution. The symptms of this psychosis are symptoms of disorder of the ighest of the functions of mind, the latest to be acuired and are in the main confined to the intellectual rocesses. False beliefs and defects of judgment are rominently in evidence while psycho-sensory disorders iay be few or even absent altogether. As we might exect, the symptoms of physical disorders in the paranoic re practically nil. He does not at any time give the apearance of being a sick man, but, on the contrary, often anifests unusual energy and activity in exploiting his hemes or in protecting himself from his persecutors.

How different a picture do we see in dementia præcox. n this disease, there is a profound defect of nervous ornization, the development does not proceed beyond the eriod of puberty. At this early age the mental life of ie individual has come to an end. In a disease due to ich a far-reaching defect of nervous organization could e reasonably expect the functions which regulate the rmonious relations of the several organs to escape? As matter of fact, the physical disorders in this psychosis e marked and wide-spread. We find all sorts of motor iomalies-reflex, automatic, and voluntary—disorders of cretion and tissue metabolism and certain chemical anges indicating the formation of toxins and thus utointoxication.

And so it is with the other psychoses. Those in which e disease is deep-seated, dependent on destructive lesns of the nervous system, manifest the more marked idences of physical disorder. In paresis, the physical mptoms may be by far the most prominent of the early anifestations. In senile and arteriosclerotic demen a due to destructive cerebral lesions and occurring on e down-hill side of life the physical signs are well deloped. Even in manic-depressive insanity, which derves perhaps as much as any of the well-defined psyoses to be classed as functional, we find physical disrbances varying all the way from the most mild to the ost severe type, but keeping pace throughout in their gree of severity with the severity of the mental symptms. In the highest degree of manic excitement there developed a picture closely resembling that of a toxic lirium.

This seems to be the general conclusion at which Tomson has arrived from his studies. Commenting on e results, he says:[2] "In this connection it should also recognized that as it is the principal function of the neral nervous system to direct the activities of the rest the organism, a failure in dirigent function would, necessity, interfere with normal activity of the vegtive organs, thus reducing their capacity for work, vering the general vitality and further decreasing the pacity of the general organism for adaptation to exnal relations, by involving the retention, not only of e waste products of its activity, but also the generon of toxic substances from the food materials taken o the digestive tract."

Insanity is a disorder of the mind due to disease of the brain and it is this underlying disease of the brain that is the essential thing manifesting itself on the psychical side as insanity and on the physical side as physical disorder. The physical disorders then are but expressions of the same disease that psychically we know as insanity and therefore, can not in any sense be set down as causes for the mental disturbances but only as correlative phenomena. Insanity is but a group of symptoms, as are the various physical disturbances found in the insane.

The physical disturbances of dementia præcox have come into prominence because they are so numerous and so pronounced. They form such an important part of the clinical picture of this disease, however, because the nervous disease is so deep-seated and far-reaching in its effects. Because of their objective character, and, too, because of our limited knowledge of the psychical, they are often of great importance in estimating the gravity of the disease and its prognosis.

MERCURIAL NEPHRITIS WITH UREMIA.

REPORT OF A FATAL CASE.

ROBERT N. WILLSON, M.D.
PHILADELPHIA.

So many cases of mercurial nephritis have been recorded in medical literature that mercury should be recognized as an agent possessing a peculiarly irritative and destructive action on the renal tissues. Certain individuals appear to be far less sensitive to its influence than others, and a few tolerate enormous quantities without apparent harm. In other instances, and in children especially, the smallest fraction of a grain of any of the mecurial salts will act so maliciously and so rapidly as to astound the physician in charge, and even to carry off the patient before his eyes. Such an instance is reported by Buchner.[1] A teacher rubbed into each of the scalps of between 80 and 90 boys about a teaspoonful of mercurial ointment for pediculosis. All the boys showed symptoms of poisoning and one died. Sackner also reports[1] a case of an adult into whose hands five grams of mercurial ointment were rubbed at one treatment for rhagades. A severe dysentery followed and the case proved fatal.

As already stated, this is only one of a long series of similar cases. With their increase in frequency it has become customary to dwell on the prominent symptoms (subjective) and to overlook the more subtile, though even more dangerous, influence of mercury on the kidneys. For this reason alone, it would appear useful to cite a case which came to my attention in the wards of the Philadelphia Hospital. My belief that its report might prove salutary crystallized into determination that no time should be lost when I read in the therapeutic column of THE JOURNAL,[2] A. M. A., the following quotation from a communication published over the name of the author physician:

I am of the opinion that heretofore many if not all physicians have overlooked the all-important bearing of "portal circulation" in inflammation of the lungs. In active practice for the last forty years, the last ten of which I have been in the habit of using boldly, and most successfully, calomel in heroic doses, adult dose gr. x every four to six hours, day and night p. r. n. The microbic bed of morbidity and mortality is freed from its pulmonic environment, and as seven-tenths

1. Quoted by Sackner, Berlin. klin. Wochft., 1892, p. 619.
2. July 2, 1904

of the disease is eliminated in from twenty-four to forty-eight hours, the remaining three-tenths is treated better by careful nursing than by overzealous doctoring. I write, he concludes, from experience.

I believe that the term overzealous is very apt in such a connection. When applied to what seems to me an over free use of a dangerous drug, it might even be bettered by the term overcareless. I feel that not only is there in this method the likelihood that the microbic bed will be freed from its pulmonic environment, but that the sick bed, whether microbic or otherwise, will be freed by death from its occupant. The following case history will further illustrate my position:

Patient.—J. W., colored, a laborer, aged 25, was admitted to the Philadelphia Hospital Oct. 16, 1903.

Course of Disease.—He ran the course of a severe and extensive pericarditis, during the course of which the urine showed a trace of albumin, but at no time casts or other renal sediment.

On October 30 he was convalescent, in the absorptive stage of pericarditis.

On November 1 there was stomatitis, and two teeth were removed by the dentist. The following day the jaws were clenched, the patient could not enunciate, the breath was fetid. There was no stiffness of the cervical muscles, no fever, no suggestion of tetanus; pulse, 72; respirations, 26.

On November 4 the stomatitis was extreme, the jaws were fixed, the patient unconscious, the breath foul and characteristically fetid; there was slight opisthotonos, and contractures of the arms and forearms. The man could be roused, but at once relapsed into stupor. There was slight pretibial edema, and slight pitting on pressure over the chest wall. The second aortic cardiac sound was loud and metallic, and the patient was in collapse. The lungs appeared clear. Death occurred on this day from uremia.

Autopsy.—Nov. 7, 1903. The autopsy was interesting, especially in regard to the heart and kidneys. The heart was enormous, the left ventricular wall measuring one inch in its greatest diameter, the muscle appearing to be studded at all points with yellow fat. There were also fibrous scars in the external wall. The coronary arteries were not markedly sclerosed. The aortic, tricuspid and mitral valves were insufficient, the former two admitting easily four fingers and the latter three. No vegetations were present. The pericardial sac was attached anteriorly to the sternum by soft lymphoid adhesions, over an area of nearly a square inch, directly behind the midsternum. The sac contained not more than one ounce of pure serous fluid. There were fine adhesions between the layers of the pericardium.

The kidneys were small, almost infantile, and very pale and anemic; the left was smaller by one-third than the right. No urine was found in the bladder. The capsule was adherent in the case of both kidneys, and there was a decided diminution of the cortical substances. Everywhere there was noted a widespread yellow fatty degeneration and infiltration. The brain showed nothing to account for the nervous symptoms other than a slight thickening of the pia, and a small quantity of semiturbid fluid at its base.

Microscopic examination showed an extensive myocarditis, as well as a high grade of chronic diffuse nephritis, with a subacute (or fresh) condition superimposed in the form of a hemorrhagic inflammation.

Apart from an unexpected disaster in the convalescence of a simple, though severe, pericarditis, the case was interesting as a study in physical diagnosis. The enormous area of cardiac dullness, supposedly corresponding to the effusion, the unusual size of the heart as discovered at the autopsy, the widespread transmission of the pericardial friction sounds, and, finally, the perfect presentation of the three stages of inflammation, effusion, absorption and recovery, all rendered the case interesting from the clinical aspect.

Suddenly the convalescence was interrupted by a severe stomatitis, to relieve which the consulting dentist extracted the two supposedly offending teeth. This procedure was followed by further inflammatory swelling and by closure of the jaws. It was then learned for the first time that the patient had received 84 successive grains of calomel within fourteen days as the result of a misinterpretation of an order for a single dose.

Unfortunately, there had been no critical study either of the urine or of the blood, as judging from the routine urinalysis the kidneys had apparently been doing their full duty. The first examination had detected only a trace of albumin and no renal sediment. The autopsy findings, therefore, assume an additional importance.

Two important lessons were learned from this undoubtedly avoidable waste of life: First, that the routine administration of mercurial laxatives and purges prior to the receipt of a careful urinalysis may occasionally result in fatality, even though the mildest mercurial salt be employed. Second, that an existing nephritis should contraindicate any but the most careful use of the drug, not excepting those cases in which it is possible to trace the renal disability to a syphilitic infection. There are instances on record of individuals who have survived enormous, almost incredible doses of calomel. Usually the medicine has been administered in a single dose, though by no means always. Pereira[3] mentions a case under the care of Hellweg, in which "a few grains" proved fatal and another treated by Vagnitius in which 15 grains caused death.

The record of a boy aged 14 is reported in the *London Medical Gazette*,[4] in which death was brought about with six grains of calomel. There was severe ulceration of the mouth, enormous swelling of the face, fetor of the breath, and death; but no ptyalism. Sixty years later Halle[5] quotes a case reported by Riegel of the prolonged administration of calomel resulting in death; and another reported by Adam, in which severe hemorrhagic inflammation of the intestines with thrombosis of the vessels and edematous infiltration of the tissues followed the use of 15 grains of calomel during the course of three days. He also refers to a case of Pel in which the patient died soon after the use of calomel, and in which considerable quantities of mercury were recovered from the kidneys. Mitchell[6] quotes two cases from Hoffman occurring in boys of 12 and 15 years. One died on the sixth day, and the other a still shorter period. Mitchell refers to an old and very plausible theory, that calomel acts differently at different times, and as he puts it, "in different epidemics." Referring to its use in cholera, he says: "In 1818 from fifteen to twenty grains of calomel operated like a charm." He then cites his later case in which were given nine drams of calomel, with oil, salts, and jalap, "without either emetic, cathartic, or sialogogue effect."

The generous doses of calomel formerly used in our western states are classic the world over. They almost rival an instance, cited also by Mitchell, in which a man, known to him, had in his possession "the last of twelve powders ordered for a cholera patient in 1833, which (powder) contained one ounce of calomel. Eleven of the same size were administered, and the patient died before the twelfth could be given." Many writers refer to the administration of 840 grains in eight days[7] as the

7. Amer. Jour. Med. Sc., vol. xxvii.

largest dose followed by recovery, but the preceding seems to surpass even its generosity. With equal frequency small doses have been responsible for fatalities such as that reported in this paper. One was that of a child, aged 11,[8] who died in 24 hours, from eight grains of calomel. Violent salivation followed with ulcerative inflammation of the mouth, face and neck, extensive destruction of the cheeks, disgusting fetor of the breath, and death on the eighth day.

With regard to the influence of mercurial salts on the kidneys of syphilitic subjects, a word of caution may also be in order. The general tendency at the present time is toward the belief that a nephritis occurring in a syphilitic, not definitely known to have had renal disability before the specific infection, should be looked on as a syphilitic process in the kidney, and treated with mercury. This belief, I suspect, is not always founded on fact, and treatment based on the theory may defeat the aim of the physician, creating a more serious condition than that already present. I have had recently under my care two young men, both suffering from secondary syphilis. In both instances, repeated urinalyses have been made since the first administration of mercury, and in both the urinary picture remains normal until a certain dosage has been sustained for a brief time.

In the first case one-half grain of the protoiodid three times a day is tolerated and usually controls a severe and otherwise persistent specific sore throat, the urine remaining normal. As soon, however, as one additional one-sixth grain is added to the daily dosage, albumin and hyalin casts appear in the urine; and on increasing the dose the patient complains of fulness under the eyes, headache, and backache, all of which disappear in a few days on discontinuing the use of the drug. This experiment has been tried for the third time during an exacerbation, when it was desirable to push the drug to its physiologic limit. There is always the same result. On each occasion, the urinary findings have eventually become normal, but each time after a long interval. The problem in this case is the decision as to the greater danger of the disease or the remedy.

The second case is very similar in its subjective symptoms, and in the early appearance of showers of hyalin casts on exceeding a certain small dosage of mercury. Up to the present, however, no albumin has been detected and even the casts disappear when the protoiodid is limited to half a grain three times a day.

It need hardly be stated that many syphilographers maintain a far higher dosage over months running, and seldom, if ever, require an examination of the renal secretion. There is still another side to the picture. Not long since I gave to a baby, syphilitic from birth, calomel in doses of one-sixth of a grain for weeks at a time, with rapidly favorable results, and with not a sign to indicate deleterious action on the kidneys. Heller claims that the form of the drug and the method of administration have much to do with the favorable or unfavorable action on the kidneys. With the bichlorid of mercury injected hypodermically he has never been able to observe a nephritis, though when using the salicylate of mercury and other insoluble salts he repeatedly produced serious forms of renal disease. He refers to numerous cases of albuminuria, following inunctions with mercurial ointment. As with most observers, his patients with nephritis recovered when the drug was discontinued. Virchow[9] cites the case of a patient aged 31, with syphilis, in whom a fatal ending followed a course of inunctions with mercurial ointment, extending over 14 days. Altogether a total of 50 grams was employed, 5 grams being used on each occasion.

Attention has been called to the danger involved in the indiscriminate use of mercury, even in syphilis, by no means with a view to discouraging its use, but its abuse. I consider it an abuse of the drug to employ it prior to a report on the urinary findings; or in the light of such instances of misfortune as have been cited, to employ it in any case in which the integrity of the kidneys is questioned.

It is also certain that in the light of these facts frequent examinations of both patient and urine form a *sine qua non* of conscientious and safe mercurial treatment of any disease. The most vigorous patient may display a violent susceptibility to minute doses of the mildest salt, while a weakling may tolerate large quantities over a long period.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN.

CHAPTER XXI.

DRUGS ACTING ON THE SKIN AND MUCOUS MEMBRANE, MAINLY WITH REFERENCE TO EXTERNAL USE.

There are so many substances which have been used as irritants under varying conditions that we can not attempt to do more than mention the more useful of the agents frequently employed for this purpose, together with some of the conditions in which clinical experience has shown them to be most beneficial.

While the employment of counter-irritants is almost wholly empirical, the regions of the skin which Brunton has indicated for their use when it is desired to influence the internal organs correspond well with those which Head has shown to exhibit tenderness of the skin in connection with diseases of the same organs.

Brunton directs the irritant to be placed over the larynx, ovaries or sciatic nerve for affections of those parts, over the ensiform cartilage for gastric disturbance, above and below the knee in rheumatism, over the ball of the great toe (dorsal surface) in gout, behind the ear in facial neuralgia, at the base of the brain and back of the neck for cerebral affections, and along the dorsal region of the back to affect the uterus.

The mildest of irritants is water or saline solution used as a bath. The shock of the cold water applied to the skin and the slight irritation of the subsequent friction, preferably with a coarse towel, are followed by a reaction attended with a considerable and lasting stimulation. Very cold water may produce too great a shock in persons who are not robust, and the result will be depression, but there can be little doubt that baths are extremely beneficial when the temperature is so regulated that a healthy glow and a feeling of well-being succeed. It seems that the question of the usefulness or the harm of cold baths, about which there has been so much contention, resolves itself into a question of individual experience. If a feeling of exhilaration and no subsequent depression follows the bath it is not harmful; if no such exhilaration occurs, but a distinct depression is observed, there can be little doubt that the bath is doing harm. In such cases a slight increase in the temperature of the water, with a shorter time and more rubbing, may secure the benefits sought. The same person may require different conditions of temperature at different times, corresponding to variations in the general health.

A mixture of salts is sometimes added to the bath to increase the slight irritant action.

Even milder than the friction, which forms so essential a part of the bath, is the irritant action of the astringents, which

have been discussed in Chapters XII and XIII, but these are followed by lessened irritation, hence they are not considered among the irritants.

Rubefacients.

Rubefaction is the result of a slight irritation of the skin. There is a slight increase in the exudate from the capillaries, and if the irritation be not long continued this exudate is reabsorbed and the part speedily returns to the normal condition.

While all irritants, mild and caustic, cause rubefaction, we shall first consider only those which are used for that stage alone, and take up the vesicants pustulants and caustics later.

ALCOHOL.

Alcohol alone, diluted with water or in the form of hamamelis water, alcoholic tinctures, spirits or liniments, is used more frequently, perhaps, than any other mild irritant, with the possible exception of the bath.

Applications containing alcohol are useful in painful swellings, bruises and a great variety of minor complaints commonly treated in the household without calling on the physician.

While it is probably quite unnecessary, at this late date, to call particular attention to the fact that there is a distinct and a very great difference between the official or ethyl alcohol and the various forms of wood or methyl alcohol, nevertheless the insidiously poisonous properties of the latter substance do not appear to be so well appreciated by the general public. The number and the variety of cases of blindness and of death that have been reported by Buller and Wood[1] amply demonstrate that even the external use of any form of wood alcohol is not entirely free from danger and that its use in any form of medicinal preparation should not be countenanced or tolerated.

Among the numerous preparations of the United States Pharmacopeia that have been and are being used as topical applications, largely because of the rubefacient properties of the alcohol that they contain, we may enumerate:

AQUA HAMAMELIDIS.—U. S.—This preparation, more popularly known as extract of witchhazel, or distilled extract of witchhazel, is now, for the first time, included in the Pharmacopeia. While the preparation itself has been known for many years, and has been used extensively as a household remedy, it has never met with much favor on the part of the medical profession. The official preparation is directed to contain 15 per cent. of alcohol and should be free from methyl alcohol or any of its derivatives.

TINCTURA ARNICÆ.—U. S.—Tincture of arnica represents 20 parts of the dried and powdered flower heads of *Arnica montana* in diluted alcohol. This preparation was at one time very popular with medical practitioners as a topical application in so-called "sprains" and in bruises, but is now seldom employed. The same is true of:

TINCTURA CALENDULÆ.—U. S.—This preparation represents 20 per cent. of the dried and powdered florets of *Calendula officinalis*, the well-known marigold of our gardens.

Probably the most objectionable feature in connection with the use of any of the official tinctures as topical applications is their tendency to stain. This objection is largely overcome by the use of the simple diluted alcohol, one of the numerous unofficial toilet waters or colognes, or by the use of one or the other of the official spirits.

In addition to SPIRITUS FRUMENTI.—U. S. Whisky, and SPIRITUS VINI GALLICI.—U. S.—Brandy, the most frequently used of the class of preparations is:

SPIRITUS CAMPHORÆ.—U. S.—This is an alcoholic solution containing 10 per cent of camphor.

SPIRITUS GAULTHERIÆ.—U. S.—This contains 5 per cent. of oil of gaultheria in alcohol.

The most widely used, as well as the most popular, of the mildly rubefacient preparations of the Pharmacopeia is:

LINIMENTUM SAPONIS.—U. S.—Soap liniment is variously known as liquid opodeldoc camphorated soap liniment and camphorated tincture of soap. It contains 6 parts of soap, 4.5 parts of camphor, 1 part of oil of rosemary and 72 parts of alcohol with sufficient water to make 100 parts. This preparation has long been popular as a topical application and is not infrequently used as a vehicle for other more active rubefacients, sedatives and anodynes.

A somewhat typical compound liniment is the

LINIMENTUM CHLOROFORMI.—U. S.—This is a simple mixture of 30 parts of chloroform with 70 parts of soap liniment, and constitutes a very good illustration of the possible uses of soap liniment as a solvent or vehicle.

CHLOROFORM.

Chloroform is one of the more active rubefacients and the action quickly passes this stage if its use be continued. Chloroform readily dissolves fat, and, being very volatile, it penetrates quickly and causes considerable redness and pain. A few drops of chloroform placed on a little absorbent cotton and applied over a painful joint, such as a bunion, in such a way that evaporation of the chloroform is prevented, causes a good deal of pain and often affords speedy relief. It should not be applied in this way for longer than ten or fifteen minutes. Chloroform may be used as a counter-irritant by putting a few drops on cotton in a wide-mouthed bottle; the mouth of the bottle is then applied to the area to be treated, for a few minutes at a time.

Chloroform liniment, noted above, is much less painful, or not at all so in most cases, and is much slower in producing its effects. Chloroform liniment is usually directed to be applied to the affected part by being thoroughly rubbed in, thus securing the additional rubefacient action of friction. It may, however, be more economically applied, and it is frequently quite as effective, if directed to be put on cotton, applied to the affected surface and then covered with several layers of cloth or otherwise prevented from evaporating too rapidly.

Volatile Oils.

All the volatile oils are irritant, their action ranging from that of the mild sandalwood or copaiba oil to the extremely irritant volatile oil of mustard or even the caustic action of oil of cloves. The use of the milder members of this series for their effects on the urinary tract has been mentioned in connection with diuretics. Some of the volatile oils, such as pennyroyal and savin oils, which are somewhat more irritant, have been employed to produce abortion by the reason of irritation of the intestine and the consequent participation in the effects by the uterus.

Official Preparations.

Of the official substances that are more or less closely connected with the turpentine group and are frequently used externally, we have:

OLEUM ROSMARINI.—U. S.—This is a volatile oil distilled from the fresh flowering tops of *Rosmarinus officinalis* and is one of the ingredients in the well-known soap liniment.

OLEUM SABINÆ.—U. S.—Oil of savin has been quite extensively used as a local irritant. It must be used with caution in order to guard against the tendency to act as a vesicant.

OLEUM TEREBINTHINÆ.—U. S.—Oil of turpentine is the volatile oil distilled from turpentine. Even as an external application it is not infrequently used in the form of

OLEUM TEREBINTHINÆ RECTIFICATUM.—U. S.—This is identical with oil of turpentine in chemical properties, but it has a more agreeable odor.

TEREBINTHINA.—U. S.—This is officially described as the concrete oleoresin of *Pinus palustris* and of other species of *Pinus*.

RESINA.—U. S.—Rosin, resin or colophony is the residue left after distilling off the volatile oil from turpentine. The last two articles, rosin and turpentine, are interesting only as constituents of several official preparations, of which the best known are:

CERATUM RESINÆ.—U. S.—This is a cerate containing 35 parts of rosin, 15 parts of yellow wax and 50 parts of lard.

CERATUM RESINÆ COMPOSITUM.—U. S.—This is a revival of the one-time official Desbler's salve. It contains rosin, yellow wax, prepared suet, turpentine and linseed oil.

LINIMENTUM TEREBINTHINÆ.—U. S.—This is a solution of 65 parts of resin cerate in 35 parts of oil of turpentine. It has

1. THE JOURNAL A. M. A., Oct. 1, 8, 15, 22 and 29, 1904.

been recommended to be used in place of the oil of turpentine as a local application when the action of the latter might be considered as too actively irritating.

Oil of turpentine may be applied either in the form of the official liniment, diluted with a fatty oil, or it may be used in substance as a stupe; the latter is made by saturating a cloth with hot water, wringing it out and then dropping on it a little warm oil of turpentine, or dipping the moist cloth into the oil of turpentine and again wringing it out and applying while still warm.

Local applications of this kind will be found useful in bronchitis. Great care must be taken in warming oil of turpentine, as its vapor is inflammable. It should be warmed by placing the bottle containing it, uncorked, in a vessel of hot water away from fire.

Plasters of Burgundy pitch, Burgundy pitch with cantharides and of resin were formerly official. In practice these old-time resin plasters have long since been replaced by the more modern rubber-base plasters. The more representative of the rubefacient plasters now in use is the

Emplastrum Capsici.—U. S.—This is directed to be made by applying a thin coating of oleoresin of capsicum to adhesive plaster.

CAPSICUM.

Capsicum.—U. S.—The dried ripe fruit of *Capsicum fastigiatum* constitutes one of the most popular of the rubefacients used at the present time. Of the available official preparations we have:

Fluidextractum Capsici.—U. S.—This is made with strong alcohol.

Tinctura Capsici.—U. S.—This is made with a mixture of 95 parts of alcohol with 5 parts of water, and represents 10 per cent. of the crude drug.

Either of these preparations may be used diluted with alcohol or with soap liniment as a local rubefacient or irritant.

Oleoresinæ Capsici.—U. S.—This is made by extracting capsicum with acetone and may be used in the shape of plaster, as noted above, or in the form of the now popular mixture with petrolatum.

A typical prescription for a rubefacient of the latter type would be as follows:

R. Oleoresini capsici.....gr. xv 1|
Petrolati.....ʒ iii 100|
M. Fiat unguentum. Sig. Use locally.

MENTHOL.

Menthol.—U. S.—This is a secondary alcohol obtained from the oil of *Mentha piperita* or other mint oils. This substance is very largely used in the form of pencils or cones, sometimes in alcoholic solution, rubbed on the skin in neuralgia. It causes a burning and then a sensation of coolness.

Camphorated Chloral.—N. F.—This preparation, quite popular in some parts of the United States as a local application, consists of equal parts of hydrated chloral and camphor. It is a thick, oily-looking liquid, which is extremely irritating. It may be diluted with the fatty oils, alcohol or soap liniment.

MUSTARD.

Mustard is official as:

Sinapis Alba.—U. S.—White mustard is the seed of *Sinapis alba*.

Sinapis Nigra.—U. S.—Black mustard is the seed of *Brassica nigra*.

Oleum Sinapis Volatile.—U. S.—This is a volatile oil obtained from black mustard (freed from its fatty oil) by maceration with water and subsequent distillation.

Charta Sinapis.—U. S.—Mustard paper is directed to be made by coating rather thick, well sized paper with a mixture of rubber cement and powdered black mustard which has been deprived of its fatty oil.

Mustard foot baths, containing one or two ounces of powdered or ground mustard, preferably the black, thoroughly mixed with a gallon of warm water, are extremely useful for the relief of mild congestions of the head and of the gastro-intestinal tract.

Prompt relief is often obtained in this way from headache and from pain in the stomach. In many cases, even mild attacks of indigestion show decided improvement almost immediately; the action is further accelerated if a hot-water bag is placed over the region of the stomach at the same time.

The feet should be placed in the bath while the legs and feet are briskly rubbed with the mustard water for ten minutes or until the skin is red and some irritation is felt. The extremities are then rubbed dry with a coarse towel and wrapped in flannel or a blanket. When a slight degree of counter-irritation is desired for some time, a mustard poultice is employed. This is made by mixing one part of the ground black mustard with about five parts of flour (or ten parts of flour in the case of children), and mixing with enough water to form a mass. This is then spread on cheesecloth and applied at once.

Mustard poultices have been largely replaced by the much more convenient mustard papers, which are dipped in tepid water and applied at once. They are prone to become worthless in damp climates, since the absorption of moisture causes the slow development of the volatile oil, which then evaporates as fast as it is formed. With proper precaution, however, they may be preserved for a considerable length of time, and they will usually be found to afford the most convenient means of applying counter-irritation.

Heat.

The uses of heat have been touched on elsewhere. They are so numerous and so well known that they scarcely require further mention at this time. We may be permitted to call attention, however, to some of the various forms of cataplasms or poultices that are frequently used for their rubefacient or irritant properties.

Among the official substances that are frequently used for the preparation of poultices we have:

Linum.—U. S.—Linseed or flaxseed is the ripe seed of *Linum usitatissimum*.

Ulmus.—U. S.—Elm or slippery elm is the dried bark of *Ulmus fulva*, deprived of its periderm.

Carbo Ligni.—U. S.—This is charcoal prepared from soft wood and powdered.

Poultices are ordinarily prepared by mixing the requisite amount of ground flaxseed, ground elm bark or other substance with enough boiling water to make a rather stiff mass, inclosing this in a piece of gauze or muslin and applying to the surface.

The rubefacient properties of a poultice may be increased by the addition of ground mustard, tincture of capsicum or of oil of turpentine. For removing fetor or to act as disinfectants, poultices may have added to them powdered charcoal, chlorinated lime or the official solution of chlorinated soda.

The present eighth edition of the United States Pharmacopeia has included one poultice, as:

Cataplasma Kaolina.—U. S.—This consists of kaolin, glycerin and boric acid, with thymol, methyl salicylate and oil of peppermint as admixture to give it a pleasing odor. This preparation, like other poultices, is most efficacious when applied hot, but, as its action depends to a very great extent on the rubefacient properties of undiluted glycerin, due precaution should be taken to prevent the absorption of water or of watery vapor during the course of preparation or when heating it preparatory to applying.

Practically the same preparation is being offered to the medical profession at the present time under a variety of trade names, and while the combination undoubtedly has uses, many if not all of the positive claims that are made in connection with it are, to say the least, somewhat exaggerated, and the preparation should not be expected to accomplish more than might reasonably be expected from an equivalent application of heat and mild rubefacients.

One other point in connection with this particular preparation that has been the cause of some controversy in the advertising pages of medical journals is the question of priority. This question may safely be ignored, as the mixture, apart from the flavoring ingredients, can not be said to be new. Glycerin magmas have been known and used for upward of half a century, and a formula for practically an identical preparation may be found in the *Pharmaceutical Journal*, London, for March, 1858.

Heinrich Stern has very recently called attention to the revival of the use of formic acid for increasing the sexual desire, much as cantharides is used. Formic acid has long been known and used in domestic practice as a rubefacient. In Germany it has found considerable favor in regular medicine and is official in the German Pharmacopeia as a 24 per cent. solution and also as a spirit of formic acid, the latter containing 4 per cent. of the official solution of formic acid in a mixture of alcohol and water.

IODIN.

The official preparations of iodin that are used as rubefacients are:

LIQUOR IODI COMPOSITUS.—U. S.—This is better known as Lugol's solution; it contains 5 per cent. of iodin and 10 per cent. of potassium iodid in water.

TINCTURA IODI.—U. S.—This is an alcoholic solution and contains 7 per cent. of iodin and 5 per cent. of potassium iodid.

UNGUENTUM IODI.—U. S.—This contains 4 per cent. of iodin and 4 per cent. of potassium iodid in a mixture of glycerin and benzoinated lard.

Iodin in the form of the tincture or of the solution is very commonly applied to the skin as a counter-irritant. Repeated applications produce a caustic effect, but the action is very easily controlled. One great disadvantage possessed by the official preparations of iodin is the dark staining of the skin. Numerous efforts have been made to obviate this by using so-called colorless tinctures of iodin, which are merely solutions of iodids. It is much better to apply the iodin until sufficient irritation is caused and then remove the stain by washing with dilute solution of ammonia water or with a solution of sodium thiosulphate.

A more modern preparation of iodin that promises to replace the official preparations as an external application is a solution of iodin in saponated petrolatum, a formula for which will be found in the edition of the National Formulary now in press.

Saponated petrolatum may be made by simply mixing:

Liquid petrolatum	℥ii	60
Oleic acid	℥i	30
Spirit of ammonia	℥ss	15

In the order enumerated, the only necessary precaution being to use preparations that correspond to the requirements of the United States Pharmacopeia.

This simple saponated petrolatum will readily dissolve iodin up to 10 per cent. of its weight. A 5 or 6 per cent. solution of iodin, however, will be found to be most useful and not too irritating.

Probably the greatest advantage possessed by a preparation of this kind is due to the fact that it causes little or no stain and may be readily washed off with soap and warm water.

Saponated petrolatum may also be used for applying a number of other rubefacients, such as camphor, menthol, chloroform, methyl salicylate and turpentine.

Clinical Notes

UNUSUAL EFFECT OF HOMATROPIN.

REPORT OF TWO CASES.

JOSEPH W. SHERER, M.D.
KANSAS CITY, MO.

The following report of an extraordinary effect of a much used drug is instructive and of interest as illustrating the idiosyncrasy of individuals in their relation to medicines. In these cases the apparent physiologic action of homatropin hydrobromid was irregular to an extraordinary degree. The two observations here chronicled are the only instances which have come under my notice of excessive persistence of the effect.

I am unable to estimate a percentage of frequency for the occurrence of this accident, but suppose it to be rare, for these two cases are the only instances which have occurred in using homatropin several thousand times. The experience of others in this particular should be of interest to all. It is of moment to every practitioner, for the reason that it is especially in the more urgent cases of persons whose time is of great value that homatropin is employed.

I have just had it forcibly impressed on me how painfully embarrassing it may be to promise an active business man removal from his important affairs for one or two days only, and then find two weeks necessary for the eyes to regain accommodation and light tolerance. For this reason the experience of others is desirable.

CASE 1.—May, 1897. Female, aged 25, housewife, mother of a family, asthenopic symptoms pronounced. A 3 per cent. solution of homatropin was used. An application was made at bedtime, on rising and at intervals of ten minutes for an hour and a half before measuring the refraction. The patient came to the office immediately after breakfast. The eyes were in no way unusual. The refraction was plus and compound and the error was of an ordinary amount only. The mydriasis and cycloplegia persisted for eight days and the patient manifested great anxiety and impatience. I could not rid myself of the impression that the perturbation and alarm were partly assumed, but as the cause was real there was absolutely no way but to counsel patience and to emphasize the certainty of recovery with the lapse of time.

CASE 2.—January, 1906. Male, aged 41, business man, very busy, neurasthenic, the lifelong subject of periodic violent attacks of migraine. Homatropin solution was used half as strong and less frequently than in the foregoing case on account of age. The same vial was used on the preceding day on a newspaper man, aged 43, with recovery in eighteen hours, and subsequently on two other patients, one of whom reported complete recovery in twenty-four hours and the other in thirty hours. The pharmacist was positive as to the accuracy of the compounding of the prescription. The effect persisted with complete cycloplegia for fifteen days. This was a source of great annoyance to the patient, who bore it, however, with much resignation and fortitude, the more patiently as he keenly felt the need of relief from his malady. The recovery was complete eventually.

In neither of these cases was there any complication such as, for example, the onset of glaucoma. In the latter case there was more danger on account of the age. Had so unfortunate a thing occurred, eserin would probably have controlled it.

VICARIOUS MENSTRUATION DURING PREGNANCY.

N. P. McGAY, M.D.
SHILOH, OHIO.

Patient.—M. D., aged 25, married about five years.

History.—The patient had a miscarriage about three years ago, probably self induced. The uterus had to be "scraped out" about three weeks later. She has always been healthy and has had no disorders of menstruation up to this time. The flow occurred every thirty days, until May 30, 1905, since which time it has been decidedly irregular. On June 29 and 30, she had severe attacks of nose bleed, but no signs of menstrual flow. July 30 and 31, the same thing occurred. On August 19 she became alarmed at the non-appearance of menstruation and consulted me. I made a diagnosis of probable pregnancy from the symptoms then discernible. On August 30 and 31, she had a return of the menstrual flow but no nose bleed. In September and October, however, she again had severe attacks of epistaxis. On November 23, I made a thorough examination and confirmed my previous diagnosis. Epistaxis again occurred on December 1. On December 10, she took a trip of about ten miles in the country over rough roads, and an hour or two after her return labor pains set in. On the morning of December 12, she gave birth to a four-pound girl which lived twenty-three hours. The patient was up in the usual ten days, but she has had neither menstrual flow nor nose bleed since

A SIMPLE METHOD OF FINDING AN EASILY ACCESSIBLE PORTION OF THE LATERAL SINUS.*

* Read before the Wayne County (Detroit) Medical Society, May 7, 1906.

EMIL AMBERG, M.D.
DETROIT, MICH.

Four right and four left temporal bones picked out at random, show that an easily accessible portion of the lateral sinus can be found when we open that part of the mastoid process which is located (Fig. 1) in the direction of the line

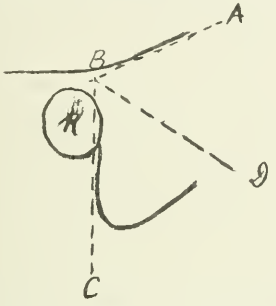

Fig. 1.—M., Meatus externus. A. B., Linea temporalis. B. C., Anterior mastoid line. B. D., Bisecting line of angle A. B. C. and directing line for lateral sinus.

which divides into two halves the angle formed by the linea temporalis and the anterior border of the mastoid process (an angle of about 115 degrees). This topographic consideration is important from a clinical point of view.

CERTAIN MOTILE ORGANISMS IN THE BLOOD PLASMA IN DENGUE.

CONRAD REICHE.
Sergeant, Hospital Corps, U. S. Army.
CEBU, P. I.

While in charge of the laboratory of the military hospital in Cebu, P. I. (Captain Kulp) it was my duty to examine the blood of all malarial and dengue patients. An epidemic of the latter disease occurred during December, 1905, and lasted about six weeks. No malarial parasites were found, but I observed in nearly every case very active, small (about 2 micron), round translucent bodies, with clearly defined edges, very motile, and easily visible with a 1/6 objective, but better with 1/12 oil immersion lens. They were seldom or never found in the erythrocytes, but often on them, as well as free in the plasma. They appeared about the second day of the fever, and could never be found after the temperature became permanently normal or after the administration of quinin. They sometimes remained active for as long a period as an hour and three-quarters. Unfortunately, the epidemic ceased suddenly and the contemplated staining and mosquito experiments had to be abandoned.

New Instruments

SET OF THREE NEW INSTRUMENTS FOR THE TREATMENT OF CHRONIC ENDOTRACHELITIS.

DANIEL H. CRAIG, M.D.
BOSTON.

The length of the three instruments is equal, and is 22 cm. This length was chosen as the shortest which would enable the gynecologist to satisfactorily accomplish the treatment without allowing his hands to come in contact with the patient. This seemed to me important because this method being designed for use at the office or out-patient clinic the thorough sterilization of the hands consumed too much time. With this length of instrument ordinary manual skill and dexterity render such sterilization entirely unnecessary.

The cervical forceps (Fig. 1) was designed to grasp the anterior aspect of the portio vaginalis as near as possible to, but not into, the external os. The tissues are here very often so soft as to tear when so grasped by the ordinary tenaculum or tenaculum forceps under the strain to which this grasp is to be subjected. The ordinary grasp with one blade within and the other without the cervical canal will later be seen to be obviously impossible in the use of either the dilator or the curette. The two pairs of opposed teeth give a grip which has never lacerated. The curve on the flat facilitates the combined use of the forceps and dilator with one hand.

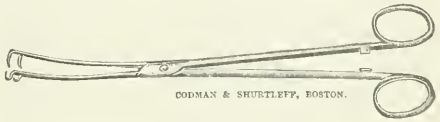

Figure 1.

The external os dilator was suggested by the conical calibrator used in dilating the external urinary meatus preparatory to cystoscopic work. Each of its dimensions is definite and has its *raison d'être*. It is of rigid steel throughout. The diameter of its tip is 2 mm., which is as small as it could be made without actually giving it an angular point (Fig. 2). The length of the cone from tip to shoulder is 2 cm. This length was chosen because being 0.5 cm. less than the ordinary depth of the cervical canal it would even permit of some eversion, due to laceration, without the tip of the cone impinging on or going through the contracted internal os. A cervix in which there is more than 0.5 cm. foreshortening, owing to laceration and eversion, is so patulous as not to require the use of any dilator. The narrow parallel surface just below the shoulder facilitates the retention of the dilator within the ex-

Figure 2.

ternal os long enough to produce sufficient relaxation without maintaining so forcible a degree of pressure as to be constantly disagreeable to the patient. The shoulder is, of course, self-explanatory. The flattened base of the handle facilitates the maintenance of a steady unirritating pressure. The perimeters of the shoulders are made hexagonal to prevent rolling and so coming in contact with unsterilized material.

The only features about the curette which need attention are the shape and width of its cutting blade. It is sharp, the edge being obtained by beveling from above downward and inward, making the blade cut as the curette is withdrawn. The blade and its fenestrum are triangular, presenting a base of 6 mm. and relatively sharp angles. The base is just twice

Figure 3.

the diameter of the normal internal os as stated by Deaver (Fig. 3). This excess width serves to render it impossible to introduce the curette past the internal os, unless it be dilated, which in itself constitutes a contraindication to the use of this curette, without the employment of sufficient force to lacerate the tissues. The sharp angles serve on the rotation of the curette, to remove the pathologic tissues too near to the internal os to be readily reached in the ordinary traction of the curette, and are especially useful in those cases in which a sharp angle exists just below the internal os due to pressure atrophy with excavation or internal laceration of the cervix. Three furrows on the appropriate surface of the hexagonal handle indicate the direction of the cutting blade. The curette is of rigid steel throughout, no necessity for flexibility having been encountered.

SATURDAY, MAY 19, 1906.

THE IDENTIFICATION OF SPECIES IN BACTERIOLOGY.

In the early days of bacteriology it seemed to some workers a relatively simple matter to distinguish between different species of bacteria and either to assign to every organism its place in an established group or else to install it as a "new species." It soon became apparent, however, that the ordinary cultural characters afforded an insecure basis for such differentiation, since micro-organisms closely related in some of their growth phenomena showed in others wide divergence, and since also one and the same bacterium varied greatly in its manner of growth and in its chemical products under different conditions and at different times. Morphologic differences were, if anything, less to be relied on than physiologic. The biologic relationship of different micro-organisms consequently became, and to some extent still remains, a subject for speculation rather than for exact verification.

The discovery of the agglutinative reaction, now so widely used in the Gruber-Widal test for typhoid fever, was looked on at first as bringing order into the chaos of bacterial types and groups, and was thought to supply a criterion of specificity to which no exception could be taken. Further investigation has shown, however, the limitation of the agglutinative reaction as a decisive standard of species differentiation. Park,[1] in an able address, has recently pointed out some of the manifold sources of error that tend to vitiate the value of the reaction as ordinarily employed, and that prevent its acceptance as a never-failing diagnostic aid. Even among typhoid bacilli, the group in which the reaction has been most widely and successfully used, inagglutinable races are sometimes encountered, so that if a bacterium isolated from water fails to agglutinate with a true typhoid serum, it can not on that account alone be contumeliously rejected as a non-typhoid organism. Among the related group of colon bacilli, as is well known, agglutination by specific sera affords no assistance whatever in identifying bacteria of similar origin and identical cultural characters. In general, the groups of common saprophytic bacteria do not lend themselves to differentiation and classification on the basis of the agglutinative test.[2]

While agglutination has, therefore, for some time, been losing ground as an absolute and final method for identifying bacterial species, another phenomenon, arising out of the injection of animals with bacterial cultures, has been considered of great importance. This is the so-called Pfeiffer's phenomenon, which is dependent on the development of a specific bactericidal substance in the body of an immunized animal. Many observers have laid great stress on the specificity of this germicidal reaction, which has been maintained to furnish proof of bacterial identity even when everything else, including the agglutinative test, failed to declare itself positively. Especially interesting, consequently, is the recent discovery by Besserer and Jaffé[3] of strains of typhoid bacilli which react atypically to the bactericidal sera. The genuine nature of these atypical typhoid organisms is shown by a variety of characters, among others by the fact that animals immunized against true typhoid bacilli were also immune to the strains in question. Susceptibility to a specific bactericidal serum must, therefore, go the way of the other absolute criteria of differentiation; absence of this susceptibility in the case of a typhoid-like bacillus is no proof that the organism is not, after all, a true but atypical strain of this species. As in the case of the agglutinative reaction, failure to respond to the test is not decisive.

LATENT TUBERCULOSIS IN CHILDHOOD.

Tuberculosis in childhood, especially latent tuberculosis, is a field comparatively neglected in the modern warfare against this disease. We have grown accustomed to concentrating our efforts on the adult consumptive and on general methods of prophylaxis and have not entered with any degree of fullness into the question of preventive measures for predisposed children. That latent tuberculosis is common in childhood must be admitted, even by those who are not willing to go so far as Behring does in this direction. Two interesting articles recently published from Heubner's clinic[4] show that the blood of many non-tuberculous children agglutinates tubercle bacilli. Whether or not this test is to be regarded as positive proof of tuberculous foci in the body is still a question, but it was significant in these experiments that blood from the umbilical cord never agglutinated tubercle bacilli and the percentage of agglutinations was lowest in children with no suspicion of tuberculosis, higher in children with chronic inflammation of mucous membranes, hypertrophied tonsils, adenoids, etc., and still higher in children evidently scrofulous. Salge found that in 12.5 per cent. of babies under a year old, apparently non-tuberculous, the blood agglutinated tubercle bacilli, and Schkarin found the same to be true of 21.1 per cent. of non-tuberculous children.

The death rate from tuberculosis in this country is not nearly so high as in Germany, and it is probable that if such examinations were made of American chil-

dren the proportion of positive cases would not be nearly so great. If, however, it were only half as great, the number of children with latent tuberculosis would be large enough to cause grave concern. It seems that the percentage is higher in school life than in early childhood, just as it is higher in childhood than in infancy. Roeder, of Berlin, reported to the Naturforscher Versammlung, in 1905, the results gained by systematic examination of school children in that city. Evidence of latent tuberculosis was found in a surprisingly large number of children, and the number increased with each year of school life.

Unfortunately, we have no statistics in this country as to the frequency of tuberculosis in school children. W. K. Chalmers has given us those for Glasgow, and by classifying the children according to the economic standing of their parents he is able to show, as one would expect, that the number of tuberculous children increases with the increase of poverty. Only 3.4 per cent. of the school children whose families occupy three rooms had tuberculous lesions, as against 5.9 per cent. of those occupying two rooms and 8.3 per cent. of those whose families were crowded into one room.

It is this last class, the children of the very poor, especially the poor in large cities, for whom a systematic campaign of prevention should be planned. A child with latent tuberculosis in a poor family has little chance of overcoming the infection. His days are spent in a crowded, unhealthful home and in a school room from which he usually graduates directly into the factory. Tenement house inspection and control of conditions in factories are legitimate functions of the municipality and their importance in the warfare against tuberculosis has been pointed out again and again; but the control of conditions in school houses is still more indisputably the duty of the municipality, for while the city does not compel a child to live in a certain house or to work in a certain factory it does usually compel him to spend the greater part of his day inside a certain school room. The child has a right to demand that, while he is there, his health should be safeguarded. Yet what is really the case? What do we do for the health of the child in school, especially of the child with a predisposition to tuberculosis? Apparently we are not so advanced in school hygiene as are our European contemporaries, for the death rate among school children in the United States is higher than in Europe.[2] Take the matter of ventilation: The great majority of school rooms, especially those frequented by unwashed children in old clothes, become close and foul long before the end of the half day's session, and it is a question whether the modern room, equipped with a complicated ventilation system which rarely works, is not worse in this respect than the old-fashioned school which depends on windows for fresh air.

In the matter of cleanliness we are still more remiss. Dry sweeping, or, at the best, sweeping with wet sawdust, is the rule in most school houses. In Boston a few years ago it was found that 41 per cent. of the schools had never had their floors washed. Chicago does better than that, for her school floors are washed five times a year, but imagine any office building with so low a standard of cleanliness as that. Dust from the streets tracked in by hundreds of feet rises from the floor to mix with the still more irritating dust from the blackboard, and in this atmosphere, often unrelieved by a single breath of fresh air, the child must spend the best hours of the day. Surely it is a wasteful and foolish policy which neglects the sanitary conditions of the school house, compels the child with latent tuberculosis to spend a large part of his day in surroundings favorable to the development of the disease, and assumes responsibility only after he has succumbed to it and become a charge on the community.

The child has a right to demand a sanitary school room: that is obvious. That he has a right to demand wholesome feeding during his school life would not be so readily admitted, yet it may prove to be an economy on the part of the city to undertake the feeding of its ill-nourished school children rather than to be obliged to assume the whole care of them in later years. This is the way the matter is regarded in many European countries. England, facing the enormous problem of her half-starved, degenerating, city slum population, has at last begun to experiment with free school dinners, provided by private charity, and it is probable that legislative provision for public relief of this sort will be enacted during the coming session. On the continent of Europe the system of free or very cheap meals for school children has been instituted in France, Germany, Belgium, Italy, Norway and Switzerland. The system is different in the different countries, but in all there is a unanimity as to the disastrous results of underfeeding in school children, the large number of underfed children in the poor quarters of most cities and the enormous improvement which follows the institution of these school dinners.

European city fathers take longer views than we do here and are serenely undisturbed by the cry of "socialistic." They have studied the economic significance of tuberculosis and have decided that, simply from the financial point of view, prevention is better than cure. And prevention of tuberculosis must be begun during the early years of life.

THE POISONS PRODUCED IN SUPERFICIAL BURNS.

In a certain proportion of cases of extensive but superficial burns, death follows after an interval of from six hours to a few days, apparently because of a profound intoxication. As evidence of intoxication, we have not only clinical manifestations, such as delirium, hemoglobinuria and albuminuria, vomiting, bloody diarrhea, etc., but, more convincingly, the anatomic findings at

2. G. K. Dickenson: "Sanitary Inspection of Schools and School Children," 1906.

autopsy, which are strikingly similar to those resulting from acute intoxication with bacterial products. Thus Bardeen found quite consistently cloudy swelling and focal and parenchymatous degeneration in the liver and kidneys; softening and enlargement of the spleen, with focal degeneration in the Malpighian bodies; and particularly degenerative changes in the lymph glands and intestinal follicles resembling those observed in diphtheria, which McCrae considers due to proliferation and phagocytosis by the endothelial cells of the lymphatic structures. Marked changes are usually present in the blood, consisting of fragmentation and distortion of the red corpuscles, hemoglobinemia, loss of water with a relative increase in the number of corpuscles by from one to four millions per cubic millimeter, an increase in the blood platelets, and a rise in the number of leucocytes to from 30,000 to 50,000. Hemoglobinuria is also frequently present, and almost constantly gastrointestinal irritation occurs with anatomic evidences of acute enteritis, acute gastritis, and occasionally gastric or duodenal ulcers. According to Korolenko, the sympathetic nervous system is seriously involved.

It seems probable, therefore, that poisons are formed as a result of the burn that have the effect of causing hemolysis, and that are also cytotoxic for parenchymatous cells and particularly for nervous tissues. These hypothetical poisons seem to be eliminated by the intestines and kidneys, which are injured by the poisons in their passage through these organs. The attempts to explain all the observed effects of burns as due to thrombosis or to embolism by altered red corpuscles seem to have failed, for the peculiar location of the lesions (e. g., duodenal ulcers, necrosis in the Malpighian bodies of the spleen, etc.) does not agree with this hypothesis, and there are too many evidences of the presence of some decidedly toxic substance in the blood. There can be no question that the poisonous substance or substances are formed in the burned area and not in the internal organs as a result of hyperpyrexia, as has been suggested, as shown by numerous observations. Thus if the burned area is removed immediately (in narcotized experimental animals), death will be prevented, whereas, if the burned tissue be permitted to remain for a few hours, death will occur. The poison appears to be absorbed from the burned area into the blood, for if circulation is shut off from the burned area no intoxication results; this probably explains why deep destructive burns of small areas, which are associated with local thrombosis, are much less serious than a superficial slight scalding over a large area.

Apparently the poison is produced chiefly or solely in the skin, for burning of muscle is not followed by intoxication (Eijkman and v. Hoogenhuyze[1]). Numerous investigators have reported finding poisonous substances in the blood, tissues or urine of burned men and animals, but the reports disagree widely in details. Thus Dietrichs states that the blood of burned animals contains hemolysins and agglutinins, which could not be corroborated by Burkhardt[2] or by Pfeiffer.[3] The latter, however, finds that the urine, serum and organs of burned animals contain substances poisonous for the same and for different species, which is in accord with the results of numerous earlier investigators. The poisons are neurotoxic and necrogenic in their properties, and act without a period of incubation. Apparently, according to Pfeiffer, they are not ptomains, nor yet pyridin derivatives, as many investigators have contended, but resemble more closely the labile poisons of snake venom. The neurotoxic substance is more thermostable than the necrogenic substance, which is very easily destroyed by heat. Pfeiffer believes it probable that the poisons are derived from the splitting of proteids altered in composition by the heat burning. The hemolysis he attributes to direct injury to the blood in its passage through the heated area, and not to the action of poisons; this is very possible, since red corpuscles fragment after being heated to 52°, and may be seriously impaired functionally at 45°. There are many authors, indeed, who consider the blood changes the chief cause of death, but the weight of evidence is in favor of the theory of the development of toxic substances in the burned skin.

In spite of Pfeiffer's researches, however, the nature of these poisons must be considered as completely unknown, for numerous other observers have described "peptotoxins" (Fraenkel and Spiegler); ptomains (Kijanitzin, Ajello and Paraseendolo), and pyridin bases (Fraenkel and Spiegler, Reiss). It remains also to be determined if the poisons are of such a nature that an immune serum can be obtained for them.

OCCURRENCE OF MENINGOCOCCI IN THE NASAL CAVITIES.

That so-called epidemic cerebrospinal meningitis is caused by a special micrococcus, the meningococcus (*Diplococcus intracellularis meningitidis*) is now generally accepted as an established fact. The manner in which this form of meningitis is disseminated and the portal of entry of the meningococci are, however, as yet not thoroughly understood. Recent investigations, especially in this country, indicate that probably the nasal cavities are important points not only of entrance, but also of escape of the meningococcus. Until less than a year ago the observations on the occurrence of meningococci in the nasal mucus in meningitis cases were rather unsatisfactory and indefinite. During the last epidemic of meningitis in New York, the opportunity to investigate this point was used to very good advantage by Goodwin and von Sholly,[1] who isolated meningococci from the nasal mucus in 50 per cent. of meningitis cases during the first two weeks of the disease. These

ıvestigators also studied the nasal mucus of 45 healthy ıdividuals living in close contact with meningitis pa-ents, with the valuable result that meningococci were ound in 10 per cent. Of 55 medical students not a ngle one gave organisms that corresponded fully to the ieningococcus. At the same time that the epidemic as running in New York, a few cases of meningitis lso appeared in Chicago, and Davis[2] demonstrated ypical meningococci in the nose and pharynx of one atient. Hence the occurrence of meningococci in the asal mucus in meningitis patients and in those coming close contact with them may be regarded as definitely ettled.

Now there is a more or less direct connection between ie lymph spaces of the nasal mucosa and the cerebral ıembranes through which infection may take place ıd possibly also elimination of the cocci. It is also ossible that the meningococci may enter the general rculation from the nasal lining as well as other parts the respiratory tract and become localized later in the erebrospinal membranes. Elser[3] recovered the meningo-occus in nearly 25 per cent. of the cases examined, and e believes that general blood invasion can be demon-rated in a large proportion under favorable conditions. is consequently possible also that the meningococcus ıay be deposited in the nasal mucosa from the circulat-ıg blood and thus reach the external world and secure ie necessary opportunity to perpetuate itself by enter-ıg a new host.

Be this as it may, the occurrence of meningococci in ie nose of patients with meningitis and their associates ıdicates the necessity of careful isolation of such cases, ot merely during the early weeks of the disease, as sug-ested by Goodwin and von Sholly, but, if possible, ntil such time as there is good reason to believe from egative results of examinations of the nasal mucus ıat the nose is free from meningococci. Furthermore, urses and others who remain in close contact with such ases should not be allowed to go about until it is known ıat they also do not carry meningococci in the nasal ıucus and thus are liable to become the unwitting dis-eminators of a terrible disease. Whenever opportunity fers, the study of the occurrence of meningococci in ie nasal cavities should be continued and extended to ie throat as well.

THE INFLUENCE OF LIGHT IN THE PRODUCTION OF CANCER OF THE SKIN.

It seems to be a well-known fact that the skin in cer-ain individuals is abnormally sensitive to the chemical r actinic rays of light. As pointed out recently by Hyde,[1] this hypersensitiveness may be evidenced in the roduction of either hyperemia, pigmentation, telan-iectasis, atrophy, hyperkeratosis or cancerosis of the skin. At times, though rarely, these different forms of reaction to the same influences may occur in one and the same person and then occasionally in a regular order of succession. This is the case in the rare disease known as xeroderma pigmentosum, a disease of childhood: here hyperemia is followed by pigmentation of the exposed parts of the body and eventually telangiectasis, spots of atrophy and of warty outgrowths (hyperkeratosis) develop and finally typical, usually multiple carcinoma.
