THE SURGICAL TREATMENT OF CANCER OF THE STOMACH.

WITH REPORT OF ONE HUNDRED GASTRIC RESECTIONS.

WILLIAM J. MAYO, A.M., M.D.

Surgeon to St. Mary's Hospital, Rochester, Minn.

In the history of medicine we have no recorded example of a cancer of the stomach cured by medical means. Yet, for some reason or reasons, such cases are sent to the medical men, are entered in the medical wards of hospitals and subjected to treatment which must result in 100 per cent. mortality.

So true is this that, while suspected cases of cancer of the breast, the uterus or the rectum are at once sent to the surgical side from the out-patient department, the possible victim of cancer of the stomach, even with a suspicion amounting almost to a certainty, is still sent to the medical ward.

Yet, of all diseases, cancer of the stomach is most surgical. External carcinomas may be treated by plasters, badly, it is true, but occasionally with success. Superficial epithelial growths sometimes disappear, at least for a time, under the *x*-ray. But gastric carcinoma has not even the small chance of relief which may be afforded by these very uncertain agents.

Appendicitis is now universally conceded to be a surgical disease, yet some cases of appendicitis are known to recover spontaneously and to remain cured. Extra-uterine pregnancy may result in a pelvic hematocele, with spontaneous absorption. But cancer of the stomach has no such possibility. These examples are adduced merely to show the inconsistency of looking for a medical side to this question. It is worse than blunder; it is crime.

Fig. 1.—Showing cancer of pyloric end of stomach, with enlarged glands, and the four blood vessels tied, and line of gastric secretion. A: Left Gastro-epiploica ligated. B: Gastric artery ligated. C: Superior pyloric ligated. D: Gastro-duodenalis ligated.

The practitioner of medicine is not to blame for this state of affairs. He has retained these cases because the surgeon has shown little or no disposition to relieve him of them. There is no controversy, and no one is more anxious to turn these unfortunate victims of a medically incurable disease to the operator than the internist.

Cancer of the stomach is the most frequent form found in the human body and can conservatively be estimated at 30 per cent. of the total. Why has the medical profession been so slow to apply surgical methods to the cure of this common malady? The reasons are two: First, the frightful mortality of the earlier operations which discouraged the patient, the physician

and the surgeon. Second, the difficulties and uncertainties of establishing an early diagnosis.

REVIEW OF SURGICAL TREATMENT.

The radical removal of cancer of the stomach was first performed by Pean in 1879, by Rydygier in the year following, and Billroth in 1881, but his was the first patient who recovered. Pean and Rydygier did not realize the importance of the subject, and it remained for the master mind of Billroth not only to see its possibilities, but to establish the principles of operative relief. These remain to-day much as he left them, the changes being in technic rather than in new discoveries. Almost appalling Billroth in the importance of his early contributions to the operative treatment of gastric carcinoma stands the name of Kocher, and in selected cases the Kocher operation is the method of choice not only in the hands of its distinguished originator, but of practical surgeons the world over.

The death rate among these early operations was appalling. The average mortality of Billroth at the time of his death was over 60 per cent. Haberkant, in 1896, collected 257 pylorectomies, with a mortality of 64.4 per cent. before 1887 and 42.8 per cent. after that time. Mr. Goffe showed that the operative mortality among the English and American surgeons was 76 per cent. before 1890 and 28.5 per cent. after that time. Guinard collated 291 cases between 1891 and 1898, with a death rate of 35.3 per cent.

The lack of enthusiasm of all parties concerned is not to be wondered at, but there has been steady progress, and since 1900 the improvement in operative technic has been so great that the mortality has become reduced to a remarkable degree.

The workers in this field have been comparatively few and the work has been so quietly carried on that the profession does not realize the enormous strides that have been taken. To-day the mortality in the hands of men of experience in the operable cases is probably not above 10 per cent. and in suitable cases nearer 5 per cent. Operations undertaken with the patient in extreme condition from starvation and hemorrhage will continue to show a large death rate.

But these disasters should no more militate against the operation in suitable cases than general suppurative peritonitis should stand in the way of early operation

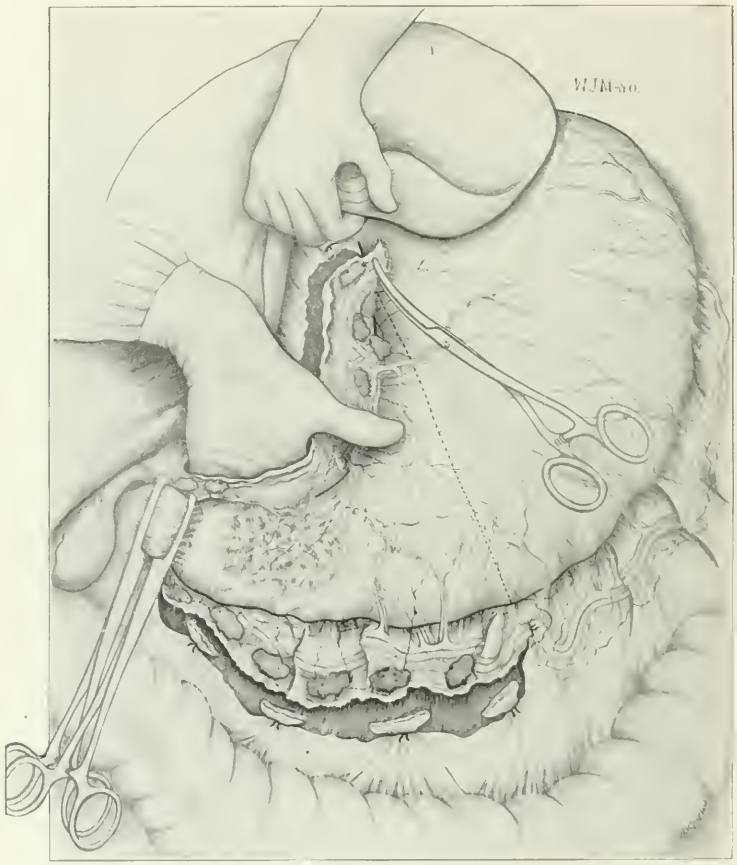

Fig. 2.—Showing duodenum clamped and pyloric end of stomach separated, ready for resection.

for appendicitis. Rather should it lead us to an increased effort to secure the patients during the curable period.

The stomach is a most favorable organ from an operative point of view. It has an abundant blood supply from four sources and the certainty of early wound healing makes plastic surgery safe. The immediate ligation of these four vessels makes radical operation bloodless and devoid of shock exactly as in the case in abdominal hysterectomy. By the use of clamps the entire area can be cleanly excised practically without opening the gastric cavity (Figs. 1 and 2).

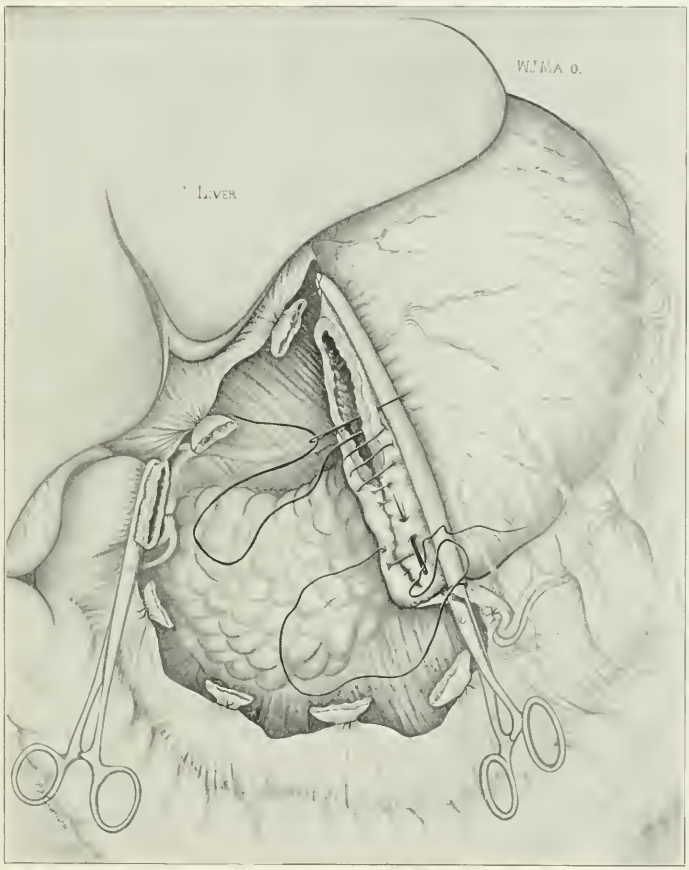

Fig. 3.—Showing closure of stomach, and the through-and-through catgut suture two-thirds completed, and outer linen continuous Cushing suture just started.

The gastric envelopes are thick, with but a loose attachment between the combined peritoneal and muscular coats and the mucous membrane, so that a firm hold of the outer tunics can be secured, insuring reliable union, while the mucous coat can be separately sutured. Running sutures are particularly effective and save much time (Fig. 3).

The entire operation of pylorectomy and partial gastrectomy can be performed in from 40 minutes to an hour and ten minutes, including opening and closing the abdomen, at which times only an anesthetic will be urgently demanded. In poor subjects the entire visceral part of the operation can be done without pain and without anesthesia. The preliminary administration of morphia hypodermatically in the latter class of cases is a valuable adjunct to the anesthesia.

We have done the Billroth No. 2, that is, the complete closure (Fig. 5), of both duodenal and gastric stumps and independent gastrojejunostomy, 76 times, and the Kocher operation 15 times (Fig. 4), and the Billroth No. 1 nine times. Each has its own field of usefulness in selected cases. For the average case the Billroth No. 2 is the operation of choice.

Granting that the statistics of operative attack are now within reasonable limitations, is the relief afforded sufficiently great to make it worth while? General statistics are unsatisfactory and we have, therefore, taken only the cases of Kocher, Kronlein, Mikulicz and ourselves.

In 1903 Kocher reported 75 cases, with an average mortality of 29.3 per cent. Of the 53 who recovered,

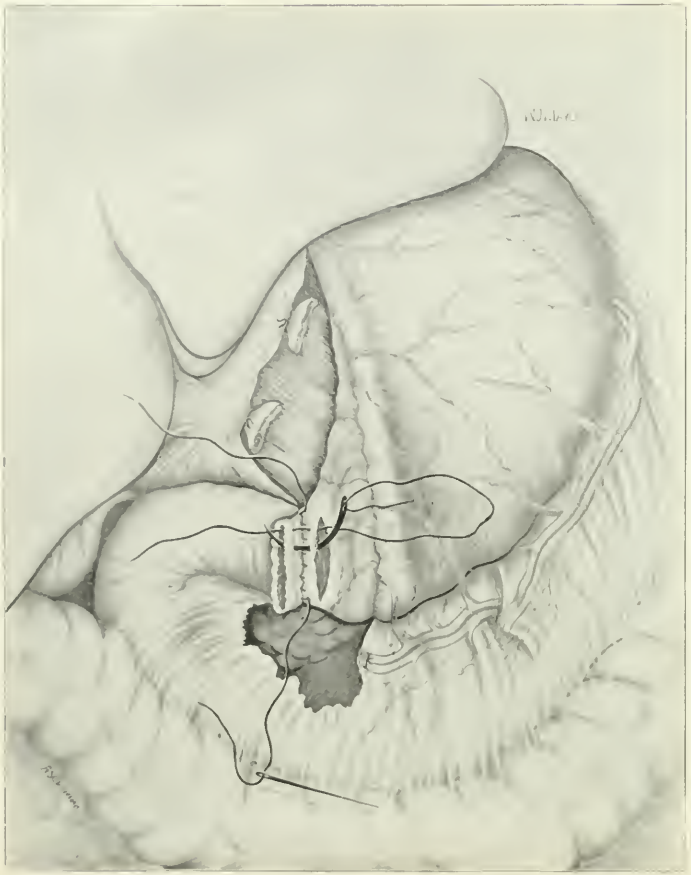

Fig. 4.—Showing restoration of gastrointestinal canal after Kocher method. Seromuscular linen suture in behind, and through-and-through catgut just beginning.

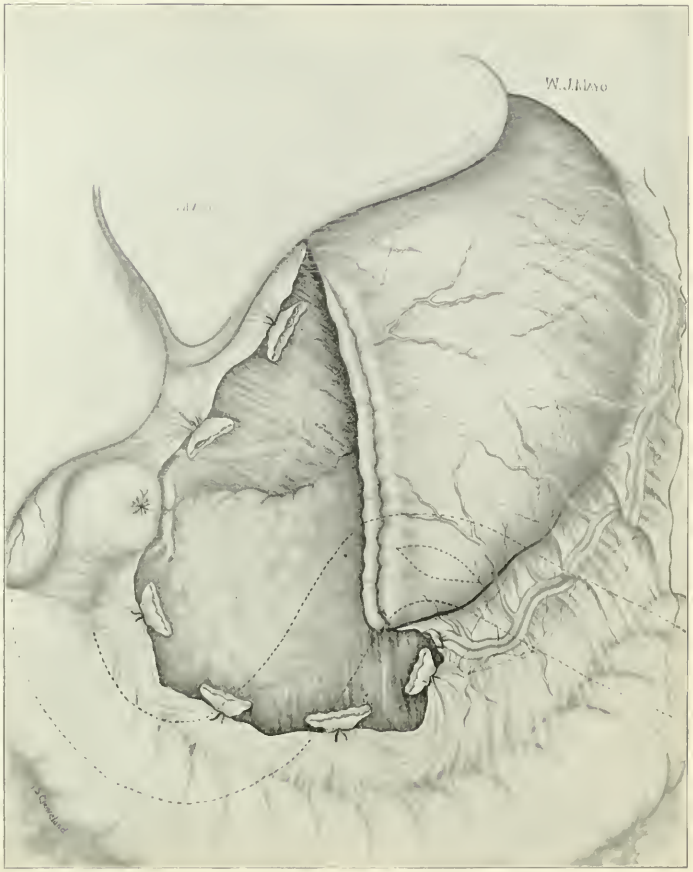

Fig. 5.—Gastrointestinal canal restored by independent posterior gastrojejunostomy, Billroth No. 2. Duodenum and jejunum dotted in as they lie behind.

21 were alive at the time of report and 6 had already lived more than 3 years, 1 alive and well after 13 years and 1 after 8 years. In the last 24 cases there were but 4 deaths, 16 per cent., and 2 of these, Kocher believes, could be fairly excluded, giving a mortality of 8 per cent. Matti, of Kocher's clinic, brings the Berne statistics up to 1904, giving a total of 100 gastric resections. There was considerable improvement in the percentage of those remaining cured over 3 years, and it was further shown that those who died of recurrence averaged 18 months of comfortable existence as gastric drainage was maintained to the end.

Kronlein, in 1902, reported 50 radical operations, with 14 deaths, 28 per cent. At the time of the report 22 patients were living, 4 three years and upward, 7 more than 2 years and 13 more than 1 year.

Mikulicz, in 1901, reported 100 stomach resections, with 37 deaths, 58 of those who recovered were traced. Seventeen were alive more than 1 year, 10 more than 2 years, and 4 more than 2½ years.

Dr. Chas. H. Mayo and I have resected the stomach 100 times, with 14 deaths, 14 per cent. This includes every case dying in the hospital, 5 after 3 weeks and 2 after more than 1 month. In the last 63 cases, beginning with Jan. 1, 1904, there were 6 deaths, 9.5 per cent., and in this group there were 25 consecutive cases, with but 1 death.

As to results, 17 of the 100 operations were excluded because performed for indurated ulcer in which gastric resection seemed indicated on account of possible existing malignant degeneration or other sufficient reason. Three cancer cases were also excluded because the diagnosis was not proved by microscopic examination. This gives 63 cases of gastric cancer in which radical operations were performed and which have been traced. Nine failed to live 6 months; 14, alive now, have been operated on too recently to be of value; 40 lived from 6 months to a year and 23 are alive now; 25 from 1 to 2 years and 17 alive now; 12 from 2 to 3 years and 10 alive; 5 from 3 to 4 years and 4 alive; 1 five years and is alive now.

It will be seen that five of our cases lived over 3 years, 1 dying in 3 years and 5 months from recurrence in the liver. As but 18 who survived the operation were operated on more than 3 years ago, we have 27.7 per cent. living 3 years and 22.2 per cent. alive and well over three years. Taking the most gloomy view possible, we have 22 operated on more than three years, with 4 dying as a result of the operation, 5 living over 3 years, or 22.7 per cent., and 18.1 per cent. alive and well over 3 years, a showing which compares favorably with the operative results for cancer in other parts of the body.

After all, the ease and thoroughness of the removal of the tributary lymphatics tells the story as to recurrence of cancer. Young people are most unfavorable subjects for operation because their lymphatics are abundant. Old people less so because, as pointed out by C. H. Mayo, all the lymphatics are undergoing a slow but sure atrophy during adult life, so that the aged have actually as well as relatively less lymphatics.

The prospect of the cure of cancer of the cervix uteri is interfered with by the proximity of the ureters, and in saving them we frequently sacrifice the patient so far as ultimate cure is concerned, because we do not thoroughly remove the tissues at this vital point.

In marked contrast to this is the arrangement of the lymphatic absorbents of the stomach, which have been beautifully worked out by Cuneo. He showed that normally no lymph glands existed to the left of the middle of the greater curvature and that the lymphatic circulation of this area was from left to right (Fig. 1).

Hartman seized on this basic principle and established the line of gastric section on the greater curvature to the left of the lymph nodes unless necessitated by the growth (Fig. 1).

Cuneo also showed that the lymphatics of the lesser curvature lay in the wall of the stomach itself. Mikulicz at once comprehended the necessity of routine removal of all the lesser curvature to the gastric artery (Fig. 1).

Kocher had already shown the desirability of the removal of the glands lying about the pylorus, especially in the groove with the gastroduodenal artery between the head of the pancreas and the duodenum. In favorable cases the entire lymph absorbents of the pyloric end of the stomach can be extirpated *en masse*. The dome of the stomach is disconnected in its lymphatic arrangement and drains into the splenic glands (Fig. 2).

DIAGNOSIS.

Exploratory incision is the only way an early diagnosis of cancer of the stomach can be established.

In spite of the remarkable development of laboratory methods the main diagnostic means are clinical, and prolonged attempts to establish a laboratory diagnosis are provocative of delay and should be discouraged. The most careful and painstaking methods of examination including these means should be insisted on, but they should not be unduly prolonged.

A suspicion of cancer of the stomach which *can not be disproved* by known methods of examination within a short space of time should lead the conservative practitioner to explain his suspicions to the patient and ask for surgical consultation. He is a reckless man who, under such circumstances, does not give the patient the benefit of the doubt.

The clinical history with the chemical and biologic examination of the stomach contents can but lead to a suspicion; and it is on this that we must act if we are truly conservative.

Given a patient of the middle period of life who, without cause, begins to lose flesh and strength, is unable to eat as before and whose digestion is delayed, we have a right to suspect gastric cancer. If, in conjunction with this, we find loss of motility and a delay of food in the stomach, with evidences of blood and reduction of hydrochloric acid, a tentative diagnosis of carcinoma is justified.

Especially must we be suspicious if in the history there are symptoms of old or recent ulceration. In our last 39 cases 56.4 per cent. showed direct evidence of carcinoma developing on ulcer. Graham showed a clinical history of ulcer in over 50 per cent. of the cases of gastric carcinoma which have come under his investigation, although years may have elapsed between the two diseased processes. It is possible that a larger number of cases in which cancer develops secondary to ulcer consult the surgeon than those without this history. The growing frequency of operation for ulcer brings to the operating table for the relief of obstructions, deformities and adhesions a considerable number of patients with gastric ulcer which has undergone cancerous degeneration.

Murphy well says: "The history of the majority of

cases of cancer of the stomach will show precancerous symptoms."

This question can not be settled by postmortem evidence. For instance, suppose we were told that the postmortem examination of one thousand women who died of cancer of the cervix uteri did not show a single one who had cervical laceration. Would not the query at once arise, If the cancer was so extensive that the patients were dead with the disease, how would it be possible for any one to know by such postmortem examination whether they had ever had laceration or not?

Is this not equally true of ulcer? Before the patient dies all trace of the ulcer would be lost in the gross extent of the disease.

The presence of a tumor is not necessarily a contraindication to operation. A small movable growth in the pyloric end of the stomach is a rather favorable indication, as the early obstruction attracts the attention of the patient by producing distressing symptoms which might not have come on at all if the tumor were in the body of the stomach.

Fortunately 80 per cent. of all gastric carcinomata are in the pyloric end and along the lesser curvature. Seventy per cent. are so situated as to interfere mechanically with motility and are, therefore, operable, while 10 per cent. are situated around the cardia, giving evidences of esophageal obstruction, and 10 per cent. in other parts of the stomach.

The earlier mechanical symptoms appear, the better the prospect of early diagnosis and cure.

There are some contraindications without exploration. One of the chief of these is the finding of typical carcinonamous glands in the supraclavicula fossa, particularly on the left side. This occasionally happens in patients in whom the diagnosis may be plain, but the question of operation is less so. Fixity of the growth and the presence of ascitic accumulations are also contraindications. Much has been written about the value of blood examination in cancer, especially as to the hemoglobin. We have had pylorectomy cases recover with the hemoglobin as low as 30 per cent. Again, some of the worst cases with obstruction may give a high percentage of hemoglobin due to concentration of blood from their inability to absorb fluids.

One can not help believing that more persistent attempts to better the early diagnosis of cancer would have followed on better operative results. There is no longer this excuse with an improving mortality of about 10 per cent. and 25 per cent. of the operative recoveries living more than three years. The time has come for energetic action. We must not disguise the truth from ourselves. All other means have failed, and exploratory incision of the suspected case is the only known means of early diagnosis. This should not discourage us, rather should it encourage better directed efforts toward securing some less formidable means of ascertaining the truth.

STEPS OF THE OPERATION.

1. Anesthesia.—We prefer ether anesthesia, giving a hypodermic injection of one-sixth of a grain of morphin 30 minutes previous to its administration. During the major part of the operation no anesthetic is required, as there is no pain in the visceral work.

2. Exploration.—A short incision is made in the midline half way between the umbilicus and the ensiform cartilage. Two fingers are introduced and the growth explored with reference to other structures. Next the extent of glandular involvement is ascertained. If the case seems fairly reasonable for operation, the incision is rapidly enlarged and the growth drawn out of the abdomen. This maneuver permits of careful examination of the lesser curvature, and especially as to whether the infiltration in this vicinity extends beyond the possibility of removal. The transverse mesocolon is then inspected, as it is often infiltrated from behind. The posterior surface of the stomach and its relation to the pancreas are palpated with fingers passed through a rent in the gastrohepatic omentum. We have dissected into the superficial surface of the pancreas a number of times without that fatality to which Haberkant (76 per cent.) and Mikulicz (74 per cent.) have called attention.

3. Mobilization of the Lesser Curvature (*Figs. 1 and 2*).—The stomach is drawn firmly downward and to the right, the left lobe of the liver raised by the fingers of an assistant, and the gastric artery tied with catgut on a needle at the highest possible point well beyond the lymphatic nodes. A pair of clamps are caught on the opposite side, and the artery and that portion of the gastrohepatic ligament which has been ligated with it are cut. With a few nicks of the knife the pedicle is partly detached from the stomach and allowed to retract. This permits of mobilization of the gastric wall and obtains a clear space near the esophagus for the division of the stomach. The superior pyloric artery and the remainder of the gastrohepatic ligament are now doubly tied and cut between, leaving the glands attached to the duodenum. This mobilizes the entire lesser curvature and makes the remainder of the work outside of the body.

4. Separation of the Pyloric End of the Stomach (*Figs. 1 and 2*).—The hand is passed into the lesser cavity of the peritoneum behind the stomach, adhesions are carefully divided and bleeding points ligated. Hot moist gauze pads are now placed in this space. Two pairs of narrow crushing clamps (Ferguson) are now placed on the duodenum well below the disease (as a rule, an inch below the pylorus) and the duodenum is divided between. The glands lying in the omentum immediately below the pylorus are carefully dissected upward so as to remain attached to the pyloric end of the stomach and a few bleeding points caught and ligated. The forceps on the stomach side with these glands is now lifted sharply upward, exposing the gastroduodenal artery in the groove between the head of the pancreas and the duodenum; this vessel is doubly tied and divided between ligatures. The glands in this region are dissected upward with the fat and hot gauze compresses placed in the space.

5. Freezing the Greater Curvature (*Figs. 1 and 2*).—The gastrocolic omentum is tied and divided in sections below the inferior coronary vessels, care being taken to avoid the middle colic artery; accidental inclusion of this vessel has caused gangrene of the transverse colon, of which it is the sole blood supply in 75 per cent. of the cases (Kronlein). Injury to the middle colic has necessitated resection of the transverse colon in a number of instances (Kocher). The lymph nodes lie close to the blood vessels, and at a point well beyond these structures the left gastrocpiploic vessel is caught and tied. Care should be taken not to destroy its branches to the stomach beyond the point of ligation as it will be the sole blood supply for the contiguous stomach wall.

6. Removal of the Diseased Structures (*Figs. 1 and 2*).—Light elastic holding clamps are now placed on the stomach an inch or more back of the proposed line of resection, a second pair grasping the tumor side and the growth with the glands and fat removed *en masse*. As

it is cut loose, several catch forceps should be applied to the margins of the cut stomach surface projecting beyond the clamp to prevent retraction. This clamp is straight, quite elastic and rubber covered so that it will not crush or injure the stomach wall. We have found those of Scudder very satisfactory. The cut gastric wall is now lightly gone over with the actual cautery, particularly at the upper part, at which point we are most liable to fail to get well beyond the disease.

7. *Suture of the Gastric Stump* (*Fig. 3*).—After rearranging the hot moist packs, to furnish ample protection, with No. 2 chromic catgut on a straight needle, beginning at the greater curvature, a running suture is placed through all of the coats after the method of Charles H. Mayo. The needle enters on the peritoneum at one margin, passes through to the mucous coat and directly back on the same side from mucous coat to peritoneum. By doing this alternately, first on one side and then the other, by a single suture the peritoneal surfaces are rolled into contact, the parts being firmly brought into apposition and the hemorrhage checked. On approaching the lesser curvature it will usually be found that the clamps are too close to the edges of the wound to permit of this maneuver and it may be necessary to unclasp them in suturing the last inch. As this situation is also under considerable tension, it is well to place one or two mattress sutures of linen at once at the upper end to completely and permanently secure it, rolling the first catgut suture in by a wide grasp of the gastric wall far enough back to permit of union without tension. Any point not well turned or showing a tendency to ooze is secured by an independent mattress suture of linen. Beginning now at the greater curvature, a fine linen continuous Cushing suture turns in the gastric wall without tension over the first row.

8. *Restoration of the Gastrointestinal Canal.*—(a) After the method of Kocher (Fig. 4).

After careful cleansing, the stomach is drawn toward the duodenum. If it is sufficiently mobile the Kocher operation is performed, the duodenum being loosened up for the purpose. The posterior wall of the stomach near the greater curvature, at a distance of one and one-half to two inches from the gastric suture line and parallel with it, is sutured to the posterior duodenal wall just below the original clamp on it by a running suture of linen. One-sixth of an inch in front of this and just opposite the duodenal clamp an incision is made through the peritoneal and muscular coats of the stomach to, but not through, the mucous coat. The clamp on the duodenum is now removed, its cavity opened up and sponged out. The posterior cut wall is firmly sutured with chromic catgut on a curved needle in front of the the posterior linen suture through all of the coats of the duodenum and stomach, using a Conuell or buttonhole stitch until the posterior inner row is completed half-way around. The mucous membrane of the stomach which has been sutured behind without opening is now cut through and its sutured lower margin inspected for hemorrhage or lack of apposition and one or two interrupted sutures of catgut applied if necessary. The through-and-through catgut suture is now continued around the anterior surface uniting the end of the duodenum to the stomach in a similar manner to that previously described in closing the stomach, the suture passing from peritoneum to mucous coat and back from mucous coat to peritoneum on the same side alternately and tied to the original end. The linen suture is now continued around to the starting point completing the second row. The entire suture line is inspected front and back and several extra mattress sutures of linen used to reinforce at points of tension. If the stomach has a tendency to drag on the duodenum the gastrocolic omentum close to the stomach is caught and anchored to the peritoneum on the left margin of the wound. The stumps of the gastrocolic omentum are brought together with a couple of catgut sutures and the entire field inspected and sponged. The deep gauze compresses are now removed. If these have been carefully placed and renewed at intervals, there will have been no contamination or exposure.

(b) Closure of the duodenal stump and independent gastrojejunostomy, Billroth No. 2 (Fig. 5).

If the stomach can not be approximated to the duodenum, the duodenal stump is turned in by a circular suture after ligature in the groove made by the forceps and a posterior gastrojejunostomy is performed without a loop, that is, within three inches of the origin of the jejunum. The opening in the stomach, however, should run from above down, right to left, so that the proximal end of the jejunum shall lie close to the suture line, the distal end at the lowest point and passing to the left. After completion of the gastrojejunostomy in the usual manner, the jejunum at once drops down into the left iliac fossa in its normal position. A few sutures close the rent in the transverse mesocolon in such fashion as to protect the suture line. If the patient is in a poor condition, an anterior or posterior Murphy button operation can be made to save time. The button must be protected, however, by at least four mattress sutures of linen at intervals to prevent separation.

9. *After-Care.*—After resection the patient should be placed in bed, the head and shoulders elevated to the semi-sitting posture and a glass female douche point introduced above the internal sphincter, through which from one to four quarts of one-half strength normal saline solution is allowed slowly to enter the rectum for absorption from a gravity bag, thirty minutes to three hours being used in this process (Murphy). This is repeated in twelve hours with a lesser amount. From one-half to one ounce of hot water is allowed by the stomach every hour after sixteen hours, and the usual experimentation of liquid foods begun after twenty-four to forty-eight hours, the rectum being used as an auxiliary for four or five days.

PALLIATIVE OPERATIONS.

The results of palliative operations for cancer of the stomach are relatively unsatisfactory. The statistics of gastroenterostomy for the relief of obstructions due to inoperable malignant disease shows as high or higher a mortality than gastric resection; the comparison, however, can not be directly made, as gastroenterostomy can be applied in cases in which radical incision can not be performed.

The average prolongation of life after gastroenterostomies is not over four to six months, and the fact that patients live beyond this time gives rise to the query: Might not radical operation have given a cure? In 143 cases of gastroenterostomy for malignant disease reported by Mikulicz the mortality was 33 per cent., the average prolongation of life 6.4 months. In 74 cases by Kronlein the death rate was 24.3 per cent. and the average prolongation of life was but three months. In 140 of our cases the death rate was 15 per cent. and the average prolongation of life, so far as known, was less than five months.

It is true that the mortality in recent cases is very much less, perhaps not over 10 per cent., but the leaving of the ulcerating, bleeding mass in the stomach to its own devices is unsatisfactory. The operation merely prolongs a chronic invalidism by a few weary months which are without hope. The judge who says to the prisoner, "I sentence you to death after five months," has not given the prisoner a desirable intervening existence.

For cancerous obstruction of the cardiac orifice gastrostomy offers the only means at our command, a palliation which is not frequently demanded by the patient when the facts are placed plainly before him.

Of gastrostomies for cancerous cardiac obstruction there were 18 cases, with 3 deaths, 16.6 per cent. Average duration of life about the same as after gastroenterostomy.

Of explorations with the discovery of hopeless gastric carcinoma there were 72, with one death in the hospital. The average stay of patients explored for incurable disease is less than five days, the deep wounds being closed with catgut, and the strong aponeurotic structures are braced with buried mattress sutures of linen, silk or silver. This enables the patient to get about at once and return to his home to spend his remaining existence with family and friends.

It will be seen that of the total 313 cancers of the stomach operated on up to Feb. 1, 1906, only 26 per cent. were early enough to permit of radical extirpation.

In conclusion, let me urge upon the profession the merits of radical operation on suitable cases of gastric cancer.

THE NEURONS.

LEWELLYS F. BARKER, M.D.

Professor of the Principles and Practice of Medicine, Johns Hopkins University; Physician-in-Chief to the Johns Hopkins Hospital.

BALTIMORE.

(*Concluded from Page 935.*)

The next questions to be decided are, (1) Do the minute fibers ending in the terminal buttons form anastomoses with one another? and (2) Do neurofibrils pass from the terminal buttons into the adjacent cell body or dendrite to form connections with the neurofibrils lying in the protoplasm there? I am unable to find them in the preparations I have been studying, nor can Ramón y Cajal, von Lenhossék, Retzius, van Gehuchten or Mahaim in theirs. Held[12] thinks that he sees such communications, and Max Wolff is inclined to a similar view. Further study is needed to decide this point. Ramón y Cajal is so convinced of the separateness of the terminal buttons from the adjacent nerve-cell protoplasm that he unhesitatingly assures us that not only is the neuron conception valid, but even the contact doctrine is better supported now than ever before, and Sherrington[13] takes the ground that the cell membranes at the junctions of the neurons (synapses) may be of very great importance in the reflex processes.

Certain it is, if one makes a quick review of all the theories which have been advanced, with the aim of discrediting the views based on the findings with Golgi's method, one comes necessarily, as van Gehuchten has emphasized, to a double conclusion: First, none of the theories opposing the neuron conception has led to the objective demonstration of the existence of a real continuity among the nerve elements, and, second, there is a marked difference between so-called neuronists and so-called antineuronists in interpreting known facts. The former, faithful to the facts observed, declare that in their preparations they find only free ramifications, and, not being able to see intercellular anastomoses, they maintain that one should not admit that they exist. The opponents of the neuron conception affirm that intercellular anastomoses ought to exist, but, not being able to demonstrate them, they themselves supply what is lacking in their preparations; using theoretical considerations and physiologic arguments as a basis, they construct the desired continuity out of whole cloth. Advocates of the neuron conception and of the contact doctrine naturally regard this negative result of the numerous efforts made to establish the continuity as a very convincing argument in favor of the real independence of the neurons. Opponents of the neuron conception think that continuity is, *a priori*, so probable that those who deny it should bring the absolute proof that it does not exist.

May it not be possible that the multiplication of hypotheses has been largely due to the supposition, thus far baseless, that the neurofibrils represent the sole conducting element in the nervous system? In an address delivered in 1899,[14] commenting on this subject, I said: "Some investigators have been tempted, very naturally, I think, to assume that the fibril-like structures in the ground substances represent the essential conducting substance, but, however plausible, this is not yet satisfactorily proven, and, even if such structures were shown to be particularly suited for such conduction, a similar function for other parts of the nerve-cell protoplasm would by no means be excluded." Bethe and Mönckeberg's argument that only neurofibrils pass through the nodes of Ranvier has no weight if it be true, as is asserted, that perifibrillar and interfibrillar protoplasm also pass through the nodes. There can be but little doubt that the neurofibrils are of some special importance for the cells, but we are as yet as ignorant of the function they subserve as we are of the functions of the fibrils in the muscle cells and in other cells of the body. Schiefferdecker[15] suggests that the fibrils are not for the purpose of isolated conduction, but that they, together with the plasma, produce a definite chemical transformation in the neuron, which is propagated through the axon and is able to excite other nerve cells or end organs.

In hibernating animals the neurofibrils are quite different in appearance from those in active animals (Fig. 16). Studies of the neurofibrils in pathologic conditions have already been begun (Marinesco, Bellot *et al.*), and it is found that they undergo definite changes when the neurons are injured.

(*b*) *The Neuron as a Physiologic Unit.*—Under this heading I shall refer to two points only: 1. The possibility of nerve conduction in the absence of the cell body of the neuron. 2. The so-called "autoregeneration" of peripheral nerves.

With regard to the first of these two points, Bethe's

so-called fundamental experiment has attracted much attention (Fig. 17). In studying the nervous system of a crab (*Carcinus mœnas*), he cut off the motor cells at the periphery of the ganglion of the second antenna, and found that as long as the sensory fibers (F. s.) and motor fibers (F. m.) of the antenna remained intact and in connection with the cell-free neuropile of the center of the ganglion the antenna behaved normally; the tonus of the muscles is preserved and the reflexes persist unaltered. Bethe thinks this experiment proves conclusively that the cell body, the part of the neuron containing the nucleus, is not necessary for the reflex functions, and that the normal tonus of the muscles does not depend on the cell body, excitation of the sensory fibers being transmissible to the centrifugal fibers in spite of the entire absence of nerve cells. If this experiment be confirmed, it will show that the whole neuron does not necessarily enter into every function, or, in other words, that there may be nerve functions which can be carried out with utilization of a part only of the cell. The experiment points also to the validity of the hypothesis, advanced by Ramón y Cajal and van Gehuchten, of the axipetal conduction function of the dendrites. It was thought at first to demonstrate the conducting function of free extracellular neurofibrils, but recent studies indicate, as has been already said, that the neurofibrils of the neuropilem are all embedded in the protoplasm of the processes of nerve cells.

The question of the possibility of autoregeneration of the distal end of a divided nerve which has been prevented from uniting with its central end is one of very great interest. Bethe has repeated the earlier experiments of Philippeaux and Vulpian, and asserts that in young animals autoregeneration takes place, the Schwann cells, uniting end to end, building the new nerve fibers and producing not only new axons, but actually new myelin sheaths and neurofibrils (Fig. 18). Bethe's experiments have been confirmed by Ballance and Stewart in England, van Gehuchten in Belgium, Barfurth[16] in Germany, and recently also by Raimann.[17] The validity of the experiments has been denied by Munzer and by Langley and Anderson,[18] the latter asserting that if anastomosis with other nerves in the limb and all possibility of outgrowth from the central stump be prevented no autoregeneration occurs. The supporters of autoregeneration are positive that they prevent any connection of the central stump of the sciatic, the nerve experimented on, with the distal stump of the divided nerve. Raimann having even excised the portion of the spinal cord and spinal ganglia corresponding to the origin of the sciatic nerve in order to prevent absolutely any central outgrowth. In view of Frossmann's[19] interesting experiments, which show the powerful positive attractive force (neurotropism) exerted by disintegrating nerve substance on living nerve fibers at a distance, it has become necessary to think not only of an outgrowth from the central stump of the *N. ischiadicus*, but also from branches of the other nerves of the lower extremity, namely, the *N. femoralis* and *N. obturatorius*. To test this point Lugaro of Florence[20] excised the whole lumbosacral cord and the corresponding spinal ganglia in three puppies. After three months the nerves of the limbs were found to be faradically totally inexcitable, and histologic examination showed entire absence of any autogenous regeneration. It is highly important that a series of similar experiments be performed, and that the truth in this matter be finally determined. Should autoregeneration actually occur, we should have another wonderful example of the power of adaptation of the body in utilizing in regeneration histologic elements of entirely different embryonic origin from those by which the structure is first formed. It would not be any more wonderful, however, than the generally accepted regeneration of an extirpated crystalline lens by the iris epithelium in Triton.

(*c*) *The Neuron as an Embryologic or Cellular Unit.*—The embryologic researches of His, which taught that the axis cylinder of a nerve fiber represents the outgrowth from a single nerve cell, had, as we have seen, much to do with the origin of the neuron conception. The neurilemma cells forming the sheath of the peripheral nerve fibers were regarded as accessories for protective or nutritive purposes. The studies of Golgi's preparations of young embryos confirmed in the most striking way the opinions of His (Fig. 19).

This doctrine of the unicellular origin of the neuron has by no means gone unchallenged. Indeed, there is a large school of investigators to-day who maintain that the peripheral nerve fibers, inclusive of their axons, arise in the embryo as the result of the fusion of long chains of cells placed end to end. This pluricellular or catenary explanation of the origin of the peripheral nerve fibers has been extended even to the dendrites and the nerve cell of the central organs, certain Italian investigators especially asserting that the rows of cells fuse inside the central system to give rise to them, their nuclei gradually disappearing.[21]

Bethe recently undertook again the study of the development of the peripheral nerve fibers from the embryologic side, and published his results in his book of 1903. He states that, before the appearance of any trace of peripheral nerve fibers, a band of spindle-shaped cells can be seen in the place where the nerve is to be formed, and it is these cells, he believes, which produce by differentiation of their protoplasm the neurofibrils of the peripheral nerve fibers and the nuclei of their internodal segments (Fig. 20). Bethe looks on this cellular band as a true syncytium, the protoplasmic part of which builds filaments, which, extending from cell to cell, finally all fuse together and become continuous with the nerve cells in the centers. Gradually each of these filaments becomes surrounded by nuclei and myelin sheath, and a large number of individual nerve fibers ultimately arise from the cellular band. Similar views of the origin of the peripheral fibers have been advanced by Apáthy and Sedgwick.

Hensen[22] has for forty years opposed the doctrine of an outgrowth of free nerve endings from the centers to the end organs. It is his opinion that, from the earliest stages of development, nerve-cell and end organ are connected by long-drawn-out intercellular bridges. As the cells go on dividing, the connecting intercellular bridges also divide more or less completely. The divided nerves gradually become separated from one another as growth proceeds. Since many of the subdivisions are

(After Ramón y Cajal, 1903.)

incomplete, there finally arises an interminable network of fibers. Hensen then assumes that certain portions of this network become useful to the body as a nervous system and persist; the unused portion of the network atrophies and disappears. The peripheral networks

have been carefully studied of late by an especial technic by O. Schultze.[23]

Up to 1904 it had become ever clearer that unanimity of interpretation of the histologic pictures of developing nerves was not to be arrived at unless some new and convincing method could be devised which would settle the question definitely. In April of that year Braus[24] published the results of some very interest-

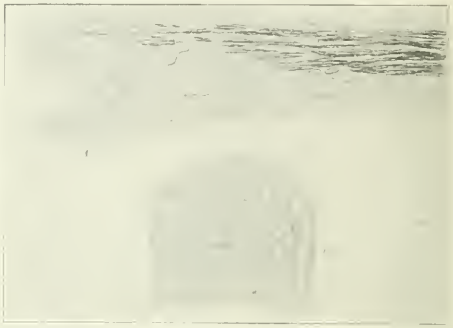

Fig. 18.—*A*, longitudinal section through an "autoregenerated" nerve; *B*, transverse section through the same nerve a little further distalward. (After Bethe, 1903.)

ing experiments on tadpoles (Bombinator). At the period of appearance of the fore limb as a minute bud, he excised this bud and transplanted it to a point between the bud for the hind limb and the root of the tail. The bud grew and gave rise to an extremity quite like a fore limb, only out of position. At the time of transplantation the limb already contains the rudiments of nerves and blood vessels. This differentiation, according to Braus, recedes during the next few days after transplantation and the tissues of the bud again come

to resemble an indifferent blastema. Braus, following the idea of Roux, believes that this bud in its further growth leads its own life, that development goes on in its tissues by autodifferentiation. Certain it is that the blood vessels, bones, muscles and nerves develop in it. As early as three weeks after the operation the nerves in the transplanted limb present a development equal to that of a normal limb. Though Braus believes that these nerves have developed "autogenetically," he admits that they are connected by means of three strands with the general nervous system of the tadpole; he feels sure, however, that these strands are too delicate to have served for the passage from the central nervous system to the limb of all the peripheral nerve fibers to be found there. It looked, therefore, at first as though the doctrine of the pluricellular origin of the peripheral nerve fibers were about to receive support from the experimental side.

In the summer of the same year (1904), however, the subject was approached in a most ingenious way by one of our American anatomists, Dr. Ross Granville Harrison of Baltimore.[25] At a meeting of the Society of Naturalists of the lower Rhine he reported some experiments in which the sheath cells or neurilemma cells which give rise to the bands of cells along the lines of developing nerves were eliminated by cutting out their source at a very early embryonic stage before any nerves whatever had developed. He found that these sheath cells arise in the region of the so-called neural crest

Fig. 20.—Transverse section through an embryo of chick after an incubation of two days, twenty-one hours. The bands of spindle-shaped cells in the course of the spinal nerves is illustrated. (After Bethe, 1903.)

along with the cells which give origin to the spinal ganglia. By cutting away a thin strip at the back of the embryo, when it is only 3 mm. long, he got embryos to grow which at the end of a week had no sensory ganglia or sensory nerves, though they had motor nerves. But the remarkable fact is that these motor nerves, instead of showing cell bands in their course, as under normal conditions, appeared as naked, non-nucleated fibers which could be traced as such all the way from the spinal cord to the extreme ventral part of the musculature (Figs. 21, 22, 23 and 24). Here, at a blow, the proof was brought that the peripheral spinal nerves may develop in the entire absence of sheath cells.

25. Harrison, R. G.: "Neue Versuche und Beobachtungen ueber die Entwickelung der peripheren Nerven der Wirbeltiere." Bonn, 1904. Reprinted from Sitzber d. Niederrhein. Gesellsch., Nat. u. Heilk., Bonn, 1904.

The first experiments were made on the embryo of *Rana escalenta;* subsequently Dr. Harrison confirmed his results on the embryos of two American species. *Rana sylvatica* and *Rana palustris.* But, true to the principles of the experimental method, Dr. Harrison did not remain satisfied with the proof—he sought the counterproof. As an *experimentum crucis,* it occurred to him to excise, in these young embryos, the ventral portion of the neural tubes, i. e., to cut away the cells which, according to the doctrine of His, give rise to the axis cylinder processes of the spinal motor nerves. Leaving the neural crest intact, that is, the region which gives rise to the spinal ganglia and the sheath cells. Harrison argued that if the opposing doctrine that the sheath cells form the motor nerves is true the latter and the sensory nerves should develop normally, even with the anterior horn cells absent. The experiment is one difficult to perform, and a number of attempts failed to give conclusive results, but Harrison has performed it a

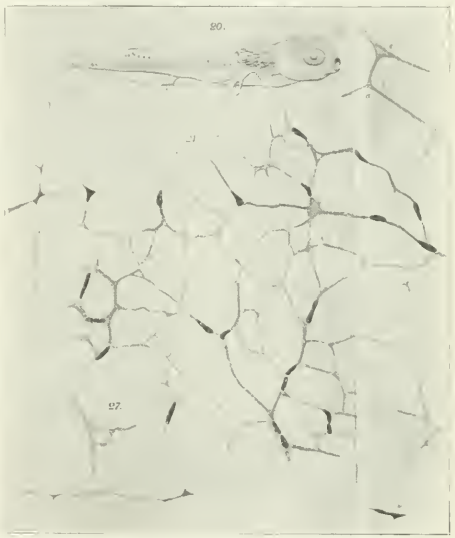

Fig. 21.—Peripheral nerve network. (After O. Schultze.)

number of times successfully. What was the result? The spinal ganglia and the peripheral sensory nerves, with their accompanying sheath cells, developed normally, but not a trace of a spinal motor nerve appeared in the region operated on, nor did the sheath cells form bands where the motor nerves normally appeared (Fig. 25). The proof, then, has most brilliantly been brought that the fibers of the motor nerves are processes of the anterior horn cells, that these processes can extend a long distance from the spinal cord to the muscles in the entire absence of sheath cells, and that the sheath cells are incapable of building these fibers by themselves. If any one could have given me my choice of doing successfully any single piece of experimental work that has been done in neurobiology since 1891, I should unhesitatingly have chosen this. It is an experimental research of the first order, one which, if confirmed, will always redound greatly to the credit of anatomic science in America.

But even should it have been made out that the neuron is pluricellular in its origin the anatomic unit, which Waldeyer called the neuron, would still have existed. It would have been an organ then, rather than a single cell.

I should like to go on to the newer work, dealing with the origin of the connection between ganglion cell and end organ, into the researches supporting the free outgrowth theory, on the one hand, and the persistent cell-bridge theory on the other, but I have already exceeded the time allotted to a Harvey lecture and must be content with referring you to Harrison's forthcoming article[26] in which these matters are discussed more ably than I could deal with them.

And now as to the validity of the neuron conception and of the various attached neuron doctrines I shall leave you to judge for yourselves. I am glad if in this hour I have been at all successful in putting the actual facts as known at present before you or in encouraging you to hold an open mind regarding theories where facts are wanting.

APPENDICITIS: ITS TREATMENT.*

O. BEVERLY CAMPBELL, A.M., M.D.
Professor of Abdominal Surgery and Gynecology, Ensworth-Central Medical College.
ST. JOSEPH, MO.

Were it possible under all circumstances, in the treatment of appendicitis, to follow the dictum to operate within the first twenty-four to thirty-six hours from the onset of the disease, we would not be confronted with the varied pathology and the many mooted questions of dealing with it in attempting to treat this disease successfully. The early operation will, however, probably never become the universal practice, and we will still continue to encounter all of the different pathologic conditions that are associated with neglected cases of the disease.

The reasons why the early operation will never become the universal practice in appendicitis are chiefly the following:

(a) The family physician, and not the surgeon, is usually called to diagnose and treat the disease in the beginning. It is expecting too much of the family physician when we look to him to diagnose the disease and to call the surgeon all within twenty-four to thirty-six hours from the onset of the attack.

(b) When the diagnosis of appendicitis is made within the first twenty-four or thirty-six hours, and an operation is advised, it is necessary to gain the consent of the patient and his friends, which it is not always possible to do within the time limit for an early operation.

So that, while the early operation should be the practice in appendicitis when possible, it must be acknowledged that its universal application is impractical, even under favorable circumstances, and we must expect to do the late operation as a life-saving measure, and the interval operation more often than the early.

EARLY MEDICAL TREATMENT.

The most usual cause of death in appendicitis is diffuse peritonitis, and the treatment of the disease largely resolves itself into the best means of preventing its occurrence, either with or without operative measures. Heretofore there has been considerable difference of opinion as to the early medical treatment of appendicitis, and the practice of purgation with salines has been the most popular and the most universally used. I wish to deprecate this practice, unless, at the very onset of the disease, or an operation has been decided on, and the patient is so situated that the operation can be performed at once. Purgation, unless in the very beginning of an attack, is capable of doing a great deal of harm, because of the resulting increased peristalsis, which tends to disseminate the infection to the general peritoneum.

The claims that have been made concerning the therapeutic effect of purgation in lessening the virulency of the attack, and tending to unload the appendix into the bowel, are certainly not based on sound reasoning. In very many cases operated on by me within the first thirty-six hours from the onset of the attack, where perforation had not occurred, the great omentum and several coils of the small intestines were softly adherent to the appendix. In several of these cases the appendix was on the verge of perforation; a necrotic area could be discerned. Had purgation been the treatment at this particular time, instead of operative interference, it is reasonable to conclude that the soft adhesions would have been torn away by the peristaltic action of the intestines and perforation of the appendix would have occurred in some of the cases, and perhaps diffuse peritonitis would have followed.

On the other hand, had operation in these cases been delayed, and, instead of purgation, a treatment had been instituted which would have arrested peristalsis in the intestines, it is as reasonable to conclude that walled-in abscesses would have occurred. The total arrest of peristalsis in the intestines will tend to protect the inflamed appendix and will not interfere with Nature's method of limiting the inflammation. Were it possible to anticipate an attack of appendicitis, thorough purgation for the single purpose of emptying the bowel would be advisable, or, at the actual onset of the attack, it would still be admissible, but the routine treatment of purgation several hours after the onset is capable of aggravating the disease. While it is the consensus of opinion that there is no medicinal treatment which can arrest the pathology in the appendix, it does seem that it has not been made plain that in cases refusing operation, or until the case is turned over to the surgeon, the treatment should be directed solely toward the protection of the peritoneum.

In a certain proportion of cases of appendicitis, variously stated at from 70 to 85 per cent., the pathology unaffected by treatment will not progress to the stage of ulceration and perforation, or to gangrene, but after an acute active course will become subacute and chronic and in some cases subside, leaving the appendix crippled and subject to recurrent attacks. This fact has led the unthinking physician to disfavor operative procedures and to rely on remedial agents directed toward the arrest of the pathology in the appendix. But the fact that, in the beginning of appendicitis, it is impossible to determine by any known method the cases which will safely pass through the initial attack and those which will perforate or become gangrenous has rightly placed the disease as a distinctly surgical one.

The physician, however, in the vast majority of cases, is expected to diagnose the disease and institute treat-

26. To appear in the Journal of Experimental Zoology; the experiments were briefly reported at the Association of American Anatomists at its meeting in Ann Arbor, December, 1905.

* Read before the Western Surgical and Gynecological Association at Kansas City.

ment until the patient and his friends agree to have a surgeon called. This frequently bodes delay, which makes it all important that the physician be capable of instituting the proper treatment until the arrival of the surgeon. That delay on the part of the physician (a) to make a correct diagnosis in appendicitis, and institute the proper treatment, (b) to promptly call the surgeon or refer his case to a surgeon, is productive of too great a number of cases of diffuse peritonitis, septicemia and pyemia as complicating pathology that it is the province of the surgeon to treat.

I believe that the many mooted questions of how best to treat the inflamed appendix until operative measures have been decided on have at last been well settled, and the treatment thus agreed on is the legitimate outcome of knowledge acquired from operative procedures during the different stages of the disease. Such knowledge, in connection with the proper understanding of the physiology of the peritoneum, the intestines, the mesentery and the great omentum has finally determined a rational treatment of the inflamed appendix, not with the hope of curing the pathology in the appendix, but rather for the protection of the general peritoneum.

It is necessary for the physician, in instituting treatment in appendicitis, to be thoroughly imbued with the following facts, which may be reasonably deducted from the present state of our knowledge of the subject: 1. The patient should be advised of the advantages of an early operation. 2. If this is impractical or will not be consented to, then treatment must be instituted to protect the peritoneum, the great source of danger to the patient, until operation is decided on or finally declined.

As no one is capable of predicting the course any case of appendicitis may pursue, whether to perforation or gangrene or to imperfect resolution, it is imperative that the early treatment in every case should be in anticipation of the occurrence of gangrene and perforation of the appendix and be directed toward the prevention of diffuse peritonitis. We should here interpret Nature's method of caring for the peritoneum, in the presence of infection within its cavity, viz., (*a*) by the formation of adhesions between the great omentum, intestines and appendix, (*b*) by the distention of the intestines and arrest of peristalsis, (*c*) by the rigidity of the overlying abdominal muscles and the underlying right psoas muscle.

It is the occurrence of the above-mentioned changes which effectually wall-in abscesses in perforative and gangrenous appendicitis, diffuse peritonitis being prevented. It is true that the above-mentioned phenomena do not occur in cases in which the inflammation does not extend through the lumen of the appendix, and are not always effectual in limiting the inflammation in perforative and gangrenous cases, but, until operation is decided on, I believe in assisting Nature's method of defense in every case.

The principles, then, of treatment should be the arrest of peristalsis in the small intestines and the maintaining of rest in bed. Peristalsis can be the most effectually arrested by abstinence from food and drink. Nourishment may be administered by the rectum. Posture may add something through the principle of gravity, so that we would place the patient in the improved Fowler position, that is, elevation of the head and left side of the bed. Lavage of the stomach should be practiced where vomiting is persistent. An ice bag placed over the region of the appendix for the first twenty-four or forty-eight hours will tend to relieve pain, but, should this measure fail, morphin should be administered hypodermically.

Cases thus treated from the incipiency of the attack, where early operation is declined, will have the usual percentage of perforation and gangrene of the appendix with walled-in abscesses, and as well the proportional number of cases of lymphatic infection with metastatic abscesses, but the proportional number of cases of diffuse peritonitis will be very much lessened.

WHEN TO OPERATE IN APPENDICITIS.

I am an advocate of the early operation in all well-pronounced cases of the disease, that is, within the first thirty-six hours. The dictum to operate as soon as the diagnosis is made may be dangerous, and should always be qualified, as the diagnosis may have been made too late for an early operation. When the case is seen too late for the early operation, as evidenced by the presence of circumscribed peritonitis or beginning diffuse peritonitis, then I would advise the abstinence from all food and drink, the instituting of rectal alimentation, the repeated administration of morphin to allay pain and the placing of the patient in the improved Fowler position. Such a plan of treatment, if rigidly carried out, will, in my opinion, safely carry a large number of cases through the first attack, and an interval operation can be made. A small percentage of such cases will have gangrene of the appendix, perforation and abscess formation, which will in most instances under such a course of treatment become walled-in, and operation may be deferred until the subsidence of acute symptoms. The fact that no one can be capable of diagnosing the extent of the pathology in and surrounding the appendix from the symptoms present, or, from any method of physical examination that can be instituted, in cases of appendicitis seen by the surgeon too late for an early operation, has led to the adoption of different methods of treatment, and it is this class of cases in which the greatest diversity of opinions exist among surgeons as to the best method of procedure.

In cases tending to abscess formation, the prevailing practice is to defer operation until the walling-in process has occurred. It has been quite well demonstrated that the pus tends to become less virulent from day to day and has been found sterile at operation. In perforative appendicitis, if the patient is in a hospital, or can be removed to a hospital within a few hours, immediate operation should be performed. However, when operation is delayed until progressive peritonitis is evident, then I would not advise operative interference, but would adopt the treatment heretofore mentioned, believing it to be more effectual in limiting the inflammation.

OPERATIVE METHODS AND TECHNIC IN ABSCESS CASES.

The question of how best to remove pus from a walled-in abscess within the peritoneal cavity successfully, without contaminating the general peritoneum, is still one of the problems in abdominal surgery. The location of the abscess, whether postcecal and extending high up behind the ascending colon, or reaching low down in the pelvis, or located anteriorly high or low in the abdomen, will determine to some extent the selection of a method of procedure. We are also confronted here by two distinct propositions—to perform drainage as a life-saving measure without the institution of complete work and to drain, remove the appendix, or, if the appendix has sloughed off, to close the opening in the cecum. The first is a mere life-saving measure, the sec-

ond radical complete work. I think I am correct in saying that the tendency is growing in favor of radical complete work, and the more competent the surgeon the more often is he able to do successful radical work. That there is, however, a certain number of abscess cases, in which the most competent surgeon would be content to do a mere drainage operation as a life-saving measure.

THE TECHNIC OF OPERATING THROUGH AN ABDOMINAL INCISION IN ABSCESS CASES.

I believe in the vast majority of abscess cases that a three- or four-inch incision along the outer border of the right rectus muscle is the best avenue of approach.

Through such an incision the abscess can be very well surrounded with pads of moist gauze and, whether adherent to the parietal peritoneum or not, can be evacuated with but little danger of infecting the general peritoneum. With such a technic one can the better do complete work, that is, search out the appendix and remove it, drainage being established through a stab wound in the flank, and the abdominal incision permanently closed. I do not favor the practice of cutting down immediately over the abscess site, unless mere drainage is aimed at or the abscess fills the greater part of the right side of the abdominal cavity. Through such an incision one must trust almost altogether to his dexterity in operative manipulation, and is never quite sure that he has not broken through the wall of protective adhesions in attempting to do complete work. While it is many times possible through such an incision to pad off the abdominal cavity satisfactorily, it can be done better through the above mentioned incision. In postcecal abscesses I prefer the incision along the outer border of the right rectus muscle, unless mere drainage is practiced, when the flank incision and postperitoneal drainage may be made; or in exceptionally favorable cases reaching well down in to the pelvis, drainage through the rectum may be practiced.

DIFFUSE PERITONITIS.

The aim of treatment in beginning diffuse peritonitis should be toward the arrest of the spread of the inflammation. It is here that surgeons differ very much as to the best method of procedure. Deaver, Morris and many other prominent surgeons recommend in this class of cases immediate operation, and this is probably the most universal practice. However, Ochsner pointed out a method by which the inflammation could be arrested by the walling-in process, in probably 90 per cent. of such cases, which would place them under the same category as abscess cases. In my judgment, the Ochsner plan of treatment is based on the proper interpretation of Nature's method of protecting the peritoneum, and as a general method of treatment I believe it to be the best.

It is also my opinion that many of the reported successes from operation in diffuse peritonitis originating from the appendix in reality have been cases in which only the right iliac and middle abdominal regions were involved, the inflammation being circumscribed. Diffuse peritonitis due to an infection from the appendix is usually of the purulo-gangrenous variety, and is very likely to become limited to the lower two-thirds of the abdomen.

It is evident at operation in diffuse peritonitis and at postmortems on these cases that Nature has most usually made some effort at limiting the progress of the inflammation by the formation of adhesions of the intestines and omentum. Nature should be assisted by favoring the arrest of peristalsis and by posture, operative procedures being deferred to a later period. Such cases will not all recover, but a larger percentage, I believe, will be saved than by operative procedures during the progressive stage of the inflammation. The operative technic in these cases should be identically the same as in large abscess cases, viz., incision and establishment of drainage.

CONCLUSIONS.

1. In incipient appendicitis, until the patient is placed in the hands of the surgeon, all food and drink should be withheld and the patient nourished by the rectum.

2. Every patient should be advised of the advantages of an early operation.

3. Radical work, that is, the removal of the appendix or closure of an opening in the cecum, should be done in abscess cases, when it can be done without additional risk to the life of the patient.

4. The practice of merely draining in every abscess case should be condemned as non-surgical.

5. Operation during a progressive diffuse peritonitis will be attended with a higher mortality than the method of procedure I recommend.

6. If the physician would direct his efforts, in the treatment of appendicitis, toward the protection of the peritoneum, until he could transfer his case to the surgeon, the mortality in this disease would be greatly lessened.

7. The adoption of the more rational method of dealing with diffuse peritonitis will convert a large percentage of these cases into circumscribed peritonitis, when they can be rightly classed as large abscess cases, having the same mortality rate.

AN OPERATION FOR PYOSALPINX WITHOUT LIGATURE, CLAMP, ARTERY FORCEPS OR BLEEDING, BY OVERTHROW PROVISIONAL SUTURE METHOD.*

REPORT OF FIFTY-NINE CASES WITH ONE DEATH.

W. D. KELLY, M.D., Ph.G.
ST. PAUL, MINN.

Pyosalpinx, or pus in the tube, is the result of an inflammatory action in and about the tube, due to an infection.

ETIOLOGY.

The most frequent causes of pyosalpinx are: Abortion or miscarriage, gonorrheal infection, tubercular infection, infection with the *Bacillus coli communis, streptococcus* or *staphylococcus* or infection through trauma or extension to tube of an appendicitis.

PATHOLOGY.

If the tube is infected from its proximal end, the mucous membrane is congested and distended with blood, thereby encroaching on the lumen of the tube. The infection is then advanced by this condition of affairs to the ampulla and then to the distal end of tube. Each and every extension causes or will cause what is spoken of by the patient as "cramp" or shooting or boring pains in the ovary. This condition is frequently spoken of by the physician as an "ovaritis," and if the patient becomes remonstrative her case is diagnosed as neurasthenic, hypochondriac or hysteric.

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association at the Fifty-sixth Annual Session, July, 1905.

The fimbriated end of the tube is approximated by omentum, and this may become sealed against the tube and thus keep the inflammatory action within certain limits. When the tube is patulous, the infection spreads to the peritoneum and is accompanied by a local or general peritonitis. This condition tends to draw the uterus inward and downward until the distal end of the tube and ovary, in the majority of cases, is found deeply fixed in the pelvis, posterior to the uterus and filling up the Douglas pouch.

I have performed the following operation for several years: After opening the abdomen, the patient is placed in the Trendelenburg position; the bowels, if possible, are pushed back; if adherent, they can be dissected free with a dry sponge and then pushed back. The general cavity is walled off with one or two large strips of gauze. Bleeding from bowel or omentum, if any, should be sought for and vessels and tissues sutured, if necessary. The broad ligament is sought for and the finger is invaginated between the ligament and the mass and the tube partially freed at the distal end.

The index finger is then forced between the broad ligament and the tumor. A cutting needle, half curved, with No. 3 pyoktannin, is passed between the mass and the broad ligament on to the finger, and the broad ligament is tied off. Scissors are used to sever the tissue between the broad ligament and tube. The finger is still further advanced, and an overthrow provisional suture, which usually includes the ovarian artery, is taken in the broad ligament.

The separation of the mass is continued by the farther advancement of the finger; application of another provisional suture, and the severing of the mass from the broad ligament with the scissors, a little at a time. Immediately on severing the tissue the provisional overthrow suture is tightened, thus preventing hemorrhage. In the majority of cases it is well to put in the provisional Billroth suture before severing the artery. The finger is still farther advanced toward the uterus, and the broad ligament is severed as before described, following the provisional suture until the horn of the uterus is reached. The provisional suture is placed in the uterus, an elliptical incision is made, and the tube is removed from the uterus and the suture tightened. Another suture, if necessary, is imbedded in the uterus and tied. The uterus is then grasped with the hand and elevated, if possible. If not, an attempt is made to separate the adhesions directly behind the uterus, and in this way gradually to shell out the mass from before backward. It may be necessary to tie off some omentum or bands of adhesions.

I do not hesitate to operate in acute cases of pyosalpinx if the tube can be felt free in the pelvis. An anesthetic is used at the first examination. In 59 cases I succeeded in saving 51 or 52 specimens, and at a meeting of the pathologic section of the Ramsey County Medical Society I had the pleasure to show 39 specimens, all of which were intact and not opened or ruptured in any way and still containing large quantities of pus; the pus noted in the recording of my cases by my assistants and internes as a ruptured tube or ovary was found to be an extratubal or peritubal abscess in almost every instance except tubes or ovaries that were so macerated as to tear in making a dry dissection.

My reasons for reporting the following operations in detail are the different conditions, features and complications found.

CASE 1.—Mrs. J. O. D., aged 30, American.

History.—There have been repeated attacks of pain in the right lower quadrant of abdomen. She has had a discharge of pus from the bowel on two occasions following these attacks. While under my care, she passed large quantities of pus in the urine; this condition remained for thirty-six hours during the first attack and about one day longer in the second attack. In neither case was there any pain in urination or any amount of blood that I could detect with the naked eye in the urine; the discharge was not offensive.

Operation was not consented to until the beginning of another attack, which occurred about three months after previous attack.

Operation.—I made an incision in the median line, and found the omentum adherent to the anterior abdominal wall, completely hiding from view the contents of the abdomen. I began to separate the omentum at or about the junction with the bladder; immediately beneath I found the bladder adherent to several loops of gut; I stripped off the gut and came on several large broad bands, which at first appeared to be a portion of the bowel. Finally I cut through and tied off several long strips of dense adhesions, with several pieces of omentum. This brought me to what I supposed was the tube; after separating more adherent bowel and clearing up the field of operation I opened into an abscess cavity which extended up over the brim of the pelvis to the junction of the large and small bowel; the tube was then located in its usual pathologic position and removed as before described.

Deep in the pelvis was an abscess which was completely walled off by a membrane which was semitransparent. The pus could be seen plainly, moving with each effort the patient made while breathing, and snugly encased in its capsule. I punctured the capsule with my finger, mopped the cavity dry, and inserted a long, narrow, loose gauze drain; I did not sew up the abdominal wall, excepting two sutures in the peritoneum.

There was considerable shock, necessitating injections of saline solution; strychnin, gr. 1/16, was given hypodermically.

Patient made uneventful recovery.

CASE 2.—Mary McC. Sept. 21, 1899, aged 18, domestic, single.

History.—About six months ago the patient began having pain with monthly flow, which was excessive in quantity. She says she had yellowish discharge from the vagina last winter, accompanied with pain in her side; she was confined to her bed about three weeks during this attack; at the present time there is a yellowish discharge from the vagina, which began about two weeks ago, accompanied by considerable pain in the left side. Patient has been confined to her bed for one week.

Diagnosis.—Single pyosalpinx (left).

Operation.—Three-inch incision was made in the median line; hemorrhage was slight. The right tube was cystic. The tumor was the size of hen's egg and was aspirated; right ovary was normal; neither tube nor ovary were removed. The left tube was distended with pus and densely adherent to all surrounding structures.

The tumor was aspirated and about 100 c.c. of pus evacuated; the ovary was somewhat enlarged. Adhesions were broken up and the tube and ovary removed; the stump was cauterized with the actual cautery, and peritoneum sewed over the stump. Several small cysts along the tube were opened and drained. The wound was packed with sterile gauze and partially closed with silkworm gut.

The patient received two hypodermic injections of strychnin, gr. 1/20 each, while on the table, and an enema of one quart of salt solution immediately after operation.

There was considerable shock, but the patient rallied well. She was discharged, well, Nov. 8, 1899.

CASE 3.—Miss G., aged 21, American, single. July 10, 1899

History.—Patient complained of backache, general malaise, bearing down and localized pain in pelvis. Menstruation was irregular and profuse. She had leucorrhea, with a very offensive discharge. The uterus was retroflexed, pushed over to the left side and fixed laterally and posteriorly.

Operation.—Medium incision was made. The uterus and adnexa were in the bottom of the pelvis. The appendix was

found to cross over the brim of the pelvis and to imbed itself in the mass. An attempt was made to separate the appendix from the mass, which was successful only after removing the proximal end by cuff and purse-string method. The right tube and ovary were removed by method described; no shock; no bemorrhage. Patient left hospital, well, Aug. 12, 1899, with exception of some leucorrhea, which has since disappeared.

Case 4.—Mrs. M. N., aged 24, American. Aug. 5, 1899.

History.—She complained of pain in both sides and was constipated. There was pain on urination. She was hysterical. The history was given me by her family physician. He said she complained of everything aching and paining.

Examination.—Examination showed gonorrheal urethritis, offensive leucorrhea and aggravated retroflexion. The finger in the vagina encountered a solid, resisting mass to the left of the median line, which proved to be the fundus of the uterus. There was a large, resisting mass in the right iliac pelvic region.

Operation.—Oöphoro-salpingectomy and appendectomy. The abdomen was opened in the median line. The appendix could be plainly seen passing downward and losing itself in a large mass on the same side. I began to free it and found an appendix 6½ inches long, adherent to the lateral and posterior walls of the uterus. The tube was removed in usual manner, after rupture of ovary, containing pus. The cavity was dried in the usual manner. Patient made an uneventful recovery and was discharged Aug. 23, 1899.

Case 5.—C. S. was admitted to hospital Sept. 3, 1899, aged 26, single, clerk.

History.—Patient menstruated last three months previously. Ulcers were noticed on labia and on vagina. Purulent discharge was present. In July there was a general eruption all over the body, with headache and pains in the bones.

Diagnosis.—Tertiary syphilis, cystic ovaries, double pyosalpinx, specific panophthalmitis, with glaucoma adhesions.

Operation.—Double oöphoro-salpingectomy. An incision was made in the median line above the pubes. The wound bled profusely and the hemorrhage was controlled with some difficulty. Right ovary was somewhat cirrhotic and prolapsed; left ovary was cirrhotic, and tube thickened and distended. The tubes and ligaments were ligated close to the uterus. Ovaries and tubes were excised and the stumps sewed over with fine catgut. Adhesions of the broad ligament to the ovary were broken up. The wound was closed with catgut and a Halstead subcuticular suture of silkworm gut. She was discharged, improved, Nov. 24, 1899.

I examined patient about a year after operation; she had gained twenty pounds in flesh and was feeling, as she expressed it, very well.

Case 6.—M. M. was admitted to hospital Sept. 21, 1899. Age, 28; married; housewife.

History.—The patient has always enjoyed good health. She has had two normal labors and one miscarriage two years ago. She began to have a discharge from the vagina several weeks ago, followed shortly by pain low down in the abdomen on both sides. Menstruation was regular; the last time it was somewhat painful.

Examination.—Patient was well nourished, the tongue was clear; chest, heart, and lungs were normal. There was tenderness on deep palpitation over both ovaries; the abdomen was somewhat rigid; the uterus was fixed posteriorly and deflected to the left side. A tumor was distinctly felt in the right side.

Diagnosis.—Double salpingo-oöphoritis.

Operation.—A median incision was made about three inches long, beginning one inch below the umbilicus; the recti muscles were separated and the peritoneum opened. The right tube and ovary were found thickened and prolapsed into the cul-de-sac; the ovary was cirrhotic. The adhesions were extensive, especially to the sigmoid on the left side. By separating the tube from the sigmoid, a small abscess was opened and the tube and ovary were freed. The broad ligament was tied off and stitched over with peritoneum. The tube and ovary were removed and the right tube and ovary were freed and brought up into the wound. The tube was separated from the broad ligament by overstitching with the Billroth suture and tube and ovary were removed. The cavity was dried and closed with interrupted sutures of catgut; the skin was closed by subcuticular sutures of silkworm gut. The patient made an uneventful recovery and was discharged well Nov. 10, 1899.

Case 7.—J. D., aged 23, married, was admitted to hospital July 6, 1900, and operated on July 14, 1900.

History.—The patient always had been sickly and had a great deal of headache. She had kidney and liver trouble. Three years ago she had a very bad cold and was treated by a physician. She had diphtheria when 12 years old. On May 2 she gave birth to a child; labor was normal. She remained in bed two weeks, got up and went to her physician at his office. He made an examination and found lacerations of vagina and cervix; he said he could not operate until discharge ceased. He gave one treatment and the patient, after being up three weeks, was compelled to go to bed again. She complained of severe pain in right ovarian region. Her appetite has been very poor and bowels irregular; she had to take cathartics.

Diagnosis.—Retroflexed uterus, pyosalpinx, (double) rectocele, cystocele.

Operation.—Double salpingectomy and appendectomy. An incision about three inches long was made in the abdominal wall down to peritoneum. The peritoneum was picked up and a small incision made. Fingers then inserted and the peritoneum torn open. The bladder,uterus, appendix and intestines were found firmly united by adhesions. The appendix was picked up and found to be adherent to posterior wall of the uterus; it was removed by being tied off with catgut, and the serous membrane was then stitched over it. The adhesions were broken up between the intestines and the Fallopian tube; by so doing, the tubes gave way and allowed from two to four ounces of pus to escape into the abdominal cavity, which was sponged out with dry sponges. The tubes were separated from the surrounding structures and tied off with catgut and removed. The peritoneum was sutured with a running suture of catgut; the muscles were approximated with catgut sutures; the skin with subcuticular silkworm catgut suture. There was considerable shock and hemorrhage. Patient was discharged, well, Aug. 22, 1900.

Case 8.—A. S., aged 34, married, was admitted to hospital July 9, 1900, and operated on July 12, 1900.

History.—Patient has had three children and has always been in good health. While going upstairs four days ago she fell and struck against a pail; she was pregnant at the time. Pain of injury seems to have been down in the left iliac region.

Diagnosis.—Pyosalpinx (left).

Operation.—Single salpingo-oöphorectomy and appendectomy. A median incision was made about four inches long. Intestines, bladder, tubes and uterus were found to be all adherent. Adhesions were broken up by dry dissection, using sponge on finger. The right tube was freed and examined; it was somewhat enlarged. It was aspirated, but, as no fluid was found, it was replaced. The appendix was found deep in the pelvis and brought up, and the serous coat was stripped back, forming a cuff. The mesoappendix was cut away and overcast with running suture of No. 2 plain pyoktannin catgut; the appendix was clamped and cut off; the stump was cauterized with 95 per cent. carbolic acid, followed by alcohol, turned in and a purse-string suture put round cuff and drawn tight; No. 2 pyoktannin catgut was used. The left tube was much enlarged and firmly adherent, deep in the cul-de-sac. In freeing the tube an abscess was opened, allowing a fluid to escape; this was sponged away, the fimbriated extremity brought out, and ovary and tube cut away. Small cuts were taken and each one followed by overcasting the stump with a running button-hole stitch. Skin wound was closed with subcuticular stitch of silkworm gut. The patient was given an enema of warm oil and whisky. Recovery was uneventful. Patient was discharged July 19, 1900. No symptoms of miscarriage.

Case 9.—S. C. was admitted to hospital July 15, 1900, married, aged 20.

History.—Patient was well until one and one-half years ago. She had a child at full term previous to admission to hospital. She remained in bed three weeks after confinement, since which

time she has been well up to one week ago, when she began to have pain in the left lower abdomen, with weakness and loss of appetite. A slight bloody discharge from the vagina was present. First menstruation since confinement occurred one week ago; it was profuse and painless and lasted four days.

Diagnosis.—Lacerated perineum and cervix; postparametritis; left tubal abscess; subinvolution; granular endometritis.

Operation.—Left salpingo-oöphorectomy. There were very extensive adhesions found between the left ovary and tube and intestine; they were tied off and removed; the abscess was aspirated. The left ovary and tube were removed by ligaturing, beginning at the horn of the uterus; the tube was excised and the peritoneum sewed over stump and raw surface. Hemorrhage was severe and was counteracted by hypodermoclysis, strychnin and rectal enema. Shock was very severe. About two ounces of pus were removed August 10. Lobar pneumonia developed in the upper left lobe. Patient was convalescent August 22, and was discharged, well, Aug. 29, 1900.

Case 10.—A. Y., aged 21, single, was admitted to hospital May 9, 1901, with a diagnosis of right pyosalpinx.

Operation.—The right tube and ovary were found to have fallen down in the cul-de-sac of Douglas and to be lying somewhat behind the left tube and ovary. The right tube was enlarged to about the size of a man's finger; the ovary was somewhat enlarged and lobulated. The broad ligament was tied off with pyoktannin catgut and the stump stitched across, as the tube and ovary were removed with scissors. The vermiform appendix was found on examination to contain a small particle about the size of a grape seed. The mesoappendix and appendix were tied off and the appendix removed, the stump being stitched over by the cuff method. The peritoneum was dissected off and rolled down. The appendix was cut off and cauterized with actual cautery; the cuff was then stitched over the stump and a few more stitches of catgut put into the mesoappendix and vermiform appendix stump. There was some hemorrhage from a small artery in the mesoappendix; this was tied off with catgut; the peritoneum closed with a catgut suture, muscles with the same, skin and superficial fascia, subcuticular silkworm gut. There was slight hemorrhage, but no shock. Patient was discharged, well, Aug. 26, 1901.

Case 11.—A. H., aged 28, married, was admitted to hospital Aug. 4, 1903.

History.—Patient has had three children; two are living. She has had two miscarriages; the last one occurred about two years ago. Last child was born in 1897. About four months ago she had chills and severe headache; these chills were of short duration at first, but are longer now and more frequent; she does not have as much headache now as a few months ago; she says she has had a pain in the left iliac region for the past ten years and pain in region of spleen, which radiates toward the back, produced by pressure in the first place. She complains of pain starting in the left iliac region and radiating down the inner side of the leg to the toes, and also complains of pain in right lumbar region for the past two weeks. Menstruation has not been regular; sometimes it is early and sometimes late. In July there was not much, but in August the flow commenced a week and a half sooner than it should and lasted just two weeks. The amount was excessive in quantity, dark in color, containing clots.

Diagnosis.—Salpingitis, pyosalpinx.

Operation.—Salpingo-oöphorectomy. An incision was made in the median line, about 2 inches below the umbilicus and extending 2½ inches toward the pubes; the fibers of the rectus muscle were separated and the fascia, thus exposing the peritoneum, which was grasped with dissecting forceps and an opening made the size of the external incision. Numerous adhesions were broken up and the uterus and left tube were found adherent to the bladder; the left tube contained an abscess and about two ounces of pus aspirated. The abscess was of the tubo-ovarian variety, and, the ovary being much involved, it was deemed advisable to perform salpingo-oöphorectomy. A suture of pyoktannin catgut, No. 2, was employed and a quilt suture was used to stitch the broad ligament and to control hemorrhage. Great care was necessary so as not to injure the bladder, as it was closely united to ovary, tube and uterus; on the latter it was united nearly to the center of the fundus. The intestines were walled off by sponges to avoid general infection of peritoneal cavity; the cavity was thoroughly swabbed out and the peritoneum sutured with pyoktannin catgut, No. 2, quilt suture. The fascia and the muscles were approximated with like suture material and like stitch, the skin was closed with subcuticular stitch of silkworm gut and a dry gauze dressing was put over wound. Patient was discharged, well, Aug. 29, 1903.

Case 12.—K. P., aged 22, single, was admitted to the hospital Aug. 20, 1900.

History.—The patient was well till three years ago; since then she has been in hospital twice with present trouble. Three years ago she awakened at night with severe pain in the right iliac fossæ; she had chill after chill, followed by profuse sweating; she vomited, but got better in the morning; she remained in bed three days and then came to the hospital, attended by her physician; she improved and went home; six months later she returned to the hospital with the same trouble; in two weeks she again went home, since which time she has never been well. There were dragging pains in the right side; painful urination and defecation. A vaginal discharge was present, white and watery at first, later becoming thick and yellow.

Diagnosis.—Left pyosalpinx; anteversion of uterus.

Operation.—Salpingo-oöphorectomy. Right ovary was cystic. The tube was excised, tied at end and sewed up with catgut; one ligature was inserted. The left ovary and tube were found diseased and bound down to the uterus and intestines by very extensive adhesions. The left ovary and tube were removed. On examination the right ovary was found cystic and was resected. Appendix was normal. There was no hemorrhage nor shock. Patient was discharged, well, Sept. 10, 1900.

Case 13.—E. L., aged 33, widow, was admitted to hospital Aug. 26, 1902.

History.—About two months ago the patient says she lifted hard and felt as if something gave way within her abdomen. For two or three days after this happened she had burning pain across the lower abdomen. She says she had a fever and pain which gradually grew worse. About a week later she began to vomit; the vomiting caused her a great deal of pain. She says that pains are sharp and that they are getting worse and worse; she has not slept well at night for past two weeks. Abdomen was swollen and very tender. She has been regular in her menses, but flowed more than usual. She has had considerable pain during these periods, but more of late. She has not menstruated for two weeks and had a slight vaginal discharge day before entering hospital. She had a great deal of pain in the region of the bladder and was unable to urinate for two or three days. She was catheterized several times.

Diagnosis.—Gonorrheal salpingitis; tubo-ovarian abscess.

Operation.—Double salpingo-oöphorectomy. The fundus of the uterus was found bound down to the intestines with adhesions which had to be dissected away. After the fundus was free the tubes and ovaries were removed. The operation was attended by considerable hemorrhage. There were adhesions to bowel and rectum. The bowel was opened into by separation of adhesion. The wall of the abscess by pressure had produced atrophy of the wall of the bowel; in fact, the mucous membrane was all that prevented opening of the abscess into the bowel. The gut was resected and a Murphy button applied. The patient was discharged, well, Sept. 30, 1902.

Case 14.—D. E., aged 18, single, was admitted to hospital Aug. 23, 1902.

History.—The patient had had diphtheria and measles. She had had rheumatism and was confined to bed all winter. About a month ago she was taken ill with pain across the lower abdomen. Abdomen was tender and somewhat swollen. She said that pains seem to go down into legs and that during the attacks of pain she vomited several times. Pains were sharp and her head and back ached. Those symptoms, except the vomiting, kept up more or less until she entered the hospital. She said that her hands and feet are always cold and clammy. She does not sleep well.

Diagnosis.—Gallstones, gonorrhea, pyosalpinx, appendicitis.

Operation.—Laparotomy; salpingectomy; appendectomy.

The appendix was found curled on itself and adherent to the uterus. The left Fallopian tube was found to be inflamed and reddened. It was taken up with a purse-string suture of pyoktannin catgut, first being freed from intestinal adhesions. The tube and ovary were excised; the broad ligament being tied ahead of them, with a running suture of pyoktannin catgut. The appendix was freed from its mesentery and the serous membrane incised circularly with a knife about one-quarter of an inch above the attachment to the intestine; it was ligated close to this attachment and cut off where the circular incision was made. The stump was cauterized with carbolic acid and alcohol; a purse-string suture of pyoktannin catgut taken round it and the stump inverted and suture drawn. The patient was discharged, well, Sept. 30, 1902.

Case 15.—A. W., aged 28, single, was admitted to hospital July, 1903.

History.—In the past three years she has been troubled with pains in her pelvis. She began to menstruate and has had discharge ever since. She does not flow much during the menstrual period. About a week previously she began to have chills and sharp pains in the lower part of abdomen. She was in bed two days; then got up and pain began in back, which at last localized to one spot with a burning sensation. This was on the right side. Bowel movements caused pain.

Diagnosis.—Pyosalpinx and ovaritis of right side.

Operation.—Laparotomy: Salpingo-oöphorectomy. An incision was made in the median line, about four inches long, between the umbilicus and the pubes. Intestines, right tube and uterus were matted together in Douglas cul-de-sac, and the appendix was adherent to the tube. Adhesions were gently broken up. The tube was twisted and kinked, being very thick and irregular nearest the uterus; a pyoktannin, No. 2, ligature was passed round it, near the uterus, and tied and the uterine attachment cut. The ovary was grasped with a pair of forceps, but its pedicle was torn and the ovary was removed and torn. The pedicle was sutured with No. 2 pyoktannin catgut and the suture continued along the broad ligament at the uterine attachment, which was cut loose. The suture was continued by a needle passed through a loop of the preceding stitch. The mesoappendix was cut and then sutured in the same way as the broad ligament, and the peritoneum of the appendix was incised all around at the base and folded down as a cuff; the appendix was ligated about one-quarter of an inch below with the same kind of catgut and then cut a short distance from ligature, the end being touched first with 95 per cent. carbolic acid and then with alcohol. The open end was closed with No. 0 pyoktannin catgut and the peritoneal cuff folded over the end and sutured with the same. The peritoneum was closed with continuous suture, No. 2, and fascia and muscles in the same way. The skin was sutured with subcuticular silkworm gut. After closing it the line of suture was irrigated with hot normal salt solution. The patient was discharged well Aug. 22, 1903.

Case 16.—A. F., aged 22, married, was admitted to the hospital June 24, 1903.

History.—The patient has had one child, which died when 4 days old. About two weeks ago she had severe pains in the lower abdomen on both sides. About five days ago pains on left side stopped, but pain on right side persists. She says that when she urinates she has bearing-down pain on right side.

Diagnosis.—Double pyosalpinx (gonorrhea).

Operation.—Laparotomy: Salpingo-oöphorectomy. The abdomen was opened in the median line. On opening the peritoneal cavity, a large mass, consisting of adherent omentum, was brought into view. On investigation of the right ovarian region, another mass about the size of the first was discovered bound down with firm adhesions and lying more in the abdominal than in the pelvic cavity. This mass was separated from surrounding intestines, which later were walled off with gauze pads. Omental and intestinal adhesions were tied and cut. The pedicle of the mass was transfixed with needle, tied off with pyoktannin catgut and cut. The mass was lifted up, but ruptured before it could be removed. It proved to be a tubo-ovarian abscess, containing almost a cupful of yellowish pus. The pus was sponged out; the stump and edges of the broad ligament were brought together and sutured, a running suture of catgut being introduced. These stitches tore out and later had to be reintroduced. The left side was investigated and another tubo-ovarian abscess was found and treated in the same way, except that a portion of the ovary was dissected from the mass and allowed to remain. The pelvic and abdominal cavities were sponged dry; the peritoneum was closed with catgut. Muscle, fascia and aponeurosis were closed with Billroth's chain suture, pyoktannin catgut being used. The skin was closed with subcutaneous stitch of medium silkworm gut. Patient was discharged, well, Aug. 31, 1903.

(To be continued.)

DIAGNOSIS OF AFFECTIONS CHARACTERIZED BY INTESTINAL OBSTRUCTION.

G. PAUL LA ROQUE, M.D.

Lecturer and Bedside Instructor in Surgery at the University College of Medicine.

RICHMOND, VA.

Since the clinical phenomena presented by incomplete or partially obstructive lesions in this tube are referable, rather to the nature and location of the lesion than to obstruction, these affections will not be studied in this paper.

Complete obstruction to the passage of the contents of the intestinal canal is generally characterized clinically by the symptom-complex of an acute affection. The causative lesion, however, may be of acute (sudden) or chronic (slow) development. In accordance with the underlying clinically recognizable etiologic factor, the different varieties of acute intestinal obstruction (ileus) may be classified as (1) dynamic ileus and (2) mechanical obstruction.

1. *Dynamic Ileus.*—This is due to peristaltic paralysis either of the entire intestine or of a segment of gut and is typified by the absolute intestinal obstruction incident to general peritonitis. It is not rarely due to mechanical and chemical irritation of the peritoneum, such as is incident to extensive operations about the mesentery, vigorous toilet of the peritoneum, prolonged rough handling, chilling and exposure of this structure and was common in the days of antiseptic abdominal surgery under the use of carbolic acid spray and other antiseptics in the peritoneal cavity. Contusion of the peritoneum due to external violence is a cause. It may also result from excessive meteorism due to enteritis. Intestinal paresis may result from splanchnic and spinal nerve degeneration, cord injury, and is a common terminal condition often directly causative of death in certain systemic diseases, particularly pneumonia, uremia, meningitis, typhoid fever and others, and especially when associated with delirium, unconsciousness, coma and excessive pain and other symptoms which at the same time divert the attention from the abdomen and predispose to constipation and to meteorism. In mild form transient paretic ileus is noted after the removal of large abdominal tumors and ascites, and is the rule after childbirth. The temporary reflex intestinal paresis incident to injury of a testicle, operative procedures about the anus and rectum, during a paroxysm of severe renal, ovarian, biliary or pancreatic colic, and often conspicuous in the symptomatology of these affections, is non-progressive is severity and transient. In many cases of mechanical obstruction, particularly when due to strangulation, there may be initial reflex paresis of the entire gut, though the proximal portion soon recovers and becomes hyperactive against the strangulated para-

lyzed segment which constitutes a mechanical obstacle to peristalsis.

2. *Mechanical Obstruction.*—This may result from strangulation of a segment of intestine or its mesentery through occlusion of its blood vessels, the strangulated portion of gut constituting an obstacle to or solution of continuity of the peristaltic wave. It is typified by the ileus incident to mesenteric embolism and thrombosis, torsion of the mesentery, constriction of the blood vessels by bands, adhesions, hernial orifices and traction, and the early stages of incompletely occlusive invagination (intussusception). Mechanical occlusion, either by obturation or stenosis of the lumen of the intestine, is the typical cause of mechanical obstruction. Obturation results from impaction of gallstones, enteroliths, fecal material and innumerable varieties of foreign material introduced either by way of the mouth or *per anum*. Stenosis may result from stricture formation, cicatrical or neoplasmic in character, constriction from without by bands of peritoneal adhesions, any abdominal or pelvic tumor, distended and displaced organs and finally volvulus (torsion) or angulation (kinking).

I. DYNAMIC ILEUS.

Cardinal symptoms: (1) In all cases the signs of pseudoperitonitis or peritonitis are present and coincide with or antedate those of obstruction. (2) Absolute constipation to both feces and flatus exists, and with this (3) absent peristalsis. (4) Pernicious vomiting, becoming stercoraceous in character, supervenes. (5) Progressive uniformly distributed abdominal tympany becomes extreme. (6) Pain, at first, is that of the causative factor. As distention increases, general abdominal discomfort, costal breathing and shortness of breath are noted. These are ameliorated by belching of gas and evacuation through the rectal tube. True intestinal colic does not occur with absent peristalsis, though this symptom may precede those of obstruction. Other forms of colic must not be mistaken. When peritonitis is the cause (and this is the typical and most important variety of dynamic ileus) the pain of this affection antedates the signs of obstruction and continues till toward death. (7) Constitutional depression is generally conspicuous. Shock may exist as a coincident symptom or may be absent. (8) The urine is scanty, concentrated and contains an excess of indican if the condition is as much as twenty-four hours in duration.

II. MECHANICAL OBSTRUCTION.

The signs common to mechanical ileus may conveniently be enumerated in two groups, (A) strangulation; (B) obturation.

A. Strangulation Ileus: The signs of this condition are divisable into those of (*a*) strangulation *per se*, (*b*) peristaltic obstruction and intestinal distension, (*c*) gangrene of gut, (*d*) peritonitis.

(*a*) Strangulation *per se*.—(1) Sudden, violent, agonizing general abdominal pain is due to nerve irritation; (2) persistent nausea and vomiting are reflex in origin; (3) profound shock is noted; (4) peristalsis is commonly reflexly diminished in intensity or paralyzed. To these is soon added: (5) urgent desire to defecate, often to the degree of tenesmus. One or two good bowel movements may or may not occur, mucus and often blood are later ejected.

(*b*) peristaltic Obstruction and Intestinal Distention.—(6) Constipation becomes absolute to both feces and flatus; (7) nausea and vomiting increase in severity, becoming finally stercoraceous. (8) Intestinal tympany is first noted in the segment of gut strangulated, later in all the intestine above this seat. Distention of the distal portion of the bowel does not occur. (9) Exaggerated peristalsis is often visible, always audible as tumultuous sounds. (10) Pain is distinctly colicky in character and presents remissions and exacerbations in intensity.

(*c*) Gangrene.—With this there is: (11) shock or collapse; (12) diminution, often subsidence of pain; (13) enfeebled but still present peristalsis; (14) foul breath, coated tongue, headache, rise of temperature to normal or slightly above. These are all due to absorption of toxines (stercoremia).

If unrelieved these symptoms are soon followed by:

(*d*) Peritonitis—This is caused by intestinal permeability, perforation or rupture, and is heralded by (16) sharp pain (may be absent); (17) reflex rigidity; (18) fever; (19) leucocytosis; (20) all the signs of dynamic ileus (see above); (21) soon the evidence of free fluid in the peritoneal cavity; (22) peritoneal facies.

B. Obturation Ileus: The signs of this are divisible into local obstruction to the lumen of the gut, proximal distention, stercoremia (autointoxication), intestinal rupture. In this condition we note: (1) Constipation. This is sudden and generally absolute, though the lower bowel may be emptied. False diarrhea may occur. (2) Intestinal colic. (3) Exaggerated peristalsis is visible and audible. (4) Proximal progressive tympany; and (5) nausea and vomiting are all pronounced, progressive and finally vomiting becomes stercoraceous. (6) Foul breath, coated tongue and moderate rise of temperature. (7) Finally, the signs of intestinal rupture are engrafted and the clinical picture radically altered. Distention becomes uniform and peristalsis paralyzed. The patient, if conscious, may have felt a sensation of rupture. There is frequently a history of the administration of cathartics.

Given a case of mechanical intestinal obstruction, the following table will be useful in differentiating strangulation from occlusion:

TABLE FOR DIFFERENTIATING STRANGULATION FROM OCCLUSION.

STRANGULATION.	OCCLUSION.
A.—PAIN.	
Generally the first symptom. Sudden, violent, continuous, little chance to progress in severity, may subside with onset of gangrene. Due to nerve irritation.	A later symptom. Less sudden, less violent at first but progressive and paroxysmal. Due to intestinal spasm (colic).
B.—VOMITING AND NAUSEA.	
Initial symptoms, reflex in character, less definitely stercoraceous. Death may occur before feces are vomited.	Later symptom, due to overfilling of the canal. Stercoraceous material is sure to be noted in late stages.
C.—SHOCK.	
Sudden, pronounced and rapidly progressive.	May not be noted early and is of gradual development. Due to pain, autointoxication, sleeplessness, starvation and exhaustion.
D.—BOWEL ACTION.	
Peristalsis in earliest stages is reflexly diminished. False diarrhea with mucus and blood in passages may be noted in mesenteric embolism and in intussusception.	Peristalsis progressively increased from the beginning. False diarrhea is less rare and may be conspicuous. No blood in passages, though watery mucoid material may be ejected.
E.—INTESTINAL TYMPANY.	
Noted first in the loop of gut strangulated and then becomes general.	No circumscribed distention of loop, distention is general from the first.
F.—AUTOINTOXICATION.	
The signs of this are obscured by those of gangrene and peritonitis.	These signs are conspicuous long before peritonitis develops.
G.—CLINICAL COURSE.	
Always violently acute and rapidly followed by gangrene and peritonitis unless relieved.	May be acute, often chronic, with recurrent exacerbations dependent on the cause (see below). Peritonitis is late, gangrene may not occur.

Diagnosis of Cause of Mechanical Obstruction.

A. STRANGULATION.

In all cases of sudden abdominal pain with violent vomiting and constipation, especially after some sudden muscular effort as heavy lifting, all the hernial orifices must be examined. In one known to have a hernia, strangulation is the most probable cause.

Strangulated Hernia.—The obstruction symptoms are those of strangulation ileus (see above). Pain may be felt at the point of strangulation, the hernia becomes painful, tender, enlarged, generally irreducible, dull to percussion, the impulse on coughing is lost. If only the omentum is strangulated, constipation is less absolute. Sudden cessation of pain points to gangrene or to reduction. Strangulation must be differentiated from incarcerated and from inflamed hernia. In neither of the latter is impulse on coughing lost. In incarcerated hernia the gastrointestinal signs are of a mild imperfect obturation of the bowel. In inflamed hernia the signs are of local inflammation, with perhaps localized peritonitis, but never positive ileus.

On excluding strangulated external hernia the signs referable to the internal hernial orifices should be sought. Diaphragmatic, obturator, sciatic, duodenojejunal and retroperitoneal hernia must be suspected.

Diaphragmatic Hernia.—In this there are, in addition to the signs of strangulation ileus with little or no abdominal distention, the signs of suddenly developing pneumothorax, generally on the left side, without pulmonary or pleural cause. Vomiting is never fecal. Obturator and sciatic hernias are characterized by pain in the region of these orifices, often referred down the thigh. Tenderness may occasionally be elicited on rectal examination. These, together with retroperitoneal, duodenojejunal and other forms of internal hernias, are generally unrecognizable save as strangulation ileus.

Strangulation and Occlusion by Bands or Adhesions.—In about 70 per cent. of patients there is a history of previous peritonitis (due to appendicitis, salpingitis or previous abdominal section) though this may have to be interpreted from previous attacks of colic, etc., rather than by knowledge of the patient. It is extremely rare in childhood. The signs are of strangulation and mechanical ileus, with complete or incomplete occlusion (see above). Constipation is absolute; there is, as a rule, no tenesmus, nor is bloody mucus passed from the empty rectum. Stercoraceous vomiting is late. Distention is gradual and central (involving chiefly the small gut). A fixed, distended paralyzed loop of intestine may be discovered. The colon is apt to be empty and collapsed, causing lateral flattening as contrasted with central distention.

Mesenteric Embolism.—This form of obstruction is characterized by the signs of strangulation ileus, with intestinal hemorrhage, soon free fluid in the peritoneal cavity and occasionally a palpable blood tumor between the layers of the mesentery. There may have been no previous disease of the intestine and no signs of portal engorgement. There must be a source of embolism, i. e., cardiovascular disease, generally valvular in character, and signs of simultaneous embolism in other parts (lungs, spleen, joints, etc.) must be sought.

Intussusception.—In this affection the signs of strangulation ileus predominate, even though there be complete occlusion of the lumen of the canal. It is almost confined to children, appearing in the midst of perfect health, though dysentery and straining diarrhea may precede and predispose to the condition. Extreme meteorism is exceptional. Flatness in the region of the colon may be noted and in this situation a soft tumor may often be palpated. In rare cases the tumor may be of sausage shape, but this must not be expected. Occasionally the invaginated bowel may be palpated in the rectum or sigmoid. This must not be mistaken for the indurated circular rings incident to hypertrophy of the circular layer of muscle in the wall of the rectum attending chronic dysentery. Tenesmus is generally conspicuous, vomiting is exceptionally absent.

Volvulus is almost confined to individuals past middle age, generally the subject of chronic constipation. The large intestine is the portion involved. The sigmoid (left flank) is commonly the seat of a rounded, tympanitic, quiet tumor, and proximal intestinal distention rapidly becomes extreme. The signs are those of mechanical obstruction and constipation is absolute. Diarrhea, even of the false variety, is exceptional and passage of blood is rare. Tenesmus is common. Vomiting is occasionally absent.

B. INTERNAL OBTURATION.

The most common cause of this is fecal impaction. There are the signs of atony of the bowel. The patient is generally anemic and the victim of chronic gastric catarrh. Constipation for days before the onset of acute symptoms is the rule. The signs are of less rapid onset. Proximal distention and hyperperistalsis are marked. A doughy tumor may be palpated in the colon; rectal examination generally discovers a mass of hardened feces. There may be tenesmus and false diarrhea incident to irritative colitis (stercoraceous) or to channeling of the fecal mass. A high enema is generally curative.

Gall-stone Impaction.—This is rare. It occurs in individuals of gall-stone age and generally a history of cholelithiasis may be elicited. The signs are of mechanical occlusion. In rare instances a hard tumor may be felt in the situation of greatest pain. Should this tumor be made to alter its position in the gut or move downward spontaneously the diagnosis may be justified. A fluoroscopic examination may be useful, but not conclusive as a diagnostic measure. The signs may remit in intensity, and spontaneous passage of the stone in the large intestine is curative.

Impaction of Enteroliths.—This is causative of internal obturation. The diagnosis can be made only in rare cases, in which the mass can be palpated *per rectum*. X-ray examination may be positive or negative. Impaction of *other foreign bodies* can be recognized only when a positive history is obtainable or the material can be shown by *x*-ray examination.

Obstruction by Stricture Formation.—The diagnosis of this as a cause depends on diagnosis of the stricture. The signs are those of mechanical ileus. Obstruction occurs always in the large bowel and toward the anus. Syphilitic and tubercular stricture are found in the rectum and sigmoid. Cancer occurs at one of the curves. Constipation is rarely absolute. Mucus and blood in the fecal matter is frequent. Pain on defecation is present when the disease is located in the rectum or sigmoid.

Congenital Obstruction.—This is caused by imperforate anus, rectum or upper bowel, or by fistulæ between the gut and bladder, uterus or vagina. The symptoms of obstruction occur a few hours after birth. If the anus is imperforate the perineum bulges when the child cries. If the anus is formed a finger in the rectum notes bulging higher up in the pelvic cavity. If a fistula exists between the bowel, bladder or uterus, meconium may be discharged through these channels.

STUDY OF INDIVIDUAL SYMPTOMS.

While in many cases of intestinal obstruction the exact nature and location of the lesion can not be positively recognized before operation, the study of individual symptoms is helpful.

Pain.—This is due first to nerve irritation, later distention and congestion, finally peritonitis. It is generally first referred to the umbilicus, rapidly becoming general. It is colicky in character when obstruction is incomplete (due to spasm); constant and of short aching character when occlusion is complete (due to distention and congestion). Extreme tenderness and true rigidity, being due to peritonitis, are rare in early stages.

Collapse and Vomiting.—In acute cases these signs are due to nerve irritation, and when early severe they point generally to high obstruction, tight strangulation or pinching of the omentum. When occurring late, toxemia is the main cause and low obstruction is suspected. Frequently repeated, easy vomiting, with moderate uniform distention and oliguria, point to high obstruction. True fecal vomiting always means obstruction either in the lower ileum or colon or paralysis of the bowel from peritonitis. When occurring later, less urgent and slowly becoming stercoraceous, while abdominal distention is great, low obstruction or peritonitis is suspected. When obstruction is in the transverse colon the right loin is more distended than the left.

Constipation.—When this is absolute, even to flatus, it means complete obstruction and points to volvulus, acute strangulation by bands of adhesions or at a hernial orifice. In other causes of acute obstruction constipation may be incomplete. Tenesmus, with the passage of mucus and blood, generally points to location at least below the splenic flexure in individuals in middle age or past; to intussusception in children.

Central Distention with Flattening of the Loins.—This sign suggests a lesion of the small gut. Great lateral distention points to the transverse colon or sigmoid as the seat of disease. The greatest tympany is always above the obstruction.

Visible Peristalsis.—Hypertrophy of the muscular wall of the gut is indicated by this sign and is rare in acute obstruction. In all forms of mechanical ileus, peristalsis is greatly exaggerated on auscultation until peritonitis develops.

Rectal Capacity.—When the obstruction is at or below the sigmoid rectal capacity is diminished to one or two pints; when above this point the rectum may hold as many quarts.

A history of biliary colic suggests gall-stones as the cause; chronic constipation suggests impacted feces; previous peritonitis causes constriction from bands; tuberculosis, syphilis and dysentery cause obstruction by cicatricial contraction of healed ulcers. Typhoid ulcers do not constrict the gut.

In children the cause is most frequently intussusception. In middle and old age volvulus, bands and malignant disease are the causes. A doughy tumor in either colon points to fecal impaction, and this in every case must be excluded. In all cases the hernial orifices and rectum must be examined. Abdominal tumors must be sought. Often laparotomy is necessary to diagnose the cause positively.

Diaphragmatic hernia may give no abdominal distention, but signs of dyspnea, etc., aid the diagnosis. They must not be mistaken for pneumothorax.

DIFFERENTIAL DIAGNOSIS.

Mechanical obstruction must be differentiated from all forms of acute dynamic ileus. Particularly that due to torsion of the spermatic cord, acute epididymitis, injury of the testicle, violent paroxysms of ureteral colic (Dietl's crises). In all these the ileus is transient, being due to pain and is non-progressive. Acute pancreatitis, perforation or rupture of hollow viscera, rupture of an ectopic gestation sac, splenic infarction must not be mistaken.

All forms of intestinal obstruction must be differentiated from acute appendicitis, tabetic crises, acute dilatation and volvulus of the stomach. The pain and often bloody diarrhea attending visceral manifestations of the acute erythematous skin affections (Osler's disease) must not be mistaken for intussusception nor for mesenteric embolism.

Acute dilatation of the stomach has been observed after injuries sufficiently severe to cause paralysis of gastric motility, and in mild degree is seen as a result of paralytic overdistention. The cardinal sign is enormous distention as determined by physical examination. There are epigastric pain and tympanitic tumor. Vomiting occurs from overflow, but when the distention is gaseous from motor nerve paralysis this sign may be absent. Regurgitation of gas occurs and is productive of relief. The affection in severe form is extremely rare.

A few cases of volvulus of the stomach are on record. It is characterized by acute agonizing abdominal pain, most severe in the epigastric region, accompanied by shock, persistent violent nausea, with retching and vomiting of small quantities of material from the stomach. A tense tympanitic tumor in the epigastrium may or may not be discovered. Vomiting is never stercoraceous and constipation is not in any way characteristic.

Acute pancreatitis is characterized by sudden, violent, agonizing, shocking pain, most severe in the upper abdomen, attended by severe reflex vomiting. Abdominal distention rapidly occurs, beginning in the epigastric region, soon becoming general. There is epigastric rigidity and tenderness, and often if these two signs can be overcome a deep-seated mass may be palpated. Constipation generally exists at least temporarily, but is not absolute, and can be overcome. Steatorrhea is a later sign, glycosuria may or may not occur. There is generally moderate fever in spite of shock, and if the latter should subside the temperature rises higher. Dyspnea and cyanosis are often observed. Slight jaundice from co-existing catarrh of the biliary passages may be present. Unrelieved there occurs rapid gangrene, peritonitis and death.

The subjects affected are generally males about middle life who have suffered with chronic dyspepsia or obstruction biliary disease. Slight traumatism may be the exciting cause. Abdominal section discovers fat necrosis in the mesentery if the condition is of twelve or twenty-four hours duration (?).

Acute pancreatitis must be differentiated from mechanical intestinal obstruction, biliary colic, suppurative cholecystitis, rupture of the gall bladder, stomach, intestine and other abdominal organs, acute appendicitis, torsion of an ovarian cyst or spermatic cord, injury of the testicle, tabetic crises and all abdominal affections characterized by acute agonizing pain attended by shock.

506 East Grace Street.

Medicine. Osler says that medicine is the only world-wide profession following everywhere the same methods, actuated by the same ambitions, and pursuing the same ends.

THE THERAPEUTICS OF LUPULIN.*

THOMAS F. REILLY, M.D.
NEW YORK.

It is not my wish to call your attention to any new chemical product of coal tar nor to any of the modern medicinal agents that are guaranteed to cure all diseases, but rather to refresh your memories as to some old and, to myself at least, new properties of one of the oldest agents in the materia medica.

The history of the use of lupulin as a medicinal agent dates back as far as the oldest medical literature. Up to the early part of the last century it was used for almost every pain or disease. Before the discovery of the iodid it was considered almost a specific for scrofula, struma and the various skin diseases. In 1852 it was resurrected by the surgeons of the French genito-urinary school, and then for the first time came under the critical eye of modern clinical observation. After a few years of glory and grand enconiums it sank, at least as far as the literature is concerned, into complete oblivion.

Lupulin occurs as minute yellow granules at the base of the scales of the hop. Under the microscope this is seen to consist of a glandular mucus. These granules are greasy to the touch, are inflammable and emit a peculiar odor. According to recent investigations, they contain lupulinic and humulic acids and a volatile oil. The bitter taste is due to amorphous hopresins rather than to alkaloids. The aroma is due to volatile oil. Much of the disrepute into which this agent has fallen is due to the poor quality of the lupulin employed. Only that derived from the best Bohemian hops (Saatz) is of any service. It must be fresh and not exposed to light or heat, otherwise it is inert.

The active principle is closely related to valerianic acid. The resinous oxidation product of lupulinic acid is inimical to the growth of the lactic acid, but has no effect on the butyric ferment. Research with the object of determining the exact chemistry and also the physiologic action of this agent is at present being conducted by Dr. Stern and myself at the Institute for Medical Diagnosis and Research. This will be reported on at a later time. When taken into the body by the mouth, lupulin gives a sense of lively warmth, first in the epigastrium and later over the whole abdomen. It also acts as a mild diuretic. In some individuals it lowers the pulse rate from 10 to 20 beats a minute.

The two principal results that I found to be fairly constant following its use are the production of sleep and the relief of pain. The use of hops in some form or other as a sleep-producing agent is as old as mankind. The employment of hop tea is well known to most of you, and every one knows that beer will often produce the same result. The ancient beers did not contain lupulin. In England from 1050 to 1530 its use in beer was prohibited, presumably on account of its sleep-producing qualities. I have found that lupulin in doses of 20 grains repeated in a half-hour, acts as a mild somnifacient. It is of especial value in the sleeplessness or nervousness following a mild debauch. It then acts nicely on the digestive organs, as well as on the tremor and restlessness. In such cases it may be combined advantageously with tincture of capsic. The bitter taste has this peculiarity in that it does not persist in the mouth as is the case with most bitter agents.

As a general pain-relieving agent it is to be classed with the milder anodynes. It frequently relieves intestinal pain when not due to peritonitis. In the colics of children it is of great service. Those who have employed it in the painful conditions accompanying acute prostatic disease speak very highly of it. In neurasthenia and hysteria it has a calmative influence, lessening the irritability and often promoting sleep. It frequently relieves the occipital headache and pains that so often accompany these ailments. The menstrual pain and backache of these patients, when not associated with pathologic lesions, are generally relieved if it be given at frequent intervals. The French genitourinary surgeons extol to the skies its virtues as a preventive of seminal emissions and of chordee.

The use of a hop poultice as an anodyne is in general use among the laity, but I can not convince myself that it has any especial value. When given internally lupulin is best administered in capsule form. For children the powder may be mixed with sugar and is then readily taken. Aromatic spirits of ammonia forms a good vehicle when it must be given in liquid form. The officinal tincture is bitter and is not a satisfactory way of administering it. The dose varies from 10 to 60 gr., repeated every half-hour. In case of gastric intolerance suppositories may be employed. As a pain-relieving agent its field of usefulness falls in the same class as that of viburnum prunifolium and valerian. It is somewhat more active than either, and we avoid the disagreeable smell and taste of these two agents. In children it can generally be substituted for opium. In old people with advanced renal disease it can often supplant an opiate when a narcotic is necessary.

In this era of a high-tension civilization the practitioner is not infrequently brought face to face with the treatment of pains and aches and insomnias which are not in themselves severe and do not have any orgauic disease as a cause. These patients are neurotic and high strung and are not suffering enough to demand the use of an opiate, and yet in these very people habits are easily formed. The coal tar series of the past decade has seemed the surest way out of such a dilemma. The laity know it as well as we do and act accordingly. Now that the formation of a coal-tar product is generally-recognized, it will probably be a major problem in the next generation. Any one who has seen the cyanosis, palpitation, etc., following the use of any of these agents in some people must conclude that they are not in any case without some harm, however slight it may be. In many of the cases described above in which we are tempted to use the coal-tar series, we may substitute lupulin and we may go home and sleep soundly, confident that the patient will have been, in a measure, relieved and that he will not be found dead in bed the next morning as has not infrequently happened when an acetanilid powder has been taken to soothe his nervous complaints.

DISCUSSION.

Dr. W. C. Abbott, Chicago, said that Dr. Reilly's recommendation which gives us something tangible out of our own hop fields to substitute for the graft on the American people that comes from the dye works of Europe ought to be grasped by every one in this country. Dr. Abbott says that he has given many doses of acetanilid, and every time he knew he had done wrong in giving it; but sometimes one judges of a remedy as to whether it will do for that time and occasion more good than harm. Dr. Abbott desires to be regarded as being strongly opposed, not only on principle, but from a pure scientific therapeutic standpoint, to the use of any and all coal-

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

tar derivatives when it is possible, as it usually is possible, to use instead thereof something that will do a great deal more good and that can not possibly do the amount of harm. Lupulin is something in which he has been interested for a long time, and he is glad to have his ideas on the subject so ably supplemented and so far overreached by the studies of Dr. Reilly. Lupulin, he said, is certainly a good thing, and all coal-tar derivatives are bad things.

Dr. John W. Foss, Phoenix, Ariz., said that he has used lupulin in a large number of cases with excellent results. He has found it a harmless yet effective drug in cases of insomnia and nervousness.

Dr. W. F. Waugh, Chicago, said that he has had a little experience with lupulin, having given about one-half ton of it as a medicine while resident physician of an insane hospital. Lupulin was the basis of the composing medicines at night, but the doses recommended by Dr. Reilly were not found sufficient. A little whisky glass was filled with lupulin, an ounce or two ounces, enough tincture of conium was poured in to wet it and then 60 grains of potassium bromid were added. That was the average dose. It is not an easy thing to find a hypnotic that the insane can take night after night, for weeks and months, and which will still produce comparative quiet; yet that combination answered every requirement. That occurred in 1871 and 1872. Dr. Waugh also mentioned the use of lupulin at that time in cases of delirium tremens—not as a hypnotic, because he does not believe in this method; but it quieted the patient's nerves, and at the same time produced added benefit by settling the stomach and restoring some amount of circulatory equilibrium. It was found to be safe and was made a standby in the treatment of that affection. While Dr. Waugh believes that there are better remedies now for delirium tremens yet, he says, there is no denying the value of this drug in these cases.

Dr. H. Stern, New York, stated that he and Dr. Reilly have made these experiments together and that he has worked on the question for the last four years. Dr. Abbott, he said, is mistaken if he thinks lupulin grows in the fields of this country. Dr. Stern said that he had experimented with almost every variety of lupulin on the market, and he is sorry to say that no first-class hops or lupulin are produced in this country. He has a friend in New York who is a "beer doctor." Beer has its diseases, and this man is a scientific expert on these diseases. In his laboratory Dr. Stern made observations four years ago. The only lupulin of therapeutic usefulness comes from Bohemia. That lupulin comes from a little place called Saaz, which is the center of the hop industry in Bohemia This lupulin Dr. Stern has compared with that in the market, especially with Merck's, which he said is inert. It can not be kept longer than seven or eight months. One must have fresh lupulin; otherwise it is useless. Dr. Stern stated that he obtained lupulin directly from Bohemia. Nobody in this country imports it. Some brewers use this lupulin in addition to hops, to give the special flavor to their beer, but very few, because of its cost. Dr. Stern called attention to the antiseptic value of lupulin. Whether this is due to the lupulin alone, or in a measure to the yeast, is hard to say at present. If to beer which is full of bacteria some of this lupulin be added, the bacteria are killed off in less than five minutes. In 1893 or 1894, at one of the German congresses, Professor Quincke said that it was very remarkable that in the epidemic of cholera in Hamburg every man who was permitted to take beer survived. He thought it was the yeast; but beer does not contain yeast. So if it was not the yeast that did the work, it must have been the lupulin. For gastric and intestinal diseases Dr. Stern has used lupulin during the last year and a half with the utmost benefit. The lupulin which he has now is almost inert, although he kept it as cool and hermetically sealed as possible.

Dr. C. S. N. Hallberg, Chicago, called attention to the fact that lupulin is an official drug and has been for a long time. There is no use, he said, of talking about some one's preparation of lupulin. There may be a superior quality of lupulin from Saaz because that is where the Anheuser Busch or Budweiser company get their hops. The same principle is in the lupulin as in the hops. If the Germans had only isolated the principles and sent it to this country then everybody would probably be using it. As it is, they have overlooked it. Dr. Hallberg said that there is no intestinal antiseptic among the 500 phenol or benzene derivatives that approaches that derived from lupulin with about 5 per cent. alcohol in the form of an amber liquid. He believes that it is the best intestinal antiseptic there is, because it adds, 5 per cent. natural alcohol to its antiseptic properties.

Dr. T. F. Reilly said in concluding the discussion that according to the *Index Medicus* nothing has been added to the literature on this subject since 1853.

THE BLOOD PLATES.

THEIR NUMERATION IN PHYSIOLOGY AND PATHOLOGY.*

GEORGE T. KEMP, M.D., Ph.D.

Professor of Physiology, University of Illinois.

WITH THE COLLABORATION OF HENRIETTA CALHOUN, A.M., AND CHESTER E. HARRIS, A.M.

CHAMPAIGN, ILL.

INTRODUCTION.

The blood plates have always had a special interest for me, since they were the subject of my thesis for the doctorate in 1886. At that time I suggested a method for their enumeration which involved the use of osmic acid as a fixative. This worked very well for the blood plates, but tended to clump the red corpuscles so that in making comparative counts the results were so unsatisfactory that I did not publish them. About six years ago I took up the work again, using formaldehyd in physiologic salt solution as a fixative, and found this method to be a success. In consulting the literature, up to that time, so many new and interesting problems were suggested that I have given as much time as I could spare to their investigation, and have also assigned such research for thesis work to graduate students in my department at the University of Illinois. Our work culminated in an expedition of six of us to Cripple Creek and Pike's Peak to study the effect of altitude on the blood.

I find the literature of this subject very much scattered; it has not been brought together in any English paper for fifteen years. There are errors which have evidently been copied by one author from another, and often work by inaccurate methods has been quoted by the side of work which is good, without any sign of discrimination. I have, therefore, undertaken the task of consulting the original papers whenever possible and of giving references, by page, to statements quoted.

I. METHODS.

The blood plates are small round or oval bodies, varying considerably in size, but on an average about one-third the diameter of the red corpuscles. Unless special means are employed to preserve them, they become sticky and clump together or adhere to any foreign substance immediately after the blood is drawn. They then undergo a peculiar disintegration which is closely connected with the process of the clotting of the blood. The rapidity with which they break down is profoundly affected by the roughness of the surface with which they come in contact and by the temperature. A surface of neutral oil or clean paraffin will preserve them for some minutes. At zero, centigrade, they are preserved. It is necessary to bear these facts in mind in order to appreciate the discussion which is to follow.

* Read in the Section on Pathology and Physiology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

For convenience of description and criticism, the methods which have been employed for counting the blood plates may be enumerated as follows:

A. Direct examination: Blood in thin layers undiluted.
B. Direct examination: Blood mixed with a fixative diluent.
C. Direct examination: Blood mixed with a non-fixative diluent.
D. Direct examination: Blood in dry films.

J. Special forms of counting chambers.
K. Devices which obviate the use of counting chambers.

A. Direct Examination: Blood in Thin Layers Undiluted.—This method was employed before definite numeration methods were suggested, and it has also been used, to some extent, since. It is untrustworthy in the highest degree. The blood plates stick to the glass where they first touch, and one may find few or many of them, according to the part of the preparation examined. Moreover, the plates are found clumped in masses, and greatly altered in form, so that a genuine numeration of them would be impossible. This may easily be demonstrated by taking a drop of blood on a cover-glass and laying it on a slide in the usual way. As soon as the cover-glass is in place get the blood in focus (low power) as quickly as possible. Next place a drop of 0.75 per cent. sodium chlorid solution on the slide so that it just touches the edge of the cover-glass, and to the opposite edge of the cover-glass apply a small piece of filter paper and allow it to remain in this position. The filter paper will draw the blood from under the cover-glass and the salt solution will rush in to take its place.

On observing the red corpuscles in the swirling currents thus set up, it will be observed that they bump against stationary islands which adhere to the glass. These islands increase in size, and, as the red corpuscles are washed away so as to make a comparatively clear field, the islands will be seen to be made up of agglutinated blood plates. The islands are thickest where the blood first touched the cover-glass. This makes a good class demonstration and will convince any one that the red corpuscles move freely while the blood plates stick to the glass and to each other. Try to count them —it will be impossible. For purposes of demonstration, the drop of salt solution may be followed by a second drop of the same solution, colored with Lugol's solution. This makes the plates very prominent and will also bring out fibrin threads if the blood has stood long enough to clot.

B. Direct Examination: Blood Mixed with a Fixative Diluent.—The term fixative is here used in its strict histologic sense, viz., one which will kill a cell and preserve it in an approximately natural form. A rapid fixative for the blood plates removes at once their power to change their form or to develop the adhesive properties referred to above, and allows them to float freely side by side with the red corpuscles. Everything else being equal, such fluids are to be preferred. Unfortunately, of the many fixatives employed in histology few can be used with blood owing to secondary effects, such as causing precipitates, decolorizing or distorting the corpuscles, etc. The only fixative fluids which we have found to be free from all these objections are those containing formaldehyd (best about 2 to 3 per cent.) in the presence of certain neutral salts. The various fluids employed by different observers for the numeration of blood plates will be discussed under fluids. With an unobjectionable fluid of this class, the ratio of the plates to the red corpuscles can be determined directly, and, the number of reds being known, the number of plates can be calculated. A simple examination would enable an experienced observer to say whether the plates were greatly increased or decreased, in comparison with the reds, without making an actual count for the ratio.

In employing this method, even for simple examinations, never let the blood touch the cover-glass until after it has mixed well with the fixing fluid. The following experiment will demonstrate the importance of this: Place on the slide a pool of several drops of fluid containing 2.5 per cent. formic aldehyd and 1 per cent sodium chlorid in water. From a puncture on the finger take on the center of a cover-glass a drop of blood the size of a small French pea. Place the cover-glass, blood side down, on the fluid on the slide and remove the excess of fluid with filter paper. Over the area where the drop first touched, the plates will be seen in large numbers adhering to the cover-glass; elsewhere they will float free, but sometimes in clumps. Now repeat the experiment by placing a large drop of the fluid over the puncture to receive the blood the instant it emerges. Take a small drop of blood and mix the blood with the fixative on the finger by a few gentle strokes with a clean needle. Place the mixed drop on a slide, lay on the cover-glass and examine. The plates will all float free and unclumped along with the red corpuscles.

These demonstrations may be made more striking by coloring the solution with methyl violet, which stains the plates. A convenient way to do this is to use an uncolored aldehyd mixture on the finger so as to judge the amount of blood taken, then blend the mixed blood and aldehyd salt solution with a drop of the colored solution placed on the slides. Cover and examine. The all-important point of the procedure is that no part of the blood drop shall touch the glass before it has mixed with the fixing fluid.

C. Direct Examination: Blood Mixed with a Non-fixative.—Non-fixative fluids are hard to discuss, as a whole. There is no general rule that will apply to them. The value of the results of observers who have used such fluids depends on the details of their method, as well as on the fluid used. One crucial point is: Does the fluid in question allow the plates to clump or to stick to the glass? If it does, it is untrustworthy to that extent. Another point is: How does it preserve the red corpuscles? Since the relative number of plates and red corpuscles is what we are after, it is obvious that each must be preserved—at least long enough to make a satisfactory examination. If the fluid or the method otherwise permits the red corpuscles to bud off small fragments, it introduces an additional source of error which is very serious, as these fragments of the red corpuscles may lose their hemoglobin and be mistaken for blood plates. We believe that the Arnold buds are artifacts which belong in this category.[1]

D. Direct Examination: Blood in Dry Films.—This method consists in attempting to judge whether the plates are increased or decreased by direct examination of dry preparations prepared in the ordinary way. As early as 1885 Schimmelbusch[2] tried to count the plates

1. Arnold: Virch. Arch., vol. cxlv, p. 1 et seq.; also vol. clv, pp. 171, 189 and 193.
2. Schimmelbusch: Virch. Arch. 1885, vol. ci, p. 229; also Eberth and Schimmelbusch; "Die Thrombose," etc., Stuttgart, 1888, pp. 33 and 34.

by this method and found it impracticable. Since then it has been unsparingly condemned by the majority[3] of those who have tried to use it. We are unhesitatingly with this majority.

E. Pipette Method (Simple).—This method consists in measuring the blood directly in some form of pipette, then mixing it with a known amount of diluting fluid, counting the number of blood plates in a given volume of the diluted blood and calculating their number per cubic millimeter just as is done when making similar counts of the red corpuscles. The Hayem-Malassez, Gowers, and Thoma-Zeiss instruments have all been used in such numerations. The chief objection to this method is the use of the measuring pipette for the blood. The adhesive properties which the blood plates develop when they touch foreign substances make them stick to the pipette. It is a significant fact that, as a rule, the counts made by this method are lower than when some method is employed which obviates this source of error. The objections to this method have been pointed out by nearly all the writers on the subject, and those who have used it have done so in default of something better, pointing out that, though the results are only approximately accurate, they are still of value. One variable factor in the error of this method is the temperature of the pipette. In a warm room the error would be greater than in a cold one. In spite of all this, we feel that there is a great deal of truth in the contention that comparative results obtained by the pipette method, while by no means accurate, need not be discarded altogether, though we would by no means advocate the method.

F. Pipette Method, with Refrigerated Pipette.—This method was devised by van Emden[4] to reduce to a minimum the adhesion of the blood plates to the pipette. The measuring pipette is placed in a dry short test-tube furnished with a perforated stopper, and the test-tube is placed in a cold bath.[5]. Further details are not given. He uses a diluting fluid, recommended by Prus, which decolorizes the red corpuscles so that they do not obstruct the view. This enables him to get a very large number of plates in the field for counting and consequently reduces the error. He has compared this method with the ratio method, which we recommend and describe below, and finds that each gives equally good results.

G. The Ratio Method (Laker's Method).—Recognizing the errors of the pipette method, mentioned above, Laker[6] and Kemp,[7] independently and simultaneously, proposed a new method for determining the number of blood plates by first getting their ratio to the red corpuscles. The number of the reds being obtained by one of the ordinary methods, the number of plates could be calculated by the simple rule of proportion. This is commonly referred to as Laker's method.

H. The Thoma-Zeiss Counting Chamber in Blood-Plate Numerations.—This is the method which has been chosen by the majority of late observers. The instrument is now in common use and is readily procurable almost anywhere. We have used it, for the most part, in our experiments. With a fluid which fixes the blood plates immediately, and has such a low specific gravity as to allow them to settle readily to the bottom of the chamber, we have found that it gives very satisfactory results; but other observers, working with different fluids, have found serious drawbacks which have led some of them to discard it.

The first objection to the Thoma-Zeiss counting chamber is that it is too deep, that often when it is desirable to employ an extra high power it can not be done. This is a valid objection, but it is not fatal to the method. In determining the ratio of the plates to the red corpuscles, the exact capacity of the space over the ruled field is of no consequence. Therefore, we have been in the habit of using, in such determinations, an ordinary cover-glass instead of the special one employed in counting the reds. By this simple substitution we can use a sufficiently high power to settle, in ninety-nine cases out of a hundred, whether or not a given body is a blood plate.

The second objection, that the plates do not settle to the bottom so as to be seen against the lines, deserves special consideration. Determann[8] cautions that the observer must not fail to focus up and down with the fine adjustment of the microscope, so as to search the fluid of the chamber from top to bottom. He says "the red corpuscles always sink very rapidly, while the plates may be seen in the upper layers of the liquid for some time later (*noch lange*)." This focusing up and down, away from the ruled bottom of the chamber, would be extremely inconvenient and, we fear, would introduce a serious error.

On examining the details of Determann's work we are convinced that the fluid he used and some of the details of the method he employed are together responsible for the difficulty. His directions are as follows: First stick the finger, then place over the puncture a drop of the diluting fluid. As soon as the first drop of blood appears and mixes with the diluting fluid, the mixed drop is taken quickly on the cover-glass and further mixed until the blood is evenly distributed through the diluting mixture. If too large a drop of blood is taken, it is further diluted on the cover-glass. He tried fourteen different diluting fluids and finally selected two, viz., 0.9 per cent. Nat'l solution colored with a little methyl-violet (practically Bizzozero's fluid), which is his favorite, and one of Wlassow's fluids (an aqueous solution of 1 per cent. sodium chlorid and 5 per cent. potassium bichromate), which he says is very good (sehr geignet). Now it so happens that, of the fourteen fluids he mentions, none combines the advantages of fixing the plates and of having a low specific gravity like the fluid we shall recommend. If the fluid has a high specific gravity the plates will settle more slowly or they may even float at the surface and not settle at all. This was found to be the case by Pratt[9] and by Helber,[10] as well as by Determann, as above referred to.

Still more serious objections may be made to the modified Bizzozero fluid which Determann used. This has a low specific gravity, but it is a very imperfect fixative. The blood plates are not wholly prevented, by its action, from sticking to glass, and, moreover, they swell (probably by the imbibition of water). Determann himself

has noticed this swelling;[11] and Bizzozero[12] calls especial attention to their sticking to the glass. We have had a large experience in examining blood plates in Bizzozero's fluid and can corroborate these observations. We see how the swelling of the blood plates might make them float, though we have not given special attention to this point; but we have no doubt about them sticking to the glass, and when we read that the fresh drop of blood, just blended with the Bizzozero fluid, is mixed more perfectly on the cover-glass, and if too much blood is taken more diluting fluid must be added, we see how this might introduce an error in the same line as the use of the pipette method, or it might group the plates just where they were to be counted and make the count too high. We are suspicious of this when we see Determann giving records in which the blood plates were four times as numerous as the red corpuscles.[13]

It is interesting to note in this connection that when Bizzozero counts the blood plates he discards his older fluid and substitutes one which contains osmic acid,[14] thus making his fluid a true fixative. Since the blood plates are lighter than the red corpuscles and settle to the bottom of the chamber more slowly, we can not determine the ratio of the plates to the reds before both have settled and can be seen lying in the squares. With the Kemp and Calhoun fluid this requires from two to three minutes, but it has been our custom to wait five minutes so as to be on the safe side.

The time required for the plates to settle was determined by the following simple method: After the drop of the diluted blood is placed in the counting chamber and the cover-glass is in position, focus on the bottom, using a 1/6-inch objective. Keep the same field under observation and note the position, with regard to the lines, of the blood plates which have settled immediately. Within the first minute it will not be unusual to see a new blood plate descend and rest on the bottom. By the end of the third minute they are all down, as may be determined by making successive counts of the ratio in the same field.

J. Special Forms of Counting Chambers.—For counting the plates Hayem[15] employs a counting chamber made especially shallow (0.1 mm.), with a thin flat cover-glass. This admits the use of a higher magnification than is customary in counting the red corpuscles (Nachet objective 6 instead of 5). The base of the chamber is ruled so that a cubic unit is a parallelopipedon having a base of one-fifth of a millimeter and a height of one-tenth of a millimeter. While this chamber was made especially shallow, it was so only in comparison with the older French form. It has the same depth as the Thoma-Zeiss counting-cell, and, therefore, may be considered as having been treated with that instrument in the discussion above. More recently Helber[16] has employed a counting chamber which he has had made specially for blood-plate work. It has a depth of 0.02 mm., otherwise it is exactly like the Thoma-Zeiss instrument. With a thin cover-glass this enables one to use a sufficiently high power to determine, beyond doubt, whether a given body under observation is a blood plate. Pratt had tried the same thing with a chamber intermediate in depth between the Thoma-Zeiss cell and the one later recommended by Helber. He was dissatisfied with the results, however, and discarded the counting chamber for a method which will be described later.

K. Devices which Obviate the Use of Counting Chambers.—The first observers to employ the ratio method for actual numeration without a counting chamber were Bizzozero[14] and Salvioli,[16] each of whom used an ocular with a scale ruled in squares, and determined the ratio of the plates to the red corpuscles, in the areas thus marked out, in ordinary preparations of blood diluted with a fixative.

Following Bizzozero and Salvioli, we made a number of experiments, using scales ruled on glass to fit in the ocular. These were prepared for us in the physical laboratory of the University of Illinois by Mr. E. F. Bracken, a graduate student in physics, through the courtesy of Professor F. A. Sager. Several scales were ruled to suit different magnifications, and the distance between the lines was calculated so that the squares represented known areas in the field of the microscope. We compared the results of this method with those obtained from the same blood, using the Thoma-Zeiss instrument, and they were found to be the same. We can, therefore, recommend this method for accuracy.

In the earlier experiments of Pratt[9] and in those of Helber, these observers tried to use the Thoma-Zeiss chamber with a 10 per cent. solution of sodium metaphosphate, and, as Pratt says, the experiments "were wrecked on technical difficulties." These, we infer from the context, were chiefly the fact that the plates floated at the top of the liquid and could not be brought in focus with the lines at the bottom of the chamber, nor could a very high power be employed. Helber got around these difficulties by using the shallow chamber described above; Pratt solved the problem by using an Ehrlich ocular. He has more recently replaced the Ehrlich ocular by a disk of cardboard, with a square hole cut in it, which is laid in the eyepiece.

We gather from a paper by Richardson[17] that this was also the arrangement used by him. This simple device does away with the necessity of any special apparatus for obtaining the ratio between the plates and the red corpuscles. The slide is moved about and the ratio is determined in a number of the places taken at random. A lens of any power can be used. We have tried the Ehrlich ocular and found that it worked, so that the same may be said for the cardboard substitute.

After our experience with the ruled squares in the eyepiece, the Ehrlich ocular, and the Thoma-Zeiss chamber, we must say we prefer the latter rather as a matter of convenience than because the others are not accurate. It was purely an accident that we began with a fixative fluid of low specific gravity, and thus avoided the rock on which the first experiments of Pratt and of Helber were wrecked. The method yielded strikingly constant results and we became used to it. We adopted the routine practice of taking a bird's-eye view of the field to see if the corpuscles were evenly distributed, just as we do before counting the red corpuscles. When the lines move with the field, it makes orientation easier, and one knows at a glance that he is not examining the same part of the specimen twice. Then, again, if swift currents are set up and continue in one direction, we can not escape the suspicion that the plates, being smaller, would be swept along more rapidly than the red cor-

puscles, and thus destroy the true ratio in any given part of the field. It was more difficult to avoid this with an ordinary slide than with the Thoma-Zeiss chamber, and it required more care to get the red corpuscles evenly distributed. For this reason we rejected preparations where the distribution was very unequal.

The Helber chamber posssesses all the advantages claimed here for the Thoma-Zeiss, and we are inclined to believe that it is the more satisfactory, though we have not tried it. Certainly instances have arisen where we have wished to swing on a higher power to examine a given blood plate and were unable to do so owing to the depth of the chamber. In counting the plates in pathologic blood, especially where the red corpuscles show signs of disintegration, or where precipitates exist in the plasma, we can easily conceive of instances in which the Thoma-Zeiss cell should not be used, and where the counting devices of Helber, of Pratt, or of Bizzozero and of Salvioli could be employed to advantage.[18]

II. FLUIDS.

The fluids used in numerating the blood plates have, in nearly every instance, become associated with the name of the observer who proposed them. So that they will be found below, for the most part, under the authors' names, in alphabetical order.

Acid, Osmic.—Osmic acid is an immediate fixative, and is recommended as an ingredient of a number of numeration fluids, especially by observers of the Italian school.[19] We have tried osmic acid in a large number of combinations, and none has been satisfactory. It preserves the blood plates, but it has a tendency to clump or to distort the red corpuscles, and in some combinations it decolorizes them. Several observers have tried osmic acid, but reject it for some more favored fluid without stating wherein the osmic acid was objectionable. Marchner[20] has been more specific, and we find that his objections are the same as ours. With fluids containing osmic acid, the results are better when neutral salts are present than when the acid is used in simple aqueous solution.

Afanassiew[21] took the suggestion, for a preservative fluid for the blood plates, from the classical researches of Schmidt-Mühlheim, Fano, and Bizzozero on the action of peptone in preventing clotting. His directions for preparing the fluid he used are as follows: In a 0.6 per cent. sodium chlorid solution, dissolve 0.6 per cent. of dry peptone, and add methyl violet about 1 part to 10,000 or even 1 part to 20,000. Boil, filter and preserve in sterilized flasks plugged with cotton. Fermentation may also be prevented by adding small amounts of methyl alcohol[22] or phenyl alcohol, or corrosive sublimate, or carbolic acid. He prefers this solution to others which he tried, because it preserves the red corpuscles and the plates and mixes well with anilin stains for coloring the latter and the leucocytes. We have not tried this fluid, but Fusari[23] finds that while it preserves the plates it decolorizes a large number of the red corpuscles, and Brodie and Russell object to it on the ground that it does not entirely prevent the plates from adhering to the glass. It can not be classed among the fixative fluids.

Aldehyd Formic.—Formic aldehyd, as a fixative in diluting solutions for numerating the blood plates, was first used by Kemp and Calhoun.[24] We have extended these earlier observations of two of our number, and are convinced that formic aldehyd, combined with neutral salts, is a thoroughly efficient reagent for the purposes for which we employ it. Our fluid is conveniently made by the following formula:

Formalin, 40 per cent. aqueous solution of H.COH.	10 c.c.
Sodium chlorid, 1 per cent. aqueous solution......	150 c.c.

(Color with methyl green or methyl violet if desired.)

This gives a 2.5 per cent. solution of formaldehyd. When the aldehyd solution was used without the addition of salt, we found that the red corpuscles were decolorized in a short time. The use of salt prevents this decolorizing effect.

About equally good results are obtained when the sodium chlorid is present in anywhere from 0.75 per cent. to 3 per cent. Above 3 per cent. the reds become crenated, and below 0.75 per cent. they may lose their hemoglobin. The percentage of formaldehyd may also be varied within wide limits, but strong solutions are undesirable as they clump the red corpuscles and form precipitates.

In the course of our work we found one specimen of our solution which decolorized the red corpuscles. We suspected this decolorization to be due to acid formed by the oxidation of the aldehyd. On testing the fluid with litmus it was found to be slightly acid. This led us to make some experiments on solutions containing varying amounts of formic acid. If to the 2.5 per cent. formaldehyd containing salt, we add enough formic acid to make a 1 per cent. solution, the red corpuscles are clumped and decolorized. The action on the leucocytes and plates was similar to that of 1 per cent. acetic acid. The formaldehyd mixture with enough acid to make a 0.1 per cent. solution decolorized the red corpuscles almost immediately. With a 0.01 per cent. solution the reds were not clumped, although they were slightly swollen and no longer bi-concave. They retained their color six hours. We found that salt was always necessary to preserve the hemoglobin in the red corpuscles. The results of a more extended series of observations are given in the following table:

Per cent. of formaldehyd.	Per cent. of formic acid.	Per cent of salt.	Time of decolorization.
2.5	0.1	None.	Immediately
2.5	0.075	None.	Immediately.
2.5	0.05	None.	Immediately.
2.5	0.025	None.	Immediately
2.5	0.001	None.	Immediately.
2.5	0.1	0.75	Immediately.
2.5	0.075	0.75	Immediately.
2.5	0.075	1.50	15 minutes.
2.5	0.05	0.75	2 minutes.
2.5	0.025	0.75	No change in 1 hour.
2.5	0.001	0.75	Not decolorized.

The proportion of blood to the fluid does not have any effect within wide limits; if the amount of blood be large and the amount of aldehyd small, precipitates, probably of albumin, are formed. The dilution should be so regulated that the field is not so crowded with red corpuscles as to mask any of the plates. The aldehyd solution will preserve the blood plates indefinitely. The figures given for our solutions refer to absolute percentages of formic aldehyd and of formic acid. These experiments show conclusively that small amounts of formic acid (0.025 per cent.) do not decolorize the red cor-

18. Additional literature on this section by Rahl will be found in Wien. Klin. Wochft., 1896, vol. ix, pp. 1061-1062.

19. Bizzozero, Fusari, Petrone, Pizzini and Salvioli. The fluid of Pro... also contains osmic acid and deserves special consideration.

20. Marchner: Prag. med. Wochft., 1895, p. 355.

21. Afanassiew: Deutsch. Arch. f. k. Med., 1884, vol. xxxv, p. 226. The English equivalent for this Russian observer's name is given as "Afanasyev" in the Index Medicus, and as "Afanasiev" in Minerva. As his work is almost universally referred to under the German spelling "Afanassiew" we retain that spelling here.

22. In the original this word is "methylen alcohol."

23. Fusari: Arch. per le scienze mediche, 1886, vol. x, p. 212.

24. Kemp and Calhoun: Proceedings of the Amer. Physiol. Soc. Am. Jour. of Physiol., 1901, vol. v, p. iv.

puscles, while higher percentages would introduce an error. They also show that higher percentages of salt retard the decolorization. In five years' experience we have used formalin from a number of different firms and have found only one specimen which contained enough acid to compromise the efficiency of the counting fluid when diluted with fifteen times its volume of water, as called for by the formula. We shook up this specimen of formalin with lead carbonate and allowed it to settle. The bottle stood for a year in the laboratory, and during this time we decanted several lots of formalin for making specimens of counting fluid, and compared these with a similar fluid made from other formalin. We found that the acidity was neutralized and that the small amount of lead salts which went into solution had no appreciable effect. We feel, therefore, that we can recommend this method for treating suspicious specimens of formalin and for keeping a stock of neutral formalin on hand.

Sodium chlorid is not the only salt which may be used in connection with formaldehyd to preserve both the red corpuscles and the blood plates. Marcano's[25] fluid for counting the red corpuscles is Malassez's classic solution of sodium sulphate (specific gravity 1020), combined with formaldehyd in the proportion:

Na_2SO_4 solution : Formol : : 90 : 10.

Marcano recommends this solution for the red corpuscles without mentioning the blood plates. We have tried it, and find that it is an excellent fixative for both of these elements. Marcano has also called attention to the fact that formaldehyd without salt will not do; Brodie and Russell[26] condemn aldehyd fluids in general, but they make no mention of having used salts with the aldehyd, so we suppose they were omitted.

After searching all the literature at our command and trying nearly all the fluids which have been recommended, we have found none which combines all the desirable points possessed by the solution which we use. We may enumerate these points as follows:

a. Rapid fixation of both blood plates and red corpuscles. The plates do not clump or stick. The reds do not become decolorized or give off buds.

b. The red corpuscles are not clumped, but are distributed perfectly freely through the liquid.

c. There is no precipitate formed to obscure the field or to be confused with the plates.

d. The fluid mixes readily with a large number of anilin dyes. Kemp and Calhoun combined methyl green with the fluid in the routine work. By using the dyes the plates may be stained and rendered more prominent. Certain histologic points may also be studied at the same time that the plates are counted.[27]

e. The fluid has a low specific gravity; hence the plates will settle more readily than in a more concentrated solution. It can be used with any counting device mentioned in Section 1, including the Thoma-Zeiss hemocytometer.

f. Neither bacteria nor molds will grow in the fluid. To all intents and purposes it will keep indefinitely. We have never had any of the fluid go bad, and we have tested specimens which have stood for several months. In making this statement we are not unmindful of the chemical properties of aldehyds: the possibility that they may polymerize or be oxidized to acid. If a specimen becomes sufficiently acid to decolorize the red corpuscles, it should be thrown out and a new solution made.

g. It is cheap and easily prepared. The ingredients are to be found in every drug store.

(To be continued.)

25. Marcano: Arch. de méd. exp. 1889, vol. xi, pp. 436-438.

26. Brodie and Russell: Jour of Physiol., 1897, vol. xxi, pp. 391 to 395.

27. The use of the methyl green was discontinued because with increased experience we felt we could see the plates well enough without it, and the clear fluid enables one to observe better the mixing of the blood with the fixative which is placed over the puncture. For beginners with the method, we might still recommend the use of a stain; and would suggest methyl violet for the purpose, as a weaker solution of this dye will stain the plates effectively.

CHAPTER XV.

CIRCULATORY STIMULANTS.

The subject of circulatory changes is entirely too extensive for anything like a comprehensive treatment in the limited space that has been allotted to this series of articles. We shall endeavor, however, to discuss some of the indications for influencing these changes and try to indicate how they may be brought about.

The term "heart tonic" has been so loosely employed that it is better to avoid it altogether, or, to use it only with reference to those drugs which, acting directly on the heart, improve the muscular tone.

The heart is but one and, in some respects, even a minor factor in the question of blood pressure, on which the state of the circulation largely depends. Hence, while a "heart tonic" implies an agent which improves the action of the myocardium, the actual changes in the circulation depend not alone on the amount of work done by the central organ, but on the combination of that and the constriction or dilatation of the blood vessels.

Since the relative amounts of blood existing in the veins and arteries, and the amount which passes through a given area or organ in a given time are dependent on several more or less closely related factors, we may direct our efforts toward influencing one or more of these factors when we wish to increase or to diminish the blood supply of an organ, or when we wish to hasten the transfer of blood from veins to arteries.

An increase in the rate of the heart or strength of the beat, without a compensating change, either in the heart itself or in the blood vessels, will, of course, increase the general circulation, and conversely, a diminished action would lessen the circulation, but so delicately is the complex circulatory mechanism adjusted that such a simple change probably never occurs alone in the intact body, though it may at times predominate over other accompanying changes.

The simplest means of increasing the blood pressure consists in increasing the strength of the individual beats, whereby the heart is more completely and more forcibly emptied, and securing just enough slowing to enable the heart to dilate more fully and to become filled with a larger volume of blood. These two actions insure a larger volume of blood being thrown into the aorta in a given length of time than occurred under previous conditions. An increased volume of blood with increased force, must, of course, insure an increased circulation in those areas in which there is no great change in the caliber of the smaller vessels.

A high blood pressure on the other hand may be most simply reduced by slowing the heart without increasing its strength, or by acting on the vessels peripherally or through the vasomotor centers, causing dilation.

The accumulation of an undue amount of blood in the veins is relieved by increasing the efficiency of the heart as mentioned for raising the blood pressure—by slowing and strengthening its beat—for, as we have seen, this improves the drainage from the veins by lengthening the diastole, while the strengthening throws a larger volume of blood into the arteries.

We may arrange the agents affecting circulation into two groups as follows: Those mainly affecting the heart, directly or indirectly; those mainly affecting the vessels, directly or indirectly.

The most important group of circulatory stimulants consists of digitalis and a number of similarly acting substances. While, as is well known, barium chlorid has to some extent a similar action to digitalis, nearly all the other members of this group that are of therapeutic importance are somewhat allied chemically; for the most part the active principles of these drugs are glucosids or resins. The exact chemistry of the drugs of this class is still obscure, despite numerous investigations, and it demands but little consideration here; their pharmacologic action, however, serves to explain their therapeutic indications, and may aid in choosing the one best suited to a given condition.

The circulatory conditions demanding stimulation are mainly those in which undue relaxation occurs, and in which an imperfectly acting heart, including such conditions as valvular insufficiency and stenosis, permits the blood to accumulate in the veins. Any increase in the work of the heart must tend to relieve these conditions, particularly if there is at the same time just sufficient slowing to secure complete distention of the heart with blood during diastole.

An increase in the strength of the contraction more completely squeezes the venous blood out of the heart muscle, which is then supplied with a larger proportion of arterial blood. The increased force of the pulse wave must first be felt more strongly in the coronary artery than elsewhere, since there is less inertia to be overcome in the much shorter column of blood between the aortic valve and the opening into the coronary artery. The longer diastole then permits a more perfect supply to the capillaries in the heart, thus improving the nutrition of the heart to an even greater degree than would correspond to the extra work thrown on the ventricles by their being compelled to contract against an increased arterial pressure.

As we have just said, the slowing of the heart should be just sufficient to enable the heart to become fully distended, for a greatly slowed heart would suffer in lessened nutrition, because, other things being equal, the rate of flow through the coronary circulation varies with the number of the pulsations in a given space of time.

This improved nutrition of the myocardium is the first essential for a sustained increase in the force of the beats, either from a more energetic action of the unaltered heart or after hypertrophy; because however much a muscle might be stimulated to unusual activity, exhaustion and paralysis must follow unless nutrition keeps pace with the work performed. Langendorff has shown experimentally that the energy of the heart is enormously influenced by the available blood supply. A drug might affect one or more phases of the heart beat, or the local and central action may be in part antagonistic and the effect on the blood pressure in the general circulation will in the latter case be dependent on the kinds of influence and the degree to which each is excited.

Slight slowing with increased strength of contraction may improve the nutrition, and it will be readily understood why it is difficult to secure equally perfect nutrition of the heart when it is made to beat more rapidly, since the only factor here which makes for an improved coronary circulation is the more frequent squeezing out of venous blood by the contractions while all other conditions are unfavorable, a greater number of contractions, each throwing out less blood and meaning more energy expended for a given amount of work performed —a more frequent overcoming of the inertia of the blood in the arteries—so that a very rapid heart soon exhausts itself. For these reasons we do not often seek to raise blood pressure or to improve the general circulation by increasing the rate of the heart unless it is extremely slow.

Shock and collapse are conditions that are due to depression of the respiratory, cardiac and vasomotor centers. The depression of the vasomotor center permits the vessels to dilate and the blood gravitates to the vessels of the splanchnic area, which are capable of holding a very large amount. This dilatation is accompanied by a fall of pressure in the general circulation, less blood goes to the centers and to the coronary circulation, the heart beats more feebly and the respiration becomes weaker. This condition obviously calls for prompt stimulation of the circulation. It is apparent, however, that a stimulation of the heart alone would only result in increased work while its own nutrition would not be correspondingly improved because the pressure in the coronary circulation can not be greatly increased while the voluminous vessels of the splanchnic area offer cavernous spaces for the blood which is pumped from the heart.

Stimulation of the constrictor mechanism of the vessels is urgently demanded in collapse, and this is secured in the mildest cases by gravity determining the blood to the head when the head is placed lower than the body. The centers are toned up by the better blood supply, and this increased tone of the vasomotor center causes constriction of the splanchnic vessels, raises the blood pressure and improves the general circulation, which in turn further tones up the centers and the heart, which is also stimulated by the improved tone of the cardiac center. The respiration is improved at the same time owing to the improved tone of the respiratory center.

Dr. George Crile has devised a pneumatic suit whereby pressure may be applied to the surface of the limbs, thus forcing a large amount of blood into the body and head, and gravity (lowering the head) may be made to assist in driving it to the head—the essential fact being to supply the medulla oblongata with blood.

Physiologic Salt Solution.

Heat, mainly supplied by hot water bottles, should be used with any other measure in shock. The amount of fluid in the vessels may be considerably increased by injecting, under aseptic precautions, into a vein, or even under the skin, normal saline solution, or as it is better to term it, physiologic salt solution, made by dissolving 9 grams of sodium chlorid in enough water to make one liter (approximately 132 grains of sodium chlorid to 1 quart of water.). The solution should be boiled (to render it sterile) and then cooled to about 40° C. (104° F.). As noted above this solution may be used hypodermically or it may be injected directly into a vein. Another, and at times a very satisfactory, method of attaining the same result is to inject slowly one or two liters of this solution into the rectum, whence it is readily absorbed into the circulation.

Drugs which act on the vasomotor centers are indicated in collapse but the simple means just enumerated serve, as explained, to tone up the centers in mild cases by an improved blood supply, and they are of course preferable to mere stimulation by drugs. Then, too, in proportion to the emergency of the case is the difficulty of securing stimulation of the centers. In profound shock the stimulants of the vasomotor centers appear to have no lasting effect or to increase the trouble. In collapse of a mild character, however, a vasoconstrictor acting more powerfully on the vessels of the splanchnic area causes the general blood pressure to rise, more blood goes to the centers, and they are placed in better tone, exactly as is the case when gravity sends the blood to the head.

Hot alcoholic drinks are very commonly employed in collapse and shock; they probably act reflexly from the stomach.

Some clinicians maintain that morphin improves a weakened heart. As a depressed center is less susceptible to shock from reflex influences, morphin may lessen shock or depression due to pain and the center will then be able to exert a better influence on the heart. It has often been claimed that opium or morphin causes an increased supply of blood to the brain by dilating the vessels of that organ, and this may account for an increased circulation to the cardiac center and hence an improvement in the heart. The depression of the respiratory center by morphin is rather strong evidence against any stimulation of the cardiac center however. Morphin has no direct effect on the heart and its vasomotor effects are variable.

The pharmacologic action of digitalis and that of its available active principles have been more extensively studied than has been done in the case of any other member of the group. The isolated frog's heart, and later the mammalian, has been used to determine the action on that organ apart from the influence through the centers. The rate of the isolated mammalian heart is either increased or little affected by

digitalis or its principles, but Gottlieb and Magnus found that the strength of the individual contractions is increased by it and that more actual work is done by the isolated heart. In the intact mammal digitalis slows the heart by stimulation of the vagus center, and the strength of the beat is increased by the action on the myocardium. The vasomotor centers are stimulated at the same time. The direct results of these several actions have been detailed in the introductory paragraphs.

Digitoxin, the most active of the principles that have been isolated from digitalis, has essentially the same action on the circulatory system as the drug itself, but being insoluble in water it is slow in producing its effects. Albert Fraenkel has found that about sixty hours elapsed after a single effective dose was injected, hypodermically, into a cat before the typical action was induced.

Digitalin, or "Digitalinum verum," is somewhat more soluble in water and its action was elicited in twenty-four hours after a dose, corresponding in activity to that of digitoxin just mentioned, was injected into a cat, while strophanthin (obtained from strophanthus seeds), which is very soluble in water, produced its effects much more rapidly. The therapeutic action of these three substances is very similar, but Gottlieb and Magnus found that digitoxin is capable of restoring an irregularly beating heart to rhythmic pulsations to an astonishing degree: indeed, they were able to restore isolated and perfused hearts to strong regular beats after they had gone into delirium cordis.

Digitalis and the other members of this group have the great disadvantage of causing cumulative effects when used continuously for some time. Digitoxin produces these effects more readily than strophanthin and digitalin. Fraenkel was able to continue the administration of digitalin daily for ninety-two days at near the toxic dose without cumulative action. No habituation occurred in this period, however, thus disproving the claims of Heide, based on a much shorter period of experimentation, that such takes place.

Gastric irritation is the first evidence of a toxic action from a single toxic dose or from cumulative action, and the drug digitalis, or any of its congeners without exception, must be stopped for a time when cumulative effects are seen. When the heart is slowed by any member of the digitalis group the action is very persistent.

Fraenkel concludes that the duration of the action on the heart is proportioned to the stability of the union which takes place between the drug and the mechanism affected, but that the interval elapsing between the time of administration and the beginning of the action is proportional to the insolubility of the principle. Gottlieb and Magnus in experimenting on the isolated heart found that digitoxin caused a constriction of the coronary arteries, but that this did not occur after strophanthin.

The following official drugs belong to the digitalis group. As noted before, there are other drugs and chemicals that possess a somewhat similar action, but it must be evident to all that nothing is to be gained, and that much harm may result from giving heed to unwarranted and exaggerated claims of the nostrum maker who lands a preparation which ostensibly depends on some little known drug, such, for instance, as the several species of cactus.

By far the most interesting as well as the most important of the official drugs of the group now under consideration is:

Digitalis.—U. S.—This consists of the dried leaves of *Digitalis purpurea*, collected from the second year's growth at the commencement of flowering. This drug is official in all pharmacopeias and is generally accepted as being particularly susceptible to chemical change. It should be carefully preserved and should not be kept for more than one year.

Average dose: 0.05 gm. (1 grain).

While the chemistry of digitalis is far from being thoroughly understood, there are a number of proximate principles derived from digitalis that are now being marketed in a commercial way and have well-defined chemical as well as physiologic properties; several of them at least are being extensively used in this country as well as abroad. The most potent of these unofficial articles is:

Digitoxin: This, as has been noted before, is soluble in alcohol but is nearly insoluble in water. The older and in some respects better known French preparations, variously called digitalin, crystallisée, or French digitalin, closely resemble digitoxin in physical properties and also in physiologic activity.

Digitalin (Digitalinum verum, Kiliani): This is a white amorphous glucosid that is readily soluble in alcohol but only slightly soluble in water. While it is less toxic than digitoxin and may be given in much larger doses, it closely resembles that principle in its therapeutic action and uses.

Digitin (Merck): This is also readily soluble in alcohol and only slightly soluble in water. While still available it is now generally thought to be physiologically inactive as a circulatory stimulant.

Digitalein (Schmiedeberg): This is readily soluble in water and is probably a mixture of several proximate principles.

Digitalin "German": This occurs as a yellowish white, amorphous powder that is soluble in both water and alcohol. It is said to consist of a variable mixture of Digitalinum verum (Kiliani), digitalein and digitonin.

The official preparations of digitalis[1] are:

Extractum Digitalis.—U. S.—This is made from the fluidextract by evaporation.

Average dose: 0.01 gm. (10 mg. 1 5 grain).

Fluidextractum Digitalis.—U. S.—Fluidextract of digitalis is made with diluted alcohol.

Average dose: 0.05 c.c. (1 minim).

Infusum Digitalis.—U. S.—Infusion of digitalis contains 1.5 per cent. of digitalis, 10 per cent. of alcohol and 15 per cent. of cinnamon water.

Average dose: 8 c.c. (2 fluidrams).

Tinctura Digitalis.—U. S.—This now represents 10 per cent. of the crude drug in diluted alcohol in place of 15 per cent. as formerly official.

Average dose: 1 c.c. (15 minims).

Strophanthinum.—U. S.—This is a glucosid, or mixture of glucosids, obtained from strophanthus.

Average dose: 0.0003 gm. (0.3 mg. 1/200 grain).

Strophanthus.—U. S.—This consists of the ripe seeds of *Strophanthus Kombé*. It is preferably administered in the form of the official tincture.

Tinctura Strophanthi.—U. S.—This preparation now represents 10 per cent. of the drug in 65 per cent. alcohol, a case 0.16x double the strength of the tincture official in the U. S. ly exPharmacopeia, 1890. ly shows

Average dose 0.5 c.c. (8 minims). the spine

Apocynum.—U. S.—This is the dried rhizome of *A* recently *cannabinum*, or of other closely allied species of apoc bilhar- This drug is said to have been used by the American Ind in various ailments, and has long been in use as a household remedy. More recently it has again attracted attention by itse possible uses as a circulatory stimulant, though the practical results that so far have been attained do not appear to warrant its use in all cases. The only official preparation is:

Fluidextractum Apocyni.—U. S.—The fluidextract of apocynum is directed to be made with a mixture of 10 per cent. of glycerin, 60 per cent. of alcohol and 30 per cent. of water.

Average dose: 1 c.c. (15 minims).

Convallaria.—U. S.—This consists of the dried rhizome and roots of *Convallaria majalis*.

Average dose: 0.5 gm. (7½ grains).

Fluidextractum Convallariæ.—U. S.—This is made with a mixture of 65 parts of alcohol and 35 parts of water.

Average dose: 0.5 c.c. (8 minims).

1. From what we know of the chemistry of this particular drug, and from the action of the known isolated proximate principles, it would appear that in this connection it was particularly unfortunate that the committee on revision did not see their way clear to adhere more strictly to the proposed international standards for the formula of potent medicaments and direct, for the extraction of digitalis, the proposed 70 per cent. alcohol in place of the diluted alcohol of the U. S. Pharmacopeia. The stronger alcohol would have had the advantage of insuring a more ready and more complete solution of the active principles, of answering better as a preservative and of materially reducing the amount of inert, and, therefore, unnecessary, extractive now contained in the official tincture.

Therapeutic Actions of the Digitalis Group.

Digitalis has been referred to under the heading of diuretics (Chapter V), and for this purpose the infusion is usually to be preferred.

As a circulatory stimulant one of the drugs of the digitalis group is indicated when the heart is weak and rapid and the blood pressure low, conditions which arise under a variety of circumstances.

In cardiac dilatation with weak systole digitalis affords an ideal remedy as may be readily understood from its pharmacologic action. In pneumonia the right ventricle suffers primarily and digitalis is indicated, for while it affects the right ventricle less than the left, and the auricle least, this does not affect its usefulness in this condition, because the nutrition of the heart—both left and right—is supported by the improved coronary circulation, a most important factor, as we have seen, when extra work is thrown on the heart and the pulmonary circulation is not affected by the general vasoconstrictor action of the digitalis. In this connection the lengthened diastole, while it undoubtedly affords a better chance for the emptying of the pulmonary veins, is a factor of but minor importance. The use of digitalis in mitral insufficiency is familiar to all and the pharmacologic action readily explains its usefulness in this connection.

Digitalis and its congeners are said to be harmful in some cases of mitral stenosis, and they may fail to prove beneficial in insufficiency of the aortic valves. It is suggested that in this condition the blood may gravitate from the brain through the aortic valve during the lengthened diastole. The action of the drugs must be carefully observed in these conditions and they must be withdrawn if they appear to be doing harm.

Drugs of the digitalis series are contraindicated in cases of fatty degeneration of the heart, since a heart so weakened could scarcely support the additional burden imposed by the increased arterial tension, nor can hypertrophy be expected to occur in such a heart. They are also contraindicated in all conditions in which an increasing blood pressure would be dangerous, for instance, in aneurism.

With digitalis particularly, one must constantly watch for the first symptoms of cumulative action, usually gastric disturbance, and it, or other members of the same group, should be temporarily withdrawn when suggestive symptoms occur.

Powdered tincture of digitalis contains a larger proportion of the soluble digitoxin than does the infusion, in which the essential principle present is held in solution by means of digitonin, from a which being the most irritant of the known principles of digitalis, the infusion, containing digitalin principally, will be found preferred.

When the heart is weak and irregular digitoxin is probably the most efficient remedy we possess for restoring it to normal beat and action. An alcoholic solution of digitoxin may be used to advantage, provided it be well diluted with water when administered or taken. It is altogether too irritant for hypodermic injection, but if the claim made by Cloetta to the effect that he has succeeded in preparing a stable, water soluble form of digitoxin, which is not very irritant, is substantiated, a distinct advance will have been made in digitalis therapy.

The dose of digitoxin as given by the different authors is somewhat variable. Cushny states that 0.02 mg. (1/350 grain) of crystalline digitoxin may be given three times daily. Schmiedeberg recommends 1.5 mg. (1/330 grain) of the crystalline digitoxin three times daily. This is the dose used by Marx with good results in Naunyn's clinic. The physician will do well not to exceed this latter dose too greatly, bearing in mind that cumulative effects may, and sometimes do, develop quite suddenly, even with a dose which has been apparently harmless.

Digitoxin and digitalin, pure or in the leaf, are changed into substances with a convulsive action in the presence of moisture by bacteriologic action, hence old infusions should not be used nor should such leaves be employed which bear evidences of not having been properly dried or carefully preserved.

Digitoxin and digitalin may be kept dissolved in alcohol and diluted as required. The dose of digitalin, or digitalinum verum, is from 2 to 6 mg. (1/30 to 1/10 grain) three times daily.

Digitoxin may be prescribed as follows:

Digitoxini (cryst.)	gr. 1/12	(0.005
Alcoholis q. s. ad	ʒiii	100)

M. Ft. solutio. Sig.: One teaspoonful in a little water three times a day.

Digitalin can be prescribed in the same way but 0.05 is used in place of 0.005 gm. thus:

Digitalini veri	gr. i	(0.5
Alcoholis q. s. ad	ʒiii	100)

M. Ft. solutio. Sig.: One teaspoonful in water three times daily.

The tincture of digitalis, diluted with water, is given alone three times a day. Owing to the slow excretion it is not necessary to repeat the dose more frequently, and the drug should be stopped for two days about once a week to avoid cumulative effects, whether one of the active principles or a Galenic preparation of digitalis is being used.

Sollmann has suggested that strophanthin may deserve an even greater popularity than digitalis, and this suggestion has found support in more recent investigations. Strophanthin is now official, whereas the active principles of digitalis have not as yet been included in our Pharmacopeia.

Strophanthin does not cause vasoconstriction and it therefore deserves the preference over digitalis and its principles when increased blood pressure is to be avoided. Thus, when dilatation of the heart is due to high blood pressure from increased arterial tension, strophanthin may be used, or if digitalis is employed, a vasodilator such as nitroglycerin or one of the nitrites should be given at the same time.

Because of its more prompt effect on the heart, strophanthin may be employed to usher in the action when digitalis is to be employed. This promptness of action would also render it preferable to digitalis in shock or collapse were it not that the vasoconstrictor action is wanting.

Digitalis, or one of its principles, may be given several hours before an operation when there is reason to apprehend shock, so that its action may coincide with the time that shock occurs instead of waiting till that condition has actually developed before giving the slowly acting remedy.

Owing to the variable quality of the strophanthus seed and the tinctures that are now obtainable, it may be well for the physician to use the pure principle, strophanthin. This is easily obtainable and is readily soluble in water so that it may be prescribed in simple solution.

Strophanthin, it should be added, is also somewhat variable in quality and composition, but since it acts much more quickly than digitalis the dose may be cautiously increased if necessary. It undergoes decomposition, and it is therefore better to prescribe it in diluted alcohol: 0.01 gm. (1/5 grain) may be directed to be dissolved in 150 c.c. (5 fluidounces) of diluted alcohol and one teaspoonful of this solution, diluted with water, given three times a day.

Dr. H. C. Wood, Jr., recommends Canadian hemp as a satisfactory and reliable circulatory stimulant, but as his published work appears to have been done with a fluidextract of *Apocynum cannabinum* and as the Pharmacopeia itself recognizes closely allied species of apocynum, that may or may not have similar physiologic properties and therapeutic uses, it may be well to await the results of further investigations before trusting too implicitly in the possible results to be obtained from this drug.

Other official members of this group have little to recommend them in preference to the more prominent ones just described.

It might be added that the alkaloid of the suprarenal gland is not suited for long continued administration. It does not influence blood pressure when given by the stomach, and but slightly or not at all when injected just beneath the skin. When injected into the muscle there is a transient rise of blood pressure. Its local use has been discussed at greater length in connection with astringents (Chapter XIII).

Autosuggestion and the Mentally Defective.—Gordon of Philadelphia, in *American Medicine*, states that mentally defective children are particularly inclined to autosuggestion, and that the same symptom is observed in adults similarly affected.

Clinical Notes

BILHARZIA DISEASE.

REPORT OF TWO CASES OBSERVED AMONG PORTO RICANS IN SAN FRANCISCO.*

HERBERT GUNN, M.D.

Instructor of Clinical Medicine, Cooper Medical College; Associate Professor of Tropical Medicine, Postgraduate Department University of California (San Francisco Polyclinic.)

SAN FRANCISCO.

Bilharzia disease, called also endemic hematuria and bilharziosis, is caused by a trematode worm or fluke inhabiting principally the portal venous system, where it deposits its eggs, the escape of which into certain organs produces the various symptoms of the disease.

Bilharz discovered the parasite in 1851, and later the disease was named after him.

The disease is quite prevalent in some parts of the world, but until recently few cases had been observed outside of endemic areas. In many parts of Africa it is quite common.

In Egypt over 50 per cent. of the population harbors the parasite. Cases have been observed in Cyprus, Sicily and Mauritius.

British soldiers returning from South Africa have probably disseminated the disease to a considerable extent, as recently shown by Douglass[1] and Hardy.

In the United States, so far as I am able to find, only six cases have been reported.

The descriptions given of the findings in two of these cases are so at variance with the teachings of authorities on the subject that one is doubtful as to the correctness of the diagnoses.

The first case was reported by Booth of Sparta in 1882 and was supposed to have originated in Illinois, but the description given of it does not warrant its acceptance as one of bilharziosis. The second case, reported in 1895 by B. F. Curtis[2] of New York, occurred in an English soldier who had contracted the disease in Egypt. The third, reported in 1897 by Brooks[3] of New York, was an imported case. The fourth was reported by Walker[4] of Indiana in 1900. This patient was supposed to have contracted the disease in the same neighborhood in Illinois as the first patient reported by Booth. What was said of Case 1 undoubtedly holds true in this case and it is impossible to consider it as one of bilharziosis. The fifth case was reported by Pool,[5] New York, in 1903 and was an imported case. The sixth was reported in 1904 by O'Neil,[6] Boston, and was also an imported case. A seventh case, not as yet reported recently came under the care of Dr. M. E. Lando, U. S. Navy, at the Mare Island Navy Yard Hospital. The patient, I understand, had been in Africa. Thus, there have occurred in the United States, so far as we know, only five cases of this disease, in all of which the urinary tract was the seat of the lesions.

The two cases I here report represent, I believe, the first appearance in this country of the intestinal form of bilharzia disease.

Manson[7] reported a case of the intestinal variety of bilharziosis occurring in an Englishman who had resided for many years in the West Indies and who must have contracted the disease there. Porto Rico was apparently not among the islands visited by this patient. Manson concluded that at least one island of the West Indies group was infected with this disease. Recent observations have proved that Manson's conclusion is correct, as the disease has been observed in Porto Rico by Ashford and others. Both of my patients resided for a time in Hawaii, and, as they had passed through the United States on their way from Porto Rico there, the source of their infection must have been one of the three places. The United States can practically be eliminated as a possible source.

The disease has never been observed in the Hawaiian Islands and is not found in China or Japan, from which countries Hawaii draws largely for her coolie laborers.

Catto[8] described a new worm greatly resembling bilharzia hematobia occurring in the Chinese and Japanese, but the ova are quite distinctive and confusion of the two would be impossible. It is safe to assume, therefore, that the infection in my cases originated in Porto Rico.

The adult worm, which is never found in the excreta, inhabits principally the portal venous system and its branches. It has been found in the vena cava and elsewhere occasionally, but it has been suggested that, if diligently sought for, it might be more frequently encountered in other organs. Several hundred worms may be present, as many as three hundred having been found.

The following description of the parasite is taken largely from Manson's work on "Tropical Diseases":

> The bilharzia hematobia or the schistosomum hematobium is a distome and is bisexual. The male is white, cylindroid, and from 11 to 15 mm. long by 1 mm. broad. There is an oval and ventral sucker placed close together. The body of the worm is flat and infolded, forming a gynecophoric canal, in which the female is inclosed during copulation. The female is longer than the male, measuring about 20 mm., and it is dark r and filiform. The genital openings are situated just back of the ventral sucker. The ovum is oval and measures about 0.16x 0.06 mm. It presents a terminal or lateral spine, as the case may be, which difference has never been satisfactorily explained. When found in the urine, the ovum invariably shows the terminal spine, but when obtained in the feces the spine is placed laterally. An exception to this rule has been recently noted by Duncan,[9] who found in the urine of a case of bilharziosis eggs with lateral spines.
>
> Considerable variation in the size of the ova may be observed. The egg often contains a ciliated embryo which, in mature specimens, may escape through a longitudinal break in the shell and swim about, frequently changing its shape. This process is expedited by adding fresh water to the specimen.

The life history of the embryo is practically unknown. In all probability some fresh water animal acts as an intermediate host.

The mode of infection can not be understood until the extracorporeal life of the parasite is more fully demonstrated. Infection is supposed to occur through the drinking water, and, according to Loos, possibly directly through the skin. The symptoms are produced by the passage of the ova through the tissues, the sharp spinous process probably being an important factor. It appears that the vast majority of persons infected with bilharzia hematobia present no symptoms whatever. Vague pains in the back and slight malaise may be all that is complained of. In the small percentage of cases in which definite symptoms occur any degree of severity may be observed from an occasional slight burning on urination, with possibly a few drops of blood at the

end of the act, to the most intense suffering with almost incessant micturition, causing excruciating pain and accompanied by quite profuse hemorrhage.

The symptoms of cystitis may remain constant, or, what is more probable, remissions and exacerbations may occur. The ureters may become involved in the inflammatory condition and occlusion be produced, either by inflammatory thickening of their walls or by stone formation, hydronephrosis or pyonephrosis resulting.

When the intestine, usually the rectum, is involved the symptoms when present are those of a dysentery of varying degrees of severity. Polypoid growths and excrescences are frequently observed.

Naturally the general health suffers greatly in severe infections, such patients being very susceptible to intercurrent diseases. The prostate or seminal vesicles may become involved, ova then being found in the semen. Urinary fistulæ frequently occur, often in the perineum. Vesical calculi sometimes result, also carcinoma. Ova have been found in the liver and lungs, where, as a rule, they produce no symptoms. They have also been observed in gall stones and recently in the thickened walls of a diseased appendix. Any degree of anemia may be present, depending on the amount of blood lost.

The blood[10] shows a decided eosinophilia, ranging between 2 and 40 per cent. and averaging about 16 per cent. The increase of eosinophiles occurs usually at the expense of the polynuclear neutrophile leucocytes. The pathologic findings naturally depend on the degree and duration of the infection. Groups of fine granular elevations are found in the mucosa of the bladder, also polypoid masses and adherent strings. Areas of ulceration may occur. Considerable thickening of the bladder walls may be found, the submucosa especially being involved.

The tissues are infiltrated with ova and on sections are dense. Areas of calcification and deposits of phosphates are formed. Sloughing of the thickened walls or of the polyps may occur or the smaller blood vessels may be completely occluded by masses of ova.

The diagnosis is made by finding in the feces or urine the characteristic ova. In cases in which but few ova are passed the last few drops of urine are most likely to show the greatest number.

The prognosis depends on the degree of infection and the effect on the general health. In regard to life it is good, death rarely resulting directly from the effects of this disease. Indirectly and from intercurrent diseases the prognosis may be grave. The parasite may die within the host, and yet results of the disease remain for years. Often the symptoms gradually disappear and the health becomes perfectly restored. Man may harbor the parasite for many years. One case is reported, in which no fresh infection could have occurred, where it was present for nine years.

The treatment is purely symptomatic, no drug having any influence on the parent worm in the portal system. Polypoid growths, calculi, etc., may be removed if necessary and the cystitis or dysentery treated. The symptoms can be relieved or ameliorated, but a cure can not be effected.

Manson, during the recent Lane lectures at Cooper Medical College, emphasized the importance of recognizing this disease from the urinary examination, thereby avoiding unnecessary and perhaps harmful manipulation and instrumentation.

10. Looss, Oct. 10, 1903.

Of the two cases that I have observed the second showed absolutely no symptoms attributable to the disease; the first showed but few symptoms that could be entirely ascribed to the infection with the distomum hematobium. Both patients were infected with *Uncinaria americana*, and appropriate treatment in that direction relieved practically all symptoms. Both harbored *Tricocephalus dispar*, and in Case 2 *Strongyloides intestinalis* was present.

Both patients lived in Porto Rico until four or five years ago, when they went to the Hawaiian Islands, where they worked on the sugar plantations. About a year ago they came to San Francisco.

CASE 1.—The patient, referred to me in February, 1905, for treatment of uncinariasis, was a male, aged 25, married.

History.—He enjoyed perfect health until two years ago, while in Honolulu, when there appeared abdominal pain, weakness, palpitation and frequent bloody stools, numbering from eight to twenty-eight a day. This condition has remained practically the same until the present time.

Examination.—There has been some loss of weight. The examination showed moderate anemia, great weakness, abdominal distention and tenderness. The stools contained small amounts of mucus and blood and showed ova of uncinaria, ova of the whipworm and very few ova of the *Distomum hematobium*.

Treatment.—After ridding the intestine of the uncinaria, practically all subjective symptoms disappeared.

Result.—There was a gain in weight of ten pounds and the patient felt perfectly well, except for occasional attacks of diarrhea. Occasionally a trace of blood is observed in the stools and a reaction for occult blood is at times present. Ova of bilharzia and of the whipworm are still present.

CASE 2.—There were no symptoms due to the bilharzia infection.

Eosinophilia was observed in both of these cases, but the presence of other parasites made it impossible to know what relation it had to the distomum hematobium.

In neither case was anything abnormal found on rectal examination.

Manson, while in San Francisco, examined the ova and pronounced them similar to those he had observed in his West Indian case. He is of the opinion that the lateral-spined ova are produced by a different species of worm from the one producing the terminal-spined eggs. Catto's discovery of a very similar parasite, but with a quite different egg, would lend color to this view. It seems impossible to account for the radical difference in the shape of the eggs and the constancy with which one apears in the urine and the other in the feces under any other hypothesis.

In my own cases I have observed that the embryo does not develop so rapidly, and when developed does not leave the shell and become free as in the terminal-pointed eggs. Specimens have been kept for weeks and months diluted with water, some in the incubator and others at room temperature, but in no case has a motile embryo been observed nor has a ruptured shell or free embryo been encountered giving evidence of motility.* Artificially the shell has been ruptured and the contained embryo expressed, but all have been motionless. This is quite a different course from that pursued by the terminal-spined variety, in which there is abundant evidence of considerable motility. This, I believe, is further evidence that a different species of worm produces the lateral-spined ova, at least that found in the Porto Rican.

* Since writing the above a few ruptured shells have been observed in a culture four months' old; the embryos could not be found.

New Instruments

NEW NASAL SNARE.

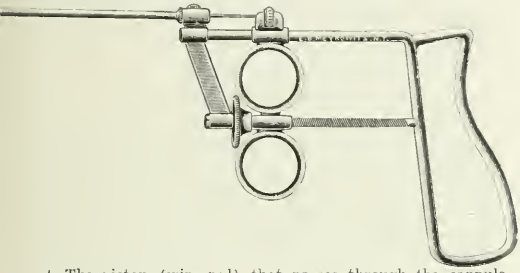
T. EDWARD DUFFEE, M.D.
WINCHENDON, MASS.

This is one of a series of instruments designed for nose and throat work, the special feature of each being the "pistol grip" handle, which allows the operator an unobstructed view of the field of operation and an easy natural position which does not cramp the hand or fingers. The nasal snare shown here is very light, being made from nickled tubular brass, is well reinforced, exceedingly strong and durable, and I believe embodies several features that will make it a valuable instrument.

1. The direct draft decreases resistance, with the index and middle fingers in the rings the operator gets a purchase which makes a much more powerful snare than any with which I am familiar.

2. The double carriage avoids binding when traction is made, at the same time reinforces the whole instrument so there is no springing even when considerable force is exerted.

3. When greater force is needed the large thumb screw (follower) is easily operated by the free hand.



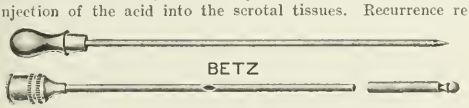
4. The piston (wire rod) that passes through the cannula or barrel is adjusted by another smaller follower set inside a slot on top of the carriage so it can be made any length desired by simply turning the thumb screw (follower), at the same time it is held securely in place, thus avoiding slipping or flying back or out. At the distal end of this rod there are two small eyes where either end of the wire after being cut the length desired may be threaded and bent so as to lay close to the rod, then drawn just inside the barrel (cannula). This method of threading is a feature that saves much trouble and is common to one or more snares now in use. After being used the piston can be very readily pushed back to be rethreaded if desired.

5. It has no nuts to work loose, no wires to protrude or slip and its general simplicity of construction will, I believe, appeal to the busy and practical operator.

A NEW INSTRUMENT FOR THE CURE OF HYDROCELE.

WILLIAM T. BELFIELD, M.D.
CHICAGO.

The cure of hydrocele by injection with carbolic acid has obvious advantages over the cutting operations. Its serious defects have been (1) uncertainty of a cure, (2) unintentional injection of the acid into the scrotal tissues. Recurrence results from failure to destroy the serous surface, and this in turn from incomplete removal of the albuminous hydrocele fluid, an adherent layer of which protects the serous surface from the caustic effect of the acid.



These defects are remedied by the following method with the instrument herewith pictured, whose distinctive feature is the window in the canula.

METHOD OF USE.

The distended scrotum is transfixed from above downward; after withdrawal of trocar and escape of fluid, the lower end of the canula is closed by the cap and the sac is distended with warm salt solution injected through the upper end. Removal of the cap allows the solution to escape; and this flushing of the sac is repeated until the escaping water shows only a trace of albumin by the nitric acid test. The cap being replaced, an ounce or more (according to capacity of sac) of carbolic acid—pure or 95 per cent.—is injected, the scrotum thoroughly manipulated to secure contact throughout, and the acid allowed to escape; residual acid is neutralized by injection of alcohol; after escape of latter the canula is withdrawn and punctures are sealed. Confinement to the house is unnecessary. The fluid which refills the sac in the next few days will be absorbed, but is better removed by a simple puncture.

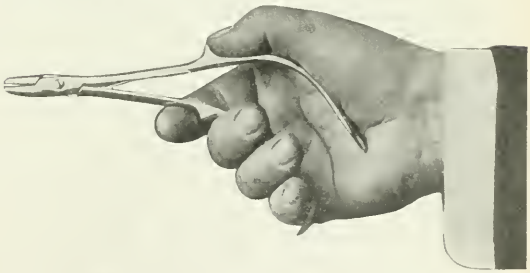
This method, employed in 17 cases without recurrence, seems to offer all of the good and none of the evil features of the various cutting operations for simple hydrocele.

A SIMPLE NEEDLE-HOLDER.

WILLIAM E. GROUND, M.D.
SUPERIOR, WIS.

The multiplicity of needle-holding devices attests the lack of an instrument that meets the requirements of the busy surgeon. Most of them, if so constructed that they will hold a needle securely, are complicated and clumsy, requiring an unnecessary loss of time in locking and unlocking. A great deal of ingenuity has been expended on the construction of a jaw that would hold any needle and with this have gone complicated-locking mechanisms, so that when in actual use the average needle-holder was about as unhandy as it was possible to make a useful article.

The different patterns of needles are as varied as are the needle-holders, so that the technic of wound suture is anything but satisfactory to the majority of operators.



It has been my object to simplify both needles and needle-holders and to limit the kind used to a few effective styles of needles, and to devise a needle-holder with which these may be handled with the utmost ease and facility.

A few years ago it occurred to me that if I had a needle-holder that would fit naturally in the hand, so that the hand could be used in an unconstrained position, I could handle any needle dexterously without recourse to catching devices, thus rendering the instrument simple, efficient and time-saving. I therefore turned my attention to arranging a handle to different styles of jaws already in use, and finally adopted the style shown in the illustration. I have used this instrument for several months and it has greatly facilitated the application of the needle and suture. The handle fits nicely in the hand, and with the hand in a natural position the shaft of the needle-holder is parallel with the forearm; in fact, is a direct continuation of it. With a full curved needle in use a mere rotation of the forearm sends the needle through the tissues, and when the hand is relaxed the holder flies open and is ready to grasp the needle as it emerges and to repeat the process with no loss of time caused by the locking and unlocking of catches.

SATURDAY, APRIL 7, 1906.

THE SERUM DISEASE.

The appearance of rashes after the injection of alien blood in human beings was noted as early as 1874, but it is only since the introduction of serotherapeutic measures that rashes and other local and general phenomena supervening on the injection of animal serum, most commonly equine, has attracted general notice. Pirquet and Schick, in Vienna, recently issued a monograph on this "Serum Disease," a brief discussion of some phases of which may not be without interest.

The symptoms traceable to the single injection of serum usually appear after an incubation period of from 8 to 12 days. Sometimes the general symptoms are preceded by a prodromal sensitiveness and slight redness of the skin above the point of injection associated with a moderate swelling of the regional lymph nodes. Fever is the most constant sign, commonly remittent but sometimes intermittent toward the end. A high fever usually accompanies morbilliform eruptions. The rashes vary not only in different individuals but even in the same person. The most common type is the urticarial. When generalized the eruptions tend to be symmetrical; their duration rarely exceeds three days. Swelling of the lymph nodes is one of the most important signs in both the diagnostic and the prognostic sense; it may become more or less generalized; its subsidence indicates the end of the disease. Articular involvement is less frequent; the joints most commonly involved are the metacarpophalangeal, the wrist and the knee. The salicylates have no effect on the joint symptoms. Edema is constant, usually in the same location as the edema of renal origin, and sometimes succeeded by a slight albuminuria.

In those receiving more than one injection of serum the symptoms may appear almost at once or in four or five days after the last injection. According to Pirquet and Schick the "immediate reaction" is the rule when the patient receives a large dose of serum for the first time, followed by a second injection in from three to eight weeks, while the "precocious reaction" occurs commonly when there is a longer interval between the two injections.

Years ago (1895) Heubner and Bókay first showed that the specific antibodies in serum play no part in producing the symptoms referred to in the foregoing. Recently Hamburger and Moro traced the eruptions to the union of the precipitins formed in the injected body with precipitable substances still remaining as residues, so to speak, of the foreign (horse) serum, the precipitates so formed causing mechanical obstructions to the circulation in the skin and possibly elsewhere. There is no constant relation, however, between the existence of precipitins and the symptoms of serum disease. Thus the precipitins usually pass out of the blood in from five to nine weeks after the first injection of the serum, while the immediate reaction referred to may appear even after twice as many months. Furthermore, eruptions and other symptoms may occur after one injection in individuals whose sera contain no precipitins, and, reversely, symptoms may fail to develop in patients whose sera contain precipitins in abundance. Hence, we are without any satisfactory explanation of the genesis of the serum disease. It remains to be seen whether the concentration of diphtheria antitoxin by means of Gibson's method of precipitation will remove fully the substances that give rise to the reactions in the injected organism comprised under the term serum disease.

HARMONY VERSUS STRIFE.

Profound economic reforms are seldom effected by force of arms; great economic problems are never solved by means of the "big stick." So true is this that one searches history in vain for an illustration to the contrary. It is true that, during the process of evolution, occasionally and incidentally, violence has occurred which has resulted in some great economic or sociologic movement. In all such instances, the violence has been due to other causes, or has, *per se*, had little or nothing to do with bringing about the result so far as economic change is concerned. During the past generation economic changes and reforms have been brought about in some parts of England and in continental Europe which seem almost incredible to one who hears of them for the first time, yet so quietly has this been done that scarcely a word of it all has reached us, and doubtless less than 1 per cent. of the people of this country have the slightest knowledge of the bare existence of these sociologic movements. Tremendous as these movements have been, with the resulting enormous betterment of certain classes of laboring people, no single act of strife worth noting has marked their progress.

Serious economic problems confront the medical profession of this country, and probably the greatest of these is the question of lodge and similar contract practice. It is purely a problem in economic sociology, and to one who gives it careful thought it becomes evident that it is a problem not to be solved by strife; the "big stick" can have no place in its solution. That this class of practice is a great and a growing evil probably no one will venture to deny; that it is an evil which disastrously affects the general public more than the medical profession will appear on careful study. When an unlimited amount of service is demanded and paid for by

a very limited compensation, that service will be slighted, no matter how conscientious the individual performing it may think himself. Any intelligent practitioner who is doing lodge practice often realizes that he is imposed on; that his services and his time are demanded when, under other circumstances, and if they had to be paid for at regular rates, he would not be disturbed. As a result, there is a feeling of resentment and the patient gets scant attention. The patient suffers from his own greed, and the people who participate in this wholesale medical service are really the ones who suffer most.

Indirectly, this class of practice reacts on all physicians and on all laymen. That a certain portion of the community is getting medical attention, of a sort, for a very small cost, soon leads the remainder of the community to believe that it, too, should get its medical attention at a less cost, and there is a demand for lower medical fees. Those who make this demand, however, do not realize that in the end they themselves will have to pay the bill. They do not appreciate the fact that, in order to keep himself up to the highest point of efficiency, the physician of to-day must have a good income. He must study unceasingly; he must constantly add to his equipment, material as well as mental; he must leave his home from time to time and study the work and the methods of other men. These things can only be done if the physician receives sufficient compensation to enable him to take a portion of his time for his own betterment.

It is thus evident that there is the fullest community of interest so far as this question is concerned; the real welfare of the general public, though now they know it not, demands a cure of this evil just as much as does the welfare of the medical profession. It is the duty of the medical profession to settle this and other economic problems affecting the public, and this duty should not be forgotten or ignored. Strife will not cure the lodge practice evil; fighting will not settle economic problems. Harmony and unity in action are the only means by which betterment may be brought about.

And this improvement must have its origin in the particular community interested; the harmony must be that of the local profession. The county medical society is, or should be, the most potent agent for effecting these economic changes. In the county society should be secured that harmony and unity of purpose and action which the welfare of the people demands. State associations can do but little; the American Medical Association can do no more; it is all in the hands of the physicians in each county. The substitution of friendly feelings for jealousy and animosity; the replacing of strife by harmony, through the knowledge of one another gained in the county society—in other words, the bringing about of an actual community of interest—will see the absolute eradication of the "lodge practice" evil.

THE QUESTION OF RECREATION.

The dependence of good health on recreation has always been recognized, though it is clear that there have been differences of opinion as to what constitutes recreation. In our day the word calls up visions of the tennis court, the gridiron or the golf links, and is generally used synonymously with sport, but it must not be forgotten that widespread as is the craving for exercise there are some who prefer the pleasures of the library or the card room. Women, while they are much more sensible regarding rational exercise than in former generations, are still too apt to regard a cooped-up afternoon at cards in a stuffy and poisonous atmosphere as recreation, and it can not be denied that the sterner sex offend the dictates of physiology almost as frequently. Even in medical meetings we have known listeners to be lulled to sleep by the carbonated air of the meeting hall. The matter of recreation has been discussed recently before the American Academy of Medicine[1] in a series of papers which attack the problem from different sides.

Used in the sense of exercise, the physiologic effects of recreation are manifest and obvious. To the individual who spends his days cooped in the counting room, the exercise of the muscles, especially in the open air, has a stimulating effect on the circulation, the respiration, and the muscular metabolism, promotes the oxygenation of the blood and increases the appetite. From the psychic side it is important that the exercise be accompanied by a certain mental stimulus. To exercise for exercise's sake is a tiresome matter, but to take exercise in the form of a game which supplies a certain element of competition, and requires mental and physical adroitness, is a pleasure. In these days of the strenuous life we are apt to be strenuous in our play as well as in our work, and it is important that we do not take our pleasures too seriously and degrade them below the level of true sport by a policy of "win at any price."

In considering the effect of exercise on the nervous system—and we must not forget that in the end the nervous system is the source of all energy—we should take into account the fact that different occupations make a call on the energy of different areas in the brain. In exercise we must attempt to rest the areas used in the daily routine and to bring into play different areas. Naturally muscle workers do not require the same sort of recreation as brain workers. In fact, the two classes need forms of recreation almost diametrically opposed. In adults, personal preference plays so strong a part that definite rules can not be formulated.

Recreation in connection with educational institutions requires special consideration, both because we are dealing with immature bodies and because the ethical aspects of play must be considered. The recent outbreak of public opinion regarding football is largely due to the fact that many of the casualties could

1. Bull. Amer. Acad. of Med. 1906, vii, 269.

have been prevented by restricting the game to the physically mature and that the ethical attitude of college men has been visibly debased by the game.

As physicians we are constantly preaching the doctrine of recreation, which we almost as constantly fail to practice. The fact is that there is a great need in our cities of means by which the mass of men can cheaply and conveniently get outdoor exercise. It is an expensive luxury for an individual in a sedentary business to keep well in a large city. The few athletic clubs which exist are as a drop in the bucket and come within the means of the rich only. It is to be hoped that in time the necessity for means of recreative exercise for those living in large cities will be recognized; that athletic outdoor sports may be regarded as necessities, not as luxuries for the well-to-do only.

TINKERING WITH THE PURE-FOOD BILL.

The Pure Food and Drug Bill, known as the Heyburn Bill, passed the Senate more than a month ago, while the House measure, practically identical, known as the Hepburn Bill, is now in committee, where two very important—not to say dangerous—amendments have been proposed. To understand the exact significance of these, it is important to bear in mind that the original measures provide that the examination of foods and drugs shall be made in the Bureau of Chemistry under the direction of the chief, by and with the advice of such experts as he may select for the purpose of determining whether or not such articles are adulterated, misbranded or unwholesome, and that if they are found to be adulterated or unwholesome the information shall be brought before a court which shall determine the facts and impose the penalty after hearing the case. It will thus be seen that the power which was intended to be delegated to the Bureau of Chemistry was in effect that of a grand jury which has no right to render a verdict, but limits its functions to a mere accusation. No usurpation of the judicial function was contemplated and the functions of the courts were left entirely undisturbed.

This bill received the approval of the medical profession, ascertained by a referendum sent into nearly every county in the United States. The enemies of the bill, it seems, have framed an amendment which provides for the appointment of a committee of five experts to consider the question of the wholesomeness of any preservatives or other substance in food, if the manufacturer or other person interested opposing the decision of the Bureau of Chemistry requests reference of the subject to such a commission. This commission is to pass on and essentially to have final jurisdiction on such questions.

There are several objections to this amendment. It limits the Secretary of Agriculture, to whom, as chief of the department which includes the Bureau of Chemistry, is intrusted the execution of the law, to a consultation with only five experts. This is a distinct and hurtful contraction of his present powers and of the powers which it was contemplated to bestow on him by the act as originally drawn. That this is true becomes apparent when it is remembered that he now has the right, which he frequently exercises, to enter into consultation with the ablest experts of the country without numerical limitation. The commission which it is proposed to establish by the amendment, and which would be more or less permanent, is further open to the objection of appointment by strictly political influence, and consequently does not give a guarantee of that careful and severe selection which would be exercised by an executive officer personally responsible for an efficient administration of the law. Furthermore, the proposed commission, vested, as it would be, with distinctly judicial functions, would be so far an infraction of the constitutional rights bestowed on the courts that the entire act would be imperiled.

In view of these facts, it becomes perfectly apparent that, under the guise of apparent fairness, the enemies of the Pure Food Bill, some of them experts employed by large food-preserving establishments, etc., have succeeded in securing the serious consideration of a proposition which in more ways than one would destroy the effectiveness, if not the actual existence, of the proposed law. Members of the medical profession, alive to the enormity of the crimes perpetrated on society through the manufacture and sale of impure foods and impure medicines, should at once and in most emphatic terms bring their forces to bear in an effort to defeat this pernicious amendment.

If, however, the preceding amendment is to be recognized as pernicious, what can be said of the second amendment, which has likewise been brought forward by the enemies of the reform in the manufacture of foods and drugs? Under the bill as first presented and as endorsed by the medical profession, it was provided that the manufacturer of any proprietary medicine containing alcohol or any enslaving drug should publish the formula on each original package. This has prompted the "patent-medicine" men to present an amendment to the effect that when an article contained in any one of these nostrums "be not described in the U. S. Pharmacopeia and in the National Formulary, and be not the prescription of a regularly licensed physician, and if the package fails to bear a statement on the label of the quantity or proportion of any alcohol, morphin, opium, heroin, eucain, chloral hydrate, or other enslaving drug, or any proportion of such substances contained therein, it shall be deemed misbranded; provided, however"—and here is where the quack medicine fiend gets in his work—"the quantity or proportion of alcohol need not be stated when not more than the quantity or proportion prescribed by the U. S. Pharmacopeia or National Formulary, as a solvent or preservative of the actual constituents of the medicines or preparation in such package used, and provided, furthermore"—and here is where the quack

medicine fiend becomes a fiend indeed—"that the quantity or proportion of opium or morphin need not be stated when the contents of the package contain not more than two grains of opium or ¼ grain of morphin to the fluid ounce, or, if a solid preparation, to an avoirdupois ounce."

This is probably the most brazen effort that has ever been made in public to promote and to continue the sale of enslaving drugs—drugs the mere unrestrained and unadvised taking of which by the public establishes the necessity for their continued consumption. The attempt to manufacture drunkards by concealing the presence of alcohol in these preparations under the specious plea that they are necessary solvents of other constituents is simply an attempt to sell poor whisky and to call it medicine. The reference to the U. S. Pharmacopeia and the National Formulary is made simply to throw dust in the eyes of the public and to give to the effort the appearance of a scientific basis, an effort that will deceive none with ordinary intelligence or possessed of the ordinary instincts of honesty and decency. If, however, this phase of the proposed amendment is reprehensible, what is to be said of the proposed attempt to exempt the publication on labels of the most enslaving drugs—drugs the most insidious in their encroachment on the mind and body of their victims. The mere proposition that these drugs, such as opium, morphin, heroin, chloral hydrate, and other narcotics, are to be exempted because they occur only in a certain apparently small proportion is as vicious as it is stupid. To enact such a law would be virtually to grant a license for the unlimited sale of enslaving drugs in a state of dilution. It is well known to every physician, as it ought to be known to every legislator, that when there is enough cocain or morphin in a preparation to do good there is enough to do harm; less than enough to do good is useless.

The foregoing considerations themselves ought to be sufficient to arouse every physician to active antagonism to the proposed measure and to prompt him to insist that his representatives in both branches of Congress shall exert their fullest possible influence not only in defeating the two proposed amendments, but in securing the enactment of the Pure Food and Drug Bill as originally drawn.

AMERICAN MEDICINE BECOMES A MONTHLY.

Our highly esteemed contemporary, *American Medicine*, will shortly cease to be a weekly and will be issued as a monthly medical journal. At the annual meeting of the stockholders the proposition was fully discussed and a large majority favored such a change. While we shall be sorry not to receive *American Medicine* every week, there is a wide field for it as a monthly. Its bright, progressive editorials, dealing with subjects always of great interest and importance to the profession, and its valuable original articles by men thoroughly competent to speak have placed it in a very high position among medical journals of to-day. The acknowledged ability of the editors and the high character of the contributed articles will insure the production of an excellent monthly journal. We wish it success and we trust that it may always stand for everything good and for nothing that in any way will hinder the progressive advance of an enlightened profession.

MARRIAGE OF DEFECTIVES IN NEW YORK.

The public seems to be on the way toward a very sane attitude on the subject of marriage of defective persons, if we may judge by a number of indications. One is a bill now before the New York State Legislature to prohibit the marriage of insane, epileptic, imbecile or feebleminded persons. If this bill becomes a law, a marriage contracted by such persons will be absolutely void. There is a provision which will allow one to be married if, thirty days before such marriage, one files in the county clerk's office a certificate signed by two physicians stating that cure has taken place and that there is no probability that the previously-existing defects will be transmitted to the offspring. This may be a loophole, but the bill, as a whole, is praiseworthy. The increasing favor with which such measures are regarded is a good sign for the future.

DRUNKENNESS.

The question was recently raised in a British medico-legal society as to the legal definition of when a man is drunk. The result can not be predicted exactly by the amount taken; for example, the judge sitting on the bench may have just taken into his system a much larger amount of alcohol than that which has brought the prisoner before him for judgment. This was considered an injustice. Since the question of individual tolerance is seldom raised, it was urged, the really minor sinner suffers. The point seems to us not well taken. The consequences must necessarily control the legal aspect of the case. In the absence of blue laws, the drunkard is not brought to court because he drank, but because of his condition which threatens peace, order and the safety of others.

DENITROGENIZING THE ATMOSPHERE.

About five years ago a noted English scientist sent out a rather disturbing prophecy that, with the rapidly increasing population of the earth, the wheat supply would become insufficient for lack of nitrogenous fertilizers. The present sources of supply are not inexhaustible, and his prediction excited some attention at the time, though we are not aware that it had any decided bull effect on the wheat market. Now comes another British scientist, Sir William Ramsay, who points out that the air over each square mile of the earth's surface contains enough free nitrogen to afford sufficient plant food for sixty years of the world's needs, and that measures are now under way to bring the atmospheric nitrogen into useful combinations for fertilizing purposes. We could probably spare a square

mile of atmospheric nitrogen once or twice a century without seriously affecting the general average of the atmosphere, and it is probable that, after having served its purpose, it would again, sooner or later, become a constituent of the world's gaseous envelope. It would be interesting, however, to note whether or not any local effects like those imagined by one or two well-known writers of fiction would be the sequence; whether we could repeat "Dr. Ox's" experiment as described by Jules Verne, for example. The vicinity of the nitrogen-combining plants, with their denitrogenized atmosphere, might be utilized as stimulating health resorts if Sir William Ramsay's anticipations are realized. There is room here for considerable fanciful suggestion, to say the least.

A NEW RADIUM DANGER.

The explosion of a glass tube in which a number of milligrams of radium bromid had been sealed up for eleven months is described in a German paper.[1] The tension producing the explosion was estimated at twenty atmospheres, possibly accumulated during that time by the liberation of helium in the tube. As physicians are using radium as a therapeutic agent it is well for them to be advised of this danger, the more so since other instances are said to be on record, and since its high cost will tend to its long keeping. The reporter of this accident, Herr Julius Precht, has undertaken to investigate the ratio in which pressure may develop from radium in a sealed tube. He publishes his experience as a caution to those who are in possession of tubes that have been sealed for a long time.

PULMONARY TUBERCULOSIS IN SCHOOLS.

The fact that phthisis is frequently spread in places where large bodies of people are gathered is too well known to require much emphasis. Schools are undoubtedly prominent in disseminating consumption, and consequently school buildings should always be as well ventilated as possible. There is at all times a considerable amount of tubercular disease among school children. The medical officer of Blackburn, Lancashire, England, in a recent report stated that he found that nearly 10 per cent. of the children examined in some of the schools had pulmonary consumption. In the Paris schools the state of affairs in this respect was even worse, the figures being from 11 to 14 per cent. among boys and from 17 to 20 per cent. among girls. At the International Tuberculosis Congress held in Paris last year the statement was made that one of the most fruitful sources of consumption among school children was the use of school buildings by adults for public meetings. It goes without saying that school rooms require plentiful ventilation, and that if they be filled with people in the evening, as well as in the day-time, that this desideratum is impossible of attainment. A speaker at a meeting of an educational society said that he thought that public meetings should not be permitted in school buildings except in rare cases, and that in order to lessen the dangers after such meetings the schoolroom should be washed with a weak solution of formaldehyd.

1. Physikalische Zeitschrift (Leipzig), Jan. 15, 1906.

THE TUBERCULOSIS EXHIBITIONS.

Both the public and the profession are to be congratulated on the interest that has been taken in the various tuberculosis exhibitions in several of the principal cities of the country. We have commented on those held in the East, and now a successful exhibition has been held in Indianapolis and another is in session in Chicago, both being well attended by the public. This feature of the campaign against tuberculosis is certainly valuable. We should be glad to see similar exhibitions concerning other communicable diseases, such as have been in operation in Germany for some time. The public is ready to be informed on all these subjects, and the medical profession certainly has work to do along this line. We congratulate all those who have labored so faithfully for the arranging and carrying out of these exhibitions and hope that their success will be a stimulus to further work in this direction.

Medical News

ALABAMA.

Coming Convention.—The Medical Association of the State of Alabama will convene at Birmingham April 17.

Established Quarantine.—The Mobile Bay quarantine board has established quarantine against Puerto Cortez, Honduras, on account of the presence of yellow fever at that place.

Personal.—Dr. Thomas J. Springfield, Ensley, who was operated on recently in Birmingham for malignant diseases of the bowel, is reported to be improving.——Dr. T. W. Ayers, Anniston, a medical missionary in Hwang Hien, China, has returned to America on a year's leave of absence.——Dr. William C. Mapes, Scottsboro, is dangerously ill with pneumonia.——Dr. and Mrs. Cunningham Wilson, Birmingham, sailed for Europe March 14.——Dr. Albert E. Meadow, Birmingham, is seriously ill with influenza.

ARKANSAS.

Bequest to Hospital. Under the provisions of the will of the late Major W. H. Davis $5,000 is bequeathed to the Davis Hospital, to be erected in Pine Bluff.

Change of Meeting Place.—The Arksansas Medical Society will not meet at Pine Bluff on May 8-10, it is announced, on account of insufficient hotel accommodations. The meeting will be held at Hot Springs.

Physicians and Surgeons' Association of Searcy.—This association has been organized with the following officers: President, Dr. John B. Grammer; vice-president, Dr. H. C. Jones, and secretary and treasurer, Dr. Luther E. Moore.

Councilor District Meeting.—A meeting of the Tenth Councilor District Medical Society was held at Fort Smith March 20. Dr. Joseph T. Clegg, Siloam Springs, was elected president; Dr. James A. Foltz, Fort Smith, vice-president; Dr. Charles E. Hurley, Bentonville, secretary, and Dr. Othello M. Bourland, Van Buren, treasurer. The next meeting will be held in Monte Ne.

New Rule in Hot Springs.—Dr. William H. Barry, president of the Government Medical Board, Hot Springs, has issued the following notice:

> Notice is hereby given to all parties whom it may concern that hereafter when a name of a physician is dropped from the list of registered physicians, neither the Department of the Interior nor the board will entertain an application for restoration to such list until the lapse of one year from the date of the dropping of the name from the registered list.

Drumming Prohibited. The Supreme Court of Arkansas has declared valid the state law passed in 1901 prohibiting the "drumming" of patients to physicians at Hot Springs. The Chancery Court at Hot Springs had declared this law unconstitutional.——Dr. T. B. Ryder, Hot Springs, was arrested March 13, charged with violation of the new city ordinance which provides that any physician convicted of soliciting or drumming patients may be deprived of his right to practice. On March 19 Dr. Ryder was found guilty, fined $100, and his license to practice revoked.

ILLINOIS.

New Maternity Hospital.—Plans are being completed for the Elizabeth Williams Maternity Hospital, to be built adjacent to the Evanston Hospital. The building will be three stories in height, fireproof, and will cost about $25,000.

Few Seek Positions.—Only twelve applicants took the examinations for nurses and chief nurses in the state charitable institutions which were held March 29 by the Illinois Civil Service Commission in Chicago, and at the Illinois Hospital for the Incurable Insane, Bartonville.

Go Abroad.—Drs. Franklin C. Vandervoort, John W. Fulwiler and Robert A. Noble, Bloomington, sailed for Europe, April 3. On March 28 these gentlemen were given a farewell dinner by Dr. Franklin H. Godfrey, at his home in Bloomington. Drs. Ernest Mammen, William E. Guthrie and the departing physicians responded to toasts.

Smallpox.—An epidemic of smallpox is said to prevail at Christopher, and the Illinois Central Railroad has declared a quarantine on that place.——A number of cases of smallpox have been reported at Rushville. The disease is also said to be present at Benton.——Smallpox appeared at Freeport in a factory and a number of persons have been exposed. The usual precautions have been taken to prevent the spread of the disease.

Chicago.

Medical Student Dies.—S. D. Haury, a senior student at the Northwestern University Medical School, who had already obtained an interneship at St. Francis' Hospital, Wichita, Kan., died suddenly in Chicago, March 18, from brain disease.

Fraternity Election.—At the annual meeting of the Rush Medical College Alumni Section of the Alpha-Omega-Alpha Fraternity the following officers were elected: President, Dr. C. Hugh McKenna; vice-president, Dr. R. L. Sensenick; secretary, Dr. William J. Swift, and treasurer, Dr. L. A. Beaton.

Deaths of the Week.—The total deaths for the week ended March 31 was 582, equivalent to an annual mortality rate of 14.80 per 1,000. Pneumonia, of course, led with 102. Consumption held, as usual, the second place, with 70. Then came heart diseases, with 48; nephritis, with 37; violence, including suicide, with 36, and nervous diseases, with 30. Ten deaths were reported from scarlet fever, as compared with one death from that disease during the corresponding week of 1905.

Deaths of the Month.—The total deaths during March were 2,463, equivalent to an annual mortality rate of 14.14 per 1,000, which compares favorably with the rate of 15.33 per 1,000, reported for March, 1905. Among the death causes pneumonia led with 421, consumption coming next with 304. Among other notable death causes were: Heart disease, with 203; nephritis, with 152; violence, including suicide, with 137; nervous diseases, with 129, and acute intestinal diseases, with 114 deaths.

Chicago's Health.—The mortality of Chicago for the first three months of 1906 was at the annual rate of 14.32 per 1,000, a decrease of 6.1 per cent. as compared with 1905. Among the decreased important causes of death were apoplexy, bronchitis, consumption, convulsions, influenza, measles, pneumonia, smallpox, suicide and whooping cough. The causes of death that showed an increase as compared with 1905 were nephritis, cancer, diphtheria, heart diseases, acute intestinal diseases, nervous diseases, scarlet fever and violence other than suicide. The most marked decrease was in bronchitis, and the most pronounced increase, scarlet fever.

Dr. Senn's Vacation.—Dr. Nicholas Senn left Chicago, April 4, for his regular summer vacation, and will return about August 4. He goes to Lisbon, where he will attend the International Medical Congress and deliver the oration on surgery for America, which will appear in THE JOURNAL. He then traverses the Mediterranean, goes through the Suez Canal and the Red Sea, down the east coast of Africa to Beira, then across country to Buluwayo, from there makes a trip to Victoria Falls, on the Zambesi, and then goes to Cape Town, where he takes steamer for England. During his trip Dr. Senn will send THE JOURNAL a report of the International Medical Congress and also occasional letters regarding his tour and the results of his study of the natives and diseases of the countries through which he passes.

Chicago Tuberculosis Exhibition.—An exhibition was opened in the Public Library Building April 2 under the auspices of the National Association for the Study and Prevention of Tuberculosis, the Chicago Tuberculosis Institute and the Illinois State Association for the Prevention of Tuberculosis. The exhibition contains everything pertaining to the cause, nature and effects of tuberculosis, also the means now used throughout the country for its prevention and cure. During the twenty-six days of the exhibition special lectures and conferences on tuberculosis will be held and exhibits will be demonstrated. The chief conferences to be held are those on the "Outdoor Treatment of Tuberculosis," "Workers and Tuberculosis," "Tuberculosis and Charity Organizations," "The School and Tuberculosis," and on April 14 a western tuberculosis conference will be held, over which Dr. H. B. Favill, Chicago, will preside, and at which Drs. Lawrence F. Flick, Philadelphia, and S. A. Knopf, New York, will deliver addresses. The exhibition is open free to the public on week days from 10 a. m. to 6:30 p. m., and also on the evenings on which addresses are to be given.

INDIANA.

Communicable Diseases.—Scarlet fever is said to be epidemic at Sardinia and Greensburg.——Whooping cough and measles are said to be epidemic at Linden.

Discourages Advertising.—The Medical Society of Shelby County has passed a resolution discouraging the use of physicians' names by the lay press, in the reports of deaths, births, accidents, etc.

New Hospital.—The Sisters of St. Francis have purchased two city blocks at Logansport on which a new three-story hospital with accommodations for 100 patients will be erected at a cost of about $50,000.

Osteopath Acquitted.—H. J. Baughman, an osteopath of Connorsville, charged with practicing medicine without a license, was declared "not guilty" March 25. The defendant admitted practicing osteopathy without a license, but claimed that the law passed by the last legislature providing for the practice of osteopathy in Indiana was unconstitutional.

Knox County Society Active.—At the regular quarterly meeting of this society, held in Vincennes, March 13, resolutions were passed urging the passage of the pure-food law, and advocating co-operation with the adjoining counties in maintaining the present fees for life insurance examinations. A committee of five was appointed to investigate any and all contract practice by members of the society and to report to the society.

Endow Fellowships in University.—A Chicago physician who does not wish his name revealed and Dr. Benjamin T. Terry, New York City, have offered to endow fellowships for pathologic research in the Indiana University, Bloomington. The first endowment is for a research fellowship in serum pathology, the second for a similar position in pathologic physiology. The income of each fellowship is $750 a year. These are conditional on the provision by the university of adequate library and laboratory facilities.

February Diseases and Deaths.—During February there were 912 fewer deaths than in February last year, and the disease prevalence was about 30 per cent. less. Pneumonia caused 403 deaths; tuberculosis, 372; violence, 109; cerebrospinal meningitis, 40; typhoid fever, 29; diphtheria, 20; puerperal fever, 14, and whooping-cough, 12. The death rate per 1,000 was 17.2 for cities and 11.7 for the country. Smallpox existed in 15 counties, but no deaths occurred. Of the deaths from violence, 5 were homicides and 20 suicides.

Personal.—Dr. Forbes H. Broughton, Wolcottville, was recently operated on in Detroit for the removal of gallstones.——Dr. Milo Gibbs, Greenfield, is critically ill with neuralgia of the heart.——Dr. Christian B. Stemen, Fort Wayne, completed thirty years of service as surgeon of the Pennsylvania Lines March 10.——Dr. Leo J. Weinstein has been made consulting gynecologist and Dr. Joseph H. Weinstein, attending gynecologist of the University Hospital, Terre Haute.——Dr. Austin Funk, New Albany, has returned from England.——Dr. John E. Owen, Evansville, is seriously ill.

IOWA.

Scarlet Fever.—An epidemic of scarlet fever is reported in Sioux City.

Personal. Dr. Andrew Marugg, Sherrills, was seriously injured in a runaway accident, March 20.

Hospital Overcrowded.—The State Inebriate Hospital, opened only a few weeks ago, is full to overflowing and the board of control has ordered that no more patients be received until vacancies occur.

Hospital Notes.—The Corning Hospital was opened last week for the accommodation of patients.

Itinerant Practitioners Leave.—The attempts of local physicians of Council Bluffs to force out of practice in that city two itinerant physicians calling themselves "Hot Springs Doctors," have been successful, and one of the individuals has gone to Des Moines, the other to Waterloo.

Hospital Accident Suit.—In the case of Mrs. Jesse Haase, Eldora, against Drs. Morton & Morton, Iowa Falls, in which the plaintiff claimed damages of $25,000 for a fall at the Ellsworth Hospital in January, 1905, the jury gave a verdict for the plaintiff, March 22, awarding her damages of $1,100.

State Asylum Report.—The second biennial report of the State Hospital for the Insane, Cherokee, shows a total of 716 patients in the hospital and a daily average for the two years of 66. The percentage of recoveries was about 27 and of deaths 5.7. The average age at death was 49 years, and 26 per cent. of the mortality was due to tuberculosis.

Summer School at State University.—The College of Medicine at the State University of Iowa, Iowa City, has decided to give a summer course. Work will be done in the departments of clinical medicine, operative surgery, pathology, bacteriology, ophthalmology, otology, rhinology, laryngology, experimental pharmacology, sanitary chemistry and surgical and applied anatomy.

KENTUCKY.

Sanatorium Bill Passes.—The state senate has passed a bill appropriating $20,000 to establish a state tuberculosis sanatorium. The bill originally called for $50,000, but the committee thought the former sum would do for a beginning. The committee to locate and build the institution will be appointed by the governor.

Personal.—Dr. John P. Ferguson, Louisville, was thrown from his carriage, March 1, and fractured two ribs.——Dr. J. Halpin O'Reilly is critically ill with pneumonia.——Dr. H. C. Lassing, Beaver Lick, was recently stricken with paralysis.——Dr. John Q. Taylor, Paducah, has gone to California for a month's vacation.——Dr. James A. Averdick, Covington, is suffering from septicemia.

LOUISIANA.

Acquitted.—Dr. John B. C. Gazzo, Thibodeaux, charged with killing Clerville Guedry near Raceland in July last, has been acquitted.

Gives Vase to Hospital. The French government has presented a beautiful Sevres vase to the Eye, Ear, Throat and Nose Hospital, New Orleans.

Reward Not Claimed.—The $5 reward offered by the New Orleans board of health for the first live stegomyia mosquito found in New Orleans in March has not been claimed.

Quarantine Against Cuba and Central America.—The State Board of Health has decided that the restrictions against Cuban and Central American ports shall become operative on and after March 15.

Found Guilty of Murder.—Dr. Albert P. Bush, Sligo, was found guilty, at Shreveport, March 7, of the murder of Jack C. Guice, an electrician, on Dec. 16, 1904. The jury returned a verdict of "guilty as charged, without capital punishment."

Quarantine Station Discontinued.—The State Board of Health has decided that the Port Eads quarantine station shall be temporarily discontinued, and that the inspection previously done at this post shall be carried out at the upper quarantine station.

Suspicious Case Not Yellow Fever.—In the case of Zeles Ebernz, supposed to have had yellow fever, the patient died, March 18, at the Charity Hospital, New Orleans. The autopsy proved that the man did not have yellow fever, but died from catarrhal jaundice.

Presentation to Dr. White.—As a token of appreciation from the citizens of New Orleans, a superb silver service was given to Surgeon Joseph H. White, United States Public Health and Marine Hospital Service, March 24. The address of presentation was made by Col. Charles Janvier, and Dr. White made a suitable response.

Personal.—Dr. C. J. Gremillion, Alexandria, president of the local board of health, is recovering from an attack of appendicitis.——Dr. Richard O. Simmons, Alexandria, has been elected president of the Rapides Parish board of health, succeeding Dr. A. R. Chapin.——Dr. Simon G. Gill, New Orleans, has been ordered to Havana as resident inspector of the State Board of Health at that point.——Dr. Elijah M. Ellis, Crowley, has resigned the presidency of the local board of health and will make his home in Fort Smith, Ark.

For Yellow-Fever Inspection and Publicity.—At a representative gathering of the citizens of New Orleans, March 6, the following preamble and resolutions were adopted:

Whereas, It is essential to the welfare of this community that the city of New Orleans should be rendered immune against yellow fever; and,

Whereas, This condition is entirely possible by the strict enforcement of the anti-mosquito ordinance and such other sanitary measures as can be readily undertaken; therefore be it

Resolved, That this meeting of citizens does hereby earnestly urge that each of the ward organizations immediately reorganize and actually prepare to perform a thorough inspection service. Be it further,

Resolved, That this meeting pledges itself to furnish all the funds necessary, and requests the following citizens to form a central committee, having power to add to its numbers, for the purpose of handling this campaign.

At the regular meeting of the Orleans Parish Medical Society, March 22, the following preamble and resolutions were unanimously adopted:

Whereas, The experiences of the past summer furnished ample corroboration of the correctness of the mosquito doctrine of the propagation of yellow fever, also the importance of prompt and full reports of cases of the disease, as well as the danger of early and mild cases; be it

Resolved, That it is the sense of this society that it is the solemn duty of physicians to report immediately all cases of yellow fever, or suspected yellow fever, occurring in their practice. Be it further

Resolved, That any member of this society failing to make such a report will be deemed guilty of unprofessional conduct, and be tried for such by the judiciary committee according to the by-laws of this society. Be it further,

Resolved, That the members of this society urge their friends, their patients and the public in general to keep all patients completely protected by mosquito bars. Be it further

Resolved, That these resolutions be furnished to the daily press for publication.

MAINE.

Hospital Completed.—The Aroostook Hospital, Houlton, is completed and will be conducted by Drs. Thomas S. Dickison and Gibson.

Fire at Hospital.—A fire in Trull Hospital, Biddeford, March 14, caused damage amounting to $15,000. The 17 patients were removed without casualty.

Hospital Corps Instituted.—General orders have been issued by the adjutant general providing for the organization of a hospital corps in the National Guard of the State of Maine.

Personal.—Dr. Charles A. Packard, dean of the medical faculty of Bath, was given a complimentary dinner by the physicians of the city, March 7.——Dr. Martin P. Judkins, Rockland, is convalescent from his recent operation.

MARYLAND.

State Tuberculosis Sanatorium Assured. The legislature has passed the bill appropriating $100,000 for a state sanatorium for consumptives.

Addition to Hospital.—The regents of the University of Maryland have purchased considerable property in the vicinity of the institution for the benefit of the school of medicine. A large addition will be erected to the University Hospital, Baltimore, in the near future.

Personal.—Drs. Henry Barton Jacobs and John C. Hemmeter, Baltimore, will visit Europe this summer. Dr. Hemmeter will deliver the annual oration before the Ohio State Medical Society at Canton, Ohio, May 9.——Dr. Eugene Jones of Kensington has been very ill with rheumatism.

Sent to Prison. Dr. John H. Tompkins, a colored physician of Cumberland, who at his second trial for causing a death by criminal operation, was found guilty and sentenced to imprisonment in the penitentiary for six years. His accomplice, a druggist, received a sentence of imprisonment for ten years.

Milk Supply of Baltimore. The seventh of the course of lectures being delivered weekly at Johns Hopkins University was given by Assistant Commissioner of Health, C. Hampson Jones, M.D., April 3, on "The Present Aspect and Needs of the Milk Supply of Baltimore." Dr. Lewellys F. Barker presided.

Appropriation for New University Buildings. The trustees of Johns Hopkins University are endeavoring to secure an appropriation of $100,000 from the legislature, so that with this sum as interest, they may be able to borrow something like a million dollars which they need for the construction of buildings on the new university site in the northern suburbs. Two years ago this beautiful site of nearly 200 acres was given to the university by some of its friends, but removal to it has thus far been impossible from lack of funds necessary to erect the buildings.

MICHIGAN.

Smallpox.—An outbreak of smallpox is reported in at least three families in Ingalls.

Fire Damage.—Fire on March 18 did damage to the extent of $500 to the residence of Dr. William A. Crandall at Hesperia.

Epidemic Disease in Kalamazoo.—Kalamazoo reports 300 cases of German measles and 200 cases of whooping cough, with a rapid spread of the diseases.

Jury Disagrees.—In the case of "Dr." Allen Raymond, Battle Creek, charged with violation of the state medical law, the defendant admitted the facts, but the jury disagreed after six hours' deliberation.

Wins Libel Suit.—In the suit of Dr. Charles J. Sorsen, Calumet, against the editor of a Finnish paper at Hancock, in which $10,000 damages was claimed for injury to the reputation of the plaintiff by the publication of an alleged libelous article, the jury returned a verdict awarding him $3,000.

Incorporated to Wipe Out Quackery.—The Calhoun County Medical Society has been incorporated with the following officers: President, Dr. Herbert A. Powers; secretary, Dr. Eugene Miller, and treasurer, Dr. Clarence G. Vary, all of Battle Creek. The society has decided to make an appropriation for prosecuting violators of the registration laws.

Women Physicians Organize.—The Women's Academy of Medicine, Detroit, was organized March 13, with the charter membership of 14. The following officers were elected: Dr. Lucy J. Utter, president; Dr. Mary G. Haskins, vice-president; Dr. Anna M. F. Starring, secretary; Dr. Minta B. Kemp, treasurer, and Drs. Florence Huson, Louise R. Thompson and Isabella Holdom, censors.

Hospital Notes.—The ways and means committee of Grand Rapids has appropriated $20,000 for a contagious disease hospital.——St. Mary's Hospital, Marquette, was formally opened February 27.——The Port Huron Hospital and Home received a check for $1,000, the proceeds of the annual hospital ball.——Mr. George F. Sonner, Benton Harbor, has given $5,000 toward the erection of a new $15,000 hospital in Benton Harbor, provided that $10,000 additional be raised before July 1.

Personal.—Dr. William H. Van Slyke, Hancock, suffered severe injuries in a fall.——Dr. Michael P. Fenelon, Escanaba, has been elected physician of Delta County.——Dr. Mason W. Gray, Pontiac, has been elected delegate of the Oakland County Medical Society to the state medical society, and Dr. Clark J. Sutherland, Clarkston, alternate.——Drs. James F. Breakey and R. B. Canfield, Ann Arbor, have been elected delegates, and Drs. Andros Gulde, Chelsea, and John A. Wessinger, Ann Arbor, alternates, from the Washtenaw County Medical Society to the state medical society.——Dr. Frederick Townesend, Sault Ste Marie, has been appointed local surgeon of the Soo Line and the Duluth, South Shore & Atlantic.

NEBRASKA.

May Not Practice.—The State Board of Health has decided that Dr. Albert C. Welch, Haigler, must not practice medicine at this time. He has, however, been given leave to file an amended petition for a license.

Hospital News.—Wesleyan Hospital, Lincoln, opened for the reception of patients last week.——It is reported that the Hospital for Crippled Children, Lincoln, will be obliged to close because of lack of funds for carrying on its work.

Pension Examiner Exonerated.—Dr. Edgar D. Cummins, Plattsmouth, a member of the pension medical examining board, charged with prejudice against Union soldiers applying for pensions, has been exonerated, after investigation by special agents of the department.

Personal.—Drs. A. E. Gerish, Auburn, and James Kay, Nemaha City, have been appointed physicians of Nemaha County.——Dr. William B. Kern, superintendent of the Hastings Hospital for the Chronic Insane, is seriously ill and has been taken to Rochester, Minn., for operation for appendicitis.

NEW HAMPSHIRE.

Suit Settled.—The suit of Lewellyn F. Hobbs, Northampton, against Dr. Joseph W. Odell, Greenland, for alleged malpractice, has been settled out of court.

Oppose Anti-Contract Action.—The fraternal orders of Concord have adopted resolutions protesting against the actions of the Central District Medical Society in opposing contract medical practice, and resenting this action as a conspiracy against fraternal organizations and physicians connected therewith.

Hospital Staff Reorganized.—The medical staff of the Laconia Cottage Hospital has been reorganized with Dr. Alfred W. Abbott, president, and Dr. Alpha H. Harriman, secretary.

Personal.—Dr. Stephen Young, Dover, slipped and fell, breaking his right leg at the ankle.——Dr. David P. Goodhue has completed 40 years of active practice at West Springfield.——Dr. Albert J. Nute, city physician of Portsmouth, has resigned, and Dr. Andrew B. Sherburne has been elected to fill the unexpired term.

Hospital Notes.—During 1905, 318 patients were admitted to the Mary Pillsbury Hospital, Concord. The permanent funds of the hospital have been increased by a legacy of $1,000 from the estate of Henry W. Randlett and a donation of $4,000 by the late Emeline Harvey Sage of Hopkinton. The children's free bed fund has been completed by the payment of $5,000 to the treasurer.——Wentworth Hospital, Dover, erected at the cost of $70,000, is almost completed and will be opened in June. The hospital has accommodations for 35 patients.——Nashua Hospital has elected Dr. Isaiah G. Anthoine, clerk, and Drs. Augustus W. Shea, Bradford Allen, Herbert L. Smith, Benjamin G. Moran, Sam S. Dearborn and Isaiah G. Anthoine, trustees.

NEW YORK.

Coroners' Physicians Increased.—The Dowling bill, which provides for an increase in the number of coroners' physicians to four in Manhattan, two in the Bronx, four in Brooklyn, three in Queens and two in Richmond, passed the assembly, March 26.

Against the Transfer of Patients.—A bill has been introduced into the legislature by Senator Fitzgerald imposing a fine of $5,000 or imprisonment for five years for any one in authority in a New York hospital who orders the removal to another hospital of a patient who is seriously ill.

Osteopathy Bill Opposed.—The county medical society at its meeting March 26, decided to oppose the bill now before the assembly entitled, "An act regulating the practice of osteopathy in the State of New York." This society construes the bill as it now stands as an act permitting the licensing of osteopaths to practice medicine without an examination.

New York City.

Smallpox on Liner.—A case of smallpox of about four days' duration was discovered among the passengers of the steamer *Rhein*, which arrived at quarantine March 28. About 230 of the 2,399 pasengers on this vessel were sent to Hoffman Island.

Want Prisoners Cleaned.—A committee has been appointed by the board of magistrates to consult with the board of health and endeavor to make some arrangement for the washing and disinfection of the filthy prisoners whom the police have been in the habit of bringing into court.

Criminal "Doctors" Out of Business.—It has been announced by the postmaster-general that 52 illegal "medical offices" in New York and Brooklyn have been practically put out of business by the efforts of the postmasters. The business done by some of these concerns was large. As many as twenty criminal operations a day are said to have been performed by some of them, and the incomes ranged as high as $2,000 a week.

The Smoke Nuisance.—Last year 187 smoke nuisances were abated by the board of health, but these were chiefly small concerns. It is now stated that the board will proceed against big corporations. Summonses are about to be issued to the Interborough Company, the Edison Company and others. The Interborough Company once defeated the health department in an action, but the health department is hopeful of getting a favorable decision this time.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended March 24, 1,952 cases of measles, with 47 deaths; 453 cases of tuberculosis, with 200 deaths; 370 cases of diphtheria, with 50 deaths; 209 cases of scarlet fever, with 8 deaths; 36 cases of cerebrospinal meningitis, with 23 deaths; 25 cases of pertussis, with 2 deaths; 15 cases of typhoid fever, with 5 deaths; 159 cases of varicella, and one case of smallpox, a total of 3,220 cases, with 335 deaths.

To Visit European Hospitals.—The building of hospitals for contagious diseases in various parts of the city and a tuberculosis sanitarium at Otisville, together with the fact that a municipal filtration plant is under consideration, has decided the board of health to send Dr. Herman M. Biggs, chief med-

ical officer of the board, to Europe to inspect the hospitals and filtration plants there. On the return of Dr. Biggs, in about three months, Commissioner Darlington will take up the question of a filtration plant with the board of estimate.

Athletic Boys Must be Examined.—The Public School Athletic League will hereafter not permit a boy to take part in contests unless he is certified as to physical condition by a physician of the department of health. It has been realized that the one flaw in the work of the athletic league was the fact that boys who were unfit physically could not be barred out of the games. The examinations will be made by the school physicians, who will add to their usual inquiries, special tests to determine whether or not the child shall be allowed to enter contests.

The Overtrained Nurse.—This was the subject of a symposium at the New York Academy of Medicine on March 29. With only one exception the speakers were of the opinion that the nurse of to-day was overtrained. There was complaint that in the present system there is too much theory and too little practice. Drs. W. Gilman Thompson, A. Alexander Smith, Robert Abbe and Arpad G. Gerster pleaded for fewer subjects and more thorough teaching. Dr. Smith spoke for the old-fashioned nurse whose principal asset was her sympathy and proper equipment of character.

Will Subpoena Medical Staff.—An investigation has been conducted in the case of Walter Crocker, who was injured by a car, taken to Roosevelt Hospital and then transferred to Bellevue, dying fourteen minutes afterward. The coroner states that the whole medical staff of Roosevelt Hospital who were on duty at the time of the transfer will be subpoenaed, and that he will compel them to produce the books that he may view the record in every suspicious case of transfer. It was stated at Bellevue that Crocker's death was due to consumption, but the coroner's physician found that it was due to a fracture of the skull.

NORTH CAROLINA.

Fire Endangers Hospital.—A fire which caused a loss of $250,000 in Fayetteville, March 25, placed the Highsmith Hospital in such imminent peril, as the flames were attacking the building on three sides, that it was necessary to remove the patients from the building.

Address Graduating Classes.—Dr. Robert Lee Payne, Norfolk, Va., has accepted an invitation to deliver the annual address to the graduating class in medicine at the University of North Carolina, Chapel Hill, May 11. Dr. Benjamin K. Hays, Oxford, will deliver the annual address to the graduating class of the North Carolina Medical College, Davidson, at its commencement next month.

Prevention of Tuberculosis.—At the last session of the Medical Society of the State of North Carolina a paper was read by Dr. Martin L. Stevens, Asheville, advocating the organization of a North Carolina Society for the Prevention of Tuberculosis. The society authorized the appointment of a committee to consider plans for organizing this society, to report to the state society at its next meeting in May. The following committee has been appointed: Dr. Martin L. Stevens, Asheville, chairman, and Drs. Richard H. Lewis, Raleigh; George G. Thomas, Wilmington; J. Howell Way, Waynesville; James A. Burroughs, Asheville; James M. Parrott, Kingston; Charles M. Strong, Charlotte; W. H. H. Cobb, Goldsboro; Benjamin K. Hays, Oxford; Albert Anderson, Wilson; Charles A. Julian, Thomasville, and Watson S. Rankin, Wake Forest.

PENNSYLVANIA.

Health of the State.—The interest taken by the medical profession of the state in the collection and compilation of data concerning the prevalence of contagious disease in the state is becoming more evident from the reports handed in each month. During the month of February there were reported to the health department 12,539 cases. Of these 11,011 were in cities and boroughs, and 1,528 in rural districts and townships. There were 2,280 cases of typhoid fever reported, of which only 116 were from rural districts, while 2,172 were from cities and boroughs. Typhoid fever during the month was reported in 51 counties, being particularly prevalent in Philadelphia, Montour, Fulton Erie and Allegheny. Measles continues to be epidemic throughout the state, the number of cases reported representing 45 per cent. of the total diseases reported from all causes. Diphtheria shows a decrease of 157 cases for the month. There were in all 885 cases reported. There were 875 cases of scarlet fever, a decrease of 4 over those reported in the previous month. There were only 9 cases of smallpox reported from the entire state, 6 of which were from cities and boroughs and 3 from the rural districts.

Philadelphia.

Keen to Close Hospital.—Dr. W. W. Keen announces that he will close his private hospital permanently after June 1. Thereafter his patients will be taken care of in the Jefferson Medical College Hospital.

Personal.—Dr. John H. Musser addresed the Alumni Association of the University of Pennsylvania in Brooklyn, N. Y., March 22. Dr. Francis D. Patterson is confined to his home with a punctured wound of the foot.

Leffmann on Health Board.—Dr. Henry Leffmann, professor of chemistry in the Woman's Medical College of Pennsylvania, has been appointed a member of the board of health by Mayor Weaver to take the place of Dr. Charles B. Penrose, resigned.

Voodoo Doctor's Sentence Commuted.—George P. Hossey, the negro voodoo doctor who was senteneed to death a short time ago, was pardoned by the state board of pardoas, which recommended that his sentence be changed from death to life imprisonment.

New Head for Blockley.—Dr. Henry Sykes, for many years superintendent of the Episcopal Hospital of Philadelphia, has been appointed medical superintendent of the Philadelphia Hospital to succeed Dr. Montgomery Biggs, resigned. Dr. Sykes has devoted practically his entire life to institutional medicine.

New Hospital Trustees.—Two new trustees have been elected to the board of the Medico-Chirurgical Hospital to fill vacancies caused by the retirement of Judge A. M. Beitler and William C. Mason. The new members are Justice William P. Potter of the Supreme Court, and Dr. William H. Green, formerly professor of chemistry at the Central High School and for several years demonstrator of chemistry in the University of Pennsylvania.

Hospital Examinations.—Examination of applicants for internships in the Phoenixville Hospital will be held in the hospital April 21. The salary is $100 per year.——The Reading City Hospital will conduct its examination for internes at the Hotel Walton, Philadelphia, April 17. For information address the secretary of the board, Dr. Israel Cleaver, Reading.——Examination of applicants for the position of resident interne in the Williamsport City Hospital will be held in the Y. M. C. A. building, Philadelphia, April 12.

Money for Charity.—The executive committee of the nineteenth annual German-American Charity Ball has decided to divide the net receipts of the ball, $2,261.92, among the following institutions: The Children's Hospital of Philadelphia, the Pennsylvania Epileptic Hospital and the Kensington Hospital for Women. As a result of the Jewish Charity Bazar, given for the benefit of the Jewish Industrial Home, the institution will receive between $3,000 and $4,000.——By the will of the late John F. Young the Episcopal Hospital will receive $700.

Health Report.—The total number of deaths for the week ended March 31 aggregated 625. This is an increase of 39 over the number reported last week, and an increase of 80 over the number reported in the corresponding week of last year. The principal causes of death were: Typhoid fever, 33; measles, 10; pertussis, 8; diphtheria, 10; consumption, 72; cancer, 18; apoplexy, 22; heart disease, 60; acute respiratory disease, 127; marasmus, 9; enteritis, 21; hepatic cirrhosis, 11; Bright's disease, 46; accidents, 11, and suicide, 2. There were 365 cases of contagious disease reported, with 45 deaths, as compared with 332 cases and 34 deaths in the preceding week. Typhoid fever is still prevalent and on the increase, as shown by 225 cases, with 33 deaths reported, as compared with 186 cases and 27 deaths reported in the previous week.

New Consumptive Hospital.—A new hospital, known as the Kensington Dispensary for the Treatment of Tuberculosis, was formally opened for inspection March 29. The hospital is located at Susquehanna and Trenton avenues, in the congested mill district of Kensington. The plan of the institution is said to be entirely new and the dispensary will be conducted on modern plans, but will have no special hospital facilities. Patients who are unable to visit the dispensary will be treated at their homes. Medicines and the diet of milk and eggs will be furnished free at the dispensary. Members of the staff and nurses will visit the patients at their homes and direct the

course of treatment. It is the purpose of the staff of the institution to deliver lectures in different parts of Kensington so as to give instructions as to the prevention as well as cure of this disease. The staff of the institution is composed of Dr. William G. Eisenhardt, chief physician; Drs. G. Ashton Bardsley and Charles Schaubel, assistants, and Dr. Aller G. Ellis, pathologist.

Vice, Its Prevention and Cure.—The symposium on vice and its prevention held by the Philadelphia County Medical Society, March 28, was in the interest of the American Society of Sanitary and Moral Prophylaxis, a branch of which was organized in Philadelphia, March 26. The principal address of the meeting was delivered by Dr. Prince A. Morrow of New York, president of the society, who gave an outline of the work of the society in the past year, and told of the great difficulties that beset the medical profession on every hand in inaugurating a crusade against the conservatism which fosters gross ignorance on the subject of vice and its physical effects. He believes that by medical instruction, assisted by other influences and agencies, the public can be enlightened to imminent dangers. A public opinion must be created to exterminate these evils by education, as the great white plague is slowly being conquered by intelligent methods. He hoped that a society such as they have in New York will be organized in every city of the country, and only then can we hope for success. He outlined the New York idea and said that work was instituted along four lines: 1, The education of the youth in hygiene and social truths through the home and school; 2, the education of the young men and women of the working classes; 3, the dissemination of hygienic knowledge in the Army and Navy, and, lastly, the education of the general public. He criticised the newspapers for the insertion of objectionable advertisements and at the same time their objection to printing articles of an instructive nature in their news columns.

VIRGINIA.

License Fee Abolished.—Dr. Robert S. Powell, Woodview, has succeeded in having a bill passed by the state legislature whereby the physicians will not have to pay $10 per year state license which has heretofore been imposed.

Medical Board Announced.—At a meeting of the executive committee of the Medical Society of Virginia, Dr. Hack U. Stephenson of Toano, James City County, was elected to succeed Dr. Junius E. Warriner, Brook Hill, as a member of the State Board of Medical Examiners. The governor has announced the following appointments for the State Board of Medical Examiners: Drs. Willard B. Robertson, Tappahannock, First district; Herbert M. Nash, Norfolk, Second; Hack U. Stephenson, Toano, Third; William W. Wilkinson, La Crosse, Fourth; Richard S. Martin, Stuart, Fifth; Samuel Lile, Lynchburg, Sixth; Robert C. Randolph, Boyce, Eeventh; Robert M. Slaughter, Alexandria, Eighth; Elliott T. Brady, Abingdon, Ninth; Charles W. Rodgers, Staunton, Tenth; A. S. Priddy, Bristol, and R. Bruce James, Danville. Drs. Millson R. Allen, Norfolk, and Dr. E. Cone Williams, Hot Springs, have been appointed homeopathic members at large.

WISCONSIN.

Physicians Fined.—Dr. Thomas Welch, Rhinelander, has been fined $30 and costs for failure to report a case of diphtheria. He will appeal the case.——"Dr." William Bentz, Menominee, charged with practicing medicine without a license, convicted and fined $50 and costs, has decided not to appeal and has paid the fine and costs.

GENERAL.

American Urological Association.—This body met April 3, at New York, to organize a second section of the association, comprising New York, Pennsylvania, New Jersey, West Virginia, Maryland, Virginia and Delaware, and to discuss a scientific program.

License Fee in Hawaii.—The law imposing a $10 license fee on physicians in Hawaii has been declared invalid by the Supreme Court of the territory on the ground that it discriminates between the holders of licenses under the amending act and the holders of licenses issued prior thereto.

Canal Zone Medical Society.—Physicians on the Canal Zone recently met and organized a medical society. A committee consisting of Col. W. C. Gorgas, Capt. Ira A. Shimer and Dr. Bates was appointed to prepare a constitution and by-laws. Dr. A. B. Herrick was elected temporary chairman, and permanent officers will be elected later.

No Longer Members of the Proprietary Association.—Messrs. Henry K. Wampole & Co., Philadelphia, ask us to announce that the firm is no longer a member of the Proprietary Association of America.

Annual Report of the Marine-Hospital Service.—In this report are given the details of the work done by the United States Public Health and Marine-Hospital Service during 1905, including the inspection of immigrants, quarantine inspection, the work of the hygienic laboratory, and by the department in the recent yellow-fever epidemic in the South. The report includes some interesting original articles by members of the service, especially one by Dr. Wyman on "Yellow Fever, Its Origin and Prevention," and one by Assistant Surgeon Salmon on "Diagnosis of Insanity in Immigrants."

Health of the Philippines.—Chief Quarantine Officer Heiser reports that during the week ending Feb. 3, 1906, there was a sharp increase in the number of cases of cholera reported for the province of Cavite, and that on investigation this was found to be due to the fact that the natives of Naic refused to observe the simple precautions which were recommended. More attention has now been given to isolation and disinfection, and there has been a marked reduction in the number of cases since reported. The bureau of health has divided the infected provinces into small districts and has placed an insular medical or sanitary inspector in charge of each district, the principal object being to instruct the natives in the means of combating cholera. If the plans proves successful it is expected that there will be a marked decrease in the near future in the number of cholera cases.

Philadelphia Branch of American Pharmaceutical Association.—A meeting for organizing a branch of the American Pharmaceutical Association was held in the hall of the College of Physicians, Philadelphia, March 28, 1906. In addition to a fair representation of the leading pharmacists of Philadelphia, several prominent physicians of Philadelphia took part. Dr. Solomon Solis-Cohen welcomed the foundation of this local branch and expressed the belief that the provisions of the by-laws that were adopted would serve as a guarantee of the trustworthiness and integrity of the active members of this section. Dr. Henry Beates, jr., after congratulating the members on the important step they are taking to improve the science of pharmacy, assured his hearers that the time was not far distant when true worth and ability, in pharmacy as well as in medicine, would command more adequate compensation and reward. The officers for the current year are: Prof. Joseph P. Remington, president; William McIntyre and William L. Cliffe, vice-presidents; M. I. Wilbert, secretary-treasurer. The next meeting will be held at the same place, April 23, when it is proposed to discuss "The Immediate Object and Aims of the Philadelphia Branch of the American Pharmaceutical Association."

CANADA.

Personal.—Dr. George Elliott, Toronto, is recovering from a very exhausting illness which had lasted five weeks.

British Columbia Health Report for 1905.—British Columbia was absolutely free from smallpox during 1905. Of diphtheria there were 146 cases, with 9 deaths; scarlet fever, 158 cases, with 3 deaths. In the treatment of diphtheria a death rate of 6.1 per cent. is an excellent showing.

Annual Report of British Columbia Provincial Hospital.—Dr. C. E. Doherty, medical superintendent of the British Columbia Provincial Hospital for the Insane, reports that 123 patients were admitted into that institution during 1905. Of this number 90 were males and 33 females; 8 came from the Yukon. Seventy-six patients were discharged during the year, 43 of whom had recovered.

Canadian Association for the Prevention of Tuberculosis. The annual meeting of the Canadian Association for the Prevention of Tuberculosis was held in Ottawa on March 28-29, 1906. The committee on organization and work urged that the association take immediate steps to secure the co-operation of the federal parliament, all provincial legislatures and municipalities and all charitable organizations of every particular. Parliament will also be asked to incorporate the association and thereby to give it more scope and wider authority; and a grant of $5,000 will be sought instead of one of $2,000. The Hon. W. C. Edwards was re-elected president; Dr. Thorburn, Toronto; Dr. Bayard, St. John, N. B., and Sir James Grant, M.D., Ottawa, vice-presidents. Sir James Grant, Ottawa, read a paper on the relation of school children to tuberculosis, and Dr. A. J. Richer, Montreal, delivered an illustrated lecture on the subject.

"Patent Medicines" in British Columbia.—A bill has been introduced into the legislature of British Columbia in response to 3,600 petitioners to regulate the sale of patent medicines in that province. It is the largest signed petition ever presented to the British Columbian legislature, and shows that the people of the Pacific province are getting alive to the evils of the unrestricted and promiscuous manufacture and sale of these dangerous nostrums. It provides that all "patent medicines" for internal use which contain chloral hydrate, ergot, morphin, opium, belladonna or their compounds, cocain, acetanilid, or sulphuric, nitric or kindred acids, must contain a label of poison on the package or bottle, with the name and percentage of the poison and the ingredients. No "patent medicines" under the provisions of this bill may contain more than 10 per cent. of alcohol except under permission of the provincial board of health. Penalties for violation are attached to the bill.

Toronto General Hospital.—Alterations have been in progress in the Toronto General Hospital, in the residence of the late superintendent, Dr. Charles O'Reilly, whereby wards are created for neurasthenic patients and some mild forms of mental disorders. The accommodation will for the present be limited to 14 beds, and will be under the direction of Dr. D. Campbell Meyers. Matters which have been rather acute in connection with the affairs of this hospital for the past two or three weeks now seem to have been finally settled. Some time ago the city of Toronto voted $200,000 to the institution, the result of this being an agitation on the part of many city physicians not on the hospital staff, that they should be permitted to follow their patients into the hospital when they paid the ordinary public ward charge of $3.50 a week. The trustees of the hospital would not accept the grant, hence the difficulty. Arrangements were made for a compromise and a new rate was fixed for semi-public wards at $7 a week, which proved satisfactory to all. Now the Toronto General Hospital has the following classes of patients: charity, public ward (which are used for clinical purposes by the university medical college), semi-public (which may be so used on arrangement with their physicians), semi-private and private.

FOREIGN.

Tropical Gangrene in Guam.—It is reported that tropical gangrene has become so prevalent in the island of Guam that Lieutenant McNamee, U. S. N., acting governor of the island, has recommended the establishment of a hospital where these cases can be isolated.

Dietary of the British Mercantile Marine.—A bill has been introduced in the British House of Commons relating to the dietary of the men of the merchant navy. It is far more generous in quantity and provides more changes than did the former scale of dietary.

Sanatoria on the Canary and Madeira Islands.—The arrangements are about completed for the German sanatorium to be erected on the Madeira Islands. A Belgian company has been formed to erect a sanatorium also on the Canary Islands. Dr. Resquisse of Brussels is medical director of the latter company.

The Finsen Monument.—The committee in charge of the subscriptions for the Finsen memorial report that 85,000 kronen ($22,950) has been received. They have decided that $13,500 is to be devoted to enlarging the Finsen Light Institute and that the remaining $9,450 is sufficient for the memorial.

Isolation of Advanced Cases of Pulmonary Tuberculosis.—A hospital has been opened recently near Northampton, England, for the isolation of advanced cases of consumption occurring in that town. In addition, a resolution was passed by the town council of Northampton to retain, at certain sanatoria, a few beds for consumptives in the early stages of the disease.

In Russia.—The *St. Petersburg. Med. Wochft.* still continues to publish each week a list of physicians arrested for political activity. Some of them have been sent to Siberia. Dr. Lebedew, who was arrested not long ago, has died of typhus contracted in prison. Some of the physicians arrested appealed to the czar still to allow them the privilege of voting for the new representative assembly, asking that the ballots of the political prisoners may be taken and counted. Many physicians in the Baltic regions have been brought to financial distress by the prevailing disturbances and a subscription list has been opened by the *Wochenschrift* for the benefit of the suffering colleagues.

The Kroenlein Festschrift.—On the occasion of the close of his fiftieth semester as professor of surgery at the University of Zurich, Switzerland, R. U. Kroenlein was presented with a *Festschrift* containing a number of articles by his present and former pupils. The surgical amphitheater was decorated and crowded, and the festivities concluded with a banquet for the "festival family." His pioneer work in the surgery of the brain, the kidneys and abdomen was duly commented on in the addresses, and the honors heaped on him at home and abroad. He is now in his sixtieth year, and was elected to preside at the German Surgical Congress this year.

Prizes Offered by Belgian Academie de Medecine.—A prize of $200 will be given for the best work on "Simulation from the Medicolegal Standpoint, in Regard to Traumatisms and Neuroses, and Means to Detect It." Articles must be received before July 1, 1906, and must be sent in anonymously, written in French, German or Flemish. Another prize of the same amount is offered for the best work on "Normal Intestinal Poisons (toxins) of Man, Their Pathogenesis and Means of Defense Against Them." Must be received before Sept. 25, 1906. A third prize offered is for "Indications for Surgical Intervention in Stomach Affections;" prize 800 francs ($160); articles must be received before June 15, 1907, as also articles competing for the fourth prize, 600 francs ($120), for the best study on paraplegia in the horse. There is also an Alvarenga prize of $140 for the best work on any branch of medicine. Address all communications to the secretary, E. Masoin, Secrétaire de l'Académie de Médecine, Brussels, Belgium.

Homage to Baccelli.—The great Policlinico at Rome is to be formally inaugurated next week, although it has been in use for some time. The official dedication of the great hospital will be made the occasion for an ovation to the famous clinician and statesman of Italy, Guido Baccelli, to whom the Policlinico owes its inception and its design. He advocated the intravenous administration of drugs in urgent cases of malaria, etc., and has served the profession and his country as cabinet minister and senator, and in other ways. While minister of public instruction he inaugurated the extensive excavations in the Roman forum which have produced such interesting results in recent years. He was born Nov. 25, 1832, the son of a prominent physician, descended from a noble Roman family, many of whose exploits are engraved on marble tablets in the Capitol. He became professor of legal medicine at 24, and later professor of pathologic anatomy when this chair was founded, mainly by his efforts. He later became professor of clinical medicine, his indefatigable energy finding an outlet in nearly a hundred scientific publications, of which his studies on malaria, on the pathology of the heart and aorta, on typhoid, a new sign of ovarian tumors, and a new means of treating aneurism of the aorta, are the best known. It was in a large measure due to Baccelli that the hotbeds of malaria in Italy have been made healthier. A gold plaque is to be presented to him in the name of his friends at home and abroad, subscriptions having long been pouring in for the purpose. The committee in charge of the arrangements have invited all the governments of Europe to send representatives to the fête, and have personally invited the ministers of public instruction in each state, and the presidents of the universities, medical faculties and academies of medicine in the different countries, as well as his friends and admirers in and out of the profession in Italy.

International Medical Congress.—This week is the last which allows physicians from this country to reach Lisbon in time for the fifteenth great medical congress of nations. Large numbers have gone, so that the United States will be ably represented both in quantity and quality. The official program of the congress has just been received, with the names and addresses of all members who had registered to March 6, a total of 836 names. The program states that the United States government sends eleven delegates, among them the present president of the American Medical Association and four ex-presidents, the chief of the Marine-Hospital Service, Dr. Walter Wyman, also Nicholas Senn, R. Matas of New Orleans, R. Guiteras of New York, A. Vander Veer of Albany, and J. C. Wise of the Navy. Nearly two dozen medical faculties and medical organizations have appointed delegates. Ten addresses are to be presented at the general assemblies, including one by Senn on the "International Study of Carcinoma" (to be published in THE JOURNAL); by Aaser of Christiania on the "Relations Between Acute Infectious Diseases and Tuberculosis"; by R. Boyce of Liverpool on "Prophylaxis of Yellow Fever as Result of 1905 Epidemic in Central America and New Orleans"; by Neumann of Vienna on "Anatomic

Causes of Syphilitic Recurrences and Means to Combat Them," and by Reclus of Paris on "Local Anesthetics." Sanarelli and Gorgas have each announced a communication on the intermediate yellow fever host. Sir Dyce Duckworth will speak on "Chorea Considered as Cerebral Rheumatism"; F. B. Turck on "Ulcer of the Stomach" (to be published in THE JOURNAL); Lombroso on the "Importance of Study of the Sleep in Different Diseases"; G. W. McCaskey of Fort Wayne on "Disease of the Digestive Organs in Pathogenesis of Arterial Hypertension"; A. Lorand of Carlsbad on the treatment of obesity and of senility, and F. Ostwald of Paris will describe his latest experiences with injections of cocainized alcohol as a means of curing facial neuralgia, a method of treatment attracting much attention at present, and described in these columns recently. The subject of tropical diseases will be treated more extensively than ever before at an international congress, and will be presented by men who are the leading authorities. Caravassili of Athens has announced a communication on "Hot Intestinal Injections (104-107 F.) as Important Topical Measure in Treatment of Infantile Enterocolitis." D. R. Brower of Chicago will speak on "Treatment of Acute Insanity in General Hospitals." Official addresses on experimental syphilis are to be presented by Metchnikoff, Lassar, Neisser, Finger and Landsteiner, all of continental Europe. The "Pre-cancer Stage" will be described by A. Ravogli of Cincinnati; J. T. McDonald of Honolulu will speak on the "Recognition of Obscure Cases of Leprosy," and A. Carrel of Chicago will describe his method of anastomosis of blood vessels. Chicago will also be represented in the section on ophthalmology in which H. Gradle will read an article on "Punctate Forms of Retinitis." A number of imposing fêtes are announced, including a royal garden party and a reception by the president of the congress, a ball given by the municipality, a reception by the Comte de Burnay, another by the congress, by the Geographical Society, and others. The list of addresses and communications fills about fifteen of the large pages of the official program, in small type, and it is truly international to a surprising extent.

LONDON LETTER.

The Medical Society of London.

The one hundred and thirty-third anniversary dinner of this famous society was held recently. Sir Lauder Brunton, F.R.S., presided. About 190 fellows of the society and guests were present. Dr. Macalister, president of the General Medical Council, in proposing the society referred to the projected amalgamation of the various medical societies, and said that it was to the advantage of the profession at large that the movement should succeed. If the government required any advice on scientific matters the Royal Society was appealed to, but for medical matters there was no such recognized body. The proposed Royal society of Academy of Medicine would supply this want. Sir Lauder Brunton in replying referred to the history of the society and to its vigor during a life of 133 years. He laid stress on its financial stability and on the value of its library. He pointed out that the society was an offshoot of the Royal Society.

Lunacy in Ireland.

The report on lunacy in Ireland during the year 1904 has just been issued. On Jan. 1, 1905, the insane in establishments of all kinds numbered 22,996—an increase of 202 on the previous year—which is the smallest increase since 1893. The proportion of insane under care to 100,000 of the population was 522. In recent years the ratio of the insane to the population has steadily increased. In 1851 it was 1 to 657; in 1891, 1 to 222; in 1901, 1 to 178.

Correspondence

Pure-Food Analyses in South Dakota.

PHILADELPHIA, March 28, 1906.

To the Editor:—I desire to direct the attention of the medical profession generally to some valuable results recently published by Prof. James H. Shepard, chemist to the South Dakota food department. These are careful analyses of high class commercial whiskies, published in a bulletin issued by the department.

There are few topics in the analysis of foods and beverages on which it is more difficult to get calm and scientific judgment than on whisky. The widespread use of this substance by all classes and the evident baleful effects of such use in many instances, has led to much casuistry. The humble citizen who gets drunk gives himself, as a rule, no concern as to moral responsibility. He drinks to secure the physiologic condition which whisky in full doses produces. The more cultured citizen frequently tries to find some excuse for his habit, or failing in that, for his condition, and in the latter effort falls back on real or supposititious adulterations of the beverage. This cry is taken up by many and we frequently see it stated that if the community could only be furnished with "pure liquors," the evils of inebriety would disappear. Among the widespread errors is the view that the principal injurious effect of whisky is due to "fusel oil," and that ageing removes this. It has long been evident that no experimental basis exists for this view, but the statement has been carried from one text-book to another, and repeated in scientific and popular essays until it has come to be almost an axiom. The late Mr. A. H. Allen, an eminent English analyst, showed some years ago that the fusel-oil theory is of little value, but the special merit of the paper by Professor Shepard, is that by analyses of the best brands of American whiskies, according to most approved methods, he has shown that the fusel-oil content is not appreciably reduced in ageing, and that its proportion bears no relation to the age of the sample. So far has the "fusel-oil fetish" been allowed to operate, that American authorities have proposed to fix a limit (0.25 per cent.) for commercial whiskies. This limit favors certain distillers who use antiquated methods of distillation. By improved stills, the amount can be reduced below 0.1 per cent. The percentage of fusel oil found by Shepard ranged from 0.0849 to 0.1936, and the whiskies represented by these extremes are, respectively, 8 years and 7½ years old.

Of late years, many who have abandoned the fusel-oil theory, have adopted the view that furfural and other aldehydic bodies are responsible for the injurious action of whiskies, and that these are removed by ageing, but Shepard's results upset these views also. The furfural content was very minute in all the samples, and in several cases the highest aldehyde content was found in the oldest samples.

I think these results are of sufficient importance to bring to the general notice of the profession, inasmuch as the original form of publication—a state bulletin—has a comparatively limited circulation. A large part of the work in establishing truth is the preliminary destruction of error, and before correct notions of the sociologic and physiologic actions of alcoholic beverages can be attained, the elimination of these fetishes must be accomplished.

HENRY LEFFMANN.

The Nostrum and Other Evils.

CANON CITY, COLO., March 28, 1906.

To the Editor:—In all that has been said about the nostrum and proprietary-medicine question, it seems to me that the real remedy has not been emphasized as it should be. If every physician would get right and keep right, these evils would soon cease to exist; and no one need to go to extremes in the matter, either. There are comparatively few "ethicals," and it is easy to select them. Those made by reputable manufacturing houses and whose ingredients are well known, and for which no extravagant claims are made, should be the only ones prescribed. We all condemn "counter prescribing" and yet keep on prescribing proprietaries and help the druggist to do a wholesale business in that line. Why not stop it, and stop it right now?

Another thing: How long are we going to subscribe for, contribute to and read medical journals that accept objectionable advertisements? A journal which I have taken for years had, in a recent number, sixteen advertisements from members of an association which is the bitterest enemy the profession has; besides quite a number of others equally objectionable. The editors of this journal are leaders in the pro-

fession in America, able, and of wide reputation. Are not these men culpable in that they do not demand the exclusion of these "ads." on penalty of their resignation? I have stopped reading this journal and all others of the kind. If every other physician would do the same how easily could the medical press be reformed. But physicians will not stand together in these matters. A striking illustration of this fact has recently come under my observation. An old-line life insurance company, for which I have been an examiner for a long term of years, lately cut the fee from $5 to $3 for examinations for policies under $3,000. I promptly returned the schedule unsigned, as I have all such propositions for the past ten years, giving my reasons for declining to accept the cut. The medical director of the company, in a long letter arguing the case, said among other things: "Thus far we have had only 900 refusals as against over 12,000 acceptances." Were the figures reversed, what a grand reform would have been effected. But no; one man stands for his rights and the honor and dignity of the profession while thirteen "bow the knee" and let the company walk over them as it pleases. Our county society recently adopted a resolution, since concurred in by every physician in the county, pledging its members to make no examinations for life insurance companies for less than $5. A resolution was also adopted endorsing the work of THE JOURNAL and also *Collier's Weekly*, the *Ladies' Home Journal* and other magazines, in their fight against the "Great American Fraud," the "patent medicine" and nostrum evil. Every medical society in the United States ought to speak out and speak plainly, if it has not already done so,, and every physician should get right at once on these questions and thus once and forever put an end to these evils.

T. B. MOORE, M.D.

Association News

THE BOSTON SESSION.

Announcement of Headquarters and List of Hotels, with Prices.

While Boston is liberally supplied with hotels of the first class, many of which are in the immediate neighborhood of the meeting places selected by the Committee of Arrangements for the annual session of the American Medical Association, June 5-8, 1906, the Committee on Hotels deems it wise to bring to the notice of those expecting to attend, the advisability of securing accommodations well in advance, since the time chosen for the session is not far from the commencement days of Harvard, Tufts, Boston University and the Massachusetts Institute of Technology, and during the same week it is expected that Eddyites to the number of some thousands will visit Boston to open a new "temple." The committee urges members of the Association, therefore, not to postpone too long the securing of rooms, and it engages to act in the matter for all who will make their desires known; but the final engagement must be made in all cases by the applicant directly with the hotel managers.

In addition to the hotels included in the list below are many of perfect respectability, but not of such excellence as to entitle them to be rated as of the first class.

LIST OF HOTELS WITH PRICES.

The following are the hotels included in the first class, with terms, and the number for whom it is estimated that there will be accommodations at the time of the session:

ADAMS HOUSE, Washington Street. European plan. Single rooms, without bath, $1.50 to $4 per day; with bath, $2.50 to $4. All rooms cost $1 additional when occupied by two persons. Accommodations, 200.

AMERICAN HOUSE, Hanover Street. European plan, $1 to $4 per day. Accommodations, 200.

BELLEVUE, Beacon Street. European plan. Single rooms, $1.50 to $2.50 per day; with private bath, $3 to $5. Double rooms, $3 to $4 per day; with private bath, $4 to $6. Accommodations, 150.

BRUNSWICK, Boylston Street. American plan. Rooms without bath, $5 per day; with bath, $6. Accommodations, 300.
The Brunswick has been chosen headquarters for the Section on Surgery and Anatomy.

BUCKMINSTER, Commonwealth Avenue and Beacon Street. American and European plans. American: $4 per day, European, $2. Accommodations, 40.

CARLTON CHAMBERS, 1138 Boylston Street. European plan. Single rooms, without bath, $1.50 per day; with bath, $2. Double rooms, without bath, $3, per day; with bath, $4. Accommodations, 50.

CECIL, Washington Street. European plan. Single rooms, $1 and upward per day; for two persons, $2 and upward; with bath, $1.50 to $4. Double rooms, with bath, $2.50 to $5. Accommodations, 75.

CLARENDON, Tremont Street. European plan. Single rooms, without bath, $1 per day; double rooms, without bath, $2; with bath, $2.50. Accommodations, 50.

COMMONWEALTH CHAMBERS, Bowdoin Street. European plan. Rooms, with hot and cold water and free public bath, $1 and $1.50 a day for one person; $2 and $2.50 for two persons. Rooms with private bath, $1.50 to $2 for one person, $2 to $2.50 for two persons. Accommodations, 175.

COPLEY SQUARE HOTEL, Huntington Avenue and Exeter Street. European plan. Rooms, $1.50, without bath, to $3 and $4 with bath, according to number of persons. Accommodations, 200.
The Copley Square has been selected as headquarters for the Sections on Obstetrics and Diseases of Women and on Pathology and Physiology.

CRAWFORD HOUSE, Scollay Square. European plan. Single rooms, with two persons in a room, $2 to $3 per day. Accommodations, 75.

ESSEX, Atlantic Avenue. European plan. Single rooms, $1.50 and upward; with bath, $2 and upward.

HEMENWAY CHAMBERS, Westland Avenue. European plan. Single rooms, with bath, $1.50 to $3 per day. Double rooms, with bath, $2.50 and $4.50. Three rooms, with bath, $4 and upward. Accommodations, 75.

LANGHAM, Worcester and Washington streets. European and American plans. European plan, $1 and upward per day. American plan, single rooms, $2 per day; single rooms, with two persons, $3. Accommodations, 100.

LENOX, Exeter and Boylston streets. European plan. Single room, without bath, $2.50 to $3 per day; with bath, $4 and $5. Accommodations, 50.
The Lenox has been chosen as headquarters for the Section on Ophthalmology.

LEXINGTON, 13 Boylston Street. European plan. Single rooms, $1.50 to $2 per day; for two persons $2.50 to $3. Accommodations, 75.

NOTTINGHAM, Copley Square. European plan. Single room, $1 and $1.50 per day; with bath, $2; two persons, without bath, $2 and $2.50; with bath, $3. Accommodations, 150.
The Nottingham has been selected as headquarters for the Sections on Diseases of Children and on Cutaneous Medicine and Surgery.

OXFORD, Huntington Avenue. American and European plans. Single rooms, $1, $1.50 and $2 per day. Accommodations, 100.
The Oxford has been chosen as headquarters for the Section on Pharmacology.

PARKER HOUSE, School Street. European plan. Single rooms, without bath, $1.50 to $3 per day; for two persons, $2.50 to $4.50. Single rooms, with bath, $2.50 to $4; for two persons, $4 to $6. Accommodations, 75.

QUINCY HOUSE, Brattle Street. European plan. Rooms, $1 per day and upward. Accommodations, 300.

REVERE HOUSE, Bowdoin Square. European plan. Single rooms, $1 per day; for two persons, $1.50; with bath, $2; for two persons, $3, with parlor and bath, for two persons, $5. Accommodations, 200.

SOMERSET, Commonwealth Avenue. European plan. Single rooms, $2.50 per day; with bath, $3. Double rooms, $3.50; with bath, $4. Accommodations, 100.
The Somerset has been chosen as headquarters for the Section on Practice of Medicine.

THORNDIKE, Boylston Street. European plan. Single rooms, with detached bath, $1.50 per day and upward (a few single rooms at $1.00); double rooms, with detached bath, $2 and upward; single, with connecting bath, $2 and upward; double, with connecting bath, $3 and upward; suite of two chambers and bath (or parlor, chamber and bath), $5 and upward. Accommodations, 125.
The Thorndike has been chosen as the headquarters for the Sections on Hygiene and Sanitary Science and on Laryngology and Otology.

TOURAINE, Boylston Street. European plan. Single room, without bath, one person, $3 per day; two persons, $4.50; double, with bath, one person, $4 to $6; two persons, $5.50 to $8. Accommodations, 40.
The Touraine has been chosen as the headquarters for the Section on Nervous and Mental Diseases.

UNITED STATES HOTEL, Beach Street. American plan; two in a room, $2.50 per day and upward for each person. European plan, two in a room, $1.00 and upward, for each. Accommodations, 150.

VENDOME, Commonwealth Avenue. American plan. Single rooms without bath, $5 per day; with bath, $6. Accommodations, 200.
The Vendome has been chosen as the headquarters for the General Offices.

VICTORIA, Dartmouth Street, corner Newbury. European plan. Single rooms, with use of bath, $2 per day and upward; with private bath, $3.50 double, with use of bath, $3 and upward with private bath, $4.50 and upward. Accommodations, 50.

WESTMINSTER, Copley Square. European plan. Single rooms, $2 per day; with two persons, $3 and upward; three room apartments, $9 to $12. Accommodations, 50.
The Westminster has been chosen as the headquarters for the Section on Stomatology.

YOUNG'S HOTEL, Court Square. European plan. Single rooms, without bath, $1.50 to $2 per day; for two persons, $2.50 to $4; with bath, $2.50 to $4.50; double room with bath, $4 to $7

The following hotels are within a few minutes' walk of the general meeting places; the others are not more than fifteen minutes' distance by trolley cars:

Brunswick.	Nottingham.	Vendome.
Carlton Chambers.	Oxford.	Victoria.
Copley Square.	Somerset.	Westminster.
Hemenway Chambers.	Thorndike.	
Lenox.	Touraine.	

The following hotels have been selected as headquarters for the general officers and for the sections:

General Officers	Vendome.
Practice of Medicine	Somerset.
Obstetrics and Diseases of Women	Copley Square.
Surgery and Anatomy	Brunswick.
Hygiene and Sanitary Science	Thorndike.
Ophthalmology	Lenox.
Diseases of Children	Nottingham.
Stomatology	Westminster.
Nervous and Mental Diseases	Touraine.
Cutaneous Medicine and Surgery	Nottingham.
Laryngology and Otology	Thorndike.
Pharmacology and Therapeutics	Oxford.
Pathology and Physiology	Copley Square.

Attention is called to the fact that, at the time of the session many seashore resorts will be open, and it is possible that these may offer more attraction to those who have lived inland than the hotels within the city proper. Those which the committee would recommend are within an hour of Boston, either by rail or steamboat. These and other available hotels will be announced later.

BOARDING AND LODGING HOUSES.

The Committee on Hotels and Transportation has secured a list of 521 private houses where board and lodging can be secured. Many of these houses are in the neighborhood of the general meeting places. These, and many more still to be secured, will soon have been critically inspected and rated. The committee will gladly act for those who desire its assistance in securing rooms and board in these houses. A list of them with rates will be furnished in a later number of THE JOURNAL.

RESTAURANTS.

By reason of the fact that many thousands of persons, residing elsewhere, conduct their business in Boston, the city is unusually well supplied with restaurants, which are equal to all possible demands on them. These are situated in all parts of the city. Naturally the greater number of them are located in the business section, but there are many in the neighborhood of the general meeting places.

CHARLES HARRINGTON, Chairman,
DAVID D. SCANNELL, Secretary,
Committee on Hotels and Transportation.

Marriages

ERIE E. BENEDICT, M.D., to Miss Matilda Simonson, both of Racine, Minn., March 21.

MICHAEL V. BALL, M.D., Warren, Pa., to Miss Grace Paterson of Buffalo, N. Y., March 14.

HOWELL BEIRNE BURWELL, M.D., Davis, Ala., to Miss Frances Laura McArthur of Rome, Ga., April 4.

ROBERT N. WOOD, M.D., Chaplin, Ky., to Mrs. Ida S. Gardner of Louisville, at Jeffersonville, Ind., March 24.

WALTER A. LOOPS, M.D., Impur, Naga Hills, Assam, India, formerly of Milwaukee, Wis., to Miss E. V. Preston, formerly of New Haven, Conn., at Madras, India, February 27.

Deaths

John Clark Le Grande, M.D. Atlanta (Ga.) Medical College, 1880; for eighteen years editor of the *Alabama Medical Journal;* one of the organizers, treasurer and business manager of Birmingham Medical College; a member of the Hillman Hospital staff; president of the Medical Association of the State of Alabama in 1900; first vice-president of the American Medical Association in 1895; president of the Jefferson County Medical Association; president of the Tri-State Medical Society of Tennessee, Georgia and Alabama, 1901-1902; a member of the Southern Gynecological and Surgical Association; one of the best known practitioners of Alabama, and a man of national prominence, died at his home in Birmingham, March 21, after a long illness, aged 51.

John H. Kulp, M.D. State University of Iowa, Medical Department, Iowa City, 1872; of Davenport, Iowa; alienist and manager of the insane department, Mercy Hospital, Davenport; member of the Iowa State Medical Society, Iowa and Illinois District Medical Society; president of the Scott County (Iowa) Medical Society; member of the American Medico-Psychological Association, and from 1881 to 1901 a member of the board of control of the State Hospital for the Insane, Mount Pleasant, died at a sanitarium in Pueblo, Colo., March 22, from septicemia, after an illness of ten days, aged 56.

Harry Hoyle Butts, M.D. University of the City of New York, 1885; a member of the American Medical Association, New York State Medical Association, New York County Medical Association, Medical Society of the County of New York and New York Academy of Medicine; surgeon to the throat and nose department of Bellevue and Presbyterian hospitals and to the Manhattan Eye, Ear and Throat Hospital; lieutenant colonel and brigade surgeon N. G. N. Y., died in his apartments in New York City, March 24, from an incised wound of the throat, the cause of which is unknown, aged 41.

W. M. S. Beede, M.D. University of California, Medical Department, San Francisco, 1884; for several terms coroner of San Joaquin County; for a time consular surgeon in Shanghai, and in practice at Manila, P. I.; a member of the American Medical Association, Medical Society of the State of California, San Joaquin County and San Francisco County medical societies, Hongkong and China Branch of the British Medical Association; chairman of the Stockton Chamber of Commerce, died at his home in that city from cerebral hemorrhage, March 21, after an illness of four days, aged 40.

Hugh T. Nelson, M.D. University of Virginia, Medical Department, Charlottesville, 1875; a Confederate veteran; formerly a member and president of the State Board of Medical Examiners; instructor in surgery in the University of Virginia; president of the Medical Society of Virginia; member of the International Association of Railway Surgeons; member of the Southern Surgical and Gynecological Association, died at his home in Charlottesville, March 26, from pneumonia, after an illness of one week, aged 60.

Benjamin Walter Carpenter, M.D. University of Vermont, Medical Department, Burlington, 1857; assistant surgeon of the Second Vermont Volunteer Infantry; surgeon of the Ninth Vermont Volunteer Infantry; chief medical officer at Camp Douglas, Chicago, and medical director of the Second Division, Eighteenth Army Corps during the Civil War, and thereafter a practitioner of Burlington, Vt., died at his home in that city, March 20, after a short illness, aged 69.

James C. J. King, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1871 a Confederate veteran; member of the State Medical Association of Texas, and once its vice-president; a member of the Central Texas Medical Association, and a member and once president of the Waco Medical Association, died at his home in Waco, Texas, March 21, from cerebral hemorrhage, after a short illness, aged 64.

Alexander H. Thompson, M.D. New York University, New York City, 1861; licentiate of the Upper Canada Medical Board, 1865; member of the College of Physicians and Surgeons of Ontario, 1866; for a number of years a member of the Ontario Board of Health, died suddenly from heart disease at his home in Strathroy, Ont., March 31, aged 69.

Jefferson D. Christman, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1876; formerly health officer and coroner's physician; a member of the Philadelphia Medical Club, Medical Society of the State of Pennsylvania and Lehigh Valley County Medical Society, died at his home in Allentown, Pa., March 30, aged 50.

Joseph B. Kingsbury, M.D. Dartmouth Medical School, Hanover, N. H., 1871; one of the oldest residents of Holbrook, Mass; for many years a member of the local school board, trustee of the public library, and member of the board of health, died at his home in Holbrook, March 24, after an illness of several weeks, aged 71.

William John Douglas, M.D. Trinity Medical College, Toronto, 1876; member of the College of Physicians of Ontario, 1876; member of the Ontario Medical Council since 1897, of Coburg, Ont., fell dead from his buggy while driving into the country to make a professional call, March 29.

Benjamin S. Roseberry, M.D. University of Maryland School of Medicine, Baltimore, 1874; professor of materia medica in Baltimore University from 1883 to 1888; a member of the American Medical Association, died at his home in Gardiner, N. M., where he went for his health eighteen years ago, March, 28, aged 52.

James Simpson Dunn, M.D. Western Pennsylvania Medical College, Pittsburg, 1900; a member of the American Medical Association, Allegheny County Medical Society and Austin Flint Medical Society, died at his home in Pittsburg, March 22, from pneumonia, after an illness of three weeks, aged 30.

Reuben B. Spackman, M.D. Jefferson Medical College, Philadelphia, 1870; a member of the American Medical Association; a pioneer practitioner of Clearfield County, Pa., and one of the most prominent physicians of that section, died at his home in DuBois, March 20, after a lingering illness, aged 65.

Allen H. Oliver, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1882; assistant superintendent of Presbyterian Hospital, New York City, for eight years, was found dead in his bed, in that institution, from cerebral hemorrhage, March 27, aged 58.

John Robert Bristow, M.D. Tulane University, Medical Department, New Orleans, 1871, of Farmington, Texas, a member of the Grayson County and North Texas medical associations, died at the home of his son, near Comanche, I. T., March 25, from chronic nephritis, aged 75.

C. B. McGuire, M.D. University of Nashville, Medical Department, 1856, surgeon of the First Tennessee Infantry, C. S. A., during the Civil War, died at his home in Fayetteville, Tenn., March 25, after an illness of several years, aged 75.

Thomas P. Hereford, M.D. Jefferson Medical College, Philadelphia, 1860, an officer in the Confederate service during the Civil War, died at his home in Elmwood, Mo., March 4, from senile debility, after an illness of several months, aged 69.

William H. Woodson, M.D. University Medical College of Kansas City, Mo., 1896, some-time city physician of Joplin, Mo., died at the home of his father in Liberty, Mo., from tuberculosis, after a long illness, March 22, aged 32.

Edward M. Southwick, M.D. Baltimore Medical College, 1898, formerly resident physician of the Maryland General Hospital, died at his home in West Philadelphia, March 25, from typhoid fever, after a short illness, aged 38.

Harry S. Ellwood, M.D. University of Buffalo, Medical Department, 1868, a member of the Erie County Medical Society, died at his home in Buffalo, N. Y., March 22, after an illness of six months, aged 67.

Walter E. Black, M.D. Memphis Hospital Medical College, 1901, of Guymon, Okla., died at the home of his father in Altus, Okla., March 24, from cerebral hemorrhage, after an illness of three weeks.

James C. Klingeman, M.D. Bellevue Hospital Medical College, New York City, 1872, died at his home in Papillion, Neb., March 20, from cerebral hemorrhage, after an illness of three days, aged 55.

Paul N. Zilliken, M.D. Homeopathic Medical College of Missouri, St. Louis, 1892, of Hoffman, Ill., died at the home of his mother in Evansville, Ill., March 18, from nephritis, after a lingering illness.

James H. Myers, M.D. University of Nashville, Medical Department, 1885, representative from Lawrence County in the legislature of Arkansas in 1903, died recently at his home in Black Rock.

George Sullivan Woodman, M.D. Harvard University Medical School, Boston, 1849, a member of the Massachusetts Medical Society, died at his home in Cambridge, Mass., March 22, aged 81.

George F. Dearborn, M.D. Albany (N. Y.) Medical College, 1857, a surgeon in the Civil War, died at his home in Rockaway, N. J., from pneumonia, after a short illness, March 26, aged 71.

James M. Kelleam, M.D. University of Louisville, Medical Department, 1882, of Fort Smith, Ark., died in San Antonio, Texas, March 23, from nephritis, after a long illness, aged 47.

Sarah J. McCarn Craig, M.D. Woman's Medical College, Philadelphia, 1863, died at her home in Rochester, N. Y., March 22, after an illness of several months, aged 74.

James W. Exline, M.D. Cleveland Medical College, 1870, a member of the American Medical Association, died at his home in Los Angeles, Cal., March 15, from heart disease.

Ralph W. Ferry, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1898, died suddenly at his home in Roseville, N. Y., March 22, aged 32.

Henry C. Ramsey, M.D. Georgia College of Eclectic Medicine and Surgery, Atlanta, 1883, died at his home in Thomasville, Ga., recently, and was buried March 23, aged 58.

Hall Wilson, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1888, is reported to have been murdered at his home in Augusta, Texas, March 24.

Fred S. Hunt, M.D. Rush Medical College, Chicago, 1881, of Stuart, Neb., was instantly killed while attempting to board a freight train at O'Neill, Neb., March 23.

James D. Easton, M.D. Homeopathic Hospital College, Cleveland, 1876, died suddenly at his home in Elmira, N. Y., from cerebral hemorrhage, March 26, aged 53.

William D. Williams, M.D. Homeopathic Hospital College, Cleveland, 1865, died at his home in London, Ohio, March 22, from cerebral hemorrhage, aged 70.

Daniel M. Redlon, M.D. (County License, Ind.), 1897, a veteran of the Civil War, died at his home near Pierceville, Ind., March 17, from paralysis, aged 76.

William J. Crawford, M.D. Eclectic Medical Institute, Cincinnati, 1869, died at his home in Jackson, Mich., March 24, from cerebral hemorrhage, aged 78.

James M. Harman, M.D. Rush Medical College, Chicago, 1876, of Fairport, Mo., died at Excelsior Springs, Mo., March 12, from nephritis, aged 51.

John B. Hunt, M.D. Homeopathic Hospital College, Cleveland, 1863, died at his home in Westerville, Ohio, March 20, from pneumonia, aged 76.

Edward C. Johnson, M.D. Barnes Medical College, St. Louis, 1897, died suddenly, from cerebral hemorrhage, at his home in Rodessa, La., March 16.

Robert S. Finley, M.D. Eclectic Medical Institute, Cincinnati, 1850, died at his home in Xenia, Ohio, from senile debility, March 22, aged 79.

Joseph W. Speight, M.D. Medical College of Alabama, Mobile, 1883, died at his home near Columbus, La., March 17, after a brief illness, aged 53.

Simon A. Hageman, M.D. Pulte Medical College, Cincinnati, 1881, died at his home in Walnut Hill, Cincinnati, March 22, after a long illness.

Seth Cook Comstock, M.D. College of Physicians and Surgeons in the City of New York, 1894, died in New York City, March 27, aged 34.

John W. Hessey, M.D. College of Physicians and Surgeons, Baltimore, 1878, died at his home in Hanesville, Md., March 29, aged 53.

Henry Fisher Camblos, M.D. Jefferson Medical College, Philadelphia, 1881, died at his home in that city, March 26, aged 47.

Frederick W. Byfield, M.D. (Years of Practice, Illinois), 1879, died at his home in Sorento, Ill., March 20, aged 78.

Lester M. Burroughs, M.D. (Years of Practice, Illinois), 1877, died at his home in Batavia, Ill., March 23, aged 80.

Queries and Minor Notes

CAUSES OF IRREGULAR HEART ACTION.

BINGHAMTON, N. Y., March 5, 1906.

To the Editor:—Can you cite any authority who can explain the cause of irregular action of the heart? In one of my male patients the intermissions of the pulse are so irregular that they occur sometimes at every fifth beat, then perhaps at every seventh, and again at longer intervals from eleventh to twentieth. The patient had not been aware of any abnormal action of the heart until five or six years ago, when after assisting in carrying a heavy trunk upstairs it was accidentally discovered that the pulse was intermittent. It might have been, and probably was so before, though the patient had not been aware of it. For perhaps two years this irregularity was present whenever the pulse was counted; then for a year or more the beat was perfectly regular, but then again became irregular, and has continued so up to the present time. The general health has all this time been uniformly good, and the patient has not suffered any inconvenience from this irregularity of the heart's action. I have nowhere seen any satisfactory explanation of this abnormal condition. Can you solve the problem for me?

M.

ANSWER.—Simple arrythmia without determinable organic change about the heart and arteries may be due to hysteria, to the overuse of tobacco or to reflex irritation from remote organs, especially the stomach and the intestine. If the element of hysteria can be

liminated, particular care should be given to the stomach or bowel. Above all, constipation should be counteracted by the use of free evacuations, and careful search should be made for the possible presence of intestinal parasites. Dyspeptic symptoms, particularly flatulency after eating, should be treated according to the ordinary principles that are adopted for the cure of these conditions. Symptomatically, aconite, given in drop doses several times a day, is the best remedy, especially if the arrhythmia is complicated with palpitation. If the symptom is not subjectively perceptible, if it is not due to tobacco nor to organic disease of the heart, if the gastrointestinal tract is performing its function in a normal way and contains no parasites, then the symptom is negligible. The prognosis, so far as restitution to normal conditions is concerned, is doubtful and uncertain. Arrhythmia *per se* is not infrequently discovered by chance, and, when it is not due to any of the above causes, the life expectancy of the individual is generally in no way curtailed by its presence.

ARSENIC IN DIABETES.

EDGERTON, WIS., March 22, 1906.

To the Editor:—In THE JOURNAL, Jan. 13, 1906, page 141, there is a paragraph entitled "Arsenic in Diabetes," which refers to the use of arsenicated waters in the treatment of this disease. Can you give me any further information regarding the waters used, their administration or the literature on the subject? W. W.

ANSWER.—The arsenicated mineral waters used by Verdalle are those of La Bourboule, a watering place in France, near Bordeaux and Cannes. The waters contain 28 mg. of sodium arsenate to the quart, and are equivalent to about 21 drops of Fowler's solution and 3 grains of sodium chlorid with alkaline bicarbonates. These are said to be among the richest hot (140 F.) arsenical waters known. Verdalle found that diabetics who had not been benefited by Vichy and other waters were benefited by moderate doses of the Bourboule waters. He classifies diabetes according as the symptoms indicate insufficiency of the liver, the ordinarily mild cases, or hyperfunctioning of the liver, with very pronounced glycosuria and azoturia, generally accompanied by hypertrophy of the liver. The arsenicated waters are recommended in the latter class, while the alkaline are better for the former. In his article Verdalle gives the details of 64 cases to illustrate the benefit from the Bourboule waters. He reports the improvement to be lasting, and even apparently permanent in many cases. He proceeds very gradually with the waters, never giving large doses. His latest communication is in Archives Gen. de Méd. for March 20, 1906.

DRUGS INTERFERING WITH THE DIAZO REACTION.

WHITING, IND., March 24, 1906.

To the Editor:—1. What drug interferes with Ehrlich's diazo reaction? 2. Is the reaction ever obtained in syphilis, and if so at what stage? E. L. DEWEY.

ANSWER.—1. Burghart states that tannic acid, gallic acid and some iodin preparations, when administered internally, inhibit the diazo reaction of Ehrlich. The tincture of iodin, but not its salts, has this inhibiting power (Arneill). Simon found that naphthalin, when given by the mouth, gives a color "which corresponds exactly to that of the diazo reaction." The statement has been made also that the tincture of opium, cascara sagrada, and hydrastis canadensis give a reaction similar to that of Ehrlich (Burghart), but this is questioned by Arneill, except in the case of the tincture of opium, which may yield a similar color. Bilirubin and urobilin interfere with the test by altering the color picture, but if these substances are removed by sugar of lead or by treating with animal charcoal, the characteristic color may be obtained in suitable urines. What has been said relates to the diazo reaction of Ehrlich, as caused by some unknown substance in certain pathologic urines (e. g., typhoid, measles, acute miliary tuberculosis), and not to numerous other diazo color-reactions which may be obtained by known chemical substances.

2. Syphilis is not one of the diseases cited as giving the reaction. Penzoldt makes a rather vague reference to its occurrence in lues, but other observers have not recorded it. On theoretical grounds, one should not be surprised at its occurrence in a case of febrile secondary syphilis, or in tertiary syphilis with extensive secondary infection. Arneill obtained the reaction in one case of amyloid disease. (See Simon, "Clinical Diagnosis," Lea Brothers, 1904, Arneill, Amer. Jour. Med. Sc., 1900, vol. 119, p. 296).

ELECTRIC LAMPS FOR THERAPEUTIC PURPOSES.

SAN FRANCISCO, March 22, 1906.

To the Editor:—The claims of a certain electric lamp, whereby the actinic rays are concentrated and focused on the part to be treated, are being vigorously pushed in this vicinity by a medical man of much eloquence. A number of subscribers of THE JOURNAL have been approached, and have been solicited to purchase the apparatus, but they are totally uninformed as to its practical value. I can find only one article referring to this method of treatment, that by Dr. A. E. Sterne of Indianapolis, in THE JOURNAL, Feb. 20, 1904. In common with other subscribers, I should like to have your opinion of the value of this method of treatment in certain diseases. ROBERT A. MCLEAN.

ANSWER.—Practically all the so-called therapeutic lamps are incandescent lamps. The incandescent electric light contains almost no actinic rays, and the only effect that is had from it is from the application of heat. It is hard to see what basis there can be for the extravagant claims made for its therapeutic value.

LIQUOR AMMONII ACETATIS.

WAVERLY, MO., March 24, 1906.

To the Editor:—I have found that in country drug stores it is very hard to get good liquor ammonii acetatis. I was told by a hospital pharmacist that it took some ability and pure chemicals to make a good product. Is there any way whereby it may be made up in parts and when needed the requisite quantities combined after the manner of Fehling's solution? Do you know any way to circumvent its deterioration? I believe this valuable old-timer would be revived if it could be more easily made up by the average rural pharmacist. W. C. O'NEAL.

ANSWER.—The United States Pharmacopeia directs that solution of ammonium acetate be made by dissolving 5 gm. ammonium carbonate, translucent and free from white pulverent matter, in 109 c.c. dilute acetic acid. The acetic acid directed is slightly in excess of that required to react with the ammonium carbonate and a solution results containing, besides ammonium acetate, a small amount of acetic acid, to which the acidulous taste is due. Since, however, ammonium carbonate changes in composition when exposed to air and the dilute acetic acid may be too strong or too weak, a solution may result which either is strongly acid or else alkaline and bitter. When means to determine the quality of the ammonium carbonate and acetic acid are not available, the following procedure will be found satisfactory: To the dilute acetic acid, add the ammonium carbonate in small pieces until further additions no longer cause active effervescence. This solution should have a faintly sour taste; if its taste be found to be strongly acid, more ammonium carbonate, or if alkaline and bitter, more acetic acid, must be added. With a little practice, the sense of taste will be a very good indication of the quality of this solution. A solution which, on standing, has become alkaline, may be at least partially restored by the addition of sufficient acetic acid to produce a solution of mildly acid taste. The practice of keeping on hand separate solutions of acetic acid and of ammonium carbonate is fairly satisfactory if the amount required of each solution to produce this faintly acidulous solution is determined as just indicated.

The Public Service

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, week ending March 31, 1906:

Crosby, Wm. D., surgeon will, at the expiration of his present leave of absence, proceed to Vancouver Barracks, Washington, for duty.

Morse, Charles F., asst.-surgeon, will, at the expiration of his present leave, proceed to Fort Howard, Md., for duty.

Wilson, Compton, asst.-surgeon, relieved from duty at Fort Howard, Md., and ordered to Fort Sheridan, Ill., for duty.

Marrow, Charles E., asst.-surgeon, relieved from duty at Fort Sheridan, Ill., and ordered to Fort Monroe, Va., for duty.

Hanner, John W., asst.-surgeon, will, at the expiration of his present leave, proceed to West Point, N. Y., for duty.

Huggins, John B., asst.-surgeon, relieved from duty in the Army Transport Service, and will proceed to Manila, P. I., for duty on transport sailing from San Francisco, Cal., March 26, 1906.

Chidester, W. C., asst.-surgeon, advanced from rank of first lieutenant to that of captain, to date from March 24, 1906.

Ashford, B. K., asst. surgeon, relieved from duty at Henry Barracks, Cayey, Porto Rico, and from further special duty under the governor of Porto Rico, to take effect April 1, 1906, and will proceed to and take station at Washington Barracks, Washington, D. C.

Turrill, Henry S., brigadier general, appointed brigadier general, U. S. Army, to rank from March 28, 1906.

Moseley, E. B., asst.-surgeon general, promoted to rank of Colonel, to date from March 17, 1906.

LaGarde, Louis A., deputy surgeon general, promoted to rank of lieutenant colonel, to date from March 17, 1906.

Straub, Paul F., surgeon, promoted to rank of major, to date from March 17, 1906.

Turrill, Henry S., brigadier general, retired from active service, March 29, 1906.

Whitmore, E. R., asst.-surgeon, assigned to duty at Fort Warren, Mass.; order suspended until return of Major Charles Richard, surgeon, to Fort Jay, N. Y.

Heizmann, Charles L., asst.-surgeon general, relieved from duty in S. G. O., Washington, D. C., April 20, 1906, and ordered to San Francisco, Cal., for duty as chief surgeon, Department of California, and Superintendent of the Army Transport Service, relieving Lieut. Col. Gen. H. Torney, deputy surgeon general.

Harvey, Philip F., asst.-surgeon general, relieved from duty as chief surgeon, Department of the Lakes, May 1, 1906, and ordered to Governor's Island, N. Y., for duty at chief surgeon, Department of the East, relieving Colonel Valery Havard, asst. surgeon general.

Havard, Valery, asst.-surgeon general, relieved from duty as chief surgeon, Department of the East, and will repair to Washington, D. C., and report in person to the Surgeon General of the Army for duty in his office, and as president of the faculty of the Army Medical School and president of the Army Medical Board.

Cowper, H. W., asst.-surgeon, relieved from duty at Washington Barracks, D. C., and ordered to Plattsburg Barracks, N. Y., for duty.

Woodbury, F. T., asst.-surgeon, leave of absence extended 20 days.

McMillan, Clemens W., contract surgeon, ordered from Fort Trumbull, Conn., to Fort Terry, N. Y., for temporary duty.

Hall, Henry M., contract surgeon, granted an extension of one month to his leave of absence.

Gardner, Fletcher, contract surgeon, relieved from duty at Fort Crook, Neb., and ordered to duty at Fort Michie, N. Y.

McMidan, Clemens W., contract surgeon, relieved from duty in the Department of the East, and ordered to duty at Fort Crook, Neb.

Whitney, Walter, contract surgeon, relieved from duty at Fort Crook, Neb., and ordered to Fort Terry, N. Y., for duty.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending March 31, 1906:

Traynor, J. P., P. A. surgeon, from the Naval Hospital, Boston, April 10, and ordered to the *Southery* and to additional duty at the Navy Yard, Portsmouth, N. H.

Munson, F. M., asst.-surgeon, from the *Lancaster*, April 12, and ordered to the Naval Medical School, Washington, D. C., for instruction.

Shaw, asst.-surgeon, from the *Southery*, April 11, and ordered to the Naval Medical School, Washington, D. C., for instruction.

Backus, J. W., asst.-surgeon, from the *Hancock*, April 12, and ordered to the Naval Medical School, Washington, D. C., for instruction.

Jenness, R. F., asst.-surgeon, from the Naval Hospital, Navy Yard, N. Y., April 12, and ordered to the Naval Medical School, Washington, D. C., for instruction.

Marshall, E. R., asst.-surgeon, from Naval Medical School, Washington, D. C., March 31, and ordered to the Naval Station, Guantanamo, Cuba, and to additional duty on the *Monongahela*, sailing from New York, April 6.

Foster, T. G., asst.-surgeon, from the Naval Medical School, Washington, D. C., March 31, and ordered to the *Chicago*.

Shook, F. M., asst.-surgeon, from Naval Medical School, Washington, D. C., March 31, and ordered to the Naval Hospital, Mare Island, Cal.

Reed, T. W., asst.-surgeon, from Naval Medical School, Washington, D. C., March 31, and ordered to the Navy Yard, New York, April 10.

Hoen, asst.-surgeon, from Chicago, and ordered home to await orders.

Nelson, H. T., Jr., asst.-surgeon, from Naval Medical School, Washington, D. C., and ordered to the Naval Academy, April 10.

Pugh, W. S., Jr., asst.-surgeon, from Naval Station, Guantanamo, Cuba, and ordered home to wait orders.

Hathaway, G. S., asst.-surgeon, McConnon, G. H., asst.-surgeons, from Naval Medical School, Washington, D. C., March 31, and ordered to the *Constellation*.

Taylor, J. L., asst.-surgeon, from Naval Medical School, Washington, D. C., March 31, and ordered to the *Yankee*, sailing from New York, April 4.

Olson, G. M., Evitinge, E. O. J., Sellers, F. E., asst.-surgeons, from Naval Medical School, Washington, D. C., March 31, and to Asiatic Station, sailing from San Francisco, April 14.

Manger, C. B., asst. surgeon, from Naval Medical School, Washington, D. C., March 31, and ordered to the Naval Training Station, San Francisco.

Landon, M. E., asst.-surgeon, from Naval Medical School, Washington, D. C., March 31, and ordered to the Naval Station, Tutuila, Samoa.

Dean, F. W. S., Dykes, J. R., asst.-surgeons, from the *Oregon*, and ordered to Washington, D. C., for special duty, thence home to wait orders.

Aloken, E. G., asst.-surgeon, from Naval Station, Tutuila, Samoa, and ordered home to wait orders.

Rossiter, P. S., asst.-surgeon, from Naval Station, Honolulu, H. I., and ordered home to wait orders.

White, E. C., Brooks, F. H., Warner, R. A., Stalnaker, P. R., Reed, E. C., Mears, J. R., Woods, E. L. asst.-surgeons, from the Naval Medical School, Washington, D. C., March 31, and directed to wait orders.

Huntington, E. O., surgeon, discharged from treatment at Naval Hospital, N. Y., and ordered to the Naval Recruiting rendezvous, New York, N. Y., April 12.

Kerr, D. H., surgeon, ordered to Naval Medical School, Washington, D. C., April 14, for instruction.

Marsteller, E. H., surgeon, to Naval Recruiting Station, St. Louis.

Asserson, F. A., P. A. surgeon, from Navy Yard, New York, April 12, and to Naval Medical School, Washington, D. C., April 14, for instruction.

Monroe, J. M., P. A. surgeon, from the Naval Recruiting Station, New York, to Naval Medical School, Washington, D. C., April 14, for instruction.

Webb, E. R., P. A. surgeon, from the Naval Academy and to the Naval Medical School, Washington, D. C., April 14, for instruction.

Meyers, G. M., asst. surgeon, from the *Constellation* and to the Naval Medical School, Washington, D. C., April 14, for instruction.

Nichols, R. H., asst. surgeon, from the Naval Recruiting Station, St. Louis, and to Naval Medical School, Washington, April 14, for instruction.

Wynn, C. K., acting asst. surgeon, from the Naval Hospital, Washington, D. C., and ordered home to wait orders.

Smith, C. G., P. A. surgeon, from the Naval Hospital, Mare Island, Cal., April 10, and to the Naval Station, Honolulu, H. I., sailing from San Francisco, April 14.

Guthrie, J. A., surgeon, having been examined by a retiring board and found incapacitated for active service on account of disability incurred in the line of duty, is retired from active service, March 23, 1906, under the provisions of Section 1453, Revised Statutes.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending March 28, 1906:

Austin, H. W., surgeon, detailed as delegate on part of the United States to represent the service at the meeting of the Fifteenth International Congress of Medicine, to be held at Lisbon, Portugal, April 19-25, 1906.

Stansfield, H. A., P. A. surgeon, granted leave of absence for three days under Paragraph 191 of the Regulations, from March 16, 1906.

Francis, Edward, P. A. surgeon, directed to proceed to New Orleans, La., for special temporary duty, on completion of which to rejoin his station.

Ebersole, E. E., asst.-surgeon, relieved from duty at San Francisco and directed to proceed to Manila, P. I., reporting to P. A. Surgeon V. G. Heiser, chief quarantine officer, for duty.

Bailey, C. A., acting asst.-surgeon, excused without pay for three days from March 25, 1906.

Frick, John, acting asst.-surgeon, transferred from Tampico, Mexico, to Vera Cruz, Mexico, for duty in office of American consulate.

Hamilton, H. J., acting asst.-surgeon, granted leave of absence for 11 days from March 5, 1906, on account of sickness.

Woods, C. H., pharmacist, granted three days' leave of absence, from March 17, 1906, under Paragraph 210 of the Regulations.

Carlton, C. C., pharmacist, granted one day's leave of absence under Paragraph 210 of the Regulations.

CASUALTY.

Richardson, T. F., P. A. surgeon, died in New Orleans, March 19, 1906.

RESIGNATION.

Stephenson, Charles W., pharmacist, resigned as pharmacist of the first class, to take effect April 11, 1906.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the surgeon-general, Public Health and Marine-Hospital Service, during the week ended March 30, 1906:

SMALLPOX—UNITED STATES.

California: Los Angeles, March 3-17, 3 cases; San Francisco, March 10-17, 7 cases, 1 death.
Colorado: Idaho Springs, Feb. 1-28, 1 case.; South Canon, 1 case.
Florida: Jacksonville, March 17-24, 4 cases.
Illinois: Chicago, March 17-24, 1 case.
Kansas: General, Jan. 1-31, 125 cases, 1 death.
Kentucky: Covington, March 17-24, 2 cases.
Louisiana: New Orleans, March 17-24, 7 cases.
Maryland: Baltimore, March 17-24, 3 cases.
Michigan: Ann Arbor, March 17-24, 1 case; Detroit, 1 case.
Mississippi: Gulfport, March 19-26, 1 case; Natchez, March 10-17, 1 case.
Missouri: St. Louis, March 17-24, 7 cases.
New York: New York, March 17-24, 1 case.
Ohio: Cincinnati, March 16-23, 5 cases.
Pennsylvania: Pittsburg, March 17-24, 1 case.
Tennessee: Memphis, March 17-24, 14 cases.
Utah: General, Feb. 1-28, 232 cases; Salt Lake City, March 3-17 39 cases.
Virginia: Petersburg, March 1-26, 21 cases.
Washington: Spokane, March 10-17, 1 case.
West Virginia: Wheeling, March 17-24, 5 cases.
Wisconsin: Appleton, March 17-24, 2 cases; Beloit, March 10-24, 2 cases.

SMALLPOX—INSULAR.

Hawaii: Honolulu, March 12, 1 on S. S. *Coptic*.
Philippine Islands: Manila, Feb. 3-10, 2 cases.

SMALLPOX—FOREIGN.

Africa: Cape Town, Feb. 3-17, 7 cases.
Brazil: Pernambuco, Feb. 1-15, 21 deaths.
Canada: Toronto, Feb. 24-March 3, 1 case.
China: Hongkong, Jan. 26-Feb. 3: 9 cases, 7 deaths; Shanghai, Feb. 10-17, 2 cases, 3 deaths.
France: Paris, Feb. 24-March 10, 21 cases.
Gibraltar: Feb. 25-March 11, 11 cases, 4 deaths.
Great Britain: Glasgow, March 9-16, 2 deaths; Liverpool, March 3-10, 3 cases; London, 1 case.
Greece: Athens, Feb. 20-27, 3 deaths.
India: Calcutta, Feb. 10-17, 118 deaths; Bombay Feb. 20-27, 7 deaths; Karachi, Feb. 18-25, 52 cases; 13 deaths; Rangoon, Feb. 10-17, 103 deaths; Madras, Feb. 17-23, 20 deaths.
Spain: Barcelona, March 1-10, 5 deaths.

YELLOW FEVER—FOREIGN.

Mexico: Merida, March 4-10, 2 cases.
Nicaragua: Managua, Feb. 10-24, 2 deaths.

CHOLERA—INSULAR.

Philippine Islands: Manila, Jan. 26-Feb. 10, 7 cases, 8 deaths; Provinces, Feb. 2-10, 195 cases, 165 deaths.

CHOLERA—FOREIGN.

India: Bombay, Feb. 20-27, 1 death; Calcutta, Feb. 10-17, 79 deaths; Rangoon, 5 deaths.

PLAGUE—INSULAR.

Philippine Islands: Manila, Jan. 27-Feb. 10, 2 cases, 2 deaths.

PLAGUE—FOREIGN.

Brazil: Bahia, Feb. 22, present.
China: Hongkong, Feb. 2-10, 6 cases, 6 deaths.
India: Bombay, Feb. 20-27, 160 deaths; Calcutta, Feb. 10-17, 32 deaths; Karachi, Feb. 18-25, 19 cases, 11 deaths; Madras, Feb. 17-23, 1 death; Rangoon, Feb. 10-17, 3 deaths.
Paraguay: Asuncion, March 28, present.
Peru: Callao, Feb. 17-26, 1 death; Lambayeque, 3 cases, 1 death; Pisco, 1 case; Mollendo, 3 cases, 2 deaths; Paita, 5 cases, 2 deaths; Trujillo, 31 cases, 11 deaths.

Book Notices

Psychiatry. A Text-book for Students and Physicians, by S. Paton, M.D. Cloth. Pp. 618. Price, $4.00. Philadelphia: J. B. Lippincott Co. 1905.

Within the past few years there has been a decided stimulation of interest in mental disorders, if we are to judge by the output of textbooks on the subject. This candidate for favor is noteworthy in many respects, coming, as it does, from one of the chief centers of scientific medicine in the country and from an author who has already made himself known by scientific original work in this department. It may be fairly expected, therefore, to give the results of the best modern acquisitions as seen from the author's point of view, which includes the latest results of pathology and the newer psychology, so-called, but fully admitting, also, their limitations.

Insanity is regarded by him as a disease of the brain, with some qualifications. Thus he considers that we can not call myxedematous insanity, dependent on disturbed thyroid function, strictly a disease of the brain—a distinction, it seems to us, less practical than theoretical. The symptoms of insanity take up the greater part of the introductory chapters, that is, the non-somatic symptoms, which are very fairly well covered in these chapters. Then follows an instructive chapter on the examination of patients, concluding with details in regard to the examination of the cerebrospinal fluid, a procedure which the author says is indicated in all doubtful cases, especially when it is necessary to differentiate between functional and organic disorders, though the exact significance of the findings can not always be clearly defined.

In the chapter on treatment, special stress is laid on hydrotherapy and the "rest in bed" treatment which, according to the author, should be a routine method. The ideal hospital for the insane is described in the succeeding chapter, and this should be distinguished from the ordinary asylum or state hospital which is the only recourse for the majority in most parts of the country. It is more strictly a curative institution of limited capacity and adapted for recent and hopeful cases. The hospital treatment should be always to the fore and the attendants have general hospital training, as well as the special instruction required for those who care for the mentally diseased. There is no question as to the value of such institutions and their multiplication in the great centers, and especially in connection with the institutions for medical instruction, is in every way desirable. But for the great mass of the insane who, for obvious reasons, do not come under the head of curable cases, the larger institutions will still be the ones chiefly available.

The causes of insanity are very well discussed in a special chapter, and a few pages are given to the subject of classification, in which the author follows a system of his own, adopting, however, the popular Kraepelin groups of "maniac depressive" insanity and "dementia præcox." The descriptions of the different forms are generally very clear and complete. Koraskow's disease receives more attention than has been given it in most recent textbooks and is described in connection with the confusional types to which it properly belongs. A little more space, it seems to us, might have been given to this class of cases from autointoxication or exhaustion, constituting, as they do, a very respectable portion of the really curable forms of insanity, and, therefore, those which would be most suited for the treatment in special psychiatric hospitals. The very comprehensive groups of "maniac depressive" insanity and "dementia præcox" receive full treatment and an almost equal space is given to the subject of paresis.

Paranoia is narrowed down to a small residual group remaining after the inclusion of most of its formerly recognized types under other heads, and it seems to us that the author's experience must have been somewhat different from that of other alienists as regards this particular and very important type of insanity. He gives as an example of the confusion of ideas on this subject the conceptions of Sander's so-called "original paranoia." It seems to us that if there is any clinical type of derangement that deserves recognition it is this, though it may be questioned whether it properly belongs under the head of true systematized delusional insanity. Typical cases are not very common and in a limited clinic like that of Kraepelin they may be rare, but they are very striking when they occur. The chapter on the paranoia group seems to be as little satisfactory as any in the book.

Taking the work as a whole, it is a valuable addition to psychiatric literature and one which no alienist can well neglect. The author is modern in his ideas and his book contains a wealth of references, especially to the German literature of the subject. A practical idea indicated by the author in his preface, is that the study of the subject of psychiatry will tend more or less directly toward enriching the brain power of mankind, and that its results will have an important bearing as applied to educational and other questions of the day.

Nasal Sinus Surgery, with Operations on Nose and Throat. By B. Douglass, M.D. Illustrated, with 67 half-tone and colored plates. Cloth. Pp. 264. Price, $2.50 net. Philadelphia: F. A. Davis & Co., 1906.

This volume will be welcomed by rhinologists and senior students. The anatomy of the sinuses and their relations to the nasal cavities, orbits and the brain are illustrated by many fine photographic half-tones of anatomic preparations. The descriptions are enforced by iteration and reiteration and by measurements of numerous specimens. The various methods of examination used in making a diagnosis of sinus disease are clearly described. Most of the standard operations on the sinuses, both conservative and radical, are outlined. The author lays especial stress on the danger of enlarging the nasofrontal duct by intranasal operation, giving five reasons for his objection. Whether the recently perfected operation by means of a flexible trephine made to follow a probe will overcome his objection is in doubt, as he did not refer specifically to this method. In the chapter on operations for deflection and exostosis of the septum the author points out that in cases of combined deflection and thickening a careful removal of the latter will in many cases render an operation for the deflection unnecessary. The subject exostosis is also considered in connection with synechiæ. Ten pages are devoted to the description of operations for the relief of nasal deformities, and a detailed description of making paraffin injections for the relief of the saddlenose deformity and the dangers to be avoided are given. It will doubtless help the profession to appraise this procedure at its true value and to rescue it to a degree from the advertising quack. The author's tonsil needle to suture the pillars of fauces to control tonsillar hemorrhage is figured and the procedure is illustrated with a cut. Laryngotomy and tracheotomy are carefully described and beautifully illustrated with colored plates and a frontispiece. The book is creditable to both author and publisher.

A Text-Book of Materia Medica, Therapeutics and Pharmacology. By George F. Butler, Ph.G., M.D., Associate Professor of Therapeutics in the College of Physicians and Surgeons, Chicago. Fifth Edition, thoroughly revised, by Smith Ely Jelliffe, M.D., Ph.D., Professor of Pharmacognosy and Instructor in Materia Medica and Therapeutics in Columbia University (College of Physicians and Surgeons), New York. Octavo of 694 pages, illustrated. Philadelphia and London: W. B. Saunders Company, 1906. Cloth, $4.00 net; Half Morocco, $5.00 net.

This is the fifth edition of Dr. Butler's well-known work, which has been thoroughly revised to conform to the new Pharmacopeia. The general arrangement of the text has been changed so that drugs whose predominant action is on any one system of the body are grouped together. As the author states, any system of grouping has its drawbacks, but this arrangement is both practical and useful. After a brief introduction, pharmacology and general therapeutics are discussed, including modes of introduction of remedies, untoward effects of drugs, classification of medicines, and weights and measures. Pharmaceutical preparations are then considered at length, including solutions, solid and liquid mixtures, extracts, and preparations for external use. Succeeding chapters deal with drugs acting on the nervous system, on the circulatory system, those acting on micro-organisms, volatile oils, resins, and balsams, antipyretics, alteratives, astringents, and drugs acting on particular organs. The book concludes with a chapter on prescriptions which is of special interest and should be of value

to all practicing physicians. Under this head the author considers incompatibility, antagonism, estimation of amounts, and the language and grammatical construction of the prescription. The book is commended as one of the most practical for the general practitioner.

HANDBOOK FOR ATTENDANTS ON THE INSANE, with an appendix giving the Regulations for the Training and Examination of Candidates for the Certificate of Proficiency in Nursing of the Medico-Psychological Association of Great Britain and Ireland. Fourth Edition. Reprinted, with Revised Regulations. Published by the authority of the Medico-Psychological Association. Cloth. Pp. 158. Price, 50c net. Chicago: W. T. Keener & Co.

This, the authorized book of the British Medico-Psychological Association for attendants on the insane, appears to meet very fairly the need which has called it forth. Not all the duties of an attendant are or can be taught by books. Natural fitness and experience are indispensable. We may say of an attendant for the insane, still more than of a trained nurse, that he is born, not made. The book also does not completely cover the course which attendants in British hospitals for the insane are called on to take up and study, but it is an essential text-book. Its republication in this country is a matter for congratulation, for, though we have some works on this subject, an opportunity for choice is always desirable. The fact that each edition is revised by committees including some of the best known and most experienced alienists of Great Britain is a strong recommendation.

TEXT-BOOK OF MEDICAL AND PHARMACEUTICAL CHEMISTRY. By E. H. Bartley, B.S., M.D., Ph.G. Sixth Edition, thoroughly revised; 90 illustrations. Cloth. Pp. 534. Price, $3.00. Philadelphia: P. Blakiston's Son & Co. 1905.

When any text-book arrives at its sixth edition it has demonstrated its value and should be considered beyond the field of the reviewer. While teachers of chemistry will differ as to the best method of presenting this subject, especially as regards the consideration of chemical theories, and while it is to be regretted that the author has considered it undesirable to bring the work in accord with modern conceptions of chemistry, all must concede that Dr. Bartley's long experience as a teacher has enabled him to present the subject in an admirable manner. Beginning with chapters on heat, light, electricity and the chemical theories, the author passes over to the consideration of inorganic and organic compounds, and finally takes up physiologic chemistry, to which more than 150 pages are devoted, and succeeds in presenting this vast material in a clear, concise and logical manner. Few text-books on chemistry designed for medical students compare favorably with Dr. Bartley's work.

LECTURES ON TROPICAL DISEASES, Being the Lane Lectures for 1905, Delivered at Cooper Medical College, San Francisco, U. S. A., August, 1905, by P. Manson. Cloth. Pp. 230. Price, $2.50 net. Chicago: W. T. Keener & Co. 1905.

Sir Patrick Manson's lectures present the chief facts concerning some of the important tropical diseases in a most fascinating and instructive manner. Seldom are the complex facts and conditions in the mode of infection and dissemination of tropical diseases so stated as to interest the reader in the degree achieved in these lectures. The eminent lecturer's own epoch-making influence and work in unraveling the etiology of filariasis and malaria and other tropical diseases are familiar to all students of medicine. His discussion in these lectures of problems of tropical medicine, still unsolved, of the future influence of the Panama canal, and of other questions of importance reveals the comprehensive grasp and imagination of the master.

MAN AND HIS POISONS. A Practical Exposition of the Causes, Symptoms and Treatment of Self-Poisoning. By A. Abrams, A.M., M.D. Illustrated. Cloth. Pp. 268. Price, $1.50. New York: E. B. Treat & Co., 1905.

In the preface the author states that self-poisoning has advanced from a plausible and fascinating theory to a verity. In the first chapter he reviews the various conceptions of life and touches on the investigations of Loeb. In succeeding chapters he discusses the history of autointoxication; the modern views of disease; the influence of fatigue mental and physical on this condition; the toxicology of the emotions and sleep, the physics and chemistry of thought; symptoms of self-poisoning; psychology of living in relation to prevention and cure of autointoxication.

State Boards of Registration

COMING EXAMINATIONS.

ARKANSAS State Board Medical Society, Little Rock, April 10. Secretary, J. P. Runyan, Little Rock.

MISSOURI State Board of Health, Barnes Medical College, St. Louis, April 10-12. Secretary, J. A. B. Adcock, Warrensburg.

WEST VIRGINIA State Board of Health, Parkersburg, April 10-12, Secretary, H. A. Barbee, Point Pleasant.

DISTRICT OF COLUMBIA Board of Medical Supervisors, Washington, D. C. April 12. Secretary, William C. Woodward, Washington, D. C.

MISSOURI State Board of Health University Medical College, Kansas City, April 16-18. Secretary, J. A. B. Adcock, Warrensburg.

ILLINOIS STATE BOARD OF HEALTH, Northwestern University Building, Chicago, April 18-20. Secretary, J. A. Egan, Springfield.

District of Columbia January Report.—Dr. William C. Woodward, secretary of the Board of Medical Supervisors of the District of Columbia, reports the oral examination held at Washington, January, 1906. The number of subjects examined in was 17; total number of questions asked, 80; percentage required to pass, 75. The total number of applicants examined was 16, of whom 13 passed and 3 failed. The following colleges were represented:

PASSED. College.	Year Grad.	Per Cent.
Baltimore Med. Coll.	(1905)	77.9
Columbian University	(1903) 78.7,	91.9
Georgetown University	(1905) 84.1,	85.2, 88.7
George Washington University	(1905) 79.4,	82.7, 84.2
Howard University	(1905)	75
New York Homeo. Med. Coll.	(1886)	76
Southern Homeo. Med. Coll.	(1904)	76.2
University of Virginia	(1905)	85.7
FAILED.		
Georgetown University	(1903) 61.8; (1905)	70.8
University of Michigan	(1900)*	

* Absented himself from part of the examination, no percentage assigned.

Illinois January Report.—Dr. J. A. Egan, secretary of the State Board of Health of Illinois, reports the written examination held at Chicago, Jan. 18-20, 1906. The number of subjects examined in was 16; total number of questions asked, 100; percentage required to pass, 75. The total number of applicants examined was 27, of whom 21 passed and 6 failed. The following colleges were represented:

PASSED. College.	Year Grad.	Per Cent.
Miami Med. Coll.	(1895)	90.4
Detroit Coll. of Med.	(1904) 88.4;	92.5
Baltimore University	(1903)	76.9
National Medical University	(1905) 84.6,	90.3
Toledo Med. Coll.	(1904)	76.4
Rush Med. Coll.	(1905) 85.5,	89.2, 91.6
University of Pennsylvania	(1880)	88.4
Illinois Med. Coll.	(1905) 90.6;	(1906) 77.1
Medical College of Indiana	(1897) 84.2;	(1905) 82.6
Hahnemann Med. Coll., Chicago	(1905)	92
Denver and Gross Coll. of Med.	(1905)	88.1
Eclectic Med. Inst., Cincinnati	(1903)	76.8
University of Naples	(1890)	82.1
Bellevue Hospital Med. Coll.	(1876)	75
Ohio Med. Coll.	(1878)	85.2
FAILED.		
College of P. and S., Keokuk	(1905)	70.1
College of Med. and Surg., Chicago	(1904)	66.9
Barnes Med. Univ.	(1904)	73
American Coll. of Med. and Surg.	(1906)*	
American Med. Miss. Coll.	(1904)*	
National Medical Univ.	(1906)*	

* Took an incomplete examination and no percentage was assigned.

Medical Organization

California.

HANFORD MEDICAL SOCIETY. At a meeting of the physicians at Hanford, February 15, Dr. Philip Mills Jones, San Francisco, delivered an address in which he urged the benefits of organization and made an earnest plea to those present to maintain the regular meetings of the society and to keep up the attendance.

Georgia.

COWETA COUNTY MEDICAL ASSOCIATION. This association was organized at Newnan, February 21, by Dr. W. L. Fitts, Carrollton, councilor for the fourth district. The following officers were elected: Dr. Thomas J. Jones, Newnan, president; Dr. Theodore B. Davis, Newnan, vice president; Dr. T. S. Daley, secretary, and Dr. R. F. Foster, treasurer.

Kansas.

MIAMI COUNTY MEDICAL SOCIETY.—Physicians of Miami County met at Paola with Dr. J. E. Sawtell, Kansas City, councilor for the seventh district, and organized a county society on the standard plan, with the following officers: Dr. Lyman L. Uhls, Osawatomie, president; Dr. J. Henry Haldeman, Paola, vice-president; Dr. John D. Walthall, Paola, treasurer, and Dr. J. Henry Haldeman, delegate to the state medical society.

HOPKINS COUNTY MEDICAL SOCIETY.—At a meeting of the physicians of Hopkins County, in Madisonville, February 15, the councilor of the second district delivered an address setting forth the benefits of organization. Following this the society was reorganized on the standard plan and the following officers elected: Dr. William K. Nesbitt, Earlington, president; Dr. A. W. Davis, Morton's Gap, vice-president, and Dr. James W. Long, Madisonville, secretary and treasurer.

OHIO COUNTY MEDICAL SOCIETY.—This society was recently organized with the following officers: Dr. Eugene B. Pendleton, Hartford, president, and Dr. A. Francis Stanley, Hartford, secretary and treasurer.

Michigan.

CALHOUN COUNTY MEDICAL SOCIETY.—To facilitate the war against unlicensed practitioners, which this county society undertook some time ago, the society has become incorporated, with the following officers: President Dr. Herbert A. Powers; secretary, Dr. Eugene Miller, and treasurer, Dr. Clarence C. Vary, all of Battle Creek.

New Hampshire.

CHESHIRE COUNTY MEDICAL SOCIETY.—At the midwinter meeting of this society, held in Keene, February 13, the constitution and by-laws were revised so as to conform to those proposed for county societies by the American Medical Association.

Texas.

FRISCO-CENTRAL MEDICAL SOCIETY.—At the joint meeting of the medical societies of Erath, Comanche and Hamilton counties, held in Dublin early this month, a new body was organized to comprise in its membership all physicians on and near the lines of the St. Louis & San Francisco and Texas Central railways in these counties. The following officers were elected: Dr. James F. McCarty, Comanche, president; Drs. William E. Hubbert, Hico; Thomas J. Farmer, Dublin, and G. H. Chilton, Comanche, vice-presidents, and Dr. O. A. Craigwall, Stephenville, secretary.

RED RIVER COUNTY MEDICAL ASSOCIATION.—This association was organized at Clarksville, March 9, on the standard plan, with the aid of Dr. Holman H. Taylor, Marshall, councilor of the Fifteenth district. The following officers were elected: President, Dr. Charles T. Clark, Clarksville; vice-president, Dr. Robert Jones, Rosalie; secretary and treasurer, Dr. J. T. Hutchinson, and censors, Drs. E. S. Chambers, English; Nowlin Watson, Clarksville, and Claud Scott.

Society Proceedings

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, Boston, June 5-8.

Tennessee State Medical Association, Memphis, April 10.
Medical Association of the State of Alabama, Birmingham, April 17.
Medical Society of the State of California, San Francisco, April 17-19.
Florida Medical Association, Gainesville, April 18.
Medical Association of Georgia, Augusta, April 18.
Mississippi State Medical Association, Jackson, April 18.
South Carolina Medical Association, Columbia, April 18.
State Medical Association of Texas, Fort Worth, April 24-26.
Arizona Medical Association, Phoenix, April 24-25.
Medical and Chirurgical Faculty of Maryland, Baltimore, April 24-26.

MEDICAL SOCIETY OF THE MISSOURI VALLEY.

Eighteenth Semi-Annual Meeting, held at St. Joseph, Mo., March 22-23, 1906.

The President, DR. JOHN E. SUMMERS, Omaha, in the Chair.

Surgical Treatment of Goiter.

DR. CHARLES H. MAYO, Rochester, Minn., based his remarks on 200 operations. He said that large cystic and encapsulated tumors within the gland can be enucleated to save useful gland substance. In exophthalmic goiter one lobe and the isthmus should be removed, and if there is recurrence of symptoms, the lower part of the remaining lobe should be taken away. In the worst cases this should be done at the primary operation. Operation is no longer experimental; medical and serum-therapy are still under discussion. Fearing malignancy, early operations are recommended in irregular and hard tumors. More than one-half the operations performed on the thyroid gland are those of expediency. Is is, therefore, necessary that a low mortality rate accompany operations for goiter. During the last fifty years the mortality has been reduced from 40 per cent. to a fraction of 1 per cent.

DISCUSSION.

DR. L. L. MCARTHUR, Chicago, said that Rogers of New York presented in THE JOURNAL A. M. A., Feb. 17, 1906, a promising method of treatment of the exophthalmic type of goiter. He was led to his investigations through the sufferings of his wife. When her condition became so severe that it seemed she was about to die, he became desperate enough to try some serum experiments. He made emulsions of recently excised goiters of the exophthalmic type and injected them into rabbits. From the rabbits he obtained a serum, one injection of which practically annihilated all the symptoms of goiter in his wife. The condition of sixteen patients treated was so alarming when the injection was made that as yet he has hesitated to put it into the hands of the profession, and has refused to use it, except in those cases that are deemed so extremely desperate that even the surgeon prefers not to undertake operative intervention.

DR. T. C. WITHERSPOON, St. Louis, Mo., has operated in eighteen cases of exophthalmic goiter; in seventeen with local anesthesia. About five weeks ago he removed an exophthalmic goiter from a patient suffering at the same time from a malignant disease of the breast. Her pulse averaged 140. One week after removal of the goiter she was in good condition. Pulse dropped to 95. He used a general anesthetic (ether), and removed the breast radically, and within five hours after the operation her pulse was 170. While on the table her condition was good. The amount of blood lost was small. There was no reason for the high pulse, except the general anesthetic. After that time the pulse quickly dropped, and she recovered. His fear has always been the ill-effect of general anesthesia.

DR. MAYO said that Dr. Rogers has undoubtedly developed a cytolysin for the destruction of the thyroid. Rogers has had twelve cases of more or less severe types of exophthalmic goiter, in many of which the results are favorable, while in others no benefit has resulted.

Pathology of the Morphin Habit.

DR. S. GROVER BURNETT, Kansas City, Mo., condemned (1) the acute hyoscin poisoning method, attended by coma, delirium and reactionary prostration of both mental and physical forces; (2) the abrupt disuse of the drug, as is enforced in jails, penal institutions and asylums; (3) the rapid withdrawal of the drug during four to eight days; (4) the so-called slower reduction requiring fourteen to twenty days. In his opinion the foregoing methods can only be applied to selected cases. Burnett gave at considerable length his preferred method of treatment.

DISCUSSION.

DR. F. E. COULTER, Omaha, said that in cases of morphin habit or drug addiction it is very essential to have the hearty co-operation of patient before one is going to be successful in any line of treatment he may inaugurate. The patient should be placed in pleasant surroundings. His associates must be congenial. The nurse must be satisfactory to the patient. Coulter employs what is known as the physiologic method.

Is Vaginal Cesarean Section Justifiable?

DR. PALMER FINDLEY, Omaha, drew the following conclusions: 1. Less time is consumed in delivering the fetus by the ab-

dominal route. 2. Greater accuracy is assured in surgical cleanliness by the abdominal route. 3. The abdominal incision is wholly under control of the operator, whereas in the extraction of the fetus per vaginam, the incision may extend beyond the control of the operator, as it has in more than one case, and with fatal results from hemorrhage and infection. 4. In an abdominal Cesarean section opportunity is afforded of rendering the patient sterile by resecting the tubes when thought advisable, and various lesions, such as adhesions, tumors of the uterus demanding hysterectomy, bands as the result of ventrofixation, and diseased appendages, can be dealt with. 5. The abdominal route assures the fetus of the greatest consideration, inasmuch as the application of forceps and the turning of the child in utero are necessarily attended by dangers to the fetus. 6. Rupture of the uterus in subsequent pregnancies through the scar of a Cesarean section is a not uncommon accident, and it is apparent that since the large majority of ruptures of the uterus are in the lower uterine segment, a scar at this point will more likely be disposed to rupture than one located in the fundus. In the light of reported cases, and judging by the results obtained in the use of other well-established methods of delivery in cases similarly indicated, vaginal Cesarean section is not destined to find general favor with trained obstetricians. The legitimate scope of the operation will be so limited that it will be little practiced.

Surgical Treatment of Total Prolapse of Uterus.

Dr. C. O. Thienhaus, Milwaukee, Wis., prefers those methods which make use of the body of the uterus as a support to the bladder, because thereby a recurrence of the accompanying cystocele, which so often takes place after other methods of surgical procedure, is made absolutely impossible. He described at length a method used by himself, a modification of the Schauta and Dührssen operations, and reported nine cases on which he had operated, with their results.

DISCUSSION.

Dr. A. H. Cordier, Kansas City, Mo., sees no objection to departing from some of the older methods for holding the uterus in proper position. If the patient has passed the menopause, and does not expect to become pregnant again, bring the uterus up and anchor it to the anterior abdominal wall. It has been his custom to do a ventrofixation in the old cases, and doing complete repair of the perineum, both anterior and posterior, not simply making a skin flap operation in the vagina, but repairing the muscles, re-establishing them, and putting the uterus in normal position.

Dr. O. Beverly Campbell, St. Joseph, Mo., said that there is a class of cases in which the procidentia has remained for a long period of time, in which the vaginal mucosa has ulcerated to such an extent that it is almost destroyed, and he has seen a few such cases, especially women, say 65 years of age, old maids or widows, where matrimony does not enter as a factor, in which he believes the more radical operation of Prof. A. Martin removing the entire vagina and uterus, and closing up the opening, would give better results than the operation described by Dr. Thienhaus. Ventrosuspension for the cure of procidentia has been a most unsatisfactory procedure.

Tumors of the Cerebellum.

Dr. F. E. Coulter, Omaha, reported a case, and discussed the question of neoplastic growths in the posterior fossa of the skull, taking up the etiology, symptomatology and diagnosis, the object being to emphasize the more common signs and symptoms of disease in this location, thus making of more practical importance the questions of diagnosis and treatment.

Blastomycetic Dermatitis.

Dr. William Frick, Kansas City, Mo., reported three cases. The histopathology of the three cases was practically the same as that described by other observers. The most characteristic thing appears to him to be the miliary abscesses which are found both in the epidermis and in the corium. It is in these abscesses that the organism is most abundantly found. Another interesting point is the large number of giant cells resembling those seen in tuberculosis. Since these cases follow a fairly definite clinical course, there seems no reason why a clinical diagnosis should not be made, which diagnosis, for the present, at least, should be corroborated by the microscope. Given a case beginning as a papule or pustule, with a considerable inflammatory zone surrounding it, which instead of improving when the pus which first forms is discharged, extends this zone of inflammation and shows near the surface the formation of miliary abscesses, the case may be expected to be one of blastomycosis. This may then be verified by microscopic findings in the pus or in small pieces of tissue, or both. The treatment consists in excision, the administration of iodin compounds, and the use of the x-ray. Since the point of entrance is usually some exposed surface of skin, if an early diagnosis is made, a complete excision will usually end the case, and is the quickest and most satisfactory method of disposing of it. This disease, while confined to the skin, may be considered a curable affection, but if it becomes systemic, it is beyond the reach of remedies now in vogue.

Dr. Charles G. Geiger, St. Joseph, Mo., said that the clinical aspects of the disease may be mistaken for three other skin affections tuberculosis verrucosa cutis, fungous syphiloderm, and lupus vulgaris. He discussed the differential diagnosis of these affections.

Intestinal Tuberculosis and Its Surgery.

Dr. L. L. McArthur, Chicago, said that it has been demonstrated that while the vast majority of cases of intestinal tuberculosis are secondary, there yet exists a goodly proportion of cases of primary intestinal tuberculosis without other discoverable lesions. With the reopening of the question which has heretofore been accepted as settled, that infection almost invariably occurs through the respiratory tract, the latest and more painstaking observations show that through the intestinal tract a far larger number of cases of infection occur than has been thought or deemed possible. Practically nursing children and milk-fed infants are the only ones afflicted with true primary intestinal tuberculosis, because (1) they are the ones exposed most commonly to infected food; (2) their intestinal tract is less resistant to such invasions.

While Eisenhardt and Fenwick found only 1 in 1,000 cases of autopsy that they considered primary, on the other hand few cases of tuberculosis of the respiratory tract escape ultimate secondary intestinal tuberculosis. Thus Eisenhardt, in his 1,000 autopsies of tuberculous adults, found 563 cases of intestinal infection, of whom 489 had cavities in their lungs. Intestinal tuberculosis is frequently overshadowed by the pulmonary disease. But inasmuch as the presence of cavities determines so regularly the intestinal infection, the absence of cavity will have a decided prognostic value in those cases that clinically come to the surgeon for aid. These will, in the largest proportion of cases, be over 25 years.

The author's study of the literature and his personal experience have led him to the following conclusions: (1) The term primary tuberculosis of the intestines is both clinically justified and often demonstrable on section. (2) In selected cases, though desperate, surgical interference offers reasonable hope. (3) The capacity for withstanding surgical interference is greater for this condition than that which obtains with other abdominal affections of like magnitude. (4) The first symptoms of this disease may begin as and even be mistaken for an appendicitis. (5) Partial or total exclusion will in some cases accomplish the desired results when conditions contraindicate excision. (6) The ulcerative variety may make numerous fistulæ, as in the author's cases. (7) Simple inflammatory processes are apt in a tuberculous subject to become tubercular, and terminate as above. (8) Surgery offers much hope to an otherwise probably fatal issue. (9) Many a case of general abdominal tuberculosis is the end result of a preceding intestinal tuberculosis which might have been at one time operable. (10) Both bovine and human tubercle bacilli, while not identical, are related varieties of one original form. (11) The cutaneous hand infections of butchers is a strong argument against absolute difference.

Postoperative Treatment of Clubfoot.

Dr. M. M. Edmonson, Kansas City, Mo., said that by beginning treatment early the foot can always be corrected by force alone. The soft tissues are stretched easily and the bones that are malformed, especially the astragalus, are soft and cartilaginous, so that they are molded readily to conform to a normal position. At this stage it will require very little force to maintain this position, and it can be accomplished without causing pain. In its new position the foot will develop normally with the rest of the body. The contracted tendons and soft tissues having been stretched, the elongated tendons will become contracted. In maintaining the corrected position at this age, a fixed dressing is probably used more than any other, especially plaster-of-Paris, but in this the ankle joint is immobilized and all the advantages of muscular exercise are lost. It is often difficult to so apply the dressing that the position is as good as that gained by the hand. The Barwell dressing has all the advantages and none of the disadvantages of the plaster-of-Paris or any fixed dressing. It is simple and easily applied.

No case should be cut that can be corrected by force. Following any method of correction some mechanical support is necessary; as the primary cause still exists, some aid must be given in maintaining this muscular balance until nature alone is sufficient, and this has only been reached when the foot can be everted and flexed as easily as it can be everted and extended. Feeling the need of a simple, yet effective retaining force in those cases about four years ago the author devised a brace which he has found more nearly meets all the requirements. The shoe used in connection with the brace is the usual one made for the normal foot. It, however, should be heavy and of the best material. This brace and its method of application were described, followed by the citation of cases.

Indirect Effects of Valvular Lesions.

Dr. W. F. Milroy, Omaha, called particular attention to the wide range of symptoms not obviously connected with the heart. These are associated with the gastrointestinal respiratory, or the nervous system, or are more general, as loss of weight, power of concentration or endurance. The date of origin of the symptoms is uncertain, their duration often many years. Endocarditis, which causes the lesion, is secondary to many general infections. A history of rheumatism suggests an examination of the heart for valvular disease, but in the writer's opinion too much importance is given this infection in the etiology. Valvular disease is of far more frequent occurrence than is generally supposed. Clinical teachers and textbook writers are at fault in not emphasizing sufficiently their indirect effects. Gross errors in diagnosis are of very common occurrence. They suggest the necessity for more attentive study of the art of physical diagnosis by the practitioner, and the wisdom of an invariable rule in making such examinations a part of every diagnosis.

Rupture of the Male Urethra.

Dr. B. A. McDermott, Omaha, said that the indications for surgical interference are not ordinarily clear, but usually present themselves as (1) the history of injury; (2) the escape of blood, either with or without urine, at the meatus; (3) the presence of shock; (4) the gradual appearance of a perineal or suprapubic tumor; (5) if a solution of methylene blue is injected through a catheter through the anterior urethra, it will be found coming out through the perineal opening, if one exists; if there be no external opening it will be found in the perineal tissues. The presence of the above conditions is usually sufficient to warrant surgical interference.

The author made a strong plea for early surgical interference based on the following reasons: (1) In cases of rupture of the urethra presenting the foregoing symptoms, immediate perineal or suprapubic section, with suture of the ruptured ends of the urethra, should be practiced. (2) By this procedure not only are the sufferings of the patient lessened, also the danger of urinary infiltration and abscess, but in a large number of cases the formation of a later stricture may be prevented. (3) In early operation the search for the posterior end of the urethra is much easier than it is later, as the tissues are not so infiltrated and the posterior end is not so retracted. The hemorrhage from the branches of the arteries of the bulb serves as a guide to the end of the canal.

Advances in the Office Treatment of Rectal Diseases.

Dr. R. D. Mason, Omaha, advocated the treatment of all minor rectal diseases by the use of local anesthesia, using weak cocain solutions of 0.5 to 1 per cent., when injected, and as high as 10 per cent. if applied locally to the mucous membrane. He advocated the injection method of treating a certain class of internal hemorrhoids, and described the cases to which it is adapted as those of the old indurated variety, in which the tumors are hard and painless, and cause inconvenience more because of their constant protrusion through a loose sphincter muscle than because of any actual suffering. He also showed that the use of sterile water as a local anesthetic is useless, except in tissue where it will be retained sufficiently long to make pressure on the nerve ends and drive out the blood. Because of the large amount of water required the tissues are so distorted that operation is difficult. He described a method for divulsing the sphincter under local anesthesia, and discussed the use of the actual cautery for the cure of hemorrhoids, ulcers and other conditions, with the technic.

Removal of the Uterus for Chronic Inflammation.

Dr. T. C. Witherspoon, St. Louis, advocated the removal of the chronically enlarged uterus whose density and vascularity are increased, which, associated with chronically inflamed and altered tubes, causes local and general symptoms that make life burdensome. Removal of the uterus brings about entire relief, but much depends on the technic of the operation. Three things must be observed: First, removal of the uterus with practically all of its endometrium. Second, avoidance of the large sympathetic pelvic brain. Third, complete closure of the peritoneum covering the pelvic floor in order to avoid bowel adhesions.

The best technic in the removal of the inflamed uterus is as follows: After entering the abdomen by a median suprapubic incision, carefully tie off the tubes, avoiding injury to the ovaries. Apply a clamp on either side of the uterus, letting its tip reach well down to the cervix; free the body of the uterus from the broad ligament attachments by cutting along the clamps; amputate through the cervix by an exaggerated V-shaped incision, the apex of the V reaching nearly to the external os. Tie the cut ends of the utero-ovarian artery loop, after releasing the clamps, with catgut. Close the stump, suturing to it the ovarian and round ligaments. Carefully cover all raw surfaces with peritoneum. Iodin catgut should be used as suture and ligature because it resists infection better than silk, linen or cumol gut.

Ligation of Common Femoral Artery for Large Aneurism in Scarpa's Triangle.

Dr. L. J. Dandurant, St. Joseph, Mo., exhibited a man, 42 years of age, who was first seen Nov. 20, 1905. Inquiry revealed a specific infection dating back ten years; also a trauma occurring two years ago in the nature of a horse kick. Examination revealed a large pulsating tumor filling the greater part of Scarpa's triangle, which was diagnosed as an aneurism of the femoral artery. Large doses of iodid of potassium and the induction of coagulation by compression, combined with the rest cure, proving ineffectual, Dandurant ligated the common femoral artery just below Poupart's ligament. All pain ceased; the tumor began to decrease in size. The circulation in the leg and foot was apparently not disturbed. There has not been a sign of edema at any time. In placing his ligature he followed the suggestion of Hunter, tying it tight enough to check the pulsation, but still permitting some blood to flow through the tumor. At the end of four or five days, however, this was entirely shut off, and today there is a well-organized clot, with perhaps a cavity at its center.

The County Sanatorium for the Treatment of Pulmonary Tuberculosis.

Dr. Richard C. Moore, Omaha, said that the indications for the successful management of pulmonary tuberculosis are surveillance, disinfection, and by appropriate means to increase the natural power of resistance. These indications can be followed out most satisfactorily by establishing and main-

taining sanatoria. Moore believes that a sanatorium in Nebraska would be a center from which information could be promulgated for the early management of such cases, and would thus in time, by instructing the people in prophylaxis and in the home treatment of consumption, greatly reduce the mortality from this cause. Theoretically the modern treatment of pulmonary tuberculosis can be carried out in the home of the patient, but practically it has been the author's experience that it is impossible to convince the laity, and many of the profession, that night air is not injurious, and that wind, rain or snow should not be excluded from the apartment occupied by the patient, when by such exclusion the free circulation of pure air is also shut out. To carry out this treatment the patient must be placed in a suitably arranged apartment and be absolutely under the constant surveillance of a trained nurse or experienced physician. In order to accomplish this desideratum the well-equipped sanatorium is probably the best, but such institutions are very costly to construct and very expensive to maintain, which renders them prohibitory in many communities. In Nebraska, where the consumptives, as shown by the statistics, are not numerous, the cheapest and most practicable manner of taking care of such cases would be in properly arranged county hospitals. Instead of the ownership and management being under state charge, each county could take care of its own consumptives as it now does its indigent sick and paupers. What is needed to carry out this plan is a well-drained location on which the county authorities can erect suitable buildings for its tuberculous patients in connection with proper facilities for the culinary department and housing of nurses. The author favors a plan similar to that suggested by Dr. Irving Fisher, New Haven, the main feature of which is an arrangement for ventilation by means of shutters, which are changed automatically to the direction of the wind.

The Expectant Mother.

Dr. E. T. Shelly, Atchison, Kas., said that the physician owes it to the expectant mother and to himself to give her the best professional attention he is capable of bestowing. As a necessary part of such attention he should, during the pregnancy, give her such guidance as her condition calls for, and to furnish it in a permanent and accessible form. The author spoke of the desirability of supplying the prospective mother gratuitously with an easily understood original pamphlet issued by the physician himself, and giving her such information as in his opinion she ought to have in order to pass through her ordeal as comfortably and safely as possible. He outlined such a pamphlet.

Rachitis.

Dr. A. E. King, Blockton, Iowa, said that in the pathology we find interrupted nutrition both in and outside of the child, and the malassimilation produces permanent alterations. Rachitis is entirely preventable and should not be associated with mollitis osseum, as the processes are entirely different, one being the destruction of bone, the other non-formation of bone. He pointed out the importance of making an early diagnosis, and of instituting proper treatment.

Surgery of the Paralyses.

Dr. John P. Lord, Omaha, said that the general practitioner has too little working knowledge of the benefits to be derived from surgical intervention. The deformities resulting from paralysis are all of a progressive character; therefore, effective treatment instituted before the deformity has begun will prevent the deformity. The mere maintenance of a limb in a corrected position not only prevents deformity, but prevents over-stretching of muscles which, unstretched and treated, might be of some service. This is more especially true in spastic conditions. Oftentimes massage, electricity, bathing, movement and use will do much in maintaining growth in bone, muscle, and ligaments, and will limit deformity. The present tendency is to limit the use of apparatus and resort to such surgical measures as will render the limbs most useful. These operations should be judiciously applied to the individual cases, and supplemented by such treatment as will furnish the greatest aid in completing the results. Time is a great factor.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Acute Articular Rheumatism.

In discussing the treatment of acute articular rheumatism Shoemaker, in the *New York Medical Journal*, commends very highly the use of salicin internally along with local applications of the oil of gaultheria. He condemns very strongly the use of salicylic acid and coal-tar preparations in the treatment of this condition and further states that the sodium salicylate has been properly succeeded by this glucosidal preparation. Salicin is more acceptable to the stomach and is less irritating to the digestive organs, and has not the depressing effect on the heart and circulation that is observed after the use of salicylic acid. In the opinion of Shoemaker, salicin bears to acute rheumatism very much the same relation that quinin does to malaria; in other words, he regards it as practically a specific for this condition. He also recommends the employment of alkalies in the treatment of acute articular rheumatism, especially potassium citrate, and the solution of ammonium acetate. Owing to the rapid anemia present, due to the loss of red blood corpuscles and destruction of hemoglobin, he recommends the tincture of the chlorid of iron, in combination with the alkalies. Basham's mixture consequently will serve the purpose, being a combination of the iron and ammonium acetate.

When the pulse is rapid and the heart's action is weak, strychnin may be added, or the infusion of digitalis given internally, combined with potassium citrate or sodium bicarbonate. He is strongly opposed to the use of antipyretics in the technical sense of the word. If, however, the temperature is high and maintains an elevation of 103 F. or over, there is always danger of the development of cerebral rheumatism, which may prove to be a fatal condition. In such conditions he recommends the cold bath, repeated often enough to keep down the temperature. It is well in these cases to precede the bath with an alcoholic stimulant, in order to cause dilatation of the peripheral blood vessels, the heart being sustained by hypodermic injections of strychnin and digitalin. The ice-bag may be applied to the precordium, to assist in combating the hyperpyrexia. He recommends morphin in doses of gr. 1/6 to 1/12 (.01-.005) each to an adult, given from time to time to relieve the pain and restlessness and to enable the patient to sleep. [This drug should be given cautiously, however, to avoid the formation of a habit.] The morphin should be combined with atropin in small doses. If the skin should become too dry, small doses of pilocarpin may be injected hypodermically, and warm drinks administered to assist its action. As the tonsils are in many instances the port of entry for many of these infectious organisms, he regards it as very important to disinfect the mouth and throat with proper antiseptic solutions. In summarizing the treatment he advises that the patient be placed in bed in a well-ventilated room in order to afford the most complete rest possible to the system. The food should consist principally of broths, stale or toasted bread and butter, weak tea or coffee, with an occasional egg, avoiding articles that ferment readily in the stomach; this includes the carbohydrates. Meat should be given only after the decline of the fever, and during the stage of convalescence. During the height of the disease, when there is severe local pain in the joints, he recommends the following combination applied locally.

℞ Olei gaultheriæ ..... ℥ii 8
Linimenti saponis q. s. ad ..... ℥ii 60

M. Ft. linimentum. Sig.: Apply locally to the joint by gentle rubbing; then envelop the joint in cotton, on the outside of which should be placed a flannel bandage.

Internally he recommends the following:

℞ Salacini ..... gr. x 65

M. Ft. chartula No. i. Sig.: One such powder to be given every hour or every two hours after the alimentary tract has been emptied by a cholagogue cathartic.

To support the heart and to counteract the anemia he recommends the following combination:

℞ Salacini ..... gr. x |65
Ferri citratis 3i 4
Liquoris ammonii acetatis 3iv 120
Syrupi aurantii rubri q. s. ad 3vi 180

M. Ft. solutio. Sig.: One tablespoonful every three hours in a wineglassful of water.

The principles of the treatment of subacute rheumatism, which is simply a milder form of the acute, are similar.

In chronic rheumatism iodin is recommended, both as an external application and internally in the form of potassium, sodium or strontium iodid. When gouty conditions exist along with chronic rheumatism, the lithia preparations, especially the mineral waters containing lithia, are of service, combined with colchicum. In the chronic forms of rheumatism massage, electricity and dry heat are of great advantage in the treatment.

In subacute rheumatism the following local application, containing mercury and salicylic acid, is recommended by Stevens:

℞ Acidi salicylici ..... gr. xxx 2
Olei terebinthinæ 3ii 8
Ung. hydrargyri 3i 30
Adipis lanæ hydrosi 3ss 15

M. Ft. unguentum. Sig.: Apply locally with friction night and morning.

Tampons in Chronic Constipation.

In considering the treatment of chronic constipation J. A. MacMillan, in *Medicine*, recommends rectal tampons in atonic constipation. This tampon should be made of absorbent cotton, cheese cloth or lamb's wool, and should be large enough to cause some distension of the bowel. It should be inserted through an ordinary proctoscope, and packed by means of a long forceps. The best location is at the recto-sigmoidal junction. A piece of string, of course, should be attached to the tampon, in order to facilitate its withdrawal after it has remained in place for from two to six hours. This treatment should be carried out every other day at first, and the interval between the treatments should be gradually lengthened as improvement takes place. The value of this treatment, according to the author, is due to the distension of the intestine. He records success in the majority of the cases in which he has tried it, although not in all of them. In most of these cases enemata and cathartics should be discontinued from the first, in order that regularity of stools may be established.

Multiple Warts.

Mantlin recommends the following combination in the treatment of multiple warts:

℞ Chloralis hydratis
Acidi acetici, āā 3iss 6
Acidi salicyli
Spiritus etheris, āā 3i 4
Collodii 3iv 15

M. Sig.: Apply locally to the warts.

Administration of Belladonna.

In the treatment of acute keratitis Stevens recommends the following combination containing belladonna:

℞ Atropinæ sulph. ..... gr. i |06
Acidi borici ..... gr. x |65
Aquæ dest. 3i 30

M. Sig.: One or two drops to be instilled into the conjunctivæ twice a day.

In cases of pertussis the following combination is recommended:

℞ Tinct. belladonnæ 3iss 6
Glycerini 3ii 8
Aquæ menth. pip. q. s. ad 3ii 60

M. Sig.: Thirty minims three times a day for a child of 3 years. The dose should be gradually increased until flushing of the face is induced.

In the treatment of hemorrhoids the following combination is useful:

℞ Ext. belladonnæ ..... gr. x |65
Acidi tannici ..... gr. vi |40
Hydrarg. chloridi mitis ..... gr. xxx |30
Cocainæ hydrochlor. ..... gr. vi |40
Unguenti petrolati 3i 30

M. Ft. unguentum. Sig.: Wash the parts well and apply locally, night and morning.

Diarrheas in Children.

In outlining the course of treatment of diarrheas in children J. H. Buffum, in *Vermont Medical Monthly*, states that in a general way all the infectious diarrheas of childhood should be treated in a similar manner. The first essential is cleanliness, together with a cool, quiet room, and an abundance of fresh air. Early in the disease all food, even breast milk, should be withheld. During the first twenty-four hours nothing should be given except a little cold boiled water, with the addition rarely, in cases of great prostration, of a little brandy or whisky. In some cases the stomach may be so irritable as to me unable to retain any substance, consequently it may be necessary to give stimulants hypodermatically. If the case is seen sufficiently early, a dose of castor oil is recommended to clear the alimentary tract and, consequently, to shorten the course of the disease. When vomiting is severe, however, calomel in small doses is preferable. Irrigation of the bowels with a normal salt solution is of value, as it assists in the removal of toxic products from the intestines, and serves to quiet the thirst and to supply the necessary fluid to the tissues. The temperature of the fluid used should vary as indicated by the patient's condition. If the vomiting should continue beyond twenty-four hours, some authorities recommend washing out the stomach, and that this procedure be followed by administration of small doses of calomel. Hot packs are recommended in cases of prostration. In some cases the vomiting and purging may be so severe as to demand morphin and atropin hypodermically. When this is necessary he recommends morphin gr. 1/100, and atropin gr. 1/800, for a child 1 year of age. When in the judgment of the physician food can be borne by the stomach, Buffum recommends barley water or albumin water, together with beef, mutton or chicken broth, either administered alone or in combination. These feedings should be two or three hours apart, and in amount one-fourth to one-half the normal. Bismuth is recommended to allay the vomiting and the tenesmus, as it is both a sedative and an intestinal antiseptic. In children it should be given suspended in mucilage, or in older children it may be given in powder form. He does not think much of the intestinal antiseptics commonly recommended.

Medicolegal

Prior Operation No Defense for Unauthorized Dissection.

By section 309 of the New York Penal Code the unauthorized dissection of the body of a human being is a misdemeanor. The First Appellate Division of the Supreme Court of New York says that in the case of Jackson vs. Savage and others, alleged to be the officers, directors and trustees of a hospital, the gravamen of the complaint was the unauthorized dissection of a body, that of the plaintiff's wife, after death. The plaintiff must establish that essential fact. Having established it, it would be no answer to prove a prior operation during life. But if, as proof of dissection after death, he should introduce proof as to the condition of the body when received by him, it would be entirely competent to prove that the said condition was the result of an operation, and not of dissection. No averments in the answer would be required for the admission of such evidence. It would go to the destruction of the plaintiff's case, but in no sense would it be a defense of the cause of action set forth.

Requirements as to Insanity as a Defense to Crime.

The Supreme Court of Idaho says, in the homicide case of State vs. Wetter, that where the defense is insanity, it is always brought into the case by the defendant, and until he furnishes such evidences of insanity, at least sufficient to raise a question of doubt in the minds of the jurors, the prosecution may rest on the legal proposition that all men are supposed to be sane and legally responsible for their acts. The mere fact that insanity may exist in his family is not of itself sufficient to excuse the defendant from the responsibility he owes to his fellow-men, neither would it avail him if he were able to prove that he was "off" at times. The question to be

determined in cases of this character is, was the defendant at the time of the homicide so mentally unbalanced that he was not responsible to God or man for the commission of the act? If he mentally knew it was wrong to take the life of a human being, and under these conditions did commit the offense charged to him with malice, hatred or revenge, he is morally and legally responsible for the act and should suffer the consequences. He might at times be "a little off," and yet entirely responsible at the time of the commission of the crime charged to him. It might be that insanity existed in his family from its earliest history, and yet that would not excuse him. It would only be a circumstance in his favor, to be considered with other evidence as to his past history, his language, acts and conduct at the time of the homicide and prior thereto. In fact, anything in his past life showing any indication of insanity should and would be considered by the jury. It would be a very dangerous precedent to say that because insanity existed he should have immunity. Further than that, it should be considered in connection with other evidence in the case showing the condition of the defendant's mind at and about the time of the homicide. It is true it would be a strong circumstance to show that he was not so mentally and morally depraved as to take the life of two human beings and attempt the life of the third, but, nevertheless, it would still be incumbent on him to show that legal insanity, and not moral depravity, prompted the act. Human life is very sacred in the eyes of the law, and, whilst courts should always guard with the utmost diligence the rights of all parties charged with crime, at the same time they should be watchful of the rights of the people and not permit parties charged with homicide to go unpunished on the plea of insanity, unless there is a foundation in fact, reason, and justice to believe that the insanity was of such a character that the party pleading it was so mentally unbalanced that he was not responsible for his conduct.

Physician Not Guilty of Negligent Homicide.

The Court of Criminal Appeals of Texas reverses, in Gorden vs. State, a conviction of a physician of negligent homicide. It says that the Penal Code of that state provides that, "If any person in the performance of a lawful act shall, by negligence and carelessness, cause the death of another, he is guilty of negligent homicide of the first degree. . . . To constitute this offense there must be an apparent danger of causing the death of the person killed, or some other. The want of proper care and caution distinguishes this offense from excusable homicide. The degree of care and caution is such as a man of ordinary prudence would use under like circumstances." The test of the offense seems to be that there must be an apparent danger of causing death. Without this it would seem this offense could not exist, or would not be made out. And the test of care or caution is that which distinguishes it from excusable homicide.

In this case the accused, a physician, was called in consultation by the attending physician of a woman who was suffering from a cancerous affection of the womb. An examination was necessary, and for this purpose he was called in by the attending physician. In order to make this examination he inserted two fingers in the vagina to detect the cause of the trouble. There was some question as to what this trouble was, but the testimony showed that the woman had been suffering from this cancerous affection, and to such an extent that she was continually confined to her bed and bled to a considerable extent. The state's contention was that the accused with considerable degree of force undertook to pull and succeeded in pulling something from the womb or vagina, and that this caused great pain. Whatever this substance was, it was laid on the bed and subsequently put back into the vagina. The evidence for the defense showed the insertion of the fingers seemed to have broken down the partition wall between the womb and the intestines, at least, this conclusion was deducible and that an intestine protruded through the cavity and out through the vagina, thus making its appearance, and that this was pushed back. At this point the theory of the state seemed to be that with the two fingers the accused pulled with such force on the womb as to tear loose and break down this partition wall, and by this means the intestines escaped, thus producing death. It was also contended by the state that this intestine was torn. But the physicians showed that this was not true, and could not have been true. In fact, it seemed to be practically demonstrated by the evidence of the physicians that the accused could not by the insertion of the two fingers into the vagina either have torn down the partition wall between the womb and the intestines, or break or tear in two the intestine after it protruded into the vagina.

Murder in second degree and manslaughter were submitted. But on each issue the jury found in favor of the accused, and convicted, as before stated, of negligent homicide. And the court does not believe that there was any evidence showing murder or manslaughter. Nor does it believe that there was evidence of sufficient character to show want of proper care. It says that the question of apparent danger under the statute under discussion is one that perhaps may be fraught with more or less trouble when applied to surgical operations. Just how far the surgeon would be responsible for negligent homicide, where there is an apparent danger of causing death of the person on whom the operation is performed, the court does not here propose to decide. Whatever that responsibility is, and at whatever point it may occur, there must be an apparent danger of causing the death of the person on whom the operation is performed; and, of course, this must be viewed in the light of proper care and caution. Many of the operations that are performed to relieve suffering humanity are necessarily fraught with more or less danger; and this is as well understood by the patient as by the operating surgeon. The court is of the opinion that the statute never intended to hold a surgeon liable for a homicide in cases of this character, unless there was a want of proper caution and care in the operation, however dangerous that operation may be. It may be proper, perhaps, to state that in some of the diseases for which these operations are performed for the relief of the patient the chances are more than equally balanced against life that death will result. Under this character of case there would be an apparent danger of causing death, but in such case, before the physician could be held responsible for the homicide, there must be shown a want of proper care and caution in performing the operation. Of course, however dangerous the operation may be and however many may be the chances of producing death, the physician could not be guilty, unless he acted without necessary caution and care. But the court does not think that question entered into this case, because it does not believe the facts justified the conclusion that there was a want of proper care.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below

American Medicine, Philadelphia, Pa.

March 24.

1 *Malaria and the Anopheles Mosquito in Pennsylvania and in Texas. A. Woldert, Tyler, Texas.
2 *Men Having Ocular Movements Similar to Those Found Normally in the Ungulates. W. L. Phillips, Buffalo, N. Y.
3 Diagnosis in Incipient Pulmonary Tuberculosis. J. H. Elliott Gravenhurst, Canada.
4 Etiology of the Hemorrhagic Diathesis. W. W. Carter, New York.
5 *Nose and Throat Diseases from a Constitutional Standpoint. J. L. Harkness, Philadelphia.
6 King's Evil and Its Cures. (To be concluded). J. Knott Dublin, Ireland.

1. **Malaria.** Woldert gives a detailed account of his personal observations made in Philadelphia and Texas regarding the anopheles mosquito. In Philadelphia he only once failed to find the malaria-carrying mosquito (invariably the *Anopheles quadrimaculata*) in the houses in which autochthonous cases of malarial fever prevailed. In Texas he has never failed to find them. He also found that the male mosquitoes became more numerous as frost came on, while the female gradually disappeared.

2. **Patients Having Ocular Movements of Ungulates,**—Phillips cites the history of two patients each presenting essentially the same conditions. They can see 20/20 with each eye separately and without glasses. It is possible for one patient to fix with both eyes, to turn either one out slowly and back again to double fixation without disturbance, while reading. He is also able to converge both eyes and to move his eyes simultaneously to extreme divergence. Besides this he can move them both to the extreme right or to the extreme left, or, by holding one in any position, from extreme divergence to extreme convergence, look at the side of his nose with the other. At no time since birth did he have double vision, and it is not produced even by the use of strong prisms. He finds that monocular vision is more restful than binocular vision, because of less head rotation. In each of these positions he has both eyes in focus, seeing with the one in front and the other at the side. The second patient could, with one eye, see to set type and at one side read proof with the other without the necessity of movements of the eyes.

5. **Nose and Throat and Constitutional Diseases.**—Harkness points out the intimate relation which exists between these organs and other organs of the body, as for instance, laryngitis, and pharyngitis of a rheumatic or lithemic origin. He also notes the relation between varicose veins of the leg and hypertrophied tonsils, and the effect of adenoids which cause gastric disturbances and *vice versa*, inanition in children, etc. He calls attention to the inflammatory conditions of the sinus (with consequent systemic effects) caused by a deflected septum, and shows the close relation existing between nasal conditions and the genitalia both in normal physiologic conditions and in disease.

7 *Modern Treatment of Fractures. C. Beck, New York.
8 Uterus and Ovary of Neurasthenia. R. L. Dickinson, New York.
9 *Appendicitis. A. E. Isaacs, New York.
10 Filtration of Public Water Supplies. C. E. Gillette, U. S. A.
11 Public Water Filtration in Massachusetts. G. Harrington. Boston.

7. **Treatment of Fractures.**—Beck sums up his views as follows: In the absence of bone injury the proper treatment consists of massage, followed by immobilization. If there is a fissure or fracture, with no displacement, manipulations of the injured area must be avoided and immobilization in the most comfortable position applied. As a rule he has found a plaster-of-Paris dressing best for this purpose. After two or three weeks the dressing is removed and massage is begun. In about two weeks a plaster-of-Paris splint is applied, which the patient can take off and reapply. If there is any displacement reduction must be tried at once. In those cases in which reposition, even under anesthesia, can not be accomplished, the fragments must be exposed by the scalpel and brought into apposition. If there be any tendency to displacement a plaster-of-Paris dressing will ensure immobilization. If the fragments slip out easily it is safer to unite them with catgut, provided there is enough periosteum to be utilized for that purpose. Otherwise it is best to keep them together with a bronze wire suture.

9. **Appendicitis.**—Isaacs records his personal observations in a series of 147 consecutive appendectomies, with fifteen fatalities. In sixty clean cases only one patient, a man, died. This was the second attack of appendicitis, and the man had, in addition, a severe influenza. He developed a postoperative general peritonitis, cause unknown. In 62 local abscess cases four patients died, and in 25 general peritonitis cases ten patients died. In eight of these death was due practically to a continuation of the general sepsis. In about 68 of the 75 cases in which the onset of the attack was noted pain was the first symptom. It was a prominent symptom in 127 cases, and in the remaining 20 cases it could be brought out as an objective symptom. The next most frequent symptom noted was constipation, which was present in 103 cases. Vomiting was present in 100 cases, including almost all the acute and some of the subacute and interval cases. The diagnostic value of the various symptoms noted, the choice of time for operation and the method of operating are discussed fully. Isaacs found that, like pulse and temperature, the leucocyte count in itself is not a positive indication of the presence or absence of pus in any individual case, yet it may be of value as confirmatory evidence in the presence of other symptoms.

13 *Cerebral Seizures with Suboccipital Pain. W. D. Ruston and E. E. Southard, Boston.
14 Gunshot Wounds of the Head and Spine. W. R. Weiser, Springfield, Mass.

12. **Cystoscopic Diagnosis.**—The value of the cystoscope as a diagnostic aid is subscribed to by Chute, who says that in cases of painless hematuria of renal origin cystoscopy is of particular value, allowing one to tell definitely which kidney the bleeding is from before the other localizing symptoms, such as pain, tenderness, and increased size, have appeared.

13. **Cerebral Seizures with Suboccipital Pain.**—A case suggesting the difficulty of diagnosis in cranial conditions anatomically simple, is reported by Ruston and Southard. A woman, 69 years of age, presented a series of cerebral seizures without focal signs, leading to a fatal issue in nineteen days. The seizures were ushered in by a boring occipital pain. The autopsy revealed several successive voluminous hemorrhages so situated in various parts of the cerebrum that the fibers of the projection system were largely spared. The small cerebral arteries, both of the cortical and the ganglionic systems, were beset with miliary aneurisms. Both vertebral arteries opposite the junction of bulb and cord showed gross aneurismal dilatation.

22 Eye Problems which the General Practitioner is Called on to Solve. R. J. Tivnen, Chicago.
23 Vincent's Angina. L. T. Royster, Norfolk, Va.

15. **Suggestion in Therapeutics.** That psychic influence has not been used more by physicians in a legitimate manner; that the profession has permitted it to become the basis of many religious cults and has allowed it to be used by charlatans to the detriment of the people, Beebe thinks is peculiar. He thinks that every individual has an influence, to a greater or less degree, on some other person or persons, and that suggestion or psychic influence may be made to play an important rôle in the healing art. All physicians, consciously or unconsciously, he declares, influence their patients in a general way. Beebe urges that more attention be given to this matter and enters into an explanation of the *modus operandi* of this form of therapeutics.

16. **Spirochete in Syphilis.**—MacKee examined twelve cases of secondary syphilis with reference to the *Spirochæta pallida* and succeeded in finding this organism in eleven cases. He has not been able to demonstrate the spirochete in tertiary lesions or in specimens taken from lesions in psoriasis, lichen planus, eczema, lupus, varicose ulcers, seborrheic dermatitis and epithelioma.

17. **Treatment of Lateral Spinal Curvature.**—The method pursued by Shands is practically that advocated by R. W. Lovett with a variation in the application of the mechanical support. The patient is treated daily at the office for several months, and then three times a week. The treatment consists of a combination of dumb-bell exercises, stretching the spine in the jury mast, and hanging on a trapeze, bobbing up and

down over the end of a table, and the application of an intermittent corrective force in the Adams machine. The patients are allowed to remain in this machine under the greatest amount of force they can stand for from fifteen to twenty minutes. After the spine has been rendered as flexible as possible the patient is suspended in the jury mast and an impression is taken of the body from the collar bone well over the hip. A solid plaster-of-Paris bust is made from this jacket. The shape of the bust is improved by shaving away a certain amount of the plaster over the apex of the deformity of both the primary and compensating curves until the necessary correction has been made. The plaster-of-Paris corset is made from this bust. When the corset is laced on the patient as much constant pressure can be brought to bear at the seat of the deformity as the patient can stand.

18. **Perforating Ulcer of Duodenum.**—A case of acute ulceration of the duodenum, about two inches below the pylorus, is reported by Austin.

19. **Colic.**—As an aid to differentiating between colic and peritonitis LaRoque has worked out a very useful table in parallel columns. Because of the length of this table the reader is referred to the original article.

21. **Unusual Case of Chlorosis.** The patient in this case of chlorosis reported by Barach was a boy, 10 years old, who, until the age of 2 years, was to all appearances perfectly healthy. For several years after that his health was not so good, and during that time he was troubled much with constipation. At 8 years of age he had a severe attack of whooping cough, lasting two months. Following that he was taken sick with what was probably a bronchopneumonia. The patient always lived in the country where he had plenty of fresh air, good food, and proper hygiene. His appetite, however, was capricious and at times uncontrollable. Barach thinks that the gastrointestinal system of the patient was at fault.

31 La Grippe. J. R. Scott, Garnett, Kansas.

27. **Cases of Epithelioma Treated by the X-Ray.**—Scott reports six cases. The first patient had an epithelioma of the left side of the nose and cheek. When treatment was started the tumor was discharging considerable pus. After the conclusion of treatment the final result was only a little depression and contraction at the site of the cavity. The second patient had an epithelioma of the nose which also yielded rapidly under x-ray treatment. The third patient had an epithelioma of the upper eyelid. The growth began to diminish after the tenth treatment and the final result was a good one. The fourth patient had an epithelioma of the cheek which was entirely destroyed and the place healed over. A recurrent carcinoma of the breast also did well and an epithelioma extending from the external canthus of the eye to the ear yielded in four months.

28. **Medical Legislation.**—Morrison states that the trouble with medical legislation seems to be not so much in the matter of the law as in securing a board that will enforce the law. This can be done only by securing a board that will represent the best interests of the medical profession. Since this board is to represent the medical profession the members of that profession ought to have a voice in determining who is qualified to represent them. This is already being done in fifteen states and the District of Columbia, and in two states the boards are appointed by the medical societies and not by the governor. Morrison recommends that the statutes be amended so that the governor would be compelled to appoint the state board of medical examination and registration from recommendations made by the state medical societies.

32. **Operation for Cleft Palate.**—The procedure adopted by Smith has for its purpose not merely the closure of the cleft, but the actual production of a new muscular velum. The method has proved satisfactory in the case of ten patients operated on. From the anterior end of the cleft an incision is made, running outward and a little backward toward the alveolus, about one-third the distance to the teeth, when the direction of the incision is changed so that it is carried in a straight line nearly to the posterior extremity of the alveolar process, care being taken that there is left sufficient tissue for the blood supply of the flap. A corresponding incision having been made on the opposite side, the two flaps thus outlined are dissected up from the bone, the periosteum being included, and are freed completely from the posterior edge of the palate bones behind.

An incision is now made on each side, beginning at a point near the last molar, where the preceding incisions terminated, and running along in a curve, close to the roots of the teeth, sufficient space being left in front for the nourishment of the flaps. This cut will usually terminate near the lateral incisors. There are thus formed two triangular flaps, composed of mucous membrane and periosteum, which are carried into the median line and sutured together. The freshened edges of the velum are now sutured, and the posterior edges of the anterior flaps are sewn to the middle of the newly-formed velum. If deemed best the tension can still further be guarded against by extra sutures, placed in the velum at some distance from the edge. In case there seems danger that the palate may be carried too far forward during the process of repair through contraction of the flaps, it is quite feasible, Smith says, to pass a suture through the periosteum at the posterior edge of the palate bones, and thus anchor the velum at the desired point.

35. **Choice of Hip Splints.**—According to Ryerson, the ideal hip splint should have as a foundation a simple Thomas knee splint; to this should be added the Davis pelvic band to allow the use of a perineal strap on the well side if abduction is present. On this pelvic band an ordinary Thomas upright and thoracic band should be carried, the thoracic band being of the same design as the pelvic band. If, however, these pelvic and thoracic attachments be permanently fastened to the lower uprights it is difficult or impossible to apply the brace, since it involves dragging the patient through three hoops, set at different angles. To overcome this Ryerson makes use of an other method. The upper end of the outside upright is carried an inch above the attachment of the Thomas ring and is ground accurately. A socket drilled to fit this post is then forged, with short anteroposterior wings to which the pelvic band is riveted at an angle of 20 degrees, to correspond with the average tilt of the pelvis. An upright from this pelvic band supports the thoracic band. This entire upper work constitutes a separate part of the brace which can easily be attached after the lower part has been applied. Ryerson has used this brace in a number of cases with great satisfaction.

47 Cause and Prevention of Postoperative Cystitis. F. J. Taussig, St. Louis.
48 Cerebellar Tumor of Syphilitic Origin. J. J. Singer, St. Louis.

41. **Darier's Disease.**—Mook reports a case of this rare affection for the purpose of showing the effect of the *x*-ray treatment on the disease. The result was remarkably beneficial. The secretions dried up promptly and in a few weeks the growths were markedly reduced in size and have continued to reduce until now they are one-fifth as large as when the treatment was begun. The treatment has also entirely relieved the pain and burning sensation which characterized the disease.

Journal of the Association of Military Surgeons of the United States, Carlisle, Pa.

52 Service of Negroes in Hospital Corps Detachments. J. H. Ford, U. S. A.
53 Grayson-Graeme Hammock Mosquito Net. C. T. Grayson, U. S. A.

50. **Causes of Accidents to Divers.**—Abbamondi discusses those accidents which may happen after the return to the ordinary pressure and those which may happen before the diver's return to ordinary pressure, that is, when he is under water. He conducted a large number of experiments on chickens which showed the following: The rapid change of pressure and principally the rapid descent under several atmospheres may be dangerous in the exercise of the diver. The chickens subjected to a rapid compression (one second), almost constantly manifested in the experiment room morbid phenomena (somnolence, lethargy, difficulty of breathing, excitation, etc.) but they did not present them when the compression was slow (five minutes). The duration of the stay in the experiment room (five to twenty minutes) had not apparently a remarkably pernicious influence when the compression was gradual. Rapid decompression (one second) on the chickens subjected to a pressure of five atmospheres (equal to forty meters' depth in the sea), only produced mortal effect in the cases when it had been preceded by a rapid compression (one second), and it rarely produced them when it had been preceded by a slow compression (five minutes).

51. **Cure for Asthma.**—Short reports the curious case of a girl who was treated by her sister with what she stated to be a sure cure for asthma. Every form of treatment, including climatic, had been tried previously, but without avail. The sister went to the cemetery and selected some pieces of bone of the skull, which were dry and bleached, washed them and pulverized them in a mortar, added the powder to a quart bottle of water and gave the patient a teaspoonful three times daily. By the time half of the mixture had been taken the patient's condition was very much improved. Short saw the solution and observed the results of the treatment. About two and a half years have elapsed since then and there has been no recurrence of the asthma. Short concludes: "In what the potency of the treatment consisted I will not attempt to state, but I can vouch for the truth of these facts."

63 *Aspiration in Acute Articular Rheumatism. F. J. B. Cordeiro, U. S. N.
64 Rationale of the Roentgen Ray. J. W. Hunter, Jr., Norfolk, Va.

54. **Mixed Toxins in Inoperable Sarcoma.**—Coley reviews the history of the mixed treatment of inoperable sarcoma and reports 11 cases of sarcoma and carcinoma which show that the toxins have a marked inhibitory action, even in carcinoma; and although this is rarely curative, he believes the results sufficiently good to justify the routine use of the toxins after all primary operations for carcinoma, as well as for sarcoma. Of 36 cases which may be classed as successful in that the tumor disappeared under the injections with the mixed toxins, the type of the neoplasm was as follows: Round-celled, 13; spindle-celled, 16; mixed-celled, 2; epithelioma, 1; chondrosarcoma, 1. In three cases no microscopic examination was made, but the clinical appearance, together with the history of recurrence, left practically no room for doubt as to the diagnosis. The results in these cases, thus far, have been as follows: Well less than a year, 5; well from one to two years, 4; well from two to four years, 3; well from three to five years, 5; well from five to thirteen years, 21. Ten patients are well over ten years. In five cases a recurrence took place and finally proved fatal. In one of these recurrent cases the patient had remained well eight years; in one, three and one-fourth years; in one, two and a half years; in one, seven months, and in one six months.

From published reports and personal communications from other surgeons who have tried the mixed toxins in inoperable cases Coley tabulates 60 cases of complete or partial success. In all of these cases the clinical diagnosis was confirmed by a number of surgeons and the patients were considered hopeless from an operative standpoint. Twenty-seven patients were alive and well from three to twelve years after treatment. In nine of Coley's successful cases the sarcoma originated in the bone; in twenty-two in the external soft parts; five were intra-abdominal growths. Of the successful cases in the hands of other surgeons twenty occurred in the bones, nineteen were intra-abdominal growths, and fourteen occurred in the soft parts. Coley has also collected twelve cases of sarcoma of the extremities in which the use of the mixed toxins has rendered amputation unnecessary and the limb was saved. In eight of these cases the sarcoma was of the round-celled variety; in two, of the spindle-celled variety, and in two no microscopic examination was made, but amputation was strongly advised by a prominent surgeon. Eight of these patients were alive and well and free from recurrence from three to six years later.

56. **Function of Prefrontal Lobe.**—Phelps cites 11 cases of cerebral injury, in which the distinctive lesion was found to be frontal, which he believes strengthens the statement made by him in 1894 that the seat of control for the intellectual faculties resides exclusively in the left frontal lobe.

57. **Double Ego.**—The case reported by Gordon is unusual and probably unique as an example of the co-existence of two egos at the same time. The patient is absolutely convinced that he is composed of two beings: number 1 and number 2. The latter is inimical to the first in every respect; suggests wrong acts, interferes with his life, even dictates to him bad language when he talks to others; briefly, number 2 is always for "the bad part of life." It is constantly in him, can not be separated from him, controls his actions, and never leaves him for a moment. The patient has a full knowledge of right and wrong and resists, therefore, the evil influence of number 2. Most of the time he overcomes it, but sometimes number 2 overpowers number 1 and takes full possession of the latter. When number 1 loses the battle the patient enters into a state of unconsciousness. In his judgment number 2 is not a material being; he does not see or hear it, he only feels its presence. The patient is intelligent, industrious, attends to his work correctly, never makes mistakes. He is an engineer, does responsible work, and never fails in doing his duties. His previous history is negative. Gordon classes this as a case of epileptic psychosis.

61. **A Sign of Unilateral Pleuritic Exudate.**—More extended observation has convinced Greene of the correctness of a statement made by him in 1902 that a rhythmic lateral displacement of the heart is a valuable sign of unilateral pleuritic

exudate. Such movement is most marked in medium-sized effusions. The heart approaches the affected side in inspiration and moves outward in expiration. The extent of movement is variable, but often amounts to two inches.

It may be measured by fluoroscopic examination, auscultatory percussion, or in the case of right-sided effusions by simple deep percussion of the free cardiac border, or in some instances by mere inspection of the apex beat. Deep breathing, and especially forced expiration, are essential to the success of the maneuver, and to obtain this morphin must sometimes be administered. Marked rhythmic lateral movement has not been found in pneumonia, tuberculous infiltrations of the lung, malignant disease of the pleura or lung, or in subdiaphragmatic abscess.

62. **Orthostatic Albuminuria.** In this case the symptoms appeared to indicate that the albuminuria began and continued for an indefinite period (more than two years) without the existence of renal inflammation or organic lesions, but that the long continued irritation incident to the disordered condition, giving rise to albuminuria, finally resulted in a nephritis. The absence of pathologic changes in the kidneys for at least the first two years is suggested by the absence of tube casts and the orthostatic form of the albuminuria. Kennedy describes in detail the tests employed and the special experiments made in this case.

63. **Aspiration in Acute Articular Rheumatism.**—It has been Cordeiro's custom to regard and to treat acute rheumatism as a surgical and not as a medical disease. Where there is enough fluid to warrant aspiration it is his routine practice to resort to that procedure. He has noticed that an aspirated joint has never been reattacked during the same or a subsequent illness. In one case the fluid removed was examined. A number of bodies which seemed to be zoöglear masses were observed and these were crowded with extremely minute round bodies which did not stain readily. Cordeiro thinks that if the specific micro-organism of rheumatism is eventually found it will be in the joint fluid.

75 Nature of Cancer. B. H. Wells, New York.

67. **Pseudomyxoma Peritonei.**—The most curious feature of Hirst's case was a complete inversion of the nullipara's vagina and the enormous distension of the pouch thus formed, evidently by the weight of the free pseudo-mucin in the pelvic cavity (about fifteen pounds). There was a semi-collapsed ovarian cyst on the left side with an opening on its posterior superior surface. Two typical daughter cysts, the size of a cherry, were found in the wall of the ileum, one exhibiting a spontaneous perforation of its wall. The collapsed ovarian tumor, the free pseudo-mucin, and the daughter cysts were removed; the uterus, which had prolapsed, was suspended.

68. **Appendicitis Complicating Pregnancy.**—Davis calls attention to the fact that appendicitis is a serious complication of pregnancy, and that adhesions following appendicitis may bring discomfort and danger to a patient who becomes pregnant after she has recovered from disease of the appendix. He also urges for consideration the proposition that in view of the serious consequences which follow appendicitis in pregnant women, the appendix be removed as soon as inflammation attacking that organ can be diagnosticated. Remembering the impossibility of differentiating between inflammation of the right Fallopian tube and ovary and inflammation of the appendix complicating pregnancy, operation should be done without waiting to make a positive diagnosis that the tube is inflamed and that the appendix is not affected, or that the contrary is the case. Six cases in point are reported.

69. **Id.**—Of the 143 cases collected by Myer, 52 occurred during pregnancy and the patients were not operated on; 69 patients were operated on during pregnancy, while 22 cases, both operative and non-operative, occurred during the puerperium. He concludes that pregnancy does not predispose to the development of an appendicitis. If appendicitis has previously existed there is usually a recurrence of the attack during pregnancy, and it runs a more grave course, as evidenced by perforation and abscess in 50 per cent. of the cases. The uterus, adnexa, and uterine contents may readily become infected during pregnancy from an appendiceal abscess. The same surgical principles are applicable when the complication of pregancy exists as in uncomplicated cases. Operation itself does not disturb pregnancy. Every care should be employed not to disturb the pregnant uterus during operation, for the prognosis improves with the amount of time which elapses between the operation and the abortion or labor.

72. **Hernia of Female Pelvic Floor.**—In the case reported by Keiller the whole vagina was everted, the infravaginal cervix uteri and its os, occupying very nearly the center of the tumor. There was no marked erosion of the vaginal mucosa. The hernia contained two-thirds of the contracted bladder, the lower three inches of the uterus, and half of the urethra: the whole vagina, which was completely everted, at least four inches of a much-elongated uterus, the canal, and 5 cm. of rectum, as well as the uterovesical and rectovaginal pouches of peritoneum. The fundus of the uterus was only slightly lower than normal.

76. **Thyroid Metastasis to the Spine.** The patient whose case is reported by Dercum suffered from a goiter for some years. This gradually became so large that the gland was removed. The patient made a good recovery. One year after the operation she began to suffer from pains, sharp and shooting in character, distributed generally throughout the body. These pains were followed by a gradual and progressive wasting of the muscles, with contraction of the extremities. The patient died from edema of the lungs. On opening the spinal canal and removing the cord a tumor was found involving the fourth and fifth cervical vertebræ, pressing on the cord and involving the dura mater. Involving the second lumbar vertebra there was a smaller tumor without adhesions to the dura. The tumor was made up of thyroid tissue. All the sections revealed the aveoli of the thyroid gland, some of them large and some of them medium-sized; others very small. All revealed the typical structure of these aveoli lined by a single row of cubical epithelium and all were filled with the characteristic colloid material. The dura was much thickened and tracts of fibrous tissue could be seen leaving the dura and spreading among the acini. Sections of the cord revealed marked areas of degeneration.

2. **Cancer of Uterus.**—According to Wilson, in one out of every four women who die of malignant disease the uterus is the organ affected. Until Dec. 31, 1905, he had performed 48 vaginal hysterectomies for cancer of the uterus, with one death following the operation. In 40 of these cases, including the fatal one, the operation was done for cervical cancer, so that the immediate mortality of the operation for this variety works out at 2.5 per cent. Reckoning that a term of five years' freedom from recurrence is equivalent to a definite cure of the disease, vaginal hysterectomy leads to the definite cure of one-third of the cases in which it is employed. Wilson states that if the methods of examination at our disposal are given a chance, cancer of the uterus can be diagnosed at its very beginning, and for some time after its commencement the disease can be cured in a large proportion of cases by the aid of surgery. The result of the examinations must be conclusive. When any doubt exists, immediate recourse should be had to the microscopic examination of portions of tissue removed in a systematic manner for the purpose. When the diagnosis is made no delay should be permitted in making the necessary arrangements for operation. The goal to be desired, says Wilson, is diagnosis within three days of the appearance of the first suspicious symptom and operation within a week after the diagnosis. The early symptoms and diagnostic methods are described in detail.

3. **Enucleation of Fibromyoma During Pregnancy.** Stewart reports a case of sessile fibromyoma attached to the left of the fundus uteri which he removed during the sixth month of pregnancy. The patient had no uterine contractions or pain of any moment, although there was a considerable injury to the wall of the uterus, neither were the fetal movements interfered with in any way. Stewart attributes this to the fact that no antiseptics were used.

7. **Atrophy of Phalanges.**—The feature of the case reported by Watson is the unique condition of the patient's hands. The skiagraph shows that the phalanges of both hands have been almost completely absorbed. The fingers, in consequence, have shortened materially, and as the skin surface has not lessened appreciably in extent, a peculiar appearance is presented which Watson calls a telescoping of the digits. The skin of the whole body is somewhat bronzed. The power to move the fingers is lost, and there is considerable limitation of the movement of the wrists. The knees are almost completely fixed in the semiflexed position, and when moved crepitation can be felt. The shape of the joints is not greatly affected and no osteophytes are perceptible. No other joints are involved. This condition followed an attack of acute rheumatism. The patient's general health is not affected.

15 Case of Impotence; a Problem in Diagnosis. C. A. Mercier.

12. **Spirochete of Syphilis.**—Richardson and Hunt believe that the *Spirochæta pallida* is the real specific organism of syphilis, and that the organisms described as *Spirochæta refringens* are polymorphic forms of the same organism, occurring only on the surface where the disease is manifested by its external lesions. They state that they have never yet seen *Spirochæta pallida* in the primary lesion without seeing many more refringens, hence they regard this organism as diagnostic of *Spirochæta pallida*. All their attempts to grow the organism in broth, agar, or blood serum from the blood of patients in which they have previously found the spirochete have failed.

13. **Spirochete of African Tick Fever.** Breinl and Kinghorn have been able to infect with the spirochete of African tick fever in addition to monkeys, a horse, a dog, rabbits, guinea-pigs, rats and mice. The rabbits, rats, mice and some of the guinea-pigs have succumbed to the infection. These experiments lead to the conclusion that the spirochete of the African tick fever differs from the *Spirochæta obermeieri*. While the animal reactions are different from those of the *Spirochæta obermeieri* the pathologic anatomic lesions are the same as those described in human beings who have succumbed to the infection by *Spirochæta obermeieri*.

14. **Spirochete of Syphilis.**—Dudgeon records observations made on twenty cases of primary, secondary, tertiary and congenital syphilis. In every case the surface of the syphilitic lesion was cleansed carefully and then firm pressure was applied for

short space of time until a small quantity of serum was evacuated. The spirochete was found in six cases of primary syphilis, in two of secondary syphilis, in one case of tertiary syphilis and in three cases of congenital syphilis. Dudgeon says that whether or not these changes are dependent on the *Spirochæta pallida* requires the necessary proof before it can be accepted.

18. **Rapid Sterilization of Water.** Ross proposes to sterilize water by using thermit, a powder of blackish gray consistency composed of a mixture of aluminum and either ferric or ferrous oxid. The thermit process produces about 4,400 degrees of heat in thirty seconds. When a small quantity of a reagent such as the peroxid of barium or chromium is placed on the surface of the mixture and a match is applied combustion takes place, together with the liberation of free iron in a molten condition and the production of intense heat. About half the thermit turns into iron and the other half into what is known as slag, which is composed of oxid of aluminum. The method and apparatus employed by Ross for sterilizing the water are described in detail.

20. **Charging Bunsen Batteries for X-Ray Work.**—Beatty washes two or three ounces of crystals of potassium bichromate in water. They are then drained and placed in a glass funnel. Concentrated nitric acid is filtered through these crystals (which after washing and drying can be used again) into porous pots. The containing jar is charged with a saturated solution of ammonium chlorid to the height of the nitric acid. This battery can be kept in the *x*-ray room as there is a total absence of nitrous fumes until the acid is nearly exhausted, which will not be for about two hours after starting. The consumption of zinc is reduced to a minimum and there is no need for the tedious process of amalgamation. The porous pots last much longer and the method is cheaper because there is not the constant outlay for mercury and sulphuric acid. After use the acid should be replaced in loosely stoppered bottles and used again until a total of about one and three-quarters hours of active work has been taken from it, after which it should be thrown away. The ammonium chlorid solution can be kept indefinitely, a few crystals being added occasionally to keep it saturated. The zinc, porous pots and carbon blocks are washed in warm water and allowed to dry. The volts and amperes of the battery remain the same as in the common method.

26. **Subphrenic Abscesses.** Treatment is exclusively surgical, but it must gives indications so that the physician can diagnose a subphrenic abscess early and thus guide the surgeon in his intervention. He also discusses the etiology and ways in which the abscess can develop.

28. **Incomplete Ileus.**—The cases of incomplete, abortive ileus to which Lejars refers may be the result of other intra-abdominal lesions, in which case they may mask the primary trouble; or they may be consecutive to mechanical obstruction of the intestine, or they may be of paralytic or spasmodic origin. He discusses each of these three types, giving the history and citing examples of each. In conclusion, he emphasizes the fact that notwithstanding their apparent harmlessness and their intermissions of subsidence, they frequently prove fatal, as they entail death from stercoremia. This condition should always cause alarm and command the strictest therapeutic vigilance. The absorption of toxins continues and the poisoning persists so long as normal function is not restored, the meteorism entirely subsided, circulation through the intestine freely re-established and peristalsis restored. A precise, detailed diagnosis should not be waited for. It is generally impossible, as there is no specially dilated loop or local resistance such as are observed in complete, classic ileus. On the contrary, there is uniform and total meteorism and a generalized paralytic distention of the bowel. Not every case requires surgical interference, but long waiting and waste of time are as pernicious in the incomplete as in the complete forms of ileus. The danger is not so urgent, but it is none the less continuous and progressive. Morphin and atropin are liable to allow the favorable moment for intervention to pass unobserved. Lavage of the stomach and high injections into the intestines are useful measures, but should not be kept up too long. The best medical measure is electricity. Applied internally to the bowels, it has a peculiarly effectual action in these cases of dragging, abortive ileus, which always are due in some measure to functional disturbance in the intestinal musculature. It is more effective the earlier it is applied, and has proved very successful in his hands. He advises using electricity as a regular routine procedure from the first, not waiting until it is the last resort before operative interference. Paresis of the bowel and the resulting passive distension play a large part in the development of the ileus, and they are liable to yield to electricity. If this fails and if the intestine remains uniformly distended and inert, surgical intervention should follow at once, without waiting for signs of general intoxication. An early laparotomy meets with good conditions if done before the intestine becomes merely an inert canal, incapable of function, and before the stercoremia becomes irremediable.

36. **Ectopic Inguinal Hernia.**—Ebner has found 23 cases of this condition recorded in the literature and reports a case in which he operated. He refers to an article published in this country which mentions 27 cases.

37. **Cure of Fistula into the Kidney.**—In Cohn's case the fistula was a sequel of pyonephrotomy. The patient was a woman of 26, with idiopathic, acute pyelitis at the third month of pregnancy. About ten liters of thin, fetid pus were evacuated from the kidney by the nephrotomy and the pregnancy proceeded normally to delivery, though the kidney fistula persisted. After her recovery, the ureter proving to be impermeable, it was catheterized at intervals of three days for a few times. The fistula was then artificially closed.

39. **Operative Injury of Thoracic Duct.** Unterberger describes a case in which the subclavian vein and thoracic duct were injured during an operation. The latter was ligated and the former sutured. There was slight chylorrhea for a time, but conditions were soon restored to normal. He summarizes 29 cases of operative injury of the thoracic duct, which he has been able to collect from the literature. The oozing out of a milky fluid is the one constant sign of such an injury, he says, and ligature is the best way to treat it.

41. **Internal Hernia.**—Delkeskamp relates the particulars of a case of intra-abdominal hernia in the foramen of Winslow. The patient was a healthy woman of 22. Immediately after a normal childbirth signs of intestinal obstruction developed, the symptoms growing progressively worse until the abdomen was opened seven days after delivery. Conditions were righted without much difficulty, curing all symptoms at once.

42. **Surgery of the Biliary Passages.**—In this long article Stieda reviews the 140 operations on the biliary passages done by Garré during the last decade. He first gives Garré's rules governing surgical intervention, and then summarizes the details of the various groups of cases. In conclusion, he remarks that whether cystotomy or cystectomy is indicated depends on the contents of the gall bladder and the findings in the gall bladder and cystic duct during operations for gallstones. Cystostomy is a compromise operation. It may take the place of cystotomy in case it is desired to retain the gall bladder, but there is no certainty that all the stones have been removed, especially when the concrements are exceptionally numerous. Cystotomy should be done instead of cystectomy, when there are serious technical reasons against the latter or when the general condition of the patient is too bad to allow it. In the cases without stone formation, treatment should be as radical as possible. In case of carcinoma of the gall bladder a palliative cystectomy may be justified under certain circumstances. The rare cases of carcinoma in the region of the common bile duct offer favorable chances for a radical cure.

43. **Treatment of Tuberculous Processes in the Knee.**—Draudt states that out of 252 cases of tuberculous processes in the knee, treated by operative measures at Königsberg, the ultimate outcome has been a success in 92.3 per cent., with only 7.7 per cent. bad results. The limb was not shortened in more than 17 per cent., and only for 1 cm. in over 15 per cent.; for 2 cm. in nearly 24 per cent., and for 3 cm. in more than 16 per cent.

47. **Osteotomy for Genu Valgum in Young Adults.**—Paetzold has been examining recently 47 patients operated on at Königsberg for this condition. He discusses the technic and results, proclaiming that osteotomy with hammer and chisel is the simplest, safest and most rational mode of treatment. It is important to determine whether the femur or the tibia is responsible, and radiography alone will decide the question and show which bone is to be operated on. The ultimate results in his cases demonstrate that the course of the line of division through the joint is the criterion. The aim should be to maintain or to restore a perpendicular line of division (Gelenkspalte). If this line of division slopes from the side above to the middle below, then the curvature is in the femur, and femur-osteotomy will produce a perpendicular line of division. If the line of division is straight to start with, then the tibia is in fault, and tibia-osteotomy alone is able to insure a straight, useful leg. If the curvature affects both of the bones, then the tibia should be operated on in mild cases or both bones in the severer ones. The main point is to keep the line of division perpendicular.

48. **Chronic Progressive Chorea in Youth.**—Lange gives the particulars of a case of Huntington's chorea in a young man whose father had suffered from the same affection. In the latter it commenced soon after a trauma when he was at the age of 48. It began in the youth soon after his two years of military service, during which he had been a constant butt of ridicule and abuse for his awkwardness.

51. **Physical Treatment of Habitual Constipation.**—Tobias describes in detail his technic for application of hydrotherapy, massage and exercises in the treatment of constipation. If due to atony of the bowels, he says, various forms of contrast hydrotherapy and food to stimulate the bowels are required. In the spastic form of constipation, all stimulating measures should be avoided. The best procedure is generally a cold wet pack once a day for thirty minutes, colder each day and the time lengthened to an hour or an hour and a half, concluding with a general douche of cold water under gentle pressure, or the douche may begin warm and be gradually cooled. In case of atony, treatment should be suspended frequently, in case of spastic constipation it should be pushed until benefit is apparent.

52. **Endoscopy of the Urethra.**—Goldschmidt distends the urethra with air or water, after which it is easy to inspect the interior with an apparatus devised on the same principle as the cystoscope. Slight distension is sufficient for the purpose.

53. **Roentgen Treatment of Cutaneous Affections.**—Bruhns expatiates on the great value of Roentgen treatment, the results far surpassing, he thinks, those of other methods, in the treatment especially of dry chronic eczema, chronic circumscribed neurodermitis, local pruritus, verrucous lichen ruber, favus, syeosis, chronic furunculosis of the back of the neck, acne keloid, psoriasis, hyperidrosis, multiple juvenile warts, fungoid mycosis, rhinoscleroma and, to some extent, in the treatment of cancer. In certain other affections, erythematous lupus for instance, good results from Roentgen treatment are sometimes but not so regularly observed. He affirms that the cautious use of the Roentgen rays under the present technics is so free from injurious effects that it should be used without hesitancy even in the milder cases of the above affections.

54. **African Relapsing Fever.**—Koch gives illustrations of the tick which serves as the intermediate host for the spirochete causing relapsing fever in Africa, also of the spirochete, and relates other results of his recent research work in the tropics. Quinin has no effect in relapsing fever, but trypan red seems to display a certain specific action on the trypanosoma and may prove useful in prophylaxis and treatment. The prospects of serum treatment also seem promising as the immunity conferred by one attack is so complete. He has learned the habits of the tick host, finding that it lurks under dry shelters. By pitching the tent in a new place every time on the caravan route, a little distance apart from the long built

shelters under which the ticks were numerous, his party avoided relapsing fever entirely, while 4 of the 5 non-immune persons accompanying them, who slept in the shelters, contracted the disease.

56. **Cutaneous Tuberculosis in Monkeys.**—The experimental research described was conducted in Batavia by individuals who had gone there to study syphilis in monkeys. The tuberculous cutaneous lesions differed completely from the lesions observed in monkeys inoculated with syphilis, resembling in many respects similar lesions in man. The effects of tuberculin treatment are briefly mentioned in this merely preliminary communication.

59. **Classification of Nephritis.**—Vogel commends Senator's classification of cases of nephritis. He distinguishes three forms, the acute, the chronic with and the chronic without induration. He distinguishes further in acute nephritis between the parenchymatous and the diffuse forms. Chronic nephritis with induration can be classified as the form with secondary induration (secondary contracted kidney), the primary indurative (chronic interstitial), and the form with arteriosclerotic induration.

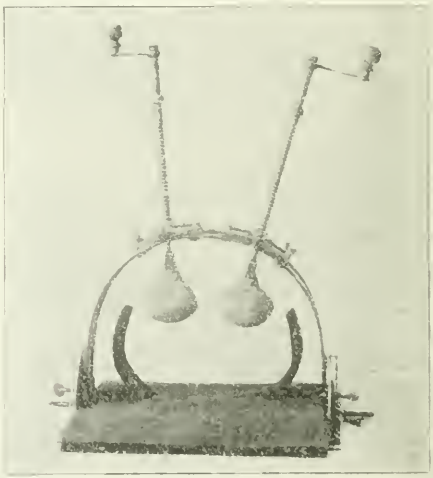
63. **Alimentary Treatment of Bile Fistula.** Gross describes his experience with a patient who had a profuse flow of bile through a fistula resulting from a cholecystostomy. After several weeks of this loss of bile Gross checked it by instituting the "alimentary course of treatment" recommended by Jaboulay and Patel. They found that the flow of bile could be checked and the healing of a fistula promoted by preventing the accumulation of bile in the natural reservoir for it, the gall bladder. This they accomplished by not leaving a long interval between meals. The meals were given at three-hour intervals, the patient being waked to eat twice between midnight and dawn. Gross ordered his patient to eat every three hours, night and day, and in twenty-four hours the amount of bile escaping by the fistula had been reduced by one-half. By the end of the ninth day scarcely any secretion escaped through the fistula, and five days later the flow had entirely ceased and the fistula soon healed over. The immediate success in this case, after weeks of persistence of the flow of bile, was too striking to be merely a coincidence.

64. **Iodin-Benzin Disinfection of the Hands and Skin.** Heusner describes a new method of disinfecting the hands and skin which he believes is destined to banish soap and water from surgical disinfection. He has been using it exclusively for the last six months, and the results have far surpassed those obtained with any other technic, while the saving in time, labor and expense would place this method above all others to date even if the results were only equal instead of being superior. A 1 per thousand solution of iodin in benzin is used in the place of the hot water, alcohol and sublimate disinfection. The cleansing and disinfecting properties of benzin render it an ideal substance for the purpose, he asserts, and the addition of the iodin enhances the disinfecting power. About 300 c.c. of the iodized benzin is poured into a basin, and the hands rubbed with a brush for five minutes. (The patient's skin is scrubbed with a gauze sponge). The hands are then rinsed in a fresh basin of the iodized benzin and wiped dry with gauze sponges, and then rubbed over with 2 per thousand iodized vaselin. When the surface to be disinfected is very sensitive, as around the genitals, 50 per cent. paraffin oil is added to the iodized benzin. It blends perfectly with it and prevents all possible irritation. The only drawback from this method of disinfection is the inflammability of the benzin, but precautions can be taken accordingly. The very slight brownish stain left on the hands soon vanishes. In spite of its high bactericidal power iodin is much less toxic than sublimate. It dissolves better in benzin, paraffin oil and vaselin than in water. The hands can be wiped off from time to time with the iodized benzin during the operation, the small amount left clinging to the hands not affecting the field of operation, which can even be wiped off with the benzin after the suture is finished.

66. **New Separator for Urine.**—Heusner's simple contrivance insures the segregation of the urine from each kidney by pressure from without on the ureters in turn. Both Nicolich and Bier have called attention to the fact that it is possible to interrupt the flow through the ureter by compressing it. The point where compression is most effectual is in the niche at the side of the fifth lumbar vertebra, where the ureter passes over the hill formed by the iliacus muscle. The patient lies on a flat standard (see illustration) which has two curved, adjustable arms to hold the trunk firm. A metal arch above carries two large pads, corresponding to each ureter, mounted on a long slanting stem with a screw thread and crank handle. This allows the pads to be screwed down on the trunk with



great pressure. The center of each pad corresponds to a point two finger-breadths above the umbilicus, their inner edge a finger-breadth from the median line. One pad is screwed down to compress one ureter and the urine secreted during a given time is collected through a catheter in a graduated vessel. The test is then applied to the other kidney. The compression is not removed from the first ureter until the cessation of all flow of urine through the catheter shows that the closure of both ureters is complete. The first pad is then raised. The findings coincide with those of other tests. Heusner has never observed any inconveniences from this test except a transient tenderness and elimination of a little blood when a diseased ureter was compressed too hard and too long.

67. **Garrulitas Vulvae.**—Veit found in one case in which a woman complained of rumbling in the vulva that a gas-generating microbe was present in the vagina. He, therefore, tamponed the vagina with glycerinated gauze which destroyed the microbes and soon freed the patient from the annoyance of which she complained. In 3 other cases he applied the glycerin tampons without taking the trouble to make a bacteriologic examination, and the prompt cure confirmed the correctness of his diagnosis.

68. **Self-Holding Speculum.**—Stoeckel invented four years ago a broad retractor to fit over the lower part of the abdominal incision and to be held in place by a cord and a weight below the level of the table. It is in use in several German clinics, and has proved very satisfactory. He now presents an improved form of this retractor which, as shown in an illustration, has two additional retractors attached, for the sides of the incision, at right angles to the first retractor. They are carried by two crossbars on the handle of the first retractor, and can be spread and fastened at any width desired, the whole thus automatically holding the lower part of the wound wide open.

69. **Shortening Ligament to Correct Displacement of Uterus.**—Sperling isolates the round ligament from its peritoneal envelope, working through a laparotomy incision. He then takes up a loop in the round ligament and another in the peritoneal cover and sutures the two together, leaving the ends of the thread projecting at the top of the loops. These projecting ends from the loops on each side are then tied together in the median line over the anterior surface of the uterus, to which they are then fastened with two or three small stitches. Before opening the abdomen he introduces a return-flow catheter into the uterus and pushes it into a slightly anteflexed position, holding it in this position with a tampon in the vagina. He then proceeds to the laparotomy. After the incision is made an assistant takes hold of the catheter and pushes the fundus of the uterus up into the opening, where it is grasped with dressing forceps. The catheter is then withdrawn. He first described this "fibro-fibrous indirect fixation" in 1904, and time has confirmed its advantages. The technic here advocated is much simpler than that originally proposed, and he regards it as a great improvement. He uses silk exclusively for the sutures, and the entire operation does not require more than twenty or forty minutes. He describes his technic in detail and states that it is applicable to all cases except possibly those in which the retroflexed uterus is certainly absolutely movable, when low vaginal fixation or the Alexander-Adam operation might be preferable. Prolapse with movable retroflexion in women approaching or past the menopause he treats with high vaginofixation.

71. **First Menstruation After Abortion.**—Engländer found that menstruation recurred after four weeks in 64.9 per cent. of 57 women who had aborted in the first four months of pregnancy; at the fifth week in 14 or 24.5 per cent.; at the sixth week in 6 or 10 per cent., and in one case at the third week. It seems evident that the female organism reacts to an uncomplicated early abortion as to an ordinary menstruation. The interval before the following menstruation is lengthened by complications. If the abortion causes hemorrhage for a few days only, and the hemorrhage recurs in four weeks, it may be regarded as an ordinary menstruation. But if bleeding recurs irregularly at short intervals, it may be assumed that it is due to retention of relics of the abortion.

72. **Pubiotomy.**—Henkel writes from Olshausen's clinic to emphasize the importance of the indications for pubiotomy (extramedian symphyseotomy). It is such a simple and easily performed operation that it has been hailed as destined to banish craniotomy, prophylactic version, etc. He protests against this exaggeratedly optimistic opinion. Within the limits of its indications it is proving more and more valuable, but it should not be applied when the true conjugate diameter is 6.75 cm. or less with a flat pelvis, or 7.5 cm. with a generally contracted pelvis. If a woman with abnormally small pelvis has been in labor for a long time and has temperature, he would advise perforation of the living child, even in case of a primipara, rather than sawing the os pubis. An eclamptic primipara with contracted pelvis is not a proper candidate for pubiotomy, generally speaking, on account of the danger of injury of the soft parts. It is not an operation that can be done safely by the general practitioner, as serious complications, severe hemorrhage, etc., have occurred in the hands of even experienced operators. In conclusion, he reports a case which shows the value of the operation in certain conditions. The patient was a multipara with contracted pelvis, in whom the true conjugate diameter was from 7.75 to 8 cm., and whose previous pregnancies had been terminated by perforation of the fetus or abortion. The present pregnancy was complicated with placenta prævia centralis. The woman was safely delivered of a living child without abnormal hemorrhage by sawing the os pubis and then extracting the child by vaginal Cesarean section. The entire intervention, including the suture of the uterus, was completed in thirteen minutes.

Kroemer describes experiences which demonstrate that pubiotomy and artificial premature delivery do not exclude but mutually supplement each other. He discusses the preferable technic, as also Seeligmann, while Jessen reports a case in which the Gigli saw broke during the operation. Unable to complete it, he finished with a symphyseotomy. The hemorrhage when the point of the saw emerged near the labium major was so severe that it could only be controlled by suture. There was no hemorrhage from the symphyseotomy. The pelvis became enlarged to an extent of 6 cm. and the child was easily extracted with forceps without any force being used. As the head emerged the vagina tore at the part corresponding to the pubiotomy wound. The cervix was also lacerated at a corresponding point. The patient was a multipara with conjugate diameter of 8.5 in a flat rachitic pelvis. Recovery proceeded without complications, but the sawed part of the bone was still tender, without callus formation, when all else had healed. The saw broke in another case on record. Kannegiesser has been invariably successful in 18 cases with pubiotomy, and ascribes his success to his subcutaneous technic. He inserts a needle from above and works it down along the posterior surface of the os pubis and out through the skin outside of the labium major. The Gigli saw is then taken up by the needle and, as the latter is drawn back, the saw is drawn into place ready for the sawing. He is careful to pull the skin to one side so that the wound in the skin will not be over that in the bone. He also refrains from touching the skin wound with the fingers, and closes it with collodion as soon as possible.

73. **Leukemic Hemorrhages During Pregnancy.**—A previously healthy primipara of 23 came to the clinic at the seventh month of pregnancy on account of hemorrhages. A physician had been treating her for a week for an abscess in the tonsil. The next day the patient became uneasy and complained of dyspnea. The pulse was 120, soft, and the temperature rose suddenly. The patient succumbed the same evening with symptoms of heart failure. The tonsils were found gangrenous in the center, the spleen was enlarged, and a large quantity of blood was found in the stomach and intestines, while other organs had a hemorrhagic aspect. Microscopic examination revealed the findings characteristic of leukemia. No one had thought of examining the blood during life.

74. **Graphic Records in Gynecology and Prophylaxis of Cancer.**—De Seigneux gives his gynecologic patients a little chart on which to record the particulars in regard to menstruation, pains and leucorrhea. These three factors form the syndrome common to all affections of the internal genitals in women. The syndrome differs only as one or two of the factors are more predominant, but this very predominance is of the utmost importance for differentiation of the affection in question. The little chart is easily kept posted to date and presents a bird's-eye view of the entire gynecologic conditions for the year. It is merely a strip of paper about 2 inches wide

by 15 long, which is marked off in squares somewhat finer than those of a temperature chart. Each row of squares represents a day, and each period of five days is marked off with a heavier perpendicular line, and each month with a still heavier one, the chart being calculated for a year. Under the name of each month are the dates over the heavy lines, 5, 10, 15, 20, 25, 30. Four heavy horizontal lines cross the chart, numbered at each end ½, 1, 2 and 3. The strip folds up into a small compass. The patient is instructed to mark with a pencil the squares corresponding to the date whenever she notes hemorrhage from the genitals, marking the top square on this date along the horizontal line numbered 1, if the hemorrhage is about that of ordinary menstruation, or only on the line numbered ½ if less than this. In case of pain an *x* is placed below the row of squares for the date, underlined if severe, and doubly or trebly underlined if unbearable. When the pain keeps up for several days a line can be drawn to connect the dates with the *x* below. A glance at the chart shows the regularity or irregularity of the menses, the exact duration of each period, the intervals between, the character of the hemorrhage, and of all other atypical hemorrhages with their duration, amount and frequency. Also whether the menstruation is accompanied by pain or not, the days on which the pain appeared, and whether it occurred outside of the menstrual periods, and whether moderate or severe. Periods of leucorrhea are designated by a horizontal line drawn above the chart, over the dates. A calendar chart of this kind enables the physician to detect trouble in its ineipiency and to get on the trail of the cancer of the genital regions when it first starts, and without frightening the patient. Women should be told to present these charts to the family physician or specialist every six months, and after the thirty-fifth or fortieth year, every three months. If medical students were taught to give out such charts to their patients and to train the latter to bring them for inspection at stated intervals, most important progress would be made in the war against uterine cancer. The day is coming, he thinks, when every well-informed woman will have some such chart and will make a point of going to her physician at regular intervals, as she now goes to her dentist, to have him examine her and see whether or not she is in good health.

75. **Radium Treatment of Inoperable Cancer.**—Schücking had only 3 mg. of radium at his disposal. He kept it in two capsules and applied them to an inoperable cancer of the uterus in a woman of 56. The growth filled the entire upper part of the vagina with a hard mass, extending into the pelvis, and was necrotic in parts. He applied the capsules for five weeks, changing their position frequently, holding them in place with gauze. The entire surface of the cancer was destroyed to a depth of several centimeters and around the edges down to sound tissue. The purulent necrosis entirely ceased, and healthy granulations developed, followed by healing over with scar tissue. The result was far better than could possibly have been obtained with the actual cautery or the curette.

77. **Does the Human Organism Require Artificial Stimulants?**—Zunker's short article, presenting affirmative views, is headed with the editorial note that reproduction of the article, even in an abbreviated form, is forbidden.

78. **The Surgical Era in Obstetrics.**—Hofmeier protests against the prevailing tendency to perform operations on the mother for the sake of the child. He remarks that the advocates of these surgical methods in obstetrics would soon think differently if it were possible for them to experience on their own body the consequences of such procedures. These may be required in eclampsia, but he does not recognize placenta prævia nor prolapse of the cord as indications for operative measures.

80. **Recommendation of Sahli Desmoid Test of Stomach Functioning.**—Kaliski joins in the chorus of commendation of this test of some of the gastric functions. (See abstract on page 760). His experiences with patients and controls suggest that the test can be used for finer differentiation than hitherto supposed. When the urine shows the effect of the stain in from four to seven hours, hyperacidity may be assumed. When the stain does not become apparent until after seven and up to twelve hours normal acidity may be assumed. Subacidity or motor insufficiency is indicated when the urine does not become tinted until the second day. He is still testing the desmoid reaction, preceding it with a test meal consisting of 200 gm. soup with the yolk of egg and white bread, 200 gm. calf's brains or sweetbread or fish, 200 gm. cauliflower, 150 gm. mashed potato, and 150 gm. preserved cherries.

83. **Combination of Positive Venous Pulse with Irregular Pulse.**—Hering expresses surprise that greater attention is not paid to the jugular pulse, whose curve is the only objective and certain clinical sign of tricuspid insufficiency. He has sometimes encountered it accompanied by regular heart action, at least occasionally regular. But he has never observed a permanently irregular pulse without the positive venous pulse (Kammervenenpuls—"ventricle-vein pulse"). In anemics, on the other hand, he never encountered the "ventricle-vein" pulse, but rather an "auricle-vein" pulse.

85. **Passive Congestion in Acute Mastoiditis.**—Stenger has been applying Bier's technic for artificial hyperemia in 11 cases of acute suppurative affections of the ear without, and in 7 with complications. His results were so good that he is inclined to believe that the Bier technic is destined to work a revolution in the treatment of acute mastoiditis, and other suppurative ear affections. He makes an incision for mastoiditis about 2 or 3 cm. long, loosens the periosteum and ligates the bleeding vessels. If no fistula is found he makes a small opening into the antrum and works a strip of gauze into this hole. The Bier aspirating jar is placed over the region and suction applied. The jar generally soon fills up with blood, pus and serous fluid and the soft parts swell, but there is no pain. The aspirating jar is held in place with a bandage. It is removed in about three hours unless filled before. It is applied again the next day after a new strip of gauze has been placed in the fistula. The jar is left in place for an hour or two each day until the secretion has entirely ceased and healthy granulations appeared.

87. **The Fate of Foreign Chemical Substances in the Body.**—Lewin discusses the elimination of foreign chemical substances by way of the various emunctories. He calls attention among other points to the intermittent way in which elimination is liable to occur, especially through the glands. This intermittent action is not sufficiently regarded in experimental research. He remarks in conclusion that for thousands of years physicians have striven to aid Nature by promoting the elimination of foreign chemical substances, but modern science is

neglecting this important branch of therapeutics. Better results would be attained, he states, if instead of devoting so much energy to the discovery of specific remedies and antitoxins, more attention were paid to stimulating the eliminating organs to energetic action on a more extensive scale by appropriate, individualized measures to this end.

90. **Passive Congestion for Eye Affections**—Renner applied Bier's constricting band to his own neck to study the effect on his eyes. The increased blood pressure in the veins of the head and consequently of the eyes which he experienced, he believes, might possibly be dangerous for elderly persons, and in his therapeutic application of the measure he excluded all patients over the age of 40. The improvement in 5 cases of parenchymatous keratitis was so striking that he is convinced that this treatment has a future in this affection. The band was applied for six or twelve hours a day for two or four weeks. No favorable results were noticed in eczematous phlyctenular and catarrhal ulcers of the cornea nor in cases of old opacity, but serpiginous ulcers of the cornea yielded more readily to treatment when the passive congestion was added to the usual measures. No inconveniences were observed in any case.

91. **Cytorrhyctes Luis as Agent of Syphilis.**—Siegel gives the particulars of the *Cytorrhyctes luis* in this profusely illustrated article, with the results of experimental inoculation of monkeys. He has modified the staining technic, and announces that an old, "well-ripened" solution of 1 part methylene blue with 2.5 parts borax and 100 parts distilled water gives clear, well-defined views of the parasites after ten minutes' contact with the sections, followed by simple rinsing under a strong stream of water. This stains the red corpuscles well, but leaves the blood plasm colorless, so that the parasites in the latter stand out distinctly. It is not necessary to waste time on sections of the organs, as the parasites show up equally well in blood, which is much more convenient for examination. He found the parasites constantly in the blood at the time of the exanthem in 20 syphilitics examined. The parasites vanished from the blood by the third week of inunction treatment. He succeeded in inoculating rabbits with syphilis, and the results resembled the picture of inherited syphilis in man. Inoculations of 30 white mice all resulted positively, the cytorrhyctes being found in the blood in all. The monkeys inoculated are still living and presenting new manifestations of the disease (eight months), so that the pathologic findings are not yet known. The three special characteristics of the parasite are its shininess, the distinct fission of the nuclei and the lighter colored edge, with flagella formation under favorable circumstances.

93. **Determination of Bacteria in Samples of Blood.**—Müller and Graf describe the simple technic followed at the Kiel Institute to determine the presence of typhoid or other bacteria in samples of blood sent in by physicians in dubious cases of typhoid.

94. **Influence of Erysipelas on Blood Diseases.**—The patient in the case described by Stadler was a woman in an advanced stage of pernicious anemia. She was a housemaid of 29 and the symptoms had attracted attention for about a month, growing rapidly worse until she lay in deep coma for five days, apparently moribund. Erysipelas then developed, spreading from the nostril over the face. By the second day the patient had regained consciousness, and her condition rapidly improved. In less than a week the erysipelas had run its course, but the improvement continued and complete health was rapidly regained. When first seen the reds numbered 792,000, with about 40 nucleated reds; the whites 2,600, and the hemoglobin was reduced to 20 per cent. Eighteen days later, the fourth day of the erysipelas, there were 3,000 of the nucleated reds, a total of 632,000 reds, 6,000 whites and 20 per cent. hemoglobin. Ten days later there were 2,288,000 reds, 60 nucleated reds, 4,000 whites, and 45 per cent. hemoglobin. The latter rose to 80 per cent. in the course of the following month. Stadler reviews a number of cases that have been published in which an intercurrent erysipelas was apparently responsible for the cure of the primary disease. Nyrop has reported a case of severe parenchymatous nephritis of four months' duration, and another of nine months, both taking an abrupt turn for the better with an intercurrent erysipelas.

101. **Treatment of Venereal Bubo.**—Migliorini compares the results in 57 cases under different methods of treatment. The results of evacuation and injection of a solution of nitrate of silver were much superior to those of other technics.

103. **Negri Bodies in Rabies.**—Bongiovanni states that the Negri endocellular bodies were constantly encountered in his researches on animals infected with "street virus." This constant finding has convinced him that these bodies are undoubtedly connected with the disease in some way. At the same time, he adds, he was never able to find the Negri bodies in his experimental work on rabbits infected with "fixed virus," even when the disease ran a very protracted course. This absence of the bodies in infection from fixed virus should be taken into account in experiments with radium or other methods of treating rabies.

105. **Antibodies in Typhoid.**—Rossi has been studying the immunizing antibodies in the serum of 8 typhoid fever patients. He was unable to detect any close connection between the agglutinins and the antibodies.

106. **Pathogenesis of Gastric Ulcer.**—Palermo analyzes the various hypotheses that have been advanced to explain the origin of gastric ulcer, and then proposes a new one. He suggests that when a solution of continuity occurs in a part of the stomach wall which is free from glandular formations, the lining epithelium is unable alone to accomplish the regeneration of the lesion, owing to the lack of glandular elements to co-operate in the work. The corroding action of the gastric juice soon induces ulceration at the point of the lesion.

107. **Myxosarcoma of Suprarenal Capsule.**—The patient was a man of 50, and the tumor weighed about seven pounds when removed. There was no cachexia, mononuclear leucocytosis or other symptom pointing to the suprarenals. The sound suprarenal must have acted vicariously for the affected organ. A tuberculous lesion is more apt to induce the Addisonian syndrome than a tumor. The patient had regained his health satisfactorily when last seen, two months after the two-hour operation.

109. **Adenitis in Appendicitis.**—Berardinone remarks that he has never seen any mention in the literature of the enlargement of one of the inguinal glands which he has found almost constantly accompanying appendicitis.

110. **Remote Results of Craniectomy.**—Vicenzoni reports in detail 7 cases of fracture of the skull treated with craniectomy. He also reviews the experiences of others in this line. In all his cases the results were very good. The wound healed over by growth of new fibrous tissue, and all disturbances vanished in every case but one. He saved the scraps of bone taken out, keeping them in a 2 per cent. aqueous solution of carbolic acid, and was able to replace them in the defect, where they soon healed in place. In one patient he was able in this way to repair the entire breach.

111. **Action of Substances Injected Under the Dura.**—Nardelli experimented with hypnotics and depressant and convulsive drugs, injecting them under the dura in dogs. Among the results observed he mentions that the persisting convulsions were of a type that did not materially affect the respiratory functions. The action of the drug injected under the cerebral dura did not seem to extend to the cerebellum. The dogs seemed to change their character after the injections, becoming aggressive, like the dogs operated on by Goltz, when the intervention was restricted to the anterior hemisphere. When the operation was confined to the posterior hemisphere the dogs became more docile and quiet. Among the drugs Nardelli injected were the salts of calcium. Calcium lactate displayed a lasting depressant action, even in very small doses, which did not interfere with the health of the animal. The facts observed suggest that endodural injections of the calcium salts might prove useful in severe cases of epilepsy.

114. **Attitude in Angina Pectoris.**—Minervini gives illustrations of the attitude assumed by a person during an attack of angina pectoris. He also describes 9 cases, all showing the constancy of this attitude sign, as he calls it. The individual straightens up and bends his head over backward, the arms hang down or one may be placed over the heart region. If standing, he leans over back against a wall, if possible; if seated, he leans his head over the back of the chair; if in bed, the attempt to assume this attitude is plainly apparent, and he also twists his body over to the right. The aim seems to be to get away from the heart. In asthma and similar conditions, on the other hand, the patient leans forward, seeking air, rushing to a door or window if possible.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

A TEXT-BOOK ON PLAGUE. by Dr. Tohiu Ishigami, superintendent Bacteriological Institute, Osaka, Japan, formerly Assistant Bacteriologist to Prof. Kitasato. Revised by Prof. Shibasaburo Kitasato, Tokyo, Japan. Translated, Enlarged and Illustrated with Pathogenic Literature. By D. Macdonald, M.B.C.M. With One Hundred and Fifty two Illustrations and Three Chromo-Lithographic Plates. In two Parts. Cloth. Pp. 180. Price, 22s. 6d. Adelaide: Vardon & Pritchard, Printers, 1905.

DISEASES OF THE EYE. A Handbook of Ophthalmic Practice for Students and Practitioners. By G. E. de Schweinitz, A.M., M.D., Professor of Ophthalmology in the University of Pennsylvania and Ophthalmic Surgeon to the University Hospital. With 313 Illustrations and 6 chromo lithographic plates. Fifth edition, thoroughly revised. Cloth. Pp. 891. Price, $5.00 net. Philadelphia: W. B. Saunders Co., 1906.

A TEXT-BOOK ON THE PRACTICE OF GYNECOLOGY. For Practitioners and Students. By W. E. Ashton, M.D., LL.D., Fellow of the American Gynecological Society, Professor of Gynecology in the Medico-Chirurgical College, etc., with 1,046 New Line Drawings Illustrating the Text. By J. V. Altenederr. Second edition. Cloth. Pp. 1079. Price, $6.50 net. Philadelphia: W. B. Saunders Co., 1906.

MEDICAL DISEASES OF INFANCY AND CHILDHOOD, with Points on the Anatomy, Physiology and Hygiene Peculiar to the Developing Period. By A. C. Cotton, A.M., M.D., Professor of Pediatrics, Rush Medical College, University of Chicago; Attending Physician for Diseases of Children Presbyterian Hospital, etc. Cloth. Pp. 670. Price, $3.50. Philadelphia: J. B. Lippincott Co., 1906.

THE AUTOMOBILE. A Practical Treatise on the Construction of Modern Motor Cars, Steam, Petrol, Electric and Petrol-Electric. Based on Lavergne's "L'Automobile sur Route." Edited by P. N. Hasluck. Special Edition Enlarged, with 804 Illustrations, 8 Full-page Plates and an Addendum. Vols. I and II. Cloth. Pp. 451-864. Price, $7.00 net. Chicago: W. T. Keener & Co.

ESSENTIALS OF GENITO-URINARY AND VENEREAL DISEASES Arranged in the Form of Questions and Answers, Prepared Especially for Students of Medicine. By S. S. Wilcox, M.D., Professor of Genito-Urinary Diseases and Syphilology, Starling Medical College, Columbus, etc. Illustrated. Cloth. Pp. 313. Price, $1.00 net. Philadelphia: W. B. Saunders Co., 1906.

INFECTION, IMMUNITY AND SERUM THERAPY. In Relation to the Infectious Diseases which Attack Man; with Considerations of the Allied Subjects of Agglutination, Precipitation, Hemolysis, etc. By H. T. Ricketts, M.D., Instructor in Pathology, University of Chicago. Cloth. Pp. 600. Illustrated. Price, $2.50. Chicago: American Medical Association Press, 1906.

A TEXT-BOOK OF MATERIA MEDICA, THERAPEUTICS AND PHARMACOLOGY. By G. F. Butler, Ph.G., M.D., Associate Professor of Therapeutics in the College of Physicians and Surgeons, Chicago, etc. Fifth Edition. Thoroughly Revised and Rewritten. By S. E. Jelliffe, M.D., Ph.D. Cloth. Pp. 694. Price, $4.00 net. Philadelphia: W. B. Saunders Co., 1906.

REFERENCE HANDBOOK OF THE DISEASES OF CHILDREN. For Students and Physicians. By Prof. Ferdinand Fruhwald, Chief of Clinic in the Vienna Polyclinic. Edited, with Additions, By T. S. Westcott, M.D. With 176 illustrations. Cloth. Pp. 533. Price, $4.50 net. Philadelphia: W. B. Saunders Co., 1906.

NURSING, Its Principles and Practice, for Hospital and Private Use. By I. H. Robb, Graduate of the New York Training School for Nurses attached to Bellevue Hospital, etc. Third edition, Revised and Enlarged. Illustrated. Cloth. Pp. 565. Price, $1.50. Cleveland: E. C. Koeckert, Publisher, 1906.

A TREATISE ON SURGERY. By G. R. Fowler, M.D., Examiner in Surgery, Board of Medical Examiners of the Regents of the University of the State of New York, etc. 888 Illustrations and 4 Colored Plates, all original. Cloth. Pp. 722. Price, $15.00 net. Philadelphia: W. B. Saunders Co., 1906.

NURSING IN THE ACUTE INFECTIOUS FEVERS. By G. P. Paul, M.D., Assistant Visiting Physician and Adjunct Radiographer to the Samaritan Hospital at Troy, New York. Illustrated. Cloth. Pp. 200. Price, $1.00 net. Philadelphia: W. B. Saunders Co., 1906.

THIRTY-SECOND ANNUAL REPORT of the Board of Trustees and Officers of the Athens State Hospital to the Governor of the State of Ohio for the Fiscal Year Ending Nov. 15, 1905. Paper. Pp. 59. Columbus, Ohio: F. J. Herr, State Printer, 1906.

GYNECOLOGICAL DIAGNOSIS. A Manual for Students and Practitioners. By A. E. Giles, M.D., B.Sc., F.R.C.S., M.R.C.P., with 35 Original Illustrations. Cloth. Pp. 242. Price, $2.50 net. New York: William Wood & Co.

THE OPERATING ROOM AND THE PATIENT. By R. S. Fowler, M.D., surgeon to the German Hospital, Brooklyn, New York. Fully Illustrated. Cloth. Pp. 172. Price, $2.00 net. Philadelphia: W. B. Saunders Co., 1906.

TREATMENT OF GONORRHŒA IN THE MALE. By C. Leedham-Green, M.B., F.R.C.S., Senior Surgeon to Out-Patients, Queen's Hospital, Birmingham, etc. Cloth. Pp. 151. Price, $2.00 net. New York: William Wood & Co.

NEW PATENTS.

Recent patents of interest to physicians and pharmacists:

S12974. Apparatus for sterilizing and cleansing bottles. T. C. Bates, Worcester, Mass.

S13344. Inhaler. Charles S. Birt, Birmingham, England.

S13363. Formaldehyd-generator. Albert E. Dieterich, Washington, D. C.

S13373. Extracting albumin from vegetable substances. F. W. Gaertner, Niagara Falls, N. Y.

S15092. Therapeutic pad. Perlam B. Hardy, Tecumseh, Mich.

S13221. Catamenial sack. W. M. Longstreth, Terra Alta, W. Va.

S12883. Door-operated air pump for atomizers. W. H. Rose, Baltimore, Md.

S13176. Self-adjusting belt for supporting catamenial bandages. Eugene Schick, Fly Mountain, N. Y.

S13256. Pipette. Shin-ichi Takaki. New York.

S13877. Instrument for removing ribs. A. W. Frentzen and J. Shoemaker, Leiden, Netherlands.

S13425. Inhaler and exhaler. J. L. Hill, Jackson, Mich.

S13829. Suppository. Heber Roberts, St. Louis.

S13740. Artificial limb. James F. Rowley, Chicago.

S14594. Preserving and precipitating casein. H. V. Dunham, Belows Falls, Vt.

S14038. Medical applicator. Hans H. Groth, Cincinnati.

S14286. Hospital or invalids' bed. W. J. Harris, Knoxbiro, N. Y.

S14342. Hypodermic syringe. J. W. Horner, Columbus, Ind.

S14484. Inhaling apparatus. Asger Velschow Oakland, Cal.

S14481. Artificial breast. Laura J. Wolfe, Columbus, Ohio.

S15954. Suture bridge. Joseph F. Chambers, St. Louis.

S14720. Emulsifier. Charles D. Monroe, Elgin, Ill.

S14795. Plastic bandage. Henry Myers, Philadelphia.

S14923. Stethoscope. Otto Stadtler, Gehrden, Germany.

S15313. Portable sterilizing apparatus. W. W. Sweeney Los Angeles, Cal.

S14829. Atomizer. W. H. Wood, Cleveland, Ohio.

TWENTIETH CENTURY SURGICAL PROBLEMS*

H. D. NILES, M.D.
SALT LAKE CITY.

No thoughtful student of medicine can fail to be profoundly impressed with the surgical work and achievements of the past century. Revolutionizing discoveries have been made, new principles established, and perfected methods of procedure evolved in such rapid succession that we who stand just within the threshold of the twentieth century, contemplating with wonder and gratitude the triumphs of the past and trying to formulate plans for the future, may feel that there is little remaining for us to do in hastening the progress of surgery.

But if we rightly construe the lessons taught by the work and workers of the past we will not long remain unmindful of the responsibilities and opportunities of the present. For they reveal more or less distinctly the great undeveloped possibilities of surgery that await the solution of problems which we and those who follow us must strive to solve—one by one—until that time shall come when there is no mortality or suffering from surgical diseases.

I trust that on this occasion we may find ourselves in sympathy with the thoughts suggested by these lessons of the past and interested to consider those surgical problems that confront us to-day. For if we are to do our part toward the advancement of surgery we must seek the elements of future success in the study of present failures.

It seems to be the tendency of modern surgery to magnify the importance of manners and methods and at times to forget that all our real advances and most substantial achievements depend now, as always, not on our inventing or blindly imitating new plans of procedure, but on our alertness in diagnosis and our faithful allegiance to sound surgical principles as they are gradually developed from our growing knowledge of anatomy, physiology and pathology.

No one who has kept in touch with our recent experiences in the surgery of the brain, lungs, pancreas, spleen, peritoneum and other organs can escape the conviction that with a clear definite idea of the physiology of these parts the results of our surgical endeavors would be infinitely more satisfactory than we are able to obtain with our present knowledge. In brain surgery our many failures can not be charged to any lack of operative skill, but to our inability to accurately locate the exact pathology early enough to insure its safe removal or correction.

The same may be said of the morbid conditions of the spleen, pancreas and in a degree of the stomach. Until we are better informed by the physiologist of the normal functions of these organs we cannot hope always to differentiate between the normal and the abnormal. The evidence that points to the one and excludes the other can only come to us through concentrated specialized efforts which the average surgeon is technically unfitted to undertake.

We have been taught to believe that the normal mobility of the gastrointestinal canal and the pelvic organs is essential to the healthful performance of their physiologic functions. But we need to know more of the anatomy, physiology and pathology of these parts if we are to take into stricter account the disturbances, distresses and diseases that may follow when they are immobilized by inflammatory lesions, pressure of tumors or surgical operations.

We need to know more of the phagocytic absorption and reparative powers of the peritoneum and other tissues of the body. In obtaining this knowledge clinical observations and the testimony of patients may be helpful, but our most convincing evidence must be based on special experimentation in our laboratories, to be afterward tested in actual practice.

The line that divides surgical diseases from non-surgical is still somewhat vague and indistinct, and one of the most common sources of error in treatment arises from the fact that we are often in doubt as to when and how far we may safely trust to the reparative resources of Nature and under what conditions we should resort to prompt operative interference. We know that many morbid conditions may yield more or less perfectly to Nature's reparative powers, and we have learned of other morbid conditions that can not be modified, corrected or removed except by mechanical means. But until the line that divides the limitations of rational medicine from the boundaries of surgery is more clearly defined the internist and surgeon will often encroach on each other's proper field, and the best endeavors of both will fail to produce the most satisfactory results. To establish this line we must again seek assistance from the physiologist and the pathologist, for we need to know not only more of the functions of the different tissues of the body in health, but we must become better acquainted with the reparative absorptive and phagocytic powers of these tissues in the presence of the various pathologic processes and in the different stages of the disease. Even this is not enough, for theories evolved in the laboratory or dead-house, however suggestive or plausible they may appear, have no established practical value until their real worth is determined when the crucial test is applied at the bedside or on the operating table in the presence of physicians and surgeons competent to pass judgment on their merit.

Those who fairly consider the mortality and suffering that attend those diseases associated with pathologic

* President's Address before the Western Surgical and Gynecological Association, Kansas City, Mo.

processes which we can not as yet positively determine or rationally treat, because of our lack of knowledge of physiology and pathology, must feel that the profession of the twentieth century has a wide field worthy of their highest endeavors. For example, epilepsy, glaucoma and exophthalmic goiter annually ruin the lives and happiness of many human beings, and until the mysterious causes of all these afflictions and the means for correcting them are made known we surely have an ample incentive to continue our studies.

We have learned how to render patients immune from the effects of certain pathogenic microbes and their toxins, but so long as tubercle bacilli, typhoid bacilli and the pyogenic bacteria elude our efforts there will still remain an incomplete chapter in the progress of medicine which only the physiologist and the pathologist can favorably conclude.

We hear much of preventive medicine and little of preventive surgery. The triumphs of the former are heralded by the internist with justifiable pride. The failures of the latter the surgeon has frequent occasion to confess with humiliation. Every too-late operation is a painful reminder of our sacred duty to prevent the possible and probable progress of a pathologic process by every means in our power, even to the employment of preventive surgery, for here preventive surgery is timely surgery.

Thus far our success in surgery has been measured largely by our ability to cope with advanced disease, after it has become an immediate menace to life and health. But the time can not be far distant when the importance of recognizing the antecedent pathology of cancer, ulcer, surgical kidney, pus-tubes, prostatitis and many other grave lesions will be impressed on the profession, and the public will be educated to choose "preventive" rather than "last resort" surgery.

Non-malignant inflammatory lesions and incomplete obstructive twists of the sigmoid are the causes of much suffering and not a few deaths, that we may hope to avert when we learns to regard surgical pathology here, as in other parts of the alimentary canal. This is a comparatively new and certainly worthy field of study that invites the attention of the surgeons of to-day.

Our present failures to interrupt the progress of inflammatory lesions, while they are yet safely accessible and before they reach dangerous stages or regions, are responsible for a large proportion of the suffering and mortality of our operative procedures. Every case of appendiceal abscess, pyosalpinx, cancer of the stomach, malignant disease of the sigmoid, mastoid disease or surgical kidney should bring to the mind of the medical attendant as well as the operator a mental picture of the antecedent pathology and serve to strengthen their determination to seek out means for recognizing it early enough to exclude the dangers of a late operation on a resultant pathology.

Every poor unfortunate creature we meet on the street who is crippled or deformed by the ravages of tubercular disease is a mute but pathetic appeal to our profession to advance preventive surgery until mankind is free from this most prolific source of misery and unhappiness.

I have briefly referred to a few of the many problems that in the progress of surgery confront us to-day awaiting solution.

As we take these problems into thoughtful account and appreciate the causes of our present failures we are forced to conclude that to-day and always our great advances in surgery can only come from a clearer comprehension of those laws of Nature that govern human life and vital processes in health and disease, and that the anatomist, the physiologist and the pathologist are destined to remain the most potential factors in progressive surgery.

But it is equally true that so long as a large proportion of these scientific workers are permitted to limit their best endeavors to the teaching of students and the filling of subordinate positions in hospitals they can never fully meet their highest obligations to surgery. And so long as physicians and surgeons are compelled to rely on their own college acquired knowledge of anatomy, physiology and pathology we can not reasonably expect to make much progress in original scientific research or much headway in solving the problems that confront us to-day.

The very nature of these problems and their vital importance demand that we surgeons should press into more active and general service and bring into more intimate association the anatomist, physiologist, pathologist and internist.

This is distinctly an age when combinations of special forces rule the world, control all its enterprises and govern the destiny of every undertaking of any magnitude. In surgery there is a greater need than ever before for an exhibition of this same progressive spirit of the times. We must combine our forces if we are to meet the necessities of the new existing conditions. Single handed no surgeon can hope to accomplish much in the face of the peculiar conditions of to-day. At present the various laboratory workers are undoubtedly inclined to attach too much importance to theoretical conclusions which may not be applied to advantage in practice, while the operator is unquestionably prone to have an exaggerated idea of the lessons taught in the operating room. The internist, on the other hand, is often placed in the embarrassing position of accepting the teachings of both, while at the same time he strives to please his patients and preserve his own self-respect.

All these workers should be brought into the closest possible relations, and in practice as well as theory they should learn to regard pathologic processes and their rational treatment from the same point of view. The surgeon and the internist certainly have need to harmonize and perfect their ideas of pathology and treatment by a more intimate association in their daily work than is usual or often possible under existing conditions. In this way the internist would often see and become familiar with a pathology as revealed on the operating table, which in his consulting room or library he could only picture imperfectly, and might be tempted to treat symptomatically.

The surgeon should find time and opportunity to study at the bedside the earlier symptoms of surgical diseases when the indications are most obscure. He needs to know more of the trials, difficulties and doubts of his colleague, if he is to be kindly in his judgment, and he has abundant reason to familiarize himself with the symptoms of pathology in every stage if he is to decide questions pertaining to "rational" and "timely treatment."

The laboratory worker should no longer rely exclusively on the microscope to furnish him with the best and broadest views, or trust alone to scientific experimentation to give him the most practical conception of disease. He, too, needs to often see and study morbid conditions in life and to know well the symptoms, suffering and danger they produce if he is to impart the most practical knowledge to students or become the most

helpful associate of surgeons. For it is not in our laboratories, but in our consulting rooms, at the sick bed and at the operating table that we have the greatest need to know more of pathology and are inspired with the strongest determination to study all those factors that have to do with the deviation and restoration of health.

If we are ever to solve the problems that baffle our endeavors to-day and place surgery on a much higher plane than it now occupies, our scientific workers must become more practical, our practical workers must become more scientific, and our physicians and surgeons must become more nearly united in their ideas of pathology and treatment. And this can only be accomplished by an organized movement tending to bring all workers into closer touch and sympathy with each other.

Such a combination of forces as I have outlined can be organized and made effective in every community capable of supporting a hospital and a medical society. And in this cause our hospitals should be willing and desirous to meet our needs, for in doing so they would in time fulfill their highest mission of usefulness by developing a great system of scientific institutions distributed throughout the world, where not only the sick and afflicted would be kindly and skilfully attended, but where earnest experienced men of mature judgment might meet and study and work harmoniously together in their efforts to solve those problems that have to do with the prevention of disease, the saving of life and the mitigation of suffering.

But if we are to secure the full benefits to be derived from our hospitals and from our colleagues, the internist and the laboratory worker we must do our part. The medical profession must either own their own hospitals or they must prove to hospital governments or hospital benefactors that our cause is a worthy one and that with their help we can and will make our hospitals a greater blessing to mankind than is possible under the present system.

We must learn to realize that every laborer is worthy of his hire, and that until the recompense of the laboratory worker is proportionate to that of the physician and surgeon the laboratory will not attract its proportion of good men.

We must see to it that this work and these opportunities be not restricted to the favored few who happen to be on hospital staffs. We need the united support and help of every member of the whole profession, and every reputable graduate in medicine should be invited, encouraged and urged to begin early their postgraduate studies and researches, and to continue them through their active life by participating in the educational and other advantages to be offered by those institutions.

These and many other questions which arise in this connection can and should be discussed in detail among ourselves, in our societies and in our medical journals, but we may be assured that in due time they can all be settled satisfactorily if we approach them in a spirit of fairness and good faith.

The workers of the past century had their duties, responsibilities and opportunities; we have ours. They had their means and methods for advancing surgery; we must formulate ours to meet existing conditions. They overcame their difficulties and achieved their triumphs; we will strive to do likewise: and when this association shall hold its regular annual meeting a hundred years hence, and a new and brighter chapter in the history of surgery is read, let us hope that chapter may not be made up of a long list of brilliant operative procedures made possible by easily-acquired methods, but rather let us trust it may record the coming of many substantial blessings and benefits to mankind through the earnest systematized and united efforts of the men of the twentieth century.

Original Articles

INFANTILE SCORBUTUS.

AN ANALYSIS OF FIFTY CASES, INCLUDING TREATMENT.

JOHN LOVETT MORSE, A.M., M.D.

Instructor in Pediatrics, Harvard Medical School; Assistant Physician at the Children's Hospital and at the Infants' Hospital; Visiting Physician at the Floating Hospital.

BOSTON.

Infantile scorbutus developed in seven cases under my direct observation. Six cases were brought to my office, nine were seen at the Infants' or Children's Hospitals, and twenty-eight in consultation with other physicians. The true nature of the illness had been recognized in but five of those seen in consultation.

The following diagnoses had been made previously in these cases and in those seen at the office and hospitals: Acute nephritis, 5; tumor of bladder, 1; excess of uric acid with consequent staining, 2; arsenical poisoning with inflammation of the kidneys, 1; rickets, 2; spinal or Pott's disease, 6; hip disease, 1; periosteitis, 1; rheumatism, 6; gout, 1; nervousness, 1; infantile paralysis, 1; syphilis of cord, 1; difficult dentition, 5, in four of which the gums had been lanced; strain, 1; injury, 1; tuberculosis, 1; gumma of eye, 1. In two other cases the physicians stated that they had no idea what was the trouble.

It is evident that the errors in diagnosis depended somewhat on the prominence of individual symptoms. It is probable, moreover, that other diagnoses had also been made which were not noted in the records. In speaking of errors in diagnosis in connection with infantile scurvy it is only fair to state that it is also possible to mistake other conditions for this disease. I have mistaken congenital syphilis and hematuria from lead poisoning for scurvy and have known septic arthritis to be mistaken for it.

Sex and Age.—The patients were nearly evenly divided between the two sexes, twenty-three being males and twenty-seven females. The age at the onset of the symptoms varied between three and nineteen months. Thirty-three or 67 per cent. of forty-nine cases with complete data were between six and ten months. Seven were under six months and nine over ten months.

The duration of the symptoms before the patients were seen varied between two days and ten months, in all but six being between one week and three months. The age of the patients when first seen varied between four and twenty-one months, thirty-seven, or 74 per cent., of fifty cases being between seven and twelve months. Four were under seven months and nine over twelve months.

Etiology.—Table 1 shows the foods which were being taken at the time when the symptoms of scurvy developed.

TABLE 1.—Foods During the Use of Which Scurvy Developed.

Proprietary Foods:	
With water	8
With milk:	
Irrational mixtures, boiled	9
Irrational mixtures, pasteurized	2
Rational mixtures, unheated, pasteurized	2
Rational mixtures, heated and peptonized	1
Rational mixtures, unheated	8

Milk and Water Mixtures: Irrational:	
Peptonized and boiled	1
Unheated	1
Heat unknown	1
Laboratory Mixtures:	
Too weak:	
Peptonized and pasteurized	1
Pasteurized	1
Rational, pasteurized	4
Home Modifications:	
Irrational, same for four months pasteurized	1
Too weak, same for months, unheated	1
Unheated	2
Rational, boiled	2
Peptonized and pasteurized	2
Barley water, peptonized and pasteurized	2
Barley water, pasteurized	1
Oatmeal water, pasteurized	1
Same for five months, pasteurized	1
Pasteurized	1
Pasteurized and beef juice	1
Barley water, unheated	1
General Diet at 13 months, but with no fruit or vegetables	1

From the point of view of modern ideas of reasonable infant feeding the food was irrational in nineteen of the cases taking proprietary foods, in four of those taking milk mixtures, and in the case of the infant on a general diet, making a total of twenty-four. Milk was used in the preparation of the food in forty-one cases, while no milk was used in eight cases. One baby was on a general diet. In the forty-one cases in which milk was used in the preparation of the food the mixture was boiled in twelve, pasteurized in nineteen and unheated in nine, while in one case there was no data as to whether or not heat was used. The food was also peptonized in four of the pasteurized and in one of the unpasteurized mixtures. The mixture was manifestly too weak in five cases, and the same mixture was continued for months in two cases. The food was often unsuitable in several ways in a single case. In one case only was a rational unpasteurized mixture being taken, and that was prepared with barley water instead of with water. Bread and crackers in two, egg in one, beef juice in one and a general diet in another case failed to prevent the development of the disease.

Analysis of the foods taken by these cases justifies the conclusions of the committee of the American Pediatric Society that "the development of the disease followed in each case the . . . employment of some diet unsuited to the individual child" and that "the farther a food is removed in character from the natural food of a child the more likely its use is to be followed by the development of scurvy." Analysis of this table also seems to show that the absence of "freshness" and the heating of the food are very important elements in the production of scurvy.

The digestion was good in twenty-three and feeble in twenty-seven of these cases, apparently showing that the scurvy was not due to disturbance of digestion and that foods may cause scurvy without causing disturbances of digestion.

The onset of the scurvy was immediately preceded by measles in one case, influenza in three, bronchopneumonia in one, and infectious diarrhea in four. It is probable, however, that these diseases had no direct influence on the development of the scurvy unless possibly by weakening the general resistance.

There were signs of rickets in the osseous system in all but nine of these cases. They were slight in twenty-six, moderate in eleven, and marked in four. There was, however, no evident relation between the severity of the rickets and that of the scurvy. It seems rational to conclude, therefore, that the rickets had no influence on the development of the scurvy and that if there was any connection between them it was merely that they were both the results of a common cause.

The only evident cause for the development of the scurvy in these cases, therefore, is found in the food. No further conclusions as to the etiologic connection of the food and the disease than those already stated are, however, justified.

Symptoms.—It seems best to analyze the private cases separately as to the order of the development of the symptoms, as it is possible to get from them a better idea of the onset and course of the disease in its early stages than from those seen after its more complete development. In all of these cases a gradual loss of color preceded for weeks or months any other symptom. This loss of color was often associated with loss of appetite. Tenderness of the back was the next symptom noticed in two, tenderness on handling in three, and hematuria in two cases. The next symptoms which developed were swelling of the gums in one, tenderness on handling in two, and paresis of an extremity in two. The time between the onset of the second and third symptoms varied between one week and two months.

Table 2 shows the comparative frequency of the various symptoms and also the relative order of their appearance.

TABLE 2.—Order of Appearance of Symptoms.

	First.	Second.	Third.	Fourth.	Fifth.	Sixth.	Total.	Private Cases Added.
Tenderness	21	12	2	1	..	..	36	43
Inflamed gums	10	3	2	..	1	1	17	18
Hematuria	7	1	..	1	..	1	10	12
Paresis	4	9	5	2	..	..	20	22
Pallor	2	2	..	..	..	..	4	11
Swelling	1	2	5	2	3	..	13	13
Ecchymoses	1	..	3	..	2	..	6	6
Hemorrhage: Bowels	..	..	1	1	..	1	3	3
Mouth	..	..	..	1	..	..	1	1
Orbit	..	..	..	1	..	..	1	1

It is noticeable how seldom pallor was noted in these cases. That it was overlooked, however, is shown by the fact that on examination pallor of various degrees was found in thirty-six, or 75 per cent., of forty-eight cases. In five others the color was noted as fair, while in only seven was it good. Examinations of the blood were made in but two cases. They both showed a marked diminution in the hemoglobin and in the number of red corpuscles with a slight leucocytosis, the relative proportions of the white corpuscles being normal. Tenderness was the symptom most commonly noted, while paresis of the extremities comes next, closely followed by inflammation of the gums, swelling of the extremities and hematuria. Tenderness on handling was the first symptom noted in nearly one-half of the cases, swollen or purple gums in about one-quarter, and hematuria in nearly as many.

Fever was never mentioned among the symptoms, but in several of the hospital cases the temperature was slightly elevated, running in one case as high as 103° F. No other causes were found for these temperatures, which diminished steadily with the cure of the scurvy. It is reasonable to conclude, therefore, that the fever was due to the scurvy and not to complications.

There was very great variety in the suddenness of the onset and in the severity of the early symptoms; for example, the gums were swollen for six months in one case, and there was hematuria in another for three months before the appearance of tenderness, while in still another there was tenderness in the legs for two months before there was any swelling. In one case there was a history of a fall, with immediate loss of power and pain in one leg; in another, marked swelling of the leg developed in forty-eight hours after a fall; while in still another a fall on the floor was followed by immediate loss of power

in the leg, this in turn being followed in five weeks by inflammation of the gums.

Physical Signs.—Careful analysis of the physical signs found in these cases shows that there must have been many errors in observation regarding the frequency and order of development of the symptoms. This has already been shown in the note regarding pallor.

Twenty-nine infants had teeth and nineteen had no teeth. The gums were normal in six and abnormal in twenty-three of the cases with teeth, while they were normal in seventeen and abnormal in only two of those without teeth. The gums were normal, therefore, in twenty-three and abnormal in twenty-five cases. When there were both upper and lower teeth the upper were involved alone in eight cases, while the lower were never involved alone. The gums were involved about all the teeth in fifteen and about part of the teeth in eight cases. Other portions of the gums besides those about the teeth were involved in eight cases.

One leg only was affected in nine cases; in seven of these it was the right and in two the left leg. Both legs were affected in twenty-five cases. The arms and legs were both affected in eleven cases, but the arms were never affected alone. Pain on motion of the extremities was noted in forty-three cases; that is, in practically all those which were not cases of simple hematuria. There was tenderness on handling in thirty-seven cases. Limitation of passive motions was noted in but ten and paresis in but eight cases. These latter figures are undoubtedly too low because of the failure to record all the observations. Swelling limited to the diaphyses of the bones was present in twenty-seven cases. In one the sternal ends of the clavicles were affected. The arms were affected in ten cases, the swelling being in the upper arm in four and in the lower in six. The legs were affected in thirty-four, the thigh being involved in seventeen, the lower leg in fifteen and the feet in two cases. The swelling sometimes involved the whole, but was more often limited to a portion of the diaphysis. The upper portion of the humerus, the lower of the bones of the forearm and of the femur, and the lower portion or the whole shaft of the tibia were most often involved. The swelling in the feet was always on the back.

The position of the legs was very characteristic in twenty-seven cases, although the completely typical position was not always present. The tendency was always to hold the lower extremity rigidly with the thigh flexed on the abdomen, the leg flexed on the thigh, the foot extended and the whole leg rotated outward.

Pain on motion of the back was noted in five cases. This proportion is undoubtedly too low, partly because of failure to record the point and partly because of the difficulty of determining the presence or absence of pain in the back when there is pain in the legs.

Ecchymoses were present in eleven cases. They were on the legs and feet in five, the eyelid in three, the face in two, the body, chest and abdomen in one each, and all over the body in one. There was also a hemorrhage into the orbit, with consequent protrusion of the eye in one case.

There was edema in eleven cases. It was in the eyelids in two, in the legs and feet in five and in the feet alone in five. This was a true edema of the soft tissues and not an inflammation or hemorrhage under the periosteum.

Cases of Hematuria.—The cases of hematuria form such a characteristic and peculiar group that they seem worthy of separate consideration. The urine was normal in twenty and abnormal in fifteen cases. In three of these, however, it was merely noted that the urine stained the diapers red or brown. There were no data as to the urine in fifteen cases. Barring pallor in two of the private cases, hematuria was the first symptom noted in eight of the proved cases of hematuria. It was the only symptom of scurvy in two and in the rest preceded the other symptoms by one-half, one-half, three and one-half, four, five and one-half and nine weeks respectively. The urine was usually red, but was sometimes brown. The blood was both normal and abnormal, but usually normal. It was often present in large amounts. The amount of albumin corresponded to the amount of blood, which was often large enough to give an alkaline reaction. Hyalin and fine granular casts and an excess of cells were found occasionally; brown granular and blood casts were also found in one instance. In one of my own cases the true nature of the hematuria was not recognized until tenderness developed, while in the other it was recognized at once. In the other cases the diagnoses, based on the hematuria, were acute nephritis in five, tumor of the bladder in one, uric acid staining in one, and arsenical poisoning in one. The response to treatment was rapid and the urine became normal in all. There was marked improvement in the hematuria in one day in two cases. The urine was clear in five days in two, in ten days in two and in fourteen days in two cases. There were no accurate data as to the duration in the other six cases.

It is evident from these figures that the earliest symptom of scurvy is, as a rule, loss of color, which is often associated with loss of appetite. The first symptom to attract attention and to justify the diagnosis of scurvy is most often tenderness or pain in the legs or back on handling. Swollen and purple gums or hematuria may, however, precede the tenderness and pain. Tenderness and pain on motion of the extremities almost always develop sooner or later, and in about half of the cases are accompanied by swelling about the diaphyses. The legs are affected about three times as frequently as the arms. The gums are affected in about half of the cases; almost always when there are teeth, very rarely when there are no teeth. Hemorrhages, except under the periosteum, are comparatively uncommon.

The order in which the symptoms develop and the intervals at which they make their appearance vary materially. The onset may be very sudden or very insidious. Mild symptoms may persist in some cases for weeks and even months before the development of others, while in other cases several symptoms may appear together or in rapid succession, the typical picture of the disease being developed in a few days.

Treatment.—Recovery from the scurvy occurred in all cases, although a few died later from coincident diseases.

The food was not changed in fifteen cases. The foods are given in Table 3.

TABLE 3.

Laboratory milk, pasteurized	2
Home modification, unpasteurized	2
Home modification, pasteurized	6
Proprietary foods with fresh milk	2
Proprietary foods with heated milk	2
Proprietary foods with water	1

In all the other cases the food was changed, the attempt being made in every case to give not only a more rational food, but one more suitable for the individual baby. Proprietary food mixtures were changed to milk mixtures and milk mixtures to better milk mixtures. Sterilization was always stopped and pasteurization was stopped if the milk supply and time of year permitted. Peptonization was stopped in every case. In fact, the

food was made rational as to its chemical composition, and everything tending to destroy "freshness" as far as was possible omitted.

One patient was given lemon juice. All the others were given orange juice, except two that were given beef juice. Eight others also took beef juice in addition to the orange juice. One who was given beef juice alone took two tablespoonfuls daily while the milk was changed. The amount given in the other case is not known and the milk was not changed. Both recovered rapidly. As has already been mentioned, scurvy developed in one who was taking one ounce of beef juice daily.

The amount of orange juice given varied considerably. Seven patients took one tablespoonful daily; twenty, two tablespoonfuls; and one, four tablespoonfuls. Four took the juice of half an orange, and seven the juice of a whole orange daily. The amount is not stated in seven. In one case in which there was no result from ten drops of lemon juice given three times daily for a week, recovery was very rapid on the juice of half an orange daily. In another case there was no improvement noted in two days while taking one tablespoonful of orange juice daily, but when the amount was increased improvement was very rapid. It seems safe, therefore, to conclude that at least one tablespoonful of orange juice is necessary daily, and that two tablespoonfuls, or the juice of half an orange, is amply sufficient to bring about a rapid cure.

Pain and tenderness were usually the first symptoms to yield to treatment and were soon followed by the return of power in the extremities. Improvement in the condition of the gums usually began later and progressed more slowly. The disappearance of the swelling was, as would be expected, always slow. Marked improvement in the swelling, even if it was extreme, was always noticeable in a week. The protrusion of the eye was gone in six days.

An analysis of the results of the treatment in these cases shows that the mildest cases were well in two days, and that many cases were entirely well in five days. Almost all showed marked improvement in three or four days. Pain and tenderness were always gone in one week, while the gums were rarely normal before one or two weeks. Most cases were well, except for the remains of swelling and hemorrhages, in two weeks, while recovery was always complete in three weeks.

How soon the improvement may begin and how rapid it may be is shown by the following extracts from letters written by the parents of some of these patients: "Immediate improvement;" "better in twenty-four hours, kicking in forty-eight hours;" "different baby in a week;" "progress simply marvelous;" "immediate response to treatment;" "improvement before taking the juice of a whole orange."

70 Bay State Road.

FEVER IN THE NEWBORN.

A CONSIDERATION OF THE FEBRILE TEMPERATURES OBSERVED DURING THE FIRST DAYS OF LIFE, WITH REPORT OF AN EPIDEMIC INFECTION OF THE RESPIRATORY TRACT IN THE NEWBORN.

WILLIAM J. BUTLER, M.D.
CHICAGO.

An interesting phase of the first days of infant life is the many deviations from the normal temperature that occur and which are so frequently overlooked unless thermometry is regularly practiced.

It is not improbable, however, that this practice, the importance of which can not be too strongly urged, is seldom pursued to any extent even in maternity wards, unless an infant presents some marked evidence of illness; whereas the thermometer only in many cases renders it possible to determine early the presence of disease which by other methods of examination might be overlooked.

That this latter frequently occurs, and that an apparent want of acquaintance with diseases of the newborn exists, is well illustrated in the vital statistics by the meaningless terms ascribed as causes of death, to-wit, icterus, convulsions, etc.

The temperature of the newborn immediately after birth is somewhat higher than that of the mother, the temperature of the latter being from 0.2 F. (0.1 C.), according to Wurster,[1] to 0.9 F. (0.5 C), according to Davy,[2] lower than that of the child. In full term babes the rectal temperature is found to average, according to Barensprung,[3] 100 F. (37.81 C.); Lepine,[4] 99.8 F. (37.7 C.); Andral,[5] 100.2 F. (37.9 C.); Hennig,[6] 100.2 F. (37.9 C.). In consequence of the cooling of the surface incident to exposure and the first bath, where employed, there is a drop in the temperature in the course of an hour or two of from 1.76 F. (.95 C.), according to Schäfer,[7] to 3.3 F. (1.87 C.), according to Sommer.[8] Eross explains this apparently wide difference by assuming that some observers take the temperature immediately following the bath and thus do not note the subsequent decline. It gradually rises after several hours, and from twelve to thirty-six hours it reaches an average of 99.8 F. (37.67 C.), according to Eross;[9] 99.5 F. (37.5 C.), according to Jurgensen;[10] 99.2 F. (37.35 C.), according to Fehling.[11]

Forester[12] called attention to a second decline on the fourth day, at which time the temperature averages 98.8 F. (37.1 C.). Following this there is a second rise, first noted by Barensprung,[3] which reaches its maximum on the eighth day, averaging 99.2 F. (37.4 C.).

Feis[13] believes that the fall in temperature between the third and fifth days is due to hunger of the infant. He thinks there exists a direct relation between the decline on the fourth day and elevation on the eighth day and the increase in the quantity of nourishment taken, which was first suggested by Eross,[9] and to the gain in weight, which latter point had been previously made by Barensprung.[3]

Raudnitz,[14] however, was disinclined to accept the explanations offered for the double rise and fall of temperature in the first week, considering them conjectural, at the same time suggesting the less plausible theory that the second decline and rise of temperature occurring between the fourth and eighth days was a slow reflected compensatory wave following the first marked decline after birth. Lepine[4] observed a somewhat higher tem-

perature in children in whom the initial loss of weight ceased early.

A number of writers in their careful studies of the temperature in the newborn confirmed the observations of Forester[12] and Barensprung.[3] Eross[9] called special attention to the limits of normal temperature on the fourth and fifth days, and stated that from his observations a rise to 100 F. (37.8 C.) or 100.2 F. (37.9 C.) occurred during this time only under pathologic conditions.

Abnormal elevations of temperature are not uncommon in the first days of life, in some instances lasting several hours only, in many a few days, and in others persisting for two or three weeks or a longer time. The exact cause of them, where no gross pathologic lesion presents itself clinically, may at times be difficult to determine. Their frequently transient character and early disappearance after the establishment of lactation led Holt[15] and McLean to style some of them inanition temperatures. To say the least, this seems paradoxical and untenable in the light of the above observations, especially when we consider that starvation in infancy is invariably associated with subnormal temperature unless an infection is present.

Demme[16] observed that within the first half hour after nursing the rectal temperature dropped a few tenths of a degree and in the next sixty to ninety minutes it rose from 0.3 F. (0.2 C.) to 1.4 F. (0.8 C.) higher than before nursing, and in the next 30 to 60 minutes it declined to the temperature noted before nursing. The disappearance of febrile temperatures coincident with the establishment of free lactation probably depends on the rapid elimination of absorbed toxic products (possibly from the cord or from abraded or inflamed surfaces) incident to the increased quantities of fluids taken, or more probably on the action of antitoxins derived from the milk.

Some observers are inclined to associate many of the pyrexias with uric acid irritation of the kidneys or anuria. In the majority of the newborn uric-acid infarcts are formed in the uriniferous tubules in the first ten days. Flensburg[17] believes they are formed by a deposit of urate of ammonium around an albuminous exudate in the tubules. Schreiber[18] considers the exfoliated epithelium of the tubules analogous to the desquamation of the skin the basis of the casts. According to Horbaczewski, the excessive excretion of uric acid is due to the great increase in metabolism and destruction of leucocytes in the newborn. These infarcts are washed out by the pressure and solvent action of urine secreted higher up in the tubules. The condition is so common to the first days of life that it is considered physiologic. When the urine is diminished in quantity and concentrated as the result of a febrile disturbance or existing diarrhea it is evident that there might be a temporary or permanent suppression of urine, which must be regarded as secondary to and not the cause of pyrexia, as anuria ordinarily is not accompanied by a rise in temperature.

While elevations of temperature in infants may be produced by apparently slight causes, it was noted by Epstein[19] that in many instances newborn, who during life presented no elevation of temperature or even showed apyrexia, succumbed to extensive inflammation of serous membranes, an analogous condition to which is occasionally found in the afebrile and virulent septic peritonitis of the adult. This would seem to suggest that the infant reacts not unlike adults to infection of similar tissues, so far as temperature is concerned. Apyretic infections, however, are the exception, as they are almost invariably associated with fever.

In 1892, in his clinical report of the diseased conditions found in a thousand newborn infants in the Gebär Anstalt in Budapest, Eross[9] stated that elevation of temperature was present in 431 cases. In 51 per cent. of these he referred the temperature to putrefactive changes in the cord, or inflammatory processes in the navel. In many of the latter the changes remained localized; in others they gave rise to general sepsis. In 25 per cent. of the cases febrile temperature was associated with dyspepsia or catarrhal enteritis. In twenty-one cases the cause of pyrexia was referable to inflammation of serous membranes or the lungs. In seventy-nine cases the source of the temperature was not determinable, but he believed it was due to foci of infection he could not locate.

While the above observations showed an unusual large percentage of infants developing temperature in the first days of life, it is quite in keeping with the earlier observations of Epstein,[19] who, in 1885, stated that in the Prague Gebär Anstalt 30 per cent. of newborn died of sepsis before the introduction of antisepsis, and that thereafter it was reduced to 5 per cent.

In 1895 Eross[9] wrote that since the employment of rigid prophylactic measures the febrile conditions in the newborn had been reduced from 45 per cent. to 11.38 per cent. No stronger evidence than these latter statements could be deduced to show that febril temperatures in the first days of life are a manifestation of infection or toxemia, even though we are unable at times to trace its origin and that they are preventable to a great degree by appropriate prophylactic measures.

The opportunities for infection in the newborn in the birth canal, at birth and subsequent thereto, are numerous, to-wit: By the contact of infectious material with the eyes, its entrance into the mouth or nose, to be later swallowed or aspirated; the introduction of the unclean finger into the mouth, and abrasions of the mucosa, which Epstein[19] demonstrated was the starting point of Bednar's aphthæ, which he also stated was capable of giving rise to sepsis in the infant; traumas incident to forceps delivery or subsequent accident; contaminated environment and unclean attendant; the existence of an always possible focus of infection, namely, the navel, which Quinquaud,[20] in 1872, was the first to suggest as the port of entry for infectious material in sepsis neonatorum, which had previously been regarded as a condition that developed *in utero* or during birth in septic mothers. The fallacy of this latter theory was subsequently proven by Runge,[21] who reported epidemics of sepsis occurring in the newborn while the mothers remained healthy.

Although infection from the navel has been enormously reduced since the introduction of asepsis, Eross[9] entertained the view that it had not been lessened to the extent that puerperal infection had in the mother. While there is a tendency to disregard changes in the cord stump or navel as a very frequent cause of temperature in the newborn, it is well to bear in mind that in pre-antiseptic days sepsis developing from this source was re-

sponsible for a large proportion of the deaths occurring among them, and that strict asepsis, with regard to the infant, is not always adhered to at the present time. Clinical observation and subsequent anatomic examinations show that even slight and superficial inflammatory processes in the navel are sufficient to give rise to general infection.

Cholomogroff's[22] bacteriologic studies showed that in the proximal part of a cord stump that is undergoing moist gangrene, micro-organisms identical with those obtained from the lochia in puerperal sepsis, namely, streptococci and staphylococci, are found. He suggests that this renders possible the transfer of septic material from the cord stump of a healthy child to the infant itself or to the mother.

In the various infections that attack the newborn, depending on its character, different micro-organisms are found. The bacteria above mentioned are those usually found in sepsis neonatorum, whatever may be its clinical manifestations.

The nasal and oral cavities are no less important as portals for entry of infection in the newborn than at a later period of infancy and childhood, and as a consequence infection of the respiratory and gastrointestinal tracts is not uncommon. Infections of the respiratory organs are far less frequent, however, than those of the gastrointestinal tube. While many of the disorders of the latter are simply functional disturbances, and others are slight gastrointestinal catarrhs, some of them assume the form of what Epstein,[19] and later Fischl,[23] described as gastrointestinal sepsis. It is a well-known fact that sepsis in the newborn may run its course as a gastroenteritis, as a general sepsis or pyemia, following navel or other local infections, as Buhl's or Winckel's diseases, the septic nature of which is no longer doubted, or under the clinical picture of an hemorrhagic diathesis,

Gastrointestinal disturbances, however, may exist as an associate symptom-complex with almost any acute disease of infancy, and, unfortunately, at times for the infant, they may occupy the entire attention of the physician, and the primary affection may be overlooked. On the other hand, the gastrointestinal symptoms may attain such a degree as to render their treatment of paramount importance. This is no less true occasionally in renal insufficiency in infants.

The following cases occurring as a ward epidemic in the newborn, presented many points of interest that appeared worthy of reporting:

CASE HISTORIES.

Case 1.—S., an infant, born Feb. 9, 1905, after normal labor. Nothing unusual was noted in the child. He weighed six pounds one ounce. Meconium was passed freely and he urinated twice in the first twenty-four hours, at the end of which time the temperature was 99.8 F. (37.8 C.) It rose thereafter, reaching the maximum elevation on the fifth and sixth days of 105.6 F. (40.9 C.), and continued as a remittent fever during his stay of fifteen days in the hospital. He nursed indifferently, was restless and vomited occasionally. Bowel movements were frequent, greenish in color and contained considerable mucus.

Examination.—Examination on the fourth day revealed a small male infant, considerably emaciated and very drowsy. Head, eyes and face negative. Throat congested. Respiratory murmur harsh. Heart area not enlarged. No adventitious sounds. Liver palpable. The cord dressing was stained with a brownish discharge of fetid odor. Cord stump was soft and of greenish color.

Examination of mother failed to show anything abnormal. Lactation was established on the third day. Breasts well filled. No excoriations or fissures of the nipples. The infant was again examined on the sixth day, when the physical findings were found the same, and in addition there was a papulo-pustular eruption on the neck, chest and arms. It was also noted that he coughed and sneezed occasionally and there was at times a slight nasal discharge present. He lost weight rapidly, and at the end of eight days weighed twenty-one ounces less than his birth weight, and did not regain any while in the hospital. The cord dropped off on the thirteenth day. The navel was excoriated, reddened and moist, an umbilici catarrhalis of Runge.

Case 2.—L., an infant, was born Feb. 15, 1905, after an uneventful labor. He appeared healthy and weighed five pounds and fifteen ounces. After receiving the usual attention he was placed in the same cot with infant in Case 1. His bowels moved regularly, but urine was not voided in the first forty-eight hours, after which time it passed freely.

At the end of the second day the temperature was 100.2 F. (37.9 C.), which continued to rise and persisted as a remittent fever for eighteen days. On the third day he weighed five pounds five and a half ounces, which he maintained until the disappearance of temperature. He was restless, slept little, coughed infrequently and nursed poorly. On the ninth day epistaxis occurred, and on the eleventh day there was considerable discharge from the nose.

Examination.—Physical examination gave practically the same results as noted in the infant in case 1, except no eruptions were present, and there was a loud systolic murmur heard over the cardiac area during the continuance of temperature, but disappeared thereafter. The cord, which apparently had undergone normal mummification, dropped off on the sixth day. With the subsidence of temperature, which had continued for seventeen days, all symptoms disappeared and he gained rapidly in weight. The mother pursued a normal course following labor and had an abundance of breast milk.

Case 3.—L., an infant, was born Feb. 15, 1905, after a normal labor. He weighed eight pounds four ounces and did not present any abnormalities. He was assigned to the same cot with the above infants. The bowels moved two to four times in twenty-four hours.

First urination recorded was forty-four hours after birth, at which time the temperature was 100.8 F. (38.2 C.), and continued to rise, reaching a maximum of 104.4 F. (40.2 C.) on the fourth day and persisting as a remittent fever throughout. He urinated freely on the third and fourth days, but thereafter there was complete anuria for six days. At first he was restless, nursed little, coughed and sneezed at times and lost weight rapidly. Later he vomited; bowels moved frequently; he was very drowsy and moaned a great deal.

Examination.—Physical examination gave practically the same as found in the infant in case 1. The cord mummified in its distal portion, but the proximal part was moist, brownish in color, with a slight discharge at its base. It dropped off on the fifth day, leaving a moist, excoriated surface.

On the tenth day he had frequent short eclamptic seizures. There was a constant and marked longitudinal nystagmus. The head was slightly retracted and later the legs and arms were somewhat rigid. After an attack of vomiting he became suddenly cyanotic and died in a few minutes.

The mother had an uneventful convalescence and a good supply of milk.

Case 4.—C., an infant, was born Feb. 18, 1905. He weighed six pounds and four ounces. There was a pressure paresis of the left facial present. He was placed in the same cot with the above infants. The nurse recorded a slight convulsion eleven hours after birth. At the end of thirty hours the temperature was 102 F. (38.9 C.) In forty-eight hours it was 106 F. (41.1 C.) Up to this time meconium and urine were regularly voided.

He was restless and, as in the case of the other infants, he coughed and sneezed occasionally. During the fourth, fifth and sixth days he urinated but once in twenty-four hours. Thereafter, with the drop in temperature, frequent urinations were recorded. The cord changes were similar to those mentioned in case 3. It dropped off on the tenth day. The mother did not present anything abnormal.

23. Fischl: Jahrb. f. Kinderhk., vol. xxxvii, pp. 290-292

Following are the findings of postmortem made by Dr. Bassoe on the infant in case 3:

Anatomic Diagnosis: 1, Acute rhinitis, pharyngitis, laryngitis, tracheitis and bronchitis; 2, uric acid infarctions in both kidneys; 3, catarrhal enteritis; 4, nodule in liver.

Examination: Weight, 2,450 gm.

There is a reddish discoloration of the skin, especially of the upper limbs. Slight excoriation about the umbilicus. The peritoneal cavity is empty. Rectum and sigmoid are distended with gas. Rest of intestine is not distended. The appendix is 6½ cm. long and bent on itself. Peritoneum is smooth throughout. Pleural and pericardial cavities are empty. Thymus is small. The pharynx contains very viscid whitish mucus. The posterior nares contain same kind of mucus. Mucous membrane of pharynx is hyperemic and smooth. No pus is found in sphenoidal or ethmoidal sinuses or in tympanic cavity. The larynx and trachea are filled with mucopus. On scraping off the mucus the membrane is smooth and very slightly hyperemic. The mucus is not blood-stained. Lungs are pink and crepitate throughout. Cut surfaces are smooth. Small amount of mucus can be expressed from the middle-sized bronchi. There are no visible areas of consolidation. Heart is proportionate in size and normal. Spleen measures 3½x2x1 cm. On section it is dark red and has a normal consistency. The tongue is smooth and has a normal appearance. Esophagus is smooth. The stomach is empty and contains small amount of mucus. Liver weighs 100 gm. Surface is smooth. There is some reddish discolorations on right lobe. Normal consistency on section. It is light grayish-red, in places pale red, lobular markings indistinct. On the surface of the left lobe is a yellowish-white, slightly raised area, 4 mm. in diameter. It extends 3 mm. into the interior, forming a globular nodule, sharply separated from surrounding tissue.

The gall bladder contains viscid bile. Kidneys of porportionate size. The capsule peels readily, leaving a smooth surface. All pyramids are of a grayish color. Urinary bladder is empty. Prostate is normal. Testicles are normal. The center of ossification in lower end of femur is 4 mm. in diameter. Line between bone and cartilage is regular.

Histology: Thyroid. Colloid very abundant, considering age of individual. In the bronchus were masses of red cells in which there are leucocytes adherent to the mucosa. The epithelium of the latter is well preserved; its vessels very hyperemic. In the lungs, septa were very hyperemic. Many alveoli are filled with red cells and leucocytes; most of them, however, remain open. No changes were noticed in the stomach and the intestine. There was considerable fatty degeneration in the liver. Urate deposits in tubules of pyramids, demonstrated in frozen sections, were found in the kidneys. On treating with H Cl, or acetic acid, uric acid crystals were formed.

Bacteriologic examination made by Dr. D. J. Davis gave the following:

The material examined bacteriologically was heart's blood, bile, cerebrospinal fluid, purulent masses from pharynx and bronchi. Heart's blood, bile and cerebrospinal fluid gave negative results.

Smears of the pharyngeal mucus showed a considerable number of an encapsulated Gram-staining diplococcus, evidently the pneumococcus, also a very large number of non-Gram cocci or diplococci, principally outside the leucocytes, though frequently within. Polynuclear leucocytes are very abundant. Smears of the bronchial mucus show the same organisms, but there are fewer pneumococci. Cultures were made on blood-agar plates from the pharynx and bronchus. Pneumococcus colonies were abundant, but far more numerous were colonies of micrococcus catarrhalis. On blood-agar the colonies of this organism are round, raised, grayish-blue, without a zone of hemolysis. It grows best on blood-agar or Loeffler's blood serum. In bouillon there is slight cloudiness at first, with formation of coarse granules, forming an abundant sediment in forty-eight hours. It does not change litmus milk and grows freely on potato. It is a non-Gram staining, small coccus, often in pairs and being frequently found in leucocytes is easily mistaken for the meningococcus. The amount of 5 c.c. of a twenty-four-hour bouillon culture was inoculated into the pleural cavity of a guinea-pig weighing 380 gm. The pig remained perfectly well, the culture apparently having no effect.

The postmortem did not show any important local changes in the navel nor an endarteritis or phlebitis of the umbilical vessels, there being noted only superficial excoriations, although during life the cord had not mummified normally and there was a brownish fetid discharge present. The bacteriologic examination of the blood, bile and cerebrospinal fluid was negative. All the clinical manifestations were, therefore, plainly referable to infection of the respiratory tract and to anuria incident to extensive uric-acid infarctions of both kidneys.

The little patients presented many points of clinical interest. They demonstrated the susceptibility of the newborn to infection of the air passages. They illustrated the rapidity of conveyance and the briefness of incubation in infection with the micrococcus catarrhalis and pneumococcus, likewise its tenacity and seriousness in the newborn. They suggested the contagiousness of what ordinarily might be termed a "cold" and gave color to the time-honored maternal observation that the "baby was born with a cold."

ETIOLOGY.

The original source of infection in these cases was not determinable. Gaertner[24] reported an epidemic of pneumonia in eight newborn in the Heidelberg Gebär Anstalt, caused by staphylococci and streptococci, which micro-organisms he was able to cultivate from the mattresses of the lying-in patients. This latter investigation does not, however, seem convincing.

Children born in the ward subsequent to my last reported case and kept in a different room did not develop temperature or evidence of disease, whereas all infants placed in contact with Case 1 and subsequent cases developed same.

The clinical symptoms presented considerable uniformity in all cases, but nothing characteristic. At times they were restless and slept little; at other times drowsy and not easily awakened. They coughed and sneezed, but infrequently, and neither could be regarded as a prominent symptom. There was a slight nasal discharge in two cases, one having epistaxis. They nursed poorly, vomited occasionally, and the bowel movement was somewhat frequent, sometimes green, and contained, on and off, mucus and curds. The urine often showed brick dust deposits. The temperature was high, remittent in character, and in the cases that recovered declined slowly to lysis.

Physical examination showed evidence of an acute rhinitis and pharyngitis. The respiratory murmur was harsh, otherwise negative. Respirations were somewhat accelerated. In two cases there were skin eruptions on neck, chest and extremities; in one papulo-pustular; in the other petechial.

Regarding the secretion of urine in these cases, it will be noted that the infant in Case 3 urinated freely for the first four days, when the temperature reached 104.4 F. (40.2 C.), after which time there was anuria for six days, when he succumbed, evidently to uremia. In this patient, as a result of the infection with accompanying temperature and diarrhea, the urine being concentrated and small in amount, was insufficient to force out or dissolve, as previously mentioned, the infarctions already formed, and instead contributed to increasing them by further deposits of urate of ammonium, the water being absorbed. Anuria resulted, leading subsequently to, in all probability, uremic poisoning.

It would seem that urinary suppression in the newborn

24. Gaertner: Quoted from Fischl in Jahrb. f. Kinderhk., vol. xxxiii, p. 289.

when associated with temperature is a result of the concentration of the urine incident to the cause of the latter, or a co-existing diarrhea, and to uric-acid infarcts in the kidneys, rather than that the temperature is due to the latter. It is hardly necessary to mention that this presupposes a normal anatomic status of the urinary tract.

TREATMENT.

The treatment of infections of the respiratory tract and all other infections in the newborn rests primarily in prophylaxis, a strict observance of asepsis and protection against infection of the infant while in the birth canal, at delivery, and subsequent thereto. The oft-repeated admonition of antiseptic douching at the onset of labor in case of suspected gonorrheal infection in the mother and the immediate care of the eyes by Credé's method ever holds good for the prevention of ophthalmia neonatorum. The douching also removes bacteria that are commonly found in the vaginal secretion and which, according to Kneise, are always present in the mouth of the newborn. The opinion was early expressed by Epstein[19] that contaminated amniotic fluid might be responsible in some instances for infection of the respiratory and gastrointestinal tracts in the newborn, and suggested the necessity of avoiding frequent examination after the rupture of the bag of waters. It is probable, however, that the pathogenic organisms of the vaginal bacterial flora which may be virulent would better explain such infections.

Of vital importance to the infant is the treatment of the cord, for which many methods have been advocated, some of which have been quite radical because of unfortunate occurrences. Because of an experience with tetanus in the newborn, Martin[25] advised cutting the cord after ligation with red-hot scissors. Dickinson[26] recommends excising the cord entirely, ligating the umbilical vessels, and suturing the skin over them, claiming that the sloughing process at the child's navel is not consistent with asepsis in child-bed. While a moist gangrene of the cord may not be, a normal mummification of the cord can not carry any such dangers.

Occlusive dressings have also been used, but Runge[21] long ago demonstrated that such a method delayed separation of the stump, which remained moist and fetid. An hygroscopic dressing of plaster-of-paris is also practiced, and Cholomogroff,[22] from his bacteriologic investigations, believed that it possessed advantages over other methods. Whatever be the method used, asepsis should characterize its treatment as thoroughly as the stump of an ovariotomy.

When an infection of the respiratory tract or any other organ or tissue develops in a newborn babe in a maternity ward it is evident from the above cases that it should be isolated, and that a nurse attending it should neither attend uninfected mothers nor children. Winckel stated that the same nurse should not at any time care for both mother and child. Where it is not practical to carry out Winckel's plan the infant should receive first care. There is little doubt that some infections in children may be conveyed through the medium of the attendant. In fact, as Kehrer[27] urged, the infant should not share the bed of its mother, nor, as might be added, the bed of other newborn, for obvious reasons. The infant should be protected against infections, acute or chronic, of the respiratory tract of the mother or nurse It is not improbable that the first infected of the above children acquired the same from the mother or the attendant.

Reich[28] reported instances of direct conveyance of tubercular infection by a midwife who was accustomed to blow into the nose of the infant to establish respiration after she had aspirated mucus from the oral cavity of the child, by aspirating directly with her mouth. Ten children so treated died within fourteen months from tubercular meningitis, although their heredity was negative. Later the midwife herself died from pulmonary tuberculosis.

The immediate care of the affected infant must necessarily be symptomatic.

In the above patients the temperature and restlessness were combated by sponging and bathing. The gastrointestinal symptoms were treated when the stools showed undigested material, by diluting the breast milk by the administration of sterile water before nursing, and in case vomiting was present, by prolonging the interval of nursing and giving lime water at that time. Enteroclysis was employed, also small doses of calomel, 1/40 gr., or castor oil.

To overcome the tendency to anuria, water was given frequently, and, at times, small doses of potassium citrate. The most effective measure in this regard, in addition to increasing fluids consumed, is the use of high rectal enemas of salt solution or sodium bicarbonate to be retained. They were given at six-hour intervals, about two ounces being used.

Concerning the immediate treatment of the respiratory tract, the nares were swabbed three or four times daily with boric acid solution. No expectorants were given because of the probability of increasing gastric disturbance.

AN OPERATION FOR PYOSALPINX WITHOUT LIGATURE, CLAMP, ARTERY FORCEPS OR BLEEDING, BY OVERTHROW PROVISIONAL SUTURE METHOD.

REPORT OF FIFTY-NINE CASES WITH ONE DEATH.

W. D. KELLY, M.D., Ph.G.

ST. PAUL, MINN.

(*Concluded from page 1017.*)

Case 17.—R. D., aged 19, single, was admitted to hospital Aug. 1, 1903.

History.—The patient had diphtheria, when a child, influenza and scarlet fever; had gonorrhea about four years ago; at the same time had four sores on labia; she was told they were chancres; had been taking blood medicine for two years; says she was cured of gonorrhea two years ago, and contracted it again for the second time and was cured; says she was rachitic when a child.

Diagnosis.—Right-sided pyosalpinx; appendicitis.

Operation.—Single salpingo-oöphorectomy, appendectomy. The right ovary, right tube and vermiform appendix were found to be bound together with firm peritoneal and omental adhesions; a large band of omentum ran across from the anterior abdominal wall to the fundus uteri. The adhesions were broken up with difficulty. The right tube and ovary were isolated, but in lifting up the tube it ruptured and pus escaped. The opening in the tube was clamped and the tube and ovary (right) removed by making a short incision in the broad ligament and whipping over the uterine edge of the ligament with Billroth's chain suture, proceeding in this way, cutting and tying, until the tube and ovary were almost removed. They were then raised up and slightly drawn on, so as to form a

pedicle, which was tied off with pyoktannin catgut, No. 3. The apex of the appendix was freed of adhesions, seized with artery forceps and raised up; the remainder of the appendix was freed and double ligated with catgut and removed by cutting between two ligatures. The peritoneal flap was closed with fine catgut suture. The patient was discharged, well, Sept. 29, 1902.

Case 18.—L. A., aged 54, a widow, was admitted to the hospital Aug. 5, 1903.

History.—The present trouble began three weeks ago with chills and vomiting. She had very severe pain in left side, which was very tender. She had chills three successive days; she went to bed, but got no better. After abont ten days she began to have a discharge from the uterus. The pain still kept up and the discharge was very offensive and yellow in color. This discharge gradually ceased and she suffers less pain.

Diagnosis.—Pelvic inflammation, pyosalpinx (left).

Operation.— Salpingo-oöphorectomy. An incision was made in the median line, about five inches long between the umbilicus and the pubes. It was necessary to make such an incision on account of the belly wall. Numerous adhesions were found between intestines and omentum. These were broken up with the fingers and the appendix was exposed; this structure was normal. The ovaries and tubes were found to contain abscesses. Adhesions were found to anterior abdominal wall, and several large adherent portions of omentum were tied off and excised. A broad ligament hemorrhage on the left side was found. A partially organized clot was found about the size of a hen's egg; it was shelled out, and a cyst of the same size was opened. A continnous over-and-over suture was employed, and the ovaries and tubes were removed with very little hemorrhage. The cavity was swabbed ont so as to free it from blood clots and other foreign substances; the peritoneum was sutured with pyoktannin catgut No. 2; also the fascia of the rectus muscle. The skin was sntured with silkworm gut, a dry dressing was pnt over the wound and the patient sent to bed in good condition, but died Aug. 16, 1903.

Case 19.—F. S., aged 19, single, was admitted to hospital Aug. 18, 1903.

Diagnosis.—Pyosalpinx, cystic ovary, appendicitis.

Operation.—Laparotomy: salpingo-oöphorectomy, appendectomy. An incision was made in the median line between the umbilicus and the pubes, about four inches in length, down to the peritoneum, which was grasped with two pairs of dressing forceps and lifted up and cut. The ovaries, tubes and appendix were then explored; the fundns of the uterns was found in Douglas' cnl-de-sac. Some adhesions were found also and a pus tube and an ovary which had a few small cysts on the surface. The left tube and ovary were taken out, the broad ligament being sntured. An extra tube abscess was opened during the operation and pus escaped, which was wiped away by sponge. All adhesions were broken up and appendix removed. A cuff was dissected and the appendix ligated, cnt off and touched with 95 per cent. carbolic acid, followed by alcohol. The cuff of peritoneum was closed over the end and the whole inverted. A ventral suspension was performed, two pyoktannin, No. 2, catgut sutures were placed through the peritoneum and through the posterior portion of the fnndus of the uterus and tied; the intestines were carefully mopped and the peritoneum was closed by continnous suture of No. 2 catgut. Muscles and fascia were then sutured with same suture and the skin closed by subcuticular stitch of silkworm gut. Patient was discharged, well, Sept. 23, 1903.

Case 20.—Mrs. H., aged 35, admitted to hospital April 1, 1904.

History.—The patient has had several attacks of gonorrhea. She complained of pain in the right and left lower quadrants of abdomen and of pain in back. Temperature, 100; pulse, 105. She had constipation, headache and furred tongue, offensive leucorrhea discharge.

Diagnosis.—Lacerated cervix; inflammation of uterus and a large retroflexed uterus fixed posteriorly; large packet found on both sides of uterus; considerable pain and tenderness in pelvic region.

Operation.—Salpingo oöphorectomy. The abdomen was opened in the median line with the patient in the Trendelenburg position. Bowel, omentum and rectal adhesions were cut away and tied. Adhesions of bowel were separated and bowel and omentum allowed to drop back from site of operation. A large piece of gauze was inserted for drainage. Pelvic peritonitis was present. The tubes were freed, and the ovarian and uterine arteries were tied on the left side. On attempting to separate the tube from its attachment to the broad ligament, the ligature slipped from the ovarian artery and the profuse bleeding was stopped with difficulty. The bleeding artery after ligating was cauterized. There was considerable oozing from freed adhesions. The broad ligament was stitched and an attempt was made to cover raw surfaces with peritoneum. The patient suffered slightly from shock, but otherwise made an uneventful recovery, leaving the hospital on the nineteenth day after the operation.

Case 21.—Mrs. W., German, aged 27, admitted to hospital April 1, 1904.

History.—Patient has no children; she has had no abortion; no gonorrhea. She is thin and anemic. She complained of a dragging pain in her left inguinal region. She had typical hysterical crouch and expression of face, with position of palsied hand when attempt is made to examine side. This paient was pronounced a confirmed hysteric. There was a tough, light-colored, stringy, tenacious discharge from the cervix. She was constipated. Temperature was 99.6; pulse, 96. She complained of headache and general malaise. She has had repeated attacks of pain in right side.

Diagnosis.—The patient was examined with much difficnlty. I found the uterus deflected to the left side, somewhat fixed laterally on the right side. I made a diagnosis of retroverted uterus. A large mass was felt through the abdominal wall, which wall was thin.

Operation.—Oöphoro-salpingectomy. The adhesions on the right side were very dense. The omentum was separated and an inflamed mass was found, a portion of which crossed the pelvis. Its middle portion and distal end were adherent, respectively, to the tube and to the posterior wall of the uterus. After tying and freeing the appendix it was removed (cuff method). The tube and ovary were removed by clamping and cutting below tube, then following up cut surface by running suture and tying off the tube at the horn. In the left broad ligament a large organized clot, the size of a goose egg, was found. The ligament was split and the clot removed, after which the ligament was closed with running suture. Patient was discharged, well, April 24, 1904.

Case 22.—Mrs. M., admitted to hospital July 15, 1904.

Diagnosis.—Left pyosalpinx.

Operation.—A median incision, three inches long, was made between the umbilicus and the pubes with the patient in the Trendelenburg position. The intestines were packed back. There were adhesions between the left tnbe and the sigmoid. The left tube was coiled aronnd the left ovary, which was normal. When the bowel was torn from the adhesions, pus appeared, which was sponged away. No. 2 pyoktannin catgut was used for provisional sutures in stump of broad ligament, as the tube was cut away. On section of removed tube pus in considerable quantity was found in the lumen of the tnbe. In removal of the tube part of ovary was also removed. The other tube and ovary, as well as the appendix, were normal. The peritoneum was sntured with No. 2 pyoktannin catgut; the fascia with No. 3 pyoktannin catgut, and the skin with a subcuticular suture of silkworm gut. A dry dressing was applied. Patient made a good recovery from the anesthesia. Pain was severe. The temperature varied from 99 to 101.4, which was the highest until she was discharged, August 3, thoroughly recovered.

Case 23.—M. R., aged 19, white, clerk.

History.—She has always enjoyed good health. The present trouble dates back two weeks. It began with constant, sharp pain in right iliac region, which disappeared in a few days and then returned in left side. Menstruation began at 13 and was regular until one year ago; it was always profuse, lasting abont two days. Menses were accompanied by pain and back-

ache. During past year menstruation has been irregular and attended with sharp pain, compelling patient to go to bed.

Examination.—Patient was well developed and had good color. Lungs and heart were normal. Pulse was regular, but fast (120). In the lower part of the abdomen and extending to one inch below the umbilicus a large mass could be felt. It was firm on palpation, dull on percussion and very painful and tender on pressure. The left side was more tender and painful than the right.

Diagnosis.—Gonorrhea, endometritis and double pyosalpinx.

Operation.—June 28, 1904, a median incision was made. The right ovary and tube were adherent. The adhesions were broken up and the broad ligament ligated by a continuous suture. The tube was removed; it was enlarged and inflamed. A number of cysts were found in the mesentery and about the left tube and ovary. The patient was discharged well July 14, 1904.

CASE 24.—Mrs. F. P., aged 32, white, housewife, admitted to hospital June 4, 1904.

History.—The patient has had three children, the oldest is now 14, and the youngest 8 years old. In February, 1904, the patient had an attack of pain in the lower right quadrant of the abdomen. This was accompanied with vomiting and fever. About three weeks before admission to the hospital she was again seized with pain in the lower right abdomen, accompanied by fever. Attempts at vomiting were painful.

Examination.—The patient was well nourished, with a good color. Her eyes were clear and bright; the tongue was slightly coated. Lungs and heart were normal. The abdomen was tender on palpation and the percussion note on the right side was dull. An abscess could be palpated filling the lower right pelvis and extending as high as McBurney's point and an inch to the left side of the median line.. Urine examination was negative.

Diagnosis.—Double pyosalpinx.

Operation.—June 7, 1904, an incision was made in the median line. Adhesions were found involving the peritoneum, omentum, intestines, ovaries, tubes and bladder. Those involving the intestines were broken up. A mass was found on the right side, involving ovary, tube and omentum and adherent to the upper posterior part of bladder. This mass was removed after a partial removal of pus from the tube by aspiration. The puncture was closed with forceps and no pus escaped. The broad ligament was sewed up by an over suture, and part of the ovary was stitched to the right cornu of the uterus. The omentum was ligated and cut from adhesion. Right and left extra tubal abscesses were opened. The broad ligament was adherent to the upper part of the uterus and a portion of the rectum, and in breaking these adhesions the peritoneum was pulled from the uterus, leaving it bare. Stitches were taken, bringing the peritoneum from before backward and from below upward and forward, covering the bare upper portion. Left ovary and pus tube were removed without rupture, and the incision was closed. The patient was discharged well, Aug. 11, 1904.

CASE 25.—B. M., aged 21, white, American, domestic, admitted to hospital May 27, 1904.

History.—When the patient was 16 she had an attack of cramps in abdomen, accompanied with vomiting, and pain on the right side. Last February she had a great deal of pain in the right side, though it did not confine her to bed. On Monday previous to admission to hospital, about 10 a. m., the patient complained of pain in the abdomen and on the right side. Bowels have moved fairly regularly.

Examination.—Patient is well nourished; her color is sallow; eyes yellow tinged; tongue slightly coated. Lungs and heart are normal. Pulse is strong and full, but rapid (100). Abdomen was tense, and she complained of pain on palpation over the umbilicus and on the right and left sides. Percussion note showed no tumor on the right. Deep palpation in the right iliac region caused pain. Temperature 101. There was no rash on the body. Urine examination was negative.

Diagnosis.—Double pyosalpinx.

Operation.—A large pyosalpinx was found on both sides, firmly adherent to adjacent parts. On breaking up adhesions on the left side, the sac was ruptured and the pus escaped into the peritoneal cavity, which was wiped out carefully, the intestines having previously been walled off, by sponges. The left tube and ovary were excised and a chain suture inserted to ligate the broad ligament. An abscess on right side ruptured in freeing adhesions, and the pus carefully wiped out. The right ovary was normal and was left *in situ*. The right tube was excised. Both tubes had become adherent to the sigmoid, and after removal two large denuded areas were sutured over by continuous suture, bringing the peritoneum over the sigmoid. On July 14, 1904, an appendiceal abscess was diagnosed and on July 16 the patient was operated on. She was discharged, well, Aug. 10, 1904.

CASE 26.—M. W., aged 18, white, American, domestic, admitted to hospital May 7, 1904.

History.—Patient complained of pain in abdomen and low in pelvis, on both sides for about two weeks. She had a temperature of 101.2 on admittance to the hospital. She denied having a vaginal discharge, but later admitted that she had. She has some pain and burning on urination. There is no history of syphilis.

Examination.—Patient is well nourished, strong and healthy. Her color is good, eyes clear and bright, tongue coated. Cervical glands are not enlarged. Heart is regular and strong, and lungs normal. There was no rash on the body. There was tenderness on palpation, low in pelvis, on both sides. Albumin was present in the urine.

Diagnosis.—Right pyosalpinx, gonorrhea, inguinal bubo.

Operation.—May 18, 1904. Large right-sided pus tube was adherent to intestines and down in cul-de-sac. It was freed by dry dissection, excised and stump overcast with catgut sutures, a buttonhole stitch covering in abraded surfaces. Pelvis was sponged dry and peritoneum closed. Patient left table in good condition. Recovery was uneventful, and the patient was discharged June 18, 1904.

CASE 28.—L. H., aged 23, white, admitted to hospital June 17, 1904.

Diagnosis.—Double pyosalpinx.

Operation.—June 17, a median incision was made. Tubes and ovaries were adherent to surrounding tissues. The right Fallopian tube and ovary were first loosened, and in so doing an extratubal abscess was perforated and the pus escaped into the peritoneal cavity, which had previously been walled off with sponges. The pus was mopped out. The ovary and tube were removed and the broad ligament sutured by continuous suture. In breaking up adhesions on the left side, another extratubal abscess was ruptured, the pus being sponged out. The tube and ovary were removed and the broad ligament treated as on opposite side. The appendix was sought for and found involved. It was removed and the abdomen closed Patient was discharged, well, July 30, 1904.

CASE 29.—Mrs. C. A. S., aged 30, white, American, housewife, admitted to hospital April 5, 1905.

History.—Patient had measles as a child, diphtheria at 11, typhoid three years ago and smallpox two years ago. Menses began at 15 and are regular. She has four children, the oldest 8 and the youngest 5 years old. She had a miscarriage last fall, fetus 6 weeks old. She was operated on for pelvic abscess last September. She has been sick for the last month, with pain in the left inguinal region and pain in the left leg. She has had a leucorrheal discharge for same length of time. She was in bed first and has been unable to do any work. Bowels are regular, but appetite is poor.

Examination.—Patient is fairly nourished, but anemic. Tongue is clean. Eyes, chest, lungs and heart are normal. Breasts almost absent. She states that they began to disappear after typhoid. She had twins 14 months old, who were still at breast at that time. There was tenderness over the left inguinal region and a mass was palpable. Urine examination was negative.

Diagnosis.—Double pyosalpinx.

Operation.—April 11, 1905. A median incision was made. The entire contents of the pelvis, including bladder, both tubes and ovaries, intestines and omentum, were adherent. These were carefully separated by means of blunt dissection. The fimbriated end of the right tube was adherent to the ovary

and there was a small abscess in between. The right ovary and tube were removed by separating them from the broad ligament by scissors and the edges of the ligament were united by continuous overstitch of catgut. An incision through the peritoneum was made in each side and the same suture continued through horn and tube. On the left side the adhesions were more complicated and involved large portions of intestines. This was all separated by blunt dissection. In one place a rather deep hole was left in the intestine from adhesions, but edges of it were stitched over. The tube and ovary were separated in the same manner as on the right side, but the tissues were so friable that they tore several times. A saline enema was given to see if there was any intestinal leakage; none was found. The abdomen was mopped out, and the peritoneum brought together by a single mattress suture above and an overstitch for the rest. Fascia and muscle were united by another overstitch, taking in line of suture peritoneum. Skin was closed. The external wound was treated by the open method. On April 15 there was a foul odor and a discharge from the vagina. On April 20 there was a profuse discharge from the abdominal wound and four ounces of pus were expressed. The opening in the bowel was searched for and found. After the bleeding was controlled, the edges of the bowel were resected, a Murphy button introduced, the parts brought together and the bowel sutured. At the time of making this report the patient is still in the hospital.

Case 30.—A. B., aged 22, married, was admitted to hospital April 2, 1904.

History.—The patient had smallpox when 3 years old and "inflammation of bowels" when 21 years old. She is married, but has no children. A week previously was seized with pain in the abdomen, vomiting and general distress. She has had profuse offensive yellowish discharge from the vagina for three weeks, and is still very tender over abdominal region. She is constipated a great deal of the time.

Diagnosis.—Double pyosalpinx.

Operation.—Double salpingo-oöphorectomy. An incision was made in the median line, about four inches long. Both tubes were seen to be adherent and greatly enlarged; a very superficial abscess could be seen in the left tube. The left tube was freed from adhesion, and in so doing an extra tubal abscess was opened, considerable pus escaping. The tube and ovary were removed and the broad ligament sutured. The right tube and ovary were freed from adhesions, another extra tubal abscess opened. They were removed in the same manner as the left. The appendix was examined and found normal, so was left alone. The pelvic cavity was sponged out. The peritoneum was closed with No. 2 pyoktannin catgut. The same suture and stitch closed muscle and fascia. A subcuticular silkworm gut suture closed skin opening. The patient made an uneventful recovery and was discharged May 20, 1904.

Case 31.—C. S., aged 22, single, was admitted to hospital April 23, 1904.

History.—The patient has been troubled with constipation and some headache. About five weeks ago she had pain in the stomach and pelvis. She has not vomited, but her appetite is poor and she feels distressed after eating. She has a discharge from the vagina of about five weeks standing and complains of pain in the back. She does not sleep well, and has menstruated three times in six weeks.

Diagnosis.—Pyosalpinx (left).

Operation.—Single salpingo-oöphorectomy, appendectomy. A median incision was made about four inches long. Intestines, bladder, tubes and uterus were found to be adherent; adhesions were broken up by dry dissection, using sponge on finger. Right tube was freed and examined; it was somewhat distended. It was aspirated, but no fluid was found.. The appendix was found deep in the pelvis; it was freed and brought up. The serous coat was stripped off, forming a cuff. The mesoappendix was cut away and overcast with running suture of No. 2 catgut pyoktannin. The appendix was then clamped and cut off; the stump was cauterized with 95 per cent. carbolic acid, followed by alcohol, turned in and purse-string suture put around cuff and drawn tight. The left tube was much enlarged and firmly adherent, deep in cul-de-sac. In freeing the tube an extra tubal abscess was opened, allowing a fluid to escape; this was sponged away. The fimbriated extremity was brought out and the ovary and tube cut away, small cuts being taken and each one followed by overcasting with running buttonhole stitch. Skin was closed with subcutaneous stitch of silkworm gut. The patient was given an enema of warm oil and whisky. Recovery was uneventful, and the patient was discharged May 23, 1904.

Case 32.—G. R., aged 24, white, American, was admitted to hospital June 2, 1905.

Diagnosis.—Double pyosalpinx.

Operation.—June 3, 1905. A median incision was made. The left tube was found much diseased and swollen; it was very thick and distorted and contained an abscess which was broken in attempting its removal. The tube and ovary were removed with scissors and the ligament caught up with suture. When the fundus of the uterus was reached the sutures were continued to approximate the edges after excision of a small fibroid. The right tube and ovary were found diseased, but contained no pus; they were removed in the same way. Abdomen was closed. The abdominal wound was closed with a modified open method. Two pieces of gauze were applied on either side of the wound and only oxid of zinc strips applied. The patient was discharged well June 21, 1905.

Case 33.—Mrs. M. S., aged 34, white, American, clerk, was admitted to hospital April 25.

History.—Patient has always had good health. She has had one miscarriage. Menses began at 12 years; regular. Seven weeks ago she began to have a yellowish discharge from vagina and shortly afterward began to have pain in the pelvic region. She refused operation at this time. She did not have menses during March, but did in April. She came to hospital on April 25, 1905, for operation.

Examination.—Patient is poorly nourished and anemic. Tongue is clear. Eyes, chest and lungs are normal. Heart gives systolic apical murmur, and second pulmonic sound is accentuated; murmur is transmitted to axilla. There is tenderness over the region of the ovaries; abdominal muscles are rigid. Urine examination was negative.

Diagnosis.—Double salpingo-oöphoritis.

Operation.—April 28, 1905. A median incision was made. The omentum was adherent to the bladder and the adjoining organs and was separated by digital dissection. The right tube was thickened and tortuous, and the ovary had a large cyst, which was ruptured in trying to remove it. The tube was severed from the broad ligament by scissors and the ligament caught up by suture from fimbriated end to horn and the tube removed. The left tube was also much thickened and tortuous and there was an abscess at the distal end which was opened in freeing adhesion. The tube and ovary were removed in the same manner as on opposite side. On the posterior surface of the uterus there was a small pedunculated fibroid, showing cystic degeneration. This was cut off and the raw surface stitched over. The appendix being involved in the inflammatory catarrhal action, was removed, and the abdomen closed. An ether mask was applied over abdominal wound and held in place by two strips of rubber plaster. It was removed on the sixth day and the wound was found completely closed, subcuticular stitch was removed, and two pieces of gauze applied on either side of the wound, held in place by rubber adhesive strip. On eleventh day the wound was entirely healed. Patient was discharged, well, May 22, 1905.

Case 34.—N. W., aged 18, white, American, saleswoman, was admitted to hospital May 29.

History.—Menses began at 12. As a rule, the flow was irregular, both in time and number of days; rather painful, but not severe enough to compel patient to remain in bed. Loss of blood was excessive. Last menstruation was on Thursday preceding admission, but only of 1½ days' duration. Full term pregnancy four years before. The present trouble began a week before admission with pains in back and in lower left quadrant of abdomen. Patient has had vomiting, loose bowel and headache for past few days.

Examination.—Patient is well nourished. Her color is good; mental condition good; eyes are bright; tongue is coated.

Breasts are well developed and firm. Abdomen is flabby and shows old scars of pregnancy, but there is no abnormality in outline. There is some tenderness over McBurney's point, but not in right inguinal region. Abdomen on right side is soft. On left side there is distinct firmness over left quadrant low down and it is tender on pressure. Both areas are tender on pressure and painful. She has a vaginal discharge.

Diagnosis.—Salpingitis (left).

Operation.—June 1, 1905, a median incision was made. Intestines were pushed aside and kept there by sponges. The left tube and ovary were much inflamed, distorted and adherent. The adhesions were all broken up and the tube and ovary removed by beginning at end and cutting them away with scissors. Broad ligament was caught up by suture to control the hemorrhage. After carefully wiping out the peritoneal cavity the right tube and ovary were examined and found somewhat inflamed, but were not removed. Abdomen was closed. Abdominal wound was treated with two strips of gauze on either side of incision, held in place by adhesive strips. Patient was discharged, well, July 3, 1905.

CASE 35.—Mrs. P., aged 38, white, German, housewife, was admitted to hospital June 9, 1905.

History.—She complains of pain in the lower part of the abdomen and weakness of legs. She has been unable to do her work for some time because of the weakness. There is a feeling of fullness in throat. She has a white vaginal discharge. She was troubled similarly two years ago and came to the hospital and was operated on. A ventral fixation was done, and the right tube and ovary were removed. Recently the trouble returned. Family history was not obtainable.

Examination.—Patient is a large fat woman, with good color and well nourished. There is a scar on abdomen from previous operation. Heart, lungs and abdomen normal. There is a leucorrheal discharge. Urine examination was negative.

Diagnosis.—Pyosalpinx (left).

Operation.—June 10, 1905, a median incision was made. The operation was difficult on account of thickness of abdominal wall. The left tube and ovary were removed by cuting the tube from broad ligament with scissors and suturing the broad ligament as the incision proceeded. There was little pus, if any in the tube, but tube and ovary were prolapsed and adherent in the cul-de-sac; there were also adhesions in this region. The tube was ruptured in removal and the ovary was removed in pieces. Hemorrhage was controlled by sutures. A tear in the peritoneum over the sigmoid was closed with Lembert sutures, abdomen closed and external wound treated by modified open method. Patient was discharged well July 6, 1905.

I have selected 35 out of 59 most interesting and complicated of my cases which I have taken from the different hospital records. The time allotted to me will not permit of my reporting all the cases in detail. In 24 which I report, but not in detail, the patients made uneventful recoveries and were discharged well.

DEDUCTIONS.

The most frequent causes of pyosalpinx are abortion and gonorrhea.

Pyosalpinx occurs most frequently between the ages of 16 and 40.

My mortality from operation is less than that from measles, being under 2 per cent.

It occurs, in the great majority of cases, either in the ampulla or distal end of the tube.

It is complicated very frequently with appendicitis.

In the majority of cases, it is accompanied by cystic ovary.

It is comparatively easy to differentiate from appendicitis.

It almost always is accompanied by a pelvic or general peritonitis.

The tube seldom, if ever, ruptures.

The operation, as described by me,* is almost bloodless and can be performed without the use of ligatures or artery forceps.

Drainage is almost never necessary.

Counter openings should not be made.

Extratubal or peritubal abscess is frequently found, in which the walls are made up of bowel, or omentum, tube, broad ligament, sigmoid, uterus, or bands of adhesions. This condition is frequently mistaken for rupture or abscess of ovary or tube, as it is impossible to separate or to encroach on this abscess without opening it.

THE STATE OF NEW JERSEY VERSUS GEORGE H. WOOD.

A REVIEW OF THE EVIDENCE AND OF THE THEORIES AVAILABLE FOR THE DEFENSE.*

PEARCE BAILEY, M.D.
Consulting Physician to the Manhattan State Hospital.
NEW YORK CITY.

On Feb. 2, 1905, about noon, George Williams, a grocer of Watchung, N. J., was found in his sleigh, shot through the back, on a lonely part of the road between Watchung and Warrenville (near Plainfield), N. J.

When last seen alive, Williams was in the sleigh with George H. Wood, the latter having hired Williams to take him from Watchung to Mt. Horeb. There was no apparent motive for the crime, Wood and Williams never having met until the fatal morning and no attempt at robbery had been made. Wood was tried for murder in the first degree at Somerville, N. J., May 15-19, 1905, before the Hon. A. G. Garretson and a jury. The defendant pleaded "not guilty," advancing as his defense that he had no clear recollection of anything between the dates of Jan. 30, 1905, at noon, and Feb. 5, 1905, when he awoke in the city prison of New York.

Such a defense, in face of the fact that many witnesses had met and talked with Wood in and about Plainfield, both on the day of the murder and for several days previously, and had noticed nothing peculiar about him, marked the case from the outset as out of the ordinary. It was circumstantially proved, with almost absolute certainty, that Wood killed Williams.

To explain the period of automatism with amnesia, alleged by Wood, several hypotheses were advanced by the experts called in his behalf, all of whom testified that Wood was irresponsible or insane at the time of the commission of the crime. These hypotheses were not accepted by the state's medical witnesses, and it was the general opinion that, had the case gone to the jury, the defendant would have been found guilty.

The defendant's counsel realized this, and at the same time the prosecutor, in view of the impossibility of showing strong motive, recognized that there was sufficient doubt as to the defendant's mental balance to justify a lesser verdict than death. Consequently, at the end of the trial, after consultation between counsel of the two sides and the presiding judge, the original indictment was withdrawn, the defendant pleaded guilty to murder in the second degree and was sentenced to thirty years at hard labor in the penitentiary, the maximum penalty.

The whole interest in the case centered in the story told by Wood. He told and retold it to many persons before the trial, he told it at the trial. It was always the same in important particulars. Under rigid cross-ex-

* Read at a meeting of the Psychiatrical Society of New York

amination few or no inconsistencies in it were brought out, and the prisoner fell into none of the traps which were laid for him. He told it, moreover, in a very convincing way; calmly, coherently, without dramatic exaggeration; in the simple, unaffected manner characteristic of the truth. Was it true? Did Wood have no recollection of what occurred between January 29 and February 5? That was practically the question the jury would have had to decide had the opportunity been given them.

WOOD'S STORY.

As Wood told it to me about seven weeks before the trial the following is the story:

On Saturday, Jan. 28, 1905, Wood, an iron worker and contractor in a small way, had a conference with two men, named respectively, Wolfe and Mack, the object of which was that Wood might obtain a loan of $1,000, the money to be advanced by Mack's father, who lived in Scarsdale, Pa. The conference took place at a schoolhouse in New York City, where Wood was doing some iron work, and no one except Wood saw either of the two men. Wood knew Wolfe pretty well. Mack he had known two years previously when working at Long Branch, where Mack was a foreman or engineer. Wolfe was a traveling man. Wood did not know where either of these men lived. Wolfe brought Mack to the conference, Wood having seen Wolfe the day before. As a result of the conference it was agreed that Mack should go with Wood to Scarsdale on the following Monday. Wood did not regard it as peculiar that Mack should endeavor to get the loan for him. As the trip was to take a week, the following day, Sunday, Wood moved his family from his flat in One Hundred and Thirty-first Street to the home of his wife's sister in Twenty-seventh Street. He himself slept in his flat that Sunday night and the next morning started out, according to the arrangement, to meet Mack at the Pennsylvania Railway ferry at Cortlandt street at 9:45 o'clock.

In the street he met Wolfe, although he had no appointment with him, and Wolfe told him that the arrangements were changed somewhat; that Mack had gone on ahead, and that he (Wolfe) and Wood would go together to meet Mack. Wood had $28 at this time. Wolfe went to do some errands for Wood. Wood went to the barber's and had his moustache shaved off, and at about 12 o'clock the two men met at Cortlandt street and took the train for somewhere, Wolfe having bought the tickets.. Wood did not know where they were going, nor did he notice the names of the few stations at which the train stopped. Wherever it was, it was a junction at which they were to meet Mack and thence continue the journey to Scarsdale with him. Arriving at the junction after about an hour on the train, Mack met them and they all went across the street to a resturant. Wood described the junction in some detail, but the description did not fit any junction near New York. At the restaurant they had something to eat and some beer. After the beer Wood remembers nothing till he woke up in the Tombs on February 5. On awakening in the Tombs he had no money. He had on a cap instead of a hat which he had started with, and a red sweater which he could not account for. The grip, which Wolfe had bought for him, and in which his things were, had disappeared.

Wood said that he had no definite recollection of anything that transpired between Monday, at the junction, and the following Sunday in the Tombs, but that he had a confused idea of a little dark man following him and leading him, of being continuously on the train, and of talking with his wife and children. He denied all knowledge of being in or near Plainfield at the time he was seen there; said he never had heard of Williams; that he had not had a pistol since the preceding August, when his own was stolen.

Such was substantially the story Wood told me. In what way he changed it in subsequent rehearsals will be referred to later.

SUMMARY OF WOOD'S REAL DOINGS.

What actually happened during the period referred to above, as testified to by witnesses at the trial, is as follows:

On Saturday, Jan. 29 Wood told his wife he was going to Searsdale with a Mr. Mack whom he had known slightly at Long Branch, and of whom Mrs. Wood had heard him speak several times. He was going to get some money, he said. Accordingly the family moved from One Hundred and Thirty-first Street to Twenty-seventh Street on Sunday, Wood going back to his own place to sleep and, probably, slept there. He was next seen at Blinn's Hotel in Plainfield, N. J., on Monday afternoon, where he registered in his own name, taking a room without board. He brought with him a valise in which were found subsequently, his business cards, letter heads, some toilet articles, and a box of 32 caliber cartridges. That evening he retired early. The next morning, Jan. 31, he hired a horse and sleigh with driver to take him to his grandmother's place at Mt. Horeb, and reached there before noon. He talked naturally with his grandmother, who said he was "never kinder or nicer." She said he had a wild look in his eyes. Wood's father-in-law, a Mr. Whitten, lived about half a mile from his grandmother, and after eating lunch at his grandmother's, Wood made a call on his father-in-law. Returning in a short while he paid the driver who had brought him out and told his grandmother he had business with his father-in-law and would spend the night with him, which he did. He said to his grandmother that a man named Mack had

The defendant in the case, George H. Wood.

gone to Pennsylvania after beams and when he came back there would be plenty of work. He said that if Mack didn't come by Saturday he would return to his grandmother's.

Wood returned to his father-in-law's house about 7 p. m. and spent the night there with him. The two men slept together and Wood went naturally to sleep. He laid before his father-in-law a proposition that he (Mr. Whitten), should come to New York and work for him as book-keeper, which proposition was accepted. He gave Mr. Whitten a $2 bill, which the latter said was an unusual performance. Otherwise he noticed nothing wrong with Wood, finding him exceptionally goodnatured and agreeable.

On the morning following Wood returned to his grandmother's. On the road he met a young man named Linnartz, whom he had known before and who was then working for his grandmother, Mrs. Pollock. Linnartz told Wood that he was going into Plainfield and would drive him in, which he did. On the way Wood took a revolver from his pocket and fired it three times, explaining that he wished to see if the dog which was following them was still gun-shy. He said the cartridges were blank. He had a cap in his pocket which he put on for part of the drive, saying it was too cold for a hat. On arriving in Plainfield he and Linnartz had a few drinks together and then Linnartz went home. That afternoon and evening Wood passed in the bar room of the hotel, talking, smoking and drinking with a number of persons. He was sociable and pleasant. At 11 o'clock the proprietor of the hotel shut up. Wood at first seemed disinclined to go upstairs, but finally did so without disturbance. There was no evidence to show that he was intoxicated at any time.

The day following, Feb. 2, was the day of the shooting. The hostler saw Wood leaving the hotel and exchanged "Good morning" with him. At about half past 9 that morning he stopped in the superintendent's office of the Kirke Iron Works, laid down his card, and inquired of the superintendent as to getting some contracts for iron construction, and after conversation relative to the iron trade, went away. He then stopped at a hotel on the outskirts of Plainfield and called for a drink of whiskey. He told the barkeeper that he wanted to go out to the Pollock place and the barkeeper directed him to Mr. Demler's, which was near by where he might find a conveyance. Mr. Demler lived next door to the house and grocery store of Williams, the victim of the tragedy. Coming to the grocery store Wood inquired for Mr. Demler, but was told that he was away. He then asked Williams if he would take him to the Pollock place and he hired Williams to do so. Before starting, and while Wood was near to and facing him, Williams took some money from his vest pocket and put it in a bag and then put the bag in his trousers' pocket. Williams drove and Woods was on the left hand side of the sleigh. A number of persons passed the two men driving on towards Mrs. Pollock's, Wood's grandmother.

At a point about a mile from Mrs. Pollock's the road is hedged in with trees, and although there is a house about 1,000 feet away, it is not visible from the road, nor the road from it. From this point, at about 11 o'clock, a farmer who was working in the woodshed of the house referred to, heard the report of a pistol. Shortly afterward, several men went down the road and saw the horse and sleigh standing still in the middle of the road, with the reins under the runner of the sleigh. Williams was sitting upright in the sleigh, alone and dead. He had been shot in the back with a 32 caliber bullet. The sleigh robes were wrapped around him, the clothes were not disarranged, his hat was on, and there were no signs of a struggle. Tracks were seen in the snow at the side of the sleigh as if a man had jumped out of the sleigh backward and had walked or run, using long steps in the snow by the side of the beaten track until he had passed the horse, and then again into the beaten track, then in the same direction along the road for a distance of about a mile. At times these tracks were close together, at other times a considerable distance apart, until they lead to a farmhouse. It is supposed that the person who made these tracks was Wood, and that he heard the sleigh bells of a neighbor coming toward him on the road and that he went into this place to hide. The tracks thence led in a straight line for two miles across country, over barb wire fences and through woods and different places, the snow being very deep, to a road which led to Millington Station. Near Millington Station, at about 12:30 p. m., a man was seen by three witnesses who at the trial identified him as Wood.

THE WIFE'S TESTIMONY.

That same afternoon, Thursday, February 2, about 3:30 o'clock, Wood appeared at his sister-in-law's house in West Twenty-seventh street. Relative to this his wife testified:

"When he came in he closed the door behind him and stood up against it; I looked at him and asked him if he got back, and he said 'Yes.' I saw he had a cap on, and I said, 'Where did you get the cap? Where is your hat?' and he said, 'I lost my hat and valise on the train,' and I said, 'Did Mack lose anything?' and he said, 'No, he had a little valise and he put that up in the rack, and I put mine in the aisle of the train and went to sleep, and when I woke up my hat and valise were gone, and this was all I could get.' I asked him if he got the money, and he said that they had went to Mack's father's, and that Mack's father told him that his money was all out in Summit,' and that they had started back. I said, 'Where is Mack now?' and he said 'I don't know where he is; I left him at Summit,' and he said, 'I was up in the mountains.' I said 'Did you see grandma?' and he said, 'Yes.' And I asked him how she was, and he said they were the same as usual. I said, 'Did you see Pop?' and he said, 'Yes!' . . . He told me he had to meet Mack at 9 o'clock that night when the train came in. My sister and my brother in-law were there. When my brother-in-law came in he said, 'Well, George, how did you make out?' and he said, 'I have not done with him yet.' Then we had supper. When we sat down to eat he only ate a little. . . . He just sat there as though he was thinking, and he looked so wild in his eyes; and he says, 'Well, I guess I will have to go now.' And I said, 'Why are you going so early if you are going to meet Mack at 9 o'clock?' and he said, 'I have a couple of other places to go to, and by that time it will be time to meet him.' I said, 'Will you come back tonight?' and he says, 'Yes, but if I don't happen to get back, don't wait up for me,' and the last thing he said going out of the door was, 'I will be back if I can get back.' And I said, 'All right, we will wait up for you.' And he did not come back all night." He did not return to his sister-in-law's until the next day, Friday, at about half-past 2 in the afternoon. Then he apparently had forgotten that he had been there the day before. His wife, in her testimony, continues: "When he came in I asked him if he had met Mack that night, and he looked at me and said, 'Met Mack? I wasn't to meet Mack.' And I said, 'Yes, you told me you were going to meet Mack at 9 o'clock.' 'Why,' he says, 'I have only just come over the ferry now.' I says, 'Why, you were here,' and he would not believe it, and I could not make him believe he had been there on Thursday. . . . He said he had been to Scarsdale, and to Mack's father's, and that they had started back from there, and I asked him if he had got the money, and he said 'No.' that Mack's father had the money out at Summit; he said that he had just come across the ferry from leaving Mack, and he told me that they went to some junction, he didn't know what junction. That they got off at this junction to wait for a through train, and while they were waiting they went in some restaurant or some place to get something to eat, and they had a glass of beer and something to eat, and he said that while they were drinking, why he didn't know no more from that time on, he didn't know where Mack went to and what happened to him. My sister and brother-in-law were in the house during this Friday afternoon and evening. . . .

"Two men came in and asked if my sister was Mrs. Bishop and Mabel said, 'Yes.' . . . And they said, 'Do you know of George H. Wood?' My husband was sitting there and he says, 'I am George H. Wood, what do you want?' And these men looked at him for a minute, and came in and closed the door, and they said, 'Have you not seen the papers?' And my husband said, 'Yes, I have seen them.' And they said, 'Don't you know detectives are looking for you?' And he said, 'No.' And they said, 'You are connected with that murder case out in Watchung, New Jersey,' and he looked at them so surprised, he did not know what to make of it, and said, 'What murder case?' and we got the paper and read it; and he did not seem to understand what they meant. And then they told him that there was a valise out in Plainfield at the hotel with his name on; and he could not understand how his valise had got in Plainfield. He said he had not been to Plainfield since last summer. Then they went on to ask him if he had ever known this man Williams, and all about it, and he told them just what he had told me.

"Then, while the reporters were asking questions, one of them says to me: 'Have you had your husband to a doctor since he came home?' I says 'No, sir.' . . . I took my husband to Dr. Ball on Twenty-eighth Street. He didn't want to go at that time. He said he would like to lie down and sleep. He said that his head ached him so he thought if he laid down and slept he thought he could think better. . . . I took him to the doctor's and he was told who he was, and I asked the doctor if he thought he had been hypnotized, and he said, 'No.'"

DR. BALL'S TESTIMONY.

Dr. Ball qualified as having had a certain amount of experience with the insane. He testified:

"This defendant came to my office accompanied by his wife and a gentleman who claimed to be a newspaper reporter; the request was made by the reporter that I examine this man Wood, without qualifying what kind of an examination it should be. I proceeded to examine him as to his physical condition. After a few questions it became apparent to me that

the man was suffering from mental defect. . . . My questions were not answered in a way which satisfied me that the man knew what he was talking about, and therefore my conclusion was that the examination was for his mentality, which I did in a rather cursory way, because it was a case concerning which, after the story had been recited to me, I did not wish to go on record, and I said very little about it at that time. As he came in I noticed he had a very shambling gait, and as he sat in the office his expression was one of complete mental apathy, looking into space. No questions of mine elicited what I would call a normal answer. His answers were rather of a negative type, all of them; his face was a complete blank, eye-balls sunken in the head and the pupils very much dilated; the whole physiognomy presented the appearance of a man who did not know what he was talking about. I had a chance to observe him for possibly twenty minutes, and maybe half an hour.. . . . Practically the same story that I have heard related here to-day was related in Wood's presence that afternoon, but Wood seemed perfectly oblivious, perfectly indifferent to what was going on. I could not arouse him to any concern or interest. . . . I had never seen this patient before that day and was not acquainted with any of his family. . . . As to his condition now as compared with what it was on February 3 last I should say physically he is a little thinner, but to me his mental appearance seems to be slightly brighter, he seems to have more expression to-day than he did that evening in my office, very much so.

CROSS-EXAMINATION OF DR. BALL.

Q.—"Now, supposing you had known at that time that a man had been riding with another man a few days before, and had shot and killed him, and then had made his way across the mountains to a station, and subsequently shaved his moustache from his face, and gone home, and that afternoon had been confronted by newspaper reporters with the charge that he was the person who was guilty of this murder, and immediately brought to your office, what would you say with respect to the effect it might have on his mentality, being of the character and nervous temperament he naturally was?"

A.—"I should rather have felt that the mental condition existed, and that he had committed the crime under that mental distress and disturbance."

Q.—"If you had known that he had been in a normal mental condition preceding, with no trouble in that direction, how would that have affected your judgment, or rather your conclusion, coupled with the knowledge of the occurrences I have narrated?"

A.—"Well, I should feel it was one of those very sudden forms of delusion or sudden insanity, possibly of the maniacal type."

Q.—"And it was impossible for you to tell at the time when that attack had gone, when the change had arrived?"

A.—"Quite impossible."

Q.—"Are these maniacal attacks characteristic of primary dementia?"

A.—"Not in the primary stage, hardly so, not ordinarily so."

Q.—"Then if that is so, your conclusion would be that at the time you examined him he was in a state of primary dementia, but unless you had some facts or circumstances warranting a conclusion otherwise you would not think that he had been previously in a maniacal state?"

A.—"I would not."

Q. (by the Judge)—"Is it possible or likely that any of these conditions you observed could have been feigned?"

A.—"I hardly think so, your Honor."

Q.—"What was the writing test?"

A.—"I asked him to write his name and address. When I handed him a pencil, in a blank sort of a way and with rather an inquiring glance he seemed to want to know what I wanted him to do, and when I asked him to write his name he made a few marks on the paper and handed me the pencil again. I shook my head and still insisted and handed him the pencil again, speaking loudly and distinctly, arousing him, so to speak, from the lethargy which was apparent; and he wrote his name in a very sprawling way; you could not know it; I would not be able to read it at all distinctly. I don't think it was in his natural hand, but that is only a conjecture of mine. I don't know how well he wrote before that, or whether he wrote at all."

Q.—"Did he give you the address?"

A.—"He wrote the address, Twenty-seventh Street, I think."

Q.—"Do you know whether it was correct or not?"

A.—"I do not."

Q.—"Is he suffering from primary dementia or was he only suffering at that time?"

A.—"I could not say. I have not seen the man except to look at him. I have not talked with the man since that day."

Q.—"Did he hesitate to do anything that you directed him to do on this examination?"

A.—"He did."

Q.—"In what respect any more than you have already stated?"

A.—"None, except as I have stated, so far as I remember at the present time—his hesitating answers, his hesitation in writing his address."

Q.—"Did he seem to be trying to aid you?"

A.—"Yes; he seemed not averse at all to aiding so far as he had the sense of perception to do so."

REPORTER'S TESTIMONY.

A reporter for the *New York World,* who was with Wood for some time Friday afternoon, testified that Wood did not look to be a man in the full possession of his senses. He said:

"He had a peculiar look in his eye; he was uncertain, vague and indefinite; and in questioning him his replies were indefinite. He could not draw on his mind sufficiently to answer properly, though he made the effort. Mr. Fuller, another reporter, and myself both appeared in the Twenty-seventh Street house together. We asked the questions alternately, as they suggested themselves to us. We asked Mr. Wood if he knew he was accused of murder; he looked at us in a surprised sort of way, and he said, 'What, me accused of murder? I don't know anything about it.' At that Mrs. Wood, who was present in the room with her three children, asked us what it was, and we pointed out to her a story in the first page of the *World* . . . and she read it to her husband, and he expressed a sort of surprise that the thing should concern him, and on questioning if he had been in that locality, he said, 'Why, I have not been in that locality for months.' Then we questioned him as to his doings from the Monday morning when he disappeared until his return, and he told the story as reported in the *World* on Saturday, Feb. 4, of having met an individual named Mack and going with him to the Pennsylvania ferry and there taking a train which he believed was for Scarsdale, Pa.; that he did not remember having reached Scarsdale; that he suffered seemingly a lapse of memory, but he rememberd getting off at a junction point. We stated a number of junction points along the Pennsylvania line, and he could not recall by name any of the junction points. We suggested several, Monmouth Junction, Princeton Junction, and such as we could recall at the time, but he could not concentrate his mind, and he said no, he did not believe it was any of those points. However, at that time he said he had not met Mack, or Mack's father, whom he was going to see to get $1,000. He remembered getting off at this junction and going to a restaurant and having something to eat. He then had a recurrence of his mind and said that he went to the depot and got on another line, and after that he suffered another lapse of memory, and if I recall correctly, in my story that appeared on Saturday morning, he said something about having arrived in Trenton, and then from the time he arrived in Trenton until he had a next recurrence of memory, I believe was in Elizabeth, if my memory does not fail me. But the facts as related in the *World* of Saturday were true."

Q.—"What were his looks, can you describe them?"

A.—"Well, his look is rather hard for a layman to explain. It was not the look, as I would say, of a sane person. I have had considerable experience in dealing with persons who were not of sound mind . . . and they generally have an odd expression in the eyes, and I can truthfully say that Mr. Wood had an odd expression in his eyes the night I saw him."

CROSS-EXAMINATION OF THE REPORTER.

Q.—"Aside from the look of which you have spoken, and the seeming loss of memory was there anything else which occurred to you at the time which indicated a want of understanding?"

A.—"No, sir, but I am not an expert on those points."

Q.—"He understood all of your questions?"

A.—"Yes."

Q.—"And he answered all of your questions?"

A.—"Yes, sir, as best he could."

Q.—"And you advised him who you were, that you were a reporter for the *World?*"

A.—"I told him, yes, sir."

Q.—"And he understood that?"

A.—"Yes, sir."

Q.—"And he realized that, he knew where he was, at home there with his wife and you?"

A.—"I don't know whether he realized that he was in his own home."

Q.—"He realized he was in New York City, did he not?"

A.—"Yes, sir, he was told he was in New York City."

Q.—"And he realized what you were there for, too?"

A.—"I believe that he did."

Q.—"You say his wife read the story in the *New York World?*"

A.—"That is, the small story the day after the murder of Mr. Williams."

Q.—"And did she read it aloud so that he heard it?"

A.—"She did."

Q.—"And did he make any comment on the story?"

A.—"No, he acted absolutely indifferent."

Q.—"Did he say nothing at all?"

A.—"I do not recall that he made any remark other than the statement I made a few minutes ago; he said that it was nonsense. He said, 'I was not within miles and miles of that place.'"

Q.—"He did not read that story himself?"

A.—"Not that I recall."

Q.—"Nothing was said at that time about Wolfe?"

A.—"No, sir, Wolfe's name did not enter into it."

Q.—"And he did say at that time that Mack had left New York with him, did he not?"

A.—"Yes, he left New York with Mack."

Q.—"Did he say to you that he not seen Mack's father in Searsdale, or that Mack's father had not the money which they wanted, but had invested it in Summit, N. J.?"

A.—"He said he remembered having got off at this junction point; he never remembered having reached Searsdale."

Q.—"Did he not say that Mack's father had invested his money in Summit, N. J.?"

A.—"That I do not recall."

DR. MAGUIRE'S TESTIMONY.

On Saturday, February 4, Wood, then a prisoner, was examined by Dr. Frank Maguire, physician to the New York City prison. After a thorough examination, Dr. Maguire testified:

"I believed him to be mentally competent and sound and sane at the time of that examination made on Feb. 4 of the present year at the city prison."

Q.—"Did he say anything about epileptic seizures?"

A.—"Denied it either in the greater or lesser form."

Q.—"What did you find about his memory and speech?"

A.—"He had no speech or memory disturbance; he had no paralysis or paresis."

Q.—"Any hesitation about answering questions?"

A.—"In a listless way."

Q.—"Any inability to comprehend or understand?"

A.—"No, sir. He understood everything properly and without much hesitation."

AUTHOR'S EXAMINATION.

I examined Wood at the county jail, Somerville, N. J., March 23, 1905.

In appearance he was rather pale, but well nourished and fairly robust. He presented no physical stigmata of degeneration, with the possible exception of prominent frontal teeth, and no marks of preceding syphilis. A slight tremor of the tongue was the only objective symptom. He said that he was 27 years of age, married, with three children, one of whom had had two convulsions at the age of 3; that his father, who was a nervous man and complaining, died of Bright's disease at the age of 54; that his mother, who was subject to nervous headaches, died of cancer at the age of 41; that he knew of no member of his ancestral family who had ever been alcoholic, insane or subject to fits. His only sister committed suicide on account of a love affair; his only brother died at 7 years of age from valvular disease of the heart.

Wood went to school till he was 12 years of age. At the age of 14 he began earning wages, and from that time he kept constantly earning a little more. He was married at 20, was domestic in his tastes and sober in his habits. With the exception of headaches, to be referred to later, he said his health was good.

At this examination Wood told substantially the same story regarding his period of alleged amnesia as has already been given. The most important variation was that, whereas the experts for the defense endeavored to make it appear that the man Wolfe was an evil genius of Wood's, that he had persecuted Wood for years, and that Wood feared and hated him, Wood stated to me that he and Wolfe were always friends, and that the only reason he had for doubting his friendship was that he had thought that, in view of the circumstances, Wolfe should come forward and substantiate Wood's story.

At the trial Wood testified that Wolfe was an illegitimate child of his father. He made no mention of Wolfe to his wife until after he had been some time in the Somerville jail. The first record of his speaking of Wolfe was to his counsel, when he was in the Tombs, in New York, five or six days after the murder. He further denied everything tending to show that he had delusions of persecution.

Of the two men, Mack and Wolfe, who figured so prominently in Wood's story, Mack was a real person who had employed Wood at Long Branch two years before, but had not heard from him since; as to Wolfe, there was no evidence at all that he ever existed outside the imagination, disordered or otherwise, of the defendant.

The only motive for the crime that the prosecution could advance was that Wood killed Williams for the money he saw the latter put in his pocket just before starting out on the sleigh ride. That no attempt was made to take the money from the dead man was explained by assuming that the murderer had been startled into immediate flight. There was considerable evidence that Wood was short of money at the time he left New York.

WAS WOOD IRRESPONSIBLE?

Three hypotheses suggest themselves, by any one of which Wood might be considered as irresponsible for his act. These hypotheses are: 1, Epilepsy; 2, amnesic automatism (non-epileptic); 3, insanity.

1. *Epilepsy.*—As to the theory that Wood was an epileptic, subject to seizures and periods of amnesic automatism, there was considerable evidence. At the time of my examination Wood's story in this respect was as follows:

At the age of 12, following an attack of scarlet fever, he first developed headaches. He said his head always ached, but that the pain became much worse at times.

In the past five years his headaches caused him to stop work 20 or 30 times. He said:

"My head aches continually, sometimes right down in the back, other times in front. Everything turns black when they get very bad. I can not stand up, get dizzy and have to go to bed. My eyes seem to pain, and at times I can not see anything. I am not sick at my stomach at these times, and very rarely faint. At different times I have lost consciousness for a few hours at a time. At some such times my wife has tried to arouse me and could not; she has been frightened and sent for a doctor. When the doctor came he said it was a headache. Sometimes these headaches come on suddenly and other times I know they are coming by an increase in the pain. I have fallen down in some of the headaches. Once I fell with a piece of hot iron across me, which my helper took off. I did not know I had got home till my wife fixed me up. This was four years ago. It has happened to me that after one of these attacks people have told me of things I have said that I remembered nothing about. Last September my partner Stevenson took me home from the Bronx in one of these attacks. He said I was talking with him at the time, but I remembered nothing about it. I was in that condition for one day. At other times I have told my men to do some work, and then not remembered having told them. The men thought I was lying about it. I never got in any trouble in any of these attacks, never fell to hurt myself, never had a fit, never found myself black and blue, have found my tongue sore in the morning sometimes, but never any blood on it. My wife has told me I had spells at night, but I don't know anything about it."

The testimony of Wood's wife in regard to epilepsy was substantially as follows: Wood at one time came home, saying he had fallen off a building. He was pale, vomited, and said he wanted to lie down. When he woke up, he did not know how he had reached home. Mrs. Wood testified to further spells which her husband had at night. He would get up out of bed, ask for a glass of water, be in a state of perspiration. He would ask his wife to speak to him, and then he would tell her that he knew what she was going to say. In the morning he would remember nothing about it. During these spells he had understood and intelligently answered questions. His wife did not consult a physician about these spells.

Wood's grandmother testified to his having had headaches for many years. On one occasion, when less than 13 years old, he fell out of a peach tree and lay on the ground for some time, "just like a corpse." In some of his headaches he "looked wild and talked strange."

Wood's aunt testified that on one occasion she found her nephew in a fainting spell. When he came out of it he asked where his wife was and he went upstairs to her.

Such was the evidence for epilepsy. No one had seen Wood fall, there was no evidence that he had ever had a convulsion. The only evidence that he had been in amnesic automatic states besides his own word (which was not substantiated by other witnesses) was that given by his wife, consisting in certain attacks he had at night. During these attacks he understood and answered questions. One of the experts for the defense elaborated an ingenious theory in support of epilepsy. It was to the effect that Wolfe had no existence, and only appeared to Wood just before a psychic epileptic seizure. Wolfe, therefore, was an aura, and after seeing him Wood was assumed to be in an epileptic state. Certainly the diagnosis of epilepsy on such meager symptoms, even were all motive to deceive absent, would be hardly possible. Such a diagnosis is made extremely improbable by the character of the crime itself and Wood's conduct after its commission.

Assaults and murders committed by epileptics during the periods of violence which may precede, follow or take the place of the fit are characterized by great ferocity and unreasoning violence, mutilation and multiplicity of blows. Soon after the deed is done the epileptic often falls into a deep sleep or coma. It is practically unknown for him to take elaborate precautions against detection. All the evidence in the present case went to show that the murderer acted with reason and intention. The deed was done with a single shot and without further violence; the body of the victim was undisturbed; the footprints in the snow left little doubt that the murderer had thought out means of escape. Wood had a mustache when he left Plainfield on the fatal morning. When arrested in New York the mustache had been shaved off, and some of his clothes were different from those he went away with. With all the facts in mind the hypothesis of epilepsy in explanation of this case seems absolutely untenable.

2. *Amnesic Automatism* (*Non-epileptic*).—It is extremely doubtful if non-epileptic amnesic automatism can ever be successful as a defense in criminal trials. It would throw the doors open to every crime being excusable by the criminal saying that he might have done it, but had forgotten all about it. That there are such amnesic states lasting considerable periods of time and uncomplicated by other motor or psychic phenomena of epilepsy, medico-psychologic annals abundantly prove. The patients perform complicated co-ordinated acts, retaining or changing their personality; they may associate with those who know them without arousing suspicion that their mental state is abnormal. After such periods, the memory of what transpired is blurred or indistinct. In certain cases some or all of the events can be brought to light by means of hypnosis. At the time of my examination an attempt was made to hypnotize Wood by Dr. H. B. Deady, late assistant director of the New York State Hospital's laboratory. Although Wood seemed to fall into a slight degree of hypnosis, he could not be made to disclose anything regarding the occurrences of the amnesic period.

In the cases of non-epileptic automatism or secondary consciousness which have come under my immediate observation, the patients have shown by their acts that they were controlled by the same fundamental morals in the secondary state as governed the primary or waking state. Some patients have been more irritable than usual, but none to the point of quarrelsomeness, and none have gotten into any trouble.

Experimental psychology tends to show that it is impossible, in artificially induced secondary states, to eradicate or even to overcome the inherited and acquired morals by which the individual has for years been guided in his normal waking consciousness. It is my firm conviction that no crime would be committed in a secondary state were not the individual a criminal at heart in his primary state, or a weak-minded person under the influence of strong and direct hypnotic suggestion. In the present case there was no question of such suggestion.

3. *Insanity.*—Mrs. Wood, in her testimony, said she had never thought her husband insane, and, leaving aside Wood's own fantastic story, there was very little evidence to support the theory of insanity. His wife said that, about one year before, after a young man and his wife who had been calling on them went away, Wood came to her and said that he had been married before, and the young woman who had just left was his wife.

The husband of the young woman in question, a Mr. Smith, testified that he had thought Wood peculiar. About a week after he (Smith) was married, he and his wife went to call on the Woods. Wood gave Mrs. Smith a very peculiar look as she came in. Later Wood told Smith that the sight of Mrs. Smith gave him a great shock. Wood said that he was married when 15 or 16 years of age, and he thought this Mrs. Smith was his wife. Later he began to question Mrs. Smith about her past. On another occasion he put his arm around Mrs. Smith, alleging that his first wife had a tender spot on her side, and he wanted to experiment to see whether Mrs. Smith were the person or not.

There was nothing in Wood's conduct while in prison or at the trial to suggest insanity. Neither delusions nor hallucinations were established. His memory, with the one notable exception, was excellent, his manner straightforward, his cerebration prompt. He seemed interested in his trial, but took no part in the conduct of it. He seemed affectionate and good natured.

But even with absence of definite proof, the most reasonable explanation of this remarkable case seems to be that Wood was insane. I have never been able to doubt that the story Wood told, clean cut and consistent as is was, was a fabrication and that he retained a full recollection of the period he said he had forgotten; I believe that he knew that he killed Williams and why. But I can not free myself from the impression that at the time that he fired the fatal bullet his motive was one that only an insane man would have acted on; that it was a product of some deep-seated delusion, which no one as yet has been able to discover.

The final disposal of the case was the most satisfactory one possible under all the circumstances. But by it is emphasized the necessity of the passage of a law by which criminals whose sanity is questionable can be placed for observation in hospitals for the insane before they are tried on the criminal charge. Such laws are successfully in force in Maine, New Hampshire, Vermont and Massachusetts.

In February, 1906, I visited Wood at the state prison, Trenton, N. J. He talked with me pleasantly. He said Wolfe committed the crime, and that he (Wood) was convicted by graft and by perjury. He said that now he remembered where he was at the time of the shooting, but that it was not in the neighborhood of Plainfield. His general appearance was the same as at the time of the trial. He laughed rather foolishly at times, and the tremor about face and tongue had markedly increased. In the shoe shop he had made the reputation of being a good workman, quiet, reserved and perhaps a little queer. His health had been good.

SUGGESTIONS IN REGARD TO DI-METHYL-AMIDO-AZO-BENZOL AS AN INDICATOR FOR FREE HYDROCHLORIC ACID IN GASTRIC ANALYSIS.

WARREN PHILO ELMER, M.D.
Instructor in Medicine, St. Louis University.
ST. LOUIS.

During the past few years several observers have noticed certain sources of error in determining the quantity of free hydrochloric acid in the gastric contents by the usual quantitative method, using di-methyl-amido-azo-benzol as an indicator.

1. The principal difficulty with this indicator is not its lack of delicacy, but the fact that certain organic acids found in the gastric contents will, when in proper concentration, give the same color change as does free hydrochloric acid. Especially has this been noted in regard to lactic acid, which is one of the most common organic acids found in the stomach under certain conditions. However, other acids give similar reactions, and the following table of organic acids which may be found in the stomach shows the concentrations in which the reaction appears:

Hydrochloric acid gives characteristic reaction diluted	1	to	13,000
Lactic acid gives characteristic reaction diluted	1	to	1,500
Phosphoric acid gives characteristic reaction diluted	1	to	1,200
Acetic acid gives characteristic reaction diluted	1	to	200
Butyric acid gives characteristic reaction diluted	1	to	100

From this table it appears that acetic, butyric and phosphoric acids could hardly be found in sufficient concentration in the gastric contents to interfere with the reaction. Lactic acid, on the contrary, is found rather often in such quantities, and herein lies the difficulty.

My plan to obviate this is as follows: First give a test meal which, as far as possible, is free from lactic acid. For this purpose the routine test breakfast which has been used for the last three years at the University Hospital at Ann Arbor, Mich., seems to be most satisfactory. This consists of one shredded wheat biscuit and 300 c.c. of water, given after a fast of eight to twelve hours and withdrawn from three-quarters to one-hour afterward. The acidity in a normal case is free hydrochloric acid 30, combined hydrochloric acid 2 to 10, organic acids 2 to 4, total acidity 40 to 45, in terms of decinormal sodium hydrate.

I have made tests of this meal outside the body as follows: Taking one shredded wheat biscuit with 300 c.c. of distilled water, I mixed them thoroughly and kept the mixture in constant motion at 37 C. for thirty, forty, fifty and sixty minutes, testing the filtrate at the above times for acids by the ordinary tests. Free hydrochloric acid was absent by all tests. Loosely combined hydrochloric acid was absent by all tests. Lactic acid was not in sufficient amount to give Uffelman's test, and the total acidity, consisting mainly of traces of lactic and acid phosphates, required from 1 to 2 c.c. of decinormal sodium hydrate to neutralize 100 c.c. of the fluid. This, then, is a practically lactic acid free meal, easy to give as a rule, not distasteful to the patient, requiring considerable mastication and of almost a constant weight.

The second difficulty, and in some cases the most important, is how to eliminate the error caused by an excess of lactic acid formed in the stomach. For this method I claim only approximate results, but its simplicity and the fact that it can be applied in conjunction with the ordinary methods, I hope, may recommend it to that class of stomach workers to whom time is an object. After many trials I found that the smallest amount of lactic acid that would respond to the di-methyl-amido-azo-benzol test was one part in fifteen hundred. The highest dilution which would give a characteristic Kelling test was one part in twenty-two thousand, or approximately fifteen times the dilution required to give the di-methyl-amido-azo-benzol test.

If, now, on diluting the stomach contents fifteen times with water and applying the Kelling test no reaction is obtained, there is no danger that the lactic acid present will interfere with the di-methyl-amido-azo-benzol test for free hydrochloric acid. If the Kelling reaction be positive, there must be at least .07 per cent. lactic acid, or enough to change the result of the di-methyl-amido-azo-benzol test for free hydrochloric acid by at least seven points. If this be the case I dilute again with an

equal volume of water and again apply the Kelling test, which, if positive, represents .14 per cent. or fourteen points.

Dilutions can also be made by making the second dilution one-half the volume of water in which a positive reaction represents at least ten and one-half points or one-fourth the volume of water, in which a positive reaction represents at least eight and three-fourths points, and so on. The amount of lactic acid thus obtained is subtracted from the free hydrochloric acid obtained and the result is approximately correct for free hydrochloric acid.

The question now presents itself, Will a quantity of lactic acid not sufficient to give the test with di-methyl-amido-azo-benzol unite with the hydrochloric acid in producing a vitiated result? To determine this point I added .05 per cent. of lactic acid to a solution of hydrochloric acid of known strength, titrated, using di-methyl-amido-azo-benzol as an indicator and obtained practically the same readings as before adding the lactic acid.

By this method of procedure the ordinary di-methyl-amido-azo-benzol indicator can be used at all times, and when lactic acid is present the results can be sufficiently rectified for clinical purposes.

612 North Taylor Avenue.

THE BLOOD PLATES.

THEIR ENUMERATION IN PHYSIOLOGY AND PATHOLOGY.

GEORGE T. KEMP, M.D., Ph.D.
Professor of Physiology, University of Illinois.

WITH THE COLLABORATION OF HENRIETTA CALHOUN, A.M., AND CHESTER E. HARRIS, A.M.
CHAMPAIGN, ILL.

(*Concluded from page 1027.*)

Bizzozero.—The reagent which commonly goes by the name of Bizzozero's fluid consists of a 0.75 per cent. aqueous solution of sodium chlorid, to which is added a small amount of methyl violet (about 1 part to 5,000).[12] This was not recommended by him for numeration work. Bizzozero preferred the Laker method, and the fluids he used for determining the ratio of the plates to the red corpuscles are described differently in different publications we have consulted. In referring to some of his old experiments made by himself in 1884, and in collaboration with Sanquirico in 1886, Bizzozero[14] states that the fluid used was made in accordance with the following formula:

1.0 per cent. osmic acid, aqueous solution	1 part.
0.7 per cent. sodium chlorid, aqueous solution	3 parts.

In referring to the same experiments in another article he[28] gives the percentage of the sodium chlorid solution as 0.1 per cent. This we take to be a misprint and regard the 0.7 per cent. as more probably correct. Pizzini[29] quotes from Bizzozero's text-book[30] that the fluid recommended is 1 per cent. osmic acid colored with methyl violet. For criticisms on these fluids see acid, osmic, above.

In addition to these osmic-acid fluids, Bizzozero also recommends a 14 per cent. solution of magnesium sulphate in water. We have tried this and find that, while it preserves the plates, the red corpuscles are distorted and sometimes buds are shed from them.

28. Bizzozero: Virchow's "Festschrift," 1891, p. 472.
29. Pizzini: Riforma medica, 1894, vol. ii, p. 376.
30. Bizzozero: Microscopic Clin., Third Edition. Year, page and full title not given.

Brodie and Russell.—Brodie and Russell[26] have usually employed a mixture of equal parts of glycerin saturated with dahlia and a 2 per cent. aqueous solution of sodium chlorid. This gradually decolorizes the red corpuscles, but the ratio can be determined before this occurs. This liquid is used without a counting chamber. We have tried this method and found that it gave good results.

Cadet.—Cadet[31] used iodized serum and also a fluid which he calls "liquid B," for which we quote his formula:

Distilled water	1000 gm.
Sodium sulphate (pure)	25 gm.
Sodium chlorid	5 gm.
Chloral hydrate (pure)	25 gm.
Chromate de soude[32]	0. gr. 20

All the ingredients must be pure. The chromate de soude must be weighed exactly. Filter each time before using. We have not tried this fluid. It was tried by van Emden, who says he prefers the Prus fluid without stating any definite objection to the fluid of Cadet.

Chromates.—With Müller's fluid and potassium bichromate solutions (6 per cent., 4 per cent. and 1 per cent.), we found that granules are formed after a time, and these, under a low power, may cause confusion in counting the blood plates.

Determann.—In most of his experiments. Determann used a 0.9 per cent. aqueous solution of sodium chlorid, colored with methyl violet. This is practically the same as Bizzozero's old fluid. It is not a fixative, and our experience with it leads us to condemn it for numeration purposes, though we can recommend it as a convenient fluid for examining the plates. It retards their breaking down, but does not prevent it. Determann's method has been fully discussed in this paper.[33] Determann also used a solution containing 1 per cent. sodium chlorid and 5 per cent. potassium bichromate. We have not tried this particular combination. Our experience with chrome-salts is given above under Chromates.

Fusari.—Fusari[23] used the following fluid: Equal parts of 1 per cent. osmic acid and 0.75 per cent. NaCl solution, colored with enough methyl violet to give the mixture a slight violet tint (leggera tinta violetta). Later he substituted an aqueous solution of Na_2SO_4 (specific gravity 1025) for the 0.75 per cent. NaCl solution in the above, and says that this makes a first-class preservative fluid (un ottimo liquido conservatore). Even with this he records cases where the plates were clumped in groups and a fresh preparation had to be taken. He counted 400 small squares of the Thoma-Zeiss instrument.

Hayem.—Hayem's[34] fluid A, which he recommends for counting the red corpuscles, and which is generally known as Hayem's fluid, is made in accordance with the following formula:

Mercury bichlorid	0.5 gm.
Sodium chlorid (pure)	1.0 gm.
Sodium sulphate (pure)	5.0 gm.
Distilled water.	200.0 gm.

It is not a good fluid for counting the blood plates, as it often produces a precipitate which is confusing. The fluid used by Hayem in most of his blood-plate numerations was the iodized serum of Max Schultze. But this is difficult to prepare and when not properly made it is unfit for use.

For Schultze's iodized serum Hayem substituted the

31. Thèse de Paris, 1880, pp. 36-38.
32. This line is copied literally from Cadet's recipe. We are in doubt as to whether he means chromate or bichromate. The "0. gr. 20" is also exactly quoted.
33. See II. under Methods.
34. Hayem: Arch. de Physiol., 1878, vol. v, p. 700; also Hayem, Du Sang, Paris, 1889, pp. 16, 28, 31 and 38.

amniotic liquid of cows and of sheep. This is carefully prepared in the winter and kept in Pasteur flasks until needed. He uses "eau oxygenée" (peroxid of hydrogen) as a preservative, and when blood plates or leucocytes are to be counted he adds a small amount of methyl violet 5 B. Hayem also used diabetic urine of specific gravity at least 1039. To this was added 6 per cent. of "eau oxygenée à 12 degrés."

The latest fluid which we have found Hayem[35] to recommend is one which, he says, is particularly adapted to human blood. It is made by preparing an iodin solution according to the following formula:

H_2O (distilled)	500 gm.
KI	25 gm.
I (metallic)	excess,

and replacing the mercury bichlorid in fluid A by 3.5 c.c. of this iodin solution.

Of the several fluids which Hayem has used we have tried only one, viz., his fluid A. We agree with him that it is not to be recommended for blood-plate numerations on account of the precipitates which it produces.

Those fluids which require elaborate methods for preparation and for preservation are obviously objectionable from a standpoint of convenience.

Helber.—Helber,[10] continuing some older work of Pratt, each in Professor Krehl's laboratory at Tübingen, used a 10 per cent. solution of sodium metaphosphate. Each of these observers found that the blood plates floated in this liquid, and so it can not be used with the Thoma-Zeiss counting chamber, as the plates and the lines are not in focus at the same time. This led to the construction of a special counting chamber by Helber.[36] Even with this special instrument, Helber does not say that the objection is entirely removed.[37] In using as high an objective as a twelfth, we feel that any fluid of such high specific gravity as to allow the blood plates to float would be extremely inconvenient and would probably introduce an error even when the counting chamber was dispensed with,[38] for the thickness of the layer of blood would be sufficient to keep the plates and the red corpuscles out of distinct focus at the same time. The solution does not keep well, it "must be made fresh every three days, and filtered each time before using."

Kemp and Calhoun.—See under "Aldehyd, formic."

Laker.—Laker[39] used Hayem's fluid A. See under Hayem.

Metaphosphates.—See Helber, Pratt, and Richardson.

Muir.—Muir[40] tried a number of different fluids and prefers an aqueous solution of sodium sulphate (specific gravity 1022), colored with methyl violet. We have tried this fluid, combined with formaldehyd, as recommended by Marcano for red corpuscle numerations, and find it effective in that form. We have not tried it in the form used by Muir.

Petrone.—Petrone[41] uses an osmic acid fluid containing salt. We do not find a definite formula, but in one place he gives the strength of the osmic acid as 1:300.

Pizzini.—Pizzini[20] used 1 per cent. osmic acid colored with methyl violet. He says that antipyretics, especially phenacetin or antipyrin, 25 centigrams to 100 c.c. of water, using heat to effect the solution, have the power to preserve blood plates almost like a solution of osmic acid.

Pratt.—Pratt[9] first used a 10 per cent. solution of sodium metaphosphate. He[9] later used a 5 per cent. solution of the same salt, and in his last communication,[42] presented at the same meeting with this work, he recommends a fluid made in accordance with a formula which we quote as follows:

Sodium metaphosphate (Merck)	2.0 gm.
Sodium chlorid	0.9 gm.
Distilled water	100.0 c.c.

We have never used sodium metaphosphate solutions for numeration experiments, but we have had considerable experience with them in repeating the work of Deetjen on the alleged ameboid movements of the blood plates.[43] We have found that all these solutions are very prone to ferment and to become mouldy. Helber states that they should be made fresh at least every three days, while Richardson says a week. Pratt's work has been painstaking and valuable, and his partiality for sodium metaphosphate leads us to believe it may have some special merit. We, therefore, propose to try this salt in combination with sodium chlorid and formaldehyd. This would have the double advantage of placing such a fluid in the more certain class of fixatives and of preventing fermentation and molding altogether.

Prus.—The original paper of Prus is in Polish, so we were not able to consult it. The only German abstract[44] which we have seen does not give the method in detail, but van Emden[4] recommends the use of Prus' fluid, so we take it for granted that he used the Prus method. This is really the pipette method, but using a fluid which preserves the plates and decolorizes the red corpuscles. With the red corpuscles thus eliminated from obstructing the view, one can use a dilution as low as 1:20 or even 1:10. According to van Emden, this brings an enormous number of plates into the field and reduces the error so greatly that the plates which are lost by sticking to the sides of the pipette may be ignored. By using a refrigerated pipette, van Emden can bring this error practically to *nil;* for at zero centigrade the plates will not adhere.

The recipe for Prus' fluid, as quoted from van Emden, is as follows:

Sol. acidi osmici (1 per cent.)	10 c.c.
Sol. acidi chromici (0.1 per cent.)	10 c.c.
Acidi acetici glacial	1 c.c.

We have not used this method, but we are impressed with the advantage of counting a large number of plates and thus reducing the error. The inconvenience of refrigerating the pipette will always be a drawback in clinical work, and without this we should always distrust the method, for the error varies with the temperature and the time it takes to measure the blood. Moreover, the pipette method not only holds back plates by adhesion, but tends to clump those which go free. In using Prus' fluid, van Emden mentions a precaution which is significant, and which tends to shake one's confidence in the method. He says that vigorous shaking in the melangeur produces a large number of small highly refracting bodies which might be mistaken for blood plates. He attributes what he calls a high count by Prus (500,000 per cu. mm.) to this cause.

Reyne.—Reyne[45] criticises the iodized serum of Max Schultze (used by Hayem) as a fluid for examining or

45. Reyne: Thèse de Paris, 1881, pp. 18-19.

counting the plates. He says it is unreliable. "Some specimens are good and others are absolutely bad without one's knowing why or how to remedy it." Reyne uses diabetic urine containing from 6 to 7.5 per cent. glucose. This is boiled and filtered through animal charcoal. To this liquid thus decolorized is added 5 to 6 per cent. of its weight of "eau oxygenée à 12°" (peroxid of hydrogen?). This preserves the corpuscles and does not deform the plates. The only objection that he urges to it is that it forms small bubbles of gas on standing. See, also, Hayem above.

Richardson.—Richardson[46] used Laker's method with the following solution:

Sodium metaphosphate	1.5
Sodium chlorid	0.8
Distilled water (sterilized, cold)	100.0

Filter and add, if desired, a small amount of gentian violet or brilliant cresyl blue. The solution will not keep well for over a week and should not be used if mold develops in it.

Salvioli.—Salvioli[16] used a fluid made according to the following formula:

Osmic acid (1 per cent.)	1 part.
Sodium chlorid (0.7 per cent.)	3 parts.
Aqueous solution of methyl violet, q. s.	

This is practically the same as Bizzozero's counting fluid. See Bizzozero and Acid, osmic, above.

Van Emden.—See Prus, above.

III. AUTHORS' METHOD IN DETAIL.

The fluid used in this method has been described under Aldehyd. The following apparatus and accessories should be ready for use before making the puncture to draw the blood:

Microscope with nose-piece, and at least one objective of low power, not lower than two-thirds; and one of high power, not lower than a one-sixth. A Thoma-Zeiss outfit for counting red corpuscles (two counting chambers would be preferable). Several thoroughly cleaned watch glasses (deep facet-form, about 25 mm. diameter, most convenient). One such watch glass full of the aldehyd fluid. One such watch glass containing three or four drops of this fluid. A glass rod about 5 mm. in diameter, about 15 cm. in length, and rounded at the ends. A clean soft towel. A clean handkerchief or rag, soft and unstarched.

In collecting blood for counting the blood plates, the great desideratum is that all parts of the blood drop shall come in contact with the aldehyd before touching any foreign object (surface of skin, glass, etc.). This is really a *sine qua non*, for otherwise some of the blood plates will adhere to the foreign body, and of those which go free some are sure to be found clumped.

If the finger is to be used for the puncture, the hands are washed with soap and water and dried thoroughly several minutes before the experiment. This is to allow the circulation in the finger to become normal. If the hands are clean this washing is unnecessary. A minute or two before the puncture is made the finger is dipped for, say half a minute, in a solution of carbolic acid, about 1 per cent., rinsed with clean tepid water and dried on a clean soft towel or handkerchief. This is also unnecessary, but it prevents soreness following the puncture, and when the fingers are pricked several times a day, for days or weeks continuously, it is a point well worth taking into consideration. Washing with absolute alcohol, followed by ether, is an unnecessary trouble. The finger must be thoroughly dry, however, otherwise the drop will spread. The best place to make the puncture is on the thumb side of the left index finger, a little distal to the root of the nail, and decidedly more towards the palmar than the volar surface. Make the puncture (most conveniently done with the ordinary spring-lance with a spear-shaped blade), and try to regulate the depth so that blood will just not flow without gentle pressure being applied to the finger. The method of procedure now differs according to the depth of the puncture. If the blood emerges the moment the lancet is withdrawn, it should be wiped away promptly with a clean rag, leaving no trace of blood on the skin. If the observer is working alone, on his own finger, a situation like this is inconvenient. He may do one of two things: either make a fresh puncture, not so deep, on another finger and proceed as will be described below for puncture of the proper depth; or he may fill a fresh watch glass about one-third full of the aldehyd fluid, and then, after wiping all blood from the finger, touch the point of puncture to the surface of this aldehyd, and withdraw the finger the instant a fresh drop of blood emerges. The blood and aldehyd are then mixed thoroughly for a few seconds with the glass rod, which must be scrupulously clean, and a large drop of the mixture transferred on the rod to the counting chamber.[47]

This transfer must be accomplished rapidly. A thin clean cover-glass is now laid on, and the chamber allowed to rest quietly for five minutes before counting. This method will give good results, but one can judge better the mixing of the blood and the aldehyd if the puncture is just of sufficient depth for the blood not to flow without gentle pressure. In this case, if working alone, the puncture having been made, proceed as follows:

Twist the handkerchief into a rope. Hold the left hand thumb uppermost, and place the handkerchief in the crotch between the thumb and index finger, with about 15 to 20 cm. lying across its palm, and the rest hanging over its back. Now hold the index finger straight and close the other fingers to grasp the handkerchief firmly in the palm. Wrap the handkerchief two or three times around the index finger, beginning at the base and stopping at the last joint; then pass the rest of the handkerchief across the palm and hold it in place with the free fingers. This should be so regulated as not to exert any marked pressure on the index finger, which is kept straight all the while. If any blood has appeared from the puncture, wipe it off thoroughly, with the free end of the handkerchief. Dip the rod in the watch glass full of the aldehyd fluid, and convey about three good-sized drops to the surface of the finger over the puncture. Now bend the last joint of the index finger, and press against the end of the thumb if necessary. This will cause a drop of blood to exude into the aldehyd. Mix the two *in situ* by passing the end of the rod gently across the top of the blended drop. Do not force the rod into the drop so as to crowd the rod against the blood, or the blood against the finger. Do all this rapidly, and then, on the rod, carry a drop of the blended fluids to the watch glass containing a few drops of aldehyd. Here mix again, without hesitating to dip the rod in liquid, for the plates are fixed by this time, and the watch glass is simply a convenient vessel for farther dilution. Now carry on the rod a large drop of the diluted blood to the counting chamber, and lay on the cover-glass. The same manipulations that apply for getting an even distribution of the blood in erythrocyte counts apply here. The height of the chamber and the flatness of the cover-glass have no bearing on the accuracy, for the object is not to count the absolute number of anything in a known volume, but simply to determine the ratio of the plates to the red corpuscles. After the cover-glass is in position, take a bird's-eye view of the field, first with the low, then with the high power. If the corpuscles are fairly well distributed, allow the chamber to rest quietly for five minutes before counting.

The beginner is apt to take too much blood and not to dilute it enough. The dilution should be such that the red corpuscles do not conceal the plates when both shall have settled to the bottom of the chamber. There should not be more than one or two plates to a small square on the ruled area. The plates settle more slowly than the red corpuscles; hence the five minutes' wait. A longer wait does no harm, for both blood plates and

46. Richardson: Journal of Med. Research, 1904, vol. xiii, pp. 99-102.

47. Salvioli employed a rod coated with paraffin, though for a somewhat different method. We find that for our purpose it is not necessary to use paraffin, but the rod must be clean and smooth, and must be wet with aldehyd before it touches the blood.

red corpuscles are fixed and preserved by the aldehyd. While the chamber is standing for the settling of the blood plates, we may proceed to numerate the red corpuscles in a different counting chamber, or, if the size of the corpuscles be normal, as in healthy blood, by the hematocrit. The aldehyd fluid we use for the plates makes an excellent counting fluid for the reds, so that no other need be prepared.

It is our custom to count both red corpuscles and plates in six frames of sixteen small squares each. This usually gives about 100 blood plates. In this matter we are guided by our judgment, just as when counting the red corpuscles. If a bird's-eye examination shows the plates and corpuscles to be evenly distributed, and four frames in different parts of the field all give the same ratio, we have, in a few instances, stopped with four frames, while if the distribution was not so regular we have sometimes counted the whole sixteen.

It is a serious mistake to count too few, especially when there is no ruled field under the corpuscles to give an idea of their distribution. The work of some authors is open to this criticism. Petrone,[48] has for instance, in one of his experiments, bases his ratio on as few blood plates as thirty-two. This, we feel, is too small a number to eliminate the error of chance-distribution. When, as in some diseases, the number of blood plates is abnormally low, a larger number of frames should be counted.

Our method of numerating the blood plates without using the Thoma-Zeiss chamber has been given.[49] Our experience in this work has been large. We have used it for the past five years in repeated observations on the number of blood plates in blood of twenty-three different healthy individuals; in experiments on the disappearance of the blood plates during coagulation, in which we employed the method of fractional defibrination,[50] and in an extensive work on the regeneration of blood after hemorrhage—which is yet unpublished.

We were also members of a party of six which went from the University of Illinois to Cripple Creek and Pike's Peak to study the effect of altitude on the blood. In this work we made daily counts of the blood plates for all six of the party for six weeks. A preliminary report of this research is all that has thus far been published.[51] As a result of this experience we can assert that we have a method which is practical, and which is accurate to such a degree that it will detect many changes in the blood of pathologic cases; changes which should be of value in diagnosis and in prognosis, as well as in etiology.

IV. THE NUMERATION OF THE BLOOD PLATES IN PHYSIOLOGY.

Numeration experiments on the blood of normal individuals have yielded widely different results. We believe this to be due, in the first place, to the different methods employed. This is the explanation which has almost invariably been given, and we do not wish to underestimate its importance, but we are now in the possession of data obtained from our own experiments which lead us to believe that there is another factor which, so far as we know, has been hitherto overlooked, viz., the season and place in which the experiments were made. Our researches have included work done in France, in Switzerland and in different parts of America. In company with Messrs. Stanley, Hayhurst and Draper, we formed a party which went from the University of Illinois to the Rocky Mountains to study the

* We regret that we have mislaid most of our notes on Cadet's counts. His paper is for the present inaccessible, so we quote him indirectly through Hayem, and van Emden. His tables include the work of Hayem and some of his students, as well as Cadet's own. Hayem says that any plate count which does not fall between 200,000 and 300,000 must be considered abnormal.

† Determann does not give actual figures; we have calculated them from the ratio for the sake of comparison.

‡ Muir gives these figures as a mean, and says that considerable latitude must be allowed on each side. He does not give the extremes. Muir also worked on dogs, but we have not his figures for these experiments in our notes, and Muir's paper is inaccessible to us at present.

|| Oster is quoted by Helber, without giving reference to the original work, so we are unable to consult it.

§ These figures are calculated by us from Pizzini's tables. They are means.

¶ Pratt gives these ratios, but indicates that there is a much wider divergence. For this reason we have not calculated the number of plates represented by them. The actual plate counts which Pratt gives in this paper range from 217,000 to 496,000.

** For Prus' method see under Prus, in section on Methods.

51. Kemp, Stanley, Hayhurst, Harris, Calhoun and Draper. Report of an Expedition, etc., Am. Jour. of Physiology, February, 1904, vol. x, p. xxxii. In the presentation of our paper at the Portland session, I gave a considerable account of this altitude work, and still more was brought out in the discussion. It was expected that I should incorporate a full report in the present publication, and it was my intention to do so. I regret, however, that pressure of other work has prevented me from bringing the literature up to date, and from preparing the manuscript. This must, therefore, be reserved for a future publication.—Kemp.

effect of altitude on the blood. We found that high altitudes have a profound effect on the blood plates; their number is enormously increased, even more than that of the red corpuscles. The full report of that expedition has not been published,[51] but all notes taken at this time have been worked up, and we may anticipate our report by saying that we believe there are other climatologic conditions beside altitude which affect the blood plates and their relation to the red corpuscles. This will be discussed further on in the present communication, but it is well to bear it in mind in comparing the discrepant results which have been obtained by observers in the past.

For convenience of comparison we have compiled the preceding table. The date of the observation can be told by referring to the literature in the footnote. The actual number of blood plates may be obtained by multiplying the number in column 2 by 1,000. The method employed is given in the third column. The fluids used may be found in connection with the names of the observers arranged in alphabetical order under Fluids. Each method and each fluid is criticised in accordance with our experience, so we will not comment further on the relative value of the results. A word of caution is necessary in comparing the results in Column 2. Some of the observers have given the maximum and minimum counts which they have ever obtained. Others have given the limits within which they usually find the blood plates to vary. The means in either case are safe to follow; where no mean is given, it indicates that the observer has likely not stated his actual highest and lowest counts.

On comparing the results in Column 2, it becomes apparent that the results of Kemp and of Kemp and Calhoun are more widely divergent than those of any other observer. These facts were, of course, known to us before the figures were tabulated. Without an adequate explanation they would prove that our method could not be relied on. As a matter of fact, however, in examining our records to find an explanation, if possible, we have come on a new and valuable generalization. In our observations (12 in the table) it will be noticed that the plate count for dogs is lower than that for man. On general principles this should not be true, and it occurred to us later that possibly the season might have something to do with it. The plate counts which we had recorded on human blood were practically all made during the winter. The work on the dogs was done in May, June and July in connection with some experiments in fractional defibrination. On looking over our records for human blood we find this fact: that the ratios we have determined in winter have almost invariably been higher than those we found in summer. Moreover, there is less variation from day to day in winter than in summer. This is strikingly shown by some observations which we made in Champaign and Urbana, Ill., before going to Cripple Creek and Pike's Peak to study the effect of altitude. The ratio of plates to reds for the six in the party is given in the following table:

RATIO OF PLATES TO REDS.

Date.	Kemp.	Stanley.	Hayhurst.	Harris.	Calhoun.	Draper.
July 7....	1 : 44	1 : 19	1 : 20	1 : 23	1 : 18	1 : 22
July 8....	1 : 40	1 : 18	1 : 19	1 : 20	1 : 18	1 : 19
July 9....	1 : 36	1 : 21	1 : 20	1 : 20	1 : 20	1 : 20

NOTE.—The variations in Kemp's record are excessive. Nothing comparable to them had been observed in his blood during the winter.

Exactly the same thing holds good at high altitudes, only there we have an increase in the red corpuscles, by the side of a still greater increase in the plates. At high altitudes the variation from day to day in the blood plates of a given individual was remarkably small. In some observations made by one of us (Calhoun) at Escanaba, Mich., during a long-continued spell of dry, very cold weather, it was found that the blood plates behaved much as they did at a high altitude—that is, they not only increased in number, but increased in size. The counts given by Kemp (10 in the table) were made in Paris during the summer. The previous winter counts on his blood were part of the observations of Kemp and Calhoun (12 in table), when the ratio and the plate counts in his blood ran nearly twice as high. A given altitude in the Alps, surrounded by snow, produced a different effect from a corresponding altitude in the Rocky Mountains at the same time of the year. There is great need for careful researches in this field, and they should be long continued and not fragmentary. We propose to continue them ourselves as opportunity affords.

Before passing from this subject we should like to say a word concerning the results which we have quoted from our experiments before going to the mountains. The ratios 1:44 and 1:40 are the highest we have ever obtained for normal blood, and they stand almost alone. The man (Kemp) on whom the count was made was apparently in perfect health, and there was absolutely nothing subjective to indicate such a condition except the oppressively hot and sultry weather. The count is undoubtedly correct; it was verified by three of the party working on blood from punctures in three different places. In all there were five separate counts made on that blood and they all agreed. It is interesting to note that both red corpuscles and hemoglobin were far from normal also, the red corpuscles were 4,400,000, the whites 4,500, the specific gravity 1061.5, and the hemoglobin 56 on the Fleischl scale.

One important fact is set forth by this, viz., that a single abnormal blood plate count should not be taken as indicating a serious pathologic condition. The count of the blood plates for that day was 100,000, and we will see in the section on pathology, which is to follow, that this would have been taken as an indication of a condition more or less serious.

MEALS AND DIGESTION.

The effect of meals on the count of the blood plates has been studied by a number of observers, but their results are not on accord. The experiment most frequently quoted to show that the number of blood plates is influenced by digestion is that of Hayem,[66] who made observations on two adults and one infant. For the adults he found the number of blood plates to be as follows:

First adult—
Morning, fasting.....216,500
One hour after first breakfast (café au lait)*.....216,500
One and one-half hours after this breakfast.....350,000
One and one-fourth hours after second breakfast†.....185,000
Three and one-fourth hours after second breakfast.....198,000
Four and one-half hours after second breakfast.....231,000
Second adult—
Morning, fasting.....186,000
One and three-fourths hours after first breakfast (as above).218,000

*This probably consisted of two large cups of hot milk with coffee and one or two French rolls with butter and honey or jam.

†This corresponds to our (hot) lunch, usually taken about 11 o'clock.

With the exception of the isolated count of 350,000 we believe all the other figures to be within the limits of error, and the second case shows no such rise to prove that the first was due to digestion. Hayem is properly conservative in discussing these results,[67] so that he is really misquoted when he is

66. Hayem: Arch. de Physiol., 1878, vol. v, p. 723.

67. Ce n'est qu'un aperçu très-imparfait de l'influence des repas. . . . Il sera necessaire de faire un très-grand nombre d'observations . . . car les hématoblastes ne sont jamais répartis d'une façon très-égale dans la préparation.

placed with those who think that digestion influences the number of plates in the blood. We have before us notes from the records of several observers who have investigated this question, but except in prolonged hunger or after a "gorge" no results have been obtained which are not within the limits of error, so we shall not take the space to quote them.

Our own observations have been confined to the effect of the noonday meal. For some of the subjects this was lunch (corresponding to Hayem's "second breakfast"); for others it was dinner. The afternoon counts tend to be a trifle lower than those of the morning, but they were within the limits of error, so we agree with those who say that meal time, as such, has no effect on the number of plates in the blood. On Pike's Peak (altitude 14,200 feet) we noticed enormous differences between morning and afternoon counts, but we do not believe that mealtime had anything to do with this, for we all ate a hearty breakfast and no counts were made fasting.

V. THE NUMERATION OF BLOOD PLATES IN PATHOLOGY.

We are strongly of the opinion that the blood plates, in pathology, offer a field for investigation which is unusually attractive in its promise of good results. This field is like a rich country which has been undeveloped owing to the lack of railroads. The methods which have been employed heretofore in numerating the blood plates have been either inaccurate or laborious or both. We believe that our method removes each of these objections to a large extent, and we trust it will be of service in opening up the new territory.

The literature on the numeration of blood plates in pathology is becoming voluminous. It contains records of some work which is of great value, and of some which is almost if not quite worthless, owing to faulty methods. On the other hand, some of the observers who have employed faulty methods have accompanied their records with clinical histories which are very complete, and their findings for the blood plates are, on the whole, interesting and suggestive in spite of errors of experimentation. We first attempted to classify this work under the heads of the different diseases, but gave it up, as it would require such a discussion of individual cases as to be far beyond the scope of a general paper on the subject. We next attempted to classify the work under the heads of diseases in which the plates are increased and those in which they are decreased in number. We abandoned this, also, because it would do more harm than good simply to quote A, B and C as finding that the plates were increased in erysipelas, for instance, while D, E and F found them to be decreased. This has been done in existing literature, and on consulting the original papers we find that A employed a method which could not be trusted; that B makes his statement from observations on only one case, while C gives clinical histories showing complications which would certainly have to be allowed for. We have gone over all the literature which we have seen recorded, and, therefore, hope that we are reporting the subject up to date. After deliberate consideration we are convinced that the best way to present this information is by authors, arranged in alphabetical order. The reference in the footnote will give the year. We will state the method and the fluid employed, so that one may judge of the accuracy of the experiment by referring to the first section of this article for the method, and to the second section for the fluid. We will also state the number of cases reported by a given author, and the footnote will show by page where these records may be found. The list of diseases investigated by each author will be given in the same order as it appears in his paper. This will save undue multiplication of footnotes. The study and criticism of the case records, etc., in any given disease, must be left to those who are making that disease a special subject of investigation. There are a few general points which seem to be concurred in by practically all observers. These will be given at the close of the article in the summary.

Afanassiew.—Afanassiew[68] used the pipette method (E) with Afanassiew's fluid. He reported cases as follows:

Leucemia	1 case	Erysipelas, facial	1 case
Typhoid fever	5 cases	Pleurisy, suppurative	1 case
Gastric ulcer	2 cases	Icterus gravis	1 case
Anemia, chronic	1 case	Scurvy	1 case
Tuberculosis	1 case	Pneumonia, croupous	1 case
Cachexia, malarial	1 case		

Aoyoma.—Aoyoma[69] makes no count and gives no special method. His method is presumably A, Section 1. He states that the blood plates are increased in bubonic plague.

Cadet.—Cadet[70] used the pipette method (E), with fluids described under "Cadet." He reported pathologic cases, especially continued fevers.[70]

Denys.—Denys[71] did not make actual counts. The method used is not stated. He reported four cases of purpura hemorrhagica.

Determann.—Determann[72] used the ratio method (G and H), with Bizzozero's fluid. He reports 85 pathologic cases, and gives clinical and postmortem notes. His cases are:

Fibroma	1 case	Chlorosis	5 cases
Struma parenchymatosa	1 case	Anemia	1 case
Phthisis pulmonalis	8 cases	Hemorrhage (chronic)	2 cases
Bronchitis (acute)	4 cases	Sarcoma	1 case
Emphysema	1 case	Serositis tuberculosa	2 cases
Heart disease, (different forms)	2 cases	Peritonitis (perforation)	1 case
Syphilis	1 case	Tuberculosis (bones and joints)	4 cases
Lead poisoning (chronic)	1 case	Anus preternaturalis	3 cases
Gastric catarrh (chronic)	1 case	Empyema (rib-resection)	1 case
Nephritis (chronic), interstitial	2 cases	Pregnancy	8 cases
Polyarthritis deformans	1 case	Childbirth	2 cases
Sclerosis, (multiple)	1 case	Infancy (newborn)	3 cases
Cerebral tumor	1 case	Icterus neonatorum	1 case
Spinal disease (chronic)	2 cases	Pyemia	1 case
Hysteria	1 case	Typhoid fever	4 cases
Apoplexy	1 case	Erysipelas	1 case
		Rheumatism, (acute art.)	2 cases
		Pneumonia	7 cases

Fusari.—Fusari[73] used the pipette method (E), with fluids recorded under Fusari. He reports the following cases:

Pneumonia	3 cases	Sea-sickness	3 cases
Typhoid fever	3 cases	Scurvy	2 cases
Intermittent fever	4 cases	Ankylostomiasis	2 cases
Articular Rheumatism	1 case	Pseudoleucocythemia	2 cases
Pleurisy	2 cases	Leucocythemia	1 case
Nephritis	3 cases	Anemia	6 cases
Ascites	1 case	Chlorosis	5 cases
Tuberculosis	5 cases		

Grawitz.—Grawitz[74] reports that he has found the plates to be increased in chlorosis. He uses the expression "*soweit man nach Schätzungen urtheilen darf*," and when criticising the results of previous observers who had made actual numerations, he mentions no method of his own, so we surmise that he used method A as already described.

Halla.—Halla[75] uses the method of direct examination (A); but he is so conservative that we quote him to show that some results even when obtained by a faulty method may be of value. He says: "Familiar as I was with the blood plates, I could not help noticing them in my examination of the blood (for other purposes) in pathologic cases." He goes on to say that he does not attempt any exact count, but by rapid examination of the blood, as soon as possible after it is drawn, before the plates have greatly altered in shape, he could de-

rmine "without difficulty," whether the number of plates as above or below the normal. We would be inclined to ubt this, especially the "without difficulty," and to feel that alla's observations were too finely drawn, but when he states, rther, that "only the grossest, most striking quantitative anges" were taken into account, we feel that such general- ations, based on a sufficiently large number of observations, e not to be discarded as entirely without value. The patho- gic cases which he reports are the following:

neumonia (croupous) . 14 cases	Meningitis (suppurative) ..... 1 case
eurisy (acute) ..... 1 case	Tonsilitis ..... 1 case
uberculosis, "very many"	Smallpox ..... 1 case
number not given)	Scarlet fever ..... 1 case
eritonitis (acute) ..... 2 cases	Malaria fever (tertian) ..... 1 case
neumatism (acute ar- ticular) number of cases not given	Typhoid fever ..... 15 cases
ysipelas (facial) ..... 2 cases	

Hayem.—Hayem used the pipette method (E), and several fferent fluids which are described under his name. His ublications on pathologic cases are scattered through a wide iterature, but he has gathered his results in his classic large onograph,[76] and his findings in the different diseases may be nsulted in the proper chapters. He has also published a ter work[85] in which he brings his treatment of the subject up date. Hayem may be said to have re-discovered the blood ates,[77] and his earlier work was the starting point for the odern study of those elements. His hematoblast theory has ot met with acceptance, but, apart from this, his pioneer re- arches on anemias,[78] on purpura hemorrhagica[79] and on a blood isis[80] in certain fevers[81] have yielded results which have been nfirmed by nearly every later observer, whatever has been e method employed. (See summary, at the end of this ticle).

Helber.—Helber[82] used the pipette method with a special unting chamber. These are described in methods E and J. he fluid he used is described under his name. He reports the llowing cases:

nemia (simplex) ..... 4 cases	Hysteria and neuras- thenia ..... 5 cases
nemia (schwer) ..... 5 cases	Sclerosis (multiple, com-
ilorosis, number of cases not given.	plicated) ..... 1 case
eudoleucemia ..... 1 case	Gangrene of lung ..... 1 case
urpura hemorrhagica .. 1 case	Spondylitis ..... 1 case
uberculosis, number of cases not given. Six cases described particularly.	Basedow's disease ..... 1 case
	Typhoid fever ..... 1 case
	Scarlet fever ..... 1 case
rcinoma ..... 3 cases	Erysipelas ..... 1 case
omach and intestinal diseases, (chronic), number of cases not given.	Sepsis, number of cases not given.

Howlett.—Howlett[83] used the pipette method (E), with owers' hemocytometer for counting the plates in normal ood. He reports one case of pernicious anemia, in which he ys the number of plates was sometimes normal and some- nes away below. He does not say he counted the blood in is case and from the context we judge that he used method B, or D. If D, he probably diluted with Hayem's solu- on A.

Laptschinsky.—Laptschinsky[84] did not count the plates. is experiments were mostly on ordinary wet preparations and refers to the "granular masses of Max Schultze" rather an to the isolated plates. This work was before Hayem's aper which brought the plates into prominence.

Muir.—Muir[85] used the pipette method (E). His fluid is scribed under his name. He has examined pathologic blood in "upwards of one hundred cases." The results of many of these examinations he has not published, but the more im- portant ones he has tabulated and often has added very full notes. His tabulated and annotated cases are as follows:

Hemorrhage ..... 9 cases	Leucocythemia ..... 3 cases
Anemia (pernicious) ... 12 cases	Lymphadenoma ..... 7 cases
Chlorosis ..... 14 cases	Cases with high tem-
Anemia (secondary) .... 11 cases	perature ..... 5 cases
Anemia (miscellaneous) . 5 cases	

Pizzini.—Pizzini[86] used the ratio method (G and H), with an osmic acid fluid as described under his name. The patho- logic cases examined by Pizzini were as follows:

Tuberculosis ..... 3 cases	Cancer (stomach) ..... 1 case
Rheumatism (articular acute) ..... 2 cases	Cirrhosis of liver (with ascites) ..... 1 case
Diabetes ..... 1 case	Mitral stenosis ..... 1 case
Pneumonia ..... 4 cases	Aortic insufficiency ..... 1 case
Pleurisy (with old effu- sion) ..... 1 case	Erysipelas (facial) ..... 1 case
Pleurisy (with ascites) .. 1 case	Anemia (simplex) ..... 2 cases
Leucemia ..... 1 case	Tetanus ..... 1 case
Epilepsy ..... 1 case	Pneumonia (with men- ingitis) ..... 1 case
Myelitis ..... 1 case	Malaria (tertian) ..... 2 cases
Pleurisy (dry) ..... 1 case	Malaria (quartan) ..... 2 cases

Pratt.—Pratt[87] used the ratio method (G and K), with a fluid described under his name. The pathologic cases which he reports are:

Purpura hemorrhagica ... 1 case	Chlorosis, number of cases not mentioned.
Leucemia ..... 8 cases	
Anemia (pernicious) .... 10 cases	Erythrocytosis, number of cases not mentioned.
Anemia (secondary), number of cases not mentioned.	*Severe* hemorrhage, number of cases not mentioned.
Leucemia myelogenous, number of cases not mentioned.	

Prus.—Prus[44] counted the plates by the pipette method (E and G), but he used a special fluid, described under his name, which made his method unique. He reports four cases on leucocythemia.

Preisich and Heim.—Preisich and Heim[88] report one case of pernicious anemia, in connection with their studies on the origin of the blood plates.

Riess.—Riess[89] does not count the plates, he simply states whether they are increased or decreased. We infer that he used method A. Riess' work is among the earliest; it was done before any definite method of counting the plates had been suggested. He reports on the following diseases, the number of cases is not given:

Anemia (pernicious).	Profuse hemorrhage (repeated).
Anemia (simplex).	Leucemia.
Chlorosis.	Pseudoleucemia.
Cachexias (such as cancer).	

Salvioli.—Salvioli[10] uses the ratio method (G and K). His work was on the blood after severe burns.

Schleip.—Schleip[90] used method D. He reports fifty-seven cases of trichinosis during the Homburg epidemic of 1903.

Türk.—Türk[91] used method A. The plates were never counted. The blood was taken undiluted and in thin layers (at a room temperature) and examined as quickly as possible. Türk himself points out that this method is very defective owing to the adhesive properties of the blood plates. He does not attempt to give numbers, but simply speaks of the plates as "reichlich vermehrt," "kaum vermehrt," etc. He also checked his observations by the examination of dry prepara- tions. See method D.

Van Emden.—Van Emden[92] used method F, with Prus' fluid. We feel that his results are trustworthy. His records are accompanied by interesting clinical notes. The cases which he reports are as follows:

Scarlet fever ..... 3 cases	Tuberculosis ..... 4 cases.
Typhoid fever ..... 3 cases	Tuberculosis (miliary) .. 2 cases
Malaria ..... 6 cases	Meningitis (cerebrospin- al) ..... 2 cases
Erysipelas ..... 2 cases	
Cardiac diseases* ..... 20 cases	Scurvy ..... 1 case
Liver cirrhosis ..... 2 cases	Purpura hemorrhagica ... 1 case
Pneumonia, number not given.	

*These cases involve so many interesting complications that we can not classify them here. The reader is referred to the original.

SUMMARY.

From a great mass of conflicting evidence, most of it obtained by methods of questionable accuracy, we may cull three important generalizations which are almost unanimously agreed on—whether the method of the observer was good, bad or indifferent. We, therefore, feel it safe to predict that they will become established facts. It is interesting, furthermore, to note that these were all pointed out by Hayem, who was the first to make approximately accurate numeration experiments on the blood plates.

The first of these generalizations relates especially to acute infectious fevers; the second, to different forms of anemia; the third, to purpura hemorrhagica. We will consider each in order.

Acute Infectious Fevers.—During the course of an acute infectious fever (especially typhoid) the number of blood plates is usually either subnormal or normal. If the fever breaks by crisis, the crisis is accompanied by a rapid and striking rise in the number of blood plates. This is the classical "crise hématique" or "crise hématoblastique" of Hayem. If this "crise hématique" fails to appear, it is the sign of some masked complication which is usually unfavorable. Most observers have found that this is true of all acute infectious diseases, but all are practically agreed on typhoid.[93] The study of the plates in pneumonia has been especially interesting. As a rule, observers have found a marked blood crisis, but they are not in accord as to whether the plates are increased or diminished during the continuance of the fever. On some other fevers there has been a wider divergence of opinion. The study of the leucocytes in fevers has attracted considerable attention. We believe that further investigations on the blood plates in fevers would lead to valuable results, besides being of use in diagnosis and prognosis for the cases under observation.

Anemias.—In the different anemias, there is a remarkable concurrence of opinion that the plates may or may not be diminished in secondary anemias—indeed, in most cases, they are reported to be increased; while in pernicious anemia they are always greatly diminished. An increase above the normal in the number of the blood plates excludes the diagnosis of pernicious anemia. If a case under treatment shows an increase in the number of the blood plates, the prognosis is encouraging; if, in spite of all that can be done, the plates continue to fall in number, the prognosis is almost certainly fatal. In this connection we can not do better than quote from the latest work of the veteran observer Hayem,[94] who speaks with especial emphasis on the study of blood plates in anemias. He says: "It is certainly wrong to neglect these elements. When their number becomes small it is always a more or less serious sign; when they become rare the retractability of the clot diminishes. . . . This double lesion rarity of the hematoblasts [blood plates] and loss of retractability of the clot) is a sign of progressive pernicious anemia, and is the most characteristic sign which we have of this protopathic form." If this double sign does not exist, the proper treatment will effect a cure and one of the first signs of improvement is a rise in the number of blood plates. If the case continues to improve, further interesting changes are noted in the relation of the plates to the red corpuscles; small red corpuscles appear in increasing numbers and there is every indication that young red corpuscles are developed from the plates.[95] Hayem's observations, so far as the numerical relations of the blood plates are concerned, have been confirmed by a number of observers, including van Emden and Pratt, whose methods of numeration are free from the objections which apply to the older method of Hayem.

Purpura Hemorrhagica.—In purpura hemorrhagica the number of blood plates is enormously diminished. Van Emden and Pratt each state that the lowest counts they have ever found have been in this disease. Hayem called attention to the slowness in clotting of the blood. Helber confirms this observation of Hayem. To distinguish the blood in purpura hemorrhagica from that of pernicious anemia, Hayem[96] says that, in the absence of appreciable changes in form in the red corpuscles, "the scarcity of hematoblasts [blood plates] and the absence of serum after the coagulation of the blood, are two signs which are constant and pathognomonic" of the disease. The few plates which are found are often of large size. The blood contains masses of small plates, but these are broken down. Fibrin threads in the clot are few, but coarse. Recovery is ushered in by a "crise hématoblastique."

93. Van Emden agrees with the rest in finding a "crise hematoblastique" in typhoid, but he says it is much less marked than in pneumonia, scarlet fever, measles, and erysipelas. In malarial fever (Sumpfieber) the "crise hématoblastique" resembles that of typhoid.

94. Hayem: Leçons sur les maladies du Sang, Paris, 1900, p. 328 et seq.

95. Hayem's discussion of this whole question is most interesting; the text is illustrated by a curve showing the changes in the different corpuscles and in the hemoglobin. It will well repay one to consult the original.

96. Hayem: Leçons sur les maladies du Sang, Paris, 1900, pp. 530 et seq., and 540.

APPENDICITIS; IDEAS CONCERNING ITS MANAGEMENT, BASED ON ONE THOUSAND OPERATIONS.*

VAN BUREN KNOTT, M.D.
SIOUX CITY, IOWA.

It is not my purpose to enter into an exhaustive dissertation on the subject of appendicitis. The field has been most thoroughly covered during the past few years, and so far as its etiology, pathology, symptomatology and diagnosis are concerned, the opinion of the profession may for practical purposes be said to be in accord.

This can not as yet be said, however, concerning the treatment of the disease, as honest differences of opinion still exist, many of them varying only in degree, but sufficiently marked to convey to numerous members of the profession the idea that the treatment of appendicitis is a subject still more or less *sub judice*.

Actuated by the belief that the various phases of the question—how shall we manage our appendicitis patients?—may be best answered by a study of the methods employed by various men, I venture to add my testimony to the large mass of evidence already in print.

During the years 1893 to 1905 inclusive I have operated on 1,024 cases of appendicitis. Of this number 640 were clean cases and 384 were pus cases. By clean cases I mean those in which the infection was still confined within the appendix; by pus cases those in which the infection had escaped from the appendix and established a septic process, localized or diffuse. Of the total

* Read at the annual meeting of the Western Surgical and Gynecological Association, Kansas City, Mo

mber 993 patients recovered and thirty-one died—a ortality rate of 3 per cent. Among the clean cases, ute or chronic, 640 in number, 639 recovered and one ed—a mortality rate of one-sixth of 1 per cent. Among e pus cases, 384 in number, 354 recovered and thirty ed—a mortality rate of 8 per cent.

It seems no more than fair to state, in passing, that ore than half of these operations have been made dur- g the past six years, and the mortality rate secured is ecause that fact has permitted the application to these tients of greatly improved methods of treatment, nong which may be mentioned posture and drainage.

Believing that appendicitis is a surgical disease, I ve always been an advocate of immediate operation, d have followed the rule of operating on every case as on as seen unless the patient was practically moribund, ith the exception of some few cases, presumably of mild pe, in which the patient presented well-marked contra- dications to any surgical procedure and it was thought advisable to operate under any circumstances. This, brief, is the plan still employed, and increas- g experience tends to strengthen my belief in it. very death from appendicitis must be charged to the count of procrastination or negligence, and the re- ponsibility for its occurrence falls on the family of the tient, his medical attendant, or the surgeon. The pa- ent or his family may to some extent evade this re- ponsibility by pleading ignorance. At this late day, d in the light of the vast array of evidence accessible all, what shall be the excuse of the physician who was lled early? It is absolutely impossible for any man, owever great his experience, to prognosticate accurately e course of any given case of appendicitis from its in- ption, but it is within his power to promise speedy and rtain recovery to every case of appendicitis operated sufficiently early.

It is not my intention to take up at length this line argument, although sufficient excuse for it is found ily in the obituary columns, and the necessity for the ppendicitis missionary has by no means ceased to exist.

CLASSIFICATION OF CASES.

For practical purposes we may divide our appendicitis ses into two classes—clean cases and pus cases—the rmer including all cases either acute or chronic in hich the infection is still confined to the appendix, and e latter including cases in which a septic process, ther circumscribed or diffuse, has been established with e appendix as its point of origin.

From the standpoint of results I have found no dif- rence between an acute clean appendicitis and those the so-called chronic type, as in 640 operations on ses of both varieties made at all stages of the disease here the infection was confined to the appendix, there as but one fatality, and that was charged to the fact at I had the night before operated on a patient suffer- g with a violent streptococcic infection of the face and eck, and although scrupulous pains were taken to pre- nt infection, the patient on whom I made a simple terval appendectomy died in forty-eight hours of acute iffuse septic peritonitis, and streptococci in large num- ers were found in the peritoneal fluid.

As to the pus cases, the results which are now being ecured in cases of diffuse septic peritonitis have render- d it much less formidable and have done much to bring ore nearly together the mortality of circumscribed and preading peritoneal infections which are the result of ppendicitis. I have had more deaths from localized ppendicular abscesses operated on during the past few years than from the series of cases of diffuse peritonitis. This of course may be partially explained by the much greater number of cases belonging to the first type which are encountered at operation and yet it is a striking illustration of recent surgical progress, for it is only six or seven years since practically all our patients with diffuse septic peritonitis died.

I am unable to estimate as yet the respective death rates for cases of circumscribed and widespread peritoneal infections, but am positive that the difference is very much less pronounced than formerly. Excluding those cases which are moribund and those in which definite contraindications to any operation exist, the treatment of acute appendicitis is preoperative and operative.

PREOPERATIVE TREATMENT.

As soon as the diagnosis of appendicitis is made, the head of the bed should be elevated at least twenty inches and the patient turned sharply on the right side. In the event of unavoidable delay in getting the patient into the hands of a man competent to make the operation, this posture will greatly assist in localizing and confining escaping infection to the region of the appendix. An ice bag should be applied to the right lower abdomen and all feeding immediately discontinued. An enema may be given if desired, but I am strongly opposed to the administration of a cathartic in any case of acute appendicitis prior to operation. I have seen many cases in which much harm has been done by the peristalsis thus set up, and as we can never be certain of the exact condition within the abdomen I do not consider it safe to "give a cathartic early" as is so frequently advised. What is early when we are considering appendicitis? I do not know unless it is the day before the disease began.

Then there is the question of morphin. Under no circumstances should a patient be given morphin at this stage. The price he may have to pay for his indulgence is too great and need not be longer dwelt on. If in any particular case operation is not to be considered, morphin might be administered, but never until the diagnosis has been established.

Whenever possible all patients should be removed at once to the hospital.

No operation should be made for appendicitis at the home of the patient when it is possible, without loss of too much time, to place him in a well-regulated hospital. As a rule it is safe to state that a patient who is not too ill for operation is not too ill to be moved. The elevated position of the head and trunk and the inclination of the body to the right should be maintained during the journey.

OPERATIVE TREATMENT.

The operation should be performed as soon as the diagnosis has been made and a competent man secured to do it. I do not recommend operations on these cases by inexperienced men. The mortality rate could not be more certainly increased in any other manner. The attempt to put a time limit on appendicitis and to decide to operate on this case because it is only "twenty-four hours old," and to postpone operation in that one because it "is the fourth day and a dangerous time to operate" has been overdone. I have seen several cases of appendicitis in which the first symptom noticed by the patient doubtless made its appearance at the time of perforation of the appendix, yet these cases were in much less promising condition for operation at the end of the first twelve hours than many other cases would be on the third, fourth or fifth day.

The only cases in which operation should be deferred

are those in which the patient is plainly dying from sepsis and those cases of diffuse septic peritonitis so far advanced that the shock of the anesthetic and even a brief operation will prove fatal. These patients, and fortunately they are few compared to the total number seen, should be treated after the plan advocated by Ochsner and described under preoperative treatment, following which, should improvement occur, they may be operated on several days later.

All cases of diffuse peritonitis, which is still spreading, should be operated on at once. The fact that the infection is not confined to the region of the appendix is not sufficient excuse for delay in these cases, as rapid removal of the offending organ with thorough cleansing of the soiled peritoneal area, followed by proper posture and free drainage, will permit a more rapid and a smoother convalescence than can be secured for those patients who have a mass of firm adhesions about the cecum, which limit necessarily the first attempt at operative relief to incision and drainage, followed by a more or less extended period of suppuration, attended by the ever present dangers of extension of the septic process and intestinal obstruction.

Cases of localized abscess should be operated on immediately. The practice of waiting for the adhesions to become more firmly established is condemned. While waiting for the adhesions to become stronger the pus may break through into the general peritoneal cavity, necrosis of the pus bathed loops of intestine is invited, and if these accidents do not occur and the adhesions do become very dense and firm, the prospect of making the operation a radical one, with removal of the appendix, is diminished and the likelihood of postoperative obstruction is increased. If the adhesions are sufficiently established to warrant the diagnosis of a localized abscess they are sufficiently established to permit that abscess to be as properly managed at the immediate operation as at one deferred for one day or a week.

Attention is again directed to the fact that early operation on a clean case removes at once the source of the disease and prevents the many distressing and often fatal complications and sequelæ, among which may be mentioned incomplete operations, protracted convalescence, hernia, sepsis, peritonitis, pylephlebitis, abscess of the liver and postoperative obstruction. These and many more are penalties still too frequently imposed on the patient by some one's procrastination, and the pity of it all is that they could and should have been avoided in nearly every instance.

OPERATION.

In clean cases, either acute or chronic, the incision is made through the sheath of the right rectus muscle. The incision provides free access to the appendix, may be easily extended at will with a minimum of trauma, and is much preferable to the so-called McBurney or muscle-splitting incision.

The meso-appendix is ligated with catgut and a circular ligature of silk is thrown about the base of the appendix flush with the cecum. A pair of hemostatic forceps is placed distal to this ligature and the appendix cut away between ligature and forceps. The stump is wiped perfectly dry and its mucosa thoroughly swabbed with 95 per cent. carbolic. The stump is then covered by drawing over it the base of the meso-appendix or a fold of the cecum and retaining them in position with catgut sutures. The stump is never inverted into the cecum, as it does not seem to me to be advisable to invite infection of a raw surface by deliberately placing it in the foulest repository within reach, despite the fact that the various methods of preliminary treatment of that stump are said to have removed its absorbing power. I have had no trouble with subsequent infection of the silk ligature and the persistence of a sinus after operation.

The wound in the abdominal wall is closed with a continuous suture of No. 2 ten-day chromicized catgut, including first the peritoneum and posterior sheath of the rectus, and then carried back through the anterior sheath of that muscle and tied. The skin is closed with horse hair.

INFECTED CASES.

From the standpoint of operative treatment we may consider three varieties of cases in which the infection has escaped from the appendix with or without perforation of that organ: 1, A more or less localized peritoneal infection in which the general peritoneal cavity is not protected by limiting adhesions; 2, An infection sharply localized and circumscribed, the general cavity of the peritoneum being protected by a wall of adhesions; 3, A diffuse widespread infection of the entire peritoneal cavity.

1. Abscesses Not Sharply Localized: The existence of the first variety may or may not be suspected prior to operation. It is frequently encountered in cases which we hope will prove clean. In such cases the incision should be extended well down toward the pubes, as the following steps of the operation, which should be rapidly performed, are much facilitated thereby.

The appendix is ligated and removed and the stump disinfected and buried as already described. The portion of the peritoneal cavity involved in the septic process is then rapidly, but very gently, mopped dry with gauze packs wrung out of hot sterile water, not forgetting the cul-de-sac, which in these cases will always be found to contain a large quantity of fluid varying in character from serum to sero-pus.

In females the cul-de-sac is then rapidly opened and a large split rubber drainage tube, one-half to one inch in diameter, introduced into the vagina. The abdominal wound is closed with interrupted silkworm gut sutures. The patient is placed in bed, the head of which has been elevated at least twenty-four inches from the floor. The drainage is removed in from six to ten days, depending on the course of the case. The age of the patient need not be considered in establishing this form of drainage. I have employed it in several cases of this kind occurring in girls under five years of age.

In males a large split rubber drainage tube, five-eighths to one inch in diameter and carrying a strip of iodoform gauze which must fit quite loosely, is introduced at the lower angle of the wound to the bottom of the rectovesical pouch. Alongside this a smaller tube one-fourth inch in diameter is placed likewise leading to the bottom of the cavity. These tubes are anchored to the skin with silkworm sutures. Through the plain tube the fluid which tends to accumulate at the bottom of the cavity is aspirated every two hours until the quantity secured at two or three consecutive dressings is insignificant when aspiration is discontinued. The employment of this second tube in the manner just described greatly lessens the demand on the capillary drain of tube and gauze.

The patient is placed in bed in the elevated posture above described. If at the operation it is ascertained that the infection is practically confined to the peritoneum of the right lower abdomen and pelvis the pa-

tient is turned on his right side and kept in this position for at least twenty-four hours. In the class of cases at present under discussion, namely, those of more or less limited infection of the peritoneal area surrounding the appendix and sometimes accompanied by adhesions which are too limited to protect the general peritoneal cavity from infection, no drainage of any sort other than that described above is ever employed. There is no reason for placing a drain in the space formerly occupied by a perforated appendix which has already communicated its infection to an area greater than such a drain can relieve. The source of the infection having been removed, the region of the cecum requires no particular and special drainage. The peritoneum from this point to the bottom of the pelvis has become involved, and, if by placing the patient in the elevated posture we secure the gravitation of fluids to the lower peritoneal pouch, that is the point to drain. Multiple drains mean multiple adhesions and greatly increase the tendency to postoperative obstruction. The introduction of strips of iodoform or plain sterile gauze for quarantine purposes may be necessary in a few cases of this type in which for some reason it has been impossible to dispose satisfactorily of the stump, or when the tissue in the immediate vicinity of the appendix makes one suspicious of approaching necrosis or gangrene. Gauze is a most useful agent when employed for the purpose of isolating septic areas, but most useless when called on to act as a drain, and should never be depended on alone for the latter purpose. Since abolishing the use of gauze in these cases, with the above exceptions, and draining them in the manner just described I have noticed that convalescence is much more rapid and smooth and the danger of troublesome complications has been materially lessened.

2. Abscesses Sharply Localized: In these cases where the septic process is sharply circumscribed and shut off from the general peritoneal cavity by a wall of limiting adhesions the safe evacuation of the products of infection and the successful guidance of the patient to complete and permanent recovery present many and varied problems, among the most important of which are:

a. Shall we incise over the most prominent portion of the abscess and establish drainage without opening the general peritoneal cavity, or, as recommended by Murphy, shall we always open into the cavity to the inner side of the pus collection, coffer-dam the field of operation and then establish drainage?

b. Shall we remove the appendix or not?

c. How may we best prevent contamination of the general peritoneum?

d. What form of drainage shall we employ?

e. How shall we prevent hernia?

f. Shall we in every instance make a second operation for the removal of the appendix where it was considered improper to attempt its removal at the first?

In reply to question *a* I must say that I think neither procedure should invariably be followed. The plan of attack must be adapted to the particular case in question.

Roughly speaking, we may divide these cases into two classes. First, those in which the abscess is situated external to the cecum. Second, those in which it is located on the inner side of the cecum. It has been my practice in all cases belonging to the first variety to incise directly over the most prominent portion of the tumor, using every precaution not to expose the peritoneal cavity. In nearly every case this may be accomplished and the pus safely evacuated without extravasation. Sudden cessation of the outward flow of pus during such an operation should be considered as indicating the possible rupture of the abscess at another point into the general peritoneal cavity. Should such an accident have occurred it is imperative that it be recognized and properly dealt with immediately. I have had four or five such cases. When the abscess is situated on the inner side of the cecum in practically every instance I open the peritoneal cavity to the left of the tumor first. The field of operation is then completely encircled with strips of plain sterile gauze. Each strip consists of four thicknesses of gauze three inches wide, with the free edges sewn fast. These strips extend from the bottom of the cavity well out on the anterior abdominal wall and when in place remind one of the old fashioned well with its brick or plank sides. Through this wall of gauze the pus may always be conducted safely to the surface. The best way to accomplish this is to make the opening into the abscess so small at first that the pus may be taken up by cut gauze sponges as rapidly as it escapes. When the pus cavity is practically empty the opening may be enlarged as necessary. The gauze strips are left in position to be removed with the drainage from the fifth to the tenth day, depending on circumstances. Coming to question *b*, concerning the removal of the appendix, I consider that no invariable rule should be established. As my experience has increased I have more and more frequently removed the appendix at the first operation. Many cases are encountered each year, however, in which it is considered inadvisable to attempt to remove the appendix at this time. This is a question which must be decided by individual operators in any given case entirely from their own experience.

The third question has been answered already in describing the evacuation of the abscess. As to the question of drainage, all drains employed in such abscess cavities should be of soft rubber, of good size and with walls sufficiently thick to prevent the collapse of the tube and obliteration of the drain. Glass tubes are not recommended because of their rigidity, which in some of my earlier cases was responsible for the appearance of fecal fistulæ. Gauze of any sort is much more frequently a cork than a drain and is never employed for this purpose. The split tube is introduced to the bottom of the cavity and brought out through the center of the well of gauze. It is removed at any time after the fifth day that the conditions of the particular case permit.

Questions *e* and *f* may be considered together. As the opening left for drainage in these cases is invariably a large one, it has been my observation that if the patient is permitted to go home after his wound is closed by granulation in the majority of instances he will develop a hernia. Acting on this observation, I tell all my patients who have been thus freely drained that they must have a second operation, that the operation could not be safely completed at the first sitting, and that they can not leave the hospital until the second operation is performed. I have never had a patient refuse to follow my wishes in this matter. At this operation, which consists in reopening the wound and freshening its edges, the appendix is removed if its removal was not accomplished at the first one. I would rather remove the appendix and repair the hernia on my cases than have them go to someone else for relief at some later day.

The removal of the appendix at some of these second operations is extremely difficult, but I consider it a wise procedure, as fully 20 per cent. of such cases would relapse. The organ is not destroyed by the suppurative process nearly so frequently as has been claimed.

3. Diffuse Septic Peritonitis: By this term is to be understood an inflammation involving, so far as we can tell, the entire peritoneum. I merely mention the steps of the procedure which is recommended.

a. Incision from umbilicus to pubis in median line.

b. Removal of appendix.

c. Thorough irrigation of entire peritoneal cavity with hot saline solution or hot sterile water.

d. Introduction of a large split rubber tube for drainage. In females from the cul-de-sac into vagina; in males from rectovesical pouch out through lower angle of abdominal wound and carrying a wick of iodoform gauze. In the latter a second smaller tube, without the gauze wick, is placed alongside the first, through which fluid collecting at bottom of pelvis may be aspirated.

e. In females the abdominal wound is completely closed with interrupted sutures of silkworm gut. In males the wound is closed with the same material down to the tubes.

f. Patient is placed in bed, the head of which has been elevated from twenty-four to thirty inches from the floor.

Operations made on patients in this condition should be rapidly performed, as they will not bear much manipulation or prolonged surgical interference.

This is the only condition in which an irrigating stream should be directed into the abdominal cavity. Its use in localized abscesses or limited peritoneal infections is most vigorously condemned.

SUMMARY.

The best results in appendicitis follow early operations.

In clean cases, acute or chronic, the operative mortality is practically nil.

The hour or day classification of appendicitis should be discarded and a pathologic classification substituted.

In spreading peritonitis immediate operation is urgently indicated.

In patients already moribund, or in those for whom the added shock of operation would determine a fatal result, operation should be delayed.

The elevated posture of the head and trunk and the resulting accumulation of septic fluids in the lowest peritoneal pouch, from which they are rapidly drained by large sized tubes, have robbed appendicitis of many of its terrors.

SOME OF THE USES OF IODIN IN SURGICAL PRACTICE.

JOHN EGERTON CANNADAY, M.D.
Surgeon In Charge, Sheltering Arms Hospital.
PAINT CREEK, W. VA.

At the present day I think I may truthfully state that the most decided tendency in the use of drugs is clearly a return to the simple life. The profession is at least partially freed from the bondage of an empirical authority, and one by one is dropping the complex and respectable myths and legends of medicine.

Inasmuch as it has been clearly shown by careful and painstaking laboratory workers that a 1-200 solution of iodin will kill the staphylococcus pyogenes in five minutes, that two minutes' exposure of the streptococcus (most virulent of pathogenic germs) to a 1-500 solution of iodin will destroy its life, that it requires thirty minutes' exposure to a 1-1,000 solution of bichlorid of mercury, the hitherto acknowledged chief of antiseptics, to accomplish the same results and that while iodin is much less toxic it is a far more powerful antiseptic than either carbolic acid or bichlorid of mercury, I have made use of this agent in much of my surgical work.

In cold abscesses in individuals of lowered resistance I have found injections of iodoform emulsion or iodin solution to be of great value. These patients are often unable to bear any more radical treatment than aspiration or injection. The iodoform may be used suspended in olive oil or glycerin or in an ethereal solution. The oil or glycerin should be sterilized by boiling and the iodoform by four days' submersion in 1-1.000 solution of bichlorid of mercury. The ethereal solution produces pain, and as it is more rapidly absorbed may produce symptoms of poisoning. Ten per cent. is usually the most desirable strength, and the amount left behind should usually vary from one dram to one ounce.

Rather recently I treated a patient by this method who had several tuberculous abscesses in the muscles of the back and chest in addition to a number of signs of lung involvement. I emptied these tubercular collections through small incisions under a careful aseptic technic, injected a 10 per cent. iodoform emulsion, closed the openings by suture and sealed them with a few fibers of cotton and flexible collodion. These sealed packages of emulsion were left alone for two or three weeks and the iodoformization was then repeated. This treatment in conjunction with appropriate dietetic and hygienic measures produced great improvement; the cough, fever and night sweats disappeared; there was a marked gain in weight and in three months the patient was apparently well.

In the treatment of sepsis from puerperal infection, also in the treatment of sapremia due to the putrefaction of retained secundines, I thoroughly curette and irrigate the uterus, then pack the uterine cavity with 10 per cent. iodoform gauze. This is removed on the third day, and if the symptoms have not subsided the uterus is daily irrigated with a 1-1,000 solution of iodin in sterile water. By this treatment we promote the absorption of a powerful yet comparatively harmless antiseptic. Occasionally I have applied the tincture of iodin to the lips and the interior of the uterine cervix for purposes of partial sterilization prior to curettage, and not infrequently I make a local application of the same drug to the entire uterine cavity after curettage in cases of chronic endometritis.

Iodin in solution in mild strength, 1-1,000, is of great value as an irrigation in the treatment of suppurative arthritis, large abscess cavity, empyema, etc. I have often used a 1 per cent. solution of iodin in the treatment of suppurating wounds and sinuses, resulting in the quick disappearance of pus and the formation of healthy granulation tissue. After operations about the genitalia and other parts where it is difficult to keep a dressing clean, I generally dispense with any of the ordinary dressings and use instead a protective ointment composed of sterile iodoform and petrolatum. By this means primary union is usually secured.

In the treatment of boils, abscesses and carbuncles I incise, evacuate the contents, wipe out carefully, curette away pyogenic and necrotic tissue and then apply thoroughly to the walls the plain official tincture of iodin. If the cavity is small, the tincture, instead of being applied with a swab, is poured into the cavity and brought in contact with its walls by gentle manipulation. This treatment is usually followed by the prompt disappearance of pus and rapid healing by granulation.

I have found the tincture of iodin to be a simple, readily obtainable and effective agent for the preparation of a small patch of skin preliminary to the insertion of the needle of the hypodermic or of the antitoxin syringe. For a year past I have been using a 0.5 of 1 per cent. iodin solution for purposes of hand disinfection in all cases in which rubber gloves were not worn. As a routine practice I wear gloves in operative work. In a certain class of cases gloves are undesirable. Again, a glove may be punctured or torn in a septic case, and the surgeon will feel the need of a reliable antiseptic, both for the protection of himself and his future patients. The use of this solution is simple and time-saving. The technic I practice is as follows: Thorough scrubbing with nail brush, green soap and running hot water. Cleanse the hands in a systematic manner. Take each part in a certain order every time, so as not to skip any part. Pay particular attention to the nail folds, subungal spaces and the skin between the fingers. Clean under short-clipped nails with a heavy metal nail file. Scrub again, wash off soap in running hot water, remove residue of soap by immersion in 70 per cent. alcohol. Immerse in iodin solution for five minutes, rinse in sterile water or let the solution dry on the hands. The light brown stain can be removed by washing in dilute ammonia water after the operation is over, or if left alone will soon disappear.

In the preparation of the site of incision I invariably observe the following routine: The evening prior to operation the area is covered by a green soap poultice, which is allowed to remain for several hours to loosen the dead and scaling epithelium; the part is shaved, going wide of any possible incision, then carefully cleansed by the use of a soft nail brush or gauze pad, liquid antiseptic soap and sterile water followed by alcohol. After this a compress wet with 1-5,000 bichlorid is applied, covered with oiled silk or other protective and secured by a bandage. This is undisturbed until the next day after the patient is under the anesthetic, when the compress is removed and the part is treated to a second cleansing with antiseptic soap, gauze pad and sterile water, followed by dilute alcohol; the solution of iodin is then applied and allowed to dry on the skin. Naturally in emergency cases much of the treatment preliminary to the use of the iodin solution will have to be omitted.

The solution of iodin used for the hands may be made up with dilute alcohol or prepared according to the following formula: Iodin 2.5 gm., potassium or sodium iodid 5.5 gm., water 250 c.c. This gives a 1-100 solution, which can readily be diluted to the desired strength. In a long series of cases in which the iodin solution has been used as described, the results from a clinical point of view have been excellent, and it is easy to conclude that as a chemical agent for at least the partial sterilization of the skin iodin is the most satisfactory substance we possess.

It must not be forgotten that this, the most harmless of antiseptics, and its compound iodoform are active agents, and as such should be used carefully. Under certain conditions they are very toxic. The pyogenic membrane lining an abscess cavity seems to be practically immune. Patients suffering from septic infection will tolerate more than the usual amounts administered. The feeble and aged are often susceptible. Iodoform irritation on the exterior of the body usually takes the shape of a severe dermatitis, not any worse, however, in character than that occasionally produced by the use of a bichlorid compress on a sensitive skin.

My conclusions are that iodin is the antiseptic *par excellence* for the skin of the hands and operation site. The solution of iodin is easily prepared and is stable. It does not coagulate albumin or form inert compounds with the tissues. It is of more value in many ways than either carbolic acid or bichlorid of mercury and not nearly so poisonous.

THE PRACTITIONER'S PART IN THE MOVEMENT AGAINST TUBERCULOSIS.*

J. C. WILSON, M.D.
PHILADELPHIA.

This remarkable exhibition and the popular interest it has aroused, which grows wonderfully as it is removed from one city to another, marks an epoch of transcendent importance in preventive medicine.

The great pests—the oriental plague, typhus, leprosy, smallpox, typhoid fever, tuberculosis—have been the scourges of mankind through successive historical epochs because of ignorance. Enlightened modes of living and knowledge of the ways by which they spread and by which they can be prevented have restricted the prevalence of these diseases in civilized communities and greatly robbed them of their terrors. Two of them only remain to-day as world pests—typhoid fever, which could not exist in a community such as Philadelphia but for the cupidity of the spoilsman, and tuberculosis, the very existence of which as a modern plague is threatened by the spreading influence of this exhibition and the great societies under whose auspices it is held.

THE MOVEMENT AGAINST TUBERCULOSIS.

In this building, on its walls and in the cases, are displayed, on a scale never before undertaken and with a precision and definiteness never before possible, facts in regard to tuberculosis which to a stricken people are glad tidings of great joy, and the facts are for the people. The exhibition is free and it is popular. Earnest and trained men, having knowledge, are here to make the subject plain and are striving faithfully and patiently to enlighten the dullest eager intellect as to the simple means of prevention and the reasonable hope of cure.

With reference to cure it is possible to be overenthusiastic. I fear that we are sometimes betrayed by our earnestness into that error. As physicians we must cultivate in this matter the judicial temperament. In individual cases we must shun the cruelty of holding out false hope. But as regards prevention there is no limit to the promise that can be fulfilled. It is only needed that the facts be known and used. Here we can not be too strenuous. Fired with a genuine enthusiasm, we can rouse the people to do the things needful, for the whole matter touches them and in sorrow they know it. Animated with a confident hope based on knowledge, we can hold out a promise of relief, the fulfillment of which is in their hands, for as the people live shall they suffer or be free. I am not of that sanguine temperament which permits me to look forward to the stamping out of consumption and the other tuberculous diseases in a decade or two or even in a generation; still I firmly believe—a belief that finds support in the history of the rise and decline of the other pests which I have named—that this great plague of our civilization can not continue to prevail as it has, but that in a future so near

* One of the addresses to physicians read at the Free Exhibition on Tuberculosis at Philadelphia.

that it will be seen by some who are here to-night this foul disease as it now prevails will also become chiefly of historical interest in our western civilization even as leprosy, the bubo plague and typhus are—a wolf baying at us and hanging on our flanks, but easily repelled and giving us no real trouble so long as we are on guard.

The three great signs of the times are (a) the diffusion of knowledge, (b) the rousing of the people, (c) organization.

a. The knowledge is simple enough. The bacillus found by Robert Koch in 1881 and its modes of existence and conveyance constitute the gist of it; but such is the inertia of ignorance that a quarter of a century passed before it became the possession of the people as a motive.

b. The rousing of the people from an apathy more than oriental is full of promise. Consumption is their affair. In ignorance they bore the evils of it and were helpless; in knowledge they will destroy it. In the way of action there were two great stumbling blocks—the doctrine of heredity, of which, in the old and paralyzing sense, science has made an end, and the conception of a pretuberculous state, which never recommended itself to sober, pathologic judgment and has now wholly ceased to darken counsel in regard to a comparatively simple infectious process. We now know beyond doubt that the symptoms once thought to indicate the pretuberculous stage are the clinical phenomena of tuberculous infection.

c. Organization has been of slow growth, but has gained momentum with the years. Its beginnings were in the private sanitarium. Then, in response to facts not to be gainsaid, came the public sanitarium. If the rich could be helped and cured, why not the poor? Then followed the association of the sanitarium with the laboratory. If patients got well, why not use them for statistical purposes; their sputa and blood for research; laboratory animals for elucidation and control; different localities and environment for comparison and the study of the part played by altitude, temperature, humidity, soil and all the factors which enter into the complex subject of climate for the part which they play in the prevention and cure of this fell pest? It followed that the influence of sociologic conditions, the home, the school, the workshop, the factory, food, habits, clothing, marriage, the rearing and care of families, should be carefully studied from the scientific standpoint as etiologic factors, and that the duty of the state and municipality to the people in the management of the disease in its early and curable stages and its developed and transmissible periods should be more and more carefully investigated. There have been devoted and unselfish men in our profession ready on all sides and in every country for this great work; and, imbued with the scientific spirit and altruism of medicine, these men have been eager to avail themselves of every opportunity to meet and discuss the subjects so near to their hearts. Hence local and national societies and international congresses. Need I say to you that the two societies under the auspices of which this exhibition is held, the National Association for the Study and Prevention of Tuberculosis and the Pennsylvania Society for the Prevention of Tuberculosis, occupy, in the scope and results of their work, the foremost place in the orderly progress of this great scheme of organization?

You have carefully studied this exhibition. You have noted its wide scope. All of us have been deeply impressed with its lessons not only to the people for whose enlightenment it was arranged, but also for the members of our profession. It is an object-lesson of the highest significance. Here you have seen in convincing array the results of the labors of the specialist, the pathologist, the bacteriologist, the phthisiologist, the sanitarian, both general and special, the health officer, the climatologist, the diagnostician, in the broad and in the narrow sense, and the tentmaker. It is true that the pharmacologist and the manufacturing druggist are not to any great extent in evidence. Like the ancients with their elements of fire, air, earth and water, we seem to have reduced our principles of treatment to fresh air, sunshine, abundant food and rest—four elements of irreproachable character. If we were to venture to add to this most respectable list, the additional measure would, it seems to me, by common consent, be household and personal cleanliness.

But I find in this great exhibition something lacking. The reason this something is not here is, I believe twofold: First, that it is little understood and, therefore, sadly overlooked, and, second, that such things as are known of it are difficult to depict and not well fitted for popular demonstration, scarcely adapted, in fact, in the present state of knowledge, for very positive assertions from the professional point of view. That "something" is the recognition and diagnosis of the very beginnings of tuberculosis in the human being.

THE PRACTITIONER'S PART.

This statement brings me back to the theme of my discourse—"The Practitioner's Part in the Movement Against Tuberculosis."

In the matter of the individual case, this is the one thing needful. The work of all the specialists whom I have named has to do with the cases that are known to be tuberculous, that almost any tyro can recognize. It is only the practitioner, the family physician, the *haus arzt,* who sees the cases in their very beginning—and often, alas! too often, not even he. For some twelve or fifteen years I have been the local examiner for patients applying for admission to the Adirondack Sanitarium, and in all that time I have only once had referred to me a truly incipient case of phthisis even under the very conservative requirements of the national association, promulgated last year. These are:

"Slight initial lesion in the form of infiltration limited to the apex or small part of one lobe.

"No tuberculous complications. Slight or no constitutional symptoms (particularly including gastric or intestinal disturbances or rapid loss of weight).

"Slight or no elevation of temperature or acceleration of pulse at any time during twenty-four hours, especially after rest.

"Expectoration usually small in amount or absent.

"Tubercle bacilli may be present or absent."

If we consider three facts in regard to tuberculosis, especially tuberculosis of the lungs, we are overwhelmed with the importance of the practitioner's part in the great movement which is now occupying the attention of the world. These facts are: First, that tuberculosis at the beginning is a local infection; second, that at this stage it is not transmissible; third, that at this period it is curable.

1. Pulmonary Tuberculosis a Local Infection.—We are not here to discuss all forms and phases of a subject on which volumes have been written. The teachings of pathology are quite clear. A man may be tuberculous and not consumptive. In fact, every sufferer from consumption, in the ordinary sense, is at first and for an

indefinite period merely tuberculous and not yet consumptive. The local tuberculous lesion may elude physical examination and cast no shadow in the *x*-rays. As it develops and extends and new lesions develop, toxins are produced and the toxemia causes symptoms, rapid pulse, slight rise of temperature, accelerated respiration, loss of appetite and weight and nervous erethism. If the lesion is peripheral there is pleural irritation and unproductive cough; if it causes bronchial irritation there is hacking cough, with a slight morning expectoration. As it extends, cough becomes more marked and constant. Tubercle bacilli are scarcely present in the beginning, while the lesion remains closed. They are the outcome of a necrotic process; the lesion breaks and becomes open. In any case negative results are inconclusive. Repeated examinations must be made. Their absence even then does not justify a negative diagnosis. This is a stumbling block to many practitioners. As the lesion extends, physical signs appear; at first uncertain and elusive, later more distinct and significant. They are deficient expansion, slight relative dullness with heightened pitch, enfeebled respiratory murmur with the bronchial character misnamed harsh and increased vocal fremitus; but all so little marked as to require careful, even repeated systematic examination for their detection. A history of pleurisy, especially of pleural effusion, is very significant.

2. Tuberculosis of the Lungs Not Transmissible in the Early Stages.—So long as the lesion has not undergone necrosis, except in extremely rare cases of tuberculous bronchitis, tubercle bacilli are not present in the sputum, and the patient is not as yet a menace to the health of those surrounding him. If the disease is arrested at this point, the lesion becomes obsolescent and the patient recovers without being aware that he has been tuberculous and without having played the part of a distributing center for the disease.

3. Curability of Phthisis in the Stage of Incipiency. The frequency of obsolescent tuberculous lesions found on the postmortem table in the bodies of those who have died of other diseases, variously estimated at from 30 to 70 per cent., affords incontrovertible evidence of the curability of phthisis at this period. It is impressive to reflect that probably in all cases such cures are spontaneous, the lesions usually being too circumscribed to have given rise to recognizable physical signs. Dr. Norris concludes a recent paper on the "Diagnosis of Incipient Pulmonary Consumption" with the following statement: "High as the mortality from tuberculosis is, a greater number of individuals recover from the disease without knowing they ever had it than die of it."

How many others who traverse the thorny path of progressive tuberculosis to its ghastly end might be saved from such a fate by early diagnosis and treatment can never be known until the practitioner recognizes his part in the great anti-tuberculosis movement and, discarding with the misleading phrases, "slight bronchitis," "spot on the lung" and "pulmonary catarrh," all false sentiment and fear, does his duty with the courage, promptitude and skill of the American physician.

1509 Walnut Street.

Training of Children.—S. Merrill, Concord, N. H., says that it is important that children should be trained with a view to fitting them mentally as well as physically for the wear and tear of the life which they will have to encounter.

THE PHARMACOPEIA AND THE PHYSICIAN.

CHAPTER XVI.

CIRCULATORY STIMULANTS (CONTINUED.)

STRYCHNIN.

Strychnin, unlike digitalis, has no perceptible direct action on the heart, but produces its circulatory effects wholly by its influence on the centers, except in so far as the local action on the alimentary canal is concerned; this may be disregarded in the present consideration of strychnin, which is commonly injected hypodermically when its circulatory effects are desired.

Therapeutic doses of strychnin cause a rise of blood pressure by stimulation of the vasomotor center; the reflexes are increased, leading to improved tone of the voluntary muscles, and increased muscular activity always tends to increase the heart rate; this tendency, however, is counteracted by the stimulation of the vagus center by strychnin, the heart being slowed or showing little change in frequency. If the slowing is excessive there will be a fall of blood pressure despite the vasoconstriction, but this does not usually occur. If the tendency to increased frequency predominates over the vagus stimulation the rise of blood pressure is further augmented.

As strychnin operates readily to produce its effects it is a most valuable remedy when a quick rise of blood pressure is required. So rapidly are its effects elicited that convulsions may occur in a frog within two minutes of the injection of a toxic dose, and after massive doses rabbits may give a single convulsive leap into the air and be apparently lifeless from paralysis of the respiratory center when they strike the operating table.

Biberfeld has investigated its mode of action on the respiratory center. He depressed the respiration by morphin, after which strychnin was injected; this usually resulted in a greater increase in volume (sometimes even exceeding that before the administration of morphin) than in frequency.

It has been suggested that morphin depressed the reflex excitability, while strychnin tends to make all reflex efforts maximum.

Biberfeld agrees with previous investigators that strychnin does not cause increased irritability of the center for sensory impulses coming from the lungs, but considers the chemic stimulation of the blood the essential factor.[1]

The following preparations are official:

Strychnina.—U. S.—This is an alkaloid obtained from nux vomica; it is also obtainable from other plants of the *Loganiaceæ*.

Strychnin is only slightly soluble in water 1/6400, but is soluble in 110 parts of alcohol.

Strychninæ Sulphas.—U. S.—This is the salt of strychnin that is most extensively used in this country; it contains five molecules of water and approximately 78 per cent. of strychnin alkaloid. Strychnin sulphate is soluble in 31 parts of water and in 65 parts of alcohol.

1. Owing to the frequency with which poisoning by strychnin occurs, its toxicology deserves brief mention here.

As is well known, strychnin causes a characteristic type of convulsion rather closely resembling tetanus. The amount of the alkaloid that is necessary to produce this toxic effect is much greater, however, than is usually supposed; but, on the other hand, when once a large amount has actually entered the circulation, there is little hope of ultimate recovery. As death is due to paralysis of the respiratory center life may be prolonged, and a possible recovery brought about, by carrying on artificial respiration. This, however, should be begun before natural respiration ceases or even before it becomes very greatly depressed.

Strychnin requires several days (3 to 8) for its total elimination. Diuretics hasten elimination and may be of benefit when the amount of the poison that has been taken does not greatly exceed the minimum fatal dose.

Cushny advises strong tea (infusion) when the patient is seen with the strychnin in the stomach. This advice seems to be based on a misconception of the capacity of tea tannin for forming the insoluble tannate.

The fact that strychnin acts directly by paralyzing the respiratory center fully explains the possible danger that may result from the use of a stomach tube, and it will not be necessary to repeat this frequent caution.

On the continent of Europe the preference is usually accorded to the nitrate. This is official in our Pharmacopeia as:

Strychninæ Nitras.—U. S.—This represents 84 per cent. of strychnin alkaloid and is soluble in 42 parts of water or in 120 parts of alcohol.

The average dose of either of the official preparations is given as 0.001 gm. (1 mg. 1/64 gr.).

Strychnin is useful in all forms of low blood pressure because of its action on the vasomotor center.

There can be little doubt of the beneficial effects of strychnin in many cases of shock or collapse, but when irrecoverable shock exists it appears to depress further the centers after an extremely brief stimulation.[2]

To secure its greatest usefulness in conditions of this kind strychnin should be given hypodermically, or to secure an even quicker action it should be injected deeply into the muscle of the arm or thigh. This method of hypodermic injection is usually to be preferred as it is less painful than injections just beneath the skin.

Strychnin is one of the best of respiratory stimulants and in an emergency large doses may be given. It is always to be remembered that strychnin is a remedy for the crisis and is not to be used as is digitalis, to maintain blood pressure for a considerable length of time.

When paralysis of the limbs is due to a lesion in the cord which completely blocks the transmission of nerve impulses strychnin can do no good, since it has no peripheral action, but if the paralysis results from a lesion in the brain the increased reflexes which strychnin causes will serve to delay muscular atrophy. It also may serve to restore the tone of the reflexes when these are lowered by functional disturbances of the cord. Thus incontinence of feces and urine may be relieved when these are due to the lowered reflex centers for the sphincters of the bladder and anus.

Caffein, which has been mentioned several times in this series of articles, is closely related to strychnin, to which, however, it is greatly inferior, so far as any influence on the circulation is concerned. It stimulates the vasomotor and respiratory centers and is useful, therefore, in the treatment of poisoning by morphin and other narcotics, in the form of strong tea, but strychnin serves the same purpose and more efficiently.

Hoffmann noticed that theobromin possessed a stimulant action on the myocardium, similar to that shown by caffein, but no vasoconstrictor effect. In therapeutic doses of either agent, however, this cardiac effect is of little importance.

ATROPIN.

Atropin causes acceleration of the heart by paralyzing the vagus endings, and this also causes an increased systole and a lessened diastole. The rate of the heart may be twice as great as under normal conditions, the result being a considerable increase in the output of the heart in a unit of time.

The effect on the circulation of the increased heart action is supplemented by the constriction of the arterioles of the splanchnic area, due to stimulation of the vasoconstrictor center by atropin, which also stimulates the vasodilator center for the vessels of the skin, particularly those of the face and neck, but this is of comparatively little influence on the general blood pressure which rises in response to the two actions just mentioned.

The influence of atropin on the heart rate is much less in children and in old age than it is between the ages of 20 and 60 years, because the vagus inhibition is slight at the extremes of life in man. The vagus is much more active in some animals than in others. In this respect the dog resembles man.

Atropin may cause a brief but unimportant slowing of the heart, due to stimulation of the center, preceding the acceleration which depends on the paralysis of the vagus endings. While it has been undeniably shown that atropin may powerfully stimulate the myocardium, this effect with therapeutic doses is so slight that it may be entirely disregarded. Atropin acts as a stimulant to the respiratory center, but it is inferior in this respect to strychnin; it increases the rate, and probably the depth, of the respiration.

The central action of atropin is exerted mainly on the motor area, but it has been suggested that the differences between the action of atropin, caffein and strychnin on the various parts of the central nervous system are in degree rather than in kind. Thus, while caffein acts mainly on the higher centers in man, stimulating the psychic functions, it is capable of causing strychnin-like convulsions in the frog. All three act as powerful respiratory stimulants in mammals.

Atropin is official as:

Atropina.—U. S.—Atropin is an alkaloid prepared from *Atropa belladonna*, or from other plants of the same family. It is soluble in 450 parts of water and in less than 2 parts of alcohol.

Atropinæ Sulphas.—U. S.—This salt of atropin is official in many if not all pharmacopeias and is the best known and most widely used preparation of the atropin group. It is soluble in less than one part of water and in 4 parts of alcohol.

Average dose: (Alkaloid or salt) 0.0004 gm. (0.4 mg. 1/160 gr.).

Atropin is indicated when the heart is considerably slowed. For this purpose the average dose given above is not usually sufficient, about 1 mg. (1/65 grain) being necessary to increase the rate; so large a dose being necessary to produce paralysis of the vagus endings in the heart. It must be remembered, however, that in children and in the very old (after 70) the effect to be expected is much less than that seen between the ages of 20 and 60. This larger dose causes stoppage, or, at least, a marked diminution of salivary secretion with consequent dryness of the mouth and throat.

While atropin has been used in shock and collapse, it can have but little influence on blood pressure or respiration in such cases. Atropin may be used to determine whether an abnormally slowed or intermittent heart results from central influences or from causes within the heart itself, since it cuts off all impulses from the center arriving through the vagus, but produces no appreciable effect if the cause lies within the heart.

Atropin has been used to prevent the reflex stoppage of the heart occurring at the commencement of anesthesia, but it has been shown that there is no danger of such a catastrophe if the anesthetic is not used in too great concentration.

Poisoning by certain fungi which contain muscarin, while rare, may best be treated with moderate doses of atropin. Pilocarpin is also antagonized in nearly all its actions by atropin, but the latter does not counteract the cardiac effects of physostigmin which acts on the myocardium.

The value of atropin in opium poisoning has been much disputed. It seems to possess no advantage over caffein and strychnin in such cases and it has the disadvantage of adding to the depression of the respiratory center if more than a small dose is given. Clinical experience seems to have abundantly proved that small doses of atropin are corrective for ordinary doses of morphin, and it is almost universally so used.[3]

Atropin is usually given hypodermically when the central effects are desired. The local action of atropin in the intestines has been mentioned, and we may have occasion to refer to it again.

CAMPHOR.

Camphora.—U. S.—Camphor is a white, volatile, solid substance having a crystalline structure and a characteristic aromatic odor and taste. Camphor has been used in the Far East for many centuries, but was not known in Europe until introduced by the Arabians. It is now official in all pharmacopeias.

Average dose: 0.12 gm. (2 grains).

Aqua Camphoræ.—U. S.—This is a saturated solution of camphor in distilled water. It is frequently used as a vehicle for other and more active medicinal substances.

2. Crile defines surgical shock as an exhaustion of the vasomotor centers, the cardiac and respiratory centers being only secondarily involved, and collapse as due to a suspension of the functions of the cardiac or vasomotor centers or to hemorrhage. Of course, an exhausted or paralyzed structure can not be stimulated. Sollmann defines both shock and collapse as a sudden depression of the activity of the medullary center; if of reflex origin, shock; if direct, collapse. We employ the terms in the latter sense. A depressed center may be stimulated.

3. A widely used combination consists of morphin sulphate 0.015 gm. (¼ grain) and atropin sulphate 0.0004 gm. (1/160 grain) prepared in the form of the now popular hypodermic tablets or dissolved in distilled water sufficient for one dose.

Average dose: 1 c.c. (2 fluidrams).

Spiritus Camphoræ.—U. S.—This is a 10 per cent. solution of camphor in alcohol.

Average dose: 1 c.c. (15 minims).

Linimentum Camphoræ.—U. S.—This preparation, variously known as camphor liniment and camphorated oil, contains 20 per cent. of camphor dissolved in cottonseed oil. While largely used as a mildly rubefacient local application it is not infrequently used for hypodermic injections or for the internal administration of camphor in the form of an emulsion. The average dose would be about half of that given under spirit of camphor.

In shock or collapse camphor is given by the stomach, producing a feeling of warmth and probably acting reflexly for the most part. The respiratory and vasomotor centers, as well as the heart muscles, are stimulated, thus causing a rise of blood pressure. The heart is usually slowed and the contraction strengthened. Camphor is almost insoluble in water and only slightly volatile at the body temperature, and its action, therefore, is very uncertain; 0.03 gm. (½ grain) may improve the pulse in some cases while twenty times as much may be required in others, hence but little reliance can be placed on it in crisis, though it is very often effective. The spirit, diluted with water, is frequently used for internal administration. A number of camphor derivatives have been employed from time to time, but they have not been shown to possess any advantages over camphor itself, or one of its more simple preparations.

Camphor is frequently employed as a diaphoretic, particularly in combination with other agents, because of its stimulation of the vasodilator centers for the cutaneous vessels.

As noted above, camphor water alone has little therapeutic value and is useful mainly as a vehicle for other substances. Camphor may be given in pill form, in capsules or in the form of an emulsion. Probably the best method of administering camphor consists in suspending the finely powdered substance in twenty parts or more of milk. For this purpose from twenty drops to one teaspoonful of the spirit of camphor may be directed to be given in one or two tablespoonsful of milk.

The several preparations of camphor are commonly employed externally as a mild rubefacient, but the action of camphor when applied in this way is largely if not entirely a local one.

MUSK.

Moschus.—U. S.—This substance has been used in Europe for several centuries, and in China and other far Eastern countries from time immemorial. The portion that is now official is described as "The secretion from the preputial follicles of *Moschus moschiferus*" (musk deer), an animal which inhabits Thibet and other parts of Central Asia.

Average dose: 0.25 gm. (4 grains).

Tinctura Moschi.—U. S.—This represents 5 per cent. of musk in diluted alcohol.

Average dose: 1 c.c. (15 minims).

Musk was brought forward nearly a century ago as a powerful circulatory stimulant, and S. Solis-Cohen recently recommended it as an efficient and dependable remedy when it can be obtained of good quality, but it is extremely expensive and subject to gross adulteration.

Musk probably resembles camphor in its action on the centers and has the advantage of greater solubility in proportion to the amount required.

Castor fiber and sumbul root, which have been recommended as substitutes for musk, are entirely devoid of any such central action as that claimed for the latter.

Musk may be given in capsules, or in some cases the tincture may be preferred.

AMMONIUM PREPARATIONS.

While ammonia, as one of the products of the decomposition of nitrogenous materials, was known from a very early period, the volatile salts of this substance were not available in Europe as medicines until after the thirteenth century, when Raymundus Lullus first produced ammonium carbonate from urine. The stimulating action of this salt, it is said, was known for many centuries to the Hindoos, and was probably known to the Arabians. It is now official as:

Ammonii Carbonas.—U. S.—This is a white, hard, translucent solid having the characteristic odor of ammonia and a sharp saline taste. The official salt is described as being "a mixture of acid ammonium carbonate and ammonium carbamate."

Average dose: 0.25 gm. (4 grains).

Aqua Ammoniæ.—U. S.—This is an aqueous solution of ammonia containing 10 per cent., by weight, of gaseous ammonia.

Average dose: 1 c.c. (15 minims).

Spiritus Ammoniæ Aromaticus.—U. S.—This is a hydroalcoholic solution containing 3.4 per cent. of ammonium carbonate, 9 per cent of ammonia water and 70 per cent. of alcohol aromatized with oil of lemon, oil of lavender flowers, and oil of nutmeg.

Average dose: 2 c.c. (30 minims).

The volatile salts of ammonium, in the form of the well-known "smelling salts," are very commonly employed by inhalation for their reflex effects on the respiratory and cardiac centers. The aromatic spirit of ammonia when taken by the stomach has a similar action. Other actions of ammonium salts have been enumerated in previous chapters.

The water of ammonia, when taken internally, merely acts as a caustic alkali. It is seldom so used. The aromatic spirit is usually added to water at the moment of taking.

Smelling salts consist of varying mixtures of ammonium carbonate, or of ammonium chlorid with potassium carbonate, and spirit of ammonia to which oil of lavender flowers is usually added as an aromatic.

ALCOHOL AND DERIVATIVES.

Alcohol, or distilled spirit, was probably introduced into Europe by the Arabians in the 10th or 11th century.[4] Apart from the several forms of alcohol that are clinical we have:

Spiritus Frumenti.—U. S.—An alcoholic liquid obtained by the distillation of the mash of fermented grain, such as Indian corn, rye, wheat and barley, or their mixtures. To conform with the official requirements whisky should be at least four years old and comply with a number of physical requirements and chemical tests that are now provided.

Spiritus Vini Gallici.—U. S.—Brandy. This is an alcoholic liquid obtained by the distillation of the fermented unmodified juice of fresh grapes. Like whisky it should be at least four years old and should conform to the tests for identity and purity that are described in the Pharmacopeia.

Æther.—U. S.—Ether or ethyl oxid was discovered by Valerius Cordus, about 1540, and described as "Oleum vitrioli dulci." The preparation appears to have been entirely forgotten and was rediscovered by Frobenius, a London apothecary, about 1730.

Sulphuric ether, the name given it at that time, although long known to be a misnomer, is still retained in connection with commercial varieties of the substance.

Average dose: 1 c.c. (15 minims).

Spiritus Ætheris.—U. S.—This contains 32.5 parts of ether and 67.5 parts of alcohol.

Average dose: 4 c.c. (1 fluidram).

Alcohol in the form of whisky or brandy is much used in shock or collapse in connection with other agents such as strychnin and digitalis. Its value is strongly asserted by some authorities and disputed by others. Ordinary doses of alcohol have little effect on the circulation in animals, but clinical evidence seems to prove that alcohol does possess some value in the conditions mentioned, particularly when a very brief respite for the heart tides over a crisis. Spirit of ether may be given by the stomach, or used by hypodermic injection, and probably acts reflexly on the centers in such cases.

ERGOT.

Ergot has been recommended in shock and in hemorrhage in inaccessible locations. The use in the latter condition is based on its undoubted power of causing vasoconstriction in certain areas. It is much less useful than strychnin in shock because of its slow action, and in hemorrhage there is no

4. According to Pereira the Arabians obtained their knowledge of distilled spirit from the Chinese, who knew and used distilled spirit at a much earlier period.

reason to expect a greater vasoconstriction at the bleeding point than elsewhere and a rise in the general blood pressure beyond that necessary to sustain the circulation in the medulla, is contraindicated in hemorrhage. This, of course, does not apply to postpartum hemorrhage, because ergot has a specific action on the uterus, causing a firm contraction and thereby closing the bleeding vessels by compression.

Sollmann and Brown have recently studied the action of ergot when injected intravenously into dogs.[4] They found that it influenced the general circulation but little, particularly when the blood pressure was much lowered. They found that it caused a temporary fall in the blood pressure with speedy recovery, generally followed by an unimportant rise. The effects were mainly due to the action on the heart, as the vasomotor action was very slight.

The further discussion of its obstetrical use does not belong here.

Ergota.—U. S.—The sclerotium of *Claviceps purpurea*, gathered from rye, and not more than one year old.

While ergot had been used in Germany for centuries as a household remedy, it was not generally recognized as an efficient drug until some time after 1777, when Desgranges published several essays on the use of ergot.

The vasoconstrictor properties of this drug appear to be due to the alkaloid cornutin, discovered by Kobert in 1884, and more fully described by Keller in 1894.

Extractum Ergotæ.—U. S.—This is a hydro-alcoholic extract of ergot partially purified by the addition of hydrochloric acid subsequently neutralized with sodium carbonate. It should represent eight times its weight of ergot.

Average dose: 0.25 gm. (4 grains).

Fluidextractum Ergotæ.—U. S.—This is directed to be made with diluted alcohol that has been acidified by the addition of acetic acid.

Average dose: 2 c.c. (30 minims).

Vinum Ergotæ.—This represents 20 per cent. of the fluidextract of ergot in fortified white wine.

Average dose: 8 c.c. (2 fluidrams).

Ergot is preferably given in the form of the fluid extract without other additions. There are a number of water-soluble preparations on the market at the present time that are intended for hypodermic use, which, it is claimed, possess all the active principles of ergot, without the odorous and nauseating contaminations.

New Instruments

SOME MASTOID INSTRUMENTS.

AND SOME APPLIANCES FOR EAR WORK.

FRANK ALLPORT, M.D.

CHICAGO.

A MIDDLE EAR SYRINGE.

Practically all middle ear syringes are unclean and frequently out of order. I submit one of glass and rubber that can always be ready for use, and which is so cheap that the surgeon can afford to possess a number of them (Fig. 1). An objection has been raised to it that the point is not large enough to enter minute perforations of the drumhead. In answer to this I contend that no middle ear should be irrigated through a minute drumhead perforation. Such tympanic irrigations should be confined to those cases where the irrigating liquid can find a ready exit, otherwise dangerous complications are likely to ensue.

A MASTOID PERIOSTEOTOME.

In stripping the mastoid process of its periosteum after the primary incision has been accomplished, an effort should be made to preserve all possible periosteum. This purpose is liable to be defeated by the sharp scraping instruments usually employed, which tear and mangle the periosteum. I desire to recommend the instrument shown in Figure 2 as one that can be passed underneath the periosteum, thus lifting and not tearing it from the bone. It has a small end and a large end, and the latter should be used where much force is indicated. This instrument can not be used when the lower portion of the mastoid is to be cleaned, for at this portion of the bone the roughened surface and tendinous attachments of the muscles make the soft tissue cling to the irregular bone surface with such tenacity that one of the scraping periosteotomes and a pair of strong scissors must be used. My instrument, however, can be used at all other portions of the bone.

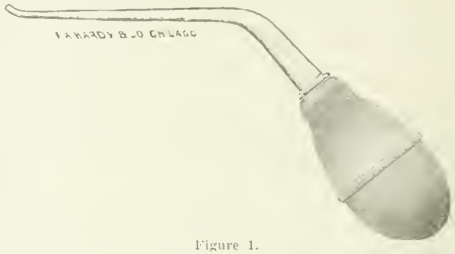

Figure 1.

The narrow end of the instrument has been gently concavo-convexed to fit the bony external auditory canal, and is used in the radical mastoid operation to pass between the cartilaginous and the bony meati, in order to separate them thoroughly and facilitate the subsequent steps of the operation. This instrument is not useful in secondary mastoid operations where dense cicatricial bands connect the soft tissue with the bone.

Figure 2.

A PERMANENT NEEDLE.

Having been much troubled with the breaking of needles in closing mastoid wounds, I have for a long time used the instrument shown in the drawing (Fig. 3). Near the point of the needle is a small opening, that can be opened and closed by pressing the button near the handle. The needle is pushed through the soft tissue with the small perforation closed, the suture is then doubled and placed in the opening, which is

Figure 3.

then closed. The needle is then withdrawn with the suture and one end of the suture pulled through when the suture will be ready for tying. I use this instrument only in my buried catgut sutures in the radical operation, as for closing the outside lips of the wound I use the metal sutures proposed by Michel.

THE MICHEL SUTURES, ETC.

For closing the external lips of the mastoid wound I have

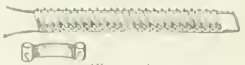

Figure 4.

for some time been using with great satisfaction the metal Michel suture, a drawing of which is here given (Fig. 4).

These sutures are easily and quickly applied, scarcely ever produce stitch abscesses, and result in a quicker healing and a more imperceptible line of cicatrix than any sutures I have ever employed. Several instruments or appliances are necessary for their advantageous employment, viz., a wire suture holder which enables the surgeon to conveniently take hold of the suture, a strong pair of forceps (Fig. 5) with points so constructed as to grasp and hold firmly the suture and to

Figure 5.

4. This Journal, A. M. A., July 22, 1905, p. 229.

grasp and hold the two sides of the wound forcefully, and a pair of forceps (Fig. 6) for removing the sutures after the wound has healed. The two ends of the removing forceps are pointed so that one end may be gently insinuated underneath the middle of the bent suture after it has been holding the soft tissues together for a few days. The two blades of the forceps are then brought firmly together at the middle of the suture, one blade being underneath and the other over the suture; this, of course, will cause the two outer ends of the suture to separate, thus removing the sharp points from the

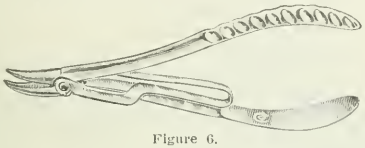

Figure 6.

flesh. The suture is now liberated and may be cast aside or straightened out and used again.

In applying a suture it should be held on the wire loop or suture holder by an assistant, the surgeon should grasp the suture with the forceps and pull it off from the loop, an assistant should grasp the two lips of the wound with strong forceps, bring them together and hold them up, thus approximated, as prominently as possible for the benefit and convenience of the surgeon, who should now forcefully clamp the suture around the lips of the wound, and bring the two

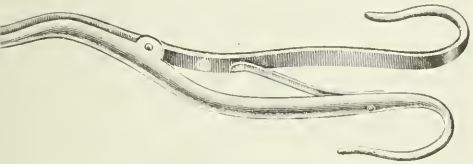

Figure 7.

ends of the suture, armed with the little needle points, as close together as possible by firm pressure of the strong forceps. Five or six sutures are usually sufficient, even in a large mastoid wound. I usually remove about half the sutures in three days and the remainder in six or seven days.

A MEATAL DIVULSOR.

For those who split the cartilaginous meatus after the method of Panse in producing healing flaps after the radical mastoid operation the instrument here shown will prove of value (Fig. 7). A grooved director is used by some to guide

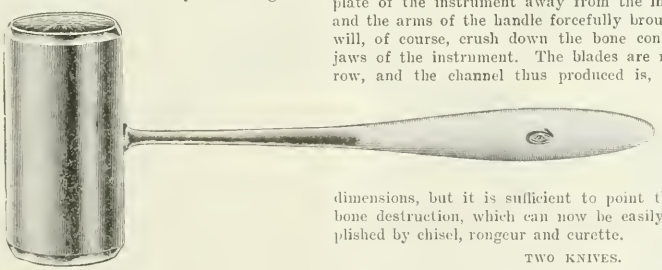

Figure 8.

the knife, strong forceps, widely spread, by others, but for a long time I have used the "meatal divulsor" as I call it. The instrument is introduced through the meatus and passed through to its further end and spread so that the cartilaginous meatus is placed on a stretch. A knife can now be passed into the tympanic end of the meatus and the cartilaginous wall easily and accurately severed up to the desired point at the conchal rim, spreading the divulsor more and more as the incision advances toward the concha.

A METAL COVERED WOODEN MALLET.

For mastoid work a silver or lead mallet is too heavy and harsh, and a rawhide mallet is too soft and soon becomes useless from boiling; a wood mallet also becomes cracked and worthless from boiling. I employ, therefore, a good-sized mallet made of lignum vitæ, encased in steel, with a strong steel handle. It is imperishable and thoroughly satisfactory (Fig. 8).

A BONE CRUSHER.

An important step in the radical mastoid operatio is the breaking down of the posterior wall of the meatus. Injury to the facial nerve, semicircular canal, etc., may follow this procedure. The complete clearing away of the upper portion of the bony meatus, without injury to surrounding parts, is much facilitated if a small pathway through the bone to the tympanic cavity, etc., can be distinctly blazed by some instrument. I have found the "bone crusher" (Fig. 9), to be of

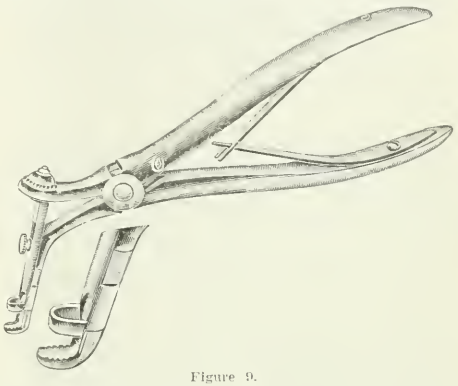

Figure 9.

great service for this purpose. Before using it the mastoid cavity, antrum, etc., should be thoroughly curetted and cleaned. The crusher has not sufficient power and strength (and should not have) to break down the entire thickness of meatal wall. The surgeon should proceed, therefore, as if expecting to destroy the meatal wall with the chisel and mallet alone, and carve away a considerable portion of the bony wall with these instruments. After, perhaps, one-half of the work has been accomplished, the footplate of the crusher should be carefully insinuated through the antrum to the middle ear, the handle firmly depressed so as to raise the footplate of the instrument away from the inner tympanic wall, and the arms of the handle forcefully brought together, which will, of course, crush down the bone contained between the jaws of the instrument. The blades are not broad, but narrow, and the channel thus produced is, therefore, of small dimensions, but it is sufficient to point the way for further bone destruction, which can now be easily and safely accomplished by chisel, rongeur and curette.

TWO KNIVES.

One of the recognized defects in the radical mastoid operation has been the deformity often produced by an abnormally wide and gaping meatus. This trouble I have been able to dissipate entirely by the use of two knives, which I will now describe, my description referring, of course, as will be seen, to the Panse flap which I use to the exclusion of all others. After everything is ready for flap making and wound closure I insert the double-edged knife (Fig. 10) into the raw posterior portion of the auricle, as near as possible to the middle edge of the meatus. The knife is carefully pushed forward

and made to reappear at the middle of the meato-conchal edge; after enlarging the opening a little the knife is withdrawn and the blunt-pointed knife (Fig. 11) is made to take its place, as the seesaw movement necessary to finish the incision up and down would be likely to produce multiple punctures on the other side of the meatus. The blunt point of the

Figure 10.

other knife renders the subsequent procedures free from such embarrassments, and the fact that the blade convexes forward on the edge enables the surgeon to complete more effectively the remote corners of the incision. The knife should be carried up as far as desired, and then down, always keeping in view the meato-conchal edge, and keeping the line of incision exactly on this edge. In this way the meatal opening is enlarged only a trifle, and the surgeon can be absolutely sure

Figure 11.

that a constant and non-deforming result will occur. The backward incision along the cartilaginous meatus can now be completed by the divulsor and knife as already described.

A GAUZE PACKER.

A good instrument for packing gauze is desirable not only at the time of the mastoid operation, but more particularly at the subsequent dressings. I have already described the packer here shown, but as two important modifications have been made in it, I venture to refer to it again. It has a cone-shaped point, flat and round at the distal extremity, which

Figure 12.

gradually diminishes in bulk as the shank of the instrument is reached, thus enabling the operator to pack down firmly the gauze without any tendency to displace the packing as the instrument is withdrawn. The narrow portion of the shank as formerly made was flexible; it is now stiff and firm. The distal end used to be smooth; it is now roughened and catches the gauze better.

A HOOK PROBE.

I have described this hook probe some years ago as a useful instrument for finding and dislocating the ossicles in the

Figure 13.

operation for ossiculectomy, and also as a generally useful ear hook and probe. I now, however, find it exceedingly efficacious in the mastoid operation as a probe for the detection of carious spots, and especially for locating openings in the roof of the tympanum, aditus, or antrum. It consists of a slender shank, bent at right angles at the end and tipped with a small round ball (Fig. 13).

THE MASTOID RETRACTOR.

I trust I may be pardoned for referring again to my mastoid retractors, now in general use for so many years (Fig. 14). They have been modified somewhat of late by making them much stronger so that they possess great power and do not break. The skin incision should be long enough to allow the operator to place two pairs of these retractors in the opening, one pair in the upper angle of the wound and another pair in the lower angle. The teeth of the arms of the retractors

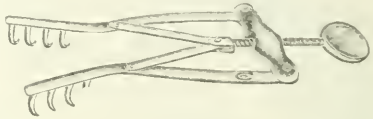

Figure 14.

should be placed underneath the periosteum and the arms should then be expanded to their utmost limits by turning the thumbscrew at the base of the instrument. I rarely use an artery forceps, and when both retractors are thus widely separated a perfect and comparatively bloodless field of operation is observed between the four arms of the two retractors. Some operators still employ the old hand retractors, one for each side of the wound, but these retractors necessitate extra hands and arms around the operative field, and they do not control hemorrhage, and no one can always maintain steady and uniform hand retraction.

A PILLAR SEPARATOR.

Robertson's pillar separator usually acts well in separating the pillar from the tonsil preparatory to a removal of the lat-

Figure 16.

ter, but it does not always cut well, which is embarrassing to the operator and frequently painful to the patient on account of the forcible dragging of the blade on the yielding soft tissue. I beg to suggest a knife with a wavy blade, like a bread knife, which, when sharp, by the use of a gentle to-and-fro movement, easily and comparatively painlessly cuts the soft tissue without much effort (Fig. 16).

A BEDSIDE TRAY.

It would seem easy to purchase a small and convenient tray for carrying a few eye and ear instruments, solutions, cotton, etc., from bed to bed in a hospital, and yet a faithful search

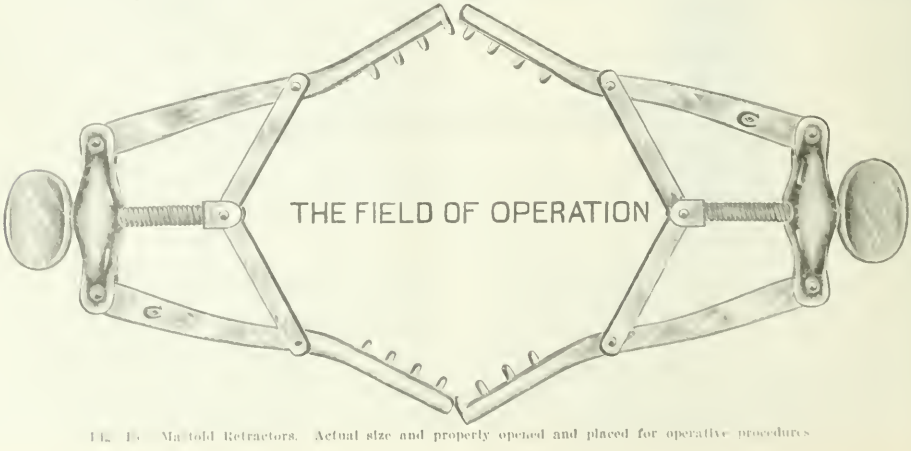

Fig. 15.—Mastoid Retractors. Actual size and properly opened and placed for operative procedures.

n instrument stores has failed to produce one. I beg, therefore, to suggest one, so simple that apologies seem necessary for the suggestion, and yet one that has seemed to answer satisfactorily the purpose for the past year at St. Luke's Hospital (Fig. 17). It is simply a small tray with a shelf for holding a few bottles, and a space of sufficient size for holding miscellaneous articles such as droppers, gauze, cotton, instruments, etc. I think it undesirable to make many partitions in a small bedside tray like the one under consideration,

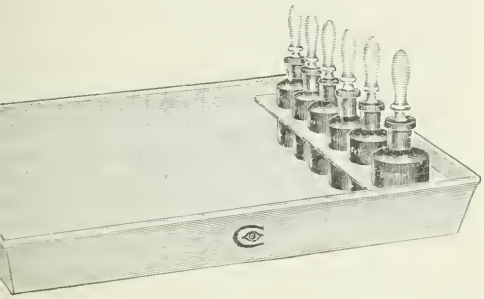

Figure 17.

and have found it much more convenient to lay in the one large space such articles as are absolutely necessary in a tour of the hospital.

A EUSTACHIAN BUR.

Curetting the tympanic orifice of the Eustachian tube is an important part of the radical mastoid operation, as, if this is not done, granulation tissue usually remains and a mucous secretion from the unclosed tube may become a constant and annoying sequel of the operation. This little procedure may be accomplished with a small, sharp spoon curette, and Whiting has devised a conical shaped bur which quickly rims out the orifice. I have, however, found his bur to be over-large for the purpose, and I do not like the conical shape of his bur, as

Figure 18.

it may be too energetic in its action, especially when attached to such a strong handle which not only invites undue force, but also obstructs the view of the bur and tube, which should always be kept in sight. I, therefore, use a bur (Fig. 18) with round outlines, which, it would seem, is capable of doing less harm, and also one possessing a straight handle (without a hand crossbar as in Whiting's), which can be rolled between the fingers when rimming out the tube orifice. It is not likely that much force will be employed in using this instrument, and the bur and tube can always be kept clearly in view.

Clinical Notes

TETANUS FOLLOWING VACCINATION

A. H. CHURCHILL, M.D.

ST. CHARLES, ILL.

Patient.—E. M. B., aged 5½ years, female, in perfect health, living in the country on a farm, was vaccinated Jan. 11, 1906, on left arm with P. D. & Co.'s vaccine from tube. Antiseptic precautions were taken.

History of Disease.—The child was not seen again until January 30, when the following history was obtained: The arm had been but slightly swollen and the child had felt well during the entire time since vaccination. She got up on the morning of January 30, apparently well, sat at table, and ate some breakfast. She seemed to have slight indisposition during the morning, but at noon she drank coffee and milk. During the afternoon the mother said the child wished to lie down and that she noticed some stiffness of the neck.

Examination.—I saw the child at 6:30 p. m. and found some rigidity of the left arm, and considerable rigidity of the neck and jaw. The teeth could be parted about half an inch. There was no rigidity of the right arm or of the back below the neck, or of the legs or abdominal muscles. The child could swallow perfectly.

Course of Disease.—The child was seen again at 1 a. m., January 31. She had had two severe spasms in which she threw herself about in bed, but she was rational when seen. The left arm was some more rigid. The right arm and legs were still normal. Temperature still normal, and the child could still swallow easily. At this time there were muscular tremors through the abdominal muscles, causing her to cry out with pain. From the onset of the symptoms till death occurred there was no movement of the bowels and no urine was passed. The child rapidly grew weaker until 9 a. m. on January 31, when she died, not quite twenty-four hours from the manifestation of the first symptom. There was no post-mortem. The arm, on examination, showed vaccination not doing well. A wound half an inch across, edges indurated and undermined, with a foul discharge.

General Remark.—At the time the vaccination was done the arm was scrubbed with soap and water, and then with alcohol. The scarifying was done with a sterile scalpel, and the vaccination was covered with sterile gauze. From that time the parents took care of the arm, as is practically always the case in the country. I did not see the child from the day I did the vaccination till three weeks later. The arm had not been troublesome, so the parents had not thought it necessary to bring the child to my office. Of course, it is possible that the infection gained entrance at some other point, but as the vaccination wound was the only open wound, I considered that must have been the source of infection. I certainly believe that the infection occurred after the vaccination and entirely independent of it, as all authorities, so far as I find, give ten days as the limit of the period of incubation, and this, as I have stated, was just three weeks after I sent to Chicago for antitoxin. The little girl died before this arrived, however. I have not seen a case recorded in which death took place so soon after the first manifestations of tetanus.

THE PULMONIC SECOND SOUND, IN HEALTH AND DISEASE.

IRVIN HARDY, M.D.

BALTIMORE.

While due attention has been given to the difference existing between the pulmonic and systemic circulations, as a result of pulmonary consolidation, there seems to be a scarcity of comment regarding a comparative lessening of intra-aortic blood pressure.

By experiment and observation I have found in healthy individuals what appeared to be an accentuated pulmonic second sound which would disappear on having the patient walk briskly for a few minutes.

The point I wish to make is that healthy people who are inactive, engaged in sedentary occupations, have an apparent accentuated pulmonic second when in reality it is only a relative one, due to lessened intra-aortic pressure, the result of deficient exercise. Use is made of exercise to bring out signs of disease of the valve segments, but I have seen no literature bearing on this subject. What theory one may have, the fact remains, or at least is constant enough, to keep one on his guard.

If this be true, it would seem that too much stress has been laid on this sign as an early indication of pulmonary tuberculosis, thus giving an opportunity, at least, for misleading conclusions.

WEIGHT AND HEALTH.

There is probably no better—certainly there is no simpler—sign of the condition of an ordinary individual's health up to middle life than his weight. There is no absolute measure of weight for each individual, for it depends on personal peculiarities and on family characteristics; but a definite idea of what any individual's weight should be according to his height can be obtained, and then variations from this normal are important indications of the state of health. This is especially true with regard to children. Children's weight should bear a definite relation to their height, there being a slight difference between males and females in this respect, and with the increase in height there should be a corresponding increase in weight. Any variation from this should at once give rise to the suspicion of a distinct impairment of physical condition and should be the signal for lessening the burdens, educational, laborious or athletic, that the growing child has to bear. Notwithstanding its importance, however, weight is apt to be neglected in the list of symptoms presented to the physician. A mother will tell much about the child's habits, waking and sleeping, and much more about the tendencies that the child is supposed to inherit, but she is not apt to have noticed anything with regard to the child's weight nor to know whether there has been a cessation of that normal increase which accompanies growth in healthy children.

Weight, however, is almost as important in adults. For many years insurance companies throughout the world, in the examination of applicants, have been particular in learning his height, weight and family characteristics in these matters. At least one company announced some years ago that it considered a lesser weight than normal as of more significance with regard to the possible development of tuberculosis than a family history of this disease when the individual to be insured was not at the moment living with those members of the family who were sufferers from tuberculosis. It was definitely proclaimed that to be 20 pounds under the weight that a man should have for his height was more important in its possible danger of permitting or encouraging the development of tuberculosis than a history of this disease on both sides in the direct line in the preceding generation. The more recent ideas with regard to the contagiousness of tuberculosis have confirmed this notion, for it is definitely understood that it is people run down in weight who are most likely to contract the disease.

There are other and more distinctly nutritional affections in which loss of weight may often be one of the earliest and most important indices of the disturbance of the physical condition. In the insidious forms of diabetes, for instance, loss of weight in spite of the presence of good appetite seems to occur especially in that group of cases in which the nitrogenous elements of the body become changed to sugar and are eliminated. Needless to say these are the severest form of diabetes and need to be cared for promptly and by a very severe regimen. Dr. Richard Cabot[1] recently pointed out that arteriosclerosis may sometimes be the important causative factor in an emaciation for which no other organic lesion can be found. It is easy to understand that the loss of elasticity in the arteries by disturbing the circulation would diminish nutritional processes, and that before the heart or the kidneys showed any signs of degeneration a reduction in weight might very well take place. In these cases it is especially important that the condition should be recognized as early as possible, so that all overexertion and the ingestion of material that may prove irritant in the course of metabolism and excretion may be avoided.

In functional affections it is recognized that a loss of weight emphasizes symptoms to such a degree as to add greatly to the discomfort of the patient. Many a nervous dyspeptic suffers more from an irritable condition of nerves produced by lack of proper nutrition than from any other cause. After a time in many persons, because of the discomfort felt during digestive processes, what Einhorn has called sitophobia, a species of fear of food develops, which leads to such a reduction in the amount of nutritive material taken as eventually to induce in the patient a mild form of inanition. A distinguished authority in nervous disease said many years ago that more of the discomfort of nervous patients could be relieved by having them eat a hearty breakfast every day for a time than by any other single procedure known to medicine. Certain it is that when there has been a notable reduction of weight, relief of functional nervous symptoms will not be secured until the weight has been regained.

Practically this makes the scale an instrument of precision that may be an important diagnostic aid as regards the general physical condition, as all physicians have found it who have come to use it in practice. It is of as much value for diagnostic purposes in obscure cases of malnutrition as is the thermometer in febrile conditions. The weight record over a prolonged period is often the best evidence that can be studied of the general condition. There seems no doubt but that in the more accurate record keeping of cases which is coming into vogue the weight variation and its connection with symptoms will be considered of as great importance as other and more difficult modes of observation.

1. The Journal A. M. A., March 17, 1906, p. 763.

URIC ACID AS A BUSINESS PROPOSITION.

The advertising pages of medical journals, the pamphlets that are deposited each day on our desks, the oratory of the ubiquitous detail man, teach us to beware of uric acid.

If we are to believe all that we read and hear, uric acid is a virulent poison, one that causes a protean array of symptoms while it circulates and a very chaos of trouble when it becomes deposited in the tissues; we are exhorted to heed this warning and to prescribe this, that and the other uric acid dissolvent or eliminator in order to rid the organism as rapidly as possible of this dangerous body. Our patients, too, have been taught to inform us that they are "full of uric acid" and must have something to get rid of it. How can it be otherwise if they believe even a part of what they are told in newspaper advertisements by certain "patent medicine" and lithia water vendors.

When we prescribe a medicine we should at least know for what we are giving it and how it is expected to act. Whoever orders so-called uric acid solvents and eliminators presumably believes that uric acid is a poison and the cause of many diseased conditions, that it needs dissolving and eliminating, and that the drug or water he orders can accomplish both these desired purposes. An analysis of the premises on which this so-called therapy is based and of the principles that are supposed to underlie it shows that both are fundamentally fallacious and inconsistent.

The error must be immensely popular, however, and the dissolving of uric acid must be a good business proposition or else so much money would not be expended by practical business men in exploiting dissolvents.

As a matter of fact, uric acid acts pathologically in gout presumably only on account of its tendency to form concretions. The immediate factors that determine the precipitation of crystalline urates in the joints, the kidneys and in other organs of predilection are independent of the circulation in excess of soluble urates; for the urates are often enormously increased in the blood without the appearance of gouty symptoms and without the deposit of urate concretions. The most notable example of this kind is leukemia, in which figures for circulating and urinary uric acid are obtained that are far in excess of those ever observed in gout, but in which urate concretions never appear. On the other hand, typical gouty lesions occur in which no urate deposits are found, and in many cases of gout neither the uric acid of the blood nor of the urine is increased.

The injection of uric acid or its salts into the veins or directly into the joints never produces a syndrome similar to gout, nor does feeding with nuclein-containing foods, with pure nuclein or with uric acid, produce any abnormal clinical signs whatsoever beyond temporary flooding of the blood and the urine with uric acid. Uric acid, when injected in a concentrated form under the skin, may, it is true, produce local inflammation followed by necrosis, but this effect must be attributed quite as much to its slightly acid character and to the mechanical irritation of the sharp crystals of uric acid as to any specifically poisonous effect.

The factors that produce the necrotic areas on which secondary deposits of urates occur are not well understood. It is possible that they vary in different cases, that they may be of a specific, infectious, or of a toxic character. Locally, there is usually some sluggishness of the blood stream that, combined with changes in the relative proportion of the acid and basic phosphates (and carbonates) of the blood, may favor urate deposits; for uric acid is soluble in basic phosphates and insoluble in acid phosphates, so that the preponderance of the latter may determine the decreased solubility of uric acid and hence favor its precipitation, provided a suitable nidus, such as a necrotic area, is provided for its deposit. This will occur whether there is an excess of uric acid in the blood or not.

If the rôle of uric acid is relatively subordinate in true gout, how insignificant it must be in that huge array of vague symptoms, involving almost every organ and function of the body, and grouped under the indefinite name of "uric acid diathesis"! Here the rôle of circulating uric acid is altogether in doubt, for there is practically no tangible evidence to show that the amounts of circulating or excrementitious uric acid vary from the normal. Most of the syndromes that are attributed to the so-called uric acid diathesis are based on some derangement of the bowel, some hepatic insufficiency, possibly slight metabolic disturbances or some neurotic element, and are often accompanied or followed by a reduction of the alkalinity of the blood.

In view of the very subordinate rôle of uric acid in the pathogenesis of gout and allied conditions and the manifold and varying factors that determine its excretion and precipitation in the urine, it is clear that treatment directed exclusively toward the reduction of the uric acid excretion is wrong.

It has been shown,[1] moreover, that the absolute amount of uric acid excreted is no true index of the amount of circulating uric acid, for the kidneys possess to a very marked degree the power of destroying uric acid, so that, even if uric acid were present in excess in the blood, this might not at all become apparent in the urine. Above all, the amount of precipitated urates is no index whatever of the amount of uric acid present in the urine, though commonly interpreted in this way. The deposit of a urate sediment is largely dependent on the relative proportion of basic, neutral and acid salts of the urine, its temperature and its concentration, so that the urine may contain abundant urates and remain quite clear, or it may contain relatively little uric acid and deposit a copious precipitate. As fluctuations in

1. Mendel: The Journal A. M. A., March 24 and 31, 1906.

the uric acid excretion are considered the main index of the success or failure of so-called uric acid treatment, it is apparent that all conclusions in regard to the efficacy of this treatment based on the urinary uric acid excretion or precipitation must be utterly fallacious.

We intend to refer to this matter again shortly.

PROFUSE HEMATURIA AND RENAL COLIC IN CHRONIC NEPHRITIS.

The occurrence of small, usually microscopic, quantities of blood in the urine of chronic nephritics is so common that it is almost to be expected if a case is followed long enough and carefully enough. Attacks of profuse hemorrhage from the kidneys, in the absence of trauma, usually lead us to think of stone, tuberculosis, or new growth; or, as a more unusual cause, a floating kidney. The fact that an ordinary chronic nephritis, either parenchymatous or interstitial, may be associated not so very infrequently with profuse hematuria or attacks of colic has not been generally recognized.

The subject has been recently studied by Askanazy,[1] who was able to collect from Lichtheim's clinic alone eleven cases, three of which came afterward to the postmortem table. A study of these cases and of the literature showed that the condition is far from being uncommon, though the hematuria and colic are not always ascribed to nephritis in reporting the cases. The hematuria occurs in some cases but once, or at any rate at very long intervals, in other cases it may occur frequently at relatively short intervals. In many instances, no immediate cause for the hemorrhage is apparent, but some writers have ascribed it to exposure or to cold, and others have tried to incriminate the strenuous physical life, and especially prolonged marching. The attacks usually come on with great suddenness and may or may not be associated with pain. In some instances the blood disappears as rapidly as it appeared after a few hours, but in other cases the blood remains present, at any rate in microscopic quantity, for several days. More rarely, severe hemorrhage may persist for months or even as long as a year.

The presence of pain with the hemorrhage is not constant, and the reverse is also true. When pain is present it may be dull and constant with exacerbations, or it may simulate by its acuity the most severe attacks of renal colic. In the latter instance, general symptoms, such as dizziness, vomiting, chills, and even fever, may accompany the pain and render the resemblance to renal colic still more striking. Usually the pain is situated in the kidney region on one side, and either side may be affected with equal frequency; rarely the pain is bilateral. Radiation of the pain to the genital organs or along the ureters, such as is commonly seen in renal colic, is not infrequently observed. At times the pain is not referred to the kidney region at all, but is situated in the lower zones of the abdomen or in the region of the bladder.

Both the attacks of pain and the severe hematuria occur in male nephritics much more frequently than in females. This is probably due to the greater exposure of the male sex to cold and the effects of physical overexertion. The occurrence of hematuria and colic with nephritis most commonly between the ages of 30 and 50 is presumably due to the fact that the disease is most frequent between these ages.

The cause of the colic and the bleeding has led to a good deal of discussion. The colic, in some instances, is doubtless due to the lodgment of clots in the ureter, for in some cases these have been passed after an attack. As the colic can occur without hemorrhage, this, however, can not always be the cause. Israel thinks that both colic and hematuria are due to an acute paroxysmal congestion, and Askanazy supports this view. Others have held that the process is in the nature of an acute angioneurotic edema, and still others that crystals in the urine, if numerous enough, can cause the symptoms even in the absence of definite stone. Whatever the cause, the incidence of the condition should be recognized, as it is one likely to lead to mistakes in diagnosis.

VACCINATION AGAINST PLAGUE.

It is rather curious that in the fight against infectious diseases in the human being vaccination in the true sense has been used but little, aside from its use as a preventive of smallpox. In the sense meant by Jenner and Pasteur, vaccination refers to inoculation with a living organism of attenuated virulence, and it seems desirable in the interests of lucidity that the term should be so restricted and should not be employed to designate forms of protective inoculation in which killed organisms or their extracts are employed.

We have frequently pointed out in these columns the difference between diseases due to bacteria which excrete their toxins and those due to bacteria in which the toxins are intimately associated with the body of the bacterial cell. Most human infectious diseases are caused by bacteria of the second group, and, as it is in animal diseases of this group that true vaccination has been most successful, it would seem likely that the same would be true of human infections of this type. Aside from the difficulty often experienced in getting human beings to submit to preventive inoculations with attenuated viruses, the physician himself, no doubt, feels some hesitation in employing this method, on account of the fact that it is difficult to be sure that the organism to be inoculated is sufficiently attenuated, and that all risk of causing a fatal attack of the disease can be eliminated.

The history of attempts to vaccinate against plague is not modern, for the plan was tried in the eighteenth century, but with disastrous results. From the experimental standpoint the subject has been attacked by in-

dependent investigators and by the plague commissions of recent years, but until recently the risk of producing a fatal issue was still too great to think of applying the results of the experiments to man. Part of the difficulty in plague has been in finding a method by which the plague bacillus could be successfully attenuated, but this has apparently been accomplished at last both by Kolle and Otto and by Strong.[1] The latter observer, after carefully testing his cultures on animals, made a series of inoculations into prisoners sentenced to death, with no deleterious results. The plague bacilli, suspended in salt solution, were injected into the depths of the deltoid muscle, and caused a slight induration, mild fever lasting for two or three days, and a leucocytosis. Suppuration at the point of injection never occurred. The study of the agglutination reactions and the testing of the serum on the lower animals gave abundant evidence that the vaccinations were effective. So far as animals are concerned, Strong states that vaccination is by far the most effective form of inoculation.

In bringing the matter to the attention of the medical profession, Strong warns against the use of any strain of pest bacillus except one which has been properly attenuated and thoroughly tested on animals. Unless the utmost care be taken, untoward results will surely follow, for it is extremely difficult properly to attenuate the plague bacillus; in fact, the process may take years. The reports of Kolle and Strong are of great interest and hold out the hope that in time we may be able to protect against plague as efficiently as we now do against smallpox, and with no more risk.

EDEMA OF THE LUNGS AS A COMPLICATION OF ETHER NARCOSIS.

To the surgeon who operates frequently, the induction of inhalation narcosis becomes a familiar and consequently a comparatively simple procedure. That it is by no means so will be readily understood from a consideration of the physiologic conditions present, and this fact has been conclusively demonstrated by the happily not frequent fatality attending the practice, even when this was not to have been foreseen by anything short of prescience. Heart failure from the inhalation of chloroform is always kept in mind by the careful operator and anesthetist, while the possibility of respiratory failure during ether narcosis or the development of some form of pneumonia as a sequel should always receive due consideration. Edema of the lungs is a rare complication of ether narcosis, and a most interesting case of this kind is added by Dr. Victor C. Pedersen[2] to the small number that have heretofore been placed on record. The patient was a healthy man, about 30 years old, who was to be operated on for internal and external hemorrhoids. Narcosis was induced by means of nitrous oxid gas followed by ether, about one gallon of the former and four ounces or less of the latter being used. Cyanosis appeared at once and excitement was marked. During the operation, which occupied twenty minutes, the color was satisfactory, and there was no evidence of undue accumulation of mucus in the respiratory passages. Cyanosis reappeared when after the operation the patient was restored to the dorsal decubitus, and soon respiration appeared about to fail. Auscultation disclosed the physical signs of acute edema of the lungs. Atropin, grain 1/25, was administered hypodermically, the foot of the bed was elevated to an angle of about 15 degrees, dry cups were applied extensively to the chest, strychnin sulphate, grain 1/20, followed by whisky, was administered hypodermically, inhalation of oxygen was practiced, and nitroglycerin, grain 1/25, was injected beneath the skin, and finally the foot of the bed was raised to an angle of 30 degrees. Improvement became evident in the course of forty minutes and continued to perfect recovery. The admirable behavior of the heart prior to the development of the edema makes it probable that the latter was primarily and directly due to the irritation of the air vesicles by the ether. In view of this fact, the greatest care should be exercised in the administration of ether by inhalation in order to avert this danger. The common practice of pushing the anesthetic when resistance appears during the stage of excitement should be abandoned in favor of a gradual and steady administration. The report of this case teaches, further, the importance of physical examination of the chest following ether narcosis, as by this means an edema of the lungs may at times be recognized that would otherwise escape observation, and even perhaps progress to a fatal termination.

2. Ann of Surg., January, 1906, p. 35.

THE METABOLIC FACTOR IN THE ETIOLOGY OF THE PAROXYSMAL NEUROSES.

Migraine, asthma and epilepsy, in addition to their periodicity of recurrence and a certain interchangeability, have in common the peculiarity that the paroxysm is not infrequently preceded by phenomena of functional derangement of one sort or other, which disappears with the attack, suggesting the possibility of some disturbance in the body chemistry as the exciting factor. These phenomena, in the opinion of Dr. Francis Hare,[1] are dependent on variations in the intake and output of carbon dioxid. The disorders mentioned also exhibit certain relations to acute articular gout. Accordingly, Hare formulates the hypothesis that all the affections named are due primarily to an accumulation of unoxidized or imperfectly oxidized carbonaceous material in the blood, the paroxysm being a conservative measure adapted to the dispersion of such an accumulation. To this condition he gives the name hyperpyremia, and from a series of observations he develops the generalization that whatever tends to reduce the carbonaceous income or to increase the carbonaceous expenditure of the blood tends to the dispersion of the paroxysm, while whatever tends to increase the carbonaceous income or to decrease the carbonaceous expenditure of the blood tends to initiate, precipitate or intensify the paroxysms of migraine, asthma and epilepsy. Accordingly, the

1. Practitioner, February, 1906, p. 179.

conclusion is reached that hyperpyremia is a common humoral factor, at least in some cases, of the special pathologic variation of vasomotor action on which depend the attacks of migraine, asthma and epilepsy. Paroxysms of these affections can be viewed in the light of conservative, though not necessarily salutary, reactions adapted to dispersion of the hyperpyremia. Hyperpyremia implies relative failure of the physical functions that together comprise the carbonaceous expenditure of the blood.

THE CAUSE OF BERIBERI.

The importance of a knowledge of the etiology of a disease before satisfactory steps can be taken to prevent it has never been more forcibly demonstrated in recent years than in the experiences of the Japanese army with beriberi. It is hardly necessary to speak of the success which the Japanese had in preventing the spread of the infectious diseases of known origin, such as typhoid fever and dysentery, for this is common knowledge, but it is perhaps not widely known that, at a conservative estimate, from 75,000 to 80,000 cases of beriberi occurred in the Japanese army. Dr. Herzog[1] of the Manila laboratory was detailed to investigate beriberi among the Japanese soldiers who had been invalided home, and in his preliminary report describes a coccus which has been isolated from the blood and excretions of patients with this disease by Dr. Kokubo of the Japanese army. Dr. Herzog is now working on the organism, and it is to be hoped that at last the cause of this mysterious and fatal disease is to be run to earth.

THE SURGEON'S LIABILITY FOR UNAUTHORIZED OPERATION.

A Minnesota physician some time ago found it necessary, in his judgment, to perform an operation somewhat different from that which had been first intended when the patient was put under anesthesia. As a result he was sued for damages, and the case has been before the courts now four times, the first trial resulting in a disagreement of the jury; the second, in a verdict of over $14,000 damages (set aside as excessive by the higher court), and the third trial, in a verdict of $3,500 damages. This verdict has now also been set aside. The judge says that had he known the evidence at the time of the third trial as he did afterward the result would have been different. The condition of the patient (with suppuration of the ear) demanded relief, because otherwise her life would have been left in jeopardy, and physicians called as witnesses testified that the procedure used was indicated. Therefore, decided the court, the surgeon would have been subject to criticism if he had not done what he did, and manifestly it is not right that he should be wrong both in doing and in not doing a certain thing. It appears from this that a surgeon who ventures to do what was not anticipated still undergoes a risk, yet in cases where his deviation was necessary or essentially life saving and can be proved to be of that character, it is recognized that he ought not to be mulcted for damages.

1 Philippine Journ. of Science, 1906, vol. 1, p. 169.

THE ARMY MEDICAL BILL.

The Act to increase the efficiency of the Medical Department of the Army was passed by the Senate March 29 and favorably reported by the Military Committee of the House of Representatives April 4. It has therefore reached the same stage as it did in the last Congress, when it failed because it was not permitted to come to a vote in the House. If brought before the House its passage is considered certain, but under the rules of that body this can not occur without a special rule fixing a day for its consideration. This is a matter which is well known to be in the hands of the Speaker. The reason given for his unfavorable action last year—the existence of a deficit in the Treasury—does not obtain this year. In view of the fact that this measure is considered by the War Department and the President absolutely essential to an efficient organization of the Medical Department, and that the medical profession generally is strongly interested in it, it is earnestly to be hoped that Mr. Cannon will not again assume the responsibility of preventing Congressional action on this most necessary and humane measure.

Medical News

CALIFORNIA.

New Hospital.—The new hospital at San Diego, erected by Dr. Joseph C. Hearne, was formally opened March 7.

Medicine Vendor Convicted.—A jury in Sacramento, March 17, found "Dr." George Hirzu guilty of selling medicine in the public streets, contrary to the city law.

Will Not Accept Contract Work.—The Medical Society of San Benito County has adopted a resolution that in future no member shall accept contract work from fraternal orders.

Will Endow Hospital.—Henry Miller, a cattleman of Gilroy, has announced that he will endow a hospital and sanatorium in Gilroy with $10,000, and will also donate ten acres of land for a site and furnish building material from his own quarries.

Donation for Medical Books.—Dr. W. Jarvis Barlow, chairman of the library committee of the College of Medicine of the University of Southern California, Los Angeles, has received a check for $500, to be used for the purchase of books for the library of the medical college.

Smallpox.—Smallpox is reported in the camps of the Yosemite Railroad, east of Merced. The secretary of the State Board of Health states that the disease is well scattered through the state and especially in railway camps.——Dr. Joseph J. Medros, Haywards, is ill with smallpox.

Court of Appeals Decides Against Physician.—The Court of Appeals has decided the case of B. J. Short against Dr. George K. Frink, San Francisco, in which the plaintiff sustained a compound fracture of the right leg and claimed $8,000 damages for alleged malpractice on the part of the defendant, in favor of the plaintiff, affirmed the verdict of the lower court and the award of $8,000 made by it.

To Aid Associated Charities. The following 11 members of the Pasadena branch of the Los Angeles Medical Society have offered to give their services to charitable purposes under the direction of associated charities: Drs. George E. Abbott, Alva McCoy, Fitch C. E. Mattison, Charles L. King, George Deacon, John M. Radebaugh, Arthur T. Newcomb, B. C. Atterbury, Maria Congdon, Mary E. Hagadorn, Albert B. Royal, Caroline McQuiston, Zachariah T. Malaby and Thomas J. Wilson.

Personal.—Dr. James H. Parkinson has been elected president of the Sacramento board of health, vice Dr. Thomas Ross, deceased.——Dr. David A. Beattie and family, Santa Clara, have returned from Europe.——Dr. Elliott H. Wortsey, Oakland, was thrown from a street car, fracturing his patella.——Dr. Joseph W. James has been appointed a member of the Sacramento board of health.——Dr. Harry E. Piper, Santa Cruz, has been elected secretary of the Santa Cruz Medical Society, vice Dr. Charles I. Anderson, resigned.——Dr. Sarah I. Shuey, Oakland, is seriously ill with septicemia.

Societies Meet.—At the regular annual meeting of the San Joaquin Valley Medical Association, held in Bakersfield, the following officers were elected: President, Dr. George H. Aiken, Fresno; vice-presidents, Drs. Fred P. Clark, Stockton; C. P. H. Kjaerbye, Fresno, and Charles T. Rosson, Hanford; secretary and treasurer, Dr. Dwight H. Trowbridge, Fresno; assistant secretary, Dr. John R. Walker, Fresno, and treasurer, Dr. Thomas M. Hayden, Fresno. The society voted that members who accepted less than $5 for an examination for life insurance should be fined $25 for the first offense, and for a second offense should be liable to expulsion from the society. ——On March 12 the Sacramento Society for Medical Improvement gave a banquet for Dr. Gustavus L. Simmons, in honor of the fiftieth anniversary of his graduation in medicine. On behalf of the society Dr. William E. Briggs presented Dr. Simmons with a silver loving-cup. The following officers were elected: President, Dr. Henry E. Wright; secretary and treasurer, Dr. Edwin M. Wilder, and directors, Drs. Gustavus L. Simmons, Henry L. Nichols, Wallace A. Briggs, Henry E. Wright and Edwin M. Wilder, and delegates to the state medical society, Drs. William E. Briggs and James H. Parkinson, and alternates, Drs. James A. McKee and Samuel E. Simmons.

COLORADO.

Pneumonia Epidemic.—An epidemic of pneumonia is prevalent among the mining camps around Ouray. During the last week in March 20 deaths are said to have resulted from the disease.

Will Not Accept Low Fee.—The Teller County Medical Society at its meeting, February 22, adopted resolutions setting forth that no member of the society should examine an applicant for life insurance for a fee of less than $5.

Personal.—Dr. and Mrs. Harry P. Packard will soon leave Denver for Persia, where Dr. Packard will take charge of the Mission Hospital at Teheran.——Dr. A. Mansfield Holmes, Denver, is convalescent after a sharp attack of pneumonia.—— Dr. Edwin S. Dodds, Pueblo, is ill at St. Mary's Hospital with rheumatism. ——Dr. Gerald B. Webb, Colorado Springs, has gone from London to Vienna.

Life Insurance Examination Fees.—At a meeting of the Lake County Medical Association, held in Leadville, March 15, the following resolutions were adopted and signed by every practicing physician in Lake County:

Whereas, In consideration of the time, skill and care necessary for an examination for life insurance, we deem that the fee of five ($5.00) dollars is a fair, reasonable and just charge for such examination; therefore be it

Resolved, That on and after April 1, 1906, each and every member of the Lake County Medical Association shall not make any examination for Old Line Life Insurance Companies for less than the sum of five ($5.00) dollars; and be it further

Resolved, That such Life Insurance Companies as are now paying less than five ($5.00) dollars be notified by the Secretary that on and after April 1, 1906, no regular life insurance examinations will be made by any members of this association for less than five ($5.00) dollars; and be it further

Resolved, That any member who violates this resolution shall be suspended from the association; and be it further

Resolved, That it shall be unlawful for any member of this association to consult with any physician so suspended.

GEORGIA.

State Association Meeting.—The Medical Association of Georgia will convene in Augusta for its annual session, April 18.

Sanatorium Sold.—The Halcyon Sanatorium, Atlanta, has been sold by Dr. Joses B. S. Holmes to W. B. Hamby for $46,000.

Acquitted.—Dr. W. B. Vaughn, physician of Barton County, has been acquitted of involuntary manslaughter in the case of a convict named Virgil Liddelle.

New Rule at Grady Hospital.—The board of trustees of Grady Hospital, Atlanta, has passed a resolution abolishing all money payments to internes of the hospital.

Election.—The Medical Society of Floyd County at its annual meeting held in Rome, elected the following officers: President, Dr. William J. Shaw, Rome; vice-president, Dr. J. C. Huell, and secretary-treasurer, Dr. W. L. Funkhouser.

Personal.—Dr. Everett Daniel, Moultrie, has been elected delegate to the state medical association by the Colquitt County Medical Association.——Dr. George H. Noble, Atlanta, has received from the Louisiana Purchase Exposition a commemorative diploma and medal.

Physician Fined.—Dr. Samuel G. Scoven, Macon, was fined $100, March 10, for contempt of court, the contempt lying in the fact that the physician had signed a certificate that a defendant in the City Court was ill and unable to attend court when in fact he had left the state.

Ask for Pasteur Institute.—A circular has been mailed by Dr. A. G. Fort, Lumpkin, to each member of the general assembly of Georgia and to all members of the Medical Association of Georgia, seeking to interest them in the establishment of a branch of the Pasteur Institute for the treatment of hydrophobia. The circular sets forth that during 1905 five individuals were bitten by mad dogs in Stewart County alone. Dr. Fort hopes that a bill may be passed covering this important matter.

Commencement Exercises.—The graduating exercises of the Medical Department of the University of Georgia, Augusta, were held April 2, when a class of 30 was graduated.——The fifty-first annual commencement exercises of the Atlanta College of Physicians and Surgeons were held April 2, when a class of 56 received diplomas.——The first commencement exercises of the Atlanta School of Medicine were held April 3. A class of 21 was graduated. Dr. George H. Noble read his report and Hon. Hooper Alexander delivered the annual oration.

ILLINOIS.

State Society Meeting Deferred.—The Illinois State Medical Society will meet at Springfield May 22 to 24 and not May 15 to 17, the date originally set for the meeting.

Hospital Staff Resignations.—The trustees of the Illinois Eastern Hospital for the Insane, Kankakee, on April 5 accepted the resignations of Drs. Beebe and Francis Walls.

Personal.—Dr. Theodore A. Johnson, Xenia, was murderously assaulted by Henry Baker, a would-be pensioner, whose petition Dr. Johnson could not endorse.——Dr. Samuel M. Wylie, Paxton, sailed for Lisbon, April 7.

Chicago Delegation for Lisbon.—Among the Chicago physicians who have left for Lisbon to attend the International Medical Congress are Drs. Nicholas Senn, Daniel R. Brower, Lucy Waite, Harriet C. B. Alexander, Fenton B. Turck and J. D. Hammond.

Interne Examinations.—Of the 53 physicians who passed the civil-service examination for appointment as internes in the county hospitals and Cook County Institution, Dunning, 40 will be appointed to positions within the next nine months, the first appointments being made at Cook County Hospital in June.

Chicago.

Fined for Sale of Cocain.—A. Monaco, a Clark Street druggist, has been fined $100 for selling cocain without a physician's prescription.

Matinee for Tuberculosis Dispensary.—The matinée musicale given April 5 for the benefit of the Chicago Tuberculosis Institute yielded almost $2,000 for the institution.

Petition Against Extension of Hospital.—Owners of frontage on Michigan Avenue are circulating a petition protesting against the extension of St. Luke's Hospital to that street.

Opposition to Hospital Ends.—After a strife of three years the village board of Oak Park authorized Dr. John W. Tope and a Roman Catholic sisterhood to erect a $100,000 hospital building in Wisconsin Avenue south of Madison Street.

Faculty Resignations.—The following members of the faculty of the American College of Medicine and Surgery (Medical Department of Valparaiso University), have resigned: Dr. Henry S. Tucker, dean, head professor of gynecology; Dr. Ross C. Whitman, head professor of pathology; Dr. Victor J. Baccus, head professor of surgery; Dr. Henry G. Anthony, head professor of dermatology and genitourinary diseases; Dr. Charles H. Francis, head professor of ophthalmology; Dr. Henry F. Lewis, head professor of obstetrics; Dr. J. Rawson Pennington, professor of rectal diseases; Dr. George E. Baxter, professor of pediatrics; Dr. George J. Tobias, professor of hygiene and preventive medicine; Dr. J. McDonald Scott, assistant professor of surgery; Dr. Mary O. Porter, assistant professor of obstetrics; Dr. Marion B. McDonald, assistant professor of otology; Dr. Clare S. Learned, adjunct professor of therapeutics and materia medica; Dr. Arthur N. Mackey, instructor in dermatology, and Dr. Charles D. Hulbert, instructor in dermatology.

MARYLAND.

Physician Active in Legislature.—Dr. Richard S. Hill's bill appropriating $90,000 for the construction of a great boulevard between Baltimore and Washington has passed the legislature and has received the governor's signature. Dr. Hill is a member of the House of Delegates from Prince George County. The road will be built under the direction of the state commission on highways.

Baltimore.

Smallpox.—During the week ended April 7 three cases of smallpox were reported.

Pneumonia and Pertussis. During March 149 deaths were reported from pneumonia. Whooping cough was prevalent.

Funds for Hospital.—Crusade Commandery, Knights Templar, have turned over $2,718.10 to the Hospital for Consumptives, the proceeds of a recent charity ball.

Delay in Removal of University.—The failure of the legislature to appropriate $50,000 to the Johns Hopkins University will delay indefinitely its removal to the new suburban site.

Personal.—Dr. William H. Welch has been elected an honorary member of the Gesellschaft der Aerzte of Vienna, Austria.——Dr. J. Hall Pleasants is now in Naples and will spend the spring in London.

State Appropriations.—It is said that $160,000 more was appropriated by the legislature to institutions than at its last session. It has been particularly liberal to the hospitals, the University of Maryland Hospital alone receiving $60,000. For the State Tuberculosis Sanitarium, to be founded, $100,000 was appropriated for grounds and buildings and $15,000 a year for maintenance.

Enlargement of Hospital.—The $25,000 appropriated by the legislature to the Endowood Hospital for Consumptives, in the suburbs of Baltimore, will permit the erection of additional buildings, the laying out of the 75 acres of grounds and the establishment of a country sanitarium. The benefits also can be extended to the poor. Private charity is expected to add $50,00 or more to the aid given by the state.

School Inspection.—Dr. Bosley, health commissioner, attributes very beneficial results to the medical inspection of public schools in the diminution of deafness, diphtheria and consumption. Parents all over the city are having their children treated for adenoids and enlarged tonsils as soon as the evil is pointed out to them by the inspectors. Many children were also found suffering from bad nutrition, the result of improper or insufficient food, and the attention of the charitable organizations has been called to these cases, disease thus being forestalled in many instances.

MASSACHUSETTS.

Report on Anti-Vivisection Bill.—In the legislature, March 26, the report of the committee on probate and chancery against the anti-vivsection bill was accepted without debate.

District Society Meeting.—At the meeting of the Middlesex East District Medical Society, held in Boston, March 14, the president appointed the following committee on the prevention and control of tuberculosis: Drs. George F. Daw, Reading; Richard Dutton, Wakefield; Francis E. Park, Stoneham; Ralph K. Stratton, Melrose; William H. Keleher, Woburn, and Harold A. Gale, Winchester.

Hospital Alumni.—The Massachusetts General Hospital Alumni Association was organized in Boston, March 24, 175 ex-internes being present. The following officers were elected: Dr. James C. White, Boston, president; Drs. Homer Gage, Worcester, Mass.; Thomas W. Huntington, San Francisco, and William S. Thayer, Baltimore, vice-presidents; and Dr. Fred A. Washburn, Boston, secretary.

Medical Library Association Organized.—The Springfield Medical Library Association, whose object is to promote the social and scientific interests of its members and to bring about a closer companionship among the medical men of Springfield, at its first regular meeting, March 9, elected Dr. Dudley Carleton, president; Dr. Edward M. Brown, vice-president; Dr. E. M. Cort, secretary and treasurer, and Dr. J. I. Butler, librarian.

District Nurses for Public Schools. Since last December the experiment of having nurses of the District Nursing Association, under the supervision of the Boston board of health, visit the public schools, has been tried with much success by two nurses. Some treatments are given in the school buildings, while other patients are followed to their homes and cared for there. In this Boston is following the lead of New York City, where there have been such school nurses for the last three years.

Personal. Dr. Simon J. Russell, city physician of Springfield, has resigned.——Dr. Charles H. Richardson, Pittsfield, and Dr. Franklin C. Downing, Lanesboro, returned from Europe, March 15.——Dr. Charles S. Holden has been chosen chairman, and Dr. George K. Roberts, secretary, of the Attleboro board of health.——Dr. George W. Galvin, for sixteen years surgeon and chief of the Emergency Hospital, Boston, has resigned that he may devote himself to private practice.

Dr. Alfred H. McCormack, Northampton, sailed for Europe, March 14.——Dr. Paul Thorndike, Boston, has been visiting in Milwaukee.—— Dr. Walter A. Harding has been unanimously elected president of the Everett Medical Society. ——Dr. John B. Hull has been elected physician of the Williamstown board of health.——City Physician George L. Black, Lawrence, has been removed, pending investigation of charges alleging conduct unbecoming a city official and physician.

Hospital Reports. The annual report of the Massachusetts General Hospital for 1905 shows that 5,096 patients were treated in the wards, of whom 2,023 paid for their care in whole or in part. There were 21,874 outpatients treated and 5,459 accidents. The McLean Hospital for the Insane and the Convalescent Home in Waverly are maintained by the same board of trustees. The expense for the General Hospital was $238,457, of which $92,226 was paid by patients, the net deficit being $27,133. This was somewhat reduced by the income of the McLean Hospital, where, with a total expense of $236,703, there was an income of $4,404 additional. The total deficit for the three institutions for 1905 was $23,446, as against $21,109 in 1904 and $64,000 in 1903. Gifts amounting to $415,039 have been received during the year and have allowed the renovation of the Townsend and Bigelow wards and the construction of a new building for women at Waverly, with 36 beds.——At the Cambridge Relief Hospital 1,866 patients were cared for during the year, and 3,400 visits were subsequently made at their homes.

Hospital News.—Waltham Hospital has received a donation of $5,000 from Mrs. Caroline Foster Stickney for the establishment of a free bed to be known as the Joseph Stickney free bed.——The new main building in the New England Sanitarium in the Middlesex Fells, Melrose, was dedicated February 28.——It has been decided to apply the Lemont G. Burnham fund of more than $150,000 to the building of a new wing for the Boston City Hospital, to be known as the Lemont G. Burnham ward. The addition will accommodate 30 patients.——Frank A. and Henry Day, Newton, who recently gave the Day Memorial Home for Nurses to the Framingham Hospital, have agreed to provide the entire equipment of the home.——Only $1,030 remains to be subscribed to make up the $22,000 needed to clear up the debt of the Springfield Hospital. ——Brockton Hospital has received a gift of $500 from George E. Keith to assist in paying the debt on the heating plant.——George Tracy Webster has announced that he will give $1,000 toward the erection of a suitable public hospital for Webster and Dudley in addition to the hospital site previously offered.——By the will of Charles H. Pew $5,000 is bequeathed to the Addison Gilbert Hospital, Gloucester.

Must Label and Give Contents.—The committee on public health of the Massachusetts legislature has reported in favor of the following bill:

Section 1. On every package, bottle or other receptacle holding any proprietary or patent medicine, or any proprietary or patent food preparation, which contains alcohol to an amount in excess of the amount shown to be necessary by the United States Pharmacopeia or the National Formulary as a solvent or preservative of the active constituents of the drugs contained therein, and to prevent deterioration by freezing or fermentation, shall be marked or inscribed a statement of the percentage of alcohol by volume contained therein; and the provisions of Section 19 of Chapter 75, Revised Laws, shall apply to the manner and form in which such statements shall be marked or inscribed.

Sec. 2. Every package, bottle or other receptable holding any proprietary or patent medicine or food preparation shall bear a label containing a statement of the quantity of any opium, morphin, heroin, cocain, alpha or beta eucain, or chloral hydrate contained therein, provided that the package contains more than two grains or opium, or more than one-quarter grain of morphin, or more than one-sixteenth grain of heroin, cocain, alpha or beta eucain, or more than eight grains of chloral hydrate. In one fluid ounce, or, if a solid preparation, in the avoirdupois ounce; and the provisions of Section 19, Chapter 75, Revised Laws, shall apply to the manner and form in which such statements shall be marked or inscribed.

Sec. 3. Whoever manufactures, sells or offers for sale any medicine or food preparation in violation of the provisions of the act shall be punished by a fine of not less than $5, nor more than $100.

Sec. 4. This act shall take effect on the first day of September in the year 1906.

NEW YORK.

Money for Cancer Laboratory.—The State Cancer Laboratory, Buffalo, will receive this year $21,000 from the state, $3,000 of which will be devoted to meet the deficit of last year.

The Mosquito Bill. A bill which seeks to exterminate the mosquito on Staten Island and has been reported favorably in the assembly, authorizes local boards of health to remove swamps which are breeding places for the insects.

Much Scarlet Fever. Since October last there have been 411 cases of scarlet fever in Utica, and 123 were under observation March 28. The board of health claims that this large amount of scarlet fever is due to the failure to maintain quarantine

Thatcher Not Guilty.—Dr. Edward P. Thatcher, Newark, charged with manslaughter in the first degree, in having caused the death of Grace Tyler, a Macedon girl, through the performance of a criminal operation, was found not guilty, March 28.

Medical Club Election.—The Utica Medical Club held its annual meeting March 15, at which the following officers were elected: President, Dr. Lewis B. Armsbry; vice-president, Dr. Andrew Sloan; secretary and treasurer, Dr. W. S. Nelson, and trustees, Drs. William J. Schuyler, Edwin Van D. Gazzami and Morris J. Davies.

Health Officers Organized.—Ontario County health officers met at Canandaigua recently and formed a society for organized effort on lines of health as regards the various villages and towns of the county. Dr. Orlando J. Hallenbeck, Canandaigua, was elected president; Dr. Duncan S. Allen, Seneca, vice-president, and Dr. Daniel A. Eiseline, Shortsville, secretary.

February Vital Statistics.—There were 11,351 deaths during February, or 44 less than the corresponding month of last year. The mortality increased from 382 deaths daily to 400. Infant mortality increased, due to the increase in measles and diphtheria. Consumption and cerebrospinal meningitis increased while pneumonia decreased. The mortality from measles was double that of last year. Pneumonia caused 15 per cent. of the total mortality, and 100 fewer deaths than in last February. The usual influenza epidemic was in progress, but few deaths were attributed to it.

Society Changes Name.—The Practitioners' Medical Society, Rochester, has changed its name to the Blackwell Medical Society, in honor of the first woman medical graduate. The following officers were elected: Honorary president, Dr. Sarah R. Adamson Dolley; president, Dr. Marion Craig Potter; vice-president, Dr. Evelyn Baldwin; secretary, Dr. Emily A. Cady Harris; treasurer, Dr. Helen De Witt Justin, and councilors, Drs. Sarah R. Adamson Dolley, Evelyn P. Ballantine and M. Louise Hurrell. The society has also revised its constitution to make it conform to the requirements of the American Medical Association.

Personal.—Dr. William Mabon, Albany, president of the state lunacy commission, is about to resign and take charge of the Manhattan State Hospital, Ward's Island, New York City. ——Dr. Richard L. Stoddard, Rochester, fell March 8, fracturing his right leg near the ankle.——Dr. Benjamin C. Wakely, Hornellsville, has been appointed coroner of Steuben County, vice Dr. Reuben F. Parkhill, Howard, deceased.——Dr. Carmi C. Thayer, physician of the Clifton Springs Sanatorium for 25 years, has resigned.——Dr. J. Nelson F. Elliott has been made chief medical inspector of schools of Syracuse.——Dr. Arthur W. Elting, Albany, was recently operated on at Johns Hopkins Hospital, Baltimore, for an infected finger.——Dr. Durrand R. Kinloch has been appointed a member of the surgical staff of the Utica General Hospital, vice Dr. M. O. Terry.

New York City.

Bail Forfeited.—Bail of $1,500 given by "Dr." William Crutchy, charged with maintaining an establishment for illegal medical practice, was ordered forfeited March 24, as the defendant failed to appear.

Acquitted.—Dr. Benjamin S. Van Zile, Brooklyn, charged with manslaughter in the first degree, in having, as alleged, caused the death of Mrs. Celia Applebaum by criminal operation, was acquitted March 27.

Under the Knife.—Dr. J. M. Pilcher was operated on for appendicitis in Bellevue Hospital by his father and brother, March 25.——Dr. Moses I. Jackson, formerly borough coroner, was operated on March 27 for suppuration at the base of the brain.

Delegates to Lisbon Conference.—Prof. A. E. MacDonald was appointed to represent the New York University medical faculty at the International Medical Congress, and Dr. Charles W. Allen has been appointed delegate from the American Dermatological Association.

Malignant and Non-Malignant Growths.—On April 18 Dr. William S. Bainbridge wil give a clinical lecture on malignant and non-malignant growths in the outpatients' hall of the New York Skin and Cancer Hospital, at 4:15 p. m. The medical profession is invited to be present.

Smallpox Aboard Ship.—The steamship *Würzburg* of the North German Lloyd Line, which arrived on April 4, was detained at quarantine because of the discovery of a case of smallpox among the cabin passengers. Before the ship was allowed to dock 1,003 vaccinations were made.

Acknowledge Donation.—The trustees of the Sydenham Hospital, at a dinner April 2, presented Isaac Guggenheim a silver loving-cup in recognition of his recent gift of $250,000 to that institution. Mr. Guggenheim has promised to build a new home for the hospital when its patronage warrants the outlay.

Field Hospital Planned.—An important step for the benefit of the medical department of the National Guard of New York is the formation of the field hospital to be attached to headquarters. The hospital will be under command of Dr. William S. Terriberry, Twelfth Infantry, New York City, assisted by Drs. William E. Butler, Brooklyn, Twenty-third Infantry, and Thomas A. Neal, New York City, late Seventh Infantry.

Contagious Diseases.—For the week ended March 31, 1,941 cases of measles were reported, with 62 deaths; 387 cases of tuberculosis, with 198 deaths; 357 cases of diphtheria, with 52 deaths; 220 cases of scarlet fever, with 11 deaths; 28 cases of pertussis, with 4 deaths; 32 cases of cerebrospinal meningitis, with 19 deaths; 20 cases of typhoid fever, with 8 deaths; 166 cases of varicella, and 2 cases of smallpox, a total of 3,153 cases and 354 deaths.

Examination for Internes.—A competitive examination will be held at Lincoln Hospital, East One Hundred and Forty-first Street and Southern Boulevard, April 17 and 18, to fill four positions on the house staff. The written examination on anatomy, surgery, medicine, obstetrics and gynecology will be held April 17 at 2:30 p. m., and the oral and practical examination at the same hour on the following day. Application for permission to take this examination should be made by letter to Dr. Benjamin F. Tilton, secretary of the medical board, 121 East Thirty-eighth Street.

Lower Death Rate.—The report of the board of health for the first quarter of 1906 shows a lower death rate than for any previous corresponding period, though the death rate from measles and diphtheria is higher than ever before. This is accounted for by a remarkable decrease in the number of deaths from scarlet fever and cerebrospinal meningitis. In 1903 there were only about 10,000 cases of measles, scarlet fever, diphtheria and spinal meningitis, with a total death rate from all causes of 19.48 per 1,000. With 30,000 cases of the diseases just mentioned for the period there was a death rate of 19.47 per 1,000.

Hospital Notes.—At the annual meeting of the Metropolitan Hospital and Dispensary, March 1, it was announced that $5,000 had been added to the hospital funds in ten donations of $500 each.——The German Hospital Society of Brooklyn has received a donation of $10,000 from Peter Wyckoff, Williamsburg.——The new St. Francis Hospital on the Bronx was dedicated with formal ceremony by Archbishop Farley, March 1. The hospital has cost more than $800,000, and will have accommodations for about 600 patients.——The new Samaritan Hospital and Dispensary in Brooklyn was formally opened March 7. It has accommodations for 25 patients.

Prevents Tuberculosis Clinic.—A judgment has been granted restraining the health department from establishing a tuberculosis clinic in Henry Street, Brooklyn. The justice who granted this decree declared that the signs placed about the city were not effective in causing the people to obey the anti-spitting ordinance. Several doctors testified that the spitting of the patients going to and coming from the clinic would make the neighborhood unhealthful. Dr. Darlington testified that the streets and sidewalks about the clinic in Manhattan were free from sputum and that he had never seen a consumptive under treatment spit in the streets.

Personal.—Dr. Amelia W. Lines, Brooklyn, fell and dislocated her hip March 8, and is confined to her bed.——Dr. L. Bolton Bangs was the guest of honor at a dinner given by the Rochester Pathological Society, March 9, after which he gave an address on "Prostatectomy."——Dr. Francis J. Quinlan, president of the Catholic Society, has been selected to receive the Laetere medal given each year by the University of Notre Dame, South Bend, Ind., to the Catholic most distinguished in good works.——The home of Dr. Simon Baruch was deluged by water from a broken main, causing damage to the extent of several hundred dollars.——Dr. William M. Polk has been elected president of the Tennessee Society, recently organized in this city.——Dr. Carl Beck was the guest of honor at the dinner of the German Students' Society on March 24. A silver vase was presented to Dr. Beck, who was the originator of this society.

Otisville Tuberculosis Sanatorium.—The purchase of land for the city farm in Orange County has been completed. The altitude of this land is from 850 to 1,400 feet. The board of

estimate has given the health department $150,000 of city bonds for carrying on the work, $20,000 of which has been released for immediate use. With this sum the buildings now standing will be put into proper condition and a number of portable houses containing three rooms, each 10x10 feet, will be installed for immediate use. During the coming summer the number of consumptives received will be limited to 100, but during the warm weather the construction of substantial buildings will be pushed so that in a short time the work can be carried along on a much larger scale.

OHIO.

Epidemic Diseases.—Diphtheria is epidemic in Millersburg, the public schools have been closed and public meetings interdicted.——Typhoid fever is reported to be epidemic in Barnerton.

Not Guilty. Dr. A. C. White, Toledo, charged with practicing medicine without having registered, and prosecuted by the state medical board, was found "not guilty" by a jury in the police court, March 28.

Hospital Association Formed.—The Union Hospital Association of New Philadelphia and Canal Dover was formed at the latter place, March 21. A modern hospital will be built which will accommodate 15 patients.

Sentenced to be Hanged.—Dr. Oliver C. Haugh, accused of the murder of his father, mother and brother at their home, near Chambersburg, Nov. 4. 1905, was found guilty of murder in the first degree and sentenced to be hanged.

Close Cheap Lodging Houses.—The Cincinnati board of health, on the recommendation of the city health officer, has passed a resolution ordering the lodging houses on the river front to discontinue the five-cent rooms, which are reported to be unsanitary in the highest degree.

Loses Damage Suit.—In the suit of Gaylord Leiey, Mansfield, against Dr. W. Perry Bennett, Crestline, for $10,000 damages for alleged malpractice, which was filed more than a year ago, and under which after the death of Dr. Bennett his wife as administratrix was made defendant, the jury returned a verdict, March 13, for the defendant, vindicating the action of Dr. Bennett.

Contract Practice.—The regular meeting of the Cincinnati Academy of Medicine, March 26, was, by special arrangement, devoted to the discussion of contract practice. The members were almost a unit in condemning this system in medicine and resolutions were adopted which will practically exclude all physicians who are engaged in contract work from becoming or remaining members of the academy. The fiscal year of the academy was closed a week ago with probably the most satisfactory showing in its history. Fully half a hundred members were added to the roll and many papers showing laborious and painstaking research work, were read.

Commend and Condemn.—The following resolutions were passed at a recent meeting of the Cincinnati Academy of Medicine:

Resolved, That the Cincinnati Academy of Medicine commend our Senator Espy and others for work done in behalf of the medical profession of the State of Ohio on the Christian Science Amendment recently lost in our state senate. Be it further

Resolved, That the Cincinnati Academy of Medicine hereby declares Senators Howe, Schmidt and Williams of Cuyahoga County; Lauman, of Scioto County; Ross, of Washington County; Duvall, of Jefferson County; Hafner, Harper and Hunt, of Hamilton County; Pollock, of Stark County; and Mayor Tom L. Johnson, of Cleveland, who urged the passage of the Christian Science Amendment, as persons unworthy of confidence in matters concerning public health. And be it further

Resolved, That a copy of these resolutions be published in the medical journals of the state.

State Medical Association.—The annual meeting of the Ohio State Medical Association will be held at Canton, May 9, 10 and 11. The pediatric, dermatologic and ophthalmologic sections of the society hold their meetings on May 8 in the same place, and the Ohio State Board of Pension Examiners meets on May 10. The meeting halls, committee rooms and exhibit halls will be under one roof in the new municipal auditorium, recently erected by the citizens of Canton at a cost of $180,000, with an auditorium seating nearly 5,000 people. Canton is easily reached, as three trunk lines run through the city and three interurban trolley systems connect with various parts of the state. The oration on medicine will be delivered by Dr. John C. Hemmeter, Baltimore, on "Intestinal Autointoxication," and the oration on surgery will be given by Dr. Harvey C. Gaylord, Buffalo, N. Y., on "Further Research on Cancer." The committee of arrangements is making strenuous efforts for the entertainment of its guests that this may be not only a memorable meeting in a scientific way, but also from a social standpoint.

Smoke Abatement.—Under the able and energetic presidency of Dr. C. A. L. Reed, the Smoke Abatement League of Hamilton County has been formally launched. The plans of the committee are far-reaching. The league has been incorporated, and will be sustained by voluntary contribution, of which there is ample promise. It intends to secure, as far as possible, the voluntary co-operation of the proprietors of offensive stacks in abating the smoke nuisance; to secure the passage of laws, state and municipal, which, when enforced, will protect members of the league and the city at large against the damage now experienced from smoke; to receive confidential complaints about smoke from members; place the same in the hands of inspectors employed by the league; and whenever a case is made out, secure the abatement by amicable means, or, in the event of failure, secure the prosecution of offenders either by the city authorities or by the attorneys of the league; and to conduct scientific investigation concerning the actual prevalence of smoke; its influence on the property and health of the people; and the actual merits of the various means for the prevention of smoke.

Personal.—Dr. Harry J. March, Canton, will leave for Europe the latter part of this month.——Dr. Hiram B. Ormsby, Cleveland, slipped and fell, March 2, spraining his ankle.——Dr. James E. Torrence, Hamilton, was nearly asphyxiated by coal gas from a defective furnace, March 26.——Dr. Eugene B. Harrison, Napoleon, was operated on, March 26, in Toledo, for prostatic enlargement and vesical calculus.——Dr. John E. Stemler has resigned as receiving physician of the City Hospital, Cincinnati, to take effect May 1.——Dr. John C. Larkin, Hillsboro, has returned after postgraduate work in Chicago. ——Dr. Mary E. Tracy, Cincinnati, has been elected a district physician.——Dr. S. Munson Hart, Marietta, is seriously ill with pneumonia.——Dr. A. Per Lee Pease, Massillon, sailed for England, March 24.——Dr. Leon B. Santee, Marlboro, has been elected delegate from the Stark County Medical Society to the state medical society, and Dr. William C. Steele, New Berlin, alternate.——Dr. Furnam E. Perry, Jefferson, has been made president of the Ashtabula County Medical Society on account of the resignation of Dr. Addison W. Hopkins, and Dr. Fred D. Snyder, Ashtabula, has been elected vice-president. ——Barberton Medical Association has been organized with Dr. William A. Mansfield, president, and Dr. Harry S. Davidson, secretary and treasurer.

PENNSYLVANIA.

Philadelphia.

Advisory Board of Anatomists Meet.—The annual meeting of the advisory board of anatomists of the Wistar Institute of Anatomy and Biology will be held on April 16 and 17 at the institute.

Reception to Dr. Sykes.—On March 31 a farewell reception was tendered Dr. Henry Sykes, who for 15 years was superintendent of the Episcopal Hospital and was appointed to the position of medical superintendent of Blockley, April 1. Dr. Sykes was presented with a beautiful gold watch and chain by Dr. Thomas R. Neilson on behalf of the physicians, nurses and employés of the Episcopal Hospital.

Bubonic Plague.—It is reported by special telegram on April 9 that four cases of bubonic plague occurred among the crew of the British steamship *Burnsfield*, from Bombay. The patients were detained at Reedy Island quarantine station and the cases have been pronounced bubonic plague after investigation by officers of the United States Public Health and Marine-Hospital Service and an expert from the bacteriologic laboratory in Washington.

Divide Chair of Anatomy.—The chair of anatomy in Jefferson Medical College, made vacant by the death of Dr. William S. Forbes, has been divided. Dr. Edward Anthony Spitzka, New York City, a son of Dr. Edward C. Spitzka, a fellow of the College of Physicians and Surgeons in the City of New York, who has devoted much study to the anatomy of the brain, has been appointed professor of general anatomy, and Dr. John McClellan, a grandson of the founder of Jefferson Medical College, has been appointed professor of applied anatomy. Dr. McClellan established the Pennsylvania School of Anatomy in Philadelphia Hospital 26 years ago, and for many years has been professor of anatomy in the Academy of Fine Arts.

Health Report.—The total number of deaths reported for the week aggregated 625, the same as that reported for the previous week. The principal causes of death were: Typhoid fever, 31; measles, 7; cancer, 21; whooping cough, 6; diphtheria, 10; consumption, 96; paralysis, 19; heart disease, 58; acute respiratory disease 120; enteritis, 18; Bright's disease,

42; appendicitis, 3; accidents, 22, and marasmus, 6. There were 320 cases of contagious disease reported, with 43 deaths, as compared with 365 cases and 45 deaths for the previous week. Typhoid fever is still prevalent, there being reported 230 cases, with 31 deaths, as compared with 225 cases and 33 deaths in the preceding week. Measles is still prevalent throughout the city and in epidemic form. The number of new cases reported for the week aggregated 519, as compared with 406 reported last week.

SOUTH DAKOTA.

Will Establish Hospital.—Mrs. H. G. Peterson proposes to establish a hospital and sanitarium in Canton, and will agree to put in $3,000, provided the citizens of Canton will raise $1,000 additional.

Personal.—Dr. Anna Baker, Deadwood, has located in Denver. ——Dr. A. J. Buffalos, Alexandria, has moved to Mitchell. On March 23 Dr. Buffalos was so unfortunate as to slip on an icy pavement in Mitchell, injuring his hip and elbow.

Insanity Discussed.—At the annual meeting of the Southern South Dakota Medical Society, held at the State Hospital for the Insane, Yankton, March 27, the superintendents of the state hospitals at St. Peter, Minn., and Cherokee, Iowa, were present, and delivered addresses on the care of the insane.

Society Meetings.—At the annual meeting of the Black Hills Medical Association, held in Deadwood, the following officers were elected: Dr. C. W. Hargens, Hot Springs, president; Dr. G. Hayward Coburn, Deadwood, vice-president; Dr. Felix E. Ashcroft, Deadwood, secretary; Dr. Frank S. Howe, Deadwood, treasurer; Drs. G. Hayward Coburn, and Lyman F. Babcock, Deadwood, and Herman S. Judd, Lead, censors, and Dr. John W. Freeman, Lead, delegate to the state medical association. ——At the annual meeting of the Aberdeen District Medical Society the following officers were elected: Dr. John R. Thompson, Northville, president; Dr. Charles E. McCauley, Aberdeen, vice-president; Dr. E. Jay Clemons, Aberdeen, secretary, and Elmer O. Miller, Aberdeen, treasurer.

VERMONT.

New Hospital.—Dr. Edward R. Lynch has purchased a house in Brattleboro which will be opened about April 15 as a private hospital, and will accommodate about 15 patients.

Opposed Contract Service.—All the physicians of Brattleboro have signed an agreement not to perform any medical or surgical services for the town or village of Brattleboro, or for any town or village adjacent thereto, or for any corporation or association, public or private, for a less price than the regular rates charged private individuals.

Alumni Meet.—The Connecticut Valley Alumni Association of the Medical Department of the University of Vermont held its second annual meeting in Springfield, Mass., March 22. The following officers were elected: President, Dr. Walter A. Smith; vice-president, Dr. Charles J. Downey, and secretary and treasurer, Dr. Vincent J. Irwin, all of Springfield.

Elect Sanatorium Officers.—The directors of the Vermont Sanatorium met at Proctor, February 20, and decided to have plans drawn for the new sanatorium to be erected at Pittsford, and elected the following officers: President, F. C. Partridge, Proctor; vice-president, F. C. Butterfield, Derby Line; treasurer, Miss Emily B. Proctor, Proctor; secretary, Dr. William N. Bryant, Ludlow, and executive committee, Dr. Charles S. Caverly, Rutland, and Messrs. D. D. Burditt, Pittsford; Olin Merrill, Enosburgh Falls, and Redfield Proctor, Jr., Proctor.

GENERAL.

Typhus Fever in Mexico.—It is reported that the typhus fever situation in Mexico has greatly improved and will soon be completely under control.

United States Naval Medical School Graduating Exercises. —The graduating exercises of this institution were held March 31. Secretary Bonaparte of the Navy presented the diplomas to the members of the graduating class.

Laryngologists to Meet.—The twelfth annual meeting of the American Laryngological, Rhinological and Otological Society will be held under the presidency of Dr. James E. Logan, Kansas City, Mo., June 11-13, 1906. A number of prizes of $100 each for essays are offered to be competed for by members of the society. Further particulars may be obtained from Dr. Wendell C. Phillips, secretary, 40 West Forty-seventh Street, New York City.

Hospital Internes Wanted.—Two medical internes are wanted for the Government Hospital for the Insane, Washington, D. C., and for similar positions when vacancies occur, and an examination will be held by the United States Civil Service Commission at the various usual cities throughout the United States, June 6 and 7, 1906. This examination is open to all citizens aged 20 or over who are graduates of reputable medical colleges. Further particulars may be had from the commission at Washington or from the secretary of the board at any regular civil service examination point.

Caution About an Agent.—A Mr. S. Josephs, who was for some months in the employ of the American Medical Association in the capacity of a solicitor of subscriptions for THE JOURNAL and the "American Medical Directory," was dismissed from our employ, but he continues to solicit orders and to make collections in spite of not having any up-to-date letter of authorization. We have called attention to the fact that physicians should not pay money to any one claiming to represent the Association unless he presents an official letter of authority covering the time of making the solicitation.

National Quarantine Bill Passed.—The national quarantine bill was passed by the House April 3. The bill places the control of all quarantine stations, grounds and anchorages under the Secretary of the Treasury, and directs that he shall select suitable places for them and establish the same at such points on or near the seacoast of the United States and on the Mexican border, in order to prevent the introduction of yellow fever into the United States. The bill further gives the secretary the right to establish a quarantine station at the Dry Tortugas Islands and at such other points at or near seacoasts—not to exceed four in the aggregate—as he deems necessary.

CANADA.

Health of Toronto. Toronto was never so free from contagion as in March. There were but four patients in the smallpox hospital. Of diphtheria there were only 52 cases; scarlet fever, 26; typhoid fever, 10. Ninety infants died in Toronto in March out of a total of 380 deaths.

Hospital News.—In Winnipeg General Hospital 348 patients were treated during the week ending March 31; 98 were treated in the outdoor department.——Efforts are being made in Winnipeg to collect $50,000 to establish a tuberculosis sanatorium. About $1,500 has been collected, and it is proposed to ask the different municipalities in Manitoba for $25,000. The balance will then be raised by private subscription.——During March 259 patients were admitted to the wards of Montreal General Hospital, and 238 were discharged. There were 19 deaths. The outdoor consultations numbered 4,318.——Mr. David Russell has donated $1,000 to the Home for Incurables, St. John, N. B.——The British Columbia government has included in its estimates this year an item of $5,000 for the establishment of a tuberculosis sanatorium for that province.——The Toronto Western Hospital has erected a new building containing 14 wards for private patients.

The "Patent-Medicine" Question Before the Ontario Legislature.—Mr. A. C. Pratt, one of the members of the Ontario legislature, has a bill before that body which seeks to regulate the manufacture and sale of "patent" and proprietary medicines. At present it does not appear that it will pass its second reading, as when it came up for that act the premier reminded the sponsor thereof that it was out of order; that any such measure must emanate from a government source and not from a private member. The bill seeks to have marked as poisons all preparations containing more than 6 per cent. of alcohol, or more than one-twentieth of 1 per cent. of morphin, heroin, cocain, or any quantity, however small, of a long list of drugs as arsenic, strychnin, prussic acid, chloral, etc. With an unanimity bordering on collusion the public press states that there is no demand for any such regulating legislation, considering it more in the light of "confiscating" legislation. The introduction of the subject into practical politics, however, has borne some fruit, as an acknowledgment is made by the press that there is no doubt that there are advertisements in the pages of newspapers which ought to be suppressed; and some papers call for a federal act to provide for frequent analysis from time to time of all "patent medicines," so that the people may know from an official and responsible source what these contain.

Toronto University and Medical Education.—A few months ago the government of Ontario appointed a royal commission to consider the best method of governing and administering the affairs of the University of Toronto. The chairman of this commission was Mr. J. W. Flavelle, who is also chairman of the board of trustees of the Toronto General Hospital. The chancellor of the university, Chief Justice Sir William Meredith and Prof. Goldwin Smith also acted on this commission.

Their report has just been handed to the government; and so far as it refers to medical matters it is of some interest. The commissioners recommend that the faculty of medicine be put on the same relation to the university as all the other faculties. It is proposed also that the president of the university be ex-officio a member of the faculty of medicine, so that as all appointments in all departments are recommended hereafter to be made on his recommendation, he will be in a better position to confer with those of the medical faculty best qualified to advise him. The subject of the medical education of women was also dealt with in the report, but that matter had already been considered and settled by the faculty of medicine and the senate of the university. It is understood that the Ontario Medical College for Women will shortly amalgamate with the medical faculty of the Toronto University; but, at any rate now, the aforesaid medical faculty is prepared to register women students and to make whatever arrangements are deemed necessary for their instruction. It may be mentioned in this connection also that it is recommended that a faculty of veterinary science be created in connection with the university.

FOREIGN.

Reduction in Number of Physicians Applying in Germany for License to Practice.—Only 725 licenses (Approbationen) were granted in the fiscal year 1904-5 in the German empire. This is a falling off of 31 per cent. from the 1,057 registered in 1903-4.

Koranyi Prize.—On the occasion of his fiftieth professional anniversary, Prof. A. v. Koranyi of Budapest founded a prize, the income of nearly $2,000. It is to be awarded in May for the first time. The subject for competition is improved methods of treating tuberculosis.

The International Medical Congress of 1909.—It is reported that the Hungarian government authorized its delegates to the impending International Medical Congress, at Lisbon, to invite the next congress to convene at Budapest. The government has already appropriated $25,000 for the purpose, and the city has voted an equal sum.

Geneva Conference.—Early in 1903 the federal council invited the various governments to send delegates to co-operate in the revision of the Geneva convention adopted in 1864. It is now out of date. The outbreak of the Russo-Japanese War put an end to the project of revision for the time being. It has again been revived, and the date of June 11 appointed for the gathering of delegates from the various nations to confer in regard to the humanitarian aspect of war.

Apotheosis of the Cystoscope.—The recent death of Max Nitze, the inventor of the cystoscope, suggested an exposition of the cystoscope and all subjects connected therewith, as a worthy memorial to him. The exhibit was held at Berlin in the new Empress Friedrich House, where the exposition was opened with memorial addresses. The *British Medical Journal* in its last issue devotes much space to an article with colored plates, based on data learned with the cystoscope.

Memorial to Nothnagel.—A statue of the late Professor Nothnagel of Vienna is to be erected in the arcades of the university, and a fund is to be endowed for an annual souvenir address by some scientist of international fame on the anniversary of his birth or death, to be delivered in the clinic where Nothnagel worked for so many years. Those wishing to contribute to the fund are requested to send to Dr. N. v. Jagic, assistant at the first medical clinic, Allgemeines Hospital, Vienna IX, 3, Austria.

Koch on Life in the Tropics. Before returning to Africa last month Robert Koch delivered an address on the medical aspect of colonization of German East Africa. He regards malaria as the greatest danger for the would-be colonist, although certain regions are free from it. He is convinced that, with quinin, it can be successfuly warded off. Relapsing fever is the next danger, but this can be avoided by keeping away from the shelters on the caravan routes and from the houses of the natives. Typhoid, diphtheria, smallpox, leprosy, ankylostomiasis and sunstroke are all rare. Dysentery plays but a subordinate rôle, and the prospects of keeping sleeping sickness away are good. There is no tuberculosis. The climatic conditions as the ground rises inland are like those of southern Europe. The sanitary measures hitherto undertaken have proved successful and others will follow in time.

Abuse and Homage for Professor Neisser.—Professor Neisser of Breslau, discoverer of the gonococcus, and a leader in syphilology, president of the Society for Prophylaxis of Venereal Disease, medical privy councilor, etc., recently came to Stettin to deliver by request an address on "Marriage and Venereal Disease." He is of Jewish descent, and acquired some notoriety a few years ago on account of alleged inoculation of a patient with syphilis. When he appeared to deliver his address a crowd began to hoot and denounce him, so that he was obliged to retire. The medical profession of the town called a special meeting, where resolutions were adopted couched in the most complimentary terms, deploring the occurrence. Neisser has not been home very long from his year of research in Java on inoculation of monkeys with syphilis. The complimentary testimonial from the Stettin physicians was signed by more than ninety names.

Damages for Slander of a Physician.—The wife of a Berlin merchant was recently fined 600 marks, about $150, for defaming a physician. He had been called to her child, who was suffering from a middle ear affection, with whooping cough prevalent in the neighborhood. The mother summoned soon after an ear specialist and a leading pediatrist in consultation, and they ordered a few further measures to supplement those commenced by the attending physician. The mother afterward went around telling her friends that the consultants were disgusted at the treatment the child had been receiving and remarked that it was incredible how a physician could have made such a mistaken diagnosis and given such orders. The physician brought suit for slander and proved that the consultants had said nothing of the kind, and that his treatment had been according to the rules of the art in every respect. The judge censured the defendant as guilty of serious defamation without any basis, and imposed the highest penalty in his power.

International Association of the Medical Press.—The *Berliner klin. Wochft.* for March 26 gives the details of the approaching congress of the International Association of the Medical Press. It convenes at Lisbon two days before the International Medical Congress opens its doors. This is the second congress of the association, and for the first time a year-book will be distributed among the members. It contains the names and date of founding, with other particulars, in respect to all the medical journals that belong to the association. The subjects appointed for discussion are "Protection of Literary Property in the Medical Press"; the "Medical and Pharmaceutical Gratuitous Journal"; the organization of a permanent central bureau for the international congresses, and the right of the members of the International Association of the Medical Press to be accepted as members of the international medical congresses without further payment of dues. The present president of the association is Professor Cortezo of Madrid, one of the editors of the *Siglo Medico*. The general secretary of the association is Dr. Blondel of Paris, who is at the head of the Bureau of Scientific Information at the Sorbonne, 103 boulevard Haussmann, Paris.

Correspondence

A Better Treatment of Pneumonia Wanted—The "Galbraith Quinin-Iron Method."

OMAHA, NEB., April 3, 1906.

To the Editor:—Recently, after having a chill and feeling badly I wondered, should my case develop into a pneumonia, whether my physician would give me the best chance to live by employing the modern treatment indicated in your recent editorial. It has been disappointing not to have learned more about the "Galbraith quinin-iron treatment" of pneumonia from those in a position to try and better their statistics. The death rate from acute lobar pneumonia is high, and hospital statistics during many years show no great improvement in its treatment. Every one acquainted with Dr. Galbraith knows him as an experienced and exceedingly practical "all-around" man; his diagnosis in a case or series of cases of pneumonia can be as absolutely relied on as that of any physician, wherever located. It is this knowledge of the man that leads me to have faith in what he writes about quinin and iron in the treatment of pneumonia, and the belief that by this treatment better results may be obtained.

The symptomatic treatment of pneumonia, mostly recommended by text-book authorities and hospital physicians, whose mortality statistics in this disease average between 20 and 40 per cent., needs a substitute. What is wanted is the lowering of the death rate, and if a method of treatment will bring about this much-desired end, let those in a position to give the Galbraith treatment a test in a series of cases do so.

It is immaterial if years ago a writer in Ziemssen's Encyclopedia did recommend quinin in enormous doses in the treatment of pneumonia. What if Drs. A. or B. have after some fashion tried it? When I was a student quinin in moderate doses was a treatment of pneumonia, the lancet was in disrepute; drugs were little relied on as specifics.

Alonzo Clark told us that "if the good Lord would forgive him he would never again pack the chest of a pneumonia patient with ice," he having lost eight consecutive cases in Bellevue Hospital by this practice. Several years after graduation I observed the practice in Vienna of applying cold cloths to the chest and giving a little red wine internally. For more than 20 years since that time I have noted that some physicians use ice locally; others, blisters, the flaxseed poultice, the Clark oil-silk jacket, etc. Internally have been administered alcohol, the coal-tar products, strychnin, digitalis, salicylate of soda and creosotal. All have kept the mortality at about the time-honored standard of from 10 to 40 per cent., in accordance with the age of the patient, his natural resistance and the character of the prevalent severity of the pneumonia.

Galbraith tells the indications for the size of the initial and subsequent doses of quinin, and insists likewise on the systematic administration of the tincture of chlorid of iron in conjunction with the quinin.

I hope the profession will give Galbraith's treatment a fair trial and report results. J. E. Summers, Jr.

Text-Books in Korean.

Philadelphia, April 2, 1906.

To the Editor:—Into how many separate languages "Gray's Anatomy" has been translated perhaps only its publishers can tell us. Another tongue has just been added to the list, owing to the painstaking labors of Dr. O. R. Avison of Seoul, Korea, formerly of the teaching force of the Toronto Medical College. The volume he so produced he has made available to ambitious young Koreans by causing a certain number of copies to be mimeographed. He has done the same with a number of other elementary text-books; but the result is, of course, far inferior to printing and the supply adequate for only a very limited demand.

The young men for whose especial use this work is being done are under instruction in a number of hospitals in different cities in Korea. Left to themselves they would have been still following the barbarous methods in vogue among practitioners of the native school, compounding prescriptions of a dozen or two ingredients, unsavory and incompatible, prohibiting nourishment, while administering drastic potions, searing regions tender with inflammation, plunging the hot needle into brain or abdomen an unknown depth, and aggravating diseased joint conditions until fetid suppuration destroys the limb. The substitution of aseptic surgical methods and of a rational therapeusis for such procedures is the beneficent work of mission hospitals; and the training of a generation of enlightened physicians is one of the inseparable accompaniments. Problems are many in connection with such an educational need, among them that of text-books.

The outlook before a young graduate in medicine in Korea renders more than usually delicate the question of the measures that may wisely be adopted in his education. The scale of fees reasonably to be counted on from most of his patients is not such as to warrant a luxurious style of life. Yet sleeping and sitting on the floor, a diet of rice, pickled cabbage, red pepper sauce and dried fish, and dressing in the flowing garb of the Korean, accord little, on the other hand, with surgical or even with personal cleanliness. To train a young man abroad is practically to train him to such a disgust with his own people that he becomes denationalized; to train him among them calls for the creation of much new material.

The members of the committee who are interesting themselves in this problem stand ready to receive and to forward contributions toward a fund for the publication of medical text-books in Korean. It seems certainly a fair proposition to ask the profession in America to provide the books from which these aspirants across the water may learn the correct principles of the great art of healing.

Palatable Castor Oil.

Chicago, March 15, 1906.

To the Editor:—Under a trade-mark name, a pleasant and palatable preparation of castor oil is being distributed among physicians. A small vial containing a sample of a sweetened, tasteless, palatable and non-acrid (I am not aware that castor oil possesses acrid properties) castor oil is sent to the practitioner, and this, in a few weeks, is followed by a circular calling attention to the sample and expatiating on the merits of this elegant and improved pharmaceutical preparation. According to this circular, this preparation is composed of nearly pure castor oil, consisting of 99.99 per cent. of absolute castor oil, the remaining .01 per cent. being aromatic corrigents and sweetening adjuvants. Even sepsis appears to be a factor in ordinary castor oil, as this special preparation is rendered "aseptic." Castor oil is and always will be *par excellence*, the laxative of choice of the laity. The physician is often called on to prescribe castor oil, and patients invariably ask him to have it made as nearly tasteless as possible. I have for years prescribed a sweet, pleasant and palatable form of castor oil, one which answers all the requirements of an elegant pharmaceutical preparation. It consists of nearly pure castor oil, being about 99.98 per cent. castor oil, the remaining .02 per cent consisting of a sweetening principle and a carminative adjuvant. The formula is as follows:

R.	Saccharini	gr. ii	12
	Olei menthæ piperitæ	gtt. v	30
	Alcoholis q. s. M. fiat sol. et adde:		
	Olei ricini	℥viii	240

Sig.: Dose same as castor oil.

John Ritter, M.D., Ph.G.

"Ambulatory" Smallpox.

Somerville, Mass., March 16, 1906.

To the Editor:—I recently had a case of smallpox and the history of its inception may be of interest to some readers of The Journal.

The case presents no features of especial clinical significance, but the wide range of the victim's travels while in the active stages of the disease, and the possibility of transmission in many localities lead me to report what is mainly the patient's story of the early days of his illness.

The patient is a young man of 20, a member of a musical organization which left Boston, February 4, for a trip through the southern states. He was not in good physical condition when he left, as he had had a busy season and was thoroughly tired out. On February 21, at Meridian, Miss., he had an attack of chills, nausea and headache. The next day he felt very feverish and had severe backache. The symptoms became more intense during the following days, though he continued to take part in the nightly concerts given by the club at Selma, Ala., Maplesville, Columbus and Tuscaloosa. On February 25 the company went to Delaware Ohio. The following morning, February 26, he noticed a rash on his forehead and wrists and went to a physician of the town. This was the first time he had sought medical advice, as he thought he had eaten something which had "poisoned" him. The doctor gave him some pills and a lotion and told him that his self-conceived diagnosis was doubtless correct and that he would be all right in a day or two. That night he fainted on the stage and was carried to his hotel.

The rash continued to spread, and on February 27, at Galion, Ohio, he says that he "was a sight," and that "the eruption looked like little blisters." He played at Warren, Ohio, on February 28, and on March 1 at Franklin, Pa. At the latter place he consulted a second physician, by whom he states he was examined for an hour or more, and who told him that the eruption resembled that of smallpox. A variety of lotions,

dusting powder and ointments were prescribed, and he was assured that the eruption would "go away in a few days." March 2, at Erie, Pa., the patient describes himself as hardly able to stand and as being unable to sleep or eat. On March 3 he played with the company at Silver Creek, N. Y., when he "excited considerable comment by his appearance, both on the stage and afterward when he met the audience socially."

The club arrived in Buffalo on March 4, and the young man paid a visit to Niagara Falls in the afternoon. He states that other occupants of the coach in which he made the trip showed a rather pardonable reluctance to sit next to him. In the evening the proprietor of the hotel at Buffalo came to him with the objection that other guests were complaining of his appearance and asked him to consult the "house doctor." The latter was called and promptly said: "Young man, you would better get home as soon as possible." The patient left Buffalo at 10 o'clock that night and arrived in Somerville on the afternoon of March 5.

The family physician was called and at once made a positive diagnosis of smallpox, and the patient was removed to the hospital twelve days after the initial symptoms were noted, and with pustules at the height of their development.

The pustulation was discrete but very closely distributed over face and limbs. It was more widely scattered on the trunk.

The case has progressed to practical recovery without incident of clinical interest. The patient claims to have been vaccinated in childhood, but no evidence of successful inoculation is to be noted.

C. CLARKE TOWLE.

A New Radium Danger.

NEW YORK, April 7, 1906.

To the Editor:—I notice an editorial reference in to-day's issue to an explosion of a radium tube in Germany. The liability to this accident was pointed out by me nearly two years ago in the *Medical Record*, June 20, 1904, as follows: "The second cause for the perforation of a glass tube is the increase of electric potential within the tube. Just as soon as this becomes sufficiently high the electricity sparks through. . . . To guard against this accident I would propose what appears to me a very simple and effective remedy, namely, sealing a small piece of platinum wire into the glass tube. It need only project a very short distance into the tube, and externally may be flush with the glass."

Radium in an aluminum tume is, of course, not liable to this accident, but to another quite as serious. If an alumninum tube is inserted into a growth, the bodily fluids will corrode it, and to my knowledge a number of tubes have been injured in this way, the corrosive going entirely through the aluminum and permitting the fluids to mix with and to injure the radium. I have protected my own aluminum tube by having it thinly coated with vulcanized rubber; this was done for me by a dental friend. On testing the tube before and after it was found that its effectiveness was impaired about 20 per cent., but this is better than taking the chance of entirely ruining the specimen. It is needless to say that the rubber employed should not contain any metallic oxids, as their presence would still further interfere with the egress of the rays.

Some of the pure radium bromid is now furnished in little cells with a mica face. This should not be applied directly to a moist surface. I have protected mine by covering the face of the cell with a collodion varnish and further wrapped the cell in a rubber dam, such as dentists use.

H. G. PIFFARD.

Mercury Sound for Dilating Esophagus.—Adam of Hamburg uses a very flexible, non fenestrated sound, filled with mercury, for dilating a stricture of the esophagus. The weight of the sound carries it down and it automatically works its way past strictures that arrest all other sounds, even those of smaller caliber. In one cancer case he has been able to keep the passage open for seven months by introducing this sound every second day. It is easy to control the position of the sound by radioscopy.—*Munch. med Wochft.*

Association News

THE BOSTON SESSION.

Some Details of the Arrangements for the Annual Session Next June.

The Committee of Arrangements is actively engaged in perfecting the arrangements for the fifty-seventh annual session of the American Medical Association to be held in Boston June 5-8. Their announcement of the hotels with prices appeared in THE JOURNAL last week. The headquarters of the various sections were named.

GUIDE BOOK.

A very practical feature of the arrangements is an elaborate guide book, which will enable the visiting physician to reach any point of interest and to understand all the historical scenes in Boston and vicinity. A good map is to be included, and special attention will be given to medical and surgical points of interest.

THE RECEPTIONS.

On one evening there will be the usual reception to the President of the Association, which is the chief social event of the week. At Harvard University's new medical school buildings there are to be afternoon teas from 4 to 7 o'clock on two or three afternoons, with music in the quadrangle and on the terraces. This will be principally for the ladies who are visiting, with the possibility of the physicians dropping in at the close of their afternoon programs. Special concerts and theater parties are being planned and a reception by the City of Boston in the Public Library.

CLINICS.

The advantages of Boston as a medical and surgical center are not to be neglected. Clinics will be held at a number of hospitals, and arrangements will be made whereby visitors may make the rounds of the hospitals or visit certain ones in the most convenient way. Some clinics are to be held in connection with some of the work of the section programs. All hospitals will provide clinical exhibits of some sort, and members who wish a change from the section programs will be able to find clinical work on any day.

Among the halls which are to be used for the section meeting places are the Y. M. C. A. Hall, Huntington Hall, the New Old South Church, Horticultural Hall, Chickering Hall, Jordan Hall and the buildings of Tufts and Harvard medical schools. The headquarters is to be at Mechanics Hall, where will be the registration and the scientific exhibit and the commercial exhibit. The House of Delegates is to meet in the Medical Library of Harvard Medical School.

EXCURSIONS.

A rate of one fare plus $1 for the round trip is to be in effect over a large part of the United States, and tickets will be sold from June 1 to 6, good to return leaving Boston up to June 11, with an extension possible to June 30. Passengers from Pacific Coast points may have return limit extended to August 31.

Among the excursions to be enjoyed in the vicinity of Boston are such historical places as Plymouth, Lexington and Concord and to points on the seashore. After the session visits may be made to the lakes of Maine and New Hampshire, the mountains of Vermont and New York, the St. Lawrence River, the Thousand Islands, the Great Lakes, Niagara Falls, etc.

MISSOURI VALLEY SPECIAL.—Arrangements have been perfected for a superb special train to Boston over the Grand

Trunk, via Niagara Falls, Toronto, Montreal, Thousand Islands, with a daylight ride down the St. Lawrence River, returning by rail. This train will run special through from Chicago, and will be made up of Pullman palace sleepers, dining-cars, buffet-library and observation cars. For reservations and itinerary address Dr. Charles Wood Fassett, St. Joseph, Mo.

LAKE SHORE SPECIAL.—The Lake Shore Railway will run a special train, a counterpart of the "Twentieth Century Limited," consisting of observation compartment car, sleeping-cars, library-car, dining-cars, on fast schedule, leaving Chicago at 10:30 a. m., Sunday, June 3, arriving at Boston, Monday, June 4, at 2 p. m. Stopover of ten days at Niagara Falls may be secured for side trips to Toronto, Thousand Islands and St. Lawrence River if desired. Write W. J. Lynch, Passenger Traffic Manager, Chicago, for reservations or any additional information.

GUESTS OF HONOR.

Prof. A. Duehrssen of Berlin writes that he will take part in the symposium on the "Duty of the Profession to Womankind," which is arranged in the Section on Hygiene and Sanitary Science. Professor Duehrssen will present a paper on the "Guarantee of Safety in the Marriage Contract." His fame as one of the leading gynecologists of the world is well known, and his contributions to gynecologic literature are numerous and varied. He has been preaching the advantages of vaginal Cesarean section since 1896. His private gynecologic clinic at Berlin was opened in 1892, but for years before and since he has been assistant obstetrician and instructor of midwives at the Charité. He is now in his forty-fifth year.

Max Joseph of Berlin is at the head of what has been called "the best private skin clinic in the world." In 1897 he founded the *Dermatologische Centralblatt*, and has always been its editor. In his early life he worked as assistant in the Berlin Institute of Physiology, then at the zoological station near Naples, and then made a special study of leprosy in Norway for his work on "Visceral Lepra." His manual on cutaneous and veneral diseases has passed through several editions, as also his atlas of the histopathology of the skin. He will be another of the guests of the Section on Hygiene and Sanitary Science.

NEW MEMBERS.

List of new members of the American Medical Association for the month of March, 1906:

ALABAMA.

Acton, W. H., Alabama City.
Britt, W. S., Eufaula.
Carlisle, S. O., Dothan.
Cocke, W. T., Hargrove.
Dickinson, N. P., Lafayette.
Dean, T. J., Union Springs.
Dryer, T. E., Huntsville.
Franklin, C. M., Union Springs.
Grady, Z. T., Lafayette.
Hargrove, R. H., Sycamore.
Harris, D. B., Munford.
Hawkins, J. P., Ragland.
Harris, E. C., Ragland.
Hixon, F. P., Perote.
Huey, G. W., Hartford.
Jackson, C. B., Dora.
McClendon, Joe, Dadeville.
McEachern, C. P., Banks.
Moody, E. F., Dothan.
Morris, W. E., Georgiana.
Nolen, A. J., New Site.
Prather, W. B., Seale.
Paschal, John, Hatchechubbee.
Ralls, A. W., Gadsden.
Rand, Edgar, Huntsville.
Reynolds, Gibson, Montgomery.
Stewart, B. C., Opp.
Terry, J. E., Red Level.
Turnipseed, D. C., Union Springs.
Underwood, N. T., Russellville.
Watson, J. C., Georgiana.
Williamson, G. W., Hartford.

ARIZONA.

Brannen, D. J., Flagstaff.
Ralph, R. T., Poland.
Shine, F. E., Bisbee.
Wiley, C. B., Camp Verde.

ARKANSAS.

Clemmer, J. L., Springtown.
Cowden, S. H., Morrilton.
Cunning, I. H., Knobel.
Dibrell, J. L., Little Rock.
Hughes, G. H., Gravette.
Luck, B. D., Pine Bluff.
Moore, A. L., Fayetteville.
Rice, C. A., Gentry.
Robinson, C. E., Clarksville.
Thompson, A. G., Pine Bluff.
Winkler, E. H., De Witt.

CALIFORNIA.

Abbott, E. K., Monterey.
Clark, Jonas, Gilroy.
Carter, P. B., Guadalupe.
Cluness, W. R., Jr., San Francisco.
De Lappe, F. R., Modesto.
Garcelon, Harris, Los Angeles.
Griffith, T. R., Riverside.
Huff, L. J., Los Angeles.
McAulay, Martin, Newman.
Mosher, C. D., Palo Alto.
Parish, H. L., Callstoga.
Stapler, D. A., San Francisco.

COLORADO.

Edwards, E. G., La Junta.
Follansbee, W. F., Paoria.
Hughes, J. G., Greeley.
Leavitt, B. C., Denver.
MacGregor, J. M., Denver.
Magruder, A. C., Colorado Springs.

CONNECTICUT.

Bevan, C. A., West Haven.
Graves, F. G., Waterbury.
Henkie, E. A., New London.
Plumstead, M. W., East Haddam.
Stoll, H. F., Hartford.
Wason, D. B., Bridgeport.

DELAWARE.

Ellis, W. W., Delaware City.
Frame, J. K., Millsboro.
France, J. L., Wilmington.
Springer, F. L., Newport.

DISTRICT OF COLUMBIA.

Reeve, J. N., Washington.
Wilson, A. A., Washington.
Wood, G. W., Washington.

FLORIDA.

Rawlings, J. E., Daytona.

GEORGIA.

Almond, Chas. B., Winder.
Ayers, Clarence L., Carnesville.
Brown, L. R., Sharon.
Campbell, J. L., Atlanta.
Coleman, E. T., Graymont.
Collier, T. J., Atlanta.
Deadwyler, O. L., Carlton.
Daughty, Wm. H., Jr., Augusta.
Derry, H. P., Macon.
Erwin, G. C., Young Harris.
Goodwyn, H. J. Roopville.
Kemp, W. M., Marietta.
Lively, M. M., Statesboro.
Mickle, C. M., Texas.
Milla, G. W., Calhoun.
Reynolds, H. V., Marietta.
Rushing, W. E., Daffin.
Shaw, W. J., Rome.
Sims, W. C., Richland.
Turner, G. H., Rico.

ILLINOIS.

Allen, H. S., New Boston.
Allin, F. W., Chicago.
Bacon, J. H., Peoria.
Beard, L. A., Polo.
Berger, G. F., Chicago.
Buford, C. G., Chicago.
Buss, F. J., Chicago.
Cook, E. A., Upper Alton.
Conlon, A. A., Chicago.
Cretors, F. G., Paris.
Champion, Joseph Van Meter, Mansfield.
Daum, E. F., Chicago.
Duncan, F. M., Marshall.
Eisendrath, J. L., Chicago.
Finch, J. H., Champaign.
Galloway, George Chicago.
Gibson, O. N., Eldorado.
Graham, Ralph, Biggsville.
Greene, E. B., Chicago.
Griffith, J. C., Bushnell.
Groth, W. F., Chicago.

Marriages

ARTHUR D. BANGHAM, M.D., to Miss Ruth Ludlow, both of Albion, Mich., March 24.

FRANCIS M. ROSEBERRY, M.D., to Miss Marie Harnasch, both of Keokuk, Iowa, March 28.

NICHOLAS D. RICHARDSON, M.D., to Miss Elise Gregory of San Francisco, Cal., March 25.

ROBERT MILLIGAN COLEMAN, M.D., to Miss Elsie May Stoll, both of Lexington, Ky., April 4.

EDMUND M. STECKEL, M.D., to Miss Emma Druckenmiller, both of Allentown, Pa., March 27.

WALTER W. OVERFIELD, M.D., Forreston, Ill., to Miss Grace Knepper of Rockford, Ill., March 20.

MARVIN L. SMOOT, M.D., Spencer, N. C., to Miss Margaret Louise Giddens of Goldsboro, N. C., April 5.

ALVAH M. DAM, M.D., Brookline, Mass., to Mrs. Hannah A. Talbot of Stoughton, Mass., at Brookline, March 26.

HENRY LARNED KEITH SHAW, M.D., Albany, N. Y., to Miss Susanne Sturtevant Burrell of Little Falls, N. Y., March 29.

Deaths

Charles A. Snodgrass, M.D. Medical Department of Washington University, St. Louis, 1903; health commissioner of that city since last November; a member of the American Medical Association and of the Mississippi Valley Medical Association, died April 6 from croupous pneumonia, at the City Hospital, St. Louis, after an illness of eight days, aged 38. Dr. Snodgrass received his preliminary education at the State University of Missouri and Chicago University. He was beginning a series of important reforms in the health department and devoted his entire time to the office. He realized that the importance of his office demanded full labor and gave it unflinchingly. He was an earnest student and a methodical worker, and the medical profession and the community lose a valued member in his untimely death.

William Edgar Wirt, M.D. University of Wooster, Medical Department, Cleveland, 1888, of Cleveland, Ohio; ex-president of the Cleveland Medical Society; professor of orthopedic surgery, Cleveland College of Physicians and Surgeons; orthopedic surgeon to Cleveland General and City hospitals; fellow of the American Academy of Medicine; a member of the Ohio State Medical Society and American Orthopedic Association, and chairman of the clinical and pathologic section of the Academy of Medicine of Cleveland; lieutenant of naval reserves during the Spanish-American War, died at Miami, Fla., March 19, from nephritis, after a long illness.

James W. Smith, M.D. Bellevue Hospital Medical College, New York City, 1882; for 15 years a member of the board of education of Paterson, N. J., and for 17 years a member of the board of managers of the State Asylum for the Insane, Morris Plains, and vice-president at the time of his death; chief surgeon of St. Joseph's Hospital, Paterson; assistant health officer of the city, died at his home in Paterson, March 29, from pleuro-pneumonia, after an illness of five days, aged 48.

William J. Mahon, M.D. Bellevue Hospital Medical College, New York City, 1897, of New York City; a member of the New York County Medical Society and of the Celtic Medical Society of New York; lecturer at the New York Polyclinic and surgeon to the Metropolitan Nose and Throat Hospital, died March 27 at the home of his parents in Hartford, Conn., from rheumatism of the heart, after an illness of seven weeks, aged 32.

Solomon C. Martin, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1866; professor of dermatology in Barnes Medical College, St. Louis, for 14 years; a Confederate veteran; editor of the *Medical Era* and associate editor of the *American Journal of Dermatology and Genito-urinary Diseases*, died at his home in St. Louis, March 27, from pneumonia, after an illness of three weeks, aged 68.

Homer J. Short, M.D. Medical College of Georgia, Augusta, 1888; for fifteen years a practitioner of Hot Springs, Ark.; twice a member of the school board and for two years its president, and a member of the city council for two terms, died at his old home, Buena Vista, Ga., March 22, from mental disease, after an illness of more than a year.

Asa Emery Johnson, M.D. University of the City of New York, 1850; a pioneer physician of Minnesota; founder and first president of the Minnesota Academy of Natural Sciences, Minneapolis; county physician of Hennepin County in 1858; for more than half a century a resident of Minneapolis, died at his home in that city, January 27, aged 80.

George G. Wise, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1866; a member of the American Medical Association; attending physician to St. Luke's Episcopal Mission, died at his home in Philadelphia, March 28, from heart disease, after an illness of seven weeks.

Jeremiah A. Cronin, M.D. Bellevue Hospital Medical College, New York City, 1896; formerly house physician of Carney Hospital, South Boston; for several years assistant surgeon of the Ninth Infantry, M. V. M., died at the home of his parents in South Boston, April 2, after a lingering illness, aged 32.

Charles S. Leonard, M.D. Cleveland Medical College, 1856, formerly of Ravenna, Ohio, and for many years a member and secretary of the Portage County (Ohio) Medical Association, died at his home in St. Louis, Mich., March 26, after an invalidism of nine years, from cerebral hemorrhage, aged 79.

Anton P. Nixdorf, M.D. St. Louis Medical College, 1856; a surgeon during the Civil War; one of the oldest practitioners of Missouri; postmaster of Pleasant Farm, Mo., for many years, died at his home in that place, January 27, after an illness of one week, aged 74.

Obadiah L. Saylor, M.D. Jefferson Medical College, Philadelphia, 1853; once coroner of Schuylkill County, Pa.; a retired presiding elder of the Evangelical Church, died from dropsy at his home in Bethlehem, Pa., April 4, after an illness of two years, aged 72.

Roscius Y. Downs, M.D. College of Physicians and Surgeons in the City of New York, 1886; health officer of Derby, Conn., died at his home in Ansonia, Conn., April 1, from septicemia due to an operation wound, after an illness of only twenty-four hours, aged 48.

Kent D. Waite, M.D. Cleveland University of Medicine and Surgery, 1888, formerly professor of surgery and lecturer in anatomy at his alma mater, died at the Cleveland State Hospital from general paresis, March 29, after an illness of two years, aged 42.

Charles H. Blaney, M.D. Medical Department, University of Southern California, Los Angeles, 1904; assistant superintendent of Los Angeles County Hospital, died in that institution, March 30, from diabetes, after an illness of more than a year, aged 31.

Michael P. O'Neill, M.D. Medico-Chirurgical College, Philadelphia, 1900; a member of the American Medical Association; formerly resident physician at St. Agnes' Hospital, Philadelphia, died at his home in Philadelphia, April 3, from typhoid fever, aged 29.

Job P. Boozer, M.D. Medical College of the State of South Carolina, Charleston, 1854, of Clinton, S. C., for many years president of the Laurens County Medical Association, died suddenly, at the home of his daughter in Laurens, April 3, aged 73.

Fletcher T. Seymour, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1866, a beloved practitioner of Haywood County, Tenn., died at his home in Eurekaton, March 29, after a lingering illness, aged 70.

Alonzo J. Weathered, M.D. Vanderbilt University, Medical Department, Nashville, 1882, formerly an alderman of Waco, Texas, died suddenly from angina pectoris, at his office in Waco, March 28, aged 54.

Daniel A. Dakin, M.D. Rush Medical College, Chicago, 1870, a member and once president of the Wayne County Medical Society, died suddenly at his home in Detroit, April 2, from heart disease, aged 69.

Wales G. Fike, M.D. Medical College of the State of South Carolina, Charleston, 1899, of Union, S. C., died at Spartanburg, S. C., March 30, from heart disease, after an illness of ten weeks, aged 34.

Ludy M. Henderson, M.D. Medical College of Georgia, Augusta, 1867, a Confederate veteran, died at his home in Waterloo, S. C., March 24, after an illness of several months, aged 72.

James Morris Crabb, M.D. Rush Medical College, Chicago, 1904, recently of Ashton, S.D., died Nov. 23, 1905, in the Presbyterian Hospital, Chicago, from sacro-iliac tuberculosis, aged 37.

Edwin G. Hawkes, M.D. Jefferson Medical College, Philadelphia, 1892, a member of the American Medical Association, died at his home in Philadelphia, April 5, aged 40.

Daniel G. R. Le Quesne, M.D. Medical Department of Adelbert College of Western Reserve University, Cleveland, 1883, died at the Cleveland State Hospital, April 1.

Edmond T. Baker, M.D. Medical College of Virginia, Richmond, 1888, of Richmond, Va., died at the home of his father, Curl's Neck Farm, March 29, aged 38.

James M. Black, M.D. Kentucky School of Medicine, Louisville, 1888, died at his home in Knoxville, Tenn., April 5, from pneumonia, after a short illness.

M. D. Shelton, M.D. University of Nashville, Medical Department, 1869, died at his home in Midway, Ala., March 26, after a short illness.

Alonzo G. Brush, M.D. University of Wooster, Medical Department, Cleveland, 1881, died at his home in Fairfax, Vt., March 26, aged 87.

Harry B. Orr, M.D. Jefferson Medical College, Philadelphia, 1883, died at his home in Pittsburg, Pa., after a short illness, March 29, aged 49.

Adolph W. Berle, M.D. New York University, New York City, 1885, died at his home in New York City, March 26, aged 45.

Deaths Abroad.

H. V. Hoelder, M.D. died at Stuttgart, March 11, aged 86. He occupied a prominent position in medical circles and was a pioneer in anthropologic research. His collection of skulls is renowned. It now becomes the property of the Stuttgart museum of natural history.

P. Stolper, M.D., professor of legal medicine at Göttingen, succumbed to a stroke of apoplexy, March 13, while delivering a medical address. He was a frequent contributor to medical literature, discussing surgery for accidents, points in medical jurisprudence, etc.

Phisalix, M.D., assistant to the chair of comparative pathology at the museum of natural history at Paris, France, died March 21, aged 50. His biologic researches have carried his name far.

The Physician.—Charles H. Lewis says that physics is the synonym of natural philosophy, and that, by the derivation of his name the physician is a natural philosopher, or scientist; but by the title of doctor he is also a teacher, and in his dual capacity the administering of remedies falls far short of measuring the field of his activities. His advice and counsel are often the most needed and most useful part of his service, and it is his duty to dispense knowledge as well as medicine.—*Journal Michigan State Medical Society.*

Miscellany

The German Circulars Warning Against Venereal Disease.

A special committee appointed by the German Society for Combating Venereal Diseases has prepared two circulars, one for men and the other for women and girls, each written in simple style. The work of the society has been previously described in these columns and its public meetings reported, as on page 1294, vol. xliv, 1905. The official title is the "Deutsche Gesellschaft zur Bekämpfung der Geschlechtskrankheiten." It is a national organization for sanitary prophylaxis, with local branches in more than twenty-two of the larger cities of Germany. The annual membership fee is about 75 cents (3 marks), and all classes of society are represented in it. The central office is in Berlin W. 9, Potsdamerstrasse 20. The society has already accomplished several notable reforms, among them the abolition of the discrimination against venereal diseases by the semi-official societies which insure against sickness. It has also secured more accommodations for venereal patients in the hospitals. The society issues a bulletin, the *Mitteilungen*, which is sent free to all the members. Independently of the society, the president, vice-president and secretary, Neisser, Lesser and Blaschko, issue a larger journal, the *Zeitschrift f. Bekämpfung der Geschlechtskrankheiten*, just entering its fifth volume. (Subscription is about $2—8 marks—a volume.) The managing board of the society consists of 49 persons, principally physicians, with lawyers, the mayors of Mannheim and Frankfurt, and some insurance and high government officials.

The circular addressed to men has been distributed by the hundreds of thousands throughout the universities, the workshops and other industrial establishments wherever German is spoken. The society has only recently issued a warning circular for women and girls which is now being distributed broadcast throughout the factories, etc. Copies of the circulars can be obtained free of charge from the central office. It will be noted that the circulars do not touch the moral side of the subject. The society replies to criticisms on this point that this aspect of prophylaxis is left to other hands.

We give literal translations of both circulars, not because they are models or worthy of imitation in style of presentation, but because they represent something actually done in the European campaign of venereal prophylaxis and because the agitation in this country is gaining such impetus.

THE GERMAN SOCIETY FOR COMBATING SEXUAL DISEASES.

CIRCULAR FOR MEN.

1. Abstinence in sexual intercourse, according to the unanimous verdict of physicians, is as a rule not injurious to health, notwithstanding a widespread notion to the contrary.

A temperate life and physical exercise in the open air (walking, gymnastics, swimming, rowing, skating, etc.,) can prevent the sexual desire from getting the upper hand.

2. The so-called venereal or sexual diseases are very prevalent among all classes of the population. The most important are gonorrhea and syphilis.

Gonorrhea begins a few days after the opportunity for contagion, with a discharge from the man's or woman's private parts, often with but also sometimes without pain, smarting or itching. It may not attract attention at all, especially in a woman, and it lends in many cases to various and sometimes very serious after-troubles. It may be still present and contagious long after the patient believes himself or herself to be entirely cured. They may then unknowingly give the disease to others. Very frequently in this way women become infected after marriage—many serious female diseases, the childlessness of many married couples, are the results of gonorrhea. The poison of the disease is liable to get into the eyes of the babe during birth, and if not properly treated, to make it blind.

Syphilis begins with a little break in the skin, a small lump or a sore, generally not until several weeks after the contagion, and leads in its further course to eruptions on the skin, sore throat etc. After these have all passed away, in the course of the next three or four years, sometimes even considerably later, the most various manifestations of the disease are liable to appear in any or every organ. Under appropriate treatment, as a rule, their course is mild and benign, but in many cases, especially when the treatment of the disease is neglected, extremely serious affections may result, with a train of distressing consequences. The disease is contagious for years, and may be transmitted to the offspring, even when the person affected seems to be apparently free from it.

3. The main source—direct or indirect—of the venereal diseases is intercourse with prostitutes, that is, with girls who give themselves up to several men for money. These girls usually take gonorrhea or syphilis or both very early, and then give them to others. Even medical inspection of prostitutes is not a certain protection—the young prostitutes in particular are especially dangerous. But also women who do not make themselves prostitutes, if they have the slightest habit of irregular sexual intercourse, are exposed to the danger of contagion, and are therefore liable to give the

disease to others. They may even be affected without any suspicion of it, and without any one's being able to detect any signs of disease on them.

4. Every sexual intercourse outside of married life may bring danger. This danger may be materially reduced by cleanliness, disinfecting washings, and by the use of special protecting measures, but they never entirely remove the danger.

5. An extraordinarily large number of venereal contagions occur under the influence of liquor; many are made worse by liquor drinking. In this way also liquor drinking causes much harm.

6. Syphilis can be taken also without sexual intercourse; contagion can occur from kissing. Also articles such as eating and drinking utensils, pipes and shaving brushes, used by strangers, should be avoided as much as possible, as they are liable to transmit the disease. A wet-nurse should never be engaged without a medical examination, and a child that has not been examined by a physician should never be given the breast.

7. Every wound or sore, inflammation or discharge on the private parts may be extremely contagious. Whoever has anything of the kind should, of course, refrain from sexual intercourse under all conditions and apply to a registered physician (not a quack) for a medical examination. By prompt recognition and appropriate medical treatment severe sufferings later may frequently be warded off. Nearly every case is completely curable, although not for years in some instances.

8. The man with gonorrhea or syphilis can not himself tell whether he is really cured or not. He must have himself examined by a physician again and again in the course of months, often years, so that the physician can follow the course of the disease and resume treatment again as it is needed.

No one should allow himself to be influenced by the advertisements of quacks and irregulars against the use of mercury in the treatment of syphilis. This treatment, according to the universal verdict of doctors, is necessary, extraordinarily effective, and harmless in the hands of a well-instructed physician. He who does not apply to a physician or who breaks off treatment or does not return for examination later has only himself to blame when he is again overtaken with manifestations of the disease, although sometimes not until many years later. By such neglect be not only injures himself, but frequently also other persons.

Before or after the apparent subsidence of a venereal disease, before a man has been declared by a physician to have got over the contagious stage, if he gives the disease to another person or exposes the latter to the danger of contagion he is liable to be sued in the civil and criminal courts and held for severe damages. The criminality is just as serious when the other party is a prostitute.

Any one who has had gonorrhea or syphilis must beware especially of marrying, or, if he is already married, of resuming sexual relations until express permission has been obtained from his doctor. Above all, persons with a venereal disease must take especial care of the cleanliness of their bodies. The syphilitic especially must always bear in mind that, even without actual contact, he is liable to give the disease to others by carelessness and infect innocent women and children.

9. Any one who has ever had a venereal disease must inform the physicians to whom he applies later of this fact. It may prove essentially important for the recognition and treatment of troubles later.

CIRCULAR FOR WOMEN AND GIRLS.

This circular is addressed particularly to girls who become wage-earners early and have no suitable persons to give them advice.

Among the most serious dangers which threaten these girls is the danger of sexual relations outside of marriage, to which they are often led by apparently harmless pleasures, such as dancing.

Intercourse with young men, in whose heedless and often absolutely dishonest promises the inexperienced girls put altogether too much trust, being led astray by advice of wanton female friends, and indulgence in intoxicating drinks—these are the allurements to which thousands of girls fall victims.

For girls sexual relations before marriage have a two fold danger—the danger of getting in a family way, and the danger of sexual diseases.

The girl who is in a family way is hindered in her work. She frequently loses her position. She falls into disgrace and poverty. The poverty grows worse when a child comes into the world. The girl then frequently falls lower and lower until she becomes a common street-walker and thief.

Although the father is bound by law to support his child born out of marriage until it is 16, yet he often manages to sneak out of this duty or is too poor to attend to it.

Besides all her other burdens the expense of supporting the child then falls on the young mother, whose weakened health generally makes her unable to work much.

Men who seek sexual relations outside of wedlock generally have intercourse with several girls, especially also with prostitutes. The consequence of this is that nearly all of these men suffer or have suffered from some sexual disease. Any one who has a sexual disease can give it to others, even when he is apparently entirely healthy, and in many cases even when he considers himself entirely cured.

On account of the widespread prevalence of sexual diseases among men, every girl who has sexual intercourse even once with a man exposes herself to the danger of contagion. Girls who change their lovers often take some sexual disease almost invariably.

The two principal sexual diseases are syphilis and gonorrhea. The latter does far greater harm to the body of the woman than to that of the man. Gonorrhea works its way upward in the female into the interior of the body and causes in some of the lower internal organs severe inflammation and suppuration. Gonorrhea frequently makes the woman a chronic invalid, permanently unable to work. The poison of the disease is liable also to get into the eyes of the baby as it is born and make it blind.

Syphilis is a disease that lasts for years, which poisons the whole body and not seldom leads to the severest disfigurements and after-troubles. Stillborn children are a frequent consequence of syphilis.

Even when the person affected has no longer any manifestations of the disease it is liable to be transmitted to the offspring and induce in them serious forms of the disease.

Hence the following advice should be taken to heart:

1. Always be on your guard, so that a single hour under the influence of liquor may not rob you of your honor, your health, your money-making capacity and your life's happiness.

Close your ears to the persuasions of go-between women. These women profit by your ruin.

Be moderate in your indulgence in beer and other intoxicating liquors, or better still, avoid them altogether, especially when in company with men, and above all, at a dance.

2. If you have once yielded yourself to a man you must always be on the lookout for the injurious consequences that are liable to follow.

Examine your body for a long time afterward with the greatest care.

If signs of being in a family way develop, then go and state your case to some benevolent-minded woman. In all the larger cities there are societies which come to the aid of a girl in this condition, and mediate between her and her parents, as also with her seducer.

Smarting and itching in the private parts, especially a discharge not noticed before, suggest gonorrhea has been taken. Any sore or lump or ulceration on the private parts, any eruption or sore throat, suggests infection with syphilis.

On finding these signs, which often do not appear until after three or four weeks, go at once to some doctor (and always to a registered physician), a man or a woman doctor (never to a nature healer or quack). If these diseases are treated correctly from the first their course is generally mild. Then and then only, as a rule, can a complete cure be effected.

It is not enough, of course, merely to go and see the doctor. His directions, especially his instructions in regard to the most careful cleanliness, must be strictly followed in all points.

3. If you have taken a sexual disease then you must heed the following advice:

Until the doctor declares that you are entirely cured all further sexual relations are strictly forbidden. If you act contrary to this rule you lose all claim to sympathy, your behavior is criminal, and you are liable to severe penalties.

You must not get married until the physician has given his consent. Otherwise your husband may take the disease from you, and your children may be diseased.

Every girl should also try to make sure that her future husband does not suffer from a venereal disease.

At every later sickness, at every pregnancy, at every sickness of your child, you must tell the attending physician of your former sexual disease, in your own or your child's interests. The physician is bound by law to the most absolute secrecy; you can confide in him without reserve. Your telling of your former sexual disease will in many cases show him the way to treat the new trouble and the pregnancy.

4. If you have had sexual intercourse and yet have not got in a family way nor taken a sexual disease do not let yourself be lulled into security. The warnings of this notice are still binding.

5. Contagion with syphilis may occur without sexual relations. For instance, a healthy wet nurse may take the disease from a syphilitic child, a healthy child from a syphilitic wet-nurse. Consequently before taking such a position both wet-nurse and child should be examined by a physician.

Syphilis may also be transmitted by a kiss and by the common use of eating and drinking utensils; gonorrhea by handkerchiefs, bandages, bed-linen, sponges, syringes and the like.

Consequently, be on your guard here also. Practice always the most painstaking cleanliness.

Heed well the advice which this circular gives you. Your happiness and your health lie in your own hand.

Nursing Tuberculous Patients.—Dr. Walter A. Griffin, in an article on this subject in the *Journal of the Outdoor Life*, calls attention to the fact that the nursing of tuberculosis patients is different in many ways from the nursing in other diseases. In any disease, he says, the patient has to be governed by the attendant, and the greatest tact is required. In tuberculosis the task is especially hard since in many cases the patient feels stronger than he really is, and if left to himself would frequently overtask his strength. From the nurse's standpoint there are three general classes of tuberculous patients, (1) those in the last stages, who are about to be relieved of their suffering; (2) those who, either at first or after having been under treatment, are taken acutely ill, but who have a fair show of recovery, and (3) ambulant (walking) cases. In the first class of patients attendance does not differ in great degree from that of any terminal illness. There is need of alleviating pain, quieting nervous fears, helping and consoling as only a good nurse can. It is not necessary to force the patient to be out in cold weather, to stuff him with food, or to chill him with cold baths unless he himself wishes it, as occasionally happens. For example, patients at times grow so used to fresh air that they will not be denied it, being made more uncomfortable if housed up. If the patient has begun on the treatment, it will at times awaken his suspicions if any laxity is shown. The sputa must be collected and destroyed with the greatest care when the patient is in this stage, and this duty usually falls to the nurse. The only rule to be insisted on is that the sputum must not become dried before it is destroyed by heat. In patients of the second class there is the comforting thought that recovery is not impossible; that the patient will without doubt get about again, and possibly be cured. It will probably be necessary to preach this gospel of hope many times to both patients and friends. Frequently the patient sees the bright side sooner than the rest, especially in these days when none speak of failure in the treatment of consump-

tion. But it is just as important that the courage of the rest of the family be sustained, so that they may reflect their hope to the patient, for there is nothing so discouraging as apprehension on the part of those near and dear. When a patient has so far recovered that he can be up and about, that is, when he becomes an ambulant case, the duties of the nurse are not so arduous. Unfortunately, at this time the patient frequently thinks that he can now dispense with a nurse altogether, and this is a mistake, since there are always times when a little watchful care will obviate the necessity of a return to bed.

A Plea for the Neurasthenic.—In an article on this subject in the *Montreal Medical Journal*, Dr. D. A. Shirres says that it is difficult and sometimes impossible to distinguish between neurasthenia and hysteria, as both conditions are due to cerebral exhaustion. In the typical neurasthenic, the marked insomnia, inability to concentrate the attention, defective memory, restlessness, fretfulness, irritability of temper, hypersensitiveness, discomforts about the head and neck, exaggeration of the reflexes, feeble pulse of low tension, and the constancy of the above symptoms, the length of time which the disease lasts as well as of the slow progress toward recovery, are diagnostic, as compared to hysteria, where there are marked psychical disturbance, and motor and sensory paralyses, the symptomatology being extremely variable in its nature and constancy. Dr. Shirres states that even physicians do not fully appreciate the magnitude of the disorder present in these cases. While gross diseases of the nervous system compel attention, he says the effects of ill health, suffering and incapacity produced by functional diseases are even more serious and far-reaching. In enumerating the symptoms of neurasthenia and differentiating it from hysteria *per se*, he states that the neurasthenic is likely to have hysterical symptoms. He declares that such a patient when obviously suffering from exhaustion should not be scolded or scoffed at, as the suffering is real. A physician should take time to listen patiently to all that the patient may wish to tell and should avoid the appearance of being in a hurry, as it is necessary that the patient should have implicit faith in his medical adviser. Treatment, he says, may be largely by suggestion, though it may be necessary to give tonics. Valerian and asafetida, he says, are useful, but bromids must be carefully used as they are liable to increase rather than to diminish the exhaustion present. Symptoms must be treated as they arise, for example, counter-irritation in local spasms, ice-bags, cold douches, etc., to relieve headache. Most remedies, he states, lose their efficacy after a time and new methods must be tried in order to exert the necessary psychic influence over the patient.

Relation of the Thyroid to Ichthyosis.—Moore and Warfield, in the *Journal of the Missouri State Medical Association*, report an interesting case of so-called fetal ichthyosis. The mother, an average-sized woman, with red hair and a freckled skin, entered the Bethesda Maternity Hospital in St. Louis, Aug. 10, 1905. She gave a history of a pregnancy with labor at the seventh month six years previously. At that time she was attended by a negro midwife, who would not allow her to see the child, which was dead, but buried it at once. During the night of August 9 (at seven months), the membranes ruptured and the following day she entered the hospital after a journey of 40 miles, during which the liquor amnii escaped freely. Pains began at 8 o'clock on that evening and the child was born at 7 p. m. the next day. The placenta came away spontaneously a few minutes later. It was intact and normal in appearance, and rather friable. Nothing abnormal was noted about the membranes or cord. The child, a male, cried vigorously at birth and presented a repulsive sight. It looked as though it had outgrown its skin and had burst through it. The entire surface of the body was covered by irregularly shaped plates of thickened epidermis, from 2 to 4 mm. thick, of an ivory color, separated by furrows of a dark red or purplish hue. The greatest thickening occurred about the head, producing marked ectropion of the upper eyelid and holding the mouth permanently open. The nose was rudimentary and there was little attempt at the formation of ears. The mucous membrane of the mouth and throat appeared normal; the glans penis was uncovered though the skin of the penis and that about the rectum was thickened. The hands and feet were distorted, the skin being drawn tightly over the bones; the fingers and toes were rudimentary. The child lived four days and during that time was fed by a dropper, suction being impossible. The skin was cold and clammy throughout, and the temperature was subnormal. All bodily functions were properly performed till death. At autopsy, eighteen hours after death, the portions of the skin which had been white were found to be dull-brownish in color, and the skin was as tough as leather. All the organs were congested. The thyroid and thymus were both small, and the other viscera showed no marked macroscopic changes. The microscopic changes in the thyroid were rather remarkable. These consisted in an enormous increase in the connective tissue of the gland, and an almost complete lack of colloid material and alveolar formation. Wherever it was apparent that alveoli probably existed, there were columnar cells lining the alveolus, and the center of the alveolus was occupied by granular material, degenerated cells, both cells with deeply staining nuclei, and those larger, with vesicular oval nuclei. At no place did it resemble the normal gland. There was marked atrophy of the thymus gland, with calcification of Hassall's corpuscles. The chief change in the skin was the enormous thickening in the horny layer. The authors state that this case supplies a deficiency in the literature in that there was a complete microscopic examination of the fetal adnexa, and they call attention to the fact that in only two of the recorded cases is the thyroid gland specially mentioned. They conclude by advising a careful study of the thyroid in cases of this disease which come to autopsy.

Climatic Conditions of Salt Lake City.—The committee of the Salt Lake County Medical Society, appointed for the purpose, has made a most interesting report on the climatic conditions of this region. The report starts with a review of the discovery and the colonization of the district, referring first to Father Silvester Veles Escalante, who, with eight of his companions, encamped at the mouth of the Provo, July 4, 1776. The report states that the great Salt Lake has much to do with the atmospheric conditions of that part of Utah, and that its influence extends for a radius of over 50 miles. Bathing in salt water is considered to have beneficial influences on a number of diseases, especially rheumatism. The range of temperature for that region is about 100 degrees. Changes in temperature are rarely abrupt. There is an average of 270 clear days in the year. The relative degree of humidity for a period of three years, from 1901 to 1903, inclusive, showed an average for Salt Lake City of 49.3. The uniform dryness of the atmosphere is one of its distinguishing features. During the summer months the humidity or moisture increases in the southern part of the state, but in Salt Lake City the relative degree of humidity is seldom more than two grains to the cubic foot. Hay-fever sufferers, asthmatics and sufferers from bronchitis are benefited and often cured by a stay in this climate. This is probably due, in part at least, the report states, to the lack of sudden changes in temperature. It takes several days for a change of 40 degrees to take place. There is no dew; the nights are as dry as the days. There is no rainy season, but periodically throughout the summer there are refreshing showers. Utah is said to be richly supplied with mineral springs which rival those of Europe in their therapeutic properties. The report concludes with an enumeration of the advantages of Salt Lake City as regards schools, hospitals, water supply, clubs, hotels, churches, etc.

Obsolete Wisdom.—An editorial in the *Medical Review of Reviews* says: "A very successful practitioner of our acquaintance was in the habit of assuring his office students that 'if they never gave anything which would harm their patients they would succeed in practice,' and therein was conveyed a fundamental truth which will never be out of date." The first

duty of the physician, therefore, according to the editor, is to do nothing at all, as thereby he will assuredly not give anything that will do harm. What a despicable lot of doctors there must be in that vicinity if this be the "fundamental" truth to be inculcated! Does the doctor tell his patients that? Are they willing to pay him for "services" on that basis? If so, they are more easily pleased than any we ever attended. The above is a type of the detracting, nasty slurs that are being hurled at us by quacks and others interested in lowering the regular profession in the eyes of the public. It is really too bad to hear it from one of ourselves. Speak for yourself, brother, if you want to talk that way, but don't make any claim to speak for the rest of the profession. For the vast majority of American physicians it is a libel. Moreover, if the man quoted practiced on that basis, we doubt if he could have been so "very successful" as the editor affirms. How could he be, if nonentity and pretense were the basis of his work?—*Clinical Medicine.*

Book Notices

The Food Factor in Disease. Being an Investigation Into the Humoral Causation, Meaning, Mechanism, and Rational Treatment, Preventive and Curative of the Paroxysmal Neuroses, etc., and Other Degeneration. By F. Hare, M.D., vols. 1 and 2. Cloth. Pp. 497 and 535. Price, $10.00. New York: Longmans, Green & Co., 1905.

The author seems to have convinced himself, apparently by purely deductive reasoning, that in certain conditions carbonaceous material can accumulate in the blood and give rise to pathologic phenomena. This condition he terms "hyperpyremia," and he seems to consider it an essential, though not necessarily the sole factor in many disorders, and seeks to establish his theories by clinical facts. He also suggests that the paroxysmal neuroses depend on hyperpyremia and consitute acarbonizing processes. He lays great stress on the regulation of diet and on fresh air, sleep, and judicious exercise. In each individual case he determines by experiment the minimum carbonaceous intake compatible with carbon equilibrium. He quotes freely and at length from many authorities. He considers the three methods of dietetic treatment: restriction of food generally, without regard to its nature; restriction of proteid, and restriction of carbonaceous foods, and gives his reasons for preferring the last. In ordering a diet for a patient Hare states that he never gives verbal instructions such as, a little, etc., as they are too indefinite. He writes his instructions in full—a custom to be commended. Bread and fats, he says, should be as carefully weighed as drugs. Migraine and asthma, which are generally believed to be due to an excess of purin bodies, and which, therefore, are usually treated by a purin-free diet, Hare thinks, may be more effectively treated by restricting the amount of carbohydrates and fats and allowing the patient meat, fish and fowl. His theories are likely to have many opponents, though they are worthy of consideration.

A Text-Book on Prescription-Writing and Pharmacy, with Practice in Prescription-writing, Laboratory Exercises in Pharmacy and a Reference List of the Official Drugs, Especially Designed for Medical Students. By B. Fantus, M.D., Professor of Materia Medica and Therapeutics, College of Physicians and Surgeons, Chicago. Second Edition. Thoroughly Revised and Adapted to the Eighth (1905) Edition of the U. S. Pharmacopeia. Cloth. Pp. 404. Price, $3.00 net. Chicago: Chicago Medical Book Co., 1906.

Part I is devoted to the writing of prescriptions and contains chapters on form and language of prescriptions, determination, quantities in prescriptions, the proper composition of prescriptions of various kinds, and prescription ethics. The author realizes that graduates in medicine are often sadly deficient in the art of prescription writing and because unable to originate prescriptions to meet the needs of their practice too readily fall into the traps set for them by the proprietary medicine merchant. This book should do much toward making graduates in medicine independent of ready-made proprietary mixtures. Part II is devoted to the pharmaceutical preparations of the various remedies, classified in the conventional way. Part III contains a brief description of the official drugs and their preparations. It is a relief to find that all chemical symbols and formulas have been omitted from the text and one can but regret that the same considerations which led the author to omit chemical symbols did not also decide the omission of such definitions as: "Eugenol—an unsaturated aromatic phenol, etc." and "Santonin—the anhydrid of santonic acid, etc." It is also to be regretted that this book, otherwise replete with well-selected, concise information, should give room to the botanic description of drugs. One can readily imagine the effect on the average student of medicine of the following: Lobelia: "Leaves alternate, pale green, pubescent; stem coarsely angled, hairy, terminating in long racemes of pale-blue flowers; capsules inflated, containing numerous minute seeds; odor slight, irritating; taste strongly acrid."

Clinical Obstetrics. By R. Jardine, Glasgow. Ninety-nine Illustrations and a Colored Plate. Second Edition. Cloth. Pp. 609. Price, $4.75. New York: Rebman Co. 1905.

Jardine calls attention to the fact that most practitioners gain their experience and knowledge of obstetrics after graduation, and states that it is for these men that his book is intended. Nine chapters are devoted to consideration of the complications of pregnancy, and one to the management of normal labor. Hemorrhages occurring in various stages of pregnancy and labor are considered at length. Complications of labor and the puerperium are discussed and obstetric operations are treated of exhaustively. The concluding chapters deal with accidents to the child during delivery, abnormalities and diseases of the new-born infant, and infant feeding. Jardine emphasizes the importance of breast nursing to the child and states that when it is impossible for a mother to nurse her child a good wet nurse is the best substitute. He gives directions for preparing the various artificial foods and for modifying cow's milk. An appendix contains statistics of thirty years' work in the Glasgow Maternity Hospital.

Lectures on Clinical Psychiatry. By E. Kraepelin. Authorized Translation from the Second German Edition. Revised and Edited by T. Johnstone, M.D. Second Edition. Cloth. Pp. 352. Price, $3.50. New York: William Wood & Co.

American physicians will find this translation of Kraepelin's clinical lectures a very instructive work on the types and the diagnosis of mental disease. As the editor says, they are thoroughly practical and their value is enhanced by the fact that there is no psychiatric teacher at the present day whose ideas figure more largely in the literature than those of Professor Kraepelin. It will be found of value, both to the alienist and to the general practitioner, on whose judgment most frequently depends the earliest recognition and treatment of insanity when it occurs. Dr. Johnstone has appended to the lectures a classification of mental disorders in accordance with Kraepelin's latest views. The translation appears to be excellent and the avoidance of new technical terms so far as possible is a praiseworthy feature.

Progressive Medicine. A Quarterly Digest of Advances, Discoveries and Improvements in the Medical and Surgical Sciences. Edited by H. A. Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia, etc. Assisted by H. R. M. Landis, M.D., vol. I, March, 1906. Paper. Pp. 304. Price, $6.00 per annum. Philadelphia: Lea Brothers & Co., 1906.

The subjects considered in this volume are: 1. The Surgery of the Head, Neck and Thorax, by Charles H. Frazier, M.D. 2. Infectious Diseases, including Acute Rheumatism, Croupous Pneumonia and Influenza, by Robert B. Preble, M.D. 3. The Diseases of Children, by Floyd M. Crandall, M.D. 4. Rhinology and Laryngology, by D. Braden Kyle, M.D., and 5. Otology, by B. Alexander Randall, M.D. The general get-up of the book, the paper, print and indexing are of an enduring quality and make its use not only profitable but pleasurable. Physicians are so well acquainted with Progressive Medicine that it is unnecessary to do more than indicate in a general way the contents of each volume.

Prevention and Cure of Tuberculosis. A Collection of Articles of a Popular Character on the Subject of Tuberculosis. By S. A. Knopf, J. H. Huddleston, D. A. Willey and Others. Compiled by J. R. Long. Cloth. Pp. 246. Price, $1.25. Denver: H. M. Brinker. 1905.

This is a reprint in book form of articles that have appeared in various medical journals on tuberculosis, by such men as Drs. S. A. Knopf, J. H. Huddleston, Day Allen Willey, Henry P. Loomis, Henry B. Dunham, Robert W. Craig, William N. Beggs, George E. Abbott, Guy Hinsdale, Chase P. Ambler,

Joseph Eichberg, and others. The compiler evidently had in mind supplying a book for the layman, but we are afraid that some of the matter is presented in a way that will not appeal directly to the public. The compiler, however, has made a selection of some splendid articles and, presenting them in a compact form, as is here done, will be an aid in propagating the knowledge that the public ought to have in regard to this dreaded disease.

SURGICAL NURSING and the Principles of Surgery for Nurses. By R. Howard, M.B., M.S., F.R.C.S. Cloth. Pp. 318. Price 6s. London: E. Arnold, 1905.

The basis of this book is a series of lectures on surgical nursing given to the probationers at the London Hospital. The author states that modern nursing has passed beyond the stage of passive obedience and that a nurse must now understand the principles on which a surgeon is working. The general arrangement of the subject matter is good and the language is clear and concise. The book is well illustrated. An appendix contains formulæ for enemata of various kinds, mouth washes, eye washes and dusting powders. There are also directions for preparing nourishment for "nasal feeding," for pancreatizing and peptonizing milk, and for test meals.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

CONTRACT PRACTICE.

FAYETTEVILLE, ARK., April 3, 1906.

To the Editor:—In THE JOURNAL, March 31, you very pertinently, as I think, reply to Mr. Stone, president of the Baltimore Casualty Company in reference to fees for examiners, partly as follows: "And no self-respecting physician ought to sell his services to such a corporation at wholesale, and have them retailed to the people of his own community at prices which have enabled these companies to amass a fortune, and, until recently to defy public opinion." All very true, but what of those medical gentlemen who along the lines of our railroads hold subordinate positions as "railroad surgeons," having signed an obligation to work for these corporations for less fees than they would serve the mechanics and laborers, among whom they reside. It is true that they are given a piece of cardboard, a pass. The subordinate "railroad surgeon" signs a fee bill supplied by the corporation, so contemptibly low as to shame the self-respect of most medical men who are not readily inflated by the title of "railroad surgeon." (What I say is true unless there has been a recent change, but I have heard of no complaint from these employés, and suppose they sign now as heretofore.)

W. B. WELCH, M.D.

TREPONEMA PALLIDUM.

NASHVILLE, TENN., March 31, 1906.

To the Editor:—What is the meaning and pronunciation of the term *Treponema pallidum*, as advocated by Schaudinn instead of the term *Spirochæta pallida*?

ANSWER.—In June, 1905, Vuillemin took *Spirochæta pallida* as a type of a new genus *Spironema*, using the specific name *Spironema pallidum*. As the name *Spironema* is preoccupied in zoology, having been used by Meek in 1864 for a genus of mollusks, the present correct name of the parasite under the international code is *Treponema pallidum*. The term is pronounced tree-po-nee-mah pahl-eedum. Its meaning is a pale, turning thread.

TOY PISTOLS AND OTHER SIMILAR DEVICES

A member of a machinery manufacturing firm of Claiborne, N. H., who has been instrumental in having an ordinance passed prohibiting the sale or use of toy pistols, fire crackers, exceeding 6 inches in length, canes, bombs and other contrivances using dangerous explosives, writes: "Inasmuch as I have taken this prominent stand in the matter, very likely inquiries will be made of me as to what explosives are considered dangerous, and what the limiting features are of the toy pistols and other similar devices for the use of dangerous explosives, and I would greatly appreciate any information you can give me along these lines. I assume you will be willing to give me this information as soon as you can conveniently do so, owing to your interest in this matter."

ANSWER.—The term "toy pistol" has an indefinite meaning that has led to confusion, and also to unnecessary legislation. There are two types of this implement. One is made for the shooting of small flat paper caps, and in all the records obtained by THE JOURNAL concerning tetanus there have been no instances of the disease due to infection of wounds caused by these caps. Occasionally injury to the eye is produced by particles from the exploding caps, but they seldom cause serious injury. The "toy pistol" that causes tetanus is the cheap contrivance made for the purpose of exploding blank cartridges, generally of .22-caliber. Many of the tetanus wounds are also produced by cheap .22-caliber revolvers, and occasionally by blank cartridges discharged in larger-sized revolvers. As to the other forms of Fourth of July explosives it may be said that there is none that has not at some time or other caused serious injury. We have records of tetanus following burns from rockets, and even from the explosion of large set pieces in the hands of professionals. However, few serious injuries have been produced by any of the display fireworks used at night, or from the small-sized firecrackers, although all of these have caused much property loss from fires. The small paper torpedoes are also practically harmless. If we can get rid of the blank cartridge, the giant cracker, and the toy cannon, the mental and physical suffering of the Fourth will be practically abolished.

State Boards of Registration

COMING EXAMINATIONS.

MISSOURI State Board of Health University Medical College, Kansas City, April 16-18. Secretary, J. A. B. Adcock, Warrensburg.

ILLINOIS STATE BOARD OF HEALTH, Northwestern University Building, Chicago, April 18-20. Secretary, J. A. Egan, Springfield.

Connecticut March Report.—Dr. Charles A. Tuttle, secretary of the Connecticut Medical Examining Board, reports the written examination held at New Haven, March 13-14, 1906. The number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 75. The total number of applicants examined was 15, of whom 11 passed and 4 failed. The following colleges were represented:

PASSED. College.	Year Grad.	Per Cent.
Maryland Med. Coll.	(1905)	75.3
Tufts College Medical School	(1903)	80.4
Harvard University	(1903)	81.3
Queen's University, Canada	(1904)	77.2
University of Buffalo	(1895)	85.4
College of P. and S., New York	(1903)	85.3
Yale University	(1905)	80.1
Tulane University	(1905)	82.1
College of P. and S., Baltimore	(1904)	82.3
University of Maryland	(1903)	80.4
College of P. and S., Boston	(1903)	84.8
FAILED.		
University of the South	(1905)	69.1
College of P. and S., Chicago	(1905)	69.1
Georgetown University	(1904) 72.8; (1905)	73.4

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending April 7, 1906.

Lambert, Samuel E., asst.-surgeon, at expiration of his present leave of absence will proceed to and take station at Fort Wright, Wash.

Duncan, Louis C., asst.-surgeon, on arrival at San Francisco, will proceed to and take station at Fort Missoula, Mont.

Richard, Charles, surgeon, is detailed to represent the Medical Department of the Army at the 15th International Congress of Medicine, to be held at Lisbon, Portugal, April 19 to 25.

Egan, Peter R., surgeon, retired from active service, April 2.

Marrow, Chas. E., asst.-surgeon, granted ten days' leave of absence.

Barney, Charles N., asst.-surgeon, advanced from grade of first lieutenant to that of captain, with rank from January 12.

Appel, D. L., deputy surgeon-general, on arrival at San Francisco, will assume charge of medical supply depot in that city, relieving Lieutenant-Colonel Louis Brechemin, deputy surgeon-general.

Brechemin, Louis, deputy surgeon-general, on being relieved from charge of medical supply depot, San Francisco, will proceed to New York City, and assume charge of medical supply depot in that city, relieving Lieutenant-Colonel William B. Davis, deputy surgeon-general.

Davis, William B., deputy surgeon-general, on being relieved from charge of medical supply depot, New York City, will proceed to Chicago, and report in person to the commanding general, Department of the Lakes, for duty as chief surgeon of that department.

Reagles, James, contract surgeon, ordered from Fort Keogh, Mont., to Fort Snelling, Minn., for temporary duty.

Chase, Alpha M., contract surgeon, ordered from Fort Reno, Okla., to Fort Clark, Texas, for temporary duty.

Mason, George L., dental surgeon, left Key West Barracks, Fla., and arrived at Fort Morgan, Ala., for duty.

Casaday, George H., dental surgeon, returned to duty at Army General Hospital, Presidio of San Francisco, from leave of absence.

Stone, Frank P., dental surgeon, left Army General Hospital, Presidio of San Francisco, on leave of absence.

Ware, William H., dental surgeon, left Fort Logan, Colo., for Fort Wingate, N. M.; and ordered to visit in succession Fort Apache, Ariz.; Whipple Barracks, Ariz.; and Fort Huachuca, Ariz.

Navy Changes.

No changes in the Medical Corps of the Navy for the week ending April 7, 1906:

Public Health and Marine-Hospital Service.

List of changes and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending April 4, 1906:

White, J. H., surgeon, granted leave of absence for two days under Paragraph 189 of the Regulations.

Rosenau, M. J., P. A surgeon, detailed to represent the service at session of the American Medical Association at Boston, Mass., June 5-8, 1906.

Fricks, L. D., P. A. surgeon, relieved from duty at Ellis Island, N. Y., and directed to proceed to Fort Stanton, N. M., reporting to the medical officer in command for duty and assignment to quarters.

Stansfield, H. A., P. A. surgeon, granted two days' leave of absence under Paragraph 191 of the Regulations.

McClintic, T. B., P. A. surgeon, relieved from duty in the Hygienic Laboratory, Washington, D. C., and directed to proceed to San Francisco Quarantine Station, reporting to the medical officer in command for duty and assignment to quarters.

Goldberger, Joseph, P. A. surgeon, granted extension of leave of absence for two days from May 2, 1906.

Olsen, E. T., asst. surgeon, relieved from duty at New York and directed to proceed to Chicago, reporting to the medical officer in command for duty and assignment to quarters.

Adams, F. B., acting asst.-surgeon, granted leave of absence for fifteen days, from April 6.

Frissell, C. M., acting asst.-surgeon, granted leave of absence for ten days, from March 22, 1906.

Luckey, J. W., acting assistant surgeon, granted leave of absence for thirty days, from March 30, 1906.

McKinley, W. R., acting asst.-surgeon, granted leave of absence for thirty days, from March 23, 1906.

Van Ness, G. I., pharmacist, directed to proceed to Baltimore, for temporary duty, on completion of which to rejoin his station in Washington, D. C.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service during the week ended April 6, 1906:

SMALLPOX—UNITED STATES.

California: Los Angeles, March 17-24, 6 cases.
Florida: Jacksonville, March 24-31, 2 cases.
Indiana: Indianapolis, March 18-April 1, 6 cases.
Kansas: General, Feb. 1-28, 233 cases; Leavenworth, March 1-31, 5 cases.
Louisiana: New Orleans, March 24-31, 9 cases.
Maryland: Baltimore, March 24-31, 1 case.
Massachusetts: Boston, March 24-31, 3 cases.
Michigan: Ann Arbor, March 24-31, 1 case.
Missouri: St. Louis, March 24-31, 5 cases.
Nebraska: Omaha, March 17-24, 1 case.
New York: New York, March 24-31, 2 cases.
North Dakota: Grand Forks County, Feb. 1-28, 1 case; McHenry County, 1 case.
Ohio: Cincinnati, March 23-30, 3 cases.
South Carolina: Greenville, March 17-24, 2 cases.
Tennessee: Memphis, March 24-31, 8 cases.
Washington: Spokane, March 17-24, 1 case, imported.
West Virginia: Wheeling, March 24-31, 2 cases.
Wisconsin: Appleton, March 24-31, 3 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, Feb. 10-24, 2 cases, 1 death.

SMALLPOX—FOREIGN.

Africa: Cape Town, Feb. 17-24, 19 cases.
Brazil: Pernambuco, Feb. 14-28, 23 deaths.
Canada: Toronto, March 17-24, 2 cases.
Cape Verde Islands: March 29, present.
Chile: Iquique, Feb. 17-24, 6 cases, 2 deaths.
China: Shanghai, Feb. 17-24, 2 deaths.
France: Paris, March 10-17, 13 cases.
Gibraltar: March 11-18, 10 cases.
Great Britain: Bristol, March 17-24, 1 case.
Greece: Athens, March 8-15, 1 death.
Honduras: Puerto Cortez, March 17-24, present; San Pedro, March 17-24, present.
India: Bombay, Feb. 13-March 6, 24 deaths; Calcutta, Feb. 17-24, 173 cases, 173 deaths; Madras, Feb. 24-March 2, 50 deaths; Rangoon, Feb. 17-24, 77 deaths.
Italy: General, March 10-17, 9 cases.
Japan: Formosa, Feb. 1-28, 12 cases; Yamaguchi Ken, March 6, 27 cases, 4 deaths.
Russia: Moscow, March 3-10, 7 cases, 3 deaths; Odessa, March 3-17, 24 cases, 2 deaths; St. Petersburg, Feb. 24-March 10, 4 cases.
Spain: Barcelona, March 10-20, 7 deaths; Seville, Feb. 1-28, 12 deaths.
Turkey: Constantinople, Feb. 25-March 11, 2 deaths.

YELLOW FEVER—FOREIGN.

Mexico: Merida, March 11-17, 1 case, 1 death; Tehuantepec, 1 case.

CHOLERA—INSULAR.

Philippine Islands: Manila, Feb. 10-24, 11 cases, 10 deaths; Provinces, Feb. 10-24, 371 cases, 293 deaths.

CHOLERA—FOREIGN.

India: Calcutta, Feb. 17-24, 65 deaths; Rangoon, 2 deaths.

PLAGUE—FOREIGN.

Australia: Freemantle, Jan. 6-Feb. 19, 5 cases, 2 deaths; Perth, Jan. 6-12, 3 cases.
India: General, Feb. 17-24, 9,717 cases, 8,312 deaths; Bombay, Feb. 13-March 6, 484 deaths; Calcutta, Feb. 17-24, 31 deaths; Madras, Feb. 24-March 2, 5 deaths; Rangoon, Feb. 17-24, 19 deaths.
Japan: Formosa, Feb. 1-28, 94 cases, 69 deaths.
Mauritius: Jan. 25-Feb. 8, 3 cases, 1 death.

Medical Organization

THE GREAT WORK BEING DONE IN TEXAS.

J. N. McCormack, M.D.
Chairman of the Committee on Organization of the American Medical Association.
BOWLING GREEN, KY.

The leaders of the profession of Texas were among the first to catch the real spirit of modern organization. Loyal, and tenacious of their opinions, many of the older members were reluctant to join in the movement at first, but, once convinced of its merits and possibilities, they have vied with the young men and each other in promoting it. I was present at the reorganization at San Antonio in 1903, and then and in subsequent visits these men have constantly reminded me of the Japanese in their activity, resourcefulness and aggressive determination.

They have had more than the usual difficulties to encounter, and have made some serious mistakes, as will appear presently, but have overcome the former and corrected the latter with such commendable temper, courage and wisdom as constantly to challenge admiration; and the good results of all this were and are to be seen at every stage of the proceedings.

Starting out with few county societies and a total state membership of 435, in one year's time 160 counties had been organized, and the membership had grown to 2,390, and is expected to reach over 3,000 before the next annual meeting, which is to be held during the present month. I can testify from personal observation that the increase in professional interest and enthusiasm is even greater than the above figures would indicate, and is still growing.

At the outset the difficulties confronting the active, earnest, self-sacrificing councilors often seemed insurmountable, but they had the genuine reform spirit and usually were able to turn these into actual advantages. For instance, there were a number of large, influential district societies to which many physicians were naturally wedded, and which at one time promised to be an endless source of contention, but, with the exercise of tact and good temper on all sides, nearly all of these were promptly woven into the new plan and made an element of real strength. The same good judgment was followed with many other of the obstacles which have given so much trouble elsewhere.

In the same spirit, their arrangements for my itinerary were more prompt and comprehensive than those heretofore made in any other state. As soon as I could give them the date of my first appointment and the length of time at their disposal, a meeting of the council was called, and, with the assistance of an experienced passenger agent, the trip was carefully planned, covering every section of the state to the best advantage in the least possible time. This was so well done that I publish the itinerary in full as a model for others who may be charged with a similar duty. See page 1134.

The widest possible publicity was given to the appointments, through the *Texas State Journal of Medicine* and the secular press, and personal letters were sent to all medical men by their respective councilors and county secretaries, explaining the purposes and importance of the meetings, and urging attendance. Later it was decided, on my advice, to extend the invitation to the laity, and this was done with most satisfactory results in many sections, although not with the full benefit which would have been possible if its desirability could have been foreseen earlier.

In magnificent distances, as in many other respects, Texas is truly an empire, but the councilors attended and actively participated in every meeting in their respective districts, and frequently in others, and the president and secretary of the Texas State Association, and chairman of the council, came to meeting after meeting, often involving hundreds of miles of travel and three or four days in time. It is largely to this enthusiastic, self-sacrificing devotion to duty on the part of those honored with office which has infused the desire for better things into every element of the profession, and which promises so much for the future of this great state.

The meeting at San Antonio may be taken as fairly typical, although the attendance of the laity was not such a distinctive feature as it was made subsequently. Unfortunately, in the excess of a characteristic hospitality, much time was consumed in an elaborate banquet which was needed for the intensely practical discussion which followed. In addition to the entire regular profession, there were present several physicians of other schools, members of the judiciary, the prosecuting attorney, legislators and many other representative laymen. This historic, health-resort city has been overrun with charlatans for years, some of them practicing under assumed names, or under authority of certificates issued to others, as is so common with this class everywhere, but so strongly had they seemed entrenched that, even after the profession had become effectively organized for other purposes, it had feared to attempt to dislodge them. After my opening talk this was taken up as one of the subjects for discussion. The provisions of existing statutes, and the possibility and methods of securing additional legislation, were frankly gone into, and it soon developed, as I had found to be the case everywhere, that the laymen took quite as active and intelligent interest in all of these matters as the medical men. They expressed surprise at the conditions unfolded to them, and that the laws had not been enforced or strengthened, and promised a most cordial co-operation in any proper efforts having these ends in view. It was the same with the "patent medicine" and other similar evils, and with securing and executing laws for the protection of the people against pestilence, and especially against consumption, typhoid fever, diphtheria, cholera infantum, dysentery and other everyday household plagues. These laymen had either ignored these matters entirely or had underestimated their practical importance, and only the plain, common-sense instructions which fearless, progressive physicians alone can give was needed to enlist their active interest.

The attendance and participation of laymen in the regular discussion marked a new feature in the growth and scope of my work and is entitled to more than a passing mention. I had often addressed distinctively popular audiences, and representative laymen had been present at some of the meetings as far back as the trip in Pennsylvania, but these had been incidental occurrences rather than part of a fixed plan. The advisability of making it a permanent feature of the work, the beginning of a campaign of education, as it were, had long been in my mind and the subject of discussion with my colleagues. After the San Antonio meeting the public was cordially embraced in every invitation. Lawyers, ministers, teachers, legislators, farmers, business men, city and county officials, and especially the women, were urged to attend and to participate in the discussions, and with most satisfactory results. It has been found easy to demonstrate to any intelligent layman that his physician, and the profession as a whole, has no interest which he does not share, and that the daily safety and well-being of his family is inseparable from the continued prosperity and competency of his physician, and of the profession of his county, state and country as a whole.

It was easy to interest the leaders of this profession almost everywhere in any practical proposition looking to the advancement of their own and the public interests. Weekly meetings were begun very generally, and regular postgraduate courses were established shortly after my visits at Waco, Austin, Tyler, Fort Worth and Amarillo and other places; that at Waco meeting three nights in each week and giving a full course in anatomy with demonstrations on the cadaver, combined with some practical subject or a clinic for each evening. In several counties conferences with the laity have been continued as the result of my visit, and, in some, joint meetings have been arranged with the farmers' organizations for the purpose of working out some systematic plan of compensation for medical services for the tenant class and other similar matters.

The harmony which had come to the profession in nearly every county in two or three years, as a result of the frequent meetings, and the promise of co-operation in advancing its varied interests, was most gratifying, and even exceeded my expectations. Almost the only discordant note heard was at Dallas, where a strong and excellent profession, with great possibilities open to it, was divided by a school fight, on the plane usually found, and not relieved by the high personal and professional character and abilities of those leading in it. So far as I could judge, there was no interest involved not entirely personal and selfish, and yet the antagonism was as outspoken and implacable as if some great principle was involved. Such conditions ought not to be tolerated in any medical center, and, knowing from my large experience the irreparable harm which school feuds have brought to us in the past, I frankly advised the profession of Texas not to send students to the schools in Dallas until those engaged in molding the character of young doctors could at least set an example in peace and harmony in their own community.

Under the general conditions portrayed in the foregoing, and seemingly so favorable on the surface, there is ample ground for serious thought, and for grave apprehension for the future, on the part of every thoughtful member of the profession in Texas. Both the medical and health laws are far from satisfactory, and, so far, it has been impossible to unite even the leaders of the profession on the character of the changes to be made. At the last session of the general assembly the members of the committee having the proposed legislation in charge were hopelessly divided in their own counsels, and, without a recognized leader, their raw medical troops, over 2,500 strong, were led against the small, compact army of quackery, which knew what it wanted, and how to go after it, with a better result than might have been expected a drawn battle. Senators and representatives should have the unselfish principles underlying health and medical legislation explained to them in the county societies and by their family and home physicians while they are candidates and in a receptive mood. Nearly every vote can be controlled by education, moral suasion, and home influence in advance, while only harm can result from bluster and threats later, when the current has set in the wrong direction.

Our friends in Texas have accomplished so much in a short time within their own ranks, they are so strong in numbers, they have such a domain, with widely separated men of equal standing and importance, that further defeats may be necessary before they can get together in these matters and unite on a leader for legislative work in whom they can place implicit confidence. They must agree among themselves, and one man, in touch with, and having the full confidence and cooperation of, the profession in each county, and not a committee, must have charge of the real work. Even if it requires years of waiting it would probably be better for them not to enter the legislative lists again voluntarily until this can be done. They have the advantage of a strong and ably edited state journal for frequent inter-communication; they have an accomplished and devoted secretary and executive officer, and a great and practically united profession, and with the discipline which frequent meetings and co-operative work will bring to them, they can and ought to be an example for other states in the field of organized medicine.

Society Proceedings

COMING MEETINGS.

American Medical Association, Boston, June 5-8.

Medical Assn. of State of Alabama, Birmingham, April 17.
Medical Society of State of California, San Francisco, April 17-19.
Florida Medical Association, Gainesville, April 18.
Medical Association of Georgia, Augusta, April 18.
Mississippi State Medical Association, Jackson, April 18.
South Carolina Medical Association, Columbia, April 18.
State Medical Association of Texas, Fort Worth, April 24-26.
Arizona Medical Association, Phoenix, April 24-25.
Medical and Chirurg. Faculty of Maryland, Baltimore, April 24-26.
Nebraska State Medical Association, Lincoln, May 1-3.
New Mexico Medical Association, Albuquerque, May 2.
American Therapeutic Society, New York City, May 3-5.
Oklahoma Medical Association, Oklahoma City, May 8.
Indian Territory Medical Association, Oklahoma City, May 8.
Utah State Medical Association, Salt Lake City, May 8-9.
Nevada State Medical Society, Reno, May 8-9.
Louisiana State Medical Society, New Orleans, May 8-10.
Arkansas Medical Society, Hot Springs, May 8-10.

Kansas Medical Society, Topeka, May 9-11.
American Climatological Assn., Atlantic City, N. J., May 12-14.

CHICAGO SURGICAL AND CHICAGO MEDICAL SOCIETIES.

Joint Meeting held Feb. 28, 1906.

The Vice-president of the Chicago Surgical Society, Dr. D. W. Graham, in the Chair.

Postoperative Intestinal Obstruction.

Dr. J. M. T. Finney, Baltimore, Md., detailed 26 cases, and after referring at length to the literature of other cases, drew the following conclusions: 1. Broca's classification into early and late varieties simplifies the diagnosis. In the former class, which so frequently is associated with peritonitis, the differential diagnosis as to variety is always difficult and often impossible. In the latter, which is composed almost exclusively of the mechanical forms, it is usually easy. 2. Adhesions are the chief factor to be reckoned with in an attempt to prevent the occurrence of postoperative ileus, and efforts directed toward this end are likely to be productive of the best results. 3. That drainage exercises a marked influence in the production of adhesions can not be denied. 4. As to treatment, prompt operation is indicated in every case after palliative measures have been given a fair trial and have failed. The character of the operation depends on the nature of the obstruction and the condition of the patient. 5. The prognosis is unfavorably influenced by the presence of infection. In its absence it is excellent.

Dynamic Ileus.

Dr. John B. Murphy, Chicago, defined ileus as a train of symptoms consisting of four essential elements: pain in the abdomen, nausea and vomiting, meteorismus and coprostasis. Using this as a guide, he subdivided ileus into adynamic ileus, dynamic ileus and mechanic ileus. Under adynamic ileus he includes all of the conditions that are due to the absence of power of propulsion. Under dynamic ileus he includes the two conditions where the obstruction is due to an excess of power, and excessive contraction of the muscular wall. Under mechanic ileus he includes all the mechanical conditions, whether of the strangulation or obturation variety, which impede the advancement of the contents of the intestinal canal in a mechanical way. The cases which puzzle the general practitioner and surgeon are those included under adynamic ileus. One of the first causes of this form of ileus is strangulation of the omentum. Strangulation of the omentum produces a reflex paralysis of peristalsis. The colic which occurs with hepatic calculus is difficult to differentiate from mechanical obstruction, because there is pain, nausea and vomiting, absence of peristalsis, with distension of the bowel coming on as the result of the paralytic condition; also coprostasis if the pain is severe.

One of the very difficult conditions to diagnose differentially is the impaction of stone in the cystic duct. There is another class of cases in which the manifestations of ileus are pronounced from the ligation of pedicles, and he thinks since the practice of ligating pedicles *en masse* has ceased, there is much less vomiting after operations and fewer cases of paralytic ileus now than formerly. Gastric tetany is another condition that is mistaken for intestinal obstruction. Peritoneal trauma is a cause of paralytic ileus. The embolic type of paralytic ileus is due to two causes—interference with the nerve supply and ischemia. Temperature is never a primary symptom in mechanic ileus, not even in intussusception in children. He thought at one time that leucocytosis was going to be of enormous value in the differential diagnosis. He believed that the infective type would show a high leucocyte count, while the mechanical type would show a low leucocyte count. But he has been greatly disappointed. He has seen a 36,000 leucocyte count (differential) in mechanic ileus. He has likewise seen a 7,000 leucocyte count in a case of septic peritonitis, so that he has ceased to place any particular value on the differential diagnosis as to the number of leucocytes.

Strangulation Ileus.

Dr. Arthur Dean Bevan, Chicago, said that strangulation ileus is best studied from the standpoint of a strangulated hernia. It is a form of ileus which comes on as a strangulated hernia does, with sudden onset, shock, pain, obstruction of the bowel, vomiting, with, later, tympany, and, if unrelieved, peritonitis takes place followed by death. It is at the beginning free from temperature. The diagnosis can be made early if the surgeon has a clear mental picture of what strangulation ileus means. A long appendix or adhesions to a tube may cause obstruction. A most common cause is probably volvulus. He recently saw a case of volvulus of the entire transverse colon which caused obstruction. The forms of ileus which are described as due to strangulation in the retroperitoneal fossæ are quite infrequent. They do occur, however, and must be kept in mind. The proper treatment of a case of strangulation ileus is immediate operation. Patients with mechanical ileus die because an early diagnosis is not made, because early operation is not done, but in whom early diagnosis and early operation would have saved life.

Obturation Ileus.

Dr. William E. Schroeder mentioned the classification of Schlange, who considers obturation ileus as including compression from without, strictures, both benign and malignant tumors in the lumen of the intestine, intussusception, and the usual obturation forms, namely, from gallstones, enteroliths, foreign bodies and fecal masses. The nature of the obstruction consists in the simple closure of the lumen of the intestine, either primarily from within, or through compression from without. He discussed the symptoms of the acute forms of obturation ileus; also the diagnosis.

In obturation ileus enterotomy is of especial value in relieving the intestine of its poisonous contents and because of the simplicity of the operation. A radical operation may follow at some future time when the patient is in better condition. In strangulation ileus it is necessary to relieve the

strangulated intestine and save it from gangrene, or to resect the gangrenous portion. Cases of ileus come into the hands of surgeons far too late. Many general practitioners wait for fecal vomiting before they transfer their cases to the surgeon.

Abuse of Cathartics in Obstruction of Bowel.

DR. M. L. HARRIS, Chicago, recently saw a patient suffering from a strangulated inguinal hernia with an enormous abdomen and vomiting every few minutes, who was still trying to get his physic down between vomits; and another with acute appendicitis where the attendant wondered why no result followed the cathartics, in which an operation disclosed a very large opening in the cecum left by the sloughing off of the appendix and through which the intestinal contents chased by the cathartics had escaped into the abdominal cavity. Other cases illustrating all the varieties of intestinal obstruction were mentioned. He said that cathartics should never be given to a patient suffering with an acute abdominal trouble until a diagnosis has been made, or if not an accurate diagnosis, at least until all of the conditions which may produce obstruction have been positively excluded, and it should be remembered that these patients are never sick because the bowels do not move, but the bowels do not move because they are sick.

DR. FERNAND HENROTIN, Chicago, said there are many cases in which catharsis is given when the diagnosis is not clear, where the symptoms are not typical, so as to render the making of an accurate diagnosis more easy, and in such the administration of a cathartic is permissible. He spoke of the value of enterostomy in ileus, and of not stopping to do a radical operation in the advanced cases.

DR. FINNEY said the plea of Dr. Harris to lessen the number of cathartics given to these suffering patients is very timely. Surgeons are agreed that cathartics have a limited place, but their administration should not be overdone.

SASKATCHEWAN MEDICAL ASSOCIATION.

Regular Meeting, held at Saskatoon, March 14-15, 1906.

The constitution and by-laws prepared by the executive committee were read and adopted. A draft of the new medical act was presented and unanimously endorsed.

Officers Elected.

The following were elected for the ensuing year: Honorary president, M. M. Seymour, Regina; president, J. W. Kemp, Indian Head; vice-presidents, T. C. Spence, Prince Albert, and H. Eaglesham, Weyburn; secretary-treasurer, G. A. Charlton, Regina; executive committee, A. B. Stewart, Rosthern; A. W. Allingham, Broadview; C. M. Henry, Yorkton.

Tuberculosis Treatment Needed by Indians.

Resolutions were passed memorializing the provincial government as to the necessity of enacting a public health act at the coming session of the legislature, and also asking measures for the prevention of tuberculosis within the province, as follows:

Resolved, That the secretary of this association be instructed to memorialize the Dominion government as to the necessity of taking immediate and definite action with regard to the treatment and prevention of tuberculosis among the Indians on reserves and in the industrial and other schools in this province by the establishment of sanitaria in the vicinity of Indian reserves. Attention is directed to the amount of tuberculosis existing among the Indian children attending schools, and the necessity of removing infected children to sanitaria where they may be treated separately, and no longer be a source of transmitting the disease to others; and also that cases of tuberculosis occurring among adults and others not in the schools may be properly isolated and treated.

Papers were read by Dr. M. M. Seymour, Regina; Dr. W. Henderson, South Qu'Appele, and Dr. G. A. Charton, Regina, and will be published, with a full report of the transactions in the *Saskatchewan Medical Journal*, which is to be issued. A banquet was tendered the members of the association by the local medical society.

The next meeting will be held at Prince Albert as soon as possible after the close of the coming British Medical Association meeting at Toronto in August.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Scabies.

The following outline of treatment is recommended by Renault in *Jour. des Pract.* in the treatment of scabies. The skin should be thoroughly cleansed with a soft soap and the following ointment applied:

℞.	Sulphuris sublim.	℥i	30
	Potassii carbonatis	ʒiii	12
	Adipis	ʒss	15

M. Ft. unguentum. Sig.: Apply locally and allow it to remain in place for twenty-four hours.

As a milder ointment the following is recommended:

℞.	Glycerini	℥i	30
	Sulphuris sublim.	ʒss	15
	Potassii carbonatis	ʒiiss	10
	Pulv. tragacanthæ	gr. iv	25
	Olei lavendulæ	m. v	30

M. Sig.: Apply locally.

If pruritus persists after the application of one of the foregoing ointments, the following combination is recommended:

R.	Acidi carbolici	gr. xv	1
	Glycerini	ʒiii	120

M. Sig.: Apply locally.

Senna.

The principal constituent of senna is cathartic acid, which causes it to rank as an active cathartic. It is said that the use of senna to correct constipation does not tend to produce constipation, as is the case with a great many cathartics. It is one of the most common laxatives administered to pregnant women, in the form of a confection or compound licorice powder, and these preparations are of value in the treatment of constipation of young children. According to Beasley, it sometimes causes griping and occasionally nausea, but it is free from any astringent effects.

The following combination is recommended by him as a draught to be taken the first thing in the morning after having taken a mercurial pill the previous night:

℞.	Misturæ sennæ co.	ʒiss	45
	Tincturæ card. co.	ʒss	2

M. Ft. mistura. Sig.: To be taken on rising in the morning.

In cases of constipation accompanied by hemorrhoids the following combination is advised:

℞.	Confect. sennæ Confect. sulphuris, āā	℥i	30

M. Sig.: One to two teaspoonfuls at bedtime. Or:

℞.	Confect. sennæ Confect. sulphuris Confect. piperis, āā	℥i	30

M. Sig.: One teaspoonful at bedtime.

In cases of chronic constipation the following combination is of value:

℞.	Sodi sulph. Potassii bitartratis Syrupi zingiberis, āā Infusi q. s. ad	℥i ℥i	4 30

M. Sig.: To be taken at one dose on rising in the morning. Or:

℞.	Tinct. sennæ co. Ext. cascaræ liq., āā Sodii sulph. Elix aromatici q. s. ad	m. xv gr. xv ʒss	1 1 15

M. Sig.: This amount to be taken in a little water twice daily.

The following is a very good combination:

℞.	Potassii bitartratis Pulv. glycyrrhizæ co.	ʒii ℥i	8 30

M. Sig.: One teaspoonful at bedtime when necessary to correct constipation.

For children the following may be used:

℞ Syrupi sennæ
Syrupi rhei
Glycerini, āā ..... ℥i 4

M. Sig.: One to two teaspoonfuls at night when necessary.

In very young children and infants the following is of value:

℞ Syr. sennæ..... ℥i 30
Mannæ ..... ℥iv 15
Syr. aurantii q. s. ad..... ℥iii 90

M. Sig.: One teaspoonful at bedtime to correct constipation, or oftener if necessary.

Neurasthenia.

Concerning the morbid anatomy of neurasthenia, Rankin, in *British Med. Journal*, states that some authorities attribute it to vasomotor inadequacy resulting from low blood pressure, the portal circulation becomes congested and the heart is imperfectly filled. Others mention its frequent association with Graves' disease, osteoarthritis and other diseases accompanied by low blood pressure.

Bouchard regards it as the result of abnormal fermentations in the stomach, with the consequent formation of toxins, which, when absorbed, impair the function of different organs, especially the nervous centers. Glenard believes that this condition is due to a visceroptosis.

The important symptoms are fatigue on slight exertion; impaired digestion, such as anorexia, eructations, restlessness, irritability, constipation; change of temperament, such as fickleness, restlessness; headaches, occipital or vertical, increased by stooping; unrefreshing sleep; sensory disturbances, such as neuralgic pains, muscular tremors, active deep reflexes; vasomotor phenomena, flushings, sweatings, palpitations, vertigo; photophobia, emaciation and various intellectual phenomena.

The first indication for treatment, therefore, is rest, both mental and physical. The patient should be separated from relatives, friends and business relations. The Weir Mitchell system is of great value in many cases, but this rigorous method of treatment should not be employed, according to Rankin, in all cases. In other words, this habit of treatment is very unfortunate and disappointing in many instances. The Weir Mitchell treatment is of value in those cases bordering on hysteria in which marked emaciation has taken place. The form of rest, then, should depend on the patient's individuality and his financial resources. A modified rest cure is more applicable in some cases by placing the patient in comfortable rooms under the care of a judicious nurse, and prohibiting all communication with relatives or business associates. The food must be regulated to suit the capacity of the digestive apparatus and should be generous. Milk and fats should be given as plentifully as possible. Regularity in meals, sleep and hours for resting should be observed. Absolute rest in bed should be the rule during the first ten days of the treatment, gradually replaced by walking in the afternoon. The patient may be allowed to read magazines, newspapers and other light literature, and may spend a part of his time in some artistic hobby. The point of weariness should never be reached.

Massage night and morning should be employed to improve the muscular system. Faradism is of value, particularly as a suggestive remedy.

Digestive disturbances often arise from unhygienic conditions of the mouth, consequently the teeth should be carefully inspected. An antiseptic mouth wash consisting of the following is recommended:

℞ Potassii chloratis
Acidi carbolici, āā..... gr. xl 2 | 65
Aquæ ..... ℥viii 240

M. To be used as a mouth wash.

Care should be given to the digestive tract. Antiseptics are recommended given combined with acids or alkalies, according to the indications in the individual case. To acid mixtures he advises adding carbolic acid in doses of two or three grains (.12-.20), and to alkaline mixtures sulpho-carbolate of soda in doses of from ten to fifteen grains (.65-1.00).

The bowels must be regulated so as to secure one good movement daily, and for this purpose he recommends the compound rhubarb powder of the United States Pharmacopeia, which is composed of the following:

℞ Pulv. rhei..... ℥vi 25
Magnesii oxidi..... ℥xvi 65
Zingiberis ..... ℥iiss 10

M. Sig.: One-half teaspoonful at bedtime.

On first waking in the morning, when the stomach is empty, from six to ten ounces of hot water should be sipped slowly; to this may be added a teaspoonful of Carlsbad salt if the rhubarb powder is not sufficiently effective. About once a week one grain (.06) of calomel may be added to the rhubarb. The diet must be carefully directed and at first should consist of milk foods, thin soups, fish, fowl and game; as the digestion improves the amount of food may be increased. The following outline of diet must be strictly adhered to: Red meat once a day only; cocoa with boiled milk; a moderate amount of sugar; no uncooked vegetables or fruit; stale or toasted bread; an abundance of fats and a minimum of two pints of milk in the twenty-four hours.

Cod-liver oil may be added to the diet as the patient improves. This is best taken in a single dose at night, on retiring, beginning with a few drops and doubling the dose each night until a maximum of a tablespoonful is reached. It is most easily taken in orange wine.

When insomnia is a stubborn factor, as may be the case in the early stages of the treatment, the author recommends the administration of small doses of some mild hypnotic at bedtime. In extreme cases it may be necessary to give morphin for one or two nights, but this should only be done when other means of inducing sleep have failed. Rankin properly emphasizes the importance of extreme care in the use of morphin so as not to create a habit. The patient should never know what drugs are being used.

If anemia is present it must be corrected. The following preparation is recommended for this purpose:

℞ Ferri et ammoniæ citratis..... gr. viiss | 50
Liquoris arsenicalis..... m. v | 30
Potassii bromidi..... gr. x | 65
Liquoris ammonii acetatis..... ℥i 4
Aquæ chloroformi q. s. ad..... ℥i 30

M. Sig.: One such dose after each meal.

Later in the course of the disease the author recommends a combination containing ichthyol, for both its antiseptic effect and its steadying influence on the vasomotor system, and cannabis indica to replace the bromid, consequently he advises the following combination:

℞ Ferri sulphatis..... gr. ii | 12
Ichthyoli ..... gr. v | 30
Acidi arsenosi..... gr. 1/40 | 005
Extracti cannabis ind..... gr. 1/4 | 015

M. Ft. capsula No. i. Sig.: One such capsule after each meal.

If iron in any form should disturb the digestion, it may be replaced by manganese oxid in from five to ten-grain doses (.30-.65). To relieve the headaches, if these are extreme, the following combination may be advised:

℞ Caffeinæ citratæ..... gr. iii | 20
Phenacetini ..... gr. x | 65

M. Ft. chart. No. i. Sig.: One powder when absolutely necessary to relieve the headache.

During these attacks of headache the tonic remedies should be temporarily omitted.

Spinal tenderness is usually speedily relieved by the application of a Pacquelin cautery along either side of the spine.

A movable kidney should be supported. A change of air and surroundings is always of benefit.

Prophylaxis can be carried with great benefit to neurasthenics in the way of arranging business to avoid fatigue, in procuring abundant sleep, regularity of meals, and short but frequent intervals of complete relief from work and responsibilities.

Medicolegal

Valuation Given to an Eye.

The Supreme Court of Wisconsin says, in Olwell vs. Skobis, an action brought to recover damages for an injury to one of the eyes of the plaintiff necessitating long and painful treatment, three operations thereon, and its removal, that, of course, there is no exact rule for estimating damages in such a case. In certain cases in other jurisdictions verdicts of from $2,000 to $5,000 for the loss of an eye have been held not to be excessive. In this case the jury assessed the damages suffered by the plaintiff, a woman amanuensis and bookkeeper, by the injury referred to, at $12,000; but this court is constrained to hold, for the purposes of a new trial of the case, that a verdict for more than $6,000 on substantially the same evidence as to damages as in this record would be deemed to be excessive.

Insane Delusions and Testamentary Capacity.

The Supreme Court of Missouri, Division No. 2, says, in the case of Sayre and others vs. the trustees of Princeton University and others, a proceeding to contest the validity of the will of Dr. John S. Sayre, who died in 1899, that, to say that a belief of Dr. Sayre that he had appendicitis, if he so believed, was an insane delusion, was utterly groundless. He was disposed to leave it to the physicians, who decided to operate for appendicitis. Reliance on the judgment of distinguished medical specialists is in no sense an insane delusion. But if, in the light of all the evidence, the court could for a moment assume that Dr. Sayre was laboring under a delusion merely as to the name of the disease from which he was unquestionably suffering, and which finally caused his retirement from the Navy, it was obvious it did not show the slightest aberration with respect to the kind and extent of his property, or any false notions as to the objects of his bounty in the most remote degree. The fact that he gave the bulk of his estate to his alma mater, Princeton University, was no evidence of insanity. It was urged that the experts testified in response to a hypothetical question that Dr. Sayre was of unsound mind. The court, besides criticising the question, answers that medical men of great learning maintain that a mind diseased on one subject must be classed as unsound, but the law of Missouri is too well settled to be gainsaid that a man's mind may be impaired in one faculty and practically unimpaired in all others. Derangement of mental faculties does not incapacitate one under the laws of the state from making a will, if it does not render him unable to transact his ordinary business, and incapable of understanding the extent of his property and of appreciating the natural objects of his bounty.

Complaints as Evidence—to Physician to Make Testimony.

The Supreme Court of Michigan says that the plaintiff in the personal injury case of O'Dea vs. Michigan Central Railroad Company testified fully as to her condition, pain and suffering, and its duration, and that this it was competent for her to do. In addition to her testimony, her counsel called a number of witnesses, who were allowed to testify to her complaints, not what she said in her own language (which the court does not imply would have been admissible), but the fact that she complained of this or that. She sent for a certain physician, not for the purpose of giving treatment, but because he was the company's physician at Owosso. She declined medical assistance at Henderson, saying she wanted to wait and send for the railroad physician in Owosso, so they could see if she was hurt, if they wanted to settle; that she had a claim against the company (for the injury), and wanted to get her proof together—wanted the railroad physician so that they would know that she was hurt. The physician was allowed to testify: "The patient complained of tenderness over the hip joint—that is, on pressure—and she also complained of some soreness in moving one shoulder." This testimony was not admissible. The plaintiff's own testimony showed that the witness was asked to call for the purpose of making testimony, and the fact that he did not come in response to the call, but for other reasons, was not important. It was the design of the plaintiff to make communications for the purpose of affecting her claim that made them inadmissible, for the reason that they were not natural expressions of present sufferings, but voluntary statements for an ulterior purpose, and therefore not within the exception to the hearsay rule. Again, the court says that it might be reasonably suggested that the plaintiff's attempt to make testimony for herself would not be likely to end with the physician, and such suggestion was a pertinent one to make to the jury, whose duty to consider the question of simulation was thereby emphasized.

Typhoid Fever and Board of Health Powers.

The Supreme Court of Michigan says, in the case of Thomas vs. Board of Supervisors in Ingham County, that it appeared that, in September, 1904, the city council of the city of Mason, in Ingham County, acting as a board of health, employed Dr. Thomas to attend a typhoid fever patient in that city. He rendered the services required; his first visit being on September 8, and his last on October 10. His entire bill came to $36, which was reasonable in amount, and was approved and certified by the local board of health. But the board of supervisors of the county entirely disallowed the bill. This was done on the ground that typhoid fever was not, in their opinion, a "dangerous communicable disease," within the meaning of the statute. Thereon a mandamus was obtained from the circuit court requiring the board of supervisors to allow the bill. The circuit judge based his action on the theory that the amendment of 1903 of the law gives the board of supervisors no power to determine whether a debatable disease does or does not come within the statute, and that the decision of the local board of health is yet final on that point.

The Supreme Court affirms the judgment of the lower court. It says that the board of health gets its power to act in these cases from section 4424 of the Compiled Laws of 1897, as amended by Act No. 7 of 1903. The provisions contained in this section, previous to the amendment of 1903, have been frequently construed by this court. It was held that, when the township board of health had acted, under the provisions of the section, its action was final, and the duty of the board of supervisors was to so treat it. By the amendment of 1903 the board of supervisors shall audit the bill, and if found that the expenses were necessarily incurred, the services actually and necessarily performed, and the amounts claimed for such expenses and services are severally just and reasonable under the circumstances, shall allow the same or such parts thereof as shall be deemed just and reasonable, and in auditing such accounts, the several boards of supervisors shall have full power to examine into the merits of all claims presented to them in accordance with the provisions herein contained. This court does not think that it was the purpose or effect of the amendment that the board of supervisors might substitute its judgment in place of the judgment of the board of health as to whether in a given case a person had a dangerous communicable disease.

The matter of the public health, the Supreme Court goes on to say, has been the subject of legislation for a great many years. Boards of public health have been created, and large powers given to them when the emergency arises for their exercise. These powers were curtailed in some respects by the amendment referred to, but it is just as much the duty of the board of health to act in case of an emergency now as it was before the amendment. When the board of health has acted in cases where it is its duty to act, and has filed the statement with the county clerk, as provided by the statute, it is the duty of the board of supervisors to proceed to audit the bill. The board of supervisors is not given the power to decide whether the disease with which the person was inflicted was a dangerous communicable one, but it is its duty to in good faith determine whether the expenses charged in the itemized statement were necessarily incurred, and whether the services for which charges were made were actually and necessarily performed, and whether the amounts claimed for such ex-

penses and services are severally just and reasonable. If it is determined they are, they should be allowed. The practical effect of a construction of the statute in harmony with the action of the board of supervisors in this instance would leave the board of health shorn of its powers. The court does not think that was the purpose or effect of the amendment.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

American Medicine, Philadelphia.

March 31.

1 *Prophylaxis of Lobar Pneumonia. J. M. Anders, Philadelphia.
2 *Imperfect Descent of Testes. A. McLean, Detroit.
3 *Two Rare Forms of Cystitis. C. C. Norris, Philadelphia.
4 Study of the Conradi-Drigalski Medium for the Isolation of *B. Typhosus*. C. L. Cole, Washington, D. C.
5 *Pathology of Rabies; Rôle of Mast-cells in the Affection. A. Gordon, Philadelphia.
6 *The Training of Nurses. J. C. Munro, Boston.
7 The King's Evil and Its Cures. (Concluded). J. Knott, Dublin, Ireland.

1. **Prophylaxis of Lobar Pneumonia.**—Anders claims that thorough and prompt sterilization of pneumonic sputum, and of the secretions from the upper respiratory tract, and then their prompt destruction by burning, is a matter of first necessity. Disinfection of the bed linen and body linen, the mattress and the room occupied by the pneumonia patient is also a primary requisite. These matters do not receive the rigid care and attention which they richly merit by the average general practitioner. The public measures of greatest value are summarized as follows: The issuance of drastic edicts against spitting on the sidewalks; the work of street cleaning and street sprinkling should be looked after by bureaus or boards of public health, to whom should be given full executive authority; there should be greater diffusion of popular information concerning efficient ventilation of our office buildings, theaters, courts of justice, manufacturing establishments, churches, public schools, and passenger and street railway cars, and also regarding details connected with the subject of the prevention of lobar pneumonia, stating simple, plain facts about the way in which the disease is spreading.

2. **Imperfect Descent of Testes.**—McLean concludes from the study of a number of cases that, (1) in many cases of undescended testes there is an hereditary anatomic weakness of the sexual apparatus; (2) there is no way of telling before exposure whether the cord will allow of the transplantation of the organ to the scrotum or not; (3) an inch or more can be added to the vas by separating it from the epididymis and the globus minor from the body of the testis; (4) the spermatic artery may be severed and the vitality of the organ maintained.

3. **Cystitis.**—Norris reports two cases. In Case 1, a vesical calculus formed around a heavy silk suture. Two years previously the patient had had a suprapubic cystotomy performed for severe cystitis. This gave temporary relief. A few weeks later the patient passed a silk ligature covered with urinary salts. Following this the patient had symptoms of cystitis and occasional interruption of the stream of urine. Cystoscopic examination revealed a stone about the size of a pigeon's egg suspended from the superior aspect of the bladder. Vaginal cystotomy and removal of the stone was done. The wound healed rapidly and the patient was discharged cured four weeks after operation. Case 2 was one of exfoliative cystitis, the patient being a colored woman with no evidence of gonorrhea. Acute cystitis occurred with sudden onset. The symptoms for the first week were very severe. Three weeks later the urethra became blocked by a sloughing mass, which on removal proved to be an entire cast of the bladder, consisting of the mucosa and a portion of the muscularis. Symptoms from this time began to subside, and two months later the patient was entirely well. This case had no assignable cause. The uterus was in normal position, there were no neoplasms blocking the pelvis, nor was the patient pregnant. No strong chemical solution had been used in the bladder.

5. **Pathology of Rabies.**—Gordon concludes that the presence of mast cells corroborates his view that the spinal ganglions are the place of predilection for rabic virus.

6. **Training of Nurses.**—Munro emphasizes the following facts: Women who take up the profession of nursing should have a love for work, sacrifice and humanity, with all that these qualities imply. The probation period should be long enough to allow the unfit to be weeded out, and this latter process should be severe, judicial and searching. The strictly professional training given in our large hospitals is sufficient, and in many respects it is more than sufficient. Except in a small special class, nurses should be taught much less anatomy, physiology, pathology, bacteriology and chemistry. It would be far better, he states, if more time were devoted to teaching nurses to be genuinely humane. More time should be devoted to teaching nurses household work, cooking, ordering of supplies, cleaning of rooms, etc. The nurse should be taught that the family routine and habits are not formed on the basis of the training school, and that they should not be disturbed except for necessity. The nurse must realize that any honorable labor is within her duties, and that these duties can not always be drawn on hard and fast lines. In the hospital training they should be taught, next to the qualities of humanity and tact, all the little details that do not demand skilled knowledge in the abstract medical sciences, but do demand observation, common sense, tact and honesty. She should be less elaborately trained in the science of medicine. A few selected women should be trained for special work and advanced work, but such selection should be exercised with great care and judgment.

9 The Homeopathic Principle. F. B. Percy, Boston.
10 *An Inexpensive Mechanical Treatment for Anterior Metatarsalgia. E. B. Young, Boston.

10. **Mechanical Treatment for Anterior Metatarsalgia.**—Young is convinced that poor muscular development and improper shoes are very often the cause of pains complained of by women and which are referred to the pelvis, lower back and hips, and for which pelvic examination shows no adequate cause. Acting on this hypothesis Young devised means for overcoming the discomforts due to the breaking down of the transverse arch of the foot. A piece of sole leather of the thickness required is cut into the shape indicated in Figure 1. The edges are beveled and the leather is touched on one side with a few drops of liquid glue. It is then placed on the sole of the boot, to which it adheres, so that its pressure is exerted

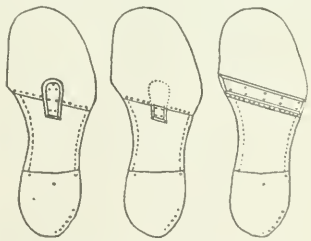

Fig I Fig II Fig III

Diagram of different methods of applying support.

just behind the heads of the metatarsal bones, and the leather nailed in position. It can also be inserted under the sole (Fig. 2) by raising the posterior edge of the sole and nailing it again in place. If there is too much pressure the leather is pared to the requisite thickness, as indicated by the comfort of the wearer. The increased depth, at the point where the leather is inserted, raises the sole over this area and slightly beyond, whenever the patient steps—this in turn supporting the anterior arch. Still another means of accomplishing the same result, and one which is especially applicable to shoes which are to withstand severe wear, is shown in Figure 3. The leather strips raise all the metacarpals slightly, and, at the same time, by varying the angle at which it is placed on the

shoe, it may be made to aid in raising the inner side of a pronated foot. In mild cases this works exceedingly well. The proper slant and thickness are adjusted to the comfort of the patients as they stand on the leather strip. Naturally, suitable exercises should be carried out in every case.

11 *New Instrument for Measuring all the Diameters of the Pelvis in the Living Woman. S. D. Jacobson, New York.
12 *Treatment of Meningococcus Meningitis in the First Medical Division of Bellevue Hospital. E. L. Dow, New York.
13 *Two Unusual Epileptic Histories. S. E. Jelliffe, New York.
14 Operative Technic and After-Treatment for Mastoiditis with Epidural Complications. W. S. Bryant, New York.
15 *Ulcus Rodens (Mooren). H. H. Seabrook, New York.

11. **New Instrument for Measuring Female Pelvis.**—Jacobson describes an instrument, the use of which he advocates for the measurement of all the important diameters in the pelvis of the living woman. This instrument also enables the physician to determine the shape of the pelvis, and in the case of abnormalities, the available room for the passage of the child. It is constructed of steel and consists of two branches hinged together at one end and in the form of calipers. There is an outer semicircular branch and an internal irregularly S-shaped branch, each one being attached to a handle. A movable gauge slides on a grooved track and can be fixed in any part of this track by a set screw. The movable branch is attached to its handle by a pin and socket, and has a loop on each side, into which a sliding catch can be made to slip, which will securely hold the inner branch, whether it points toward or away from its fellow. The upper tips of the branches can be separated about twelve inches, the distance being indicated on the sliding gauge. A graduated leather belt accompanies the instrument. The fixed branch always remains outside of the body, while the other is used internally. The writer then gives detailed instructions for the employment of this instrument.

12. **Treatment of Meningococcus Meningitis.**—Dow declares that the only way the poisons or the bodies of meningococci can be nullified with our present knowledge is by assisting the patient to do it himself. Probably the best remedy for diminishing the intense cellular activity is the use of some derivative of opium. An accessory measure is the maintenance of a normal body surface temperature. This, by allowing the blood to remain at the surface of the body, relieves the congestion of the brain. The weather and the temperature of the ward appeared to have much to do with the progress of the cases which Dow has studied. The results were uniformly bad at the beginning of the epidemic during the cold months, and uniformly good during the warm months. An elevated posture was found to be beneficial in cases of severe tuberculous meningitis with extreme motor restlessness, as well as in cases of meningococcus meningitis. Ice to the head may be of some value. Lumbar puncture during the first few days of meningitis, or of its relapse, is of service. Laxatives and enemata are in order. Complications should receive appropriate treatment. Food, air and sunshine seem to be the only remedial measures of value in hydrocephalus.

13. **Two Unusual Epileptic Histories.**—Jelliffe's first patient was a girl ten years of age, who until she was eighteen months old, was perfectly well and normal. At this time otitis media developed, a moderate purulent discharge from the ear beginning on the second day. In a few days, the pain and local symptoms subsiding, the child was taken out of bed. It was found at this time that she was paralyzed on the left side, and later epileptic phenomena developed. The general condition of this child has greatly improved, including a gain in weight of twenty-five pounds. She is mentally unchanged, being as bright as the average child of her age. About a year and a half ago examination showed a small cicatrix on the right drum membrane. Jelliffe thinks it not improbable that the otitis was followed by the development of an abscess, the paralysis and epileptic phenomena being due to pressure or partial destruction. He believes also that the recovery, if such it proves to be, may be attributed to the rupture of a secondary cyst and the relief of pressure. The second patient had always had fair general health until an attack of santonin poisoning. This accident offers a plausible explanation of the convulsive seizures, the amblyopia and the nephritis which followed. The author states that the relation of santonin to naphthalene suggests the type of pathologic change that occurred in this child's nervous tissues. He has little doubt that the seizures from which this child suffered were distinctly epileptic.

15. **Ulcus Rodens.**—Seabrook describes a patient, a perfectly healthy man, thirty-seven years old, with rodent ulcer of over eighteen months' standing. All the cornea except a small patch outward had been involved. Treatment of various sorts failed. At this point pure carbolic acid seemed to check it, except for occasional relapses at the upper part of the ulcer, for several months, when the anterior layers of the cornea began to break down along the whole edge of the ulcer, except that directed toward the corneal limbus. Carbolic acid shortened the attacks and ameliorated the symptoms. Gray lines extended from the point of application into the lymph channels of the cornea.

20 Surgical Treatment of So-called Idiopathic Dilatation of the Stomach. C. A. L. Reed, Cincinnati.

16. **Infantile Scurvy.**—Two cases of infantile scurvy complicated by extensive sub-periosteal hemorrhages are reported by Coutts. The first patient was aged eight months. The lower end of the right femur was thickened and the swelling was evidently painful to touch. There were no cutaneous hemorrhages and no history suggestive of hemorrhage into any of the viscera. The patient died. Surrounding the femur, almost its entire length, was a layer of bone formed in the detached periosteum, the space between the bone and periosteum being filled by a blood clot. In the case of the second patient both thighs were swollen and tense and there was evidence of sub-periosteal hemorrhages in both the legs and the arms. Both the lower and upper epiphyses of the femora were detached, and each shaft lay free in a cavity formed by blood clot and blood-soddened muscles. Instead of bone having formed in the detached periosteum that membrane had undergone a process of necrosis and no trace of it was discoverable in either limb.

17. **Local Anesthesia.**—During the year 1903, 105 patients were operated on by Witherspoon under local anesthesia produced by cucain in one-tenth per cent. solution with good results. When an operation requires much time in its performance and necessitates a good deal of handling of tissue, Witherspoon gives the patient an injection of morphin and atropin before beginning the operation. The area of infiltration of the skin should be made directly in the line of the proposed incision and should be long enough to allow of easy exposure of the tissue beneath. When the operation is to extend into the deep tissues it is best to infiltrate step by step and not to attempt to infiltrate the whole tissue at once. Among the operations performed under this anesthesia were partial thyroidectomies for exophthalmic goiter; ligation of arteries; radical operations for malignant disease of the breast; gastrostomies; gallstone operations; appendectomies; renal decapsulation; nephrectomy; nephrotomy; hysteropexies; myomectomies; radical inguinal and umbilical herniotomies; perineal cystotomies and operations for hallux valgus.

21. **Scopolamin-Morphin-Chloroform Anesthesia.**—The danger of this anesthesia led Whitacre to institute animal experiments for the study of this question. Fatty degeneration followed regularly the prolonged administration of both chloroform and ether, the liver being the organ involved when chloroform was used, and the kidney when ether was used. Ten animals were given repeated doses of scopolamin 0.01 grain for from eight to fourteen days. Most of these animals showed degenerated changes in some degree, and five showed distinct fatty degeneration of the liver and kidney; two a probable fatty degeneration of the heart. Ten animals were given scopolamin, 0.01 grain, and morphin one-sixth grain, for corresponding periods of time. Five animals showed fatty degeneration of the kidney and of the liver. Whitacre concludes that scopolamin-morphin narcosis is not devoid of danger, and that the use of these agents alone is not justifiable or practicable. However, a single dose given two hours before operations lessens the discomforts attendant on the operation.

22. **General Infection Through the Tonsil.**—Adler emphasizes a few points of practical interest. He says that whenever there is a tendency to attacks of follicular tonsillitis, even if only very mild, be the attacks ever so slight, be the tonsil ever so large, there is a serious menace to the system, and the tonsil should be put out of harm's way. Adler advises burning over the surface of the tonsil either with a broad Paquelin burner or with the galvano-cautery. He thinks the best results were obtained when the entire surface of the tonsil down to a considerable depth is destroyed and converted into scar tissue, thus rendering it impermeable to further infection.

23. **Postoperative Femoral Phlebitis.**—The 48 cases reviewed by Schenck occurred among 7,130 patients operated on. The date of onset was markedly constant. The earliest was on the sixth and the latest on the twenty-second day, while in 25 instances it was between the twelfth and sixteenth day, and in all but 4, after the tenth day. Pain, of a dull throbbing character, sometimes in the thigh, often in the calf of the leg or in the popliteal space, and tenderness along the vein were observed in all cases. Tender, enlarged glands were present in only six instances. Edema occurred in 38 per cent. of the cases. The observation of Singer, that the pulse curve, as related to the temperature curve, is higher than that usual in other conditions, was not confirmed. These 48 cases occurred after: perineal operation alone, 4; hysteromyomectomy and myomectomy, 19; ovarian cysts, 9; hysterectomy for carcinoma, 5; suspension of the uterus, 3; suspension of the uterus, with repair of the perineum, 4; hysterectomy for pelvic inflammatory disease, 1; miscellaneous operations, 3. In about 60 per cent. of all cases there is never complete freedom from attacks of pain and swelling. If the symptoms persist longer than six months there is small chance that they will ever disappear.

24. **Conjugate Lateral Deviation.**—The salient features of the case reported by Claiborne were the following: Conjugate lateral paralysis, with deviation to the left; fugacious left hemianesthesia and hemiplegia; the location, by exclusion of the lesion, at the nucleus of the right sixth nerve; the absence of hemianopsia; the obvious predominance of the paralysis of the external rectus, as opposed to the internal rectus, and the retention of normal convergence.

36. **Reversal of Circulation.**—Experiments were undertaken by Carrel and Guthrie with the view of studying the changes of the circulation of a limb after reversal, and of finding a method of preventing gangrene when the arteries of the limb become unable to carry the red blood to the capillaries. The experiments performed demonstrated that the reversal of the circulation in the limb of a dog can be established by an end-to-end arterio-venous anastomosis. At first the valves prevent the reversion of the circulation in the veins, but after a short time the valves gradually give way and the red blood flows through the veins as far as the capillaries. Finally it passes through the capillaries and the arteries are filled with dark blood. Practically complete reversal of the circulation is established in about three hours after the operation. Under the same conditions lateral anastomosis does not establish the reversal of the circulation.

38. **Cardiospasm.**—Twenty months have elapsed since the operation in the case reported by Erdmann. The patient, a female, aged 33, first noticed a peculiar swallowing rattle in throat, which in four or six weeks was followed by difficulty in swallowing foods, giving her an impression of pressure back of the the lower portion of the sternum. All things seem to go down the wrong way. There was invariably, after a short period, vomiting of the material swallowed, varying in extent from the entire quantity to about two-thirds of that swallowed. All palliative measures failing to give relief, Erdmann operated. The stomach was exposed through a median epigastric incision and was found lying in an absolutely transverse position and contracted so that it was less in diameter than the large intestine. It was impossible to introduce the finger through the contracted cardiac opening. The lower end of the esophagus formed a large pouch. The contracted opening was stretched with the fingers, passed in through an incision made in the long axis of the stomach, from 4 to 6 c.m. The opening in the stomach was closed by three rows of sutures, the first and second being continuous chain stitch and the third Lembert. The patient made an excellent recovery.

39. **Treatment of Diffuse Septic Peritonitis.**—LeConte outlines the treatment employed by J. B. Murphy and reports the history of two patients treated successfully according to this method.

40. **Extroversion of the Bladder.**—Moynihan cites the case of a youth, aged 19, who fifteen years before that had a plastic operation performed for extroversion of the bladder, which was not successful. The patient was given relief by transplantation of the bladder into the rectum. The bladder was isolated, leaving only at its pedicle the two ureters. As much tissue was left as possible round each ureter so as to avoid the possibility of damage, either to the ureter itself or to its vessels. The serous covering was then stripped upward from the front of the rectum until 4 or 5 inches of the bowel lay exposed at the bottom of the wound. Along its anterior surface an incision about 3½ inches in length was made. Into this opening the bladder was placed, being turned upside down so that its former anteror surface became posterior, and its former lower end became the upper. The ureters instead of passing forward to the bladder passed backward, and the catheters passed into the rectum and out at the anus. The edge of the bladder and the cut edges of the rectum were sutured together by two Lembert sutures that were continuous, one taking the right side and the other the left. A few additional interrupted sutures were necessary here and there. The wound was dried and the skin edges along the original

median incision were drawn together. At the upper end the edges came well into apposition, but about an inch at the lower part had to be left open. The catheters which had been introduced into the ureters now passed out of the anus; the sphincter had previously been stretched. The operation lasted an hour and a half. The after progress of the case was satisfactory.

43. **External Metal Support for Fractured Long Bone.**—Bartlett reports a case of extensive injury of the arm necessitating resection of two inches of the humerus. Four days after the injury the patient commenced to suffer great pain in the injured arm and this persisted until the ninth day, when the parts were placed at rest in the following manner: With the arm flexed at the elbow, Bartlett applied a plaster bandage, which included the chest, forearm and hand, the upper arm being left free, of necessity. A steel arch anchored at one end in the plaster enclosing the chest, and at its other in the bandage around the forearm, was suspended just above the upper arm. Beneath this arch was placed a vertical rod, which had attached to its lower extremity a silver splint which rode on the ends of the bone like a saddle on a horse, and prevented their natural tendency to rise up out of the wound, while an extension of the vertical rod fitted between the ends of bone, thus keeping the apparatus from gliding toward shoulder or elbow. Under the influence of this direct splint, however, the free bony ends showed a tendency to point downward and to project through the gap on the posterior surface of the arm. Hence, five days later, a silver wire was passed under each extremity and carried out through the anterior wound, to be attached to the steel arch above. After this was done the humerus remained absolutely rigid, there was no difficulty in dressing the large anterior wound by stuffing gauze in around the rod and the wires, the patient was occasioned absolutely no inconvenience by the apparatus, and except for tightening the wires as they stretched, the appliance caused no concern during all the weeks that it remained in place. It is worthy of note that there was no more spontaneous pain after the application of the splint.

48. Id.—Oct. 28, 1905, page 1349.

49. Id.—Nov. 4, 1905, page 1437.

50. **Submucous Resection of Septum.**—An illustrative discussion of the submucous resection of the nasal septum is presented by Ballenger, with a complete description of all the instruments employed, including his swivel-knife and a forceps for fracturing the deformed vomer from its attachment to the superior maxilla. His method of operating is so well-known that it is not necessary to describe it at this time. It shortens the three major steps of the operation, lessens the shock and shortens the time required for performing the operation. The operation has been employed successfully in more than 100 cases. Ballenger presents the following axioms: 1. Never do a long operation when a short one will do as well. 2. Make haste slowly in starting the elevation of the mucoperichondrium. Any other manner of haste is liable to result in a permanent perforation. 3. Do not extend the Killian incision through both mucous membranes, as to do so is tempting Providence in the form of a perforation. 4. A few instruments, infrequently introduced between the membranes, should be the aim. 5. Don't "fish" for what you want, but look, see, feel comprehend, then remove what you want. "Fishing" in the cavity is liable to tear the mucosa. 6. A sharp pointed instrument in a cavity is a dangerous thing. A dull one is safer. 7. The mucoperichondrium is easily and quickly lifted with a blunt elevator in 95 per cent of all cases. 8. The external ridge of the nose needs support, hence, leave plenty of cartilage in this region, for this purpose. 9. Never make a move until you know what you are doing. Then do it. 10. Do not operate to straighten the septum, but rather to remove obstructive adhesions of the septum. 11. Operate with a view to the patient's comfort and permanent relief. That is for what he employs you.

51 *Treatment of Hemorrhoids. C. B. Kelsey, New York, L. H. Adler, Jr., Philadelphia; B. M. Ricketts, Cincinnati, H. M. Bishop, Los Angeles; S. G. Gant, J. P. Tuttle, New York, and T. C. Martin, Cleveland.
52 *Exophthalmic Goiter Treated by the Roentgen Rays. G. E. Pfahler and M. C. Thrush, Philadelphia.

51. **Treatment of Hemorrhoids.**—The two operations referred to by Kelsey are the Allingham ligature operation and his own clamp operation, either of which, in selected cases in which no stretching of the sphincter is necessary to reach the tumors, may be performed under local instead of general anesthesia. For purposes of local anesthesia Kelsey does not believe in the use of simple water injections. He describes an operation which he has employed with success for about ten years. It is done without dilatation and by means of a speculum, and under eucain anesthesia in the office. From ten to fifteen minims of a weak eucain solution is first deposited in the most prominent part of the tumor, and after a few minutes a platinum wire heated to the point of redness is plunged fairly into the substance of the tumor. The source of electricity is the street current, and the needles used are those generally employed in nose and throat work. One or at most two applications are enough at one time, and these should not be made oftener than twice a week at first. The time consumed by the method in an ordinary case is usually several weeks.

Adler prefers the cautery method for the radical cure of internal hemorrhoids and excision for external hemorrhoid. For the treatment of the large single or large multiple pile, Ricketts prefers the submucous ligature operation, but for the treatment of a small single pile other methods are urged. Bishop still favors the operation which he devised and published about twelve years ago. Gant repeats his now well-known views on sterile water anesthesia in the operative treatment of internal hemorrhoids. He prefers the ligature operation for the removal of internal hemorrhoids in the office, at the patient's home, or in the hospital where sterile water or other local anesthetic is employed. Tuttle claims that in office practice the operative treatment of hemorrhoids resolves itself into excision with suturing of the edges or ligature with or without transfixation. The ligature is the easiest and quickest of application, and in most cases it is eminently satisfactory. He says that it is no longer necessary for patients to suffer from hemorrhoids on account of the fear of the general anesthetic or of the hospital. Most of them can be cured in the office or at home, and without taking ether; but success in this method requires proper office equipment, careful attention to aseptic details and skill in the art of local anesthesia. According to Martin, the ligature operation is an antiquity undeserving of a place except in the archives of proctology. He advises clamping the hemorrhoid, cutting it away, applying the cautery intermittently only to coagulate the lymph to plug the blood vessels without accidentally destroying normal tissue, and then suturing the pedicle with catgut by means of the lock or buttonhole stitch. He describes his method in detail.

53. **Desert Thirst.**—McGee cites a most extraordinary case. A man named Pablo was lost in the desert just eight days (and nights), with one day's water; he rode in the saddle thirty-five miles and walked or crept between 100 and 150

miles. For nearly seven days, or fully 160 consecutive hours, he was wholly without water from sources exterior to his system, save the few drops extracted from the agave stipes and insects—a desert record without parallel known to McGee; for half the victims of desert thirst die within 36 hours of deprivation, another quarter within 48 or 50 hours, and nearly all known to survivors, within from 70 to 80 hours (three days and nights), or hardly half of Pablo's stress. For some five days he consumed his urine; ordinarily, the reconversion of excreted liquids is hardly helpful if not wholly harmful, yet in Pablo's case it seems to have materially prolonged vitality. For nearly nine days his bowels were inactive, and for two days his kidneys failed to function. The eight-day siege lost him 35 or 40 pounds (or 25 per cent. of his weight), chiefly through evaporation from skin and membrane; he also suffered fully two-score cuts, scratches and bruises each of sufficient severity to give some shock to the system; and his mouth, esophagus and stomach were seriously deranged by his desperate efforts to relieve the thirst torture. The most striking feature of the case was the absence of wholly insane delirium; he was, indeed, affected by the revulsion against gold, as shown by the abandonment of his nuggets and the casting away of his money; he was possessed of hallucinations as to the wetness of sands, the moisture of articulates and shrubs, and the nearness of Tinajas Atlas; he was obsessed by the desire for vengeance against his comrade, who he thought had deserted him, the dream of casting himself in Tule Well, and the delusion of death—yet he never lost his trail sense, and apparently squandered little vitality in those aimless movements that commonly hasten and harden the end of the thirst victim.

57. **Peritoneal Adhesions.**—According to King, peritoneal adhesions about the cecum and appendix are not necessarily of inflammatory origin, as is generally supposed, but are evolutionary processes of adaptation. The adhesions are probably produced by abnormal immobility of the parts consequent on lack of thigh pressure on the abdomen such as occurs in the natural conquiniscent posture during defecation. Such adhesions having occurred, the peristaltic function of the cecum is impaired, with resulting constipation, retention of toxic matter in the intestine, and infection of the appendix. When the adhesions are suddenly, violently and repeatedly stretched, lacerated or otherwise traumatically disturbed by the muscular strains incident to bicycling, polo, tennis and similar exercises, peritonitis, typhilitis and appendicitis are produced. To prevent this "sea of troubles" civilized man must secure to the peritoneal surfaces their daily normal movement, by reverting to the natural conquiniscent posture of his ancestors in defecation.

63. **New Ophthalmotrope.**—The instrument devised by Shute demonstrates the conformity of the tilted axis hypothesis with clinical observations in ocular palsies. The model consists of a somewhat narrow rectangular box open at the top and at either extremity (20 cm. long, 10 cm. wide and 5 cm. high). The sides of the box support movable, clamp-arms carrying perpendicular adjustable supporting rods which are for the purpose of receiving and keeping in a fixed position the extremities of a stout steel hatpin passed through an india-rubber ball. The hatpin represents an innervation-axis (physiologic axis) of the eyeball, the rubber ball, of course, representing the eyeball. This ball is about 8 cm. in diameter. At one place it is painted to represent the cornea. Passing through the center of the cornea to its horizontal and vertical limits (of course at right angles to each other) are arcs of the horizontal and vertical meridians (great circles) of the ball. At the posterior pole of the ball representing the fovea centralis two other arcs are drawn at right angles to each other like those on the cornea. They are segments of the horizontal and vertical meridians. In the proper quadrants of these spherical right triangles at the posterior or macular pole of the ball, are drawn in red ink three arrows and in black ink one arrow. This is for the purpose of studying the character of the diplopia and represents the eyeball under the influence of the resultant of all the remaining tensions of the eyeball, the sound eye being imagined in the straightforward primary position. This rubber ball representing the paralytic right eyeball is depicted with a tilted axis. The adjustable placing cup holds the rubber representative of the eyeball in the correct primary position until the hatpin is securely supported, then it is lowered and removed. The corneal gauge is a support carrying an adjustable upright which is surmounted by a ring for receiving a movable watch crystal. The crystal is marked with a horizontal and a vertical line, intersecting at its center. When the rubber ball is in the correct position over the box and its hatpin axis is properly secured by the supporting rods, the corneal gauge is placed in the box in front of and quite close to the rubber ball, and is so adjusted as to have the horizontal and vertical lines of the watch crystal in the planes of the corresponding horizontal and vertical meridians of the cornea. Any displacement of the center of the cornea in consequence of rotation of the rubber ball on its steel axis can readily be noted and its character studied. By placing the proper marks of identification for puncture and counter-puncture with a hatpin, the same rubber can be used for study of ocular palsies of all the extrinsic muscles and, therefore, pathologic rotations on axes out of Listing's plane. Also physiologic movements on axes in Listing's plane can easily be studied. The model has a second corneal gauge for studying the movements of the posterior or macular pole as well as the anterior or corneal pole.

65. **Double Appendix.**—Prentiss describes a vermiform appendix which has a double lumen. There was a very thin layer of connective tissue between the lumina and they are held firmly together by peritoneum. He considers the specimen a partial reversion to a lower type.

66. **Adrenalin Chlorid in Variola.**—Eliot used adrenalin chlorid in a 1 to 1,000 solution in four cases of hemorrhagic smallpox; two were distinctly confluent, one was of the discrete variety, and the fourth was not classified, as it was so rapidly fatal. Three patients died and one was still under treatment on the day of writing. In the first two cases the effect of the adrenalin was to check the effusion of blood into the skin and into the points of eruption, but large bladders formed on different portions of the body, notably on the legs; the skin assumed a wrinkled appearance and peeled off when pressure was made on any part of the body, as in lifting the patient. In the third case, in which larger doses were given, every point of eruption on the body necrosed; some points were arrested superficially, while others, principally those on the thighs and legs, became deep sloughs of greater or less size, and the toes of each foot became gangrenous. Each point of sloughing was surrounded by an elevated broad border of pus, a distinct line of demarcation.

7 *Ethyl Chlorid. H. A. Knight.

2. **The Cancer Problem.**—Wade submits that there is good reason to suspect that the origin of cancer may be connected intimately with senile changes in the nerve endings or in the cells, or perhaps with both these combined.

3. **Transmissibility of Syphilis to Apes.**—Grünbaum and Smedley inoculated a male chimpanzee on the eyebrow by rubbing into it a portion of a chancre freshly excised. Signs of infection appeared on the sixteenth day, followed by general swelling and induration of the eyebrow and an exfoliation of the skin, leaving its surface yielding a serous or seropurulent secretion. The general health of the animal was unaffected. The spirochete was not found until the thirty-seventh day after inoculation.

4. **Anesthetics and Renal Activity.**—Thompson reports the result of an experimental investigation into the effects of prolonged chloroformed narcosis. His findings are summarized as follows:

1. The volume of urine secreted by the kidney is, as a rule, affected during chloroform narcosis in two ways. In the early stages, when the anesthesia is light, the quantity is frequently increased. During full anesthesia the secretion is always diminished, and may be suppressed.

2. The after effect is invariably a great increase, which in certain periods may reach to four times the normal volume for the same period of time. The maximum outflow occurs about three hours after removal of the anesthetic.

3. The total excretion of nitrogen is, as a rule, greatly reduced—more so than the quantity of urine. The averages taken from experiments with diminished urine volume show that during the anesthetic period the excretion of nitrogen fell to 18 per cent. of the normal, whereas the quantity of urine in the same series fell only to 35 per cent. of that amount. In a minority of the experiments with increased urine volume the total nitrogen per period was also increased, but to a much less extent than the volume of urine in the same experiments.

4. The urine secreted during chloroform anesthesia is almost invariably more dilute (contains less nitrogen per cent.) than the normal urine. This holds good even when the volume of urine is diminished, hence it is inferred that chloroform affects not only the blood flow through the glomerulus, but also the secretion of nitrogenous solids into the tubules and the latter even more than the former. The result, therefore, favors the theory of urinary secretion advanced by Bowman.

5. There is a general but not accurate correspondence between urine outflow, kidney volume, and blood pressure. The relationship between the first and second is closer than between the first and third. A state of almost complete suppression may coexist with a comparatively high blood pressure.

6. In prolonged narcosis, with marked diminution of urine volume, there is a considerable exudation into the renal tubules of leucocytes, which subsequently escape with the urine. The condition is probably produced by more or less vascular stasis in the glomerular vessels.

7. The excretion of chlorids is much increased both during and after chloroform narcosis. In the fourth period after removal of the anesthetic the amount may be ten times the normal quantity in the urine of the dog.

8. Albumin appears in a small proportion of experiments after chloroform inhalation.

9. Reducing substances other than glucose are almost invariably increased. The nature of the reducing substance has not been definitely determined.

5. **Experiments in Density of Chloroform.**—Chapman examined into the percentages of chloroform supplied by Junker's inhaler. He found that the plain vulcanite mask is safer than the more expensive form of inhaler with rubber-rim cushion, but the compression bulb must be worked gently and steadily. The air inlet apertures should never be closed and ought to be unclosable. Owing to variability of the percentages of chloroform vapor supplied, the apparatus is not suitable for more prolonged operations, although when all precautions are observed, the use of the apparatus, with the mask, is fairly safe in careful hands for short periods of anesthesia.

6. **Ethyl Chlorid as a General Anesthetic.**—McCardie claims that ethyl chlorid is less safe than ether and far less safe than nitrous oxid. The latter should be used whenever it is reasonably possible, and ethyl chlorid should be used when nitrous oxid is impossible, and when ether and chloroform are unnecessarily powerful and lasting in their effects. McCardie compares ethyl chlorid to chloroform in the ease and convenience of its administration and its high power of narcosis, while nitrous oxid is likened to ether in the difficulties and complications entailed in its inhalation and in its weak narcotic effects.

7. **Id.**—Knight considers ethyl chlorid a very reliable anesthetic, although in the hands of the untrained he thinks that it is not nearly so safe an anesthetic as nitrous oxid. When the administrator is accustomed to it, it is probably safer than any other anesthetic because so small an amount is necessary to render the patient insensible to pain, recovery from a light anesthesia is rapid, and there is no cyanosis or venous congestion. Only in very rare cases has Knight found it impossible to anesthetize a patient with it. The drug is not suitable for prolonged administration on account of the strain on the anesthetist and the expense. As a preliminary to chloroform anesthesia it is especially valuable.

12. **Spirochete in Syphilis.**—Out of 18 cases examined by Shennan six showed the presence of the *Spirochæta pallida*. In three others spirochetes were found which could not with certainty be placed either with *Spirochæta pallida* or *Spirochæta refringens*. In five cases the results were absolutely negative. The remaining cases were doubtful. As regards the lesions, five hard chancres showed positive results; in two the results were doubtful, and in three they were negative. Two non-ulcerated papules gave positive results: two dry papulo-squamous syphilids gave negative results, and two roseolar rashes also were negative. Four condylomata were examined; three were negative and one was doubtful. Four glands were examined and in none could undoubted *Spirochætæ pallidæ* be found. One rupioid syphilid was examined with a negative result. Typical *Spirochætæ pallidæ* were found only in hard chancres and in closed papules—i. e., in typical syphilitic lesions.

Shennan says that while there is a very considerable probability that *Spirochæta pallida* bears an etiologic relationship to syphilis we require to know more about spirochetes in general and to have better methods of distinguishing the many forms intermediate between the typical *Spirochæta pallida* and the typical *Spirochæta refringens* before we can unreservedly accept this as a completely proved fact in pathology. One can say very little as yet with regard to the peculiar loop-like and rounded bodies found in syphilitic glands, and to such bodies as the flagellated structure he described in a film from a hard chancre.

13. **Rupture of Uterus.**—In the case reported by Hunter the rupture occurred about four hours after the commencement of labor. The placenta was delivered about ten minutes after the cessation of the pains. Examination per vaginam disclosed a large irregular tear in the left posterior region of the uterus, with the uterus firmly contracted behind the symphysis and the child in the abdominal cavity. The condition of the patient was such that a laparotomy could not be done. On the other hand, the natural passages were roomy and the tear was judged extensive enough to allow a normal child to pass with little further damage. At the same time it was remembered that, with no history of injury, abnormality in the child was almost certainly the cause of the rupture. The head of the child then was felt for and when it was reached the abnormality was found to be hydrocephalus. Perforation of the head and delivery *per vias naturales* were decided on. The feet were drawn together through the tear, followed by the trunk with the upper limbs. The head, steadied over the tear by a hand in the vagina and two hands over the abdominal wall, was then pierced by a perforator. A rush of fluid followed and the child was easily delivered. After the delivery the abdominal cavity was thoroughly washed out with sterilized normal salt solution at a temperature of 100. To do this a hand was passed in through the tear and the nozzle of the douche guided by it, and with this hand in the abdominal cavity the abdominal contents were well washed. A piece of omentum which presented at the mouth of the vagina was replaced by the nozzle of the douche. Finally, a gauze drain was passed into the abdominal cavity through the tear, a pad was put on over the vagina, and a tight binder was applied. The patient made an uneventful recovery.

23. **Conservative Operations in Case of Double Uterus.**—Quénu and Le Sourd have found in the literature reports of only 3

cases of double uterus with independent fundi in which mere puncture or incision was attempted to evacuate an accumulation of blood. These cases all terminated fatally. In another group of 7 cases with hematometra, one-half of the double uterus was removed by a laparotomy, with ablatiou of the adnexa on one side. The results were favorable in all. The list includes one case personally observed by Quénu, which is described with all the particulars. He states that whether or not a conservative operation is permissible depends on the condition of the cervix. As a rule, the intervention must be a supracervical hemi-hysterectomy. It is extremely important to determine beforehand the permeability or non-permeability of each cervix. The adnexa will probably be found degenerated on the obstructed side. He has collected from the literature another group of 3 cases of double uterus with independent bodies, not complicated by hematometra, but with symptoms on the part of the adnexa. Total hysterectomy was done in each case, and the results were excellent. Bousquet found in the literature reports of 4 cases of dual pregnancy in a double uterus, each half containing a fetus, expelled by abortion. No instance is known of pregnancy in the organ left after hemi-hysterectomy, but theoretically there is no reason why it might not occur.

26. **Peptic Ulcer of Jejunum After Gastroenterostomy.**—Gosset remarks that it was only six years ago that peptic ulcer of the jejunum was observed for the first time, and after a gastroenterostomy. Since Braun first noticed it, 30 cases have been published, and Gosset has had opportunity to observe a case personally. His patient was a man of 42. Two years after posterior transmesocolic gastroenterostomy, a peptic ulcer in the jejunum perforated into the transverse colon. Ileo-sigmoidostomy was done after the perforations in jejunum and colon had been sutured. Recovery was uneventful. In the 31 cases reported, only 2 of the patients were women; the ages of the patients ranged from 4 months to over 50 years. Five different varieties of gastroenterostomy had been employed. The interval before the peptic ulcer developed sufficiently to cause symptoms was from ten days to seven years, the majority occurring within a year or so. In most cases the signs of perforation appeared without any preceding symptoms. In another group, symptoms developed similar to those observed with gastric ulcer, localized peritonitis with infiltration of the abdominal wall, the palpation findings resembling actual tumors in some cases. There is still a third group in which the ulcer scarcely attracts attention until it perforates into some adjacent organ, generally the transverse colon. The diagnosis is not difficult if the possibility of peptic ulcer after a gastroenterostomy is borne in mind. The prognosis of the fulminating form is grave; the form with localized peritonitis yields readily to operative measures, yet the danger of recurrence must not be forgotten. In 9 of the 20 cases in this group there was recurrence. In one case five operations were necessary, and, finally, a gastrostomy. In 2 other cases jejunostomy had to be done at last. The gastroenterostomy had been done for non-cancerous stenosis of the pylorus in every instance. Hyperacidity was the rule in the cases with recurrence, although there were some exceptions. The constant coincidence of stenosis, hyperacidity and great dilatation of the stomach is suggestive. The conclusions deduced from this long article are that medical treatment, with care as to diet, should be kept up for a long time after a gastroenterostomy, and that in operating the opening should be made as far from the pylorus as possible. The details of the various cases are tabulated and summaries given.

27. **Intermittent Distention of the Gall Bladder.**—The outlet of the gall bladder may become transiently obstructed, causing an intermittent distention of the organ. The gall bladder becomes enlarged at intervals, and the subsidence of the tumefaction is accompanied by agonizing paroxysmal pain. The obstruction in the cystic duct may be caused by kinking of the duct or by a stone or stones acting like a valve to close the passage at times. The patients usually have had a "gallstone past," and the paroxysmal pain is located in the right hypochondrium or epigastric region. It is atrocious, and may radiate like gallstone colic, and, like the latter, may cause reflex phenomena, but without temperature.

29. **The Sahli Test for Hyperacidity.**—Rubow states that he has examined the stomach functioning in 704 patients with various dyspeptic disturbances. Of the total number only 213 were found with a hyperacidity of 75 or over. He classifies these hyperacid cases and tabulates the findings for comparison, giving the highest in each case. Not a single individual was found with an acidity of more than 125, in which the acidity could be ascribed to the hydrochloric acid secreted. The large majority showed an acidity (due to hydrochloric acid) of not more than .44 per cent. Only in 4 cases was it higher, reaching 124 and 125, that is, 0.45 or 0.46 per cent. He has become convinced that the secretion of a genuinely hyperacid gastric juice must not be regarded as necessarily a pathologic factor. His extensive experiences with the Sahli flour and butter soup test were not favorable. There is too much room for error in the stratification of the soup and the stomach contents, the fat rising to the top.

31. **Hydrotherapy of Nervous Dyspepsia and of Organic Stomach Affections.**—Sadger gives minute directions for hydrotherapy based on wide experience. In the chronic gastric affections, and in nervous dyspepsia, powerfully stimulating general applications are indicated. Even the local applications are given in their most stimulating form. The sitz bath, for instance, is taken with water as cold as from 8 to 14 C. (46 to 57 F.), for three, five or fifteen minutes. In organic affections, especially in case of round ulcer, he has often found that small pieces of ice introduced into the rectum act like magic in arresting acute hematemesis. Cold fluids introduced in the rectum, he found, reduce the temperature of the stomach in some way. Swallowing scraps of ice has the opposite effect and actually favors hemorrhage as the water accumulates and becomes warm. A cold coil over the stomach, over a cold compress, is an effectual adjuvant, the flow of ice-cold water through the coil being kept up continuously possibly for a week. A sheet is wrung out of cold water and laid over the trunk, tucked in around the sides, and over this the cold coil is applied over the stomach. The patient is fed with tepid, sweet or sour milk in small portions for four or five weeks. Sadger commences with a teaspoonful every fifteen minutes and increases the amount to a tablespoonful, then to half an after-dinner coffeecupful, and finally to a teacupful, increasing the intervals to thirty or sixty minutes. He insists on this diet after acute hemorrhage and also in the treatment of chronic ulcer. Even on the day of the hemorrhage, it is possible to commence with minimal amounts of the milk (ice cold). Sadger quotes from Winternitz that the factors inducing round ulcer of the stomach are a chlorotic tendency, reduction in hemoglobin, reduced alkalinity of the blood and hyperacidity of the gastric juice, with spasmodic contraction of the blood vessels in the stomach mucosa. These factors, he says, induce a predisposition to gastric ulcer. Hydrotherapy, which has such a powerful action on all these factors, forms thus a truly causal treatment for the resulting predisposition to gastric ulcer. It seems to be the general experience that the main contingent of gastric ulcers is presented by chlorotic girls. The chief reliance is on general stimulating measures, with procedures to influence the circulation in the stomach lining and walls. These include cold sitz baths for about four

minutes, stimulating packs, generally in combination with the hot coil, which, however, is never left in place for more than ten or fifteen minutes. Sometimes the cold coil is applied to the heart to improve the general and local circulation. These measures are supplemented by a strict milk diet. Sadger applies an abdominal pack, changed every three hours. Once or twice a day a coil of hot water (40 C.—104 F.) is inserted in the pack for ten or fifteen minutes. Once a day a sitz bath is taken with water at 46 or 57 F. for from three to five minutes. Early in the morning the body is rubbed off with a cloth wrung out of very cold water, avoiding the chest and abdomen. Later, alternating hot and cold procedures are used. A good arrangement for home use is a cold pack until the sheet gets warm (20 to 30 minutes), with a half bath afterward at 22 or 20 C. (68 F.) for two or three minutes. Milk is the only food allowed for four or five weeks, commencing with a teaspoonful every fifteen minutes. The milk must always be very slowly sipped.

32. **Influence of Silver Nitrate on Gastric Juice and Motor Functions.**—The conclusions of Baibakoff's numerous experiments and clinical experiences are that silver nitrate has the property of increasing the secretion of hydrochloric acid and, hence, the total acidity of the gastric juice. The use of the drug is consequently contraindicated in cases of pre-existing hyperacidity. It is indicated, for the same reason, in cases of deficient or lacking secretion of hydrochloric acid, as in mucous gastric catarrh. The silver nitrate also aids in the digestion of albumin. The drug has further an anticatarrhal and an antifermentative action, so that it might be used to advantage in cases of abnormal fermentation. Experience to date has further demonstrated that the silver nitrate promotes the emptying of the stomach. In case of relaxed stomach musculature this property might be utilized. The various effects of the administration of silver nitrate mentioned above were observed with small doses (0.002 gm. three times a day), as well as with large amounts (0.03 gm. three times a day). The findings in 16 cases before, during and after the administration of the drug are given in tabulated form.

33. **Plastic Operations by Mobilization of Urethra.**—Von Hacker has performed 13 operations on the penis requiring stretching of the urethra, and the results have been extremely gratifying in every instance. He gives the details of all his cases and reviews the history of this technic. It proved successful in his hands in 5 cases of hypospadia; in 1 of a defect resembling hypospadia, remaining after an ulceration; in another case for the transformation of a perineal into a penal hypospadia; in 2 cases for the cure of a lip fistula of the urethra; in 3 cases of stricture, and in 1 of traumatic rupture of the urethra. The operations were done under infiltration or general anesthesia, but in future he proposes to use spinal analgesia. He prefers the tunneling technic as insuring primary healing. Among the various technical points which he mentions are the following: The urethra must be mobilized for about twice the length of the part it is to substitute. The urethra should not be stretched to a length of more than one and a half times its length in the unstretched condition. The limits of resection and stretching for plastic purposes can be more extensive when the conditions are such that retention of the urinary functions alone and not of the sexual is sought, as, for instance, in case of cancer.

36. **Cancer of Small Intestine.**—Kanzler adds 2 to the 23 cases of cancer of the small intestine which he has been able to collect, giving the details of the entire number. Fourteen of the patients died without an attempt at operation, being generally moribund when first seen. Only one patient, a man, survived out of the 11 operated on, and he succumbed nine months later to pneumonia. Six of the patients were in too advanced a stage of malignant disease for the operation to be more than palliative, and only 3 obtained relief and brief lengthening of life. In one case in which five feet of small intestine were resected, the patient lived for five months. In the single case in which the operation was done in two sittings, the patient, a man, survived for nine months until he contracted fatal pneumonia. Any operation on the small intestine is dangerous. Scarcely 50 per cent. of the material analyzed exhibited symptoms allowing a clinical diagnosis. Vague resistance was noted in a very few cases, and a subjective sense of pressure in a few others. Adhesions with adjacent organs were frequently encountered. Intestinal hemorrhage was observed in only 2 instances.

42. **Protracted Pregnancy in Case of Antefixation of Uterus.**—Ahlfeld noticed in 2 cases that the pregnancy was unusually long and the children abnormally large after preceding antefixation of the uterus. In looking over the literature he found records by eight authors of pregnancy from forty-three to fifty-two weeks in length in multiparæ who had been previously treated by antefixation of the uterus.

43. **Prognosis of Carcinoma of Vulva.**—Grünbaum reports 5 cases from Landau's clinic which confirm the conclusions drawn from study of the literature, namely, that radical removal of carcinoma of the vulva was followed by freedom from recurrence in a certain proportion of cases, even when there was metastasis in the inguinal glands. To insure the best prognosis it is necessary to extirpate with the primary growth the inguinal glands on both sides, far into sound tissue, irrespective of the findings on palpation.

44. **Intoxication from Stovain.**—Trantenroth describes a case of severe intoxication consequent on lumbar injection of 0.06 gm. stovain, preceded by 1 to 1,000 solution of adrenalin. The patient was a parturient in difficult labor and the anesthesia was preliminary to forceps extraction. Ten minutes after the injection the patient complained of suffocating, the lips and vaginal mucosa became cyanotic, the pulse slow and small, respiration slow and shallow; she became unconscious, but revived somewhat after injection of 2 gm. of a 20 per cent. solution of camphor. The muscles were completely relaxed and both arms and legs were paralyzed.

The child was safely extracted, with surprisingly little loss of blood. By the next day all symptoms had subsided except difficulty in moving one leg. Three days later intolerable headache developed, with pains in the shoulders, radiating into the limbs, worse at night. After these severe pains had lasted for four days, a sudden sensation as if an electric current had been passed through her body, was followed by a remission of all pains, but she felt stiff and her right leg was subjectively ice-cold. Fourteen days after the injection symptoms of a local spinal meningitis and of a right neuritis of the roots developed. The woman was unable to leave her bed until five weeks after the lumbar injection, and her gait was not normal for several weeks later, owing to a painful cramp in the knee. Trantenroth ascribes the meningitis to chemical irritation from the stovain, and remarks that an ascending suppurative meningitis might have developed if there had been puerperal infection. The irritation is not surprising, he remarks, when we consider that the solutions of stovain have an acid reaction, induce hyperemia and irritate the tissues. Braun has even witnessed gangrene from their use. In Sonnenburg's case a 10 per cent. solution of stovain was injected into the abdomen on account of a septic process. The hyperemia, irritation and possibly gangrene which it induced at the point of injection evidently provided a good culture medium for the streptococci in the blood, and fatal suppurative meningitis developed. Trantenroth has been much impressed with the advantages of lumbar anesthesia in obstetrics. The anesthetic does not affect the child, while chloroform is liable to act on the child and to increase the tendency to asphyxia. Lumbar anesthesia does not favor hemorrhage later, as chloroform does, but has a directly opposite effect. It also enables a laceration of the perineum to be sutured at once without further anesthesia, after waiting tranquilly for the termination of the third stage of labor.

45. **Steam Douche to Promote Expectoration.**—Lissauer has been using for a year a method of stimulating the secretions which has proved very effectual and harmless in his hands. A spray of steam at a temperature of from 43 to 52 C. (110 to 125 F.) is sprayed rapidly over the upper part of the body for fifteen seconds, followed by a cold fan douche for three or five seconds, after which the patient is rapidly rubbed down and dressed. He cites 16 cases in detail to show the prompt effect on the expectoration induced by this procedure. It does not produce much of an appreciable reaction on the skin, but the patients feel the relief very soon.

46. **To Reduce Blood Pressure in Arteriosclerosis.**—Erlenmeyer regards the abnormally high arterial pressure in arteriosclerosis as a self-regulating process. When the blood pressure is not high treatment should aim to raise it, possibly by carbonated saline baths, not over 30 C. (86 F.) in temperature. In cases with moderately increased arterial pressure, the viscosity of the blood should be gradually reduced and kept down by a gradually progressive course of iodids. In patients with very high arterial pressure the danger of rupture of a blood vessel should be averted by periodically repeated venesection, keeping the viscosity of the blood reduced with iodids.

51. **Malachite Green Culture Media for Typhoid Bacteria.**—Loeffler has now had several years' experience with malachite green agar, and regards it as a great improvement in the technic for differentiation of typhoid and allied bacteria.

54. **Acute Iodin Intoxication and Acute Inflammation of the Thyroid.**—Lublinski was treating a syphilitic with iodid when the thyroid began to swell; the course of the case demonstrated that the iodid was causing acute thyroiditis. This condition subsided on suspension of the drug, but increased again as it was resumed. He reviews a few similar cases on record.

59. **Rupture of Liver.**—The patients in Thole's 2 cases were healthy soldiers. In one the esophagus had been ruptured as well as the liver, but it caused no symptoms and was a surprise when discovered at the autopsy. Thole discusses the indications and best technic for treating ruptures of the liver. He advocates tamponing without suture for all bullet wounds and for rupture with much crushing of the tissues and ragged edges. He remarks that the liver in even very young children takes a suture as well as that of the adult. The rupture of the liver in the patient who recovered was a comparatively smooth tear, and it was sutured with three stitches with No. 6 catgut. Notwithstanding internal bleeding, the pulse is liable to become stronger after a time. The first disturbance in the pulse must be regarded as merely a sign of reflex nervous shock. The area of liver dullness grew rapidly smaller owing to the local traumatic paralysis and distension of the transverse colon.

60. **Traumatic Cysts in Pancreas.**—Honigmann devotes 74 pages to a study of this subject, to which his interest was attracted by a case personally observed. The patient was a healthy young man; the symptoms indicated contusion of the left kidney after trauma affecting the left upper abdomen. A retroperitoneal tumor gradually developed, which was reached by a lumbar incision, as it was uncertain whether it originated in the kidney or pancreas. The cyst found in the pancreas, contained all three of the pancreatic ferments, and there were indications of traumatic perinephritis. Honigmann reviews 70 similar cases that he has found on record, the age of the patients ranging from 2 to 62 years. The tumor is the clue to the diagnosis, especially the fact that it is covered by the stomach above and by the transverse colon below when these parts are inflated. General weakness and progressive emaciation are other important symptoms. The cramp-like pains sometimes noted subside after eating. The intestinal functions are disturbed, and constipation amounting to actual occlusion has been observed in some cases. The prognosis is favorable with opera-

tive treatment, but a case is known in which diabetes developed after an interval of eight years of health. In conclusion Honigmann remarks that any traumatism affecting this region demands caution. A spontaneously arrested hemorrhage would offer less chances for cyst formation or other disturbances later if the patient were kept in bed for several weeks and carefully supervised.

61-62. **Resection of Carcinomatous Stomach.**—Brüning analyzes the experiences at Giessen, where resection of the stomach on account of carcinoma has been done thirty-two times. The mortality was among the smallest on record, 18.8 per cent., only surpassed by that of Maydl, who has reported 18.6 per cent. mortality in 25 operations. The deaths were due to pneumonia in three instances, and to collapse, embolism and chloroform once each. Some patients succumbed to recurrence of the growth two and one-half and four and one-half years after the operation, the average survival of those who succumbed to recurrence later being about sixteen months.

Ito and Asahara report from Japan a case of total resection of the stomach on a much debilitated patient who succumbed to collapse. In a second case the resection was partial and the patient survived six months. They remark that cancer of the stomach does not reach the surgeon until in such an advanced stage that radical extirpation is scarcely possible. The results in such cases, however, should encourage the surgeon to operate in cases from which he has hitherto held aloof as scarcely indicating such serious measures. The article concludes with an extensive bibliography of international literature.

77. **Treatment of Fractures.**—Heusner describes his method of applying extension to the limb while at the same time allowing the patient to be up and about. The apparatus for the arm consists of a long strip of metal bent in the shape of the arm with four half bracelets soldered to it, one of which embraces the forearm, two the upper arm and one fits in the axilla. The metal strip is bent with an extra U-shaped turn at the elbow, to impart elasticity to it, and the strip projects beyond the hand. Extension is applied from the hand with an elastic band passing over a pulley in the outer end of the strip and fastened to the U-shaped projection of the strip at the elbow.

78. **Stones in the Bladder.**—Finsterer's long article is devoted to study of the urinary calculi included in the Billroth-Hochenegg collection at Vienna. The monograph is illustrated and a bibliography of 70 references appended.

79. **Carcinoma of Female Urethra.**—Knoll had occasion to observe the case of a woman of 68, previously healthy, who was suddenly affected with profuse hemorrhage from the genitalia. This was followed by pain in micturition and an adenocarcinoma originating in the urethra was found and removed. He has found reports of 32 such cases published in medical literature.

81. **Tuberculous Affections of Cecum and Appendix.**—The results of various methods of operative intervention in such cases have been diligently compiled by Campiche, the list of titles of works consulted numbering 202. The total number of cases is 379, with a mortality of 18.6 per cent. More than 33 per cent. of the patients remained in good health for months and years afterward. On the whole, about 37.9 per cent. of all the patients succumbed sooner or later to their tuberculous affection or its results. Ileocecal resection makes the best showing; during the last five years, with the frequent side-to-side union of the stumps, the recoveries amount to 86 per cent. When resection was supplemented by the construction of an artificial anus, more than 80 per cent. of the patients thus treated succumbed. Very extensive resections were always followed by the speedy death of the patient. Exploratory laparotomy seems to be a serious measure in these cases; only 15.7 per cent. of those thus treated remained permanently healthy. Simple incision of the abdominal wall was well tolerated, but most of the patients died not long afterward, and in more than a fourth of the cases a fecal fistula resulted. The Murphy button was used in 19 cases, and once was the direct cause of death. It is being used more frequently now than heretofore and without mishaps. Appendicectomy gave 86.4 per cent. of immediate recoveries, but as the almost invariable tuberculous process in the adjoining intestine persisted, the condition was not much improved, and only 13.6 of the 22 patients can be regarded as permanently cured. The material is classified and tabulated and the article written as objectively as possible.

85. **Pyelography.**—Voelcker and Lichtenberg have coined this term for radiography of the kidney and ureter after these structures have been filled with a solution of a silver salt. The fluid is introduced into the hilum of the kidney through a catheter in the ureter. The shadow cast by the Roentgen rays discloses any bending or kinking of the ureter, any obstruction or dilatation of the parts, and anomalies generally. They give some of the radiograms thus obtained in an experience with 10 patients, all women but one. The radiograms were failures in four instances, but in the others they were remarkably distinct.

86. **Upward Squint.**—Miller was able to banish evidences of irritation of the vagus and a diversified train of symptoms in 10 cases by correction with prisms of an existing upward squint. His first patient was a young woman who had suffered for months from extreme nervousness, oppression and cramps in the stomach, eructations, loss of appetite, nausea, cardiac oppression and other symptoms of pronounced neurasthenia. She also suffered excessively from seasickness and from nausea when riding in the cars or swinging. Correction of the squint banished at once all these symptoms in this and in all the other cases.

87. **Stones in Common Bile Duct.**—Ehret calls attention to the differentiating signs of stones in the common duct. The temperature is generally normal, but after longer or shorter intervals, from four to twelve weeks, the temperature may rise sometimes as high as 41 C. (105 F.) and persist high for one—or more rarely for two or three days, and then drop abruptly to normal. It remains normal between the attacks. These periodical rises in temperature are accompanied by exacerbation of an existing icterus, or its appearance if not already present. The icterus develops rapidly but declines very gradually. The liver is generally tender on pressure, but there are no spontaneous pains in the liver region. Ehret knows of two cases in which these attacks recurred at intervals for years, and yet there never were any spontaneous pains. One patient noticed merely an outbreak of sweat and a certain feeling of weakness before an attack. This triad of recurring temperature and icterus without pains has been observed by Ehret in 17 cases; its occurrence may be accepted as positive evidence of a stone in the common bile duct, although its absence does not necessarily exclude such a contingency. The symptoms are the expression of exacerbations of cholangitis, and stones in the common bile duct are peculiarly liable to promote such a process.

88. **Roentgen Examination of Stomach and Intestine.**—Rieder reviews some of the important findings that can be studied on the living subject after ingestion of a suspension of 10 or 15 gm. of bismuth in 50 c.c. of water. The large intestine can be examined by aid of a rectal injection of 100 gm. bismuth in a quart of milk, oil or water.

91. **Improved Technic for Mobilization of Spine in Scoliosis.**—The patient takes hold of a ring suspended as high above his head as he can reach. He is then instructed to raise the knee on the other side as high as possible and to clasp the

hollow of the knee with the free arm, bending the head far over on that side. The arms are then reversed, and this exercise is repeated ten or twelve times. Nieny states that it is remarkably effectual and convenient.

95. **Serum Treatment of Anemia.**—Norsa's experiences with 4 anemic patients treated with a prepared anti-anemia serum were not promising. The serum treatment caused a transient increase in the number of figured elements in the blood, but this soon passed away, and no permanent benefit was apparent.

97. **Epidural Injections in Treatment of Incontinence of Urine.**—Bruni tried this treatment in 6 patients, from 11 to 17 years old, with negative results. In 7 others, from 10 to 15, one or two injections permanently cured the incontinence. Eleven others, from 6 to 15 years of age, are still under treatment, and the improvement observed presages a cure in time. He commends this method of treatment as harmless and liable to prove extremely effectual. He found that 10 c.c. was not too large an amount to inject and was preferable to smaller doses. In an experience with more than 100 injections he never had any by-effects and never had any difficulty in introducing the needle into the saeral tract. See abstract, page 83, vol. xliii.)

98. **Petteruti Test for Hydrochloric Acid.**—Barba has been experimenting with the test devised by Petteruti of Naples. It is based on the fact that Congo-red paper is not affected by hydrochloric acid in combination with albumin, while it turns blue under the influence of even a trace of free hydrochloric acid. The yolks of two eggs are stirred into 300 c.c. of bouillon and the whole filtered. About 250 c.c. are then ingested by the person to be tested, and the rest of the bouillon is set aside. An hour later some of the ingested bouillon is withdrawn with the stomach tube. A 2 per thousand solution of hydrochloric acid is then added, a drop at a time, to 5 c.c. of the bouillon that had been set aside, testing each time to see how many drops are necessary to saturate the bouillon until the Congo-red reaction occurs. The procedure is then repeated with 5 c.c. of the stomach content. The difference between the results, multiplied by 50, represents the number of cubic centimeters of the solution of hydrochloric acid containing an amount of hydrochloric acid equivalent to that secreted in the stomach in the course of one hour. Experiments on healthy persons with this test showed that this amount was from 0.2 to 0.5 gm. Multiplying by 4 to bring the 250 c.c. to 1,000 c.c., the physiologic limits were 0.8 and 2 gm. The test was applied on 11 patients with stomach troubles and the results confirmed the clinical findings. The simplicity and rapidity of the test commend it, although it shares with similar tests the drawback that the secretion of gastric juice varies with different stimuli and with different people.

100. **Cure of Trigeminal Neuralgia with Radiotherapy.** The patient in the case described was a man of 33, who had suffered for six years with trigeminal neuralgia. He had undergone three operations for its relief, including Gasserectomy, but the neuralgia recurred always after a brief interval. The attacks of pain recurred every five minutes and the patient was much debilitated, as eating had become so painful that he refrained from solid food. Radiotherapy was then tried and improvement was apparent after three sittings. The "localizer" attached to the Roentgen tube was introduced into the mouth and applied directly to the edge of the upper jaw. Four H units were given at the first sitting, the rays corresponding to the number 5 on the Benoist radiochromometer. The sittings were repeated a week later and after the third week, and then were suspended for a month, as a slight reaction was apparent on the mucosa. Six sittings were given in all, representing a total of 26 H units. The neuralgia entirely vanished after the third sitting, and there has been no recurrence during the six months since. The patient can now eat like other people, but be is careful to refrain from washing with cold water.

101. **Blood Findings in Mushroom Poisoning.**—Tables are given of the findings in 3 cases of mushroom poisoning to demonstrate the marked leucocytosis which accompanies it. Experimental research showed that muscarine has the most powerful action in this respect. Also, that it might be possible to utilize in the clinic the antagonistic action of atropin, which, like pilocarpin, digitalin, carbolic acid, typhoid infection and malaria, reduces the number of colorless corpuscles.

102. **Radium Treatment of Rabies.**—Tizzoni's research on this subject has been chronicled in these columns, as also the fact that the government has provided him with radium to carry on his experiments on a larger scale. He here announces facts which seem to show that the germ causing rabies passes through two distinct phases in the cycle of its evolution. The first phase corresponds to the onset of the disease; in this stage the germs are fragile and easily destroyed by the influence of the radium. In the second phase they are more resistant and are influenced very little, if at all, by the radium rays. This renders more promising the prospects of successful radium treatment of hydrophobia in man if applied in the incipiency of the disease.

104. **Surgical Treatment of Biliary Affections.**—Cignazzi remarks that the Italian surgeons have not taken up the operative treatment of cholelithiasis and of cirrhosis of the liver as much as surgeons in other countries. In this and in his long article concluded in No. 48, he reviews the whole field of biliary surgery and discusses the various technics, with report of his successful intervention in 10 cases of stones in the gall bladder. In conclusion he classifies the various indications which call for cholecystostomy, for omentopexy or for splenopexy.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

MALARIAL INFECTION IN CERTAIN NATIVE VILLAGES OF THE CANAL ZONE.

ARTHUR I. KENDALL, PH.D.

Acting Chief, Board of Health Laboratory, Isthmian Canal Commission.

PANAMA.

When a body of men is sent to occupy a foreign country for any purpose, one of the first tasks of the sanitary authorities is to investigate and take precautions against the prevailing infectious diseases. The American occupancy of certain portions of the Isthmus of Panama was inaugurated by an investigation of the malarial fevers, for which this region has long been famous, and the results of this investigation form the basis of this paper.

In October, 1904, I was detailed to visit certain native villages, examine as many natives as might be necessary to insure accuracy of results, and to report on the percentage of inhabitants whose peripheral circulation harbored malarial parasites. The object of this work was not so much to determine the actual number of sick *per se*, but to include in the statistics indiscriminately the population of a certain area, noting just what proportion of the people harbored malarial organisms irrespective of symptoms. Obviously, after selecting the section to be examined, the best and most satisfactory method of procedure would be either to go from house to house personally or to send messengers armed with the necessary authority to compel the natives to report in person at a convenient station. In either event care must be taken to insure the presence of all members of each household at the time of examination; this necessitated the co-operation of the alcalde in each town, together with men who were personally familiar with the inhabitants. The local police aided much in this work, coming in contact with each and every native as they did; they were able to furnish lists of people living in a certain district and to keep them in town for examination.

Both the method of making house-to-house visits and that of requiring natives to report to a definite station was tried; in the former case it was found necessary to take houses irregularly, because the natives soon learned to anticipate our arrival and leave a day or two before their turn came, returning when their particular district had been worked up. In one case the population of a house at the time of our arrival was three; two days later it had risen to eight; the cause of this increase was a sense of security on the part of the natives that they would not be again troubled, together with an unexpected visit on the part of the police officer detailed to collect the inhabitants of that place for further examination. The plan of sending out a messenger was fully as satisfactory from the point of view of obtaining natives for our work, and saved much time that previously had been lost going from house to house.

By keeping track of the houses examined it was possible to obtain results which were derived from practically the whole population of the desired district, and the returns showed that in this respect the data on which the results are based were sufficiently comprehensive for our purpose.

Many problems aside from the primary object of this work presented themselves as preparations went on; only those, however, which could be made with the minimal expenditure of time other than that required for the real question to be solved were undertaken. They comprise the following:

(1) Primary data; ratio of infected to non-infected natives in certain locations as shown by the presence or absence of malarial parasites in their peripheral circulation. (2) Types of malarial parasites found during the course of the investigation, both with respect to species and stages in development. (3) Comparison of race, sex, age, occupation and relative immunity among the different peoples examined. (4) Species of mosquitoes, with particular attention to the genus *Anopheles*. (5) Effect of cinchonization.

In order to facilitate reference, this paper is divided as follows:

1. General technic, methods of examination, data upon which the methods herein described were based.
2. Towns visited, reasons for their selection.
3. Varieties of malarial parasites encountered; species of *Anopheles*.
4. Results of investigation.
5. Summary and conclusions.

I. GENERAL TECHNIC, METHODS, STAINS.

There are two methods available, practically, for the demonstration of malarial organisms in the blood: by using blood films, in which case the blood is not subject to any process which materially changes its morphology, for a time at least, and by fixing, drying and staining.

Authorities differ in their opinions as to the relative accuracy of these methods. Manson, who has had much experience with malarial blood and the technic of malarial examination contends that the film method is more reliable, while many other observers are in favor of stained preparations, although most of them admit that the latter method is perhaps more liable to misinterpretation in the hands of the inexperienced. I made two series of observations on this point to settle the matter as far as the work here was concerned. In choosing the method used in this work one must consider not only accuracy, which is the most important point, but such factors as time, convenience, simplicity and amount of material to be transported in case the relative accuracy between the two methods is approximately the same.

The first series consisted in the examination of nearly six hundred blood slides, both stained and unstained, to

become more familiar with the various forms of malarial parasites encountered in Panama, and secondarily to form some idea of the relative value of the two methods. The second series consisted in a careful study of one hundred cases as they came into the hospital, making one stained and one unstained preparation from each patient. The cases were not necessarily malarial, but were taken in order as they presented themselves. The results are:

Total cases examined	100
Total cases positive stained	69
Total cases positive unstained	68
Total cases positive stained, and negative unstained	3
Total cases positive unstained, negative stained	2

The slight difference, about 2 per cent., in favor of the stained preparations is well within the limits of error along other lines of the investigation, particularly with respect to the choice of a district for examination, which shall represent fairly the status of the whole town.

At Bohio, which is a fairly large town, for example, it was impossible to examine every native, and the probable error in selecting a representative section is at least 2 per cent. On the other hand, the rapidity which could be obtained with film preparations was much greater than would be the case with stained preparations. To reduce the working error as much as possible, the specimens of blood for examination were made in duplicate, and the results show that about 4 per cent. of the cases were positive on the second slide which were negative in the first examination. The fact that one could examine quickly a fresh preparation to determine its suitability for malarial examination was the final factor which led to the selection of the film method; one could examine two films to determine their excellence in a very brief interval, and in case another was needed it could be obtained before the native had left the station, a very desirable procedure, because the inhabitants were wont to depart as soon as they were allowed.

Technic of Preparing Films and Stained Preparations.—Cover glasses and slides more than sufficient for the day's work were cleaned in strong soap solution, rinsed several times in rain water, and stored in alcohol. When about to make either a film or smear the lobe of the ear was cleaned with alcohol, rubbed briskly and freely punctured with a lancet, which was kept, when not in use, in 5 per cent. phenol solution. The first drop of blood was wiped off, and the second, after it had welled up to a suitable size, placed on the slide or cover glass. In no case was the glass allowed to touch the ear.

If the slide and cover glass were perfectly clean there was no difficulty in obtaining a suitable film; the blood flows evenly between slide and cover glass, forming eventually a spread which contained the blood cells spread in a thin, uniform layer with the cells just far enough apart that they do not overlie one another. If this result was not obtained the first time a second film was made.

Stained preparations were also made after the preliminary cleaning of the ear; the blood drop was placed on one end of a slide, another slide was so placed that it lay between the blood drop and the end of the slide; if now the top slide was brought up to the drop of blood, the latter would flow along the edge of the upper slide, which could then without pressure be gently drawn along the lower slide in such a manner that the blood would form a thin, perfectly spread layer which would dry almost instantly. As a rule one could be certain after five minutes' examination of a film that it was posttive or negative; frequently one would find parasites in a positive slide almost at once.

Staining.—Although most of the staining was done toward the close of this investigation, it may be well to include the methods in use here because there are a few points not men-

Fig. 1.—Ancon Hospital, Canal Zone; capacity 400 beds. Seen from Tivoli Hill. (We are indebted to Dr. Henry Emerson Wetherill, of Ancon Hospital, for this and the illustration on the opposite page.)

tioned by other authors which have been found useful in this connection.

Intravitum Staining.—I have tried with a certain amount of success to make an intravitam stain which shall stain the parasites in films; such a procedure would be useful because the blood would not be previously subjected to drying or other harmful agent which almost certainly must affect to a certain extent at least the morphology of the parasites.

Methylene blue has for a long time been used for this purpose, and this substance is the basis of the stain I used. The methylene blue is polychromed in such a manner that it contains a certain percentage of a substance or substances variously called polychrome methylene blue, or azur. It is probable that azur is the correct term, and it will be referred to as such in this paper. It is formed as follows: ½ gm. pure silver nitrate is dissolved in about 50 cm. of water, and precipitated by 10 per cent. caustic soda solution. The resulting precipitate is washed with distilled water by decantation until the wash water is free from chlorids, then added to the following solution while still moist: 1.2 gm. pure sodium chlorid are placed in 100 cm. of distilled water, thoroughly dissolved and filtered; 1 gm. pure methylene blue is added, thoroughly dissolved, and again filtered. To this solution is then added the precipitated silver, and the whole placed in the 37 degree thermostat and allowed to remain a week. At the end of this time it will be noted that the color of the liquid has changed from blue to a purplish tint, which is due to the formation of azur. The amount of azur may be determined roughly by adding a small amount of the solution of chloroform; the latter dissolves the azur, producing a more or less pronounced purplish color, the depth of which is approximately an indication of the amount of azur in the solution. The sodium chlorid is added to make the solution isotonic with the blood. After filtering the solution containing azur it is ready for use; one places a drop of this stain on a slide, and drops the cover-glass containing the blood drop to be examined in the drop of stain. The two mix instantly, and one has but to wait about a minute for the various elements to absorb the color when the preparation is ready for examination. Such preparations keep rather longer than films without this stain. Preparations made this way show a slight darkening of the field, which makes the contrast between the erythrocytes containing parasites and the serum somewhat greater, as the organisms, while not stained, stand out more.

The extracellular forms of both the tertian and estivo-autumnal parasites stain; the crescents of the latter stain a deep blue. Leucocytes show a certain amount of metachromatic staining in their granules, and even after being deeply stained do not lose their motility. Blood platelets stain blue.

Staining Films and Smears.—There is a great variety of stains from which to choose, but the majority of investigators at the present time use some modification of Leishmann's stain, usually Hastings' or Wright's. The former has given us the best and most constant results. Until recently we have been unable to obtain the powder for this stain from the United States which shall always give us the best results, and we have been in the habit of making the stain in the laboratory. At the start considerable difficulty was encountered in making the stain exactly the same each time; the time necessary to perform the various steps necessarily varies, but the relative coloring of chromatin and protoplasm of the parasites should remain the same. This variation seemed to be due to the fact that the addition of the eosin to the methylene blue could be stopped at various intervals, obtaining at each interval a stain which had an affinity for either protoplasm or chromatin; beginning at one end one observed that the protoplasm was heavily stained, while the chromatin was quite unstained, and by varying the proportion of eosin relative to the methylene blue the chromatin could be brought out, with the protoplasm uncolored. I finally hit on the scheme of adding a small proportion of eosin, after preparing the polychromed methylene blue as recommended by one of the writers, then withdrawing a small portion of the fluid after stirring, and placing it on a porcelain plate. On the white background one could add experimentally repeated small portions of eosin to see if it had the desired effect; then repeat the performance in the bulk of the stain. It was found that when

Fig. 2.—Entrance to Ancon Hospital, Canal Zone, showing part of the hospital grounds.

the precipitation had gone far enough, the precipitate separated very quickly from the rest of the fluid, leaving a liquid which was almost colorless except for a substance which, apparently derived from eosin, resembled superficially fluorescene. This titration method has been tried again and again and invariably has given a stain that is very constant in its results. Aside from this, the stain used was made exactly according to the Hastings formula, and always gave excellent pictures. In order to save time in staining a long glass dish was provided with two glass rods, placed two inches apart. On these rods one could place ten slides and stain them at one time. The appearance of the malarial parasites when stained by this stain is so well known there is no need of discussing this point at this time.

II. TOWNS VISITED; REASONS FOR THEIR SELECTION.

Statistics bearing on the distribution of malaria in a given region must, to be of value, represent in the ultimate analysis the mean condition of the population in this respect. The mean may be derived in a variety of ways—by selecting a town or section whose medical returns show an average number of sick per unit population when compared with similar statistics from other towns; by taking equal numbers of cases from each of two or more towns of approximately equal size which, on the one hand, represent maximum infection, on the other minimal infection; or, finally, by comparing relatively the same numbers of inhabitants from the different races or nationalities living in the same zone.

The inherent error is necessarily great, no matter how one elects to make these observations, and it was finally decided best for the work here to examine a representative portion of the town of Bohio and practically the whole of the village of Gatun. These towns are in the Canal Zone, under the sanitary jurisdiction of the United States government, and they are very favorably situated and easily reached.

Bohio.—Bohio is situated on the line of the Panama Railroad, about seventeen miles from Colon and half a mile from the Chagres River. The population is about eight hundred, composed, to a considerable extent of West Indians, and more particularly of Jamaicans. They have lived in this climate a relatively short time and presumably have not acquired, to any considerable degree, an immunity to malaria or even to any extent a malarial tolerance, if such a thing occurs.

The location of this town on the railroad, its proximity to the proposed Bohio dam, and its situation on several important trails leading into the interior of the country have combined to make it a place of considerable business importance. Many of the inhabitants work either directly or indirectly for the United States government, and the agricultural interests are much less important here than in the town next to be described. The percentage of native-born to foreign-born inhabitants is small, contrasting in this respect also with the other place chosen for investigation.

In both Bohio and Gatun the inhabitants do not use mosquito bars nor do they screen their houses. This has an important bearing on the dissemination of malaria and the introduction of preventive measures against this disease. Most of the houses in Bohio are frame, with corrugated iron roofs—a very common type of structure here. This town, then, represents a fairly large settlement with a great preponderance of foreign-born inhabitants and a considerable commerce with the interior and the sea coast, factors which are not without significance in the study of malaria. Very little difficulty was experienced in obtaining the required number of inhabitants for examination: a section of the town representing about one-third both in area and population was selected and the inhabitants were brought to the local dispensary in detachments by a special messenger. The school children, however, were visited in the school houses.

Gatun.—Gatun is the opposite of Bohio both in the character of the people and in the structure of the houses. Both places, however, are surrounded, to greater or less extent, with swamps, and both lie on the Panama Railroad line. It is chiefly the difference in the people, both in regard to their ancestry and customs, which is responsible for the differences which will be commented on later.

This town is situated on a little island in the Chagres River about three-fourths of a mile long and three-eighths of a mile wide in the widest portion. It is formed by the Chagres River in front and the canal in the rear: the canal is water-containing for some distance above this point at the present time. The land slopes gently from the center of the island to the water on all sides, making a sort of natural drainage, although at no point is the land very much elevated above sea level. Except for a few swampy spots on the ends of the island, the island itself is free from stagnant water.

The natives are very primitive both in their manner of living and in their customs; they occupy huts such as one would expect to find in central Africa, made of cane sides with thatched roofs or adobe. Their furniture is very primitive, composed chiefly of hammocks made of a species of tough grass and a few rude chairs covered with raw hide. They still grind rice and corn with huge wooden mortars and pestles, and use boats made from hollowed-out tree trunks. They have lived on this spot for generations, and civilization has made remarkably little headway in changing their customs. They are superstitious, reserved and difficult to approach, and it was with much trouble that we succeeded in getting their permission to make our observations, although when they finally saw that the work would benefit them they reluctantly consented.

Bohio and Gatun, it will be seen, differ greatly in their houses, inhabitants and manner of living, and admirably lend themselves to this work.

(To be continued.)

PLASTIC RECONSTRUCTION OF THE LOWER JAW.

CARL BECK, M.D.
CHICAGO.

The removal of a portion or of the whole mandible has its effect on the functions of the jaws and the form of the face. The effect on the functions of the removal of a portion of the jaw will depend greatly on the part of the bone removed and its size. If a small portion of the middle part of the jaw is removed the function may not be disturbed at all. If half of the ramus is removed the mastication and the speech may be greatly impaired, and if the whole jaw is removed the function of the lower jaw will be entirely abolished. Even a small resection, however, will have an effect on the shape of the face which, as a rule, will be shown by disfigurement or deformity.

The jaw plays such an important rôle in the formation of the face, through support of the cheeks and the prominence of the chin, that the symmetry of the face and the esthetic effect is greatly disturbed if a part is

missing. This is shown in those cases in which, through lack or asymmetry of teeth, or through atrophic changes, the face becomes disfigured.

These points have to be taken into consideration in cases of operation on the lower jaw; more especially on account of the possibility of preventing such deformities by the proper treatment during operation.

There are many indications for operations on the mandible which call for a partial removal of the bone. Inflammatory conditions which lead to necrosis of the bone, and especially tumor formations, are the main causes for such operations. Whether the resection of the jaw is made permanent or only temporary is of great importance. If a permanent resection is made it is the duty of the surgeon to see that the part removed is in some way replaced by some resistant tissue which will give support to the soft structures and which at the same time will allow motion. It will be necessary to replace the removed bone by some material which will give to the face the normal expression and shape. The best method at present is the replacement of the removed structures by foreign bodies in the shape of dental plates. A plate which holds the teeth and imitates the shape of the jaw is well borne within the mouth, ordinarily causes very little irritation, gives to the soft structure a support, and restores the shape and symmetry of the face. Many surgeons, among them Bardenheuer of Cologne, have tried to restore a jaw by autoplasty, but the results are not very gratifying. The majority of experienced men have decided in favor of the prosthesis. Difficulties arise, however, when the prosthetic appliance is to be put in place, some time after the operation, because the deformity and impairment of function takes place immediately with the removal of the bone.

Hence it becomes necessary to apply the prosthesis at the time of operation and this is a difficult task because the operation is undertaken by a surgeon and the prosthesis is applied by a dentist, and hardly ever is the surgeon at the same time a good dentist or the dentist at the same time a good surgeon. It was, therefore, a very natural result of experience that Dr. Claude Martin of Lyons, who is a dental surgeon of great ability, should be the first to give to us a method of removing the jaw without causing disfigurement or impaired function. Although he was not the first one to expound the idea, he was the first to apply the method practically and a large number of patients operated on with good results are a proof that his method is practical and successful. He prepares a prosthetic appliance before he removes the jaw, or part of it, and implants it at the time of the operation in the cavity remaining on the removal of the jaw. The appliance is made of hard rubber, with a complicated system of channels through which the cavity, which naturally secretes a great deal of pus, can be irrigated and kept clean. This hard rubber prosthesis is only temporary and is replaced later by the permanent dental plate with teeth which can be removed for cleansing purposes and carried in the same manner as the ordinary plate after the removal of the teeth which hinges on the alveolar process. Each individual case requires an individual plate, so that no such plate can be bought from a manufacturer. Some operators have objected to this method in some particulars, although they accept the principle of it, namely, that a prosthetic appliance is necessary, but as material they have used metal instead of hard rubber. Boennecken and Partsch of Breslau have suggested the use of metal splints; the former suggested a wire splint, the latter a plate which can be cut to a desired size and fastened into the jaw when needed. Of course this means that the splint can be applied only in median resection, but when one-half of the jaw is resected clear up to the joint, the metal appliance is out of the question. Martin's method, however, allows even in these cases, or in cases of total removal of the mandible, the application of a prosthetic appliance. The accompanying illustration (Fig. 1.) is from photographs of two models which I received from Claude Martin, through the kindness of Dr. Carrel, and which represent the average case of a central and lateral resection. Dr. Martin is especially proud of the innovation of a certain flange to prevent the lateral displacement of this appliance. He calls this flange "ailette." I find, however, that Dr. Thomas Gilmer of Chicago, as early as 1891, recommended a similar device and has

Fig. 1.—The upper figure is the jaw of the patient. The two others are Martin models.

even gone so far as to prevent the displacement of the flange by applying an additional device which keeps the lower jaw from opening too much, through an elastic band from the chin to a skull cap. His paper was published in the *Dental Review* and has not found entrance into the general medical literature.

This would be a general outline of plastic reconstruction of a jaw in case of removal by any method during the operation. What shall we do, however, when this precaution has not been taken and the jaw has been removed partially or totally, the cavity allowed to shrink, when mastication, speech and other physiological functions are impaired and when the face has become greatly disfigured? A case of this nature has come under my observation during the last year and has given me a chance to study this branch of plastic surgery.

Patient.—Miss D., aged 32, a school teacher, comes from a healthy family. She had never been sick up to the time when her present ailment began, that is about three and one-half years ago.

History of Disease.—She began suffering from a toothache in the middle portion of her lower jaw. Her teeth seemed to be perfect. She was a good looking girl with perfectly symmetrical features. A dentist whom she consulted about her

Fig. 2.—Before cosmetic operation. Front view.

ailment incised a small gum boil, but the process did not heal out. On the contrary a larger tumor appeared on the site of the old one. A doctor was called in consultation and he in turn incised the larger abscess, without relieving her condition.

Operation.—After a few weeks of palliative treatment he decided that something radical had to be done and he took the

Fig. 3. Before cosmetic operation. Side view

girl to a hospital where he removed, in one operation, the whole jaw from one joint to the other. The accompanying illustration (Fig. 1) gives the aspect of this jaw and it shows that the ascending arch and portions of the horizontal arch are perfectly normal, that the central portion of the jaw was the seat of a central necrosis within an osteomyelitic focus. A large portion of bone had been destroyed, but there were some pieces of healthy bone tissue remaining. Such an extensive operation was entirely uncalled for; but if it had to be done, a preliminary prosthesis of the kind described above would have been the proper method of treatment. Instead of that, an incision was made from one ear to the other underneath the chin, the jaw was removed in sections, leaving only some shreds of periosteum, fortunately for the patient, because spiculæ of bone afterwards formed from this periosteum and aided materially in the treatment of the case.

Fig. 4.—After cosmetic operation. Side view.

Postoperative History.—The wound did not heal entirely by primary union. The retracted scars on the face show where deep and long suppurating fistulæ kept the cavity draining. Ultimately, however, the wound healed. The result is apparent from the accompanying illustrations (Figs. 2 and 3). It will be seen that instead of a prominent chin there is a small lobule of contracted tissue which allows the comparatively

Fig. 5.—After cosmetic operation. Front view

large lips to droop. The upper lip is projecting a good deal and the teeth of the upper jaw are prominent. The nose apparently projects a good deal more. The cheeks are retracted and behind the cheeks are hollow spaces into which a thumb can be placed where the ascending arches had been removed. The speech of the patient was greatly impaired. The constant running of the saliva from the mouth was a very disagreeable symptom. The mouth cavity was exposed to the air and on

account of this exposure easy disintegration of food particles within the mouth took place and a penetrating odor made the patient's breath particularly offensive. These symptoms not only produced a great deal of discomfort and suffering, but they also brought the patient to the point of losing her position as teacher. This is mentioned because it shows the importance of reconstruction of the jaw and how much the surgeon ought to try to prevent such a disastrous result.

Cosmetic Operation.—Dr. Goslee, a dentist of great ability, especially in the line of prosthetic work, had charge of this case and he tried with an ingenious device in the form of a plate hinged to the upper jaw to restore the function of the mouth and the shape of the chin; but all of his trials failed because there was no support and a plate could not be borne. He finally gave it up. After a consultation with him I thought first of trying Dr. Claude Martin's method by restoring the cavity in which the jaw had lain, excising all the scars and forcing Martin's plate into the new cavity. This seemed feasible, but the more I studied the question the more convinced I became that a septic infection would be inevitable and that the patient, who had been suffering so long and was in delicate health, would succumb to this extensive and uncertain method of plastic surgery. I decided, therefore, to try another method. After finding some small spiculæ of bone, the longest about one inch, within the scarred tissue I thought hard paraffin would form a good support for the soft tissue and if tolerated would ultimately allow us to restore the original shape of the jaw. I began with the injection of a small quanity into the deepest portion in front of the ear. The injection was done in the usual manner, with a syringe devised by my brother, Dr. Jos. Beek. The paraffin was well borne and there was no reaction. I became bolder and injected larger quantities, first into the side, then into the center and gradually to the whole extent of the missing jaw. Of course it was impossible to straighten out immediately the deepest portion where the fistulæ that had been draining so long were situated.

Result.—The result was getting better with every injection. Not only did the salivation stop, but the movement of the jaws was possible and the appearance greatly improved as the accompanying illustrations show (Figs. 4 and 5). The offensive odor disappeared, the speech is perfectly normal and the patient has resumed her work as teacher.

Several months have now passed and when the patient was exhibited at the Chicago Medical Society, September meeting last year, the members of the Society could satisfy themselves of the fairly good functional and cosmetic results. I hope that the paraffin, which has not diminished in size up to the present, will remain for a long time, but even if it does not, I think that injections can afterward be made to replace the missing material. After a time an attempt will be made to form a ridge within the mouth for a plate.

ILEOSIGMOIDOSTOMY WITH OBLITERATION OF THE ILEOCECAL COMMUNICATION, FOR THE TREATMENT OF ULCERS OF THE COLON.

R. C. COFFEY, M.D.

Surgeon to and Medical Director of the North Pacific Sanatorium.

PORTLAND, ORE.

For many centuries past chronic dyspepsia, obstinate constipation, cramps and colics and peritonitis have been valuable cloaks by which medical men have been able to hide their ignorance of pathologic conditions within the abdomen. Asepsis and the rapid development of abdominal surgery have enabled us to study living pathology in recent years. This has taught us to place peritonitis in a class with dropsy, in that it is a result of some other real disease, directly connected with the digestive, eliminative or reproductive organs in the abdominal cavity. Patients treated ten or fifteen years ago for abdominal cramps and colics of recurrent type are now known to have had, in the great majority of cases, either appendicitis or gall-bladder disease, neither of which is curable by medical treatment. More recent years have brought to light the fact that a large percentage of the persistent incurable gastric disturbances or dyspepsias are due to ulcer of the stomach or duodenum, obscure gall-bladder disease, occasionally pancreatic disease and other conditions in the abdominal cavity, of a mechanical nature. The diagnosis and treatment of these conditions are being rapidly put on a scientific basis.

Other cloaks which hide much abdominal pathology are obstinate constipation and persistent diarrhea. Medical men are recognizing more all the time that many of these cases are due to lesions of the colon in the form of ulcers, etc., but admit that medical means are

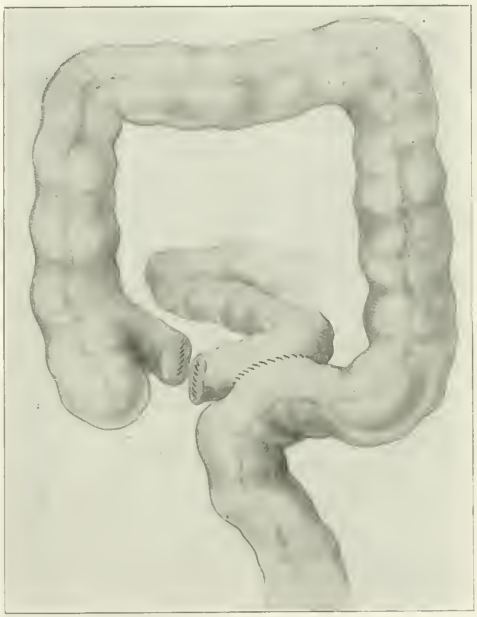

Fig. 1.—Ileosigmoidostomy with obliteration of the ileocecal communication.

but partially successful in the treatment of these diseases. The persistent and tireless work of Mayo, Moynihan and many other surgeons, on the stomach and duodenum have taught us that the proper and successful way to treat an ulcer is to give it rest. Success along this line has been little short of marvelous. By draining the stomach at its lowest point into the jejunum, almost all ulcers of the stomach and duodenum are curable. It is somewhat strange that more has not been done in the treatment of ulcers of the colon, which, while not so frequent or fatal as ulcers of the stomach, are much more frequent and have produced many more invalids than we have heretofore imagined.

Weir, by bringing the appendix through the abdominal wall, to be used as an irrigating tube, has unquestionably added much to the efficiency and convenience of medical and topical treatment of diseases of the colon.

This will, no doubt, be sufficient in many instances. There are many cases, however, which are not perceptibly benefited by any kind of medical or local applications, even when in more accessible portions than the upper parts of the colon. Therefore, surgery will again be called on for permanent relief.

Cheyne, Burghard and others have recommended and applied, in a number of cases of persistent ulcers of the colon, colostomy, using the ascending colon, thus eliminating the functions of the colon for several months or years at a time, and have been very successful in the cure of these conditions. Treves and M. H. Richardson have removed large portions of the colon for abnormal dilatation and gaseous distension, with very good results. Osler recommends this procedure as justifiable. Some surgeons, notably the Mayos, have removed or short-circuited almost the entire colon for cancer and extensive fecal fistulæ, and have concluded that the colon is by no means essential in the process of digestion and assimilation, and that its ablation, even as far down as the sigmoid flexure, apparently produces no disturbance.

Therefore, in view of the fact that it is well known that ulcers are best treated by absolute rest; that rest can only be produced by relieving the part as far as possible of its function; that medical and topical applications are only partially successful in many cases; that drainage of the colon by a colostomy on the right side has proved successful in the treatment of ulcers of the colon; that non-use of the rest of the colon apparently produces no degenerative changes, and that the colon apparently plays no vital part in the process of digestion and assimilation, I have felt justified in doing the operation described in the title of the paper. The case in which the operation was done is related below.

Patient.—Mr. S., aged 22, had been troubled with constipation, more or less obstinate, for four years. For the past two years the pain and pressure of the gas in the bowels, with other effects of the obstinate constipation, had been so marked that the patient had been unable to perform his labor as a farmer. His trouble had gradually grown worse during this time, notwithstanding the fact that he had consulted a number of eminent physicians concerning his trouble. All they were able to make out in the way of diagnosis was constipation. As his trouble grew worse, he was unable to get normal action of the bowels for several days at a time with even severe cathartics, and then only with the aid of high enemata, which were used with some result. He came to me Oct. 3, 1905, giving the above history.

Treatment.—After examining him thoroughly I agreed with the diagnosis which had been previously made and referred the man to an internist for treatment. He pronounced the case one of spastic constipation, and put him on a special diet and line of treatment. Nov. 23, 1905, the patient returned to me, stating that he had obtained no relief from the medical treatment and that he had lost all hope of relief in medicine. He suffered constantly from pain, which he located chiefly at the splenic flexure of the colon, stating that it seemed that the contents of the bowels, including gases, were obstructed at this point and could not pass. The distension of the colon was so marked and distressing that he could locate it very accurately himself, which location could be verified by percussion.

Operation.—At his request I made an exploratory incision, cutting down through the right rectus muscle. This revealed a somewhat congested and markedly distended ascending colon. The appendix was not seriously diseased, but was removed, lest it might be acting as a source of irritation. Another incision was made through the left rectus muscle, which allowed an examination of the splenic and sigmoid flexures. Examination revealed no visible stricture or obstruction at this point, but showed a congested and distended colon.

Postoperative History.—As soon as the man had recovered from the immediate effects of the operation we found that he still complained the same as before. His trouble continued, and we had an opportunity to observe carefully his condition and found that no amount of cathartic medicine would produce a free action of the bowels except with the use of high enemata. Severe cathartics would nauseate him, but would do no more. His pain seemed to be intense, as described before. At the end of three weeks from the time of this exploratory operation he made the arbitrary demand that we open him up again and do something more radical, as he preferred death to his condition. We delayed this, hoping that he might get better, but with no avail. At the end of five weeks, having been thoroughly convinced that the basic cause was ulcers which we had failed to locate at the exploratory operation, we suggested the idea of making a colostomy, draining the right side. This he refused to have done on account of the inconvenience of the artificial opening, so the following operation was proposed and performed Dec. 29, 1905:

Second Operation.—The abdomen was opened in the median line and the ileum cut in two near the ileocecal valve, between clamps. The two ends were turned in and an ileosigmoidostomy was performed with clamps and sutures, after the manner ordinarily used in the modern method of gastroenterostomy (Fig. 1). At this operation an ulcer was located about two inches above the point of anastomosis of the sigmoid flexure and another about three inches higher up on the descending colon near the mesentery. We were not able to examine the splenic flexure through this wound, but believe that there was unquestionably another ulcer at this point, which was overlooked at the former exploratory operation.

Result.—After this second operation the patient made an uninterrupted recovery. Three days afterward he began to take nourishment, and in ten days he was on a full and regular diet. He has never had pain in his colon since, nor has he had the distension. His bowels have acted almost every day since the operation without a cathartic, and yet without diarrhea. His appetite has been good and his digestion has been perfect, so far as we can see. At the early date of Feb. 13, 1906, the case looked like a complete success.

February 16 the patient returned, stating that his bowels were not acting properly and that he could feel gas in the colon as far around as the cecum. On examination I found it also. On giving him a cathartic no action was obtained, but the patient said the action seemed to pass upward into the descending colon. By digital examination no fecal matter was found in the rectum. By giving a high enema in large quantities the bowels could be made to act. The same thing was repeated and was kept up for ten days. All the fecal matter, according to his sensation, passed first down deep into the pelvis and then back up into the left side. On thoroughly studying the case I finally made a correct diagnosis. I opened his abdomen and found that the point of junction of the former anastomosis had become adherent to the abdominal wall, thus fixing it. The sigmoid flexure above the point of anastomosis, which was nearly twelve inches in length, had prolapsed to the bottom of the pelvis, making a sharp kink at the point of anastomosis and thus directing the fecal current into the sigmoid instead of the rectum. This was lifted up and the sigmoid sutured to the peritoneum just above the psoas muscle in the left flank. The loose sigmoid flexure was shortened by plication from above downward with a number of transverse rows of catgut sutures. This relieved the condition and prevented prolapse of the sigmoid. The bowels are acting well at this date (March 21), and patient is up and feeling well. I think this is an important observation in connection with the operation and my mistake was in not attending to this at the previous operation, as the danger was foreseen at that time.

This case is typical of the condition which has been described by certain authors under the head of spastic constipation. The continuing cause, which may have been secondary to an atonic constipation, was apparently the ulcers. The symptoms were immediately relieved by short-circuiting the affected part. The final result of this procedure is, of course, in the future.

In studying this subject, there seems to be a pathologic parallel between the stomach and certain portions of the colon. For instance, food is detained in the stomach for a few hours by the action of the pylorus. There is, then, no depot till the cecum is reached. Fecal matter is somewhat detained here by gravity. It is next detained above the so-called sphincter Oberne and held in the sigmoid flexure and descending colon for some time. The final depot is the rectum.

Overwork, nervous strain, indiscretion as to diet and hours for meals, disturb and change the secretions of the stomach, producing indigestion and, finally, gastric or duodenal ulcers. By irregular habits as regards the bowels, nervous strain, etc., an habitual and atonic constipation is produced. By mechanical pressure of hardened feces or from the effects of decomposition ulcers are produced in these parts of the colon.

Ulcers of the stomach, when irritated by the passing of food over them, produce a spastic condition of the pylorus which prevents the healing of the ulcers, holds the contents of the stomach too long and in some cases produces a dilatation and consequent increase in the disorder of the secretions. Ulcers of the colon, at times, apparently produce a spastic condition of the intestine at or near the point of the ulcer which has the same effect.

These depots in the alimentary canal are the ulcer areas in the young and the cancer areas in later life.

Short-circuiting and draining cures ulcers of the stomach and thereby may prevent cancer to an extent in later life. It is probable that the same is true and reasonable in the treatment of ulcers of the colon.

WHITHER ARE WE DRIFTING IN THERAPEUTICS?*

CLARENCE H. VAUGHT, M.D.

Vice-President State Association of Railway Surgeons; President Central Kentucky Medical Society.

RICHMOND, KY.

I believe that one of the greatest questions of our time is before us and one that we can have more influence in solving than can any other class of men or profession with which I am acquainted.

"The patent and proprietary medicine conspiracy," which has reached the climax of human endurance, is being assailed from many quarters, and the rankest of these gigantic frauds are on the run, and I want this society to get on the firing line and, if possible, to assist in their speedy extermination.

A number of high-class periodicals, the *Ladies' Home Journal, Collier's Weekly* and others, are the means, and Edward Bok, Norman Hapgood, Samuel Hopkins Adams and M. J. Sullivan are the men behind the means, that have caused such an awakening among the profession throughout the country. These men are real pioneers in this noble work. Is it not strange that a great profession like ours, with the massive intellect among our members, has been so stupid to the real situation, so well satisfied, so afraid, perhaps, that some wag might accuse the members of selfish motives, that not an effective word has been written or said against this monster curse? Suppose we are accused of selfish motives and every other thing in the calendar. This should not disconcert us or cause us to swerve so much as a line from out duty to ourselves and to humanity. I believe that every medical association in this country should elect to honorary membership these men who are doing such conspicuously good work for all the people and our profession as well.

Since this great question has been brought to our very door by laymen in a lay press, I thought it might be pertinent to ask, "Whither are we drifting"? Have we, by careful analysis and deduction, made any advancement toward a higher and more perfect therapy, or have we, like so many others, been drifting by the enormity of the advertising matter and the seductive wiles of that ever-present and always agreeable gentleman, the detail man of proprietary medicine, back to the abyss of neeromacy, ignorance and superstition? Have we not been cajoled by this means into giving at least our tacit indorsement to most, if not all, the proprietaries and specials that we see, many of which are without merit, others absolutely harmful?

No man can foreknow what will be the action of from ten to fifteen medicines together, even could the action of a single one be foretold. Your office and mine are being liberally supplied with samples of these new compounds, almost daily, of every imaginable name, some beautiful, others poetic, but we could never tell from the name what one of these compounds contained. The reason for this, I suppose, is because a name that means nothing can be as easily copyrighted as one that means something. The idea is to protect patent or secret formulas from other vultures, whose prey is human hope and credulity, and the ignorance or carelessness of the profession of which we are or should be representative.

THE DETAIL MAN.

The detail man calls on you at your office—doesn't want to take much of your valuable time, but has something that he knows is of interest to you when you have a moment's leisure. With visions of the importance of the message and of the fact that a stranger is within, you rush matters, and the doctor, it may be, who has failed in practice or a young one who uses this means of saving sufficient money to enable him to begin the practice, shows you what he has to offer (always ethical and meeting every test), gives you enough literature to last you and your family a month, and a liberal supply of samples, and expresses the hope that you will try them.

THE DESIRED EFFECT.

Strange as it may seem, at your first opportunity you do try them. The visit had the desired effect. You accept the statement, ethics and all, and some unfortunate, it may be the first patient who comes to you, is made the victim. It makes little difference for what the patient consults you, as many of the proprietaries are fully recommended, and testimonials from thoughtless physicians are not wanting to show you that you have a specific for any disease that confronts you. The medicine is tried on different patients, some of them have told you perhaps that the medicine at least was palpable, sailing seems easy, a ready-made prescription for all who call, so easy to write, perfectly simple, the other fellow doing the work you should do, while you get the pay.

Behold your surprise, however, in the course of a short time. You have been called to a home. After your visit has been concluded, you perhaps have suggested the use of some medicine for a poultice, you give explicit directions that the medicine should be applied to a cloth, then to the offending part. At this time some godly grandmother elevates her spectacles and asks, "Doctor, is that medicine, you are going to send, this Philogistine"? It may be some younger and more

* Read before the Madison County Medical Society.

charming member of the household who thus rudely breaks in on your dreams of what you expected to accomplish with the new remedy for all inflammatory conditions (for each member of the household knows all about it). You are compelled to answer, "Yes, this is the medicine I intended to send you." Grandma will say to you that "Mrs. Jones used it on her cow's leg, and Mrs. Smith used it on her husband's leg—they had some of it left and sent it over—we tried it, but it didn't do John's lungs any good." This is simply an illustration that could be duplicated many times in the course of a year with this and hundreds of other proprietaries.

You will, no doubt, say that this and that one has done good service for you. Perhaps this is true, but have you at such times taken into account that great law of natural therapeutics, the operation of the *vis medicatrix naturæ*, the manner and processes of healing which occur independently of our art? It is this law that enables the homeopath to relate his sugar cures and the medical skeptic to smile in his infidelity and that brings you and me out of the many close places into which proprietaries and carelessness have placed us. And thus have we not been duped ourselves in seeking some more potent means to relieve the suffering that we see around us?

SEEKING REMEDIES.

Yet we ought not to be criticised for this alone, as it has been truly said, "Man from the earliest antiquity has continually sought for means for the relief of pain."

"The most ancient record of the race introduces the hero of the flood, plunged in a deep and scandalous sleep under the influence of wine which he had prepared. At the siege of Troy the Grecian surgeons were skilled in the art of assuaging pains of injured men by the application of alcohol and carbonic acid to their wounds. Thus the venerable Nestor came to the relief of the wounded Macheon, with a poultice composed of onions, cheese and meal, mixed with the wine of Pramos.

"Other agents still more potent were known to the wise men of Egypt, and by them transmitted to their friends in other lands. Some preparation of opium or Indian hemp it may have been with which the beautiful Helen, after the siege was ended, once more in her lawful home, coming out of the 'sweet smelling lofty room chamber,' drove away sad memories from the minds of her husband and his friends by making them drink of wine into which she had cast a drug, chosen from the cunning and excellent stock presented to her by an Egyptian princess. Most potent drug this must have been, for we are told that it delivered men from grief and wrath, and caused oblivion from every ill."

Seeking relief from pain is certainly our province and our duty. We see that this idea has been handed down to us from the earliest antiquity, but whither are we drifting in its pursuit? You will observe from the history of these early times that people then and now in no way connected with the art or the practice of medicine prescribed and found others ever ready to swallow the potion regardless of its contents. There is or must be a charm or witchcraft in the act of prescribing, especially so for the other fellow, for this practice began at an early day and shows a steady growth all down through the ages until now. There is certainly nothing that we can imagine that so delights the laity as to prescribe something for the relief of a condition of which they are profoundly and totally ignorant.

PRETENDERS.

There is no profession which is more frequently used as a cloak by all kinds of mountebanks, charlatans and pretenders than is ours, and these pretenders too often prescribe for conditions concerning which they are ignorant. The medical profession is noble and beneficent in its aims, presenting more opportunities for doing good than perhaps any other, and yet within its ranks practitioners of the black art flourish on the credulity of the people with whom they come in contact. The medical profession offers a fertile field for men of this class, especially in this day of proprietaries and secret formulas, when little or no skill is required in writing or in filling a prescription.

USING PROPRIETARIES.

You might flatter yourself that only the ignorant and unlettered could become the victims of this class of medicine men, but in this you are sadly mistaken, for you will often have your pulse beat faster and your quiet indignation pitched to its highest point by seeing some of your most cultured people falling in line, possibly your best friend or your best patient.

Sir Dyce Duckworth, before a scientific body in London, England, recently stated that "the art of medicine is fast declining," and he links together, inadvertently no doubt, literary culture and scientific habit. The editor of *Hospital*, in same city, regrets that this should have been done, exclaiming that they are incompatible and adds, "Men of literary culture, but destitute of scientific training, furnish most conspicuous examples of incapability to observe accurately and of inability to reason correctly, which we witness every day in the world around us. They are the patrons of quack medicines and anti-societies; they are apt to dogmatize serenely concerning matters of the very elements of which they are profoundly ignorant."

This well illustrates my oft repeated statement that ours is a profession that none can know anything about save the initiated, and all of them unfortunately do not know. But whither are we drifting? I fear I tell but the truth when I say that, with the great commercial spirit of the day, we are drifting toward proprietaries and quack medicines. Some of us perhaps have anchored. To them I would say, cut loose from your mooring. We are not drifting into this habit altogether by preference or for the interest of our patients, but carelessness and ease, I think, are likewise responsible for part of it. This habit, insidious as it is, I believe our worst enemy. Samuel Hopkins Adams states, in *Collier's Weekly*, that "ignorance and credulous hope make the market for proprietary medicines."

I do not mean to imply that all proprietary medicines should be condemned. Many have been found useful, if their preparation requires greater skill or more complicated apparatus than your druggist possesses, and if the formulas are known and approved they should be used when indicated. Imagine yourself prescribing something that you know absolutely nothing about except what the genial detail man has told you. Imagine, again, if you will, that same gentleman telling you the indication for the use of the medicine that your case demands; you accept it and use the medicine suggested to you by this source. In doing so do you not lower professional standard, your own dignity and become the dupe of the manufacturer of the drug and the well-groomed agent who tells you in what class of cases to use it?

WHAT IS OUR DUTY?

The state of North Dakota has a law that prevents the sale of patent medicine (and this includes secret proprietaries), unless the formula is printed on the package; and Kentucky has a bill now pending to make a

similar law (presented by Hon. L. F. Johnson of Franklin County). I hope that a similar law will be enacted in all the states. If we were to do our duty, we would need no law to protect us and our patients whose lives are put in our keeping, and we should not under any conditions or circumstances prescribe a medicine that we were not absolutely familiar with.

I trust that the members of this society will join with me in resolving to use in the future only those drugs from which we can reasonably expect results, and, if possible, to have all remedies compounded by our own druggists. We should also notify the druggists that we shall accept only pure chemicals, such as those made by reputable firms. It is not our province altogether to find only palatable drugs. Let the homeopath have a monopoly along this line if he will; that which we most desire is results. Occasionally a medicine that is pleasant to the taste can have little or no therapeutic value, except for its mental effect on some of our most unfortunate cases. That we will appeal to the intellect rather than to the superstition, prejudice and ignorance.

I see each succeeding day signs of better things and that there is room for improvement no one can doubt, since it is estimated that over $100,000,000 has been expended annually for patent and proprietary nostrums. No wonder is it that legislatures are slow to enact laws to modify the sale of these "patents"; no wonder it is that the manufacturers of these miserable compounds are on the run, because at least $75,000,000 of this money must be profit, and if there is any one thing that will invite a keener interest than another it is the probable loss of money.

Then think what so vast a sum as this could and would do in influencing legislation that would be detrimental to this nefarious business. The manufacturers use every device known to the professional pirate and plunderer, such as threatening newspapers with loss of their advertising and appealing to retail druggists to help protect their property rights. These vendors want and demand our closest secrecy in protecting their rights, as they say. Afraid even to let the uneducated class of their countrymen know what they have been swallowing for all these years and for what they have paid so many honest dollars, notwithstanding the fact that these manufacturers know that the users of their medicines are, of all people, most gullible! I have seen it estimated that 75 per cent. of all the prescriptions that are written by the medical profession of this country call for proprietaries whose formulas are known and proprietaries whose formulas are secret, about one-half each. Is this not a shame when we know that many of the so-called proprietaries are no better than the rankest of the patents?

Let us see to it that we have a druggist prepare our prescriptions who is competent so to do; that we demand of him a square deal and only the purest medicines that can be had, asking no quarter from any source and showing none, save when compatible with the highest sense of duty to our patients and to ourselves, and lend our assistance in this campaign of education wherever and whenever we can be of service. Thus the people with whom we live and practice our art will have a higher regard for our ability and fidelity.

Corpora Aranti.—These structures in the brain are named after Giulio Cesare Aranzio (English, Aranzi; Latin, Arantius), an Italian anatomist, born at Bologna in 1530, died in 1589, according to the *Medical Book News*. He was professor of anatomy for thirty-two years in the university at Bologna, and physician to Pope Gregory XIII.

FOUR POINTS OF INTEREST IN MAJOR ANESTHESIA.

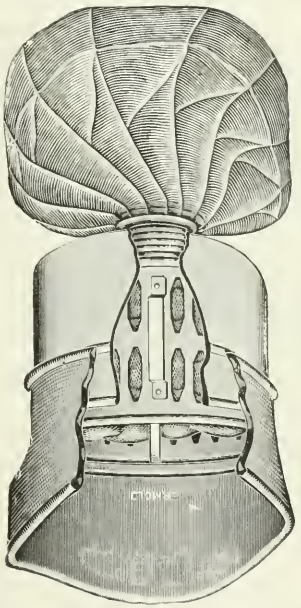
ROBERT H. M. DAWBARN, M.D.

Professor of Surgery, New York Polyclinic Medical School and Hospital. Surgeon to the City Hospital.

NEW YORK CITY.

The first of these points on anesthesia has to do with the use of ethyl chlorid prior to the administration of ether. Since the safety of this very pleasant method has been demonstrated it has rapidly grown in popularity. Dr. V. C. Pedersen, anesthetist to Roosevelt Hospital, has informed me that, unless otherwise directed by the surgeon, this is now always his preference instead of beginning the anesthesia with liquid laughing-gas.

Six months ago a certain New York firm informed me that hereafter they intended to manufacture their own ethyl chlorid instead of importing it; and, through their representative, asked my advice as to the best size of tube to supply. After som experimenting I advised



The inhaler. This illustration does not show the relative size of the thin rubber air-bag, which is large enough for the tidal air of the largest man.

a 5 c.c. tube. This is drawn to a fine point at one end, easily broken off and sealed by a blowpipe flame.

I also recommend the following method of usage: Assuming that the Clover air-bag principle of ether inhaler is the one to be used (the simple and cheap form known by my name and used for nearly 15 years at the City Hospital has never yet been followed by ether pneumonia), two or three of the 5 c.c. tubes of ethyl chlorid are wrapped each in an opened gauze sponge, with an elastic snapped about this jacket, and are then dropped within the air-bag. With the face-piece in position, the tip of one of these tubes is broken—through the rubber bag—and the anesthesia is at once commenced. Thus there is no waste, and the gauze wrapper prevents cutting the air-bag during breakage. If instead the tube be broken outside the bag and then

dropped within it, so rapid is the escape of this most volatile liquid that one is fortunate to secure the services of half the tube's contents.

If need be, the second and third tubes can be broken too. As soon as the patient is thoroughly asleep the ether-cage is slipped home in the face-piece, and gradually the ether anesthesia replaces that from the ethyl chlorid where a long operation is required.

Of course, where much more complicated and expensive ether inhalers are to be used, this tube of Squibb's is not indicated; and instead a spray of ethyl chlorid is directed into an opening in the inhaler for the purpose, from a large container. At present, however, we are assuming that the simpler kind of apparatus—which is presumably in use by a large majority of practitioners—is to be used. Chilling the lungs by ether continually poured on and using a towel-and-newspaper cone, or an Allis inhaler, is so obviously the chief cause of ether pneumonia that it would seem that the re-breathed, lung-warmed ether of the Clover air-bag principle should by to-day have commended itself to all members of the profession. If there be still some who differ, however, it may be worth while to add that all the experts in anesthesia in New York—I mean the men who do nothing else—are agreed on this point. This method also results in a great saving in ether, and the patient recovers more certainly and sooner, being far less saturated with the drug.

2. The second point to be mentioned is a means of preventing trouble from chloroform when this is used at night in presence of a naked flame in the room. Experience has shown that before the end of a long operation the surgeon and his assistants will be coughing in consequence of the chloroform becoming decomposed and giving off nascent chlorin. About fifteen years ago —perhaps more—it occurred to me to try hanging, not far from the lamp or gas jets, handkerchiefs dipped in ammonia. The resultant chemical affinity at once produces ammonium chlorid and prevents the cause of the coughing. Recently I mentioned this to Dr. Thomas L. Bennett, perhaps the best known of the men doing exclusively anesthesia work here, and he said he had never before heard of it. As I have not found it mentioned in a rather hasty review of text-books, I assume that at least this plan ought to be more widely known.

3. The third suggestion of this paper is far from original, but how forgotten it is in practice! I refer to giving the anesthetic during the natural sleep. In all possible instances of major operating during the earliest years let us select an hour which is regularly that of the child's daily sleep, and, entering the darkened room noiselessly, let us anesthetize so cautiously and gradually—using chloroform mask held far from the face, employing the drop method and being in no hurry—that the little sleeper only awakens when the operation is ended!

It makes an astonishing difference in the amount of chloroform required whether this safest of plans (and most neglected) is used, or whether instead the frightened child is awake, struggling and screaming. Also, be it remembered, it earns the mother's gratitude.

Although cases of accomplishment with chloroform well in childhood, during natural sleep, such anesthesia, may elect, is far more difficult, almost impossible indeed, and rarely can be done on adults at all.

The fourth and last of the four small points I wished to bring out—if, indeed, anything is small that makes at all for the patient's comfort or safety—is in reference to the advice which, without exception, one sees included in the instructions to the young anesthetist; namely, always to remove from the patient's mouth any plate containing artificial teeth.

In my opinion, there are exceptions to this, and the physician should be entitled to use his judgment. Obviously the plate should be removed when it is so small that, if dislodged, it might prove dangerous either by being swallowed or lodged in the gullet. In many instances, however, the patient is wearing a complete or nearly complete set or sets and possesses only an ordinary size of pharynx. In such cases, swallowing or choking on the plate is out of the question; and when it is taken out the cheeks and lips so fall in as to encroach, in some patients, to a serious degree on the breathing space within the mouth. This is worth remembering, especially when there chances to be much nasal obstruction, which is far from rare.

In a recent conversation with Dr. James T. Gwathmey, anesthetist to the City Hospital, I was pleased to observe that on this point he holds the same views.

ACCURACY IN DIETETICS.*

DUDLEY ROBERTS, M.D.
Associating Visiting Physician, Brooklyn Hospital
BROOKLYN.

The general trend toward accuracy in many departments of medicine serves to emphasize the prevalent disregard for a similar advance in dietetics. The importance of carefully selecting the articles of food for certain cases is very generally urged, but not as commonly practiced. Although it would seem to be a subject of equal importance, but little stress is ever laid on the necessity of regulating the amount of food to fit the exact known demands of a particular individual. That the demands and hence the supply of food should vary with the weight, shape of the body, age and condition of activity has been too well proved to permit of question.

We can only account for the prevalent neglect of this factor in dietetic ordering by supposing that the matter has never been presented in practicable form. It is essential that the number of nutrients in a given food substance be quickly determined and that the patient receive instructions as to the amount of food in such terms as can be readily comprehended by the average invalid or nurse. Food weighing must be discarded, as it certainly can not be carried out in the ordinary household, public eating place or even in the average institution. Unquestionably we must consider not what is served, but rather what is actually eaten; otherwise one may be misled into making serious errors.

Fortunately the number of simple foods, the value of which it is necessary to know in order to prescribe a dietary to the class of cases that should have definite diet lists, is comparatively small; from these simple foods one can readily calculate the value of such compound foods as are ordinarily used in these diets. In the accompanying Table[1] the most convenient unit of household measure has been taken and the food value of its content of food in the state in which it is eaten has been calculated; the value of the various articles in the raw state has been taken from the works of Atwater, Rubner, Chittenden, Hutchinson and others. While these units may not at any time be exact, in a number of meals the deficiencies and excesses balance.

It is not contended that more than a small minority of patients need to be put on regular diet lists; very

* Read before the Medical Section of the Kings County Medical Society.

1. The author, on request, will furnish these tables of food supply and demands on a card in vest pocket size.

often dietetic treatment is demanded, but a few instructions as to the amount and kind of food or a few interdictions will suffice. There are, however, a considerable number of individuals afflicted with diseases of an acute nature, chronic gastrointestinal disease, chronic undernourishment anemias and toxemias who need absolute and accurate instruction as to the amount and kind of food that is desirable for them to take; if this be not done, dietetic treatment amounts to nothing, the patient being guided in the choice of food by convenience or passing whim.

In addition to the value of such a table as a ready means of arranging suitable dietaries, we would emphasize its value in calculating the amount of nutrition that has been taken by a particular individual. Even with many conditions to a slight degree, we may say that the weight of the particular individual and the amount of muscular activity indulged in largely conditions the number of calories required. This may be expressed as in Table 2, on the basis of an average person of 150 pounds weight.

TABLE 2.—FOOD DEMANDS OF ADULT PER DIEM.

CONDITION.	No. of calories to each 2 lbs. body wt.	Total Calories	Gms. proteid
At rest in bed	25	1800	72
Slight activity	30	2200	88
Light work	35	2600	115
Moderately hard work	40	3000	120
Very hard muscular labor	45-55	3375-4100	135-160

The proteid demands of the adult under different conditions have been added to the above and the proteid, in terms of grams, is given in Table 1 for each food that has any import-

TABLE 1.—VALUES OF COMMON FOODS IN HOUSEHOLD MEASURES.

FOODS AS EATEN.	Actual Amount.	Household Measure.	Calories	Grams proteid.	REMARKS
Milk	8 oz.	a glassful	160	8.4	
Buttermilk and skimmed milk	8 oz.	a glassful	80	8.0	
Cream	8 gms.	a teaspoonful	20	0.2	
Condensed milk, sweetened	20 gms.	a heaping teaspoonful	50	1.8	
Condensed milk, unsweetened	20 gms.	a heaping teaspoonful	30	1.8	
Cocoa powders	10 gms.	a heaping teaspoonful	40	2.0	
Chocolate powders	10 gms.	a heaping teaspoonful	90	1.2	Greater nutritive value depends on larger amount of fat.
Beef juices, beef tea, bouillon clear soup	5 oz.	a teacupful	5-30	1-3	
Proprietary beef fluids	8 gms.	a teaspoonful.	1-10	4-2	
Beef and egg powders	10 gms.	a heaping teaspoonful	30	8	
Thick or cream soup	8 oz.	a soup-plateful	100-250	.....	Nutritive value increases as the thickness is made greater by proteid or carbohydrate addition to milk.
Alcohol	1 gm.		7		
Whiskey, brandy, etc.	1 oz.		85		
Wines	1 oz.		15-40		
Sugar	10 gms.	a heaping teaspoonful	40		
Eggs, whole	50 gms.	one	70		
Eggs, yolk		one	55	2.4	
Butter	10 gms.	a one-inch cube	65	0.6	
Cheese	10 gms.	a one-inch cube	45	3.0	
Meat and fish, lean	50 gms.	heaping tablespoonful	60	12.0	¼ lb. of lean steak will thus give 185 calories an ordinarily generous portion of rib-roast with moderate fat about 225 calories.
Meat, medium fat	50 gms.	heaping tablespoonful	100	7.0	
Meat, very fat	50 gms.	heaping tablespoonful	150	4.0	
Oysters, small	8 gms.	one	2	.5	
Oysters, very large	25 gms.	one	10	1.5	
Bread, slice, 4x4x½ in. thick.	25 gms.	one slice	50	1.5	
Crackers	3-10 gms.	one	12-30	.3-.6	
Cereals, in cooked state	30-40 gms.	a teacupful	110-150	3-5	A cupful equals a saucerful; a bowlful equals 2 cupsful.
Cereals, eaten as purchased	5-7 gms.	heaping teaspoonful	18-25	.5-.7	
Shredded wheat	30 gms.	one	100	3.	
Triscuit	15 gms.	one	50	1.5	
Peas, fresh or canned	35 gms.	heaping tablespoonful	25	2.0	The apparent low value due to large amount of water.
Peas, dried	25 gms.	heaping tablespoonful	100	6.0	A tablespoonful of dried peas to a plateful of soup.
Beans, dried	25 gms.	heaping tablespoonful	90	5.0	
Beans, fresh or canned	30 gms.	heaping tablespoonful	30	1.0	
Potatoes, medium size	90 gms.	one (3 inches long)	80	1.0	
Jelly, sweetened	.....	a teacupful	50-120	.....	Value depends on amount of sugar and gelatin used.
Apples	100 gms.	one	40	.2	
Oranges	125 gms.	one medium size	60	.5	
Bananas	50 gms.	one medium size	45	.7	
Dried fruit, prunes, etc.	100 gms.	medium size saucerful	100-200	1-2	Value depends largely on the sugar used as preservative.

the ignorant can tell with a certain degree of accuracy the amount of food ingested in these simple household measures of bulk; from these estimations given by the patient one can quickly calculate the nutrients ingested and compare them with the bodily needs of the particular individual. This is often a matter of the greatest importance in deciding whether such symptoms as loss of weight and strength and poor general condition are due to deficient intake of energy or to some pathologic condition exhausting the bodily energy.

By the term caloric estimation of food is meant the calculation of the energy contained in terms of the large heat unit, the large calorie, the amount of heat it takes to raise the temperature of one liter of water one degree centigrade. We know that one gram of fat when completely oxidized gives rise to about nine such calories; one gram of carbohydrate or proteid to four calories. While the demands of the body vary ant content. It will be noticed from the above that I accept the teaching that 16 per cent. of the nutrients ingested by the adult should be proteids. In Table 3, to the tabulation by Atwater I have added the necessary number of grams of proteid per diem; it will be seen that the ratio here of tissue building proteids to the distinctly fuel foods—the fats and carbohydrates—is different from that which obtains in a proper adult diet, the calories supplying 19 per cent. of the nutrients.

TABLE 3.—FOOD DEMANDS OF THE CHILD.

AGE.	Proportion of food of adult at moderate work	Calories	Gms. proteid
Under 2 years	30 per cent.	900	42
3-5 years	40 per cent.	1200	55
6-9 years	50 per cent.	1500	70
10-13 years	60 per cent.	1800	85
Boy, 14 to 16 years	80 per cent.	2400	115
Girl, 14-16 years	70 per cent.	2100	100

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN.

CHAPTER XVII.

CIRCULATORY DEPRESSANTS.

The circulation may be depressed by acting on those structures the stimulation of which causes an increase in blood pressure. Hence we might divide these agents into two groups: 1. Those acting on the heart mainly, directly or through the centers. 2. Those acting for the most part on the vessels, directly or indirectly.

An agent which slows the heart without causing a compensating increase in the strength or the amplitude of the contraction, or a constriction of the vessels, must cause a fall in the arterial pressure, as will be readily understood by reference to what has previously been said in regard to acceleration of the heart causing a rise in pressure. Here, too, we have in every case a combination of effects, and the resulting change in the circulation must depend on the predominance of one or another. As a matter of fact, we have no circulatory depressant which is used therapeutically to slow the heart by direct action on the myocardium, but there are a number which induce slowing by indirect action.

Aconite.

Therapeutic doses of aconite cause slowing of the heart by stimulating the vagus center, without materially affecting the strength of the individual contractions or the condition of the vasomotor center. The result, therefore, is a fall in arterial pressure.

The lessened cardiac action is accompanied by a decline in the temperature, whether this was previously normal or that of fever. This effect is commonly ascribed to the change in the circulation, but it has not been proved that the heat regulating center is not involved in the action.

It will be noticed that the effects of digitalis and aconite on the circulation are diametrically opposed, except for the slowing of the pulse rate, which both induce.

Toxic doses of aconite act directly on the heart, causing acceleration with diminished force of contraction. In mammals the acceleration is prevented for a time by the vagus stimulation, and the heart is actually slowed, but in reality only a therapeutic dose has been absorbed in the early stage of the action; this stimulation rapidly gives place to depression and then to paralysis of the center, the acceleration becoming marked and being soon followed by great irregularity. Delirium cordis occurs before the heart stops in diastole.

Paralysis of the respiratory center is usually the immediate cause of death, hence atropin is capable of saving a certain percentage of animals experimentally poisoned with a barely fatal dose of aconite. If an excessive dose has been taken even artificial respiration will prolong life only for a short time as the heart soon becomes paralyzed after the phenomena enumerated above.

Despite the fact that it was well known and long in use as a familiar poison, particularly for wild animals, aconite is a comparatively recent addition to our materia medica, having been introduced by an Austrian physician, Störck, about 1762.

The official preparations of aconite are as follows:

Aconitum.—U. S.—This is the dried tuberous root of *Aconitum napellus*, collected in autumn. When assayed by the process given in the Pharmacopeia it yields not less than 0.5 per cent. of aconitin.

Average dose: 0.05 gm. (1 grain).

Fluidextractum Aconiti.—U. S.—This is made with a mixture of 75 parts of alcohol and 25 parts of water and should contain 0.4 per cent. of aconitin.

Average dose: 0.05 c.c. (1 minim.)

Tinctura Aconiti.—U. S.—This preparation has been materially reduced in strength and now represents 10 per cent. of the crude drug, or approximately one-third of the strength of the tincture that was official in the Pharmacopeia for 1890.

It may be added that the change was made in conformity with the recommendations of the international conference for the unification of formulæ of potent medicaments and that, in addition to being in harmony with this international standard it will be found to be more uniformly active than the stronger but more variable tincture official in the earlier pharmacopeias.

Average dose: 0.6 c.c. (10 minims).

Aconitina.—U. S.—This is an alkaloid obtained from aconite. It is the most active and most potent substance in the Pharmacopeia. The aconitin now official is the crystalline alkaloid and should not be confounded with the amorphous substance formerly official or the comparatively weak eclectic preparation of aconite.

Average dose: 0.00015 gm. (0.15 mg. 1/400 grain).

Aconite finds its greatest usefulness in cases of high blood pressure with a strong, rapid heart, particularly in fever in robust patients. It then simply slows the heart, lessening its output and causing a fall in temperature and in arterial tension.

Fever alone is not an indication in every case for the use of aconite. In continued fevers and in any case in which the heart is feeble or the arterial tension low from any cause (even though the pulse may be rapid), aconite is contraindicated.

Since the antipyretic benzene derivatives have come into general use the employment of aconite in fever has correspondingly declined, but we have seen that the synthetic antipyretics are far from being the harmless substances that the manufacturers would have us believe, and aconite deserves to be used more frequently in suitable cases of fever.

"Colds" are troublesome forms of congestion resulting from circulatory disturbances which are often relieved by repeated small doses of aconite. For this purpose 3 drops (about 1 minim) of the tincture of aconite of the present Pharmacopeia, which would be equivalent to about 1 drop (1/3 minim) of the tincture official in the Pharmacopeia, 1890, well diluted with water, may be given every fifteen minutes for two hours, then hourly until relief is obtained.

Aconitin is so intensely irritant that it is not suitable for use without great dilution, and as there is some chance of confusing the much more potent article now official with the eclectic or the amorphous preparations, it will be found preferable to use the tincture of aconite in nearly every case, more particularly since this is now required to be of a definite aconitin strength. Because of its irritant action aconitin is not adapted for hypodermic use, but it may be given, largely diluted with water, as follows:

R.	Aconitin (crystalline)	gr. 1/12	(005
	Alcoholis	ʒiv	15|
	Aquæ q. s. ad	ʒiv	120|

Sig.: A teaspoonful may be taken every three hours.

The disadvantage, not to say danger, of trying to weigh such small amounts is apparent, and serves to illustrate the advantage of using the tincture.

The tincture is usually given alone, except for the water used in diluting it.

Veratrum.

Veratrum rather closely resembles aconite in its therapeutic action, and it was widely used at one time for the reduction of fever. The extent of its use was largely due to its popularization in the form of Norwood's Tincture of Veratrum, but it seems to possess no advantage over aconite, and it is now but seldom used internally. The official preparations are:

Veratrum.—U. S. (Veratrum Viride.—U. S. P., 1890).—Under the single heading veratrum the Pharmacopeia now recognizes the dried rhizome of *Veratrum viride* or of *Veratrum album*. While it is true that there is no marked difference between the two drugs some physicians prefer the American root and therefore should specify "Veratrum viride, U. S. P., 1890."

Average dose: 0.12 gm. (2 grains).

Fluidextractum Veratri.—U. S.—This is directed to be made with alcohol.

Average dose: 0.1 c.c. (1½ minims).

Tinctura Veratri.—U. S.—This preparation represents 10 per cent. of the crude drug in alcohol and is practically one-fourth the strength of the corresponding preparation in the Pharmacopeia for 1890.

Average dose: 1.0 c.c. (15 minims).

Veratrina.—U. S.—This is a mixture of alkaloids obtained from the seeds of *Asagræa officinalis*. Veratrin should not be confounded with the eclectic preparation of the same name.

Average dose: 0.002 gm. (1/30 grain).

The Nitrites.

The nitrites, organic as well as inorganic, lower the blood pressure by causing vasodilation. Therapeutic doses exert but little influence directly on the heart. It has been shown that the nitrites act on the muscles and nerve endings of the arterioles, and that even the veins undergo dilatation.

Any considerable dilatation of the arterioles and veins of the splanchnic area must inevitably lead to a decline in the general arterial pressure, regardless of the action on the heart. In man the heart actually does show acceleration in the first stage of the action with amyl nitrite because of the depression of the vagus center; the blood pressure remains high and the vasodilation affects the face and neck, because of depression of the vasoconstrictor centers for those areas; but as the dilatation extends to the splanchnic and other areas the general arterial pressure falls.

There has been some diversity of opinion in regard to the effect of amyl nitrite on the cerebral circulation. Leonard Hill agrees with those who believe that there are no nerves controlling the diameter of the cerebral arteries, and he declares that the arterial pressure in the brain simply follows that in the carotids. Wiggers has found that adrenalin constricts the cerebral vessels and we have Elliott's dictum, based on his masterly research, that the constrictor effect of adrenalin on vessels is proof of sympathetic nervous control. Brodie and Dixon also found that the action of adrenalin is exerted on nervous elements. Should Wigger's results be confirmed there would be little reason to doubt that the nitrites do effect the caliber of the cerebral vessels.

The nitrites are capable of causing some dilatation of the vessels in excised muscles when the nerve endings are not concerned; hence they must also act on the muscular elements of the vessels to some extent.

The nitrites produce methemoglobin in the blood, but do not cause the destruction of the corpuscles, as other methemoglobin formers do, and in man this does not arrest oxidation completely, because the tissues reduce methemoglobin slowly. This is not an important factor, however, with the therapeutic doses of the nitrites.

O. Loeb suggested as a possible explanation of the value of amyl nitrite in angina pectoris that the coronary vessels, like those of the face and brain, may be dilated at first, before the action on the general circulation begins. Filehne showed that the therapeutic dose of amyl nitrite caused vasodilatation by central action, and Loeb found it did not affect the vessel tonus independently except when in such concentration as to prove poisonous. Small doses were found to have no constant effect on the vessels of the coronary circulation in the excised heart. Amyl nitrite acts very rapidly when inhaled, but the action is over in about twenty minutes.

The effects of glyceryl trinitrate or nitroglycerin are much more slowly induced and they persist for some hours. Sodium nitrite is decomposed by the hydrochloric acid of the gastric juice thus giving rise to irritation of the stomach. Glyceryl trinitrate is not decomposed in the stomach, but it has the disadvantage of often causing headache. In some cases this action does not occur after the drug has been used for some time. Glyceryl trinitrate is decomposed in the blood, with the liberation of the nitrous acid radicle, hence it acts like the nitrites.

Spiritus Glycerylis Nitratis.—U. S. (Spiritus Glonoini—U. S. P., 1890)—Commonly, though incorrectly, termed nitroglycerin, is an alcoholic solution containing 1 per cent. by weight of glyceryl trinitrate.

Average dose: 0.05 c.c. (1 minim).

Amylis Nitris.—U. S.—This is a liquid containing about 80 per cent. of amyl nitrite.

Average dose: 0.2 c.c. (3 minims).

Sodii Nitris.—U. S.—This usually occurs in white, or nearly white, fused masses, soluble in less than two parts of water. The salt deliquesces on exposure to air and is also gradually oxidized to sodium nitrate and thus becomes unfit for use.

Average dose: 0.06 gm. (1 grain).

The nitrites, including glyceryl trinitrate, are of prime importance in the depression of the circulation and may be used, when it is deemed necessary, to lower the blood pressure, for example, when a weakened heart is becoming exhausted by contracting against a great arterial resistance, and the contractions are incomplete, as in arteriosclerosis. A slight lowering of the aortic resistance often enables the heart to contract more perfectly while a coronary vasodilation secures a better nutrition of the heart.

This group is contraindicated, however, when the blood pressure is already low (however weak and rapid the heart may be), because a certain degree of arterial tension is absolutely essential for maintaining the coronary and medullary circulations.

Amyl nitrite is to be preferred when a speedy action is desired, as in acute attacks of angina pectoris. When the constriction of the vessels is of spasmodic origin the nitrites usually give relief, but in the latter stages of arteriosclerosis, when most of the muscular tissue has been replaced by fibrous, thus narrowing the lumen of the vessels, it is obvious that such vessels cannot be caused to dilate by any means.

It must not be forgotten that while relief is often obtained in the acute attacks of the early stages of angina pectoris, the nitrites are merely palliative and in no sense curative. The nitrites, and more particularly amyl nitrite, are indicated in vasomotor spasm occurring in any disease, unless specifically contraindicated by other conditions.

The action of amyl nitrite is very speedily elicited when it is inhaled, but when spasm of the respiratory muscles interferes with the inhalation it may be injected into the deep muscles of the thigh.

Spirit of glyceryl trinitrate is to be preferred in chronic conditions of abnormally high blood pressure, because of its more protracted action. One minim is given three times a day, or the dose is increased till effective. It may be injected hypodermically or given by the stomach, as it passes through that organ unchanged, and, therefore, causes no such disturbances as are seen with sodium nitrite.

While this substance is usually considered as being extremely poisonous it is said that more than 12 c.c. (3 fluidrams) have been given in the course of a day with no bad effects. Aqueous solutions of glyceryl trinitrate are unstable and are frequently quite worthless. The spirit sometimes gives almost immediate relief in headache, when this is attended with high blood pressure, but, on the other hand, it may increase the headache if the blood pressure is low. As is well known, the headache which glyceryl trinitrate commonly causes is one of the greatest objections to its use.

The nitrites, and particularly the spirit of glyceryl trinitrate, may be used to counteract the vasoconstrictor effect of digitalis or strychnin when that action is undesired.

Because of its ready decomposition spirit of nitrous ether does not yield enough of the nitrous acid radicle to exert any therapeutic action on the circulation. The action of the spirit is exerted reflexly as in the case of alcohol and ether.

The spirit of nitroglycerin may be given in simple solution in order to avoid the measuring of such small doses as one minim. It may be prescribed as follows:

℞ Spiritus nitroglycerini.....m. xv 1|
Aquæ .....ʒii 60|

The dose of the solution is a teaspoonful. Large amounts should not be prescribed or dispensed.

The following illustrates the method of prescribing sodium nitrite:

℞ Sodii nitritis.....gr. xv 1|
Aquæ (recently boiled).....ʒii 60|

This solution should be kept well corked. The dose is one teaspoonful.

The well-known "pearls" of amyl nitrite afford the most convenient form for dispensing that substance; they must be kept cool to avoid loss by breakage, and when used one is crushed in a handkerchief and the contents inhaled by the patient at once.

Bloodletting was formerly in vogue as a routine procedure when it was desired to reduce the blood pressure, but in healthy animals the vasomotor center exercises such perfect control over the blood pressure that the loss of blood produces very little lasting effect unless it is so great as to cause collapse symptoms. While the loss of a moderate amount of blood is well borne by robust patients, and in some cases may even prove beneficial, aconite and the nitrites are nearly always to be preferred as temporary measures, while the control of the diet (including liquids) and the use of saline purgatives will serve to diminish the amount of blood for a longer time in suitable cases.

Chloral hydrate is one of the most effective agents in our possession for lowering the blood pressure by depressing the vasomotor centers and while this action is much employed in laboratory experiments, it is not elicited in man by perfectly safe doses such as are used to induce sleep.

Clinical Notes, New Instruments, Etc.

A PECULIAR INFECTION OF CERTAIN CERVICAL GLANDS WITH TYPICAL LOCAL AND GENERAL SYMPTOMS.

HELIODOR SCHILLER, M.D.

CHICAGO.

Under the title of "Pfeiffer's Glandular Fever" I recently published reports of five cases and I have since had an opportunity of seeing six similar cases.[1]

A close study of these cases and comparison with those already reported, shows that they do not correspond exactly with the cases described by Pfeiffer, but that they have distinctive features which may be considered as those of a well characterized and typical disease.

CASE 6.—On October 24 I was called to see a baby boy, aged 2½ years. Since the previous evening the child had had fever, had coughed somewhat and had vomited once.

Course of the Disease.—When I first saw the child his temperature was 102 F., his throat was reddened and several râles could be heard over the lungs. He was constipated, and for this calomel was given. Next morning the temperature was 99.8, and the following day 103. The redness in the throat had disappeared entirely on the fourth day and the temperature was 101, with no other symptoms. On the fifth day the glands on the left side of his neck, especially those before and behind the proximal end of the sternocleidomastoid, were very much swollen. The swelling came on rather suddenly; on the previous day there was no trace of it, and it consisted of three enlarged glands, each larger than a hazelnut, and of the consistency of hard rubber. Each swollen gland was distinctly palpable. The skin over the glands was normal, the glands were hardly tender, and somewhat painful only on hard pressure.

Cultures taken from the throat and from the seropurulent discharge from the nose on the second day showed streptococci and staphylococci. Throughout the disease the temperature ranged from 101 to 104.5. There was no exanthema on the skin or scalp, and nothing abnormal in the ears.

On the tenth day the glands on the right side of the neck were found to be swollen and showed the same characteristics as the glands on the other side. This swelling was followed by higher fever and vomiting. Adenoid vegetations in the throat were present in a slight degree. Constipation was obstinate and the child lacked appetite.

On the eleventh day the baby complained of pain in the ear, but nothing pathologic could be seen there. The liver and spleen were both found enlarged, and the mother noticed that the urine, which on the eighth day was normal, was lessened in quantity on the twelfth day. It was found to contain albumin and some white and red blood cells. On the sixteenth day there were traces of albumin only.

The fever continued for three weeks and a half, reaching as high as 104.6 degrees, but in spite of this the baby did not look very emaciated. The glands swelled more; I had the impression that they were smaller on some days, but the day following they would seem as large as before. The fever disappeared gradually and at the end of the fourth week it was gone. The glands became gradually smaller. When the temperature became normal the appetite came back, the baby recuperated quickly, and by December 15 the glands were reduced to the size of a small pea. Dr. Abt saw this case with me.

SUMMARY OF CASE 6.

At no time was any fluctuation felt; the glands were always movable, there was no periadenitis. The teeth were normal and there is no history of tuberculosis in the family. There was no sign of scrofulosis nor was there any symptom which would alow me to consider the case as an acute tuberculous infection of the glands. It is known that in cases of acute infection of glands with tubercle bacilli, with the formation of a large amount of epithelial cells, and consequent infiltration with round cells, the glands may swell in a comparatively short time, considering the chronic character of the tuberculous disease. These glands may swell to double their size inside of a week or ten days, but never over night; besides, the more acute tuberculous infections of the glands are invariably followed by caseous degeneration, and then by suppuration, whereas in the case just referred to absorption took place.

The so-called hypertrophic form of tuberculous glands most often disappears by conservative treatment, but it comes on very slowly and its course is contrary to the one here described. It is afebril, and other symptoms tending to tuberculosis will not be missing. In this case there was sudden onset of fever, weak feeling, headache, backache, and then the sudden and large swelling of the cervical glands, which are not painful, but only slightly tender, and hard in their consistency, swelling of the spleen and of the liver, nephritis, constipation, mouth-breathing, decline of the fever by lysis, slow absorption of the inflamed glands and slow disappearance.

We can not very well call this a case of common tonsillitis, because the pathologic changes which the tonsils and the throat showed, were very little. The sympathetic swelling of the glands in a case of tonsillitis is different, the glands are painful and disappear with the disappearance of the process in the throat or suppurate. Also the affection of the kidneys, spleen, and liver, in so marked a degree, and the long lasting fever are certainly not the symptoms of tonsillitis.

CASE 7.—A woman, aged 34, called on me September 14. She said that on September 9 she felt ill, had a headache, pain in the back, was very weak, and that toward evening she noticed a swelling of the glands on the left side of her neck. She believed that this swelling, which was not painful at all, came from her teeth, but her dentist failed to find any reason for trouble from that source. A physician who paid a friendly visit prescribed a liniment, which was used without result, and the swelling grew constantly, but did not cause any trouble. At no time was there any pain in swallowing, or very much pain in the swollen glands, except in quick movements of the head.

Examination.—When I saw the patient the temperature was 100, pulse 88. On the left side of the neck there was a glandular tumor the size of a child's fist, composed of two distinctly separated glands before and below the proximal part of the sternocleidomastoid. This swelling was hard and elastic and not very tender. The heart and lungs were normal; the liver was somewhat enlarged. The tonsils were enlarged with deep but empty crypts. The palate and pharynx were reddened,

1. The Journal, A. M. A., Aug. 5, 1905, p. 401. The cases reported in this article are numbered consecutively following those reported in the previous article.

there was no skin affection, the ears were normal, urine was normal, and the patient complained of weakness and nausea.

Course of the Disease.—On September 16 the temperature went to 103, and on September 17 to 103.5. The glands were still hard but movable; there was no fluctuation and no marked periadenitis. On September 18 I made a trial puncture and at the depth of more than an inch I found a thick yellow pus, which I removed by incision. That evening the temperature went to 104.4, and then gradually subsided and was normal on September 21. On September 26 the incision was healed, but the glands were still enlarged, though very much reduced in size; the patient felt fine and began to gain.

On the evening of September 26 I was called to her, and, to my surprise, I found the glands just behind the sternocleidomastoid in its upper part swollen, and one gland in the middle of the neck also swollen to about the size of a nut, hard and not very tender. The whole thing came on in a few hours; the temperature rose to 100.6 and the pulse to 96. There was no pain except in moving the head; the throat was normal, but a general weakness was felt.

On September 27 the condition was the same, the highest temperature was 101, and the urine contained traces of albumin. The fever increased and the swelling of the glands was the same.

On September 30 I again made a trial puncture, and found one-third of a Pravatsche syringeful of pus in the gland behind the sternocleidomastoid. I made an incision along the needle, but found no more pus.

The temperature gradually subsided and on October 6 it was normal once more, but the swelling did not decrease in size, though there was no fluctuation. Trial punctures revealed no pus. On October 26 I advised *x*-ray treatments, and after ten treatments with medium hard tubes at 10-inch distance and ten minutes' exposure by Dr. Reichman all the glands disappeared. In the pus of the glands typical influenza bacilli and streptococci were found. The blood examination showed leucocytosis 13,000.

SUMMARY OF CASE 7.

The objection could be raised that the process was nothing but a common tonsillitis. Not all cases of tonsillitis are followed by pain in the throat, the affection in the throat or tonsils is accompanied by large yellow plaques, is very often found there by change, and patients do not always complain of pain there. The changes in the tonsils could have disappeared quickly, but the whole course of this disease is not at all similar to any of the hundred varieties of tonsillitis; the sudden swelling of the glands, their consistency, the slight tenderness, the increase in size after the supposed process in the throat disappeared, the finding of influenza bacilli in the pus, and the lengthy duration of the process are enough to show that we have to deal with a well characterized, distinct disease.

CASE 8.—A girl, aged 2½ years, the daughter of the patient in Case 7, five days after an attack of rhinitis and pharyngitis, which lasted two days, complained of pain in her ears and neck, and vomited once or twice.

Examination.—The tonsils were red and somewhat swollen. There was a seropurulent discharge from the nose; the ear drums were somewhat retracted; the lungs and heart were normal. The child was healthy looking and seemed to be a well nourished, strong baby. In the discharge from the nose staphylococci and large diplococci were found, but no diphtheria bacilli were demonstrated in the specimen taken from the throat.

Course of the Disease.—The next morning the glands on the left side of the neck, on both sides of the upper end of the sternocleidomastoid were swollen to the size of a hazelnut, being hard, not very tender and movable. The child was constipated, breathed through her mouth and was very cross. The redness in the throat disappeared in two days, but there was no change in the course of the disease.

On October 13 a thick pus was removed by an incision from one of the glands, and in the pus were streptococci only. The other glands, which did not suppurate, remained about the same.

By October 20 the incision was healed. Then rather suddenly, without any symptoms other than temperature of 101, the symmetrical glands on the right side began to swell, traces of albumin were found in the urine, and the temperature kept rising until October 30, when the spleen and liver were distinctly enlarged. The glands on the right side were easily movable, hard, elastic, with the skin above them perfectly normal, and they remained about the same.

After the disappearance of the fever the child improved quickly, the glands became smaller and in the beginning of December they were reduced to the size of small peas.

CASE 9.—The servant in the family had a very similar but much milder affection.

CASE 10.—This was a case belonging undoubtedly to this species, but was very mild, though showing all the symptoms.

CASE 11.—This patient, a boy, 7 years old, had had a cold for several days, and suddenly, on the evening of November 8, it became worse. He had headache, felt weak and complained of pains, especially in the abdomen, but also to some extent all over.

Course of the Disease.—Temperature was 100.8, pulse 102. His throat was red, and the next morning the glands on both sides of the neck were swollen, but the right side was the worse. Except for a slight fever and the swelling of the glands, no other symptoms were present, the throat being normal and the highest temperature 100.8. The boy felt well, had a good appetite and did not want to stay indoors. After the fever disappeared the glands became somewhat smaller. There was no exanthema, no peeling of the skin.

On November 24 the boy did not act normally, and the mother observed that there was blood in the urine. A specimen showed all the signs of an acute hemorrhagic nephritis. During the next twenty-four hours 11 ounces of bloody, dirty-looking urine were passed, and the next day 15 ounces. In spite of this the boy felt well and did not believe that he was sick. His temperature was 100; the spleen and liver were enlarged.

On November 26 the urine, 56 ounces, contained albumin, granulated and epithelial casts and cubic fatty degenerated epitheliums.

On November 30 the urine contained traces of albumin, only at this time also the glands were very much reduced in size, and the latter part of December had nearly disappeared.

SUMMARY OF CASE 11.

In this case there was not one symptom of common tonsillitis. Of more importance in this as well as in the case of the little girl is the "cold," which may have been the source of the infection of the glands. The patients hardly felt sick, the only symptom in the beginning of Case 11 was the swelling of the glands and a slight fever, scarlatina could be excluded.

SUMMARY OF ALL CASES.

I have observed eleven cases of a well-characterized disease. The most striking and characteristic symptom of which is the sudden swelling of certain glands of the neck. In Case 1 the swelling of the glands was noticed the evening before any pain in the throat started. The enlarged glands in Case 2 were observed by the mother before the boy complained of any pain in the throat or neck, and in Case 3 immediately after the first chills the glands were observed to be swollen.

In Case 6 the swelling appeared on the fifth day, while in Case 7 the swelling of the glands was observed on the evening of the day when the patient first felt sick; the second swelling of the glands came as a surprise to both patient and doctor, and was the first symptom of the relapse.

In Case 8 the swelling occurred on the second or the

fifth day, respectively. In Case 11 the glands swelled the second or the fifth day—according to whether we count the "cold" in the disease or not. In neither of these cases was the swelling of these glands accompanied by any severe pains. The glands were not tender, but were hard, they showed no marked periadenitis and what must be considered as especially characteristic, the swelling concerned most often the glands anterior and posterior to, and behind the upper end of the sternocleidomastoid only. This rule had only one exception. In Case 7 the disease opened with chills, headache, pains in the abdomen, back, and sometimes vomiting. Complaints of some pain in the throat were present in all cases. In no case were the pains so severe as in a case of real tonsillitis.

The affection of the kidneys in this disease is rather striking. Among eleven cases three patients had acute hemorrhagic nephritis. The nephritis began in one case on the fifth day, in another on the seventh, and in the third on the eleventh day after all symptoms had disappeared and the glands had begun to get smaller. There is no other disease, except perhaps scarlatina, known in the course of which the kidneys become as severely involved as in this disease. Case 7 the patient had, besides small quantities of albumin, white and red blood cells and cubical epithelium in the urine. Traces of albumin were found in nearly all cases, even when the fever was low. The spleen and liver were somewhat enlarged in all cases, the spleen so much so that it was easily palpable, and the liver one inch below the ribs. Pain in the abdomen was a frequent complaint, and constipation a regular one. Adenoid vegetations were found in five of the cases. Characteristic for all cases was the lengthy duration of the swelling and the slow absorption. In three of the cases suppuration of the glands occurred. All cases were accompanied by fever, but in one case only did this reach as high as 105 degrees, while in the other cases it ranged between 100 and 104. It was a continual fever and disappeared by lysis.

The bacteriologic examination of the pus of three cases showed as follows: In one pure cultures of influenza bacilli, in the second influenza bacilli and streptococci, while in the last streptococci only were found. In Case 1 streptococci were found in the throat; in Case 3 influenza bacilli, diplococci and staphylococci; in Case 8 staphylococci and large diplococci; in Case 6 streptococci and diplococci.

The diseases had all the characteristics of an infectious disease, Cases 7, 8 and 9 would even justify one in calling the disease contagious. The prognosis is good in all cases. In Case 2 only, I felt uneasy for several days.

A SIMPLIFIED HEAT METHOD OF STERILIZING AND STORING CATGUT.

WILLARD BARTLETT, A.M., M.D.

ST. LOUIS, MO.

So many prominent surgeons have adopted my suggestions for the preparation of catgut[1] that I wish to describe methods which make the procedure vastly simpler in its application, and which at the same time remove any element of uncertainty regarding the results likely to be attained.

Catgut prepared according to this formula has been used by the Mayo brothers in almost 5,000 operations and has been adopted by such well-known surgeons as Drs. Burrell, Collins, Cushing, Deaver, Finney, Frazier, Meyer and Murphy, as well as the men on the staff of the Massachusetts General Hospital and on that of the Pennsylvania Hospital and many others. This is a sufficient testimonial to the worth of the procedure, and I am more than certain that the present modification of it here described can not fail to attract new users.

As at present recommended very little time or trouble need be expended in carrying out the preparation of catgut. The materials used are exceedingly cheap, while the requisite apparatus, as shown in the accompanying illustration, is very crude and can be found in any hospital or in any physician's office.

The process can be divided into three steps: (1) The physical preparation of the material, (2) its sterilization, (3) its storage.

1. The ordinary commercial ten-foot catgut strand is divided into four equal lengths, each of which is made into a little coil about one and one-half inches in diameter. By twisting the last free end about four times around this little coil the latter will maintain its shape. These coils in any desired number (I usually take about 120 of them at a time) are strung on a thread like beads on a string in order that the whole number may be handled at once. This string of coils is hung in a metal can, better still in a beaker glass, but is not allowed to touch

the bottom or sides. I suspend them by carrying the two ends of thread through a small opening in a pasteboard cover, which is placed on the receptacle. The same opening serves to admit a thermometer, which is carried down to exactly the point where its mercury bulb is on a level with the topmost coils. Liquid petrolatum is now poured in, the quantity being sufficient to immerse the catgut and the bulb of the thermometer.

2. The vessel is set on a pan of sand, under which is placed a tiny gas flame or merely sufficient intensity to raise the temperature of the oil to 212 F. within from one to two hours. A little practice enables one to guess the size of flame necessary for this purpose. This is best done in the evening, and the temperature allowed to remain at about 212 F. (a few degrees variation does not matter) until morning. The heat is then increased to such an extent that the temperature will run up to 300 F. in an hour; the gas is then turned off and the temperature of the oil allowed to return to about 212 degrees.

3. The pasteboard cover, together with the string of catgut coils, is lifted off, the superfluous oil is allowed to drop off, and then the thread is cut, allowing the coils to drop into the following mixture:

Columbian spirits	100 parts
Iodin flakes	1 part

1 "A Simple Heat Method of Sterilizing and Storing Catgut—Preliminary Report." Interstate Med. Jour.

The catgut is now ready for immediate use and will keep without deteriorating for any length of time. The jar may be opened any number of times, so long as a sterile instrument is used for removing the coils, since the iodin protects the coils that are left behind from accidental contamination.

The physical qualities of catgut so prepared will astonish the surgeon who uses it for the first time. I am very certain that a blind man used to handling catgut prepared by other methods would not recognize this product if it were placed in his hands. It is as supple as silk, highly elastic and almost as strong as the raw material. It is easily seen on account of its color, will not untwist when it gets wet on account of the oil remaining in it, and for the same reason is more than usually resistant to absorption. That the strands are sterile as well as antiseptic goes without saying.

A SIMPLE DEVICE FOR IRRIGATION OF THE BLADDER.

HUGO EHRENFEST, M.D.

Assistant Professor of Obstetrics, St. Louis University.

ST. LOUIS, MO.

The inadequacy of a piston syringe for irrigation of the bladder is a generally appreciated fact. A few of the numerous models of bladder syringes will stand boiling, but they are all rather expensive and easily get out of order. So long as the piston fits tightly, the fluid unavoidably is injected in jerks and not in a continuous stream. In spite of these obvious disadvantages of the piston syringes they are recommended by the majority of text-book writers, because they permit an exact estimation of the amount of fluid injected into the bladder—a point of considerable practical importance. In actual practice, the piston syringe is frequently supplanted by the glass irrigator or the rubber fountain syringe. The glass irrigator, while it permits an exact mensuration of the injected fluid, is not easily sterilized. The fountain syringe can be boiled, but precludes the determination of the amount of fluid which passes into the bladder. For this reason the rubber fountain syringe may prove a dangerous instrument in the hands of the inexperienced. The Pollitzer bag, which is used by some physicians, seems preferable; it can be boiled, at least a few times, and allows a rough estimation of the quantity of fluid injected.

It must be admitted, therefore, that an improvement of our present appliances for bladder irrigation seems desirable.

I present here the description of a simple apparatus, which I constructed some time ago, and which in my hands has proved extremely satisfactory. The principle of the device can be briefly outlined as follows: By means of air pressure fluid is forced out of a bottle, exactly as in Fowler's bottle used for hypodermoclysis. The fluid is conveyed through a rubber tube to the bladder. By the interpolation of a three-way stop-cock the solution can be alternately injected into and removed from the bladder by a corresponding turning of the handle of the stop-cock.

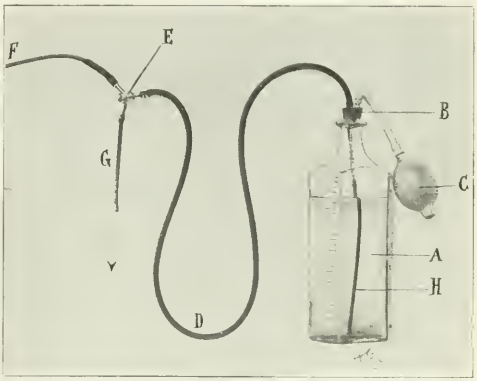
DETAILS OF CONSTRUCTION.

In the accompanying illustration the bottle A is a common one-quart medicine bottle such as can be bought in almost any drug store. These bottles, as a rule, carry a double graduation, on one side in ounces, on the other in cubic centimeters. The bottle is closed with the rubber stopper B. This stopper is perforated by two bores into which are screwed pointed metal tips for the attachment of rubber tubes. To the one tip is connected the air bulb C. The other bore connects on its under end with a rubber tube H reaching to the bottom of the bottle. The rubber tube D connects the bottle with the stop-cock E. This is a three-way metal cock which, I believe, can be bought in any instrument store. To this is attached a No. 10 or 11 Nélaton catheter F. The handling of the stop-cock is facilitated by a shortening of the catheter. Especially in gynecologic work, a catheter of about 7 inches is long enough. To the third tip of the stop-cock is joined a rubber tube G, which leads to the waste jar.

METHOD OF USE.

The apparatus is used in the following manner: The air bulb is detached and the rest boiled; it seems unnecessary to sterilize the bottle every time it is used. Of course, this bottle contains only sterile, as a rule antiseptic, solution. The bottle can be kept sterile and ready for use, if immediately after its use the rubber stopper, together with all the rubber tubing atached to it, is removed, and the bottle closed with another rubber stopper which has been boiled with the tubing.

Into the bottle is poured the fluid to be employed for irrigation. This solution can be kept in stock in a higher concentration, and with the help of the graduation of the bottle may be diluted to the desired concentration by the addition of sterile water. The stopper B is fitted tightly and the air bulb C attached to the corresponding tip. The stop-cock is turned so that it connects tube D with catheter F. Air is pumped into the bottle until the fluid escapes from the eye of the catheter. In this way the whole system is freed of air. If the apparatus is used preceding a cystoscopic examination, the stop-cock is set to connect tube D with G. The air is thus removed only from tube D, while the air within the catheter is permitted to pass into the bladder, where it forms the bubble which, during the cystoscopic examination, marks the vertex of the bladder.



The stop-cock is set into a middle position, which shuts off all three ways, while the catheter is introduced into the bladder. By turning the handle of the stop-cock with the thumb of that hand which holds the catheter between the first and second finger, the catheter is placed into communication with the waste tube G and the urine drawn from the bladder. The handle is then turned 90 degrees upward and tube D will be connected with the catheter. The other hand (usually the right one), now grasps the air bulb and slowly pumps air into the bottle. The escape of the fluid, both its celerity and quantity, are exactly observed on the graduation of the bottle. It may be mentioned in this connection that in this manner the capacity of the bladder can be ascertained in a most convenient way. If enough fluid is injected into the bladder the stop-cock is turned another 90 degrees with the thumb of the left hand, and the solution escapes from the bladder into the waste jar. This procedure can be repeated *ad libitum*.

I have given the description of the construction and technic of this little device for irrigation of the bladder in this detailed form, in order to prove that this apparatus can be reliably sterilized, is not likely to get out of order, permits the aspetic irrigation of the bladder under exact control of the flow, and can be used without the help of an assistant, practically without any preparations. It is obvious that the apparatus is cheap and can be put together by every physician. In an up-to-date office building, in which every room is supplied with compressed air, an appropriate hose attachment such as that commonly used by laryngologists for sprays can be connected directly with the bottle.

Of late convincing proof has been furnished that the cystitis subsequent to catheterization can most effectively be prevented (as first demonstrated by Baisch) if the bladder is irrigated with an antiseptic solution after every catheterization. The appliance described here is extremely suitable for such a routine combination of catheterization with bladder irrigation.

PYONEPHROSIS.

REPORT OF A CASE IN A NURSING CHILD OF SIX MONTHS. OPERATION, RECOVERY.*

CHARLES P. STACKHOUSE, M. D.
WILKESBARRE, PA.

History.—Charles S. was born Sept. 8, 1904, was entirely breast fed and was a typical healthy babe. As far as can be ascertained, no solid food had entered his stomach until the morning of the attack, when he was given a small piece of cracker. The bowels were regular and there was free excretion of apparently healthy urine.

On Monday morning, March 6, 1905, about 10 o'clock, he began to cry loudly, as if in intense pain. A laxative and some colic cure were at once administered, and after a couple of hours he was cooing as if nothing unusual had occurred. In the afternoon he was somewhat restless, and all night he was feverish. A laxative and a dose of niter were administered and a moderate response was obtained, with little or no diminution of restlessness.

Examination.—I saw him on the afternoon of the second day and found him very restless. His hands were in constant motion from the wrist, there was a continual closing and opening of the fists, some tossing of the head from side to side, and a slight grunt accompanied each expiration—all indicating severe pain.

The lungs were normal, the pulse was 130 and of good quality, and the temperature 102.6.

The abdomen was distended and tympanitic above the umbilicus, with considerable resistance and tenderness in the right hypochondriac and lumbar regions, while below the umbilicus there was little or no distention, resistance or tenderness, permitting careful examination of the lower abdomen without discomfort.

An enema of olive oil was immediately followed by a very free, normal bowel movement, and fractional doses of calomel given during the night gave free action of the bowels and kidneys, which resulted in a marked improvement in all his symptoms, although the temperature was still 101.4 and pulse 130.

On the fourth day his temperature and pulse became normal and apparently he had returned to his usual healthy condition.

Second Attack.—One week from the onset of this attack occurred a second, which differed somewhat from the first. After a few hours of restlessness and evident distress he began to retract the head and body, roll the eyes back, and appeared to be going into convulsions. There was the same pinched, anxious expression on the face, and each expiration was accompanied by a pathetic moaning cry. Examination found no trouble in the lungs; pulse was 130 and of good volume and temperature 103. There was now no distension or tenderness in the right hypochondriac region as in the first attack, while in the right iliac region the muscles were rigid and exquisitely tender, the slightest touch eliciting cries of pain. The same peculiar action of the wrists and hands was present at this time and continued until the operation.

After a very restless night the disturbance in the appendiceal region seemed accentuated, and there was added to the symptoms already described flexion of both thighs on the abdomen. At this time it was first noticed that he would cry just before micturating and that the urine had a strong odor and left a dark stain.

Wednesday, the third day of the second attack, he was decidedly weaker and the temperature was higher, while the pulse still remained 130 and of good volume. The facial expression was one of general misery. He had passed a very restless night, apparently in constant pain. Believing pus to be present, I asked for a consultation and Dr. Wolfe saw him with me, but as no mass was outlined it was decided to tarry a day or two, seeking, if possible, to avoid subjecting the little fellow to so dangerous an operation.

On Thursday he was restless and weaker, the temperature was higher, going to 104.2 toward night. There was extreme pain in the hypogastric and lumbar regions.

On Friday his condition was one of extreme prostration; the abdomen was distended and tender, the face was anxious and pinched, both legs were flexed, temperature was 103.4 and pulse 150. Dr. Wolfe was again summoned and the patient was examined under chloroform, when it was thought a small mass could be felt in the right iliac region.

Operation.—The condition was considered so urgent that operation was performed the same afternoon at the Mercy Hospital, Dr. Wolfe assisting. Through a small incision over McBurney's point, an abnormally long appendix was delivered and removed, but presented only slight thickening and congestion of the mucous membrane near the base and for the last inch of the distal extremity. Feeling positive that the severe symptoms could not have been produced by an appendix so little damaged, careful examination was made and a mass found posterior to the colon, lying on the lumbar vertebræ and extending below the crest of the ileum, which proved to be the greatly distended right kidney. The incision was extended upward, a small cross incision made on the lumbar side, and the kidney, which was freely movable, was delivered out of the abdomen. It was almost the size of the acute parenchymatous kidney of an adult, irregular, almost lobulated in shape, of bluish red color and fluctuated on pressure. On puncture nearly a teacupful of thin, brownish-yellow, offensive pus was obtained.

The parenchyma was about three-fourths of an inch thick and of a dark red, congested appearance. The fluid appeared to be chiefly in the pelvis of the kidney, but extended by at least two openings, into the kidney substance. The ureter was followed with the finger to the bladder and no obstruction was discovered, but as there was no sterile instrument small enough to pass from the kidney through the ureter into the bladder, and the condition of the patient did not justify waiting for one to be prepared, the kidney was anchored to the abdominal wall and the abdomen closed, leaving free drainage into the pelvis of the kidney.

Postoperative History.—For a week following the operation the condition was precarious. There was very free drainage of urine from the wound, but we had no evidence that the ureter was patulous. On the fourth day an aqueous solution of methylene blue was injected into the pelvis of the kidney, but no trace of it was found on the diaper.

One week after the operation, March 24, the patient was anesthetized and two filiform bougies were passed through the kidney and ureter into the bladder, when there was an immediate gush of urinous fluid from the wound. The ureter was apparently occluded for at least an inch. The bougies were left in place for two days, during which time no urine was voided naturally, but both kidneys were drained through the wound. After the filiforms were removed, both kidneys were drained through the bladder and the urinous discharge gradually disappeared from the wound. There was still a slight amount of pus on the dressings and occasionally there would be some urinous discharge, but by April 10 the wound had almost entirely closed.

On April 13 the temperature and pulse increased and there seemed to be swelling and distress over the kidney, indicating a blocking up of something. On inserting a probe considerable pus oozed out and he had immediate relief, with prompt closing of the wound.

From April 20 to 25 the kidney was apparently drained entirely through the wound. On April 25 he voided from the bladder, with very highly colored urine, about an ounce of thick, creamy or caseous material, resembling thick pap, after which he voided urine normally and the wound closed at once.

The wound opened again on May 7 and drained the kidney

* Read before the Luzerne County (Pa.) Medical Society.

until May 11, when he again passed the caseous material, followed by immediate closing of the wound, which has not been open since—now over six months ago.

It was interesting to watch the return of the kidney to its normal condition. The microscopic appearance of the urine was especially interesting, as it showed the gradual opening up of the individual tubules by the presence of hyaline casts, of red blood casts and of hyaline casts stained blue by the methylene blue used in testing patulency of the ureter. These, apparently, were casts of the entire tubule, some of them extending entirely across the field of the two-thirds-inch lens. These were observed as late as six months after the operation. At present the urine contains a trace of albumin, some pus cells and a few hyaline casts.

REMARKS.

As to the etiology of this condition I have reached no conclusions. It may have been the result of a congenital hydronephrosis; it may have resulted from torsion of the ureter from floating kidney; there may have been occlusion of the ureter from uric-acid infarct, or there may have been an acute pyelitis,[1] followed by occlusion of the ureter from the resulting detritus. The child has a slight phimosis, but I hardly think that could have caused the difficulty, except that it might have been a possible cause of the pyelitis.

The treatment following the operation was largely symptomatic. For the first week he was given enemeta of salt water with stimulants. Hexamethylenamin (urotropin), potassium acetate and Basham's mixture were tried, but neither of them was as satisfactory as potassium citrate.

210 Parrish Street.

A NEEDLE HOLDER, WHICH CARRIES A CONSTANTLY THREADED NEEDLE.

SELDEN I. RAINFORTH, A.M., M.D.

NEW YORK.

The necessity of repeatedly threading the needles that are commonly used and of inserting them in holders, when many sutures have to be placed, led me to devise an instrument which I have used for over a year with great satisfaction. The needle is set at right angles to the shank of the holder, is fastened in its socket by a small thumbscrew, and need be released only when the operator desires to replace it by another needle of different size or shape. The eye is near the point of the needle. Suture material, silk or catgut, is sterilized on a bobbin made to fit into the handle of the instrument and the thread unwinds as it is used. From the bobbin the suture passes through the hollow shank of the holder to an opening near its distal end, then across to and through the eye of the needle.

Fig. 1.—A needle holder which carries a constantly threaded needle.

Fig. 2.—Needle holder opened for threading.

Sutures are placed just as ligatures are passed with an aneurism needle. The two edges of a wound are pierced successively by the needle, the end of the suture is then grasped and the needle withdrawn. If the thread is now cut near the needle a single interrupted suture has been placed, and the needle, still threaded, is ready for the insertion of another suture. Similarly, any form of interrupted suture, plain, Czerny's or Lembert's, can be very rapidly put in, and even a Halsted's quilt suture, by introducing the needle a second time through the lips of the wound before the thread is cut. A continuous suture, except a continuous quilted suture, can not be made, of course, with a fixed needle.

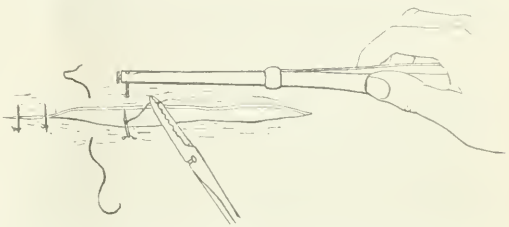


Fig. 3.—Needle passed through two edges of wound, forceps grasping the end of the suture to hold it while the needle is withdrawn.

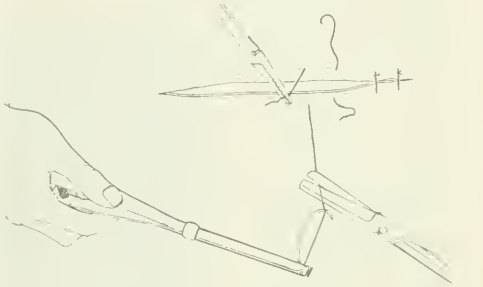

Fig. 4.—Needle withdrawn, still threaded, leaving suture in place ready to be cut off at the desired length.

An important point is the simplicity of construction of the needle holder and the ease with which it may be cleaned.

In laparotomy the proper closing of the abdominal wound in layers is tedious, but by the employment of this instrument the time required for that part of the operation is shortened at least one-half. The value of the needle holder as a time saver in perineorrhaphy, radical cure for hernia, and all operations of a similar character, needs no comment.

Broadway and Sixty-first Street.

1. Marcel Hartwig: Berliner Klin. Woch., Nov. 30, 1903.

The Record of the Schoolchild. When school opened last fall at Nice, France, a small blank book was given to each child, in which was recorded his name, age, residence, birthplace, date of vaccination, weight, height, chest measure, aptitude for games, and other particulars. Brief notes on hygiene are also contained in the little book. A corresponding card is made out for each pupil, which is kept by the medical inspector of the school on the card catalogue system. The book and card are to be brought down to date each year, and the physician can thus have an oversight of the growth and development of all the children in the school. The parents also can see from the booklet the physical progress their children are making. Morbid tendencies will be detected early, allowing a chance for correction. This combined system of cards and booklets was originated by Dr. C. Roux of Nice, and has been formally adopted by the municipal authorities.

AUTOMOBILES FOR PHYSICIANS' USE

ARE THEY PRACTICAL? ARE THEY DESIRABLE? ARE THEY ECONOMICAL? ARE THEY BETTER THAN HORSES?

THE AUTOMOBILE A GREAT ADVANTAGE TO ANY PHYSICIAN.

JOSEPH B. EARLE, M.D.
GREENVILLE, S. C.

THERE is no question about the usefulness of an automobile to a physician. It is so much quicker and can be left standing anywhere without an attendant. It can easily cover twice the ground in a day that a horse can, and in the summer, when the warm weather is hard on a horse, the auto is a great advantage, as both machine and driver are cooler when going fast.

Twice the Work of the Horse for the Same Cost.

The cost of running just about equals that of a horse and buggy ($12 to $15 a month)—and this is in favor of the machine, when everything is taken into consideration, as it will cover twice the ground and save much valuable time.

Every physician should equip his car with a good acetylene headlight for night driving. He should also have a pair of chain tire grips for muddy roads. During winter some of the roads here are at times impassable for a few days. Still, there are very few days during the winter that I can not go almost anywhere. I can always go within the city limits.

I have been using an automobile in my practice for about two years. I operate it myself and look after everything necessary to keep it in order unless I have an accident or want it overhauled—which I have done in the spring. I am using a single cylinder, 5x6 seven-horsepower runabout (103*), hung on side springs, and have a top and curtains and storm apron to protect from the rain. It cost $650 with $25 additional for rubber top.

My little car has surely done noble work, and it would be very difficult for me to keep up without it.

Fig. 1.—What one country practitioner calls the best investment he ever made.

THE AUTO AS A PHYSICIAN'S VEHICLE.

F. M. CRAIN, M.D.
REDFIELD, S. DAK.

DISCARDING the old reliable horse for the automobile requires so much expenditure of money, and involves so much uncertainty of success that many physicians are deterred from making the change. The experience of those physicians who have been pioneers in the use of the motor car, in their practice, scattered as they are throughout every state in the Union, ought to be a fairly reliable test as to the merits of the automobile as a physician's vehicle.

The testimony of those who have tried the automobile will undoubtedly differ widely. I have no doubt the difference is not in the machine, but in the men who run them. Some men are incapable of running machines of any kind, while others possess mechanical ability, either natural or acquired. To the latter class the automobile will prove reasonably satisfactory after they have studied the mechanism of their car and learned from actual experience those valuable lessons that come only from practical use and which may be learned at considerable cost and annoyance.

The Carburetor the Heart of a Gasoline Machine.

The trained ear of a physician, which quickly detects the least departure from normal heart sounds, serves him well as an automobilist. The normal sounds and pulsations of a gasoline engine are as characteristic as normal heart sounds, and when the regularity of these sounds become intermittent in character he quickly diagnoses the trouble.

An automobile is capable of doing the work of three good driving teams, and the driver can accomplish three times the amount of work, with more ease and comfort, than with horses. The auto enables the physician to spend more time in his office, that can be profitably employed in studying or recreation, the value of which can not be computed in dollars and cents. While it is a pleasure to drive a good team, their endurance is soon taxed to the limit under the pressure of long drives. Not so with the automobile. It is true that it has a limit of endurance, but so long as it is in working order and properly cared for, it is ready to do your bidding.

I have made over a hundred miles in eight hours, including eight professional calls, and the machine was capable of duplicating the trip without any extra work except replenishing the gas and oil. A machine that is capable of running continually for an indefinite period certainly commends itself to the busy physician. In country practice, where physicians are often times compelled to make from 50 to 100 miles a day, the horse can never compete with an automobile in the hands of an intelligent operator.

My troubles have grown less as I became familiar with my machine. During three seasons I have had to be towed in only twice, once on account of a broken chain and once a broken gas pipe. Last season I had practically no trouble, except a little tire trouble, the expense of which did not exceed $6. My necessary repair account during the entire season did not exceed $20.

Graft and Robbery.

There are combinations, however, that are operating not only to keep up the price of the automobile, but to make it expensive to procure repairs. Take for instance the cost of tires. It cost me over $200 to change my car from 3x28 to 3½x30 tire. This cost, without a doubt, represents a big graft, made possible by the rubber trust that controls every department of the rubber industry. Even the railroad companies seem to think the automobilist is a legitimate subject

* Reference numbers are explained editorially

for plunder, and proceed to work their graft, charging double first-class rates on automobile parts.

The Features of an Ideal Car.

An ideal physician's car has not yet been placed on the market. The nearest approach to it, in my opinion, is the car that combines: 1, Simplicity of construction; 2, accessibility to all the vital parts; 3, the minimum cost of operating; 4, superior material and workmanship in its construction; 5, the least amount of labor required to operate. To be more explicit, a 10-horsepower, single cylinder, gas engine runabout, water cooled, chain drive, two speed ahead, one reverse, geared to a speed not to exceed 25 miles an hour, equipped with a standard double-tube tire not less than 3½x30. After operating a single cylinder, 10-horsepower, for three years, and comparing my experience with those who have driven multiple cylinder cars, my opinion as to the superior merits of a single cylinder has become thoroughly fixed. A 10-horsepower single cylinder develops sufficient power for a tonneau attachment, whereby a physician's runabout may become a family vehicle.

I care for and operate my car (128). I usually spend half an hour before breakfast getting it ready for the day's work. I enjoy caring for and keeping it in order, but the height of enjoyment is reached when I operate the throttle on a good stretch of road. I frequently take my family on long country drives and they all enjoy the exhilerating influence of an automobile ride. My son, 12 years old, operates my machine with the confidence of an expert operator.

Permit me to relate the following to illustrate the confidence I place in my machine: Late one Saturday night I got a call to a town 38 miles distant. The entire trip would have to be made after 10 o'clock, and as the night was dark and the roads bad, I concluded to take the night train. I could not return before Monday morning. I told my daughter (17 years old) that she could drive out for me Sunday morning. About 10 a. m. she drove into town accompanied by another young lady. They were unacquainted with the roads and went 6 miles out of their way, making the 44 miles in three hours. I was at home at 3 p. m., ready for more long drives.

Fig. 2.—The car of a southern physician who lives in a region of very bad roads.

The greatest problem in automobiling is the tire question. The cost of keeping the car equipped with serviceable tires is far in excess of all other expenses.

One of the beneficial results of the use of the automobile as a means of travel is the effect it will have on the good road movement, thereby benefiting the general public as well as the automobilist.

DETAILS FROM EXPERIENCE.

C. H. BRYAN, M.D.
CHICAGO.

THE practicability of the automobile for business purposes is, I think, well established. In my five years' experience with several types of gasoline automobiles I have come to the following general conclusions:

1. The simpler the machine and the less parts, the less is the possibility of trouble.

2. The lighter the weight, the longer will be the life of all parts.

3. To be in the range of practicability at all, it must not have pneumatic tires.

4. It must be air cooled.

5. For city use it must be able to run in street-car tracks without damage to tires.

6. It should be high enough from the ground to prevent the vacuum from sucking up dust into the machinery and car and to clear obstacles, such as large stones and high centered roads.

7. It should have at least two cylinders.

A car possessing the above qualities and in the hands of a man who is willing to learn a few things about how to adjust it, is a great saver of money, time and physical energy.

Trouble Galore.

About five years ago I purchased a second-hand runabout with the idea that I could have it overhauled and made into a practical doctor's vehicle. After spending about $900 I found that I could not make it practical. Every change I made in any part would necessitate a change of other parts, from motor to tire. I soon abandoned this idea and purchased a cheap runabout, water cooled, pneumatic tired, with single cylinder and planetary transmission. It was fine for one day, then I hit a spike and put a tire out, then in rapid succession came pump trouble, leak in radiator, leak in gasoline pipe, broken spring, flooding carburetor, bent axle, broken balls, cutout cones, broken connecting rod, short-circuited coil, broken commutator and other troubles.

My average was about three professional calls to one to repair shop or tire store, with big bills in proportion, and a horse in the stable to pay for besides.

A large part of my trouble, as I know now, was due to cheap material and construction and to the fact that properly designed parts were not to be had at that time. In about five months this machine was down and out.

Trouble with Water Cooling.

My next experience was with a larger and heavier single cylinder car, with a detachable tonneau. It was rated at about 8 horsepower, water cooled clincher pneumatic tires, and altogether was a very respectable looking car. I had success with this for two months, after that I went over the same old route, except that my repair bills were larger. In winter I used all recommended drugs in the water to prevent freezing, with poor success, and when winter was over calcium chlorid had eaten up my water tank and radiator, all assurances from dealers notwithstanding. I think a galvanic circuit was formed between the different metals used in the construction of the water circulation. The principal trouble with this car was with pneumatic tires. After running the car a year and spending about $250 for tires, I devised a resilient solid rubber tire (106). After this I had very little trouble, and sold the car, after having used it two years, to try a new kind which looked more economical and practical. The old car, however, after three and one-half years, is still running in the hands of its new owner and the tires are still good.

Success at Last.

About a year and half ago I got my fourth machine (105), a high-wheeled affair, looking like a buggy. It had a double

equipped with roller bearings in every place possible to reduce wear. This buggy automobile I have found to be the most practical of all, for business or pleasure. It has very few parts to get out of order; no water to freeze, no puncturable tires, rollers in the wheels, consequently no axles to grease. The engine is well made and reliable. The air cooling actually cools. It will run in street-car tracks without injury to the tires; it is noiseless and speedy. On long country runs it does not raise dust or give any other trouble. Some object to it on account of its looks, but I find it so practicable as to remove this objection.

I find that with a good practical machine a physician can make better time and do more business with less physical effort than by the horse route. If a horse goes lame it may be weeks before the trouble can be fixed. If the machine breaks it can be replaced much quicker and easier. A machine will not suffer out doors in cold and stormy weather. It will not wander away and can be cared for by oneself much easier than a horse.

This machine is cheaper than a horse in the city and much more satisfactory in every way.

I now use my auto for all my work and pleasure and do not find it necessary to keep a horse or to take the street car.

THE AUTO TOO MUCH TROUBLE TO KEEP IN ORDER.

F. A. SWEZEY, M.D.
WAKONDA, S. DAK.

IN my practice, which is entirely country work, I have used, for two seasons, an 8-H.P., one cylinder, water-cooled, gasoline runabout (1111), and I find that the automobile is not practical for such work, owing to bad roads and inclement weather. They are more for pleasure than for general business use, and I would not advise any physician in country work to buy one and to rely entirely on it. In night work or in wet or cold weather an auto is very annoying; in fact, I have sold mine, and will never buy another. As my friend, Dr. Jepson, of Sioux City, expressed it, in reply to my question as to whether or not he was using his much, "I am not, as I do not get time to run it." The worst drawback is keeping them "tinkered" up every day before using, with the dirt and grease that goes with it. The expense for repairs is very little, but the time put on it is valuable.

IT ALL DEPENDS.

H. A. RODEBAUGH, M.D.
COLUMBUS, OHIO.

THE automobile consists of many working parts and, like all other delicate machinery, requires frequent, intelligent inspection, and prompt correction of little wrongs in order to secure efficient and economical service.

The physician who keeps his horse and buggy in the pink of condition by looking after the food, drink, shoeing, etc., of the former, the oiling, tightening of nuts and other little repairs of the latter, and whose office equipment, batteries, instruments and all other appliances are always ready for instant use, will have no difficulty in operating an automobile as economically as he would maintain horse-drawn vehicles for the same service ($20 to $30 a month).

The Careless Physician Will Have Trouble.

On the other hand, the doctor whose horse is always lame or sick, whose buggy rattles and looks rusty, whose office batteries are always out of order, whose instruments are often about, sandwiched between books and bottles, one, in short whose office resembles a jungled-up junk shop, will be easily disappointed in his effort to use an automobile unless he is willing to employ a chauffeur.

To use an automobile successfully the physician requires a first class machine. The cheaply constructed auto of any kind can not be operated economically nor efficiently.

For the physician's use, an automobile should be light, strong, speedy and easily operated. To conform to these requirements it is necessary to have an air-cooled cylinder to diminish weight and to eliminate plumbing troubles. My machine is representative of this type, and it is extensively used by physicians (101).

One Way to Swell Expense Account.

Next in importance is a thorough knowledge of the mechanism of operation. A physician who was condemning automobiles because of the cost of fuel was found, on investigation, to be running his machine with the throttle wide open, regulating the speed by the ignition lever, thus entailing enormous loss. He was astounded at the result when this error was corrected. It is estimated that 90 per cent. of the motorist's difficulties are due to ignition troubles.

In the case of physicians who are supposed to be familiar with electricity and batteries, these annoyances should be reduced to a minimum.

AN OUTLINE OF THE IDEAL CAR.

C. P. THOMAS, M.D.
SPOKANE, WASH.

I BEGAN using automobiles exclusively four years ago, giving up two horses. I have spent a considerable amount of money in trying and discarding rigs, having owned seven (196).

I am unequivocally in favor of the automobile for the physician in any country where one can be used. It would pay the majority of busy country practitioners to have autos for use at the time of the year when roads are passable, discarding horses except when the mud is so deep that it is impossible to travel in an auto. My auto costs me about $24 a month. To keep two horses cost me $36 a month.

It is necessary, however, to buy the right kind of a car. I would exclude altogether any other motor power than the gasoline engine with electric explosion. Steam and electric cars are very heavy, bunglesome, more dangerous, shorter lived and less satisfactory in many respects.

Four Cylinders Best.

I would advise wheel steer and multiple cylinders (in front and not under the car where they are inaccessible). Four is the best number, since they may be small, causing less car vibration during explosion, and the pull is steadier, thus greatly lengthening the life of the rig. Another marked advantage in multiple cylinders is that if one goes out of commission for a few minutes the others will take it along comfortably until the dead one comes in again. I believe upright cylinders to be more satisfactory, the wear of the rings is more even and the machinery less complicated. Chain drive with planetary transmission is satisfactory if well protected from dirt. The shaft drive, if well made is all right, and permits three speeds forward, which is of marked advantage, allowing hills of considerable grade to be taken with ease in the intermediate speed.

Advises Air-Cooled Engines.

Air cooled engines are far superior to water cooled ones, because they cost less to build, permit great reduction of weight (involving less fuel and tire expense), save much expense for repairing of plumbing (the water radiating system being delicate and easily deranged), and do not freeze up in cold weather. I know from two and one half years' personal experience that the air cooled engines are sufficiently cool for good service. Large cars should have fans attached to increase the circulation of air.

The physician should buy an automobile with at least two horsepower (actual, not estimated) more than there are hundreds of pounds weight of the rig. For comfort in riding over rough roads, speed and durability, the car should not much exceed 1,000 pounds weight, having preferably 12 horsepower. There should be seats for two and only two.

Two Weeks' Course of Instruction.

The next most important factor is that the driver must know his car. It is unsafe for any man unfamiliar with gasoline engineering to attempt long trips until he has spent at least two weeks with a good skilled demonstrator, who has shown him why and where everything works. Many little matters can be adjusted in a minute if understood, but they can lay one up for a day if one does not know how to find them. This lack of knowledge on the part of operators has tended to make the use of automobiles less popular.

Any busy practitioner in city or country can do three times as much work, if he has it to do, with a good auto than with the best team. It is more comfortable, more cleanly, more pleasant and less nerve wracking and not more expensive than the use of horses.

Autos Used Every Day in the Year.

In this climate in the city, even off the pavements, I operate my wagons (197) every day in the year, having them washed and oiled daily at the garage. I also have all adjustments done there, but most of them I could do if I cared to take the time. The weather is never too wet, or too cold or too hot or too dry to leave the auto out in front of your office, hospital or patient's residence while you attend to your business, unconcerned about the welfare of some poor beast of burden.

It must be remembered that a wagon filling the above description (which should, by the way, have a canopy top with glass front for the winter use, the glass being removed if preferred during the summer) can not be purchased in the market for much less than $1,500. While there are a number of small single cylinder rigs for sale cheaper, some of which give very good service on good roads and in good weather, I do not believe it wise to purchase them, the cheaper rig being more expensive in the long run.

A HIGHLY COMMENDATORY STATEMENT.

A. N. COLLINS, M.D.
DETROIT.

My experience has been with two small one-cylinder cars, weighing 750 and 1,150 pounds. I have used them constantly for over four years in my practice, which is largely limited to the city of Detroit. I have cared for my machine nearly all the time. The first year I ran my light runabout one year at an expense of $20 per month. The machine enabled me to do much more work, to have more leisure than with two single rigs, to dispense with the coachman and to have much pleasure and satisfaction. The drawbacks were an occasional let down at an inopportune moment, greasy clothes and, at times, disappointed patients.

Auto Far Cheaper Than Horses.

Covering a period of twelve years, my expenses for two single horses and rigs with man, board, etc., figured $113 per month, $1,350 per year. I paid for my machine (107), paid all its expenses and was $175 under the cost of horses the first year. Owing to the tire and other delays, I decided that two machines would be the only solution of the difficulty. In March, 1904, I purchased a second runabout (108) which I now use. Largely owing to the uncertainty of tires, I was still annoyed by the uncertainty of getting to my patients. I nearly always had a machine in reserve, but that helped me little when a tire went down in the middle of my rounds.

Solid Tires Solved the Difficulty.

In May, 1904, I equipped my latest purchase with four-inch solid tires (109), on which I have run constantly with perfect comfort since, now nearly twenty-three months. After putting on solid tires, I found little or no use for a second machine. I sold my first purchase for $220 in June, 1905. Since that time have had as little inconvenience and delay with my machine as I would experience with horses. My monthly expense for twenty-three months has been under $18 per month for all expenses. I have entirely eliminated the tire expense and delay, having had not one cent's expense during this time. Aside from gasoline, oil, alcohol and batteries, the main expense has been one repainting and three overhaulings to put on new sprocket, gears and chains. I have worn out three sets of sprockets, gears and chains. The expense of these replacements has averaged about $50 each time for labor and new parts. I have had no breaks that are not common to the same machine equipped with pneumatic tires.

Twenty Thousand Miles on Solid Tires with Comfort and Economy.

A modern well-made machine should run at very small expense when one eliminates the tire expense, as can be done by using solid tires. I have demonstrated this beyond any question, the machine men and tire men to the contrary notwithstanding. Solid tires can be used with perfect comfort, and are a much better winter tire than pneumatics. My machine has made over 20,000 miles, and the tires look good for another year. The most helpful experience I can contribute is this feature of having demonstrated the practicability and comfort of using solid tires for daily work. To have a tire that never goes down or gives trouble or expense does away with 95 per cent. of the uncertainty of the auto.

No Trouble with Water-Cooling Device.

I can not speak for country work, but for city use there can be no question as to the economy and efficiency of the auto in our work. We need a strong, light machine, well wired, with strong axles and easy springs. I have for three seasons used for an antifreezing mixture, simply water with 25 per cent. wood alcohol. I have never had any trouble with it, never burst a radiator or broken a pump. At first I added glycerin. I found no benefit from it. One-half the usual quantity of cooling solution is ample in cold weather. Keep the solution well down in the tank. The proportion of alcohol should be kept up.

Auto Ranks Next to Fishing as Recreation.

My machine is kept in my basement, where I have my work bench and tools. If one is inclined at all to mechanics, the few minutes each day or the occasional hour or two spent at putting the machine in shape is a pleasant diversion and gives a perfect rest from the line of thought ever in our minds. I look on it as next to fishing for forgetting other work. A few moments before breakfast is sufficient to oil it, inspect it and put it in order for the next twenty-four-hour run. It seldom needs anything further. In this way you become a part of your machine and it becomes a part of you. I no sooner think of my machine not going than I do of my legs not going. My whole experience is wholly in favor of the auto as compared with horse power in our work.

THE DIFFICULTIES OF EXPERIMENTATION WITH AUTOS.

C. B. MILLER, M.D.
HELENA, MONT.

In the spring of 1903 my son, while East brushing up on professional topics, became interested in the automobile, investigated a number, and finally ordered one, which was to be shipped in a month. A month's interest on the money did not look large to him, so he paid full price and the vehicle was shipped *four* months later. In the meantime, he concluded not to remain here, and, when the machine arrived, *my* experience began. The first evening I drove about 2 miles, up and down some pretty steep grades, and was well pleased. The next evening I went to see a patient 6 miles in the country (having my horse and buggy follow). I made the trip out in excellent time, but on the return a carburetor trouble developed (as was afterward discovered from a lump of solder lodging on top of float) and much gasoline leaked out.

When we got well into town the commutator loop had worn through and was giving a spark that would have done credit to the best *x*-ray machine. This set the gasoline on fire, and but for a lawn hose that was being used near by my subsequent trials might have been avoided. The manufacturers promptly sent me a new commutator and ignition cords, for which they charged full price. Being about as good mechanic as doctor, I repaired the old loop, making it much better than when new, wrapped the burned wires with adhesive plaster and soon had the thing going again. I tried two other carburetors before getting one that was a success and had several so-called experts working on the machine while I was daily acquiring experience—and possibly losing religion. I never started out with the certainty that I should not have to be hauled home, as frequently happened. I returned the motor to the factory in December, 1903, but it did not do any better, and in January, 1905, after an accident, the manufacturers said it would cost $40 or $50 to repair the motor, and I shipped it to them again. They returned it *in five months* with a bill of $75, but after an exchange of a few pleasantries, they generously threw off $10. By this time the expense had reached the sum of $223.40, not counting original cost or freight, and I had driven less than 200 miles, and kept my horse and buggy as before.

Fig. 3.—The car of an Indiana practitioner.

Runs Through a Montana Winter.

In reconstructing the motor the company greatly improved it, and since that time I have driven 405 miles, through snow, mud and on ice without the slightest fear of having to be hauled home. One trip was 14 miles in the country and back, through from two to eighteen inches of snow, considerable of the distance drifted and unbroken. I dispensed with a horse and have done all my work with the machine, out every day and frequently at night. We have had an unusual snowfall this year and two months of nearly continuous sleighing, and no other auto has been on the streets except occasionally on a fine day. We have no level streets, all have grades of from 2 to 25 per cent., and this makes the use of a machine more difficult than in most cities.

All Expense Less Than Five Dollars a Month.

My total expense since September 24 has been $25.25, which includes an improvement on the brake, change in connecting rod and cover over rear of body, in all, $8.25, $5 rent of ground, two sets of batteries, a few minor repairs and 25 gallons of gasoline, of which I have 5 gallons on hand. My horse cost $25 per month for board, besides shoeing and repairs to buggy and harness, and I would dislike very much to return to the use of one. I use a vehicle (110) with 44- and 48-inch wheels, solid rubber tires, stationary roller-bearing axles, double opposed cylinders, air-cooled, sliding-gear transmission, with two speeds forward and reverse, chain-driven counter shaft, rope drive to rear rims of wheels, maximum speed of about 20 miles. I believe this is the best kind of a machine for a physician who does his own driving and care taking. It is easily controlled, clears the ground 18 inches (a great advantage on country roads), runs as fast as the laws of most states permit, is not high priced, and under ordinary circumstances is not expensive to maintain. Being air cooled, it can be used in the coldest weather, may be left standing out all night—as mine has frequently—without fear or sympathy for the horse, and does not cost anything when not in use. For use in daily practice of medicine, I would not exchange mine for any of the numerous cars in the city costing from $650 to $3,500.

Enjoys Repairing in Leisure Moments.

As to housing, I leased a part of a vacant lot near my office and had a corrugated iron building 10x12 constructed. It contains a bench, vise and necessary tools for ordinary repairs, and I can do most of them in my leisure moments and enjoy the diversion. I have washed out crank case once and cleaned spark plugs twice in five months, and it requires little time to fill gasoline tank and oil cup occasionally. I can run the machine out and make an ordinary call in the time I waited for my horse.

Simple things often cause great annoyance, none more frequently than electrical disconnections. I have known autoists to have to be hauled home, and it once happened to me, on account of a broken or loose battery connection. While a volt-ammeter is valuable in ascertaining condition of battery cells, a much more useful article is an ordinary buzzer, such as is used as a substitute for an electric bell. By attaching two short cords which can be applied to the elements, any break in the circuit can be readily ascertained. The strength of the battery or of different cells can also be sufficiently determined. It is inexpensive and worth its weight in silver, at least, to the automobilist, and one should always accompany the machine.

If I desired a machine for pleasure or touring I should want one with three to six cylinders, 30 to 40 horsepower, air cooled and shaft drive, but such are too expensive for ordinary practice.

Manufacturers Do Not Deal Fairly.

The trouble is that many manufacturers, after getting your money, do not seem to care at all whether the machine meets your expectations or not. If living at a distance you pay for it without knowing whether it is properly assembled or will turn a wheel, and the guarantee is practically valueless. No one should buy an automobile of any kind or make without expecting "a heap of trouble on the old man's mind."

AN EXPERIENCE OF FOUR YEARS WITH ONE CAR.

IRA M. COMSTOCK, M.D.
NEW YORK MILLS, N. Y.

AFTER four years' experience with the same motor vehicle (125), getting better service each year from it, and a twenty-five years' experience with horses, I prefer the automobile for my use. The vehicle that can shorten distance from one-third to one-half is pre-eminently the doctor's best transportation.

The requirements in a motor vehicle for a physician's use are light weight, high power, simple mechanism, large wheels, long springs, few bearings, and equipped with both batteries and magneto, as a little mud, water or oil will queer the magneto at times, and if you have a set of live batteries, switch them on and go on without loss of time. My machine has 10 horsepower, triple-cylinder motor and weighs 950 pounds.

Sent His Man to Factory to Learn Care of Auto.

My machine is kept in the barn with my carriages, and is cared for by my man of all work, whom I sent to the factory for two weeks to familiarize him with the construction of the vehicle from the ground up, to learn how to keep the machine in the most serviceable condition, to make ordinary

repairs and adjustments; in fact, to see that it is always ready for use.

The cost of the motor carriage was $1,250 at the factory. The total expense of maintenance for four years, including freight and express charges on machine and parts, accessories, repairs, new rims and tires, gasoline, cylinder and lubricating oils, batteries, magneto, insurance, registration fee, tags and number, expense of sending man to the factory for two weeks' instruction, the expense of an expert from the factory to start and give me instructions, in fact, every expense caused by the ownership of the machine, $749.28, a yearly average of $187.32, which is very close to the cost of maintaining my horse and carriage for the same time, and the auto has done the work of two horses.

Cheerful Audiences at Roadside Repairs.

The tires have been the most troublesome part of the machine. The disadvantages are the frightening of some horses and their timid drivers, the occasional necessity of making roadside repairs in the presence of an audience of guying smart Alecks, dodging missiles thrown by hoodlums and the discovery that there are some "road hogs" who are not automobilists.

THE PHYSICIAN'S AUTOMOBILE INDISPENSABLE.

HENRY ENOS TULEY, M.D.
LOUISVILLE, KY.

THE question must be approached from several standpoints: cost, maintenance, repairs, and finally comparison with horse and buggy. For ordinary city use the air-cooled machine probably has some advantages, as no trouble is had with antifreezing solutions made necessary in winter in the water-cooled cars. In my judgment the water-cooled car has many advantages in long-distance driving and touring.

Tires the Chief Source of Trouble.

Eliminating tire troubles, which on city streets will continue to be the principal and greatest source of trouble, the automobile is the decidedly best method of transportation for the busy doctor. I have been driving a single cylinder, water cooled, 1905, machine (102) for a year, at a cost in repairs and maintenance decidedly less than for the keeping of one horse. My machine is oiled and washed in my own stable, and a garage is not visited except for the repair of punctured tires (I find it decidedly more convenient and less troublesome to have this repair made by men of experience than to attempt it myself). For those who have the time and inclination a great deal of troublesome tire difficulties would be obviated by the use of the quick detachable tire devices put on the market during the past year.

The runabouts, or the small, four-seated touring cars, such as mine, are the only practical machines for the every-day use of the physician. I look on my machine as indispensable to my work, and even at a cost decidedly greater than the horse and buggy, I would still be in favor of its use.

SYNOPSIS OF A CHICAGO EXPERIENCE.

ARTHUR R. EDWARDS, M.D.
CHICAGO.

WHEN I bought an automobile over three years ago some friends laughed rather indulgently, but the machine has done exactly what I hoped for. The first months were full of surprises, stops and suppressed—as well as distinctly voiced—invectives.

Some annoyances were due to mechanical imperfections which have been removed by recent improvements, but most were due to my own ignorance of the simplest mechanics. The grinning spectators of my initial troubles were rather irritating, because I was never certain that I could locate the trouble. Nowadays nothing stops the tried autoist for more than a few minutes. The tyro doubts such optimism because of unhappy experiences with the dealer, repair man and garage keeper, who too frequently impose on his helplessness. The autoist is never happy till he knows exactly what the difficulty with his engine is; long delays and longer bills are the price of his ignorance, which is often not much less than that of the so-called mechanic.

Advantages of Air-Cooled Motor.

There are many splendid water-cooled machines on the market, but I believe that the following advantages are proved in favor of the air-cooled motors for a physician who wants to run his own car:

1. *They can not freeze.* I have run every day for three winters, through snow and at as low as 20 degrees below zero. The car can stand out of doors for hours during office hours, or even over night. No shelter is needed nor a driver to keep the engine moving lest it freeze.

2. *They do not heat.* With accessory exhausts they climb long hills and traverse muddy or difficult roads fully as well as water-cooled cars.

3. *They are lighter.* Since the heavy water jackets are unnecessary, they are easier on tires.

4. *They are more simple.*

Fig. 4.—A city physician in one of the parks.

Good Service on Roads of All Kinds.

1. *Service.*—I have done all my work with my machine (136). The only time it was out of service was two half days when improved auxiliary valves were installed—a voluntary, not an enforced, interruption. Our city roads are fairly good, but I have gone through deep mud and horrible roads in town. In addition, with my wife and small boy I went to New York and back, going over every kind of road, some equaling the artillery roads of France and others full of stones, ruts, piles of gravel and huge masses of plowed turf, thrown on the roads to "improve" them. We went up steep hills, through washout, sand, deep mud and water axle-deep.

2. *Expense.*—Reviewing my closely kept expense account, my total expense for the year has been $336, an average of $28 a month. This includes $15 a month at the garage (rent, washing and polishing but not delivery, for I call for it), oil, gasoline, charging batteries, $75 for new tires or vulcanizing, and $25 for new or extra parts, accessories, tools, etc.

3. *The Daily Attention Required.*—This I figure at fifteen minutes. The machine should be well oiled every two or three days and once daily flooded—while the motor is running—with kerosene to cut out the thickened oil, carbon and dirt. The vibrator points and springs in the coil need a few minutes' attention about three times weekly, to keep the platinum surfaces even. Once or twice a week every bolt should be looked after.

How to Eliminate Sources of Trouble.

4. *Troubles.*—a) Plugs: I have not touched a plug for [illegible] months, the accessory valves carrying off contaminating oil and carbon. (b) Vibrators: (See above). (c) A dead battery: One should always carry an extra battery. (d) Tires: Punctures are few with tires of foreign make, though the American product seems better in the last year. There are vulcanizing preparations with which the punctured tube can be made good as new when one returns home. Two or three extra inner tubes should always be carried. I have gone eleven months without a puncture and then had eight in one afternoon! (e) Chain: A broken chain may be repaired in fifteen minutes if there are always some master links in the tool box. Breaks are positive "heart blocks" without these links, a cold chisel and a hammer. (f) Slipping, skidding and spinning in mud, ice or snow are prevented by using detachable chains on the rear wheels. Loamy roads are very hard to travel. Much trouble is due to other meddling with or actually running the machine. Switch locks prevent any one else from starting the car.

5. *Time Saved.*—On short trips one saves half his time and even more on longer courses.

6. *Accessories.*—The auto driver must carry extra plugs, inner tubes, a few master links, an extra battery, and extra float (for the carburetor), a pump, jack and set of tools well secured under lock and key and, therefore, always at hand.

7. *Health and Recreation.*—The saving of time, the fresh air, the absorption in the car in motion and the possessing of a hobby which one enjoys while actually doing the work brings one home at night fresh and ready for his reading.

THE AUTOMOBILE IN MAINE.

LANGDON T. SNIPE, M.D.
BATH, MAINE.

CHIEF among the questions which confront a prospective buyer of an automobile are: "Can I afford it?" and "Can the machine do the work of the horse?" The first question each man can easily decide for himself after studying the cost of the machine and of the upkeep.

Uses Horses in Winter.

The second question is largely one of roads. In some localities the machine can be used with pleasure all the year, while in others a very satisfactory solution of the problem is found by using a machine in summer and fall and a horse in winter and early spring. I belong to the latter class, and after one year's trial of this plan I would be sorry to return to the permanent use of the horse.

I began using my gasoline machine (120), May 20, 1905, and continued using it till December 14, when I returned to a horse. In this period the machine never failed me, and as I was ignorant when I started and still am for that matter, this is an excellent recommendation for the machine.

An Itemized Expense Account.

I [illegible] has been as follows:

FIRST COST.	
Cost of machine	$1,300.00
Freight	30.00
Insurance [illegible]	20.00
RUNNING EXPENSES.	
Gasoline	$42.76
Lubricant	5.90
Batteries	0.65
Repairs	4.65
Labor	8.16
Accessories	18.57
Repairing tires	2.10
Total	$88.79

SUMMARY.	
Running cost per mile (2,744 miles)	$ .032
Running cost per mile (omitting accessories)	.025
Building automobile house	160.62
Registration and license fees	4.00

It is almost unnecessary to say that an expense account for a single year is liable to be deceptive, as the experience of a series of years is necessary for real comparison and economy.

Great Diversion to Care for the Machine.

I keep the machine in a house 16x14½ feet, built for the purpose, and I care for the machine myself. This I find a great pleasure, and as a mental and physical diversion it is of much value. If one chooses to have a man care for the machine much time is saved compared with the use of the horse.

The simple fact that an automobile is not used the whole winter is no argument against the advisability of a physician's owning one. With a winter like the present one the use of the automobile or the horse is largely, if not entirely, a matter of personal choice. In city practice or in the country if there is little snow, an automobile in which the driver is well protected would be all that could be desired, but in Maine the horse will continue to be superior in winter. It may be on account of this fact or it may be notwithstanding this fact my enthusiasm for the machine is as great as ever, and I anticipate the enjoyable and satisfactory use of it when the roads are once more in good condition.

Unless a man expects to buy a new machine each year he should avoid the cheaper grades. If used for a series of years the higher priced runabouts are in the end cheaper. For the greater part of the year, though a machine costs a little more than a horse, it is much more comfortable and enjoyable and a great time saver.

AN OUTLINE OF THE PHYSICIAN'S IDEAL CAR.

C. E. ROGERS, M.D.
MONTEVIDEO, MINN.

I HAVE owned three cars and have traveled enough miles in them to equal more than twice around the world. My observation along the lines of design, construction, operation, etc., has been extensive, but my affirmations must be accepted as my personal opinions.

The engine should have multiple cylinders; gasoline is best and cheapest fuel; sliding-gear transmission, best type; drive, of the shaft pattern; cooling system, water (alcohol, glycerin and water for winter use); half elliptical springs; double tube tires; storage battery for spark or ignition; acetylene lamps (lens mirrors and gas tank), etc. An ideal car for a physician should be single seated (capacity two persons only); have plenty of carrying space; weigh not more than 1,000 pounds (less if possible); possess 12 H. P.; have a ground clearance of not less than 12 inches; have a full top; a speed of 40 miles per hour and cost not more than $1,000. Type of engine, transmission and drive, mentioned above, allows of easy access from upper side of car to all working parts and is easy to care for. Gloves only need be soiled in care of car, such as oiling, filling gasoline tank, etc. Wheel steer is generally adopted.

Price, weight, ground clearance, etc., mentioned above, are the lacking essentials at present of my idea of a model car, but leaving these questions out, several cars made at the present time correspond closely to my ideal.

Would Not Accept a Team as a Gift.

I have never been stalled on the road with my present car (123), and it has given me no trouble whatever. I have never paid out a cent for repairs, and have covered nearly 3,000 miles with it in all kinds of weather and on all kinds of roads. I can make twice the number of miles with it on good roads that a team can make and with more comfort and at an expense not to exceed one-fourth of what a team would cost. A team would not be accepted by me as a gift for use in practice. I do not mean to say a team is useless, because when the snow is deep and drifted badly, it discounts any automobile yet made. The fact is, under such conditions, an automobile is worse than nothing, but exclude snow and snow drifts, and the horse is simply "not in it" with the automobile.

A word about sliding transmission, three speeds forward

What is known as the intermediate gear is of incalculable value for time making as compared with a two-speed forward transmission. Many times when the roads are too muddy or rough to run on fast gear the intermediate works beautifully. Also, when a hill can not be made on fast gear. Shifting from a fast to slow gear on a two-speed forward transmission makes too much difference in speed of car. Here is where the intermediate gear shines.

Members of the profession, feeling the need of better help in time making, get rid of your horses and buy an up-to-date automobile. If you desire to take your family or neighbors out for pleasure, buy a touring car, but for the practice of medicine, a runabout.

THE CITY PHYSICIAN SHOULD HAVE AN AUTOMOBILE.

J. B. BOUCHER, M.D.
HARTFORD, CONN.

I WAS a great lover of the horse until two years ago, when I transferred my affections to an automobile. The first year I ran a single cylinder air-cooled machine 5,000 miles. It was out of commission but one day. I then sold it and bought a two cylinder of same make (117). This covered 5,000 miles during the past season and was out of commission about two days. It has been on the road all winter, excepting about two weeks in deep snow. There is no comparison between it and the horse for convenience. I keep it in a barn back of my office, it is ready night and day, it is cared for by my man—I believe that's one reason why I have had such good success with it. It may be my notion, but I have little faith in the garage.

Costs Same as Horse in Long Run.

Now for trouble. Last year I had only one tire puncture, this year three or four. I believe the large tire is more economical. There are a number of little things that must be looked after; small adjustments, etc., most of which I think can be done under the instruction of the owner if he understands his machine. I would advise the physician to learn to know his machine thoroughly, and not to depend on others or he will have many an annoying stop. As to economy, during the season repairs, gasoline, oil, etc., cost about one-half as much as a barn bill when you require two horses, but when you take into consideration tire trouble (ordinary wear) and the depreciation in the value of a macine from year to year, realizing that on a $1,600 machine run one season you would have to sacrifice five or six hunderd dollars if you sold it, I question if there would be much difference in the price of automobile and two horses at the end of five years. I believe the balance, if any, would be in favor of the auto, but, as I said, the convenience far surpasses the trouble.

Far More Pleasant Riding in Auto.

There is another side to it: You can accomplish much more work in a day with the auto. There is a fascination about the machine that grows and makes the work of travel a pleasure instead of labor, as is often the case with a poor tired horse. I believe the city doctor can run a machine with better success than the country doctor. I also believe that if I practiced in the rural districts I would not change the faithful horse that is always sure, although a little slow.

TESTIMONY FROM THE SOUTHWEST.

J. A. BOWLING, M.D.
ALVA, OKLA.

I AM an enthusiastic advocate of the auto for the physician. I live on the Salt Fork of the Arkansas River, and up and down stream the roads are sandy and very hilly, but away from the river the roads are generally good, except after going west and south 15 miles, then the country is sandy and hilly again. But I have not had any trouble yet on any of these roads.

I have a single-cylinder, copper-jacket, water-cooled gasoline engine, rated at 10 horsepower, chain drive with detachable tonneau, planetary gear, two speeds forward and reverse (132). By spending one-half to one hour each day, looking over and making any adjustment that may be needed, I am always ready for emergency calls. I have two oil lamps and one large acetylene lamp, which give ample light for night driving.

The cost of running my machine has been less than keeping one horse so far. I have 3x30 pneumatic tires, but I believe solid cushion tires would be best, for they would last longer and do away with puncture troubles.

Cold Weather Stole a March on Him.

About the only trouble that has amounted to anything was a freeze-up this winter. I made up some antifreezing solution, but waited for cold weather before putting it in; but the cold weather came in the night, and when I arose in the morning, behold, my radiator was frozen and bursted. I sent for a new radiator, but before it came a repair man fixed the old one. I am reserving my new radiator until after freezing weather is over.

Had it not been for the freeze-up I would not be out one cent for repairs, except I broke one leaf in my front spring, which I had to have welded.

A doctor should study his car and understand its anatomy and physiology; then if something goes wrong on the road he can remedy the defect and go on, and will not be compelled to send for the repair man and to suffer delays and expenses.

Saves Him Time for His Practice.

I received my car Oct. 11, 1905, and have run about all the time since, except when the roads were very muddy. I do not believe it pays to run an auto when the roads are muddy and slippery, because if you try to go fast you are liable to skid into the ditch or into the fence. I often make drives into the country of 25 to 30 miles, and if I use a team it will take me all day or all night, and the team is nearly played out and so am I. But with the auto I can easily make the trip in one-half of the time, and thus I do not have to neglect my patients at home so long.

Taking it all in all, I would not like to be deprived of my auto. Besides making calls in one-half the time, there is something about the auto that is infatuating, and the more you ride the more you want to ride.

THE QUESTION OF ROADS.

A. A. BONDURANT, M.D.
CAIRO, ILL.

THE practicability of the automobile as a vehicle for physicians should be discussed honestly and fairly from every viewpoint. One should weigh well the opinions of all, both of the enthusiast who has money to waste, of the other extremist who either has little means or from custom will not release a dollar until sure of its return with compound interest. I have had four years' experience with cars (using two since last July).

The Auto Will Not Succeed in Deep Mud or Sand.

If this was for a newspaper I should be tempted to evade the truth in deference to our city, but as only doctors will see it, and as they are educated to overlook the shortcomings of people, I will say we have as few good roads as any place I ever saw of its age, size and amount of business. More than half of our streets are not graded, and those that are are poorly kept. They are uneven; crossings are above the surface and mud is brought on them by vehicles from other streets. With our variable seasons, this is for its size about as undesirable a place for autos as one could easily find. An automobile will not do good work in sand or mud. A car with sufficient power can go in some mud and sand, but if I expect to encounter very much of either I leave my car at home, as the wear of machinery and worry of such travel does not justify the attempt.

A physician with no mechanical taste shouldn't buy an automobile unless he wishes to keep a chauffeur.

My experience is with gasoline, water-cooled cars with good tops, and yet they are very unpleasant things to handle in cold weather, often hard to start and requiring too much exposure to the cold if they need adjusting away from barn.

Expense has been about the same as that of my horse and cab. I do the oiling and some minor repairing. I keep the machine at home and run it myself for the convenience of having it ready at all times. I use it about nine months in the year, depending on the winter. I have thus spoken plainly of the disadvantages, but I will not be without one, for when not in use there is no expense and attention required.

Can Do More Work with an Auto.

My first car was accidentally burned and cost me $220 to rebuild. Not long before that my $300 horse sickened and died, so I eliminate possibilities. I have had no serious accident from an auto, but several slight injuries, with narrow escapes, from severe results from horses; chances probably about even. I can do more work with a car than any other way. It starts quicker, goes more rapidly, stops on shorter notice and requires no hitching or unhitching. I have made well-paying calls at a distance which would not have been

Fig. 5. In winter, in front of the office. No need of sympathy for the poor horse.

conveniently made in any other manner. The car does not fret at flies or mosquitoes, neither is it punished by heat, cold or rain.

I not infrequently make a call and return to my office by the time the livery man would have gotten my horse to the office. It being easy to make calls, I am more apt to do it at the desired time. I do not have to wait for the car to eat and rest. With good streets and roads distance is practically eliminated. My first car is single vertical cylinder, of 3½ H. P., weight 800 pounds (121). It was a high-priced car and is doing good work now when needed, but the reach is not great enough for comfort on rough streets. But few times in four years' hard service was that car brought in by other than its own power.

My second car, running since last July, including 400-mile trip from the factory, has never been assisted home. It is a double horizontal cylinder of 16 to 18 H. P. (122), weight about 1,400 pounds, rides with more comfort and I feel safer in it at a distance from home than in the small car, because of its greater power and second cylinder, but it is not as convenient in narrow streets, where short turns are desirable at times. Gasoline averages about three-fourths of a gallon a day (11 or 12 cents) for old car and about twice that for the new.

AN IOWA EXPERIENCE.

M. G. SLOAN, M.D.

DES MOINES, IOWA.

A VERY expensive experience has convinced me that it decidedly doesn't pay to buy a "cheap" machine. My present machine (114) is almost two years old, but as nearly as I can tell is just as good as new. I tried a cheap auto (115) for two years previously, and an account of the grief of all sorts that I had would fill a good-sized book.

In country practice—in Iowa at least—it is simply impossible to use an auto a certain portion of the year on account of the deep mud. Makers may make all the claims they choose to the contrary, but it isn't so that they can be used successfully in deep mud. On paved streets there is no trouble in running a good machine every day in the year, regardless of the weather, unless the snow is deep enough to stop street-car traffic.

I am sure an auto is less expensive to keep and run than is a team of horses; it is very much more satisfactory because of the constant readiness for a quick start and the speed with which a call can be made. Very often I have been able to get to a patient two miles from my house in less time than would be consumed in getting a team ready to go.

I would advise no physician to buy an auto unless he has some mechanical genius in his make-up. The most simple derangement of the mechanism will prove his undoing. Tire troubles are most vexatious of all. Lately I have placed solid rubber tires on my rear wheels, and, although they do not ride quite as easily as pneumatic tires, they are so decidedly superior in every other way that I consider them a success.

THE ELECTRIC AUTOMOBILE.

GEORGE D. KAHLO, M.D.

INDIANAPOLIS.

FOR physicians' use the automobile is no longer an experiment; it is a practical utility. In a city with comparatively level roads, good pavements, and where a limited distance is covered, the electric machine, in my judgment, is the most practical vehicle which one can have. Its particular advantages are simplicity of operation, cleanliness and absence of noise.

My experience with this type of vehicle covers a period of about eight years. My first machine (118) was one of the earliest models and was not a complete success because the electric machine had not at that time been fully perfected and because so few persons understood its mechanism that it was almost impossible to have it properly cared for. After returning to horses for a period of two or three years, I bought another machine (119), which has always given me most excellent satisfaction.

Comparison of Electric with Gasoline.

Such a machine sells for about $1,000, and its cost for maintenance in a garage is somewhere in the neighborhood of $35 per month, the principal items being: Storage, cleaning and delivery, $20; tires, $8 to $10; and incidental repairs, $3 to $5. The life of a battery in constant use is usually from fifteen to eighteen months, and the cost of new plates will be from $100 to $150, depending on the number of cells.

The initial cost of a gasoline runabout is somewhat less and the expense of maintenance is less, but such a machine is not always to be depended on, and styles in gasoline machines have undergone so many changes that when one takes into account the loss in replacing an old machine with one of a late model the total outlay is considerably more. On the other hand, very few changes have been made during the past four or five years in the style of the electric machine, and these have been largely in improvements, the installation of which involves but comparatively slight expense.

The gasoline touring car is undoubtedly the most luxurious of all vehicles, but to the majority of physicians it is almost too much of a luxury, for not only is the original outlay considerable, but the cost of maintenance is correspondingly great, and besides, for making a professional visit, a lighter and simpler machine is more convenient.

Compared with horses, automobiles of all types offer many advantages, especially in a city practice. One can get about so much more quickly and one has not to consider whether the horses are going to run away, whether the driver is having his ears frozen and, last but not least, one is relieved of the constant companionship of a coachman. In a country practice, where long distances must be covered over rough roads, I can readily see how horses would be more serviceable.

My machine is delivered at my residence at 8 o'clock in the morning and is rarely back in the garage before midnight. Whether I am at home, in my office or visiting a patient it is always at the door, and it would take three or four horses and two coachmen to do the equivalent amount of work, to say nothing of the greater convenience and comfort in getting about.

FOUR YEARS' SUCCESS WITH A STEAM CAR.

J. G. HENRY, M.D.
WINCHENDON, MASS.

My interest in the development of the horseless carriage was greatly stimulated in the spring of 1900 by a friend who purchased a small steam runabout, the first automobile in town and one of the first in this section of the state.

During the ensuing winter I placed an order for a two-seated runabout (165) with a firm who have since become one of the best known makers of steam cars in this country. After a vexatious delay of several months, I secured my car late in the fall of 1901, and have used the same machine since, doing practically all of my work with it for about half of each year.

For some years before getting the auto I had kept three horses all the time. Since then, from about May 1 till late in October, I have kept only one in the stable. I have kept a careful expense account during this time, and know exactly how much it has cost each year for operating expenses and repairs.

The first cost of my car was $600. I have since spent $180 for various improvements and changes that can not be properly charged to the repair account. These items include lamps, improved steering gear, extension front and dash, clock, odometer, touring basket, etc., and also the very important item of changing from a chain to a gear drive. My engine is now geared directly to the differential and being entirely enclosed, is much easier to keep in order and there is no chain to bother with.

I take the entire care of my machine and make all of the minor repairs that I can and thus obtain a better knowledge of the machine and its capabilities, besides keeping my repair bill down. Each morning I spend from twenty to thirty minutes in getting it ready, filling tanks, oiling machinery and firing up.

Steam Up All Day.

After making my round of calls, the car stands in the stable with the pilot light on the remainder of the day and at any time can be made ready in two minutes for a fresh start. During most of the season it is under steam from 6:30 a. m. till bedtime. As I usually have one horse in the stable I plan to use that in bad weather and for night calls, but my long trips I do with my auto, day or night. I consider this machine as reliable as a horse, and only twice in the four years has it been necessary to be towed home. It has proved a great time saver, especially on my long trips which I can do in about half the time required with horses, and my long rides in hot weather are delightful and never tiresome.

The gasoline consumption I rate at about one gallon for 10 miles. As my gasoline tank holds 13 gallons I can run at least 125 miles without refilling. The water tank holds enough for 20 or 25 miles on ordinary roads. Taking water with the syphon at any tub is a very simple matter and requires but three or four minutes which is a convenient time for oiling the engine.

I have made it a rule to replace any part of the machinery as soon as it showed signs of wear, and I think this plan has saved me some expense, and now after four years of hard service the car looks like new, runs as smoothly as ever, and all vital parts are in excellent condition. I am now putting on artillery wheels, with 3-inch clincher tires in place of the old 2½-inch single tube, and am also adding a folding top. With these improvements I expect to find it a much more comfortable vehicle in bad weather, easier to clean and hope that my tire bill will be less. The machine weighs about 1,100 pounds with the tanks filled, and easily carries my family (combined weight of four, 475 pounds) over all roads we have yet encountered. It is very smooth and quiet in operation, rides easily, is very fast and a great hill climber.

Carries a Fire Extinguisher on His Auto.

Perhaps the principal objection to any steamer is the ever-present possibility of fire. I am blessed with a large bump of caution and early added a fire extinguisher to my boiler, consisting of about 5 feet of hose connected to the blow-off and carried coiled under the rear seat. In case of need I can instantly turn a jet of steam under my full boiler pressure on any part of the vehicle. Another defect is the occasional blowing out of the pilot light when the car is standing on a windy day. It is annoying when in a hurry to find the fire out and raw gasoline dripping from the burner.

Fig. 6.—A South Dakota physician about to start for his country calls.

The automobile has not only proved a decided help in my business, but has been a great source of pleasure to my family. With it we have had many delightful trips each summer, sometimes going 150 miles in a day and sometimes but a short distance to some pretty lake or other point of interest. As a means of summer recreation I consider the automobile ahead of anything else.

I stable my car in a small house 10x12 that stands in my back yard, about 50 feet from the house and stable. This is fitted with a small work bench and vise and is a safe and convenient house for summer use. A year ago, in making an addition to my office, I made a basement room for winter storage. This is 15x9 feet with cement floor. It is steam-

heated, has running water and electric lights and makes a nice work room in cold weather.

I have had but little trouble with horses and do not think anyone need be deterred from getting an automobile on that account, provided that he is willing to exercise proper care and a little judgment while on the road. If I meet a horse that shows signs of fright I make it a rule to stop at once, and if necessary I lead the horse by and thus have obtained the good will of many drivers.

Two Hundred and Twenty-five Dollars a Year Expense.

As the operating expense is to the most of us an important consideration, I hereby append my full account for repairs and gasoline for the four years, during which I figure my mileage at something over 16,000.

The first year my repairs and new parts amounted to $36.60; second year, $46.07; third year, $27.30; fourth year, $11.04, making a total of $121.01. Add to this for retouching, paint and varnish three times, $26.42, makes a total of $147.43. For new tires I have paid $110.70 and for tire repairs $20.25, making a total tire bill of $130.95, making a total for repairs and tire expenses of $278.38.

The amount paid for gasoline for the four years was $207.52, and for oil $3.75, making the total cost for all operating expenses for four years of $489.65, an average of $122.41 for each year.

This is the debit side. To offset this the machine has saved me the board and care of two horses for twenty-two or twenty-three weeks each year. Ten dollars per week is certainly a conservative estimate of the cost of board, care and repair of equipment for two horses, or an average of $225 a year. Deducting from this the cost of operating the machine, leaves a net saving in favor of the auto of a little over $100 per year. It has also saved considerable in railroad fares, and the amount of enjoyment it has afforded I can not compute.

I am still looking for the ideal doctor's car, and as there seem to be many minds on the subject, will briefly give my idea of what it should embody. I think it will be a gasoline machine of four cylinders, 12 to 15 H. P., air-cooled motor, long wheel base, solid rear axle, and most important of all, have wheels at least 40 inches, with solid tires. It should not weigh over 1,200 pounds, and the cost ought not to exceed $600. Such a car, if honestly built, will be a boon to the country physician, and with it he ought to be independent of horses all the year round, except perhaps in the deepest snows. After nearly five years' experience with small wheels and pneumatic tires, I predict that the car of the near future will be equipped with large wheels and solid tires.

I hope that none of my readers who are thinking of discarding the horse and taking up the automobile will be too much influenced by my experience. My advice to such is that unless they have had a mechanical training, or a natural taste for machinery, it would be well to get with the car they purchase, of whatever kind, a written guarantee that it will afford all the trouble they want.

TIRES AND ROADS ARE THE CHIEF AUTOMOBILE TROUBLES.

W. A. PUSEY, M.D.
CHICAGO.

My experience with the automobile has extended over five years, and has made me an earnest supporter of it as a means of recreation and as a time saver. When I can use my automobile instead of the cars it converts my traveling about the city from a laborious task to a distinct recreation, so that when I am confronted with an automobile expense account that rather hurts my conscience, I try to console myself that I have had the worth of my money.

The difficulties about automobiling are the initial expense of the machine, the expense of maintenance and roads.

I began automobiling with a large, two-cylinder runabout (129), of the best make, which I used for four years, and I have since used a standard four-cylinder touring car (130). I believe now that neither machine was a good purchase from the standpoint of economy. As far as I can see, a runabout, such as is sold at from $700 to $1,000, would have answered all of my purposes just as well and saved me a good deal of money. For the doctor's use on good roads I believe such runabouts are the best machines, and that his chance of getting satisfactory service out of such machines is quite as good as with the higher-priced machines. He won't get as much speed and he won't get as much style, but he will get all the speed he can use and escape the police, and his machine won't look very stylish after the first year, anyway.

Another Endorsement of Solid Tires.

My expense of maintenance has been high; but with care and intelligent use I think I can see how a runabout could be maintained at an expense of about $100 per annum. The most uncertain factor in expense, as it is in reliability, is tires. I eliminated that four years ago by putting solid tires on my machines; not any of the patent tires, but plain soft rubber tires (131), with a width at the base of 2½ inches and a height of about 2 inches. I had them first on my runabout of about a ton weight, and I have them now on a little heavier touring car, and I wouldn't have any other kind. As far as I can see there is no difference in the way the machines rides and no difference in the wear and tear on the machinery, and none of the other things happen that are urged as objections to solid tires. They are really softer than well-inflated pneumatic tires. I don't know how they would work on small wheels, say 28-inch wheels. Fortunately for my experiment, the wheels of my machines have been 34 and 36 inches in diameter and my machines have been very heavy and strong. I would be afraid to put solid tires on a machine if I had any uncertainty about the strength of the front axle.

Mud a Waterloo for the Auto.

In the use of an automobile you have to consider the roads. Over roads that are solid and even fairly smooth, the automobile is all right, but the ordinary automobile is impracticable in mud or in deep sand. You can pull through mud or sand six inches deep for an indefinite number of miles, but it is a procedure that you don't want to repeat often, and you are liable to get into trouble every time you try it. When it comes to bad country roads in winter time, such roads that you have to let a horse go at a walk in a buggy, the automobile is practically out of consideration. A horse can easily pull a buggy through mud that puts an auto completely out of service. In country practice as I have known it, I am sure most of the trips could be made to good advantage with an automobile during the season of dry roads. From the time the roads get bad in winter until the time they dry up in the spring, I should not expect an automobile to be of any service over dirt roads.

THE MERITS OF THE SINGLE CYLINDER CAR.

J. P. HETHERINGTON, M.D.
LOGANSPORT, IND.

In July, 1903, I purchased my runabout and have used it continuously every day in the year—except when in the paint shop—since that time. I never rode behind my horse since purchasing the machine, and have not owned a horse for over two and a half years, depending on the machine except for an occasional livery horse when the roads are too muddy.

I watch the machine closely, am careful with it, and as a result it has never had a horse hitched to it. It is in use every day in the year, and I find it as reliable as a horse. It is a little more expensive to maintain—counting repairs, garage, etc.—than one horse, but it will do the work of two or three, is swift, tireless and needs less care.

The first two years I kept it in an ordinary livery stable—hot in summer and cold in winter. The last year we have had a garage where it is washed and oiled, but I never allow it to be repaired or to have anything done to it unless I am present. I know its peculiarities, and by watching it closely, it needs few repairs.

Comparison of Single Cylinder Cars and Others.

Being a single cylinder engine it is very simple. A double cylinder runs more nicely, but a four cylinder is still better. If one does not care for complication, the four cylinder would be very desirable. It is about the same with the transmission. The planetary is easier handled, but allows only two forward speeds. The sliding gear or individual clutch gives a third forward speed, which is very desirable. One of my colleagues has a sliding gear. The transmission is completely worn out in less than a year, and his machine is now in the garage useless, waiting for a new transmission that will probably cost more than my repairs for a year, while I am using the same old one. My machine is light, with lower power and lower speed. I can go as fast as any man should on our roads. If I get stuck in the mud or snow I can push it out because it is light. If he gets stuck his is too heavy to get out without help. His power increases wear, uses more gasoline and is more liable to break something. His machine is heavier and harder on tires. My machine, after nearly three years' use, seems to be as good as ever.

In deep sand, snow or mud a machine is almost useless. In shallow sand or mud it pulls hard. Slick mud requires a chain wrapped around the rear tires so they will stick. Shallow, dry snow or dry ice is no impediment. Wet snow or wet slick ice or wet streets make the wheels slip and require care in swift running. Rubber will not stick well to anything wet. I never hesitate to run fast on slick ice if it is dry.

Never Expects to Own Another Horse.

In choosing a machine a physician should, above all else, get one that has an engine that will start promptly in cold weather. Nothing will disgust a man quicker than pumping and wearing himself out on a cold or rainy day trying to start a balky engine. My single cylinder, planetary transmission, tiller-steered, black-colored car (124) has done good service for nearly three years, and will soon be put in the paint shop to prepare for another year. I never expect to own another horse.

THE KIND OF AUTO THE PHYSICIAN NEEDS.

LOUIS LEROY, M.D.
NASHVILLE, TENN.

BEFORE purchasing an auto the first thing to be decided is the use to which it is to be put, for a machine is in a measure a carriage, and it is obvious that a surrey is not calculated to meet the requirements of a man needing a buggy or phaeton. It is therefore presumed that to practice medicine a physician will desire a machine to take the place of a buggy or phaeton. That point being settled, he is at once in a position to exclude any consideration of the heavy and expensive touring cars. As the auto may be used as a pleasure vehicle, there are a number of cars which have been made with a detachable tonneau, which can be attached in a very few minutes, thereby converting a runabout into a car capable of carrying four passengers very satisfactorily, and still not requiring the extra weight to be carried nor the tonneau to be exposed to the inclemency of the weather during the work-a-day use of the machine.

Must Be Kept in Good Order.

I should emphatically advise against any physician buying a car who lived at any distance from a well-equipped repair shop, as the life and satisfactory service of the car depend more on keeping it properly adjusted and "trued up" than on any inherent quality of the mechanism. With the present development an auto will give better and more satisfactory service than horses, at a lower price, provided it is driven with the same degree of care and intelligence, and the more a man has been in the habit of using a whip with his horse the less satisfaction he may hope to enjoy from an auto unless he decides early to change his tactics. The average cost of keeping an auto in this city is $20 each month. That figure will vary according to the amount of use demanded, and of course the current prices of repairs and storage differ much in different locations. In Nashville the most satisfactory arrangement is to pay a moderate amount—$5 a month—for storage, and extra for washing, polishing, oiling, etc., so that the cost is in exact ratio to the service obtained.

Independent of Railroads and Trolleys.

Many prefer to stable the car at home, and there is no doubt that this is better, especially where any amount of night work has to be done, for, with a gasoline machine, one can be at his destination in about the time required to harness a horse, a feature of some importance, especially in emergency calls. Again, if a man will take the trouble to familiarize himself with his machine, he can very readily dispense with a driver, thereby saving nearly the cost of maintenance. Where the work is more or less scattered and the distances are moderate, a good deal of time can be saved, at least an hour a day, and in a country where the roads are good and the railroad or trolley service only fairly convenient, an auto renders the physician entirely independent of them for consultations or occasional visits up to 15 miles or so.

In the case of the large touring cars, the question of steam or gasoline motors is a debatable one, but for a physician's runabout there seems to me to be no chance for argument. The gasoline motor has every advantage, and the one point of having to wait fifteen minutes sitting around in the cold

Fig. 7.—The comfortable electric.

waiting to "get up steam" before being able to start on a night call is in itself prohibitive, not to mention about double the consumption of gasoline when it is used as a fuel or the danger from fire when gasoline is confined under pressure in the neighborhood of a flame.

With heavy cars, say 1,800 pounds and over, the sliding gear type of transmission with three speeds forward gives the only satisfactory means of transmitting the power to the driving mechanism, but a good type of planetary transmission is far more convenient to manipulate, and as made now by several of the good manufacturers, wears as well, if not better than the sliding gear, especially in cars of about 1,200 or 1,400 pounds weight.

Water-Cooled Cars Are Best.

A water-cooled car is superior to the air-cooled system, as since the discovery of the value of wood alcohol as antifreezing mixture, there is no danger of trouble from any degree of cold, and there is no doubt that machinery will wear better at a temperature of 200 F. or less than it will at 400 F. or over, as is sometimes reached by the air-cooled type. With tire chains to prevent skidding in the mud and 10 per cent. wood alcohol and 10 per cent. glycerin to prevent freezing, a motor car is a practical proposition over any road or climate that a horse and buggy can travel.

THE AUTO SUPERIOR TO THE FINEST BLUE-GRASS STEED.

CHARLES MOIR, M.D.
LOUISVILLE, KY.

FOR two years I have been using an automobile, and my opinion of the difference in the two methods of getting to my patients is best described in the following sentence: If some one were to make me a present of one of the finest horses in our blue-grass state; add to that one of the finest vehicles that could be built; and then add a promise to maintain the outfit on condition that I use it in preference to my automobile, I would certainly refuse it.

Why the Auto Is Superior.

My reasons for this extreme preference are:

1. *The Rapidity of Getting Around.*—I can see more patients in one-third the time and devote more time at the bedside of my patients than I could when using a horse and buggy. I also get more time at home for study and for enjoying the home comforts.

2. *Cost of Maintenance.*—This is less than for the horse. The day is never too cold nor too hot, and no degree of inclement weather ever stirs up that humane spirit for an auto that would naturally appeal to anyone in the use of the

Fig. 8.—A Pacific coast surgeon's car, with characteristic scenery in the background.

horse. So I never think of street cars or calling carriages in bad weather, but make my machine take me around. So by using my auto all the time, keeping it in good order and not waiting until it is almost ready to quit running before having it attended to, the cost to me has not been over one-half that of the horse.

Guyed by the Madding Crowd.

The first two months that I used my machine (I had scarcely any trouble at all after that time) parts of the mechanism would need adjusting. I would depend on the experts to do all this, but often these parts would get out of order while running along the street. When you stop to fix anything about an auto it always attracts a crowd, and I seemed to be a special target for remarks about like this: "What's the matter, Mister?" "Won't she run?" "Your trolley's off," etc. I thought the vocabulary of forceful and expressive language ought to be rewritten for me to express my opinions of autos and of the crowd. Then I would have to wait for a specialist to come and get me started. This, of course, added to the cost of keeping up the machine.

P. G. Course on the Auto-Cadaver.

In desperation I came to the conclusion that the fault was largely with me. I did not know the working of the machine so I bought a pair of blue overalls, put on an old coat and made a thorough dissection of it; result: no more street scenes, as I can get it started now before the crowd gets around; and, as for the vocabulary of interjaculatory speech, I do not need it re-written, and am now going to teach a Sunday school class.

The Saving Effected by Learning the Mechanism.

The expense of running my machine has been about one-half that of the horse. When using a horse and buggy the cost of maintenance was $30 to $32 a month. The cost of maintenance for my auto has averaged $19 a month since I learned how to keep my machine in repair. This includes gasoline, repairs, tires, etc. Before that time I used up $50 of $60 a month. I use a light, two-passenger gasoline runabout car (145), 4½ horsepower, single engine, top and full storm protectors. Its cost was $700, complete.

3. *Pleasure.*—After a hard day's work, particularly in the summer, my wife and I take a spin to some of our beautiful parks. We return refreshed and ready for a good night's sleep.

In conclusion, let me advise all of my medical friends who are having trouble with their autos to make a thorough dissection of them, and, as has been my experience, they will find most of the trouble in the nervous system, or, in other words, in the electrical supply.

As the English king said: "A horse! A horse! My kingdom for a horse!" I say, "An auto! An auto! My kingdom for an auto!"

STATISTICS ON AUTO, HORSE AND PULSE.

CHARLES P. SYLVESTER, M.D.
DORCHESTER, MASS.

WISHING to be able to compare accurately the expense of my machine (170) with that of my horse and two carriages, I entered in their respective diaries every cent expended, either directly or indirectly, on them. For instance, on May 1, 1904, the first day on which I drove the machine, two punctures and several secondary hemorrhages from the wounds, necessitated its detention over night in a roadside hospital several miles from home, at which latter place I arrived at 10 p. m., weary and footsore and experienced. One dollar for dinners by the wayside and 10 cents car fares were charged that day against the auto.

An Exact Cash Account.

Such entries as the following will give an idea of the completeness of the comparison: Auto hat, coat and gloves, $11; license and registration, $4; loss of eyeglasses while raising a 30 mile breeze in the woods, $5.25; gasoline, $1; repair of bicycle which ran into me, $2.50 (several) dogs which tried a similar blackmailing scheme were repaired by me without expense). So the items were entered until, at the end of seven months, when I stored it for the winter, the total amount was $121.65. I deducted from this amount $10 which which was paid me by a patient for a 25-mile ambulance service to a hospital.

As this is one of the uses to which one can sometimes put his machine, when he could not his horse, it seems fair to deduct the amount, leaving a balance of $111.65.

There were sixteen weeks in the summer when the auto was stored in my own stable; so to make the comparison fair, we will add $48, making $159.65. The care of the machine during the sixteen weeks is already included in the $111.65.

Now, for the same seven months, with my bay pacer, Red Devil; his board and lodging bill each week was $6 half the time and $7 the other half.

In this account appear: Repair of check-rain, 65 cents; cooler, $4; sugar, 8 cents; veterinary fee for colic, $3; gin, 50 cents; hire for another horse, $3; shoeing, $4; repairs on horse and carriage out of commission ten days as a result of steamrollerphobia, $8.35 (and the patient to whom I was hurrying at the time moved away without paying his bill).

Saves Money By Auto.

The total for the seven months amounted to $268.10. As with the auto, there is one credit both the account and to

the horse—$8 for winning second money in Hull Old Home Week free-for-all ($50 which I lost backing him for first place is not entered).

Therefore, my auto cost me for first seven months just $100.45 less than my horse.

My machine was stored in my own stable during the winter at no expense. I could have stored my horse there, but it would have cost at least $3.50 a week for his board and care, which illustrates the fact that one does not have to feed or exercise a machine unless disposed to.

The total expense for the auto for the same period the following year was $173.80, or $52.15 more than the previous season, $25 of which was paid for painting. The tire bill was about $6 more, while the only repair bill on the machine was $20 for a very thorough overhauling in the spring; $2 for repairing chain, which broke on two different occasions, and $6.25 for pump. Excluding the painting and overhauling, my expenses were less than the first year.

My car received plenty of exercise, for during the summer months I use it between my Boston and Hull offices, 23 miles each way, doing about 7,000 miles in the two years. Although I had no pedometer on my horse, it is safe to say that he made no such record.

Excepting the chain and pump and an occasional tire, I had no troubles, except with the police. They were very lenient, or my expense would have been higher.

The sale of my equine outfit was a natural sequence of the above experience; therefore I can figure approximately the depreciation. The original cost of each outfit was about the same. The horse and carriages, after three years' use, sold year. Add to this $484 which it cost me annually to keep the same, and the expense yearly is $600.

An $800 auto would not depreciate over $800 in four years, or $200 a year. Add to this what it has averaged me for twelve months, $240, and we have $440 for an auto against $600 for a horse. Now, if you should compare the cost per working mile, which should be considered in order to make the comparison really scientific, the result must be greatly in favor of the automobile.

I also have had a similariy pleasant three months' experience with an electric runabout in my city work, and only gave it up, because, on lung runs, it would not answer the purpose.

Effects of Motoring on Pulse and Health.

Now, let me end this paper with an interesting observation on my pulse. Believing that automobiling is a transition from the simple life to the pace that kills, I recorded my pulse on several of my first and fast long drives, being careful not to inflate my tires or to crank my machine before starting. The result was always an increase of about six in the number of beats per minute, with an increase in the tension. In a few weeks the pulse remained at the high level and not until the end of a midwinter vacation did it return to normal.

Increased exercise might have been the cause, but in my mind it was due to a chauffeur's responsibilities regarding the police, public and passengers, order reversed. (The public's pulse probably went higher.) This may be a form of auto-intoxication which we should bear in mind in examining our patients.

Therefore, if the danger and expense to health, traumatic or otherwise, could be carefully figured and itemized, the complete comparison between horse and auto might pretty nearly agree with the law of physics, that action and reaction are opposite in direction.

NINE MONTHS FOR SIXTY DOLLARS WITH A FIVE-HUNDRED-DOLLAR AUTOMOBILE.

EUGENE F. TALBOTT, M.D.
GRINNELL, IOWA.

In 1899 I purchased a light steam runabout (126). After about three months' use, at an expense of $100 a month, I put the thing away. It was so very unreliable that I will not inflict on you any of my experience in that busy three months—not busy attending the sick, for the auto took first attention and a great deal of it. Well, the auto died, and now is buried in my memory, although it haunts me still.

Used Up One Pneumatic Tire Each Month.

The dose, however, was very effective in curing me of motorphilia, and I remained cured until the spring of 1905, when I purchased a gasoline runabout (127), single cylinder, at an expense of $500. My engine is water cooled and in winter I use a solution of glycerin, wood alcohol and water and have no trouble. After nine months' use of the auto, I would not be without one, although the expense is more than keeping a horse. My car had single-tube tires. I know better now. My car used up six tires in as many months, which made it necessary for me to quit either pneumatics or automobiling, as a business proposition. I quit pneumatics and put on a popular solid tire and after three months' use I can say I wouldn't have anything else. With full elliptical springs the car will ride as easily as pneumatics. The only difference I am aware of is that in turning a corner the car will skid more if going fast. In mud roads, as we have in Iowa, the pneumatic tire is too wide to go into the rut made by wagon wheels, and the solid, being narrow, will go in same rut, a very great advantage in rough and frozen roads. The satisfaction of knowing that when you start on a trip you are going

Fig. 9.—With storm apron, this gives protection from weather.

to get back without having to stop and repair a tire makes riding a pleasure.

During the nine months I have used my auto all the time with the exception of about thirty days. The mud of summer has not stopped me, but when we had 18 inches of snow I quit, although in a foot of snow I went along nicely. Again, when after muddy roads the ground was frozen, I had to wait until the roads were smoothed down some.

The only accident I have had of any importance was in breaking my rear axle, but let me add that this occurred when I had pneumatic tires.

Great Pleasure to Oil Up the Machine.

My wife and I took a 300-mile trip last summer and got home without the least accident or break. The gasoline used on this trip was 12 gallons. I keep my machine in my barn and care for it myself, and nothing gives me such pleasure and rest of mind as an hour spent in the morning oiling and looking over the rig.

Tires Are Chief Expense.

Now, as to my expense. My repair bill, which included the new axle, amounted to $25.65. The gasoline expense I do not know, but as one gallon would, on good roads, take me 28 miles, that expense was light. The tire expense is much with pneumatics. My expense for season was $179.33, which included a new set of solid tires, but the solids are nearly

new, and that expense should not all be charged up to one season's expense. My machine is now second-hand in name, but as for as use goes, is good for several seasons. If I had put on a solid tire when machine was purchased, my total expense for running nine months would not have exceeded $60.

PLEASURE AND CONVENIENCE IN CARING FOR ONE'S OWN AUTOMOBILE.

S. S. CROCKETT, M.D.
NASHVILLE, TENN.

PREVIOUS to Aug. 1, 1903, I kept two horses, one carriage and two buggies, at an investment of about $1,300. The fixed monthly livery charge for keeping the horses and vehicles, including shoeing, was $35. The expense for replacing the horses and vehicles and repairs on vehicles is difficult to determine.

Aug. 1, 1903, I sold my horses and bought a four-seated automobile (167) for $850, which I used continuously in my work for two years, going during that time a road distance of 14,000 miles, at a total average monthly cost of about $30. Aug. 1, 1905, I sold my old car and bought a new two-seated one of the same make at a loss of $375.

Fig. 10.—A southern physician under very favorable conditions.

My second car has now been on the road continuously since Aug. 1, 1905, and has cost me less than $10 on shop repairs; $45 for new tires; $5 a month for gasoline; $2 a month for lubricating oil; $7.50 a month for housing and washing.

It can be readily seen that if used continuously a car will cost more than one horse and buggy, but less than a pair of horses.

Occasionally Hires a Horse.

I find that in active work it is necessary to hire a horse for a part of a day about once each month because of some small derangement that I have not the time to fix. I find it not only more satisfactory, but entertaining and diverting, to adjust and to oil the car myself. This is usually done at night when I take my car to the barn, and usually consumes about one hour one day in the week and fifteen minutes during each of the other six days. I find it a great satisfaction to spend a few minutes going over the car each night and seeing that it is supplied with water, gasoline and oil, and that the spark plug is clean and in working order. In that way I start out in the morning free from apprehension. I take my car out in the morning by 8 o'clock, and it does not go back to the barn until I finish my work at night. It stands at my door during my office and meal hours, it does not have to be sent to the stable to be fed and requires no time for rest

Does His Work in Half the Time.

I am able to do my work in about one-half the time I used to consume, and during that time I am absolutely devoid of any sympathy for an overworked and hungry team.

Of course I have troubles; but, as I save half my time, I can put up with that. Any man with average intelligence who applies himself to studying the way the machine should be cared for, can soon learn to remedy ordinary road defects.

Machinery will break, it will get so dirty that it will not work, and it will wear out, and an auto is no exception to the rule. I have been pulled in by another machine only once in the past year—during a travel of about 7,000 miles.

THE MOST SATISFACTORY INVESTMENT FOR THE COUNTRY PHYSICIAN.

HARRY P. ENGLE, M.D.
NEWTON, IOWA.

WHEN I purchased an automobile three years ago I had had no experience with machinery of any kind, knew practically nothing concerning the principles of a gas engine and did not know a float feed carburetor from a commutator or a compression chamber from a planetary gear.

The Sorrows of the Novice.

Soon after signing a check giving me the sole right to own, control and operate this red devil, I proceeded to exhibit my ignorance by filling the gasoline tank with water and found the result extremely disappointing. One drop of aqua pura, in a float feed carburetor, can certainly dampen all the energy in a gas engine, but when I had made a diagnosis of the difficulty, I thanked my guardian angels that I had not come to an untimely end by filling the water tank with gasoline.

The things that I did not know about an automobile were certainly voluminous, but the one thing I did know was that if I ever expected to make the complicated affair go for any length of time I must learn its anatomy as well as I once knew the points of interest on the petrous portion of the temporal bone. And so, after subscribing for a great number of automobile journals, reading every book I could get concerning a gas engine and separating the machine into so many pieces that I would doubt my ability ever to get it together again, I have found that the little difficulties that are sure to arise are easily taken care of and that this purchase has been the most satisfactory one I have ever made.

The Pleasures of the Experienced Autoist.

My three years' experience in a motor car has been with a single-cylinder, 9-horsepower, water-cooled gasoline machine (168). I have taken care of it myself and have had very little experience with repair men; in fact, I do not look on them with much favor. I have averaged over 3,000 miles each year and have found the cost of driving a motor car to be less than keeping a team, and the comfort, convenience and pleasure place the automobile so far ahead that I never expect to own another horse. I have driven the machine at all times of the year, over all kinds of roads, and never have found a hill that caused any trouble in climbing. With the patent chain tire grips for mud and ice, calcium chlorid for zero temperature you can always be sure of getting back home.

After driving the car about six months I sold my horses, but when the roads are very bad I depend on the livery, preferring, as I did when I owned a team, to drive the livery horses over the worst roads. Mrs. Engle is also an automobile enthusiast and handles the car with perfect ease, starting the engine without difficulty, and I feel sure that everything will be all right when she is out driving.

Tires Cause Ninety-five Per Cent. of Trouble.

Ninety-five per cent. of all my trouble has been with the pneumatic tires, using the first year the single tube pneumatic tires, which were an abomination. Now I have the double tube clincher, which gives very much less trouble, but a medical friend tells me that he has completely solved this difficulty by putting the solid rubber on his machine, and I know there is no difference in the way his car rides, and he

informs me that the solid tires do not (as is claimed by the pneumatic people) jar the machine to pieces; they eliminate all tire trouble; so I have concluded to try them when in need of new tires.

Steam Cars Not to Be Seriously Considered.

For country use, over Iowa roads, the steam and electric machines should be mentioned only to be dismissed, and if I should buy another car it would be a gasoline machine, with multiple cylinder, abundant horsepower, larger wheels than the 28x3 I now have and probably solid tires. Recently I have had my car completely overhauled and only two worn parts were found, which were easily replaced at a cost of less than $2. It is as reliable as ever, and I see no reason why it can not be used for many years yet; but, if like the old "one hoss shay," it falls to pieces on the next trip I will feel that, in its three years of reliable service, I have been amply repaid for its purchase price, and, as I said, it is the most satisfactory investment I have ever made.

THE AUTO IN A MUDDY COUNTRY.

E. F. COOKE, M.D.
FORRESTON, TEXAS.

WHEN it rains in a black-waxy-soiled country such as this, the mud is sticky, and when dry the roads are first very rough and then later become splendid until another rain. Last August I purchased a second-hand runabout (137), which had been fitted with a steering wheel instead of the regular tiller. I have had a great deal of trouble, but I still believe in the auto for our use. I put my troubles down as being due to two factors: 1. The greatest was my absolute ignorance of what an automobile really is and errors made in consequence wrought damage to the machine and kept me in hot water. 2. I bought a second-hand machine and had to learn all its weak points at once. It is certainly a most fascinating way of getting around. It saves a good deal of the doctor's time and permits hours of sleep and study that would otherwise be spent on the roads.

Be Your Own Repair Man.

I believe that pneumatic tires are superior to any form of solid or semi-solid tire. One ought to be able and willing to work, as many small repairs are constantly necessary, such as tightening bolts and making other adjustments. These machines will pull through most mud, but sometimes it is necessary to give the driving wheels a grip by using chains or winding a rope around the tire. There is some danger, of course, as a man will travel just as fast as his machine will go and then want to buy a faster machine, but I feel fully as safe in mine as I do behind a horse. No matter what make one buys, it is just as well, if he is in a country practice, for him also to keep a horse.

THE AUTO A SPLENDID FINANCIAL PROPOSITION FOR THE PHYSICIAN.

H. COOPER, M.D.
AMESBURY, MASS.

AS an ordinary country physician for twenty years, I have sometimes owned one horse, sometimes two. The question of the horses eating their heads off was a cause of much study. In the evolution of time the bicycle appeared. I mastered it with the idea of getting rid of one horse. This innovation was an advantage in two ways—personally and financially.

What Horses Cost.

The cheapest method per annum with a horse was $350, which included board and care at a stable, shoeing, taxes, insurance, repairs and the natural depreciation. To add another horse would mean another expense of $250, without considering the depreciation, making a yearly expense of $600 for the one item of transportation from one patient to another. The items of pleasure and recreation do not enter into this computation. All work and no play make a tiresome existence for the physician, and death comes to us altogether too quickly, to say nothing about inviting it by too close application to the ills and woes of our patients.

I have found a way to stave off the Reaper, to enjoy life, to make hard work pleasant and to render every trip to one's patients, by day or night, a real pleasure.

Twenty Thousand Miles on a Bicycle.

When the bicycle came I bought it instead of another horse and made many visits every day on the wheel. It was undignified in the eyes of some, but what matters the ideas of a few if it was a financial saving, and at the same time it gave the physical exercise necessary to excite the liver and bowels into activity, so that those ever troublesome headaches and bad tasting mouth were gone forever.

While I was pedaling over 20,000 miles with much pleasure—to say nothing of improved health and enlarged pocket-book—the automobile was being perfected. In 1902 I sold my team, gave my bicycle away, and bought a runabout (148) of 4½ horsepower. I soon found that I had from three to five more hours each day—for more work or for more recreation.

Fig. 11.—A rolling auto gathers much mud—in Iowa.

Cheap Cost of Maintaining Auto.

I used this faithful little servant eight months, covering 3,000 miles with less than $5 breakage, and at a saving of $250, as compared with a team. The horse hire, electric car fare for the remaining four months' winter service was about $25. In 1903 I used the same car with another 4,000 miles travel and no greater amount of additional cost. In two years I had covered 7,000 miles at a total cost of $175. including breakage, replacements, painting and varnishing, gasoline, lubricant and tire troubles. I then sold the car for 50 per cent. of the first cost.

There had been so much comfort in my work and pleasure at other times that I contracted the touring-car fever. In the spring of 1904 I bought a 16-horsepower touring car (149), and a 5-horsepower runabout (150), the small car for work near at home and the larger car for long and hard trips, or if I wished to take friends for a pleasure ride. I ran the touring car 9,000 miles in the two seasons of 1904 and 1905 with less than $10 breakage. Three of the original tires are still on the car.

In October, last year, I sent it to the repair shop for the first time, that is, after it had covered 9,000 miles of city and country roads. The repairs and replacements cost $197, the retreading of the three original tires cost $30, and $48 was the cost of the new tire. The car is now in first-class condition for another two seasons' use.

An Excellent Financial Showing.

The cost of gasoline, lubricants and batteries for the touring car was about $100 a year. To recapitulate, I have an expense of $550 for four years' experience of using the auto in my practice, whereas the expense of a team for the same period would have been from $1,400 to $2,400, whether I had one or two horses. Getting left on the road never occurred, neither did the auto refuse to move.

CONVENIENCE OF THE AUTO FOR NIGHT WORK.

WILLIAM C. LEARY, M.D.
SPRINGFIELD, MASS.

MY car was bought ten months ago, a runabout (133) costing $1,300, with double opposed horizontal engine, water-cooled, individual clutch transmission, three speeds forward and reverse, throttle and spark lever control, folding front seat and victoria top. During that time I have

Fig. 12.—A Connecticut physician and his faithful steed.

driven it every day through snow or mud over city and country roads and, while it has done the work of two horses, my expense account, accurately kept, shows that the cost has been little greater than the keeping of one horse.

Ten Months at $28.50 a Month.

I figure the cost of each horse at $25 a month—a conservative estimate, since I never paid less than $22, sometimes $24, for board, while the bill for shoeing would easily bring the total up to $25 a month. The cost of driving my car 6,020 miles has been:

Oil and gasoline	$ 62.18
Repairs	40.39
Tires	127.70
Barn rent, washing, etc.	54.75
Total	$285.02

Auto Ready for Night Calls in Three Minutes.

While this cost has averaged but $3.50 a month more than one horse, the great value of the auto lies in the celerity with which regular and emergency calls can be made, thereby saving from two to three hours each day. To the busy practitioner whose time for study or recreation is very limited, this is of inestimable value. At night there is practically no delay, the only preparation necessary consists of lighting the lamps. The livery stables here will not deliver horses after 9 p. m., and often after I had telephoned to have my horse ready it would not be hitched up when I arived there some *fifteen* minutes later. To walk to the barn and return with the auto takes *three* minutes.

His Car Always Brings Him Home.

I rent a barn a short distance from my office and personally see that the oiler is working properly and there is a good supply of gasoline. The tank holds six gallons and the running averages in the city 13½ miles to the gallon; in the surrounding smaller towns, where speed regulations are not so stringent, 18 miles. Each morning I also inspect the motor attachments, springs, steering and running gears and to this I ascribe much of my success. I have never met with an accident, except tire punctures, and my car has always brought me home.

No Dismounting To Crank.

Another feature, my car is started and operated from the seat, thereby insuring as much pleasure driving on muddy streets or stormy days as in pleasant weather.

My idea of a physicians' car is one of at least two cylinders, all parts easily accessible, 15 to 20 horse power, sliding gear transmission, shaft drive, started and operated from the seat.

Pay Enough to Get a Good Car.

I would advise paying a good price in order to get a reliable car. A few hundred dollars may save many vexatious delays and much religion.

After nearly one year's experience with a car I shall never use horses again. If handled carefully, and given proper attention, the auto is the ideal vehicle for a physician.

THE PHYSICIAN AND THE AUTOMOBILE MUTUALLY ADAPTED TO EACH OTHER'S NEEDS.

AMOS AVERY, M.D.
SAPULPA, IND. TER.

I THINK that the automobile is just the vehicle for the physician and that he is just the man for the auto.

A physician is generally a man who has an idea of the natural order of things, what results to expect and how to get results. The every-day training of his powers of observation are such as to help him greatly in caring for and in running an automobile. For these reasons I think that he is just the man for the auto. This is fortunate, for he is the very one who needs transportation on very short notice and in the shortest possible time when hurry calls come in. Time spent on the road is but lost time. Cutting this down one-third or one-half makes it possible for him to do just so much more business.

How to Crank When Crank Is Lost.

I first commenced using an automobile in my practice, in 1904, when I got a light single-cylinder runabout of the buckboard pattern (158). I was then living in eastern Connecticut, where the roads are very hilly, and though the machine was of small horsepower I never failed to make any of the hills in the county. I had the usual run of small accidents, misunderstandings that fill the experience of a beginner. One day an axle broke, but in a few days another was put in its place. At another time I lost my starting crank when 15 miles from home. I managed to get started again by pulling on a small rope that I wound around a pulley that was attached to the protruding end of the engine

shaft. Again, I pushed the car (it weighed only 500 pounds) to the brow of a small hill, and then getting aboard, after sufficient momentum was attained, the clutch was thrown in and the motor started thereby.

I attended to most of the small repairs myself, and in that way I knew daily just the condition of the machine. I ran the buckboard at times all the following winter, and found it worked admirably, for it was air-cooled and there was no danger of freezing any water-cooling apparatus.

In the spring of 1905 I moved to Tulsa, Ind. Ter., and used the little machine there for about six months. Though there was some very warm weather in that place I found that the atmospheric conditions are better out this way for air cooling than they are in the far east, and I had no trouble to keep the motor cool when the mercury was standing at 100 or over.

Arguments for Air-Cooled Motor.

There are two leading arguments in favor of an air-cooled motor: First, it eliminates the danger of freezing in cold weather; second, it cuts out quite a complicated mechanical arrangement, thus simplifying the mechanism and thereby eliminating quite a number of minor troubles that follow.

The town in which I now live Sapulpa, is not suitable for the use of an automobile, for there are no culverts or bridges, and there are so many loose rubble stones.

The Poetry of Motion.

There are a few points of vital importance to be borne in mind if one wishes to run a motor vehicle successfully. When run successfully, it is the pleasantest means of travel for a physician. As an Irishman put it, "it is the very poetry of motion."

Lubrication must be accurately and carefully attended to. If the compression becomes diminished the valves must be ground. More power is lost by lack of attention to this important detail than by any other thing. It is essential to have a mud apron in wet and muddy weather.

I used single tube tires, and was fortunate enough to have very little trouble with them, and the original tires are still on the machine, though I did have a few punctures.

Total Forty-three Dollars for Eighteen Months' Expense.

My bill of expense for running the machine a year and a half was $43, and this included everything: Gasoline, oil, batteries, spark plugs, tire repair, and every other item of running, maintenance and repair, all are included in the above amount of expense. I do not know the exact number of miles traveled, but it goes into the thousands. The more I use an automobile the more I can see the grand future it has for the busy practitioner, in either his business or his pleasure trips.

If the physician chooses to take care of it himself, I would recommend a runabout of two or more cylinders, with an air-cooled, gasoline motor and with 10 or more horsepower. If in a rainy country he certainly would need also a good top and storm apron. Equipped thus he is in a position to do the work that ordinarily would require at least three horses, and at less expense.

AN INSTRUCTIVE NEW HAMPSHIRE NARRATIVE.

WALLIS D. WALKER, MD.
PORTSMOUTH, N. H.

RELIABILITY is the primary quality necessary in a car to be used by a physician. Speed, power, gears and transmissions, although related, are of secondary importance. The doctor's car must be always ready to take him to a patient and back without mishap, at all hours of the day and in any condition of weather and roads.

Between this ideal and the actual car in use to-day there is a gap, and the extent of this gap depends largely on two factors: First, and most important, the personal equation as manifested in the care, use and abuse of a car; second, the judgment shown in the primary selection.

The Auto Needs an Intelligent Owner.

By the personal equation, I mean a man's ability to deal intelligently with the small adjustments necessary to the best working of the highly differentiated mechanism of an automobile, to keep his tank supplied with gasoline, his cylinders with oil and his radiator with water. A man without some love of machinery should leave an automobile alone, for the present at least, until he can afford to hire a mechanic.

The ideal automobile for the physician should combine as many of the following points as possible: A four-cycle engine, of either two or four cylinders, placed forward under a hood; cylinders water cooled; sliding gear transmission, with three speeds forward; shaft drive, geared direct to axle; developing no less than 16 H. P. The combination of these five points, in my experience, makes the most reliable, satisfactory and economical car.

The Engine.—The future must decide between the relative merits of the four-cycle and the two-cycle engine. At the present stage of motor development, the four-cycle has outstripped the two-cycle in general use. A single-cylinder motor is not sufficiently powerful, and the vibration is objectionable. Two cylinders of sufficient size will develop ample power, and if opposed and properly balanced, will produce a smoothly running engine. A four-cylinder motor has little advantage over a good double opposed, and must be more bothersome. The engine must be accessible for inspection, cleaning and adjustment. Engines hung under the body do not fulfill this requirement.

Fig. 13.—Comfort and convenience in New England.

Chooses Water-Cooled Motor.

Cooling.—Although cylinders can be successfully cooled by air, and although the absence of water during cold weather is a convenience, I choose a water-cooled motor, partly because of the deleterious effect of the high temperature of air-cooled cylinders on the exhaust valves and spark plug, and partly because I believe that the evener temperature of the water-cooled cylinder gives better efficiency. Two parts of wood alcohol to three of water will not freeze in the ordinary New England winter.

Transmission.—I have had no experience with friction drives. For runabouts of a thousand pounds' weight, and not over 10 horsepower, the planetary type is satisfactory, but for the heavier and the higher powered cars, I consider the sliding gear transmission essential. The friction bands of the planetary drums wear continually, and must be adjusted, and few transmissions of this type provide for more than two speeds forward. Sliding gears wear little and are absolutely positive. Three speeds forward is the rule on most well-built models.

The Drive.—Chains can not be kept clean or well oiled. Chains have not yet been made that will not stretch and require adjustment. So I prefer the shaft-driven car. Moreover, cars driven by single chains usually have the engines hung under the body, which is objectionable.

Fig. 14.—The touring car used by a physician in Evanston, Ill.

Power.—For the city physician, with good roads and no bad hills, 10 horsepower would perhaps be sufficient, but for country roads, up hill and down dale, in slush, mud, and sand, there is no hope for satisfaction in anything less than 16 horsepower. It is very trying, when in a hurry, to worry through a stretch of sand or mud on low gear for want of sufficient power to keep on the high, and I have heard many men denounce their cars as unsatisfactory merely because of the failure of an 8-horsepower engine to do the work of 16 or 20 horsepower.

Factors to Remember in Comparisons with Horses

Expense.—There have been many comparisons drawn between the horse and the car as to practicability, reliability, expense and what not. Unless the factors entering into such a comparison be equal, no just conclusion can be drawn. One man feeds his own horse, curries him, beds him down. Perhaps he raises enough hay back of the house to keep him half a year. Another man hired a coachman to do these things. The cost to the first man is infinitely less than to the second, though, perhaps, the horses do equal work. It is the same with a motor car. The actual cost of gasoline and oil can be kept as low as a cent and a half a mile, but it is the repairs, due to careless handling, the garage charges, the outside labor spent on adjustments, that bring up the running expenses. Taking into consideration the first cost of a good car and the rapid decrease in sale value, a man will spend more actual cash on an automobile than on a horse. Leaving out the original investment for the moment, I doubt if the running expenses of a car, driven by a competent person, will exceed the expenses of a horse-drawn vehicle, while the mileage will be vastly in favor of the machine.

When I have used a horse, I have hired one at $11 a week, everything included. The monthly expense of maintenance of my auto (16 3), including care, repairs, gasoline, oil and acetylene gas for searchlight, is approximately as follows:

Gasoline, 30 gals., at 20c.	$6.00
Oil and grease	1.30
Repairs and replacements	5.00
Total	$10.30

Care of the machine is not included in this. If one keeps the car in his own stable this item is practically nil. If the car is boarded at a garage the price will vary from $8 to $15 a month.

Delays Are Few.

Reliability.—I have come to consider the chance of serious delay with my runabout as no more than equal to the chance of delay on a well-managed electric road. From February 26 to December 31, last year, I was not delayed ten minutes at any one time, and that with a total mileage of over 4,000. I was, however, exceptionally free from tire troubles, experiencing only one puncture. I attribute my freedom from delay largely to the fact that I made a point of knowing that the car was always in the best of running order before taking it out. A man must know his car thoroughly and must treat it, not as an automatic contrivance that needs only to be run, but as a complicated and delicately adjusted piece of machinery that requires constant care and attention.

There is no doubt that the automobile is a practical conveyance at all times and under all conditions, except in the deepest snow. During the winter of 1903-1904 my car was laid up about six weeks. In 1904-1905, one month at a stretch, I could not conveniently use the machine. During this last winter, there have been only two weeks when I could not run, though this present heavy snow will keep the car housed for ten days more besides. At all other times my machine has been ready and able to do my work.

THE AUTOMOBILE SOLVES THE TRANSPORTATION PROBLEM.

W. H. CURTIS, M.D.
WILMINGTON, ILL.

WITH a year's experience, I should say that under ordinary conditions the automobile is not only practicable, but eminently satisfactory for country use for approximately ten months in the year, while for city usage it is "always in season." Its utility depends now not so much on structural defects in the machine itself, which have been largely eliminated, but mainly on the condition of the road.

No Machine Made Will Go Well in Bad Roads.

In my opinion, no power machine yet invented or to be invented can by any possibility make transportation an unalloyed pleasure over our badly constructed and illy cared for country turnpikes at certain seasons of the year. While machines of the type I use will go wherever a horse can and sometimes where they can not, it must be at the expense of an amount of power by both machine and driver that inclines the balance in favor of the horse-drawn vehicle. In my locality, however, these conditions are ordinarily of but limited duration.

Fig. 15.—A New York doctor's handy conveyance.

Given ordinary dirt or gravel roads, one's time spent on the road is cut down one-half or three-fourths, which increases one's earning capacity to an equal extent, while at the same time one's physical discomforts are reduced to a minimum—for I consider my machine the easiest riding vehicle I was ever in.

The machine I use (135) has wheels 44 and 48 inches in diameter, respectively, with solid rubber tires, and differs in no important particular from the ordinary carriage wheel, which is the evolution of many years of experiment. Power is

supplied by a double opposed air-cooled engine, developing 10-horsepower, which is transmitted to the wheels by means of wire and hemp cables, thus doing away with unreliable and breakable transmission gears and greatly simplifying mechanism. It is effectively and easily controlled by two simple hand levers, which permit of no confusion and consequent mistakes. It will run 30 miles an hour; I ordinarily drive it at from 15 to 20, which is rapid enough for me.

Runs Up Hill Like a Scared Rabbit.

It will run up hill like a scared rabbit—and, in short do anything demanded of it except talk Russian. I care for my own machine and find it a very small burden, rather pleasurable than otherwise; for this reason I think I can say my machine, after a year's hard work, is now in better shape than when it came from the shop, for it has now "found itself"—a term any sailor or mechanic will understand.

Any new beginner will have troubles; mine have been slight and mostly of my own making and not the fault of the machine. I think my auto leaves very little to be desired as a means of transportation for the physician.

My machine cost $650. Monthly expenses have been nil, with the exception of cost of gasoline—about $4 a month. The only repairs I have had to purchase was a broken change gear (of a weak and obsolete pattern not now used), $15. My expenses for maintenance of a span of horses has for many years averaged me $650.

GREATER ECONOMY AND BETTER SERVICE WITH THE AUTO.

A. C. MAGILL, M.D.
PITTSBURG, PA.

My first car (159) was bought six years ago, and I believe that I was one of the first physicians in America to adopt the automobile exclusively in making professional calls. In this 5-horsepower car I traveled 16,000 miles, mostly over the worst roads in western Pennsylvania. My expense was somewhat less than half what a horse-drawn vehicle would have cost for the same mileage, as I found it a simple matter to keep my car at my own garage. With a little care in operating it the adjustments were very few, and I could take care of them myself. It was very seldom that I did not have the car in daily service.

Fig. 16.—Ten horse and one dog power.

After using this car for three years I decided to purchase a later model of 8 horsepower, with a low-compression, high-speeded motor, which I believe is the most serviceable and economical. This car (160) I am using at present, and have had two years' service out of it, having in that time traveled 14,000 miles; and it is in condition at present to travel as many more.

From my experience with automobiles I am perfectly satisfied that they are more economical and give better service than the horse-drawn vehicle for physicians' use.

THE PHYSICIAN WHO SHOULD NOT PURCHASE AN AUTO.

W. W. BEVERIDGE, M.D.
ASBURY PARK, N. J.

For the last four years I have been using machines in my practice with very good success. Except in the winter months, I have practically abandoned the use of horses for both business and pleasure.

The Careless Physician Can Not Run An Auto.

I am convinced that the utility of the auto for physicians depends almost entirely on the skill of the man who operates the machine. Did you ever meet a physician whose instruments were always out of order when he wanted to use them, whose books were always loaned when he needed them, and whose general equipment was always out of use? If you chance to meet him, advise him not to try the automobile in his practice. Such a man will always have trouble. I believe the unsuccessful owners of machines among physicians are largely of this class. For the successful and economical operation of machines great skill is necessary. Almost all accidents and annoyances on the road are due entirely to negligence, ignorance or bad management on the part of the operator.

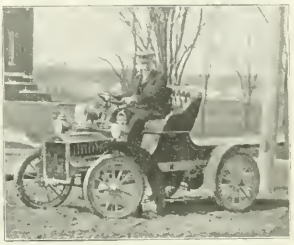

Fig. 17.—An automobile used in the southwest.

Begin with a Simple Machine.

The choice of the machine, to my mind, is a matter of secondary importance. Any good machine will do good work, and, I believe, will be very satisfactory in the hands of a skillful man. While passing this part of the subject, however, I would say in a general way that in point of economy, the lower powered cars will give more satisfaction, less trouble and are the cars that all beginners should use at first. But, of course, in a hilly country, or where the roads are heavy only a very powerful machine will do at all. It is also a great advantage to have a machine that is made near home, as new parts can be obtained more quickly, and at far less expense. Compound engines are never easily mastered by one who is not familiar with the single-cylinder engine.

Auto the Most Useful Thing in Doctor's Whole Equipment.

In putting so much emphasis on the skill of the owner in operating his machine, I do not wish to be understood to speak disparagingly to the prospective purchaser, for requisite knowledge to run a machine successfully can easily be acquired, and is really one of the easiest attainments that the physician can reach. Remember, that it took you three or four years to become a doctor, and at that time your trouble just began. What seemed very difficult or impossible to do at that time is perhaps very easy for you now. So do not imagine you are a chauffeur the first few months you own and operate a machine. Perhaps years of experience have made the art of healing easy for you; so, too, months of experience will make you proficient in handling what should be the most useful thing in your entire equipment.

Success Depends on the Operator.

When we read of some skillful operation performed by some noted surgeon, we do not stop to inquire what kind of knife was used or who the manufacturer of it was. The chances are that the surgeon himself did not know who made the instruments; and possibly they were not of his selection. The same implements in the hands of the unskillful would fall in ill-repute, and the surgical triumph would not be achieved I believe that if these facts are always borne in mind, the physician will always speak a good word for the automobile.

I have used a steam car (146) and three runabouts (147), mostly for business. Last year I think it cost me about $50 for gasoline and oil; for repairs and new parts perhaps $40. I use my machine for pleasure and side trips as well as for business, and the expenses of these trips are perhaps more than the actual cost of the machines while at work.

I feel like recommending here a certain heavy oil (156), a crude petroleum, which, when filtered through a felt hat, is the best lubricating oil that I ever used. I gave it a severe test and know its value. The chief point of interest is that it costs $5 a barrel instead of 75 cents a gallon. It is a light oil, although it is called heavy. I buy it from the producer and find it a great saving, for at that price one can use oil freely, and that is the life of the machine. I keep my horses and machine together in the same stable, and the same man cares for and drives both, so another item of expense is combined. My stable and man cost perhaps $1,200 a year.

I would be glad to write further to any one specially interested if I can be of any service to them.

PRESENT LIMITATIONS AND FUTURE POSSIBILITIES.

DEFOREST LAMBERT, M.D.
SALEM, MASS.

SEVERAL years' use of the motor car in all kinds of weather, both summer and winter, have convinced me of certain definite points in regard to its present limitations and future possibilities as a physician's utility vehicle.

Experience with both types has convinced me that for physicians' use the air-cooled engine possesses such great advantages over one cooled by water that the latter need not be considered, any more than steam, for all-the-year-round service.

Fig. 18.—An auto that looks much like a buggy.

Motor Should be Accessible.

For reasons of accessibility, single and double-cylinder engines hung in or under the car body should be discarded in favor of the vertical multi-cylinder type placed in front under a hood. Chain drive, single or double, is noisy, expensive to maintain and dirty, and should give way to enclosed shaft drive through bevel gear to a live rear axle of floating type.

The differential is probably not necessary in its present form, and as many accidents occur which may justly be attributed to its action on slippery roads, a more positive drive is desirable. Such result may be secured by the employment of a screw and friction device at each rear wheel.

For smoothness of action, power and economy a two-stroke engine is far superior to the four-stroke type so commonly used at present, and as soon as the manufacturers sit up and take notice it will become the prevailing style for service cars.

The proportion of engine power to vehicle weight is all important and should be about one-horse power for each fifty pounds. This will allow the change speed gear to be dispensed with if a proper clutch is used which may be slipped for starting and when necessary on hills. The usual means of starting the engine by crank should be displaced or at least supplemented by a mechanism operated from the seat.

Details Desirable in the Ideal Car.

The wheels used at present are much too small and should be at least three feet in diameter; they should be of the pressed-steel double-disc type, and shod with solid rubber tires, for pneumatic tires are worse than useless on a business vehicle intended to replace a horse.

Experience shows that a physician's car should weigh about 1,000 pounds, and have a four-cylinder, two-stroke, air-cooled vertical motor under hood in front, metal-to-metal clutch running in oil, direct-shaft drive, bevel gear, and floating rear axle with wheels driven by differentially acting friction clutches. All mechanism must be completely protected from mud. No brakes should be located on transmission members, but all braking effect should occur at rear hubs. Large steel disc wheels are best, and they should be equipped with solid rubber tires. The body should be metal and no wood or other combustible material used in the construction of the car, which should be finished in aluminum paint from hood to muffler. Such a machine will soon be on the market.

Fig. 19.—Room for company in this doctor's car.

The machines which I have been using during the past few years do not correspond to the above description, but they have shown me in what direction improvements are needed. With all its faults, I like my present car (151) much better than horses in my practice, and find it less expensive to maintain than enough horses to do the same work.

THE AUTOMOBILE FOR PREVENTION OF CRUELTY TO HORSES.

H. B. KENDALL, M.D.
MENASHA, WIS.

SINCE March 28, 1904, I have operated an automobile over 6,000 miles on all kinds of roads, fair, bad and worse, in a circuit of thirty miles, and have been hauled home but once (a broken axle arm).

Before buying the automobile I was obliged to keep two or three horses; now I keep none, although for one or two months in the winter a horse is often a necessity; yet a road that is fit for a horse is fit for an automobile. The greatest benefit

to the public roads would result from the establishment of a like width of track for winter and summer.

I am a great lover of the horse, and it was this, more than anything else, that caused me to consider the automobile. The miserable condition of city streets and country roads for from five to six months of the year made it actually cruel and inhuman to drive the animals, even under the kindest guidance; and the often unavoidable exposures to cold, storms and flies which the faithful beast was compelled to endure gave me automobile fever and I haven't got over it yet.

Dives Into a Snowbank.

With the instructions sent by the company I alone, set up, started and operated my machine. The first thirty rods we drove, the pesky thing made a bee-line for a three-foot snowbank at a fifteen-mile clip and plunged in. The guiding lever failed to act because the gray matter in the driver's cranium

Fig. 20.—This physician has run this car 55,000 miles.

failed to direct the hand that controlled it. Of course the automobile was to blame for this. No harm was done, no horse needed; we pulled it out alone, swung to starboard, and were off—a little wiser. My experiences and observations have convinced me that carelessness, incompetency and lack of mechanical skill are a trio of factors that go far to cause biased and prejudiced feelings toward the automobile.

My car (162) has gasoline motor, two opposed cylinders; cooling positive on both high and low gear, whether vehicle is in motion or not, by a large special fan flywheel. The motor being mounted horizontally, the vehicle runs without any vibration that can be felt by the occupant. Get the highest horse power motor possible to apply to your automobile.

The Auto Will Not Run Without Being Cared For.

My car is kept in an ordinary old barn. It has the same wheels, in perfect condition, same body, paint and trimmings, and same tires (solid rubber) that were on when I received it. I care for and operate it myself; and now we are so well acquainted that I know better than to blame the commutator or brushes or spark plugs for every degree of failure of the motor to act properly; nor do I find fault with the carburetor, or some of the internal mechanism of the motor for such effects when a bank of weak batteries, an empty gasoline tank, or poor lubrication is the cause. Treat the automobile with the same consideration with which a good horseman treats his horse and it will serve you well.

My actual expenses with the automobile are rather less than keeping a good horse, with necessary paraphernalia, if I cared for it myself. A horse wears continually whether he works or not, and the expenses are about the same. Practically, an automobile costs nothing when not in use; it can only get out of style and behind in improvements, which are brought out every few months. In fact, most of the expense to my car is the result of this very thing, the addition of improved devices. Old will do, but up-to-date is better.

My car is either one or two-seated, and, as no dust wraps are needed in summer, the pleasure we get out of country rides and trips to neighboring towns more than compensates for its care.

Relative Cost of Keeping a Horse and an Automobile.

HORSE AND RIGS.		AUTOMOBILE.	
RELATIVE FIRST COST OF EQUIPMENT.			
Two horses	$400	Automobile	$700.00
Buggy, rubber tire	100	Fur robe	20.00
Cutter	50	Heavy lap robe	8.00
Cart	25	Summer robe	2.00
Two sets harness	40		
Two day blankets	20		
Two night blankets	10		
One fur robe	20		
One heavy lap robe	8		
One summer lap robe	2		
SUPPLIES FOR ONE YEAR.			
Oats, 390 bushels, at 30c.	$117	Gasoline, 120 gals., at 18c.	21.60
Hay, 2 tons	28	Lubricating oil	4.20
Straw, 6 tons	30	Spark plugs	6.00
Farrier services	75	Inlet valves	4.00
REPAIRS AND HIRED MAN.			
Repairs (ordinary)	40	Repairs (average circumstances	50.00
Man	100	Man	25.00
Total	$1,065	Total	$840.80

No. of months' service, 11 No. of months' service, 10.

These estimations are calculated on a basis of two years' service.

Time saved in making trips, 40 per cent.

I will give details of operation, etc., to anybody on demand.

Fig. 21.—A very comfortable appearing vehicle.

THE AUTO IN COUNTRY PRACTICE.

F. E. DAIGNEAU, M.D.
AUSTIN, MINN.

FEELING that I was wasting too much time on the road when making calls in the country, I decided in 1903 to dispense with livery hire and to invest in an automobile. Accordingly I bought a single cylinder runabout of a popular type (175), with governor timed ignition and gravity circulation. This car I used with fair success for two years, but found that when the roads were heavy, in spring and autumn, I did not have sufficient power. I then began an investigation of the different cars on the market for a doctor's use. The car (176) I finally purchased as most fully meeting my requirements was a three cylinder 15 H. P., 1,250 pound machine with large wheels, giving high clearance, and equipped with low tension magneto make and break ignition which practically eliminates all ignition troubles. The simplicity and accessibility of the mechanism leaves nothing to be desired.

This machine has done away with previous difficulties and as I take care of it and make all small repairs myself the expense of upkeep is comparatively light.

The Auto a Problem in Winter.

For eight months of the year I can use it in my work, but in winter I have to go back to livery hire. While the city physician can run his car nearly every day in the year the country doctor will find that winter use is not practical. Unless the car is kept in a warm place it is almost impossible to start the engine on account of the thickening of the lubricating oil. A light fall of snow does not prevent the running of a car, but snow does not remain spread out and the car is not made that will go through large snow drifts.

The automobile is certainly a practical vehicle for a city practitioner, and it has many advantages for the country doctor. Barring accidents, it is always ready, day or night; much less time is spent on the road than with horses and the doctor has more time for office work, study, or social duties. Also the auto is a delightful form of recreation.

Tires form the biggest item of expense in running an auto, but one should bear in mind that the wear and tear on these is greatly diminished by large wheels and a light car. I advise any physician who contemplates buying a car to get one with plenty of power and of light weight. Then let him acquire a thorough knowledge of its mechanism and be able to make small repairs on it himself if he would operate it successfully and economically.

Fig. 22.—A New England physician whose car is not hindered by any ordinary amount of snow.

A CONCISE ENDORSEMENT OF THE AUTO.

M. CLAYTON THRUSH, M.D.
PHILADELPHIA.

DURING the last two years I have used an automobile constantly in my practice. My car (177) is an 8¼ H. P. machine, run by gasoline, has single cylinder, water cooled, and has two seats. The complete cost of car was $830. I store the car on my premises.

The cost of maintenance has been carefully recorded, with the following result: Gasoline, oil, and dry cells average about $2.50 each month; repairs of all kinds average $3.00 each month. One set of tires lasts a season; the tires cost $35 each.

Economy and Satisfaction.

My car covers about twenty miles daily in Philadelphia and suburbs, is now being used for the third season, and gives as good service as the day it was purchased. The total time out of service for repairs of all kinds would not average twenty-four hours in a month. I drive my car myself and obviate expense of chauffeur. It requires about fifteen minutes daily to keep car in running order. Under above conditions the total expense averages about $18 each month. A horse and carriage would be more expensive to maintain with the same amount of time expended, and one cannot travel nearly as rapidly.

THE BUSY PHYSICIAN SHOULD STICK TO THE HORSE.

W. C. CLARKE, M.D.
CAIRO, ILL.

ORIGINAL cost of any new machine that will stand wear and service must figure at least $1,000. To keep in garage will cost from $10 to $30 each month. This includes repair work of all kinds, but new parts, if broken, cost extra. In my experience this item has been extremely small. Gasoline at the least costs $6 each month and oil $2. Our garage man keeps machines cleaned, oiled and fed, delivered at my door when called for.

My runabout cost me $800 without horn, lights, hood, covers, etc. My searchlight, bull's-eye lights, side lights, horn and Gabriel horns, clock, speed meter and top cost about $400 extra. The entire cost of maintenance, including expense for repair, gasoline and oil, has not exceeded an average of $25 a month. The expense of horse and buggy keep will average $20 a month. One will buy a new horse each year and a new buggy every two years.

Immense Saving of Time.

An automobile has the advantage of 75 per cent. when weather and machine permit. You do not have to untie or hitch, harness or unharness, and with a good machine you can go where horses can go. In making night calls it is at its best, for here you can save fully 95 per cent. of time. A point always to be considered is that in cold weather the auto must be kept in a warm place or you can not crank the machine.

A Plaything for Grown-up Boys.

Horse and buggy can not be mentioned in the same day with an auto for genuine pleasure, health and excitement. For the overworked doctor it is better than medicine, vacation or religion. It makes one forget he is living, or that he must some day die. It makes him feel that if he must die the auto route is the best. In fact, it is the only pleasure greater than our boyhood days of brass-toed boots and circus parades.

A Poor Business Proposition.

For a busy doctor who wants to know the truth of the automobile compared to a horse as a business proposition, I can say that the auto is not to be considered. You can not get along without a horse and buggy, winter or summer. At least, this is the experience of myself and two colleagues (154, 155) and we all own good machines.

In conclusion, I think automobiles belong to the class who have plenty of time for pleasure, who are willing to pay for it, and who know that they get the only real pleasure money can buy. The doctor who is busy and who is making money had better stick to the horse and buggy until his boys have graduated as machinists.

ESSENTIAL POINTS IN AN AUTOMOBILE FOR COUNTRY USE.

H. W. CHAPMAN, M.D.
WHITE HALL, ILL.

FOR the past two years I have been using an automobile in my work during the summer, when the roads are at their best. My machine (161) has many good points which I deem essential for economical use on country roads.

In the first place, it looks like a road wagon and, in consequence, is an object of less terror to horses than an automobile of the usual pattern. The wheels are 44 and 48 inches in diameter, with solid rubber tires. Two horizontal air-cooled cylinders of 6 H. P. are hung close to level of axles, which together with the wheels constitute about all the weight of the machine.

Complaints About the Makers.

This machine clears the road more than any other and has a speed of 20 miles an hour. There is no differential, and the transmission is exceedingly simple in construction; these things make it durable and economical as to power, but render

the driver's work a little more complicated. These wheels stir up almost no dust, and for good roads the machine is a success and reliable since I have worked it over; as it came from the factory, however, because of careless construction and adjustment, it caused great trouble and expense during the first season.

The legitimate expenses for repairs for the two seasons have been less than that of keeping one horse shod. Fuel and oils amount to less than the feed of one horse, as the machine only eats while working. The time consumed on the road is just one-half that required by a horse. For pavements and hard roads the machine would be all right every day in the year, but for country roads it has insufficient power if there is any mud, or if the steep hills are not smooth.

This machine is for two passengers, and had it been provided with a 15 H. P. motor it would probably be able to propel itself on steel tires which should be provided with self-sharpening calks that would hold on ice and greasy roads. With a wheel of this size a man should be able to ride 20 miles an hour on a steel tire, which is all the speed any machine should have for use on public roads.

Expects Little Improvement Until Market Relaxes.

If one can eliminate the pneumatic tire, the water-cool, the differential gear and the complicated transmission and have an honestly made engine of sufficient power at a price within reach of men of moderate means, our farmers and business men would soon have them and the prejudice against their use on the roads would rapidly disappear, provided the drivers had succeeded in reducing the golden rule to every-day practice. Up to the present, however, prospective purchasers do not know what requirements are essential, but trust the manufacturer, who is usually in the same position, but chiefly interested in converting his machine into cash. So long as the supply of inexperienced purchasers holds out there is but little inducement for the manufacturer to alter his models.

THE AUTO ADVANTAGEOUS IF UNDERSTOOD AND WELL CARED FOR.

PHILIP SCHUYLER DOANE, M.D.
CHICAGO.

FROM my own experience and that of my friends I have drawn a few comparisons between runabouts and the single horse and doctor's buggy. The original expense or outlay for the automobile is little greater. The cost of maintenance is, if anything, a little less—when the car is run carefully and intelligently. I feel confident that the experimental stage of the automobile is over and that the gasoline or steam machine has become a practical thing—almost a necessity to the busy doctor of the present day. In large cities and in the country, physicians doing general work must cover considerable territory. It must be done with the least possible loss of time—day or night. The well-constructed type of runabout will meet these demands as a horse or horses can not.

Pay Enough to Get a Good Car.

Great mistakes are made in the original purchase of an inferior machine which sells cheaper than the standard makes. The cheap car usually runs well for a few months, but then troubles commence and expenses multiply for repairs and new parts; and there is great loss of time and wear and tear on one's nervous system.

Learn Your Car and Care for It Yourself.

The knowledge of mechanics is desirable, but not necessary in the management and running of an automobile. Every physician is more or less a "natural-born" mechanic, and it does not take him long to form a very close acquaintance with and a warm friendship for his machine. He will soon know its very pulsebeat and be able to diagnose any difficulty that may exist in any of its vital organs. This intimate friendship is of the greatest importance if one would get the best results at the minimum cost.

Keep your machine in your own barn or rainproof shed. The average keeper of a garage has an idea that the automobile owner has a bottomless pocket. For the first six months that I owned my car (157), I kept it in a garage and the monthly expense, for washing and cleaning and delivering it to me daily, was $20. This is exclusive of gasoline, batteries, etc., of course.

With Experience One Can Save Much Expense.

I then moved out to our summer home and kept the car in our own barn. Our gardener washed and cleaned it and I looked after the machinery. This method brought the expense down to a minimum. I purchased a 60-gallon tank and bought gasoline at wholesale rates on account of the quantity.

The amount of gasoline consumed is governed by how much the car is run—the beginner always using up more oil than the expert for the same amount of mileage.

If you take care of your own car, very little time need be spent on it, if you look after the details carefully before you start out for the day. It is necessary that you have someone to wash and clean it for you, and this same individual can be taught to keep the tanks filled with gasoline, oil, water, etc. A few hours each week will suffice to go over the engine, clean it carefully, and tighten the bolts and screws.

Tire difficulties are the bane of an automobile owner's life. For that reason I think that the car that is well constructed but not too heavy is the car a physician should look for. The air-cooled machine, as it stands to-day, has no advantages over the water cooled; whereas, the latter has the advantage of not getting overheated in summer—that time of the year when the automobile is the greatest pleasure to you and your family.

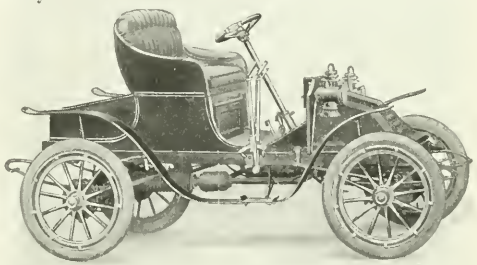

Fig. 23.—The runabout of a country practitioner in the northwest.

I have a water-cooled car, and have secured a 1906 pattern of my original purchase, and hope to continue to enjoy it and to prosper in my professional work, with my runabout to hurry me about in this large city and its many outlying suburbs.

FROM THE STANDPOINT OF THE LARGE MACHINE.

JOSEPH A. ROBERTSON, M.D.
NEW YORK.

ALTHOUGH my greatest trouble has been with the tires, it has not been from punctures but from rims cutting through the sides of the outer tire, resulting in "blowouts." The support being removed, the presure is thrown entirely on the inner tube, causing it to rupture with great noise like the report of a pistol. I have had this happen with new tires. These occurrences take up a great deal of time. The causes of this rim cutting are, mainly, three: 1, poorly constructed tires; 2, improperly fitting tires to the rims; 3, fast motoring. Manufacturers have given this subject very careful study during the past year, and now claim to have obviated this troublesome problem. Being in this quandary I replaced the American rims and tires (171) by French rims and large tires (172) supplied by a leading French tire manufacturer. Since changing the tires I have had no such troubles as in the past.

Motoring as a Health Giver.

I can heartily recommend motoring as a health-giver. It keeps you out in the fresh air and sunshine. The constant

vibration, changing panorama, etc., are conducive to building up a firm foundation for a long life. I believe a great many overdo this pleasure-giving recreation. People who find it to be a tremendous nervous strain to drive their own cars should not continue, as nerve exhaustion soon follows. I have seen several persons whose nervous systems have suffered from driving their own cars, causing insomnia, loss of weight, etc.

Protect the Eyes with Goggles.

The traumatism of the conjunctiva in motoring is very severe and one should always wear goggles. Particles of dust and dirt are constantly getting into the eyes, even with goggles on, and I advise to have constantly on hand some 1 per cent. solution of cocain and a saturated solution of boric acid. I also prescribe after a long motor run to douche the nose and throat with some mild antiseptic, thus obviating any infection which might be in the dust which has accumulated in the nostrils, nose and throat.

It is of great importance for one to understand very thoroughly the individual car one is driving. Learn the carburetor construction piecemeal, as this can be called the heart of the gasoline engine.

Important Construction Details in Large Cars.

Lubrication ought to be from the dash-board to the principal bearings. This system should be mechanically operated. The splash system should be used in the engine case and gear case.

Fig. 24.—Ready for the day's professional calls.

The multiple metal disc clutch and internal expanding clutch are the two best types. I give the preference to the internal expanding type as this obviates any thrust on the engine shaft and bearings.

The large Hess-Bright type of ball bearings for a car has given the best results. These bearings are being used by the leading automobile manufacturers in the engine bearings, wheel bearings, gear case bearings and transmission throughout. Flexible joints between clutch and transmission are used for alignment. The universal joint is commonly used.

In an automobile greater than 24 H. P. the wheels of such a car should be very strong. Many accidents have been called to my notice by the breaking of a front wheel from skidding or turning sharp curves. I know of one case where the front wheel broke on an automobile that was going at a speed of 30 miles an hour, and the car was thrown over as a result, causing serious injury to several of the occupants. The frame should be of a strong steel. For all around usage I would recommend a 24 to 35 H.-P. automobile, water cooled, mechanically operated inlet and exhaust valves, with carburetor of the cool air type. For the axles, shafts, gears and wherever strains are heavy nickel steel should be used. Springs ought to be long, large and strong. This will eradicate using any shock absorbers, which are not necessary if springs are properly constructed. The suspension of the car frame in the rear should be of the three point spring type. Piston rings four to five in number give the best results. The chassis should have at least 110 inch wheel base. Some modern cars have a wheel base of 120 inches. The longer the wheel base the easier the car rides.

On average roads I would advise the chain drive. For a very sandy region where there are also pebbles the bevel direct drive is the best as many chains are broken by pebbles getting in them. This kind of drive, however, has not been successful on the very high powered cars. The gears of the shifting selective locking type are the most modern and must be considered before any others.

Carry Outfit for All Emergencies.

For all motorists I recommend a full set of tools, extra inner tubes, shoes, tire pump, chains, tire chains, repair tire outfit, fire extinguishers and plenty of lamps for night driving. The supply of gasoline to the motor is best accomplished by the pressure system, using compressed air and the exhaust pressure in the gasoline tank. The Limousine body is the most adequate for a physician's use.

Cost of Keeping Large Cars in New York City.

I have driven a 16 to 22 H.-P. 4-cylinder, double chain driven gasoline touring car (173) nearly 19,000 miles unaccompanied by a chauffeur, mostly in New York and vicinity, over good roads. The longest run I took was to Lake George via Saratoga and return. All kinds of roads and grades on this run were encountered.

The accommodations for a machine in New York are very fine, and my machine was kept at one of the garages. I did all of the minor repair work on the car. The heavy repair work, which involved more time than I could give to it, was done by the repair shop at the garage.

It is more expensive to purchase and to keep up an automobile than a horse. The cost of maintaining an automobile in New York City, along the lines I mention, is, in round numbers, $60 a month. This includes storage, which amounts to $25. If one has a chauffeur, the expense would amount to $125 a month. If one has his own stable, this large storage bill would be eliminated.

The cost of an American automobile of the horsepower I advise is from $3,000 to $5,000. With such a machine you can figure on one gallon taking you from 12 to 18 miles.

I have called attention to modern ideas about the larger cars instead of relating my minor mishaps and experiences. These general ideas have arisen from experiences and observations I have had and made with automobiles of all kinds (174). "Experience is the best teacher."

Weighing the time of going from one place to another, where distances are great, the automobile should be given the preference. In a very hilly country the wear and tear on an automobile is very great, and I would recommend the use of a horse in preference.

THE AUTO INVALUABLE IN GENERAL PRACTICE.

A. C. KIMBERLIN, M.D.
INDIANAPOLIS.

FOR actual service, pleasure and satisfaction the automobile is invaluable for one engaged in general practice.

Five years ago I began to use an auto. The increasing difficulties attending the selection and maintenance of horses and keeping a coachman made it necessary to adopt some other means of transportation, as the attention required by these details seriously interfered with my practice and added much to my work.

Use a Gasoline Car.

I first tried electric cars for about two years, and found them impracticable because of the expense of maintenance, the limited capacity of service and the time required in keeping them charged. I decided to try a gasoline car, and purchased a four-cylinder, air-cooled machine, because of its simplicity of construction and the avoidance of difficulty with water in freezing weather. I very much prefer a four-cylinder engine because of the smoothness with which it runs and the advantage of enabling you to get to and from houses of sick people with much less noise than a single or double cylinder machine. The added H. P. of a four-cylinder engine while not often required, is frequently very much needed, and the selection of a car of too low H. P. is, to my mind, one of the serious mistakes often made in the buying of a car which is intended for every-day work over roads and under conditions which you can not select or control. Occasionally, as in our recent heavy snowfall, which lay on the ground for a period of two weeks to a depth of 12 inches on a level and in many places where the snow had been swept from the sidewalks and street-car tracks into the street the depth exceeded two feet, to be able to drive every day and meet with practically no delay in speed convinced me of the supreme importance of having plenty of reserve power. For two days of our recent snowstorm, when our street cars were tied up and horses soon fagged out or made very slow speed at best, to be able to go without delay and without inconvenience except the difficulty of steering, certainly makes me almost an enthusiast in the use of an automobile for a physician engaged in general practice. There is a great advantage in selecting a car of good and simple construction and then using one make. Most of the inconveniences experienced by those who have had no experience with gasoline engines arose from trifling things which could easily have been avoided had the driver any understanding of the proper care of his car, and yet the machine was condemned as being impractical when the fault was the driver's ignorance.

Nominal Expense for Maintenance.

As to expense, my gasoline, lubricating oil and repairs average less than $10 a month the year through. To this must be added, of course, the expense of new tires (about $140); if properly cared for the outer casing, in my experience, will last about one year. The total expense is very much cheaper than the same amount of work could be done with the use of horses, to say nothing of the extreme satisfaction as well as the economy in time in getting about. On a busy day I save about two hours' time by the additional speed which I am able to make.

Less Worry Less Expense, More Comfort.

Formerly I kept three horses for my work, but the selection and caring for them caused me very much anxiety aside from the dread of always being dependent on a coachman, a very unreliable employé at best. With my machine, which I always drive myself, my hurried or long calls and night work are done with little of my former worry, and with my enclosed car, the body of which I had built and put on the chassis of the same style that I formerly drove, rain and snow, and most of all, the cold wintry winds, no longer annoy me, and after a day's work with practically no exposure, I have a feeling of supreme pleasure of having made a very great saving of time. At first I kept my car in a garage, but this soon proved unsatisfactory because of the expense and the impracticability of having it delivered to my house or office. I now keep my car at my home for less than half the expense of storage. As I employ a man for my house and yard at all times, I find with a very little time and explanation as to the care and attention to essential points which I am able to point out to him, my car is always ready, and I can stand a strike on the part of my stableman much better than when I was keeping horses. I train my man to wash, oil and care for the important parts of my car, but do not permit him to drive it, as I find that the average man as soon as he is able to take a car on the road has little interest in anything else.

My first car (1880) I drove about 10,000 miles, using it in all kinds of weather, hot or cold. My last enclosed one (1810) I have not driven such a milcage, but it has proven much more comfortable and convenient, and requires, if possible, less attention owing largely to the better perfection in detail of the carburetor, commutator and spark coil used in its construction. The box deck on these cars I find a very convenient place to carry my cases and other paraphernalia.

I can not praise too highly the real value of an automobile for the use of physicians regularly engaged in general practice, for when properly cared for, as well as driven, which is too frequently not the case, I find on average good roads it can not be compared to a horse.

THE MOTOR CYCLE FOR THE COUNTRY DOCTOR.

W. NICHOLAS LACKEY, M.D.
GALLATIN, TENN.

REALIZING that it is good to have a hobby—one to ride in reality and not figuratively speaking—and having a mechanical turn of mind, my hobby for the past five years has been mechanically propelled vehicles.

Autoists Must Study Their Cars.

During the last four years I have driven half a dozen makes of cars (191), and on numerous occasions I have driven the automobile to see patients under trying conditions of road and weather.

Fig. 25.—Protected in a pouring rain. The physician has dropped the rubber curtain while the photograph is taken.

Let me say right here to prospective purchasers of automobiles, for country practice, if you don't like machinery and are afraid of getting grease on your hands in acquiring a thorough knowledge of every part of your car, and don't feel that you have the time to read up on the principles of the gasoline engine, don't be deluded into buying an automobile, for you will meet only with disappointment in its use. Your success in using it in your practice will depend on the amount of knowledge you possess of its every part, for even the best constructed gasoline motor will at times give trouble. With a bit of trash clogging the nozzle of your carburetor, or a loose or broken commutator spring, or a short circuit in your wiring, you will be just as helpless ten or twelve miles from home, and the town mechanic, as you would be if your car had dashed against a stone wall and converted itself into a scrap heap.

The expense of upkeep, and especially that of replacing injured and worn-out tires, are the principal objections against the automobile for the country doctor, who is usually in moderate circumstances financially. The low cost of keeping a horse and buggy in the country and in the small towns makes it hard for the automobile to compete, from the standpoint of expense, though the saving in time, a greater range of mileage, will, to a certain extent, throw the balance in favor of the automobile. The price of one full set of new tires, however, in my town, will nearly pay the feed bill for "old Dobbin" for seven or eight months. In the city the expense of the horse-drawn rig is, of course, greater, so there is not such a disproportion between the expense of the two modes of locomotion.

Manufacturers Are Indifferent.

I don't believe that the automobile has yet been constructed which is in every way as thoroughly practical for the country doctor every day in the year, winter and summer, as it should be. The cause is the indifference or ignorance on the part of the manufacturers, of the practical requirements of a car which would be adaptable to the needs of the doctor.

Ideal Car for Country Doctor.

My idea for a car for the country doctor is as follows: The car should be of the runabout type, two air-cooled cylinders, from 7 to 12-horsepower. It should be equipped with solid tires—several makes of solid tires are now on the market. While they decrease the speed and increase the danger of injuring the machinery from the jars and shocks unavoidable on the road, still if driven with care over rough road this objection, to a certain extent, would be overcome; but the freedom from delay on starting on a hurry call and finding a deflated tire, delay on the road from punctures and blowouts, longer life, and the doing away with the actual manual labor of pumping up tires, recommend them over the very unreliable pneumatic tires, for the doctor's use, anyway. The car should be equipped with a Holley carburetor, which, owing to its giving your cylinders a better mixture, will produce from one and one-half to two additional horse-power. The saving in gasoline alone will pay for it in a few months. The ignition device should be of the most reliable type, for this is usually, with the exception of the tires, the most unreliable part of the automobile. The body should be so constructed that every part of the machinery is easily accessible for cleaning, oiling and adjusting. The planetary change-speed gear and transmission is practical for the runabout, and with proper care rarely gives trouble. The car should strike the happy medium when it comes to weight. The light but strong runabout, with engine of ample power, can negotiate muddy and sandy roads, where many of the heavier machines would come to grief. The tool box of the doctor's car should contain everything necessary to make any reasonable repair while on the road. A top with a full complement of side curtains and storm aprons, also a well-fitting boot, to protect the engine and especially the carburetor from mud and water. All are necessary for the doctor's car, which is to be used in all kinds of weather.

Points in Selecting Car.

To my mind, the points in selecting the car for the use of the country doctor should be in the order named: Reliability, durability, economy of upkeep, hill-climbing ability, price, ease of control, speed, and lastly, appearance. Our roads in Tennessee are above the average, those in middle Tennessee being macadamized turnpikes, but it is not how fast the car can run over the roads, but how fast the roads will let the car run without racking it to pieces. This I know from experience, in driving through the country in a car equipped with a speedometer, to be from 15 to 18 or 20 miles an hour (usually between 16 and 18). Almost any make of car has speed to spare, but the other points named are of much more importance and are not possessed by all makes of cars by any means.

Expense.

Avoiding bad accidents, a doctor who understands his car houses it and does most of the adjusting and small repairing, should drive his car at the expense of from $175 to $200 a year This is not counting depreciation on car and interest on money invested.

A doctor equipped with a car somewhat as above described, and a good reliable make of motor cycle, ought to be independent of the horse, provided he has no patients who live very far off the roads.

Advantages of Motor Cycle.

I believe the up-to-date motor cycle (1908) to be the automobile for the poor country doctor—at least during the summer and fall months when the roads are dry. They can not be used in the mud. Even if he possesses the more expensive automobile, he will find himself learning more and more to enjoy the powerful little machine in its exhilarating rush up hill and down to the bedside of his patients. One of these machines will save many a dollar on operating expenses in a season on an automobile. I have ridden thousands of miles on a motor cycle and have never failed to reach my patient on time or had to walk home. I have ridden long distances in emergency cases, in the country, at a 30-mile-an-hour clip, and have also responded to calls at night on my motor cycle (1912), which is equipped with a strong acetylene lamp. The white road spinning beneath my wheels, with the dark shadows fleeing before the light, with the cool night air blowing on my face, have added not a little sport to the occasion.

$3.50 a Month for Expenses.

The expense of operating one of these machines is about $3.50 a month, including gasoline, batteries and oil, tires not included. One set of tires usually lasts two seasons.

You can get more downright service and comfort out of one of these little machines, the weather permitting, than out of an automobile. Before I bought my motor cycle I was extremely skeptical as to its practicability, but a few months' constant use proved to me the wonderful amount of work that can be accomplished with one of these little time savers.

The automobile enables the country doctor to cover five times the amount of territory in his practice that could be traveled with a horse. The great amount of time saved to attend to his office work, more prompt answer to emergency calls, the long irksome drive converted into an actual pleasure rather than a thing to be dreaded. Last, but not least, the advertisement afforded by the automobile is not without value as a practice getter. These are a few of the advantages of the automobile.

In conclusion, let me say, don't purchase an automobile because of its paint or gaudy appearance. The motor is the heart and soul of your new steed. Study the subject theoretically and practically, if possible, on the machines owned by your friends, and then with the advice of a trustworthy and competent mechanic, make your purchase of a new and up-to-date model. Don't make the mistake of buying a second-hand car. There are some exceptions I know, but my experience is that it costs more to get a second-hand car in good shape than it does to purchase a new one outright. The automobile, used with due consideration to the people who drive horses, will add to your influence as a modern and up-to-date practitioner of medicine in your community.

THE AUTO SUPERIOR TO THE HORSE.

A. E. MACKAY, M.D.
PORTLAND, ORE.

FOR the use of a motor car the climatic conditions here are almost ideal at all times of the year, but the lack of good roads in outlying districts interferes considerably during the wet season, for it must be admitted that the automobile requires fairly good roads to ensure economy and comfort.

For the past four years I have used almost continuously a machine of the runabout class and have kept accurate account of all expenses in connection with the use of the vehicle. My first machine was a small runabout (1910), used every day, summer and winter, for two years and four months, at an average cost of $21 a month. Including the loss on sale when disposing of it to buy my second vehicle, the monthly expense amounted to $34. My second machine of the same type, and for eleven months' use, including the loss on sale, showed an average monthly cost of $37. My third venture was slightly more pretentious, a touring runabout, which has been in constant use for ten months, and will average, including an estimate for overhauling and painting this spring, about $28 each month. These estimates include all expenditures, gasoline, carbide, tires, repairs and a garage charge of from $10 to $15 a month, which one might easily save if a private garage or stable could be secured at home.

Suggestions for a Prospective Purchaser.

Most of the up-to-date automobiles are very reliable and fairly fool proof. An investor should insist on a machine being thoroughly protected from dust, water and mud, should demand that hand levers, steering posts and such other means for controlling the car be so placed that a driver could enter his car from either side, should choose a vehicle with clutch drive and simple air-cooled engine, with modern wheel base, so that complete towns could easily be made on an ordinary thoroughfare, with moderate weight, thus obviating undue wear on tires, and with one seat, so that the temptation to overload the car will be avoided, and then work for good roads and streets first, last and all the time.

In reviewing my experiences and comparing them with those who employ the horse-drawn vehicle, everything seems to favor the automobile. When the motor car is disabled it requires but a short time to place it in commisson again, but with a horse disability means either a long holiday in pasture or the policeman's bullet. The automobile is patient, reliable, ever ready, and after a hard day's work it still can be used for a pleasant evening drive or as a means of conveyance for oneself and wife to theater or social function.

To the prospective purchaser, my advice would be: Look over your field of activity and if fairly good roads prevail, buy your choice of motor car, giving preference always to the manufacturer who has a reliable agent in your town or near vicinity, and I feel assured that the large amount of time saved and the pleasure and diversion obtained will amply repay for additional expense over other means of transportation.

WRITES OF MUCH TROUBLE, BUT IS NOT DISCOURAGED.

BY A CHICAGO PHYSICAN (211).

BEING naturally fond of machinery, I took the automobile fever early, but managed by prudence to hold it in check for about four years. At length I purchased a small second-hand steamer (212) that I kept about three months. I ran it altogether about 400 or 500 miles, and finally sold it at a total expense of about $300. Later, I bought a new strong gasoline machine, which I think is one of the best on the market. The first year my bills for gasoline and repairs were only $600, although the repairs were mostly made by my son at no cost for labor. The next year I thought I would take a short country run, so started out one fine June day with my son as chauffeur and my brother and daughter as guests. For the first 60 miles I thought I was having the finest time in my life. Trouble came thick and fast for the next 20 miles; then I sent my daughter on by train; the rest of us stayed over night and the next day we limped into the town of our destination, 100 miles from the city, eighteen hours behind time. The next day being Sunday, we visited with our friends and the following morning my daughter and myself came home by railroad, leaving my brother and son to make repairs and to come with the machine. They were finally towed into the city five days later. My repair bill, as my son did all the work, was only $50, but I had to send the machine to the shop immediately. There they tinkered with it about two months, on four different occasions, pronouncing it all right; but on taking it out it would balk absolutely within from 5 to 15 miles on fine boulevards. The total mileage for these few weeks was about 100, cost $200. I then sent the machine to the factory, where it was put in good order, and it has since that time run beautifully whenever the wheels and tires would permit. In the meantime, I had bought another new car, which was a fine piece of machinery, but my troubles have not lessened materially. I have kept an accurate account and the expense of maintenance, including chauffeur and depreciation, has not been far from 75 cents a mile; but we have never had any very bad luck, have never hurt anyone else, never been sued for damages, only arrested once and never caused an actual runaway. My man had his leg and arm badly hurt by kick-backs, which cost considerable time, but as I was a physician the doctor's bills were small. My son had his arm broken in the same way, and this kept him home from college for six weeks, but we think we have a great deal to be thankful for. I am still optimistic. I own two machines now, though just at present neither of them is in commission, but I anticipate a great deal of pleasure in the future.

The Enthusiast Forgets His Troubles.

I have a suspicion that those who report very little trouble often have short memories; but I am sure the best time to own a car is before it is six months old, and that afterward one must expect a lot of trouble. The machines are being constantly improved and the time will come when they can be handled almost as easily as a sewing machine.

I am a thorough believer in the automobile, but think that at present its cost is fully twice that of horses and carriages, but when it runs it beats the latter "all hollow."

AUTOS NOT YET PLANNED FOR PHYSICIAN'S NEEDS.

HERBERT T. CLOUGH, M.D.

BANGOR, MAINE.

DURING the spring of 1905 I purchased a three-cylinder gasoline runabout (139), with top, in appearance more like a phaeton than like the conventional type of automobile. I keep the machine near my office and look after it myself, this work affording me quite as much pleasure and recreation as the use of the vehicle on the road. I used the machine continuously until snow began to fly last fall, under all conditions of weather which might be expected during the summer and fall seasons and over all kinds of roads—mostly bad roads—for we haven't anything in the way of roads to boast of in this section of the country.

Trouble Less Than with Horses.

On the whole my troubles have been fewer and less annoying than has ever been my experience with the horse-drawn vehicle for the same number of miles traveled; while the exhilaration, and freedom from anxiety for the horse's welfare affords a real rest in a long drive, which is absent when a horse furnishes the power.

Less Than Three Dollars a Year for Repairs.

My expenses for repairs during the entire season was $2.50, but I had no tire trouble. Allowing for tire repairs (for most men will not be so fortunate as I) I think $8 to $10 a month will cover all cost of maintenance. My machine is very easy on tires, most of the weight being on the rear wheels, which are 36 inches in diameter.

I believe the automobile can be made a thoroughly practical vehicle for the every-day use of the physician, and that in time it will add to his income, pleasure and span of life; but that time has not arrived—at least, not to all physicians. To those, who, like myself, enjoy caring for their machines, or at least supervising such care, many of the faults as now constructed can be kept righted and trouble anticipated and avoided. Such men will find pleasure in the use of the automobile, while those who lack interest in machinery, and who, therefore, give no attention to the mechanism, will leave the way open for troubles which will discourage its use.

Mechanical Perfection to Come in Future.

Later, the faults will have been largely eliminated, and at the same time a class of mechanics will have been educated in the care of these machines, so that when an accident does occur it will be easy to step into a shop and have it remedied, just as now when a horse loses a shoe. Little attention has been given the automobile as applied to the physician's needs, nor can we expect such attention so long as the more reliable makers can find a market for their product as now turned out, faster than they can turn it out. The demands of luxury must first be met; when these are supplied, then inventive genius will find the way to eliminate the troubles, and to attain that reliability which a physician, above all other users of the automobile, needs. The difficulties are not insurmountable, and will be remedied as soon as the industry has caught up with the demands of the public.

ADVANTAGES AND DISADVANTAGES.

S. B. DICKINSON, M.D.
WATERTOWN, S. DAK.

HAVING used an automobile for nearly three years, both winter and summer, I am convinced of the truth of the following statements: 1. The average physician can use an automobile to advantage in his practice. 2. It must be a practical machine. 3. He should know it from stem to stern. 4. He should have as much consideration for his machine as he should for a horse.

The advantages may be summed as follows: Time saved, conveniences too numerous to mention, recreation and precedence. The disadvantages may be boiled down to this statement: less the liability of trouble on the road.

Requires More Patience Than a Hysterical Woman.

By the average physician, I mean the physician who has a reasonable amount of self-control. A man can not be impatient or "rattle-headed" and operate a car successfully through thick and thin. Trouble will come, and he must often have more patience than is sometimes necessary with a hysterical woman.

A physician requires a machine with plenty of power, moderate speed, 25 to 30 miles an hour, reliable in every particular, plenty of luggage space and high enough from the ground to clear stones and ridges. I know of no machine on the market to-day that meets all these requirements unless it be one make of machine with high wheels, solid tires and cable drive, and I can not help but look with favor on this machine.

Tires Are the Hardest Problem.

Do not expect a machine to do proper work unless properly oiled, properly adjusted and properly housed. I have left my machine (138) standing over night in a temperature 25 degrees below zero and started it the next morning and kept it running for fifteen or twenty minutes and then stopped; but I do not claim that it did the machine any good, for the oil was so thick that it did not lubricate the cylinder. I have also run my machine without water in the cooler, thinking I could make a certain point before stopping; by so doing I caused a crack in the water jacket.

I shall never discard the auto for the horse in my practice.

PHYSICIANS' CLUB TO MANUFACTURE IDEAL MACHINES.

L. M. ALLEN, M.D.
SOUTH NORWALK, CONN.

DURING the past three years I have been using a 10-horse-power, single-cylinder, water-cooled, gasoline automobile (140), costing $850, and I expect to use the same car three years more, unless something very much better is put on the market at a reasonable price. In my practice the automobile has not been nearly as expensive as two horses and a man, but somewhat more expensive than one horse boarded at the livery stable. Maintenance and repairs cost a little over $35 a month, while to keep a horse at the livery stable costs $20 a month; shoeing, $2; a boy to drive, $15; wear and tear something over $5 a month.

Keeps in Running Order All the Time.

During the past winter I have depended on my car entirely. Last winter I used my car until the first of February and the winter before that until the first of January. My car is seldom out of commission, and is almost always tuned up to do its best, because I usually spend about half an hour every morning looking over it and making little improvements in the adjustments, and the time so spent is a pleasant pastime.

I have been waiting and expecting every year to see something more suitable for the doctor's use put on the market at a reasonable price. If we could have something of about 15 horse-power, geared with several speeds, one speed of about 8 miles an hour for very heavy roads, we could push through everything at that speed, up hill and down, through mud and snow; whereas now we have to take the bad places under slow speed. Some may think 8 miles an hour very slow, but that is only for the very bad roads.

Club Together and Buy One Thousand Ideal Machines.

Here is an idea that persists in presenting itself to my mind. There are so many physicians looking for suitable automobiles for their work, and there is such unanimity of opinion regarding the power and general style of automobiles required, why not club together and give the contract to some reliable manufacturer to build a thousand automobiles (or ten thousand, if needed), all of one style and power? Such a car could be built for a little more than half the price now paid, by saving the big commission now paid to the agent and the enormous expense of advertising and by getting the advantage of the reduced price of building a great number of duplicate parts.

The contract might be given to the lowest bidder who would build the cars according to specifications. If some manufacturer were only alive to the opportunity, he could get orders for any number of cars, and a deposit on them before the cars were commenced.

THE GASOLINE AUTOMOBILE A FAILURE.

E. J. GALLAGHER, M.D.
NEW YORK CITY.

I HAVE had the painful experience of having been one of the pioneers in the use of the gasoline automobile (144) as applied to a physician's use, and I unqualifiedly say that they are failures, for several reasons. They are unreliable and always in trouble and require an engineer to run and to take care of them. They need daily care; one can't let them go two or three days without oiling, tightening loose bolts, etc., as with a buggy.

Continued Trouble and Worry.

Of course, a horse needs some care, but the liveryman or stableman will do that and clean the buggy also for $25 a month in this city. In the garages, on the other hand, they simply wash the automobile and polish the brasses for from $15 to $25 a month; all the oiling, etc., the physician must do himself or have it done and pay for it extra. Even when one pays for it the men in the garages either forget to do it or half do it, so one goes out in a pleasant frame of mind and after a mile or two is obliged to get out the oil can and get busy hunting for that squeaking bearing, and at the same time add some oil and grease to both hands and clothes.

The Auto Can Not Be Depended On.

The garage charges do not include gasoline or cylinder oil or oil for wheels and bearings (the latter is usually supplied by the liveryman if one uses a horse). It is very difficult to convey any idea of the unreliability of the automobile, but it is so unreliable that it is practically useless to a busy man. It is expensive, as any small part is charged for excessively by the makers of the car, and, in addition, the repair men have a very playful habit of charging from 60 to 70 cents an hour for their work, and even then are not satisfied, but will charge for thirty hours when they have only worked ten hours on the car.

The tires are very expensive and a nuisance; if they are pneumatics they puncture and blow out and require constant care. The solid tires are expensive in first cost and make the car anything but an easy-riding vehicle.

Horse a Thousand Times More Reliable.

While the automobile can be shown to be much cheaper than the horse (on paper), I am satisfied from my experience that the horse is far cheaper and a thousand times more reliable. The automobile that is reliable enough for a physician's use in the city is not made, so what can be said of it for a country doctor's use?

Every Autoist Praises His Own Car.

This is a strange thing to say, but many people (doctors, as well as others) always praise their automobiles, and, no matter how many troubles they may have with it, or how much the expense may be, they never say a word (in public) against that particular machine. Whether they are ashamed to show how badly they have been victimized or not, I don't know, but it is a fact that if one becomes an owner of a car he also becomes a selling agent for that car. Knowing in his heart that it is not suited for his or any physician's use, still he praises it as the only car worth buying. The troubles of the auto are many and the expenses heavy, for nearly all of the repair men are a pack of cormorants and charge excessively for any work they may do. If any of your readers want more of my experience they can have it willingly.

THE SIMPLE RUNABOUT FOR THE PHYSICIAN.

WILLIAM THOMPSON, M.D.
CHICAGO.

HAVING used motor cars for work and pleasure for over three years, I feel that I have had some experience. My first machine (206), a one-cylinder runabout, was among the first of that particular manufacture to reach Chicago, and had many weak points, but I suppose it represented a fair article at that period of automobile development in this country. The expenses for repair and general up-keep for this machine were more than they should have been because I was a beginner and had to learn. My next experience was with a so-called ten-horsepower, four seated touring car (207) of pretentious appearance and very much noise; thank heaven, it has become obsolete. My next machine (208) was of standard make, two-cylinder under a bonnet, rated at 12 to 14 horse power, but as nearly as I can calculate 8½ horse power was about the proper rating. It gave good service, however. I next invested in a four-cylinder car (209) of good size and power, assembled by a local dealer who only put out about a dozen of the same type and who, I believe, has not brought out any since. The engine was made in a reliable factory and the chassis from one of the best part houses in the country and was generally satisfactory. The engine is as good as ever and I believe that for the amount of wear and tear this machine has seen it ranks equal with any modern priced touring car on market. My expenses for the year 1905 for repairs of all kinds, gasoline and storage, have amounted to a little less than $300. Since October, however, I have had my own barn and of course have had no storage bill, but the expenses for cleaning, etc., have been just the same.

Much has been written regarding the physician's ideal car, but I do not think that it is yet on the market. It is certainly not the horseless buggy that advertises itself as ideal, nor some of the runabouts of cheap material and poor assembling. The nearest to it which I have seen are the 6 and 8-horsepower cars (210) that are so popular among English physicians or the small Peugeot type which is no longer manufactured.

Runabouts Are Not Well Made.

In this country the greatest advancement in motor car building has been made in touring cars and commercial vehicles; vanadium and chrome nickel steels are not used in runabouts as they are in touring cars, and until the manufacturers use the same grades of material in runabouts that they put into higher grade touring cars the runabout must be short lived.

Not all physicians would consider runabouts the most desirable for their purposes. In large cities, with well-paved streets, and particularly where one wishes occasionally to take his family into the suburbs for short runs, the touring car is preferred.

The Need of Fool-Proof Mechanism.

We hear a great deal about four cylinders as giving a much more even torque than the two cylinders; granted this advantage to the four-cylinder car, I don't think that we should underestimate the well-balanced two-cylinder or one-cylinder car, particularly when the two is a horizontal opposed under a bonnet and in front of the driver. For simplicity and "get-at-ability" it is the ideal for the novice. One whose mechanical ability is below the standard should have a machine with simplest "fool-proof" mechanism unless he employs a skilled mechanic. The more experienced motorist who has graduated from the runabout and who has a fondness for things mechanical will find more pleasure in the touring car.

Avoid fads and novelties and adhere to standard types built by reliable firms. Buy your motor as you would your horse, not for one season, but for many. Study its anatomy and physiology and all the pathology that you can acquire—I do not believe that any one man can know all the pathology of the motor.

THE EXPENSIVE REPAIR SHOP.

PARKS RITCHIE, M.D.
ST. PAUL, MINN.

EITHER I was unfortunate in my selection of a complicated machine, easily and frequently out of order, or, like the gentleman traveling from Jerusalem to Jericho, I "fell among thieves." Besides the salary of my chauffeur, my expenses for 1905 averaged $70 per month; too much for a two-cylindered runabout (112).

Too many boys are learning their trade in the garage at the expense of the unfortunate owner. It is marvelous how the hours roll up in the repair of the most trivial part of the machine.

Never Knew Before What Luxury Was.

In January, 1905, I changed to an electric with coupe top (113). I never knew before what luxury meant. The serious objection is the short mileage and limitation to city streets. The ideal combination would be the electric for comfort and pleasure on good streets, and a gasoline runabout for hurry calls.

Could Not Again be Content with Horses.

In the near future the automobile garage will be conducted more on business principles, and the boys who learned on our machines will be able to do skilled work. In spite of some grievous experience, I could not be content again with horses.

THE AUTO A LUXURY FOR THE WELL-TO-DO.

BY A PHYSICIAN ON THE WESTERN PLAINS (193).

FROM a practical standpoint, for a man doing business in the city, an electric auto is a convenience and a delight, and is much more satisfactory than a horse. If necessary to leave the paved streets, it is about as unreliable as anything can be. It does not work well in the mud; this from observation.

I own a gasoline motor car (194) of the Stanhope type. On the pavement, even in bad weather, except in winter, it is a constant source of pleasure and a great time saver. In muddy weather, off the pavement, it is about as useless a piece of property as one can conceive of. I have had only one winter's experience with it—a very unsatisfactory one—but I admit that I have not used an antifreezing mixture.

Unless Well-To-Do, Stick to Your Horse.

The chief trouble with a Stanhope or any small car is the want of power. The constant demand is for more power. If a Stanhope type could be constructed with a 30 or 40-horsepower engine, I believe it would be an ideal machine for all conditions. One could get speed if he needed it, and power enough to maintain a greater speed under nearly all circumstances.

I am a firm believer in the automobile, but at the present time, if I may judge of them from my own limited experience, I would say that they are a luxury to be enjoyed by the well-to-do. The poor devil had better stick to his horse.

SUGGESTIONS AS TO THE PURCHASE OF A RUNABOUT.

GEORGE L. RICHARDS, M.D.
FALL RIVER, MASS.

LITTLE value, it seems to me, can be derived by the intending purchaser of an automobile from the statements of users during the last two or three years, because the first machines were very crude and necessarily cost considerable to operate, and were only partially satisfactory even then; whereas at the present time machines that run well can be purchased at reasonable cost.

The Engine Should Be Very Accessible.

The physician who intends to use his automobile for his daily work should choose it with due regard to the needs of that work. Since the average physician is, as a rule, not much of a mechanic and is seldom dressed in a mechanic's garb, his machine should be of the simplest possible construction and with all parts as nearly accessible as possible. After experience with engine under the body and under the hood, and with chain drive and shaft drive, I should discard entirely the chain and the engine under the body, for the reason that the chain is dirty, constantly lengthening and not infrequently breaks; the engine under the body is inaccessible, and even slight adjustments and repairs can not be made without getting oneself covered with grease and dirt, whereas a suitably constructed engine placed under the hood is accessible as to simple adjustments and even small repairs without the necessity of changing one's clothing and without having to get on one's back.

I should discard the single cylinder entirely, on account of its noise and general shake. A double opposed, horizontal, two-cylinder engine or a two-cylinder vertical, if of sufficient size, will furnish ample power. The two-cylinder horizontal opposed will make much less noise and will be more comfortable for the rider than the vertical engine, but is not as accessible. I use a two-cylinder, 10-horsepower horizontal opposed, engine under hood, shaft drive machine (199) for my work and find it satisfactory.

As a physician uses his machine in all weathers, it should generate about twice as much power as would ordinarily be needed, and should run for the most part on its high speed, which should be capable of being throttled down for all ordinary emergencies without requiring the use of the low speed at all. Where two cylinders are used they should not be less than 4x4, and preferably 5x5, since heavy roads, mud and hills often put extra strain on the engine. Two-cylinder motors of the runabout class can be obtained at from $800 to $1,000, and should give a sufficient amount of power for one person. These are all water-cooled motors.

Air-Cooling Mechanism Favored.

Now, water-cooling, while satisfactory eight months in the year, requires an antifreezing solution in cold weather; if one forgets to put this in in time, cylinders, radiator or pump will freeze, with a resultant bill for repairs. Hence, other things being equal, a successful air-cooled motor should appeal to the physician rather than a water-cooled one. On the other hand, there is no air-cooled motor at present on the market which can be had for less than $1,400 for a four cylinder physician's runabout (200). I am not sure, however, but that the difference in price would be more than made up in comfort to the owner. Many physicians of my acquaintance use air-cooled motors with perfect satisfaction. For non freezing I have used both calcium chlorid and a combination of two-fifths alcohol and three-fifths water. If the calcium chlorid is pure, I do not think it acts on either the copper radiators or the rubber tubes. It is cheaper than alcohol and has the advantage that as the water evaporates by the heat, all that is required is to add more water, while the alcohol solution constantly uses up the alcohol by evaporation and has to have more alcohol added.

Whatever engine is chosen should have a simple clutch mechanism. For a physician's use I think the simple, two-speed planetary clutch with direct drive on the high speed is as advantageous as any, and with an engine of sufficient power so that nearly all work can be done on the high speed, makes much less noise and is really more satisfactory than the more elaborate three-speed, sliding-clutch transmission mechanism, which makes considerable noise on both the first and second speeds.

Importance of Good Oiling Service.

An efficient oiling arrangement should be an essential part of a car and should be carefully looked after by the intending purchaser, as gasoline engines running at high speed require constant lubrication, and there is immediate trouble in case the lubrication is at fault. This should be looked out for early, and if there are many tubes the owner should see that all of the tubes feed oil properly. I have had the experience of having one tube clog, with the result that one of the piston cranks heated, the babbitt all melted and the entire cylinder had to be taken out for repairs, due entirely to defective oiling.

The car should be light and of long wheel base, and a weight of not much over 75 to 80 pounds per horsepower. The extra weight is of no advantage, requires power to move and increases the tire cost.

The Tire Problem.

Tires have been one of the great bugbears, but I have found that if a tire a little larger than the maker provides on the machine be used, the tire cost is very much reduced. Although all the makes of tires cost the same price, there is a great difference in the quality and in the way the purchaser is treated by the individual tire concerns (202) and if the physician chooses his tire right there will not be as much trouble in the future. I prefer the simple clincher, which goes on and off the rim easily and can be detached and a new tube put in in a very short space of time even on the road (201). I have made experiments with various forms of tire covers and have abandoned them all as impracticable and not commensurate with their cost. The rear tires can be equipped to advantage with the Bailey tread, which is put on by all tire makers. The statements which accompany the advertisements of a tire amount to nothing. The only way you can find out about them is from users.

After having various things tumble out of my first machine (203) while it was going, I made one change in design which I think could be adopted with advantage by makers of runabouts for physicians' use, namely, the addition of a three-inch side-piece to prevent small things and one's bag from tumbling out of the car. As a physician often carries various bags and bundles, this small point is one of some importance. It is also easier to keep the feet warm in winter when the side panel is employed.

It will probably cost more to keep an automobile than a horse, yet the machine does a great deal more work than the horse and does it very much more quickly; one can also take his family or friends in it to an extent that a horse-drawn vehicle would not be capable of. I live a portion of each year 17 miles from my office and make the trip in from fifty minutes to an hour, when the length of time required by street car would be so great as to preclude the possibility of such residence.

The Manufacturers of Whom to Buy.

Every automobile built requires attention and repairs. The intending purchaser should choose that one which seems the most simple, has abundant power, whose manufacturer is anxious to have the machine satisfactory to the purchaser (many manufacturers do not seem to care), and it should receive constant oversight from its owner. Under these conditions it is doubtful if many physicians, who once begin the use of an automobile, will return to the horse.

Automobilia of Punbad the Railer.

Judge not an auto by its smell; all comparisons are odious.
It is a short ride that hath no mending.
All does not go that glitters.
An auto is not without odor save in its own front seat
Oils well that ends well.
To speed is human, to be caught is fine.—*Century*

A TERSE ENDORSEMENT.

E. H. KESSLER, M.D.
ST. LOUIS.

ON paved streets the automobile is practicable the year round. The roads are the only consideration, the condition of the weather cuts no figure.

To say what car a physician should buy is not easy. After nine years of daily use the car which comes nearest my ideal is the following for a runabout: The engine in front. A three-speed sliding transmission, shaft drive, with engine and transmission well protected from below from mud, water and dust. The car will weigh 1200 to 1400 pounds, and the engine will develop 12 to 14 H.-P. When the doctor has such a car as I describe he will have the best the world is producing to-day.

Can the average doctor run an automobile and look after it himself? Sure; it is not near as complicated a piece of machinery as the human body. With a couple of weeks' application any one of average intelligence can get along fairly well with the average car. For winters' use a few extra things must be considered, which in the summer give no trouble.

THE OBJECTIONS TO THE USE OF THE HORSE.

HARRY SUMNER KISKADDEN, M.D.
DETROIT.

EIGHTEEN years' experience with horses and two with an automobile convince me that the machine is preferable, because the same calls, especially if scattered, can be made in about one-half the time, icy streets and slippery asphalt are gone over like dry summer pavements, raw winds, cold rains, sleet and snow never make you pity the poor horse, you never shorten your call because your horse is standing, overheated, in a cold rain, nor go to the window to see if he is tired of waiting for you and gone to the barn; you don't have to stop to tie and blanket, nor untie and uncover, you can leave your machine stand in any kind of weather, in front of your office for hours, you never smell of a sweaty horse, nor are you covered with hair blown on you from his loose spring coat.

The automobile has many troubles which only he who drives one can know about, but with each year's improvements these defects are disappearing. My experience has been with a gasoline machine (204), a two-cylinder 16-H. P. type, with engines under the body and chain drive. For winter I used an ordinary top with plate-glass storm front, which kept me perfectly warm and dry in all kinds of weather. I now drive a three-cylinder, 28-H. P. machine (205), with two-cycle engines under hood, sliding gear transmission and shaft drive. This machine starts on the spark without cranking and is much quieter and cleaner than the old machine was with its engines under the body.

In Long Run Auto Is More Expensive.

While the upkeep and operating expenses of an automobile are about the same as that of a pair of horses, the life of the machine is not as long as that of the horse, and the necessity of a new one in two or three years makes the auto, in the long run, the more expensive. My first machine cost $1,200. The maintenance was $25 to $30 a month. After two years' use I sold it for $700; this would bring maintenance and depreciation up to about $50 a month. One of my boys took care of the auto; had I kept a man, as I did with horses, the average cost a month would have been $85 or $90. My machine with five passenger body cost $1,500. The extra coupe body for winter use will cost about $500 more. This is a two-cycle engine machine, and I believe it can be maintained at an average cost not to exceed $15 a month. A two-cycle engine has twenty-five to thirty less small parts to get out of order than a four-cycle engine, and I believe is the coming motive power for automobile use. The maintenance of a pair of horses, kept in my own barn, including man's salary, was about $65 to $70 per month, not including depreciation of horses and four vehicles (closed carriage, single top buggy, surrey and cutter). The maintenance of two horses, closed carriage and single buggy (not including driver) in boarding barn was about $45 a month. This one fact must ever be kept in mind, that you go so easily and so fast with the machine that during the year you make three or four times the mileage that you make with a horse.

Ignorance Is Not Bliss.

Know the anatomy of your car and be able to tell by its pulse and respiration whether it is doing healthy, perfect work. I know a man who drives an automobile and knows so little about it that on one occasion when the lap robe caught on the switch and threw it off he abandoned the machine, took to a street car and sent a man to get the "thing"; the man had only to throw on the switch, crank the engine, get in and ride home.

A PLEA FOR SIMPLICITY IN CONSTRUCTION.

WILLIAM FULLER, M.D.
CHICAGO.

EXPERIENCE with five different machines, during as many years, has almost at times convinced me that a good old horse had many desirable and unappreciated qualities, and that the trolley and cable cars were very economical as a means of travel and entailed but very little worry or responsibility.

But that the automobile has come to stay, and that it will eventually supersede all other means as an aid to the physician in his work, lacks no further proof or demonstration. The real question then arises, what machine will prove most practicable and satisfactory under all conditions of weather, and will give not only the least trouble, but prove the most economical? In my judgment it is that machine which is simple in construction, with four or preferably two cylinders, air cooled and with 10 to 20 horsepower. It should weigh 1,000 pounds or less and be equipped with solid tires. I use a machine (188) which cost me $650, without top, and which has cost me less than $15 each month for repairs, gasoline, oil and electricity.

The Tire Trouble.

The average automobile in use to-day is unsuited for solid tires, as it would make a very hard riding vehicle, and be very detrimental to the machinery. There is, however, on the market a machine or two with wheels of large diameter, taking solid tires and, with the proper springs, as easy riding and comfortable as a horse-drawn vehicle. The original cost of this particular solid tire is small, much less than the cost of the ordinary inner tube; it never punctures and will wear like the tire on the Goddard phaeton.

Pneumatic tires are a source of great expense and much trouble, and the life of the best is at most about one year. It is often less than half this, not to mention the numerous punctures and the expense of having the casings recovered, which is necessary, as a rule, at the end of four or five months' wear. The annual or more frequent replacement of the medium-sized pneumatic would mean at the most conservative estimate $200 per year. The car requiring such tires would run up a good expense account in repairs, and with the needed yearly overhauling, would amount to $300 or more and, in numerous instances of my own knowledge, twice that amount. If now the salary of the chauffeur, and cost of gasoline and oil, be added to this amount, some sort of an idea may be had regarding the expense of running the average automobile.

The Beauty of Simplicity.

Granting that the income of the physician would permit this expenditure, it remains a fact that just as much service can be had from the use of such a machine as is above recommended for at least 75 per cent. less money. Such cars as this have no friction clutches, live axles nor differential gears, are equipped with the most simplified driving mechanism, and when annoyances arise their adjustment is an easy matter and is done without incurring expense. These automobiles can be operated without a man, and actually require but little of the owner's time to keep them in running order. The hired man, in many instances, is almost as much of a nuisance

as the pneumatic tire. He remains long enough to learn the machine, then without notice quits his job, thus making it necessary for the physician to duplicate the experience.

The details of a simple machine are soon mastered, and perfect knowledge of its workmanship and familiarity with it in every way will enable one to tell almost without inspection just where the trouble lies when it does come, or render it possible to locate it without delay. There is, too, like driving your own horse, a great advantage in knowing your own machine. It runs better, will last longer, and the time actually devoted to it, furnishes very desirable and beneficial recreation.

A light car, air cooled, with solid tires, and rather under than over 20 horsepower, thoroughly understood, operated and looked after by the owner himself, will prove an economical, satisfactory and practical proposition, and lies within easy reach of every physician.

ONE ENTHUSIAST'S EXPERIENCE.

CHARLES H. DeWITT, M.D.
GLENWOOD, IOWA.

DURING the past two years I have learned many things about the automobile. At the time of purchase (March, 1904) I knew nothing about it—in fact, very little about any machinery. My first experience was with an 8-horsepower runabout (186), which I used about two months; I then concluded that I needed a car of more power, so changed to a 16-horsepower, two-cylinder machine (187), which I have used ever since.

I had much trouble and many discouragements in my early experience. One of my farmer friends used to say that he kept the harness on his mules night and day to prevent delay in hauling me in.

My car has two speeds, a forward and a reverse. Speed varies from 6 to 35 miles an hour. During the last year and a half the car has never been in the repair shop, all adjustments and repairs being made by my hired man, who has become an expert. I keep the machine in my barn, where all work is done on it. I formerly kept two teams. I now keep one family horse and very seldom resort to livery hire. In the first few months of my motoring slight troubles, such as a disconnected battery or a wire either from coil batteries, spark plug or governor, would make me entirely helpless, but now they are easily found and repaired in a few moments.

I am an enthusiast and believe that the extension of rural free delivery and better roads in consequence will not only make the automobile practical, but almost a necessity for the country doctor. I can go anywhere that I can go with a team, except in deep mud. In snow, except in drifts, that would greatly handicap a team, a motor car is entirely practical.

THE NEED OF A PHYSICIAN'S GOOD AUTO FOR FIVE HUNDRED DOLLARS.

EDWARD H. ABBOTT, M.D.
ELGIN, ILL.

ABOUT two years ago I purchased a small, water-cooled, single-cylinder runabout (213) with all the improvements and conveniences of that time. I wanted it to take the place of the horse-drawn vehicle in my work. I did not expect to be free from troubles in the new way of locomotion, since I had been closely watching some of my friends who had already taken the step. I immediately released my driver and disposed of my horses and so was compelled to trust entirely to the new vehicle.

My first troubles were tire trouble and, until I had disposed of all four tires (214) and second a set from another maker (215) my troubles continued. The second set of tires did good service throughout the remainder of the season and all through the succeeding season. I had but one puncture during the season of 1905. Notwithstanding my inexperience, I did all of my work until late in the season in the year 1904, excepting in the most stormy weather, when I used the street cars and a few livery rigs. During the winter I had the machinery overhauled and the body repainted and varnished. My machine cost $750 and the season's maintenance cost $175, including one complete set of tires, new tanks and other repairs.

Needs Eternal Vigilance to Keep Bolts Tight.

In 1905 I found various ways of improving the vehicle. I put in copper tanks of large capacity, a new carbureter and circulating pump. This brought my machine up to date again, and it served me fairly well throughout the summer season. Most of the troubles I had in these two years were: 1, With the poor quality of tires; 2, with the water circulatory apparatus; 3, with the insufficiency of valves; 4, minor troubles with shaking loose bolts, and with starting the motor. The tire troubles were overcome by disposing of the first set. With the water circulation I have always had more or less trouble. I have also found that the motor valves need frequent attention and regrinding and that eternal attention is required to keep every bolt and nut secure.

The Ideal Vehicle.

I believe that the doctor's ideal vehicle has not yet appeared, although several new models show a tendency in that direction. In my opinion, the ideal running gear will be large wheels like those of a carriage, with carriage tires; a double-cylinder two-cycle motor, air cooled, with automatic lubricator; a transmission without gears; a differential also without gears, with a fixed rear axle; more carrying room in the box; and a speed of from 15 to 25 miles an hour on level roads. The motor should be so arranged that each cylinder could be shut off or turned on at the will of the operator, thus making it possible to run with one cylinder, except where the roads are heavy or where grades are to be climbed. When such a vehicle can be produced, and at a moderate price, say $500, I believe that every doctor will consider such an outfit as necessary in his general work as his medicine case, his operating chair or table, or any of the essentials of his equipment for practice. I am satisfied with my experience in the use of the automobile and shall continue to be a devotee of its use.

THREE YEARS' EXPERIENCE IN NEW JERSEY.

D. EDGAR ROBERTS, M.D.
KEYPORT, N. J.

AUTOMOBILE experience had its beginning for me in 1903, when I bought a second-hand, curved dash runabout (182). I did not expect it to do all my work, but bought it to learn something about gasoline motors. It saved my horses some, and is doing fine service as a pleasure car still. My work is in town and country practice. The main roads are good, with some pretty stiff grades. The cross roads have some heavy sand and very steep hills. My drives vary from 10 to 50 miles daily.

What Is Needed Is a Physician's Auto.

After using the runabout a few months, my ideas of what I needed were formulated about as follows:

1. The tread must be the same as for carriage, which, in New Jersey, is 58 inches from center to center of tires on ground. For business purposes I would have nothing else.

2. The vehicle must carry two, have a top, plenty of space for satchels and must ride easily.

3. There must be high power and light weight, compatible with safety.

4. Ease of access to working parts and of removal of all parts is necessary.

5. The car must take all ordinary hills on high speed, as well as sandy roads, with ability to make 20 miles an hour.

After a long search I found a car (183) with three cylinders, weighing, with top, tool box and tanks full, 1,225 pounds, with 36 inch rear wheels. It filled all my requirements. I began using it in April, 1904, and used it both that year and the next with great satisfaction. My driver does all the work, as I have no time for that. When trouble comes, if not apparent, I generally make the diagnosis. Exclusive of the work at home, my expenses were about 10 cents a mile.

Mileage, about 4,500. I used horses a great deal, both from necessity and comfort. My car has been thoroughly overhauled at an expense of about $100, and it seems better than ever. It was a little expensive for me, needed much adjusting and the pneumatic tires were uncertain and expensive.

For several years I had been watching the development of a runabout whose peculiar mechanism interested me, and in January of this year bought one (184). It has high wheels, solid tires, plain bearings; is air cooled; has no gears; no differential, no live axle, no gaskets, no clutch. It rides comfortably as a carriage at same speed. It has two sets of sprockets and short chains high up out of mud and dust. It has given excellent satisfaction, does good work in mud and snow and on hills, but is not quite what I could wish for in sand. I still use two horses part of the time.

I feel very sure my troubles and expenses will both be reduced one-half on my last car. It is very easy and cleanly to care for. Each car does about 15 miles an hour on our roads. My horses do about 10 miles an hour. One will have more trouble and expense than the auto advertisements lead one to believe. Some manufacturers are very unaccommodating.

THE AUTO ON THE PACIFIC COAST.

H. A. L. RYFKOGEL, M.D.
SAN FRANCISCO.

I AM using my third automobile. The first was a light runabout (220), with a 3½-H. P. French motor on the rear axle. I drove this machine 20,000 miles in three years. Although I did more running around with it than I could have done with a pair of horses, the expense amounted to less than the care of one.

My present (221) is a 1200 lb. runabout with a two-cylinder opposed motor under the bonnet. I find it very much more satisfactory than a team. It is just as reliable, does away with the necessity of keeping a driver, can be left outside my office without attention, is no expense when not in use, can be used at a moment's notice, day or night and, of most importance, can get over ground so rapidly that it adds much time to the length of one's day.

The Terrible Repair Man.

There are some objections to the automobile which fortunately are overcome by its many advantages: 1. The rapacity and incompetence of many of the repair shops. 2. Trouble with the tires. If one is careful to select a competent mechanic to make repairs and then specify exactly what is to be done, the former difficulty can be avoided. The second question is purely a matter of luck.

On the whole I believe in the automobile for the physician but I should advise him not to buy a cheap machine nor one that is only in its experimental stage. If he does, the repairs will soon eat up the difference and he will not have had the satisfaction that comes with a well-made article.

THE COUNTRY DOCTOR AND THE AUTOMOBILE.

W. P. HARTFORD, M.D.
CASSVILLE, WIS.

NO class of men is so vitally interested in the automobile question as the country doctors, and it is a great mystery why some enterprising manufacturer has not built a machine for our special use. It costs more to keep tires in repair than all other bills combined. Transmission is a nightmare to the builder and user alike. Cooling, especially in the winter, is a problem that is of vital interest to the country doctor. The air-cooled motor appeals to him every time. He must have a car that will almost climb a tree and light enough so that he can pry it out of a ditch with a fence rail. It must be uncomplicated, as he is not a machinist, but from the very nature of his business he is a man of resources and quick to diagnose the trouble, but he must have a machine that will not break down. A broken plug or wire or bad adjustment of carbureter is quickly remedied after the trouble is located. Of all men (I won't except any, not even the trained mechanic) the country doctor will be the quickest to learn to locate and repair any minor ill such as constitute 95 per cent. of the motor failures. Exhaust and admission valves simply can not be made so that they will stay in good order.

The price—there is the rub. The country doctor is hard up. He won't own up to it, as the dear public won't employ the man they think is not successful, so he is obliged to put on a bold front, but when automobiles are cheaper, quicker and equally certain, he will quit horses.

Now, with a machine with the above trouble-making features eliminated, there will be left a car that will have only three points to look out for: Compression, which can be tested infallibly in a fraction of a minute (anyone who has swung the balance wheel nearly to the compression point and felt the live, springy elastic rebound, will recognize it instantly ever afterward); fuel supply, which is easily learned. The spark, which is usually to blame, is easy to test out. If these three are right, the engine will run. They are the heart, lungs and stomach of the machine. Of course, it will have attacks of indigestion, and I have sometimes suspected it of malingering, but always found some real cause for the illness.

An automobile with three or four three-part, two cycle cylinders without any transmission gears, would be a long stride ahead. The two cycle is very much cheaper than the four cycle; has about 1.8 as much power as the four cycle of the same weight; has only three moving parts, the piston, connecting rod and crank, none of them liable to get out of order; with three or four cylinders it can be slowed down to one hundred revolutions a minute; runs backward as well as forward; and with a jump spark can be reversed while running. If made with well-fitting pistons, it can be started some little time after it has been stopped by turning on the switch. Solid tires on large wheels would be an improvement on the pneumatic tire. There would be no punctures at any rate, and a solid tire on a large wheel would probably ride as easy as a pneumatic pumped up hard on a small wheel.

The country doctor who could buy an automobile for $500 that would go through anything and go sure every time, make 15 miles an hour and last ten years, would sell his horses and buy one to-morrow.

FACTORS IN SUCCESSFUL AUTOING.

WALTER RUPERT WEISER, M.D.
SPRINGFIELD, MASS.

EXPERIENCED physicians agree that the practicability of the automobile, as a vehicle for physicians' use, is no longer a problem to be solved, and that, with fair roads, a physician can do a large practice more expeditiously and with less expense.

Buy a Car Proved Good by Others' Experience.

The character of the roads, the type of machine used, and the operator, are all factors in the degree of success obtained. In a locality where six to eight inches of mud or snow are the rule during eight or nine months of each year, the pleasure of operating decreases, while the cost of maintenance increases. Again, many of my friends have not met with a full measure of success, because they have made their first experiment with a machine that was worn out by a previous owner, or one that was built to sell cheaper than a good substantial automobile can be sold. Finally, the man who forgets to lubricate his car, or who fails to replace a bolt or two when they have dropped out or runs through a pile of glass, instead of around it, will naturally have many more troubles to relate than the operator who occasionally has his car looked over and uses it as a piece of good machinery should be used.

My experience covers a period of six years, during which time I have owned ten machines of various types, and operated many others. With my last car (178), I covered nearly ten thousand miles at a cost, including fuel, oil, repairs to car and tires of $160. It is necessary to keep my car at a public

garage, so that for storage, washing and delivering the car I pay an additional $15 a month.

It is unwise to buy a new and untried type of car. They all look beautiful in the splendor of new paint and upholstering, and ride splendidly in the hands of the expert agent, when new, but when you are giving the machinery such work as is required by a physician in bad weather and bad roads the results are different.

Cars Are Made Better Now.

Each successive gasoline car I purchased was better than its predecessor, until now I have practically no troubles and my expenses are small by comparison with an equal mileage made with horses. This perhaps is due to the facts that automobiles are built better and that experience in operating saves many difficulties. My total mileage has been about seventy-five thousand miles, having spent several vacations in touring the New England and Middle states, besides continuous use for six years in a consulting practice covering a large territory. From the experience thus acquired I submit the following conclusions:

1. Electric cars are quiet, easily controlled, clean, and start without cranking, but they are heavy, due to excessive battery weight, the batteries require much attention, and are easily injured.

2. Steam cars are quiet, easily controlled and start without cranking, but the many things to watch and care for render it impossible for the operator to do or think of much else.

3. Gasoline engines have the disadvantage of starting with a crank, but an operator soon learns to manipulate the starting device and the trouble is forgotten in considering the many advantages gained by using this type of engine.

Annoyance Replaced by Satisfaction.

I run my car every day in all sorts of New England weather, and during 1905 my total outlay was less than one-fourth of my expenses during the last years' work with horses. To be ready in an instant when in a great hurry is a satisfaction only appreciated by those who have had the experience. To be called at night when your driver is out, or incapacitated, is one of the most annoying episodes in the practice of medicine. With a gasoline machine in the barn, you are off with the simple turn of a crank. Arriving at your destination there is no horse to tie and blanket, and if detained several hours on a cold night one feels relieved in that his horse is not out in the cold and storm. You will have more time with your books and your family, especially if your work is scattered, and your outdoor work will become a pleasure.

SIX YEARS' SUCCESS WITH ONE CAR.

H. C. MARTIN, M.D.
SPRINGFIELD, MASS.

SOMEWHAT analogous to chronic ulcerative phthisis is the history and life of my little wagon; it has coughed and coughed and coughed for nearly six years and it is still living and coughing.

When I purchased it, July 17, 1901, automobiles were not considered sufficiently reliable to supplant the horse as a method of transportation for the doctor, and comparatively few doctors were using them in their practice in this vicinity.

Since then have used it constantly in my practice with the exception of portions of the winter when the snow was too deep to navigate. The little three wheeler (216) has traveled many miles more than 50,000, which record I dare say is equaled by few.

The Secret of Success.

I attribute my success to observing the following precautions: From one-half to three-quarters of an hour every morning is devoted to cleaning, oiling and thoroughly examining the whole wagon, tightening bolts, filling gasoline tank and riders. Oil is cheaper than wagons. When a part begins to show wear I get a new part and keep it handy, and as soon as I feel the old one will not last much longer I put in the new one, not waiting for the old one to break on the road. A man doesn't wait till his horse loses all his shoes before having him shod. Why do differently with an automobile?

I know it is easier, better and more economical to use an automobile in practice than horses, provided the roads are half decent. But they must have care. If a man pays $800 to $2,000 for an equine equipment he has a man to look after it, and if that man is not working on that equipment all the time he is advised to look for other employment. Many a man pays $800 to $2,000 for an automobile and doesn't hire a man to care for it, nor care for it himself, except to pour in gasoline and oil. Then he tells his friends what a lot of trouble an automobile is. How inconsistent!

NOT A PARTICLE OF ENCOURAGEMENT.

STERLING GIBSON, M.D.
THOMSON, GA.

I TRIED most faithfully for 14 months to get some satisfaction out of my automobile (225) but words are too feeble to express my experience, for I can not give the country physician one particle of encouragement. My practice extends from 10 to 15 miles all around Thomson and we have fine roads, too.

I always keep two horses, but got my machine with a view of selling one or both, but found I would have to get the third horse if I kept trying to use the machine.

I am now getting some solid tires and am going to try it again when I havn't much to do, nevertheless it is a very dear luxury for I often had to carry a machinist along and in a small town it is always trouble to get an automobile repaired. Their place is in the city, as they are too much expense for a country physician. I find it less expense to ke p two horses and a man to look after them than to use an automobile.

DOCTOR'S AUTOMOBILE ASSOCIATION OF AMERICA.

DAVID EDWARD HOAG, M.D.
NEW YORK.

AT present, manufacturers do not cater to the needs of the doctor. Their aim is to make and sell the large touring car, as the proportionate profit is greater. The manufacturers who make a high-grade runabout for doctors' use, do so only at a price nearly as great as the larger car. Not all doctors can afford two cars, so the result is, that much as a man may desire a large car for family use or for touring purposes, he is barred from possessing one on the grounds of expense—first cost, and later, maintenance. True, a man may possess a car with detachable tonneau, but even in that, there is something crude and inconvenient which does not appeal to the artistic conception of the average man, be he a layman or doctor. Then, too, the many petty annoyances of the average automobile, restrains the doctor from being quick to invest, much as he may desire one in other ways. I refer principally, to the inaccessibility of the machinery in many cars; the unwieldy and ofttimes unmanageable levers; the stubborn and undignified "cranking" of the gasoline motor; the dirt and smell of oil and gasoline when it becomes necessary to "fix things". It must be remembered that the doctor is not a sportsman; that is, he does not aim to be, while in attendance on professional duties. The enthusiastic automobilist who is out for pleasure, clad in his rubber armor or other motoring paraphernalia, does not mind to such an extent, dirt, noise and smell. He may even glory in it as an ear-mark of his devotion to the sport.

That the automobile has come to stay, is an undoubted question, and it is safe to predict, that as a conveyance in both city and country, its use will be prominent for many years to come.

A Doctors' Stock Company.

A small coterie of doctors, of whom I have been chosen as an official mouthpiece, have considered the advisability of taking steps to form an association to be known as the "Doctors' Automobile Association of America," the aims being largely that of that other organization, known as the "Automobile Association of America," namely, that of concerted influence on legislation which will promote good roads, the holding of

annual or semi-annual meetings, promoting social intercourse among automobilists, the establishment of a uniform system of rules and regulations governing the conduct of automobilists, the training of chauffeurs, etc. It is difficult to enumerate the benefits that might be derived from co-operation of this kind. The automobile industry, being still young, it seems reasonable to assume that to engage in the manufacture of the same, should hold out great inducements as a profitable enterprise. With this end in view, we have also considered the advisability of forming a stock company of doctors only, to embark in the manufacture of automobiles, particularly those automobiles adapted to doctors' use. In fact, we have gone so far as to prepare a prospectus and it has been our intention to send copies to every doctor in the states of New York, New Jersey and Connecticut. Our watchword is, "Automobiles for Doctors, by Doctors." It is not our intention to place any doctor under the slightest monetary obligation. What we want most at present, is the voice of the profession, its views, its opinions, and later, possibly, its hearty co-operation. This must be considered primarily as an investment, and secondly, to put upon the market an automobile which shall embody all the requirements of the doctor's automobile, as regards ease and safety of handling, speed, comfort, and at a price as low as manufacturing conditions will permit.

The Need of a Good Doctor's Car.

The circumstances that have gradually led up to placing this proposition before doctors, has been the absolute incompleteness of any small cars yet turned out by the manufacturers, as well as the extreme variation in price. Since it is a notorious fact that dealers do not encourage the manufacture and sale of the small car, and it is often cumbersome, both in bulk and price. Just as soon as the enterprise takes on some tangible form, efforts will be made to secure manufacturing facilities.

Among the other advantages to be derived from co-operation would be the establishment of garages at convenient locations in and about the territory referred to, and maintained under the auspices of the company. Stockholders would thus have the benefit of reliable care for their cars. The question of car maintenance would, in the aggregate, be reduced to a minimum, lessening the expense to the doctor by at least one-third, and at the same time showing the profit to the company.

This is briefly a synopsis of the plan we had in view. We should be very much pleased to hear from doctors in the different parts of the country, either approving or disapproving of the plan, with such suggestions as might prove of value.

49 West Thirty-third Street.

REPAIRMEN'S RUINOUS ROBBERY

J. C. STINSON, M.D.
SAN FRANCISCO.

WHAT it costs to run an automobile depends largely on whom you have dealings with. My first car was a single cylinder runabout (222) and I really hate to tell you what it cost me. The more I think about it, the madder I get. I bought this car from a local agent Aug. 2, 1903, and ran it myself until February, 1904. My original investment was $983, including the price of a tonneau, lamps and horn.

Greedy Garage Grafters.

It was nothing but graft from the time I received the car until I got out of the clutches of this octopus agent. I was charged up with more than enough gasoline to run a four-cylinder car, and the agent always found some work to do on it. It was never kept clean, and the lamps never did shine, while the charges for repairs, replacements, etc., were excessive. In proportion this was a greater graft than ar thing outside of the life insurance companies. I tried vainly to get some pleasure out of this car, but it was so poorly taken care of that I was stalled on the road a great number of times. My first bill of expense from Aug. 20 to Sept. 31, 1903, was $243.30.

I had a slight accident. I was let down by a street car running into my left hind wheel. I was going slowly and was not thrown out or in the least injured. The following charges were made by the agent: Going after car and bringing it to repair shop, work on rear axle, straightening pump handle, work on left front wheel and steering gear, and labor, $45.75; drayage on rig from repair shop to store, $5; express on wheels, $9.85; telegram to factory for parts, $1; one new steering knuckle, $12.50; two rear wheels, $50; three brass dust caps, $2.25. On showing the above charges to several capable, honest auto mechanics and other experts, I was informed that political grafting was nothing compared with this. The bills so far amounted to $1,226.30. My supply bill from Oct. 7 to 31 was $14.50. Repairs to Oct. 31, 1903, amounted to $51.45. Expenses from Oct. 31 to Nov. 30, $108.85; gasoline bill and storage to Dec. 1, $36; repairs, etc. to Dec. 29, $97.30; supply bill to Jan. 31, $14.

Thus, you see, I had a small single-cylinder car that cost me while it was in the hands of this agent $565, for four and one-half months' partial use; over $125 a month, some of which time it was in the shop. I afterward sold the car for $600, and I understood that the present owner is getting very good service out of it. If the above charges are not enough to make a man wild, I do not know what else would.

What Are Fair Running Expenses?

Now, what should be considered a fair running expense for such a single-cylinder car? I have carefully inquired into the matter at much trouble to myself, and averaging the opinions of practical auto men, I find that for a run of 35 miles a day, such as a physician would make in his calls, a single-cylinder car would use 3 gallons of gasoline and 3 pints of oil. It would take nine hours' time to cover this distance, allowing for stops, and this would use every bit of power in the machine. Total repairs, year in and year out, would amount to $15 a month; gasoline, $22.50; oil, $7.80; a set of tires complete last five or six months, $148; storage for such a car, $20 or less a month. Some physicians may want a chauffeur for such a car, but this does not appear necessary to me. A competent, reliable chauffeur can be obtained at $60 a month. Such a man can store this car for $5 to $10 a month and in other ways save you many expenses.

I bought my two-cylinder, 16-horsepower touring car (223) Jan. 23, 1904, and used it up to the time I bought my four-cylinder, 30-horsepower car (224), some months ago. To run the two-cylinder car, it cost me $1,162.42 for eleven months' expenses, or an average of about $106 a month.

The cost of running a two-cylinder car is not much more than a single one. For a 35-mile trip 4½ gallons of gasoline is required, making $33.75 a month for gasoline; $1.30 covers oil and $25 repairs. Tires last five months and cost $208 for a complete set. With stops for calls it takes a two-cylinder car eight hours to run 35 miles a day, and this uses the engines right to their limit. Storage is $20 to $25 a month. Any physician ought to readily run his own two-cylinder car.

Four Cylinders Most Satisfactory.

With the four-cylinder car, to run 35 miles a day, will consume 4 gallons of gasoline per month, while oil comes to $2.60. Repairs year in and year out, amount to $20 a month; storage costs $35 a month. Tires $252 for a set which will wear four to six months. A chauffeur will cost $75 a month. Reckoning all expenses, a four-cylinder car (including driver) should not cost more than $175 a month, including breakage, replacements and tire bills.

Horses are things of the past for the physician's use. I have fully made up mind that the four or more cylinder car is the one for the present and future. It is quiet, fast and fairly reliable; you do not often use all the power in it, you go quietly to your patient, with no noise or disturbance. This cannot be said of the single or two-cylinder cars, as they are all more or less noisy.

Advantages Over the Horse.—Dr. E. M. Hetherington, Kansas City, writes: 1. The auto saves from 25 to 40 per cent. of time in making calls. 2. It saves about the same per cent. in cost. 3. It saves much trouble and worry and it is more comfortable than a horse-drawn carriage. Garages I found exhorbitant. When a man has learned his machine and handles it carefully he will have little trouble with it. I would not exchange my automobile for the best team, outfit and coachman.

SATURDAY, APRIL 21, 1906.

THE EFFECTS OF SPASM IN SCLEROTIC ARTERIES.

To the trained finger palpation of the pulse discloses two conditions, the state of the circulation and the condition of the blood vessel, and it is of the highest importance that the two be differentiated. The former is an index of the action of the heart, while the latter may be due either to local influences or may be part of a more or less widespread disturbance. Blood pressure and vascular tension depend on the relation between the volume of blood and the energy with which it is propelled on the one hand and the state of the vessel on the other hand.

The vessel wall may be thickened as a result of either functional or organic change. That is, the muscular coat may be contracted in greater or lesser degree in response to various stimuli; or one or other tunic may be the seat of hyperplasia or degenerative change. For the first we have at command certain measures of prevention and relief, while the second, apart from its dependence on syphilis, is beyond the reach of therapeutic intervention. It is, accordingly, important to recognize the part played by each of these sets of conditions in the development of the symptoms in any given case.

Atheroma and arteriosclerosis, with or without calcareous degeneration, are the common causes of organic vascular thickening and are to be expected after the middle period of life, although occasionally they appear earlier. It should be borne in mind that vessels so affected may exhibit in addition, thickening from contraction of the muscular coat. Some of the cerebral manifestations observed in the presence of such associated conditions are described in a recent communication by Dr. William Russell.[1] For example, there may be sudden paralysis, hemiplegia, monoplegia, aphasia—without loss of consciousness. If the circulation through the contracted vessel is soon restored, spontaneously or therapeutically, perfect return of function will take place. Otherwise, the disturbance will be permanent. The result is in some measure dependent on the power of the left ventricle. If the action of the heart be feeble, the circulation may not be restored; while, on the other hand, if the heart's action be unduly strong, the diseased artery may be ruptured.

Among other symptoms attributable to spasm in sclerotic arteries are vague pains in the head, attacks of giddiness, restlessness, insomnia and mental excitement.

1. Practitioner, March, 1906, p. 306.

In the presence of paralysis the condition must be differentiated from cerebral hemorrhage, thrombosis and embolism, and the diagnosis may be of exceeding difficulty. As has been pointed out, hemorrhage may actually take place as a result of rupture of a contracted sclerotic artery if the action of the heart be exaggerated, while a thickened blood vessel with narrowed lumen affords favorable conditions for the formation of a thrombus, particularly if the circulation be sluggish. Embolism is usually associated with valvular disease of the heart and can occur only when it is possible for a plug to be detached in some portion of the circulation and to be swept into the blood stream. Even then, the cerebral vessels are less likely to be the seat of obstruction than other larger vessels. The effects of the three conditions mentioned, namely, hemorrhage, thrombosis and embolism, are more likely to be permanent than those attending spasm in sclerotic arteries.

The prophylaxis, in the presence of a tendency to spasm of sclerotic arteries, consists in avoidance of the causes, among the most important of which are absorption of toxic matters from any source and deficient elimination on the part of the emunctories. The treatment comprises not alone the removal of these faulty conditions, but also the administration of vasodilators, with or without appropriate cardiants.

PROTECTION AGAINST DANGEROUS MEDICINES.

In our news columns last week announcement was made that the Committee on Public Health of the Massachusetts Legislature had reported in favor of a "patent medicine" bill, which evidently is a substitute for several bills previously introduced. This substitute bill contains an amendment which provides that unless the package contains more than two grains of opium, or more than one-quarter grain of morphin, or more than one-sixteenth grain of heroin, cocain, alpha-eucain or beta-eucain, or more than eight grains of chloral hydrate, in one fluid ounce" it is not necessary to mention on the label that these drugs are contained in the preparation.

As we understand it, practically the same principles are incorporated in an amendment to the national Pure Food Bill tentatively adopted, at the request of the proprietary medicine interests, by the Committee on Interstate and Foreign Commerce. These modifications are made, undoubtedly, with the best of intentions on the part of the members of the committees, as a compromise to satisfy the Proprietary Association of America.

We respectfully suggest, however, that a law carrying such provisions will not protect the public from that dangerous class of preparations against which it is directed. For instance, Kopp's Baby's Friend, Mrs. Winslow's Soothing Syrup, Bull's Cough Syrup, and analogous preparations containing opium or its deriva-

tives, can still keep up their deadly work. Some of these preparations may have to reduce the amount of the narcotic they contain, in which case all that will be required is an increase of the dose. It is the opiate in these preparations that sells them—that does the work. Take it away, or reduce its content to a point that it will have no effect, and there will be no demand for the preparation. If a medicine contains any habit-forming or dangerous drug there must be a sufficient quantity to produce a therapeutic effect. If it does not contain a sufficient quantity of the drug to produce this effect, then it is the acme of foolishness to put it in at all. On the other hand, if there is sufficient to do good there is sufficient to do harm. This can not be denied. Reduce the amount of the opiate in Chamberlain's Cough Syrup to the point where it will have no appreciable effect and it will no longer control the cough. Let a sufficient amount be retained to control the cough and it will certainly be enough to produce the habit or to kill if taken in a sufficiently large dose.

The proprietary medicine men realize that the people in certain states are sufficiently aroused to demand legislation, and so they bend all their efforts to make it so mild that it won't hurt them. They realize the seductiveness of the plea that there is no danger in small doses, and push this idea for all it is worth. But every physician knows that right here is where the danger lies. Drug habits are not formed by commencing with full doses. It is in the insidious small dose, gradually increased, either in time or in size, that the danger lurks. It is in the overdose taken accidentally or premeditatedly, without knowing the peril, that the danger lies.

There are occasions when it is wise to compromise and to take the proverbial half a loaf rather than no bread at all. But it is never justifiable to compromise with crime, and that is what will be done if the proposed amendments are allowed to be incorporated in a law. Better no legislation at all than that which legalizes a business that thrives on the moral and physical degradation of human beings and the slaughter of children.

If a layman should go to a drug store and ask for, say, a half-grain of morphin, the druggist would refuse to sell it until he had inquired into the use to which it would be put; but if the same layman should ask for a two-ounce bottle of a proprietary medicine containing the amount allowed by this proposed amendment, he would get it, although the medicine might be nothing but the morphin and simple elixir, or simply morphin and water. The same layman might be refused a half-dram of chloral hydrate, but he could buy an eight-ounce "proprietary" mixture containing more than a dram of the drug without question. A druggist in Chicago would be, and is, punished if he sells a layman half a grain of cocain; but, according to the above, he can sell it if it is in a "patent medicine," provided it is dissolved in an eight-ounce mixture, no matter what the mixture may be—simply water, possibly—and he would be justified in so doing by these proposed amendments. Thus the proposed amendment to the Pure Food Bill would make legal that which is illegal in many localities.

It must not be forgotten that, while it is comparatively easy to detect some of these drugs—morphin, for instance—it is often exceedingly difficult to determine quantitatively the amount present. Thus it would be hard to prove that a certain medicine contained more than the amount of the drug allowed by law.

We repeat: There should be no compromise with this crime. Better let matters go on as they are until the public is awakened a little more rather than adopt such a law as is now proposed in Massachusetts and in the amendment to the Pure Food Bill. If these dangerous drugs are to be allowed in patent medicines, then let the label tell.

THE TOXINS AND ANTITOXINS OF POISONOUS MUSHROOMS.

The most important of the poisonous fungi is *Amanita phalloides*—"deadly amanita." A hundred years ago Bulliard, the great French mycologist, named it "destroying angel." Its abundance, its superficial resemblance to edible mushrooms, its delicious taste, and its extreme toxicity—a third of the top of a small plant has killed a 12-year-old child—fully justify these characterizations.

At present our therapeutic measures are of no avail in the treatment of severe cases, and consequently scientific studies of the toxicologic properties of toadstools may give results of practical value. The recent study by Ford[1] of the poisons of the "deadly amanita" show (1) that they are of the nature of true toxins in that their action on the animal body becomes apparent after a period of latency or incubation; (2) they produce lesions similar to those of certain bacterial intoxications, and (3) they produce in animals on immunization specific antitoxins.

Right here attention may be called to the fact that the word toxin is being used in a loose manner likely to result in confusion of ideas. In a strict sense only relatively few poisons, microbic or otherwise, are true toxins. Strictly speaking, toxins are soluble poisonous products of bacterial, vegetable and animal origin of as yet unknown chemical nature, but resembling organic ferments in great sensitiveness to heat and other influences. The action of toxins in the susceptible animal body becomes apparent after a variable period of latency and in suitable animals they give rise under special conditions to specific antibodies, antitoxins that neutralize the respective toxins *in vivo* as well as *in vitro*. These characteristics sufficiently demarcate toxins from other poisonous substances of diverse origin, and physicians should not, as is now commonly the case, apply the word toxin indiscriminately to all the poisonous bodies concerned in infections and certain intoxications.

1. Jour. Infect. Dis., 1906, vol. iii, p. 191.

Returning to the toxins of *Amanita phalloides,* Ford succeeded in immunizing animals so that they were able to withstand multiples of fatal doses of phalloides extract and to yield a serum, 1 c.c. of which neutralized 10 times the fatal dose of the extract. The best known of the toxins of *Amanita phalloides* is the phallin of Kobert, which is a strong laking agent for red blood corpuscles. Immune serum was found to suspend this power, that is, to be strongly antihemolytic.

Whether or not sera of still greater strength and suitable for therapeutic purposes can be obtained from larger animals, like the horse, remains to be seen. In spite of the general knowledge now prevalent in regard to mushroom poisoning and of the differential characteristics of mushrooms, cases of such poisoning are bound to occur, the majority always from "deadly amanita." Consequently, there is a need for curative sera. The diagnosis is usually easy, and death, which is the case in from 60 to 100 per cent., usually occurs a few days after the actual poisoning, so that the natural conditions are favorable for specific serum treatment.

THE RELATIONS BETWEEN HUMAN AND BOVINE TUBERCULOSIS.

In 1898, Theobald Smith established two races or types of tubercle bacilli, namely a bovine and a human type. He pointed out that the differences demonstrated in the two types of bacilli indicated that the fear with which bovine tuberculosis was regarded at that time probably was unreasonably exaggerated.

In 1901 Koch startled sanitarians the world over by the announcement that in his opinion the bovine disease need not concern us in our struggle against human tuberculosis because there was a most radical distinction between the human and bovine types of the disease.

There followed a general re-investigation of the problem out of which two facts have emerged as definitely settled, namely: (1) The existence of two types of mammalian tubercle bacilli, the bovine and the human; and (2) the occasional occurrence of bovine bacilli in cases of human tuberculosis. How frequent invasion of human beings by bovine bacilli actually is can not be stated. Attention so far has been given principally to intestinal tuberculosis and Theobald Smith, in his last review of this subject,[1] believes that the ratio of cases of intestinal tuberculosis associated with bovine bacilli may be estimated roughly at from 20 to 40 per cent. Now intestinal tuberculosis is a relatively rare disease; not infrequently it becomes stationary; and it is encountered, especially when associated with the bovine bacillus, almost entirely in children under ten years of age. So far as we know now, phthisis and other forms of tuberculosis in the adult are practically always of human origin.

Assuming that these statements represent truthfully the actual present state of our knowledge concerning the relation between bovine and human tuberculosis, then there is no escape from the conclusion that bovine tuberculosis is a minor source of tuberculous infections as compared with the other and major source, the tuberculous human being.

The problem of reducing this minor source of tuberculosis to the minimum must be left in the hands of our boards of health and cattle bureaus. In this case the question of adjusting fairly the interests of public health and economic considerations is a delicate one. The fact that bovine tuberculosis, regardless of its relation to human infection, causes annual losses to cattle owners, may prove a powerful factor in the gradual elimination of bovine tuberculosis.

THE AUTOMOBILE FOR THE PHYSICIAN.

To no class is the development of the automobile of more importance than to physicians. How to reach their patients in the quickest, surest, easiest and cheapest manner is a practical problem to them. The doctor's buggy is a familiar object in every hamlet, village, town and city, and is often looked for with an anxiety verging on impatience by rich and poor alike. In such cases the horse has always been too slow; nowadays it is always too slow, especially for the ambitious or busy doctor. As the horse has been superseded by electricity in street car transportation, so must the faithful old steed step aside for the automobile, either now or very soon.

This week we give the opinions[1] of a large number of physicians who have had experience with the horseless vehicle. Our readers who were already in doubt whether or not to give up the horse and buggy for the newer, swifter (sometimes) conveyance will, we are afraid, remain in doubt when they finish. Certainly "doctors differ" in this instance. But, analyzing the opinion of all these physicians, we are forced to the conclusion that the automobile, while far from perfect, has reached that stage where it is a practical and an economical conveyance under certain conditions. To the physician who has some mechanical genius it is not only a welcome substitute for the horse, but it is a valuable means of recreation and diversion.

There are probably 50,000 physicians in the United States who are using some kind of conveyance and who either use automobiles or would do so if the automobile were in every way practical for their use. The first practical point—and the important one in most cases—is the price. While many are able to invest $1,000 or more, the majority can not pay more than $500 or $600. Hence, for the average, the doctor's car should not cost over $500. Undoubtedly the present profits are very large; they are so acknowledged by manufacturers themselves. A certain man who has a practical knowl-

1. THE NAMES OF THE AUTOMOBILES. For evident reasons the names of the automobiles and tires (and of some contributors who so requested) are not given, reference numbers being substituted. Readers who wish to have a number explained may write us, enclosing a self-addressed stamped envelope, and we will send the information.

edge of the subject affirms that nearly all the cars now in the market could be sold at a profit at two-thirds the present prices. If a standard make were once adopted, so that the various parts, including the woodwork, could be made in large quantities, the present prices could be almost cut in two and still a good profit would remain. There is no doubt whatever that a good practical physician's car can be made and sold for $500. But what is a practical physician's car?

First.—It must be durable; its life, with moderate repairs, should be five years, and yet there is hardly a car on the market at a moderate price that will last this long. There are too many weak points in the machinery, but they are points that can be made strong with only slight increase in weight or price, if the manufacturer would look more to future reputation for durability. Durability has not been striven for; immediate sale, with a year's good service, with little thought for the future, seems to be the principle on which most cars are made. This will change soon—must change.

Second.—Compact engine with power enough to climb any hill that a horse and buggy will climb. The speed is immaterial, fifteen miles is fast enough, twenty should be the limit of any machine. Heretofore there has been a craze for speed, and the sooner the craze is over the better. Speed is simply a question of mechanics, nothing else. What we need is a law forbidding the making of an automobile for ordinary road and street use that will go faster than twenty miles an hour. This is fast enough for all purposes. Durability and power has been sacrificed to speed.

Third.—Simplicity of construction, with all parts easily reached. This will enable almost any physician who can succeed as a practitioner to succeed as an autoist. The average man wants to care for his machine and to be able to understand its every detail. This means pleasure as well as saving of money, temper and time. Not only will simple mechanism be easily repaired when out of order, but the need of repair will be more rare.

Who is the manufacturer and what is the car that will meet the physician's demands?

THE MEDICAL EXAMINATION OF CHAUFFEURS.

The numerous accidents from motor cars call for special legal requirements as to those who handle them. The rigid rules which are applied to locomotive engineers might, it would appear, be very reasonably paralleled by somewhat similar requirements as to the qualifications of chauffeurs who run fast automobiles. The locomotive engineer runs his locomotive on an exclusive and well-protected track. The motor car operator runs often at equal speed along a public road utilized by vehicles of every kind and with no protections at the crossings. It would be only fair, therefore, that his special senses and general physical condition should be required to be in as good a state as those of the locomotive engineer. While the possible results of accidents are less serious in the case of the chauffeur, the chances of them are certainly more numerous. If an automobilist is out of health, nervously weak, defective in sight and hearing, or under the influence of drugs or stimulants, he is not a safe man to run an automobile. The proposition which has been made in France to require a medical examination and certificate as an essential condition for licensing chauffeurs seems an eminently reasonable one. Considering the amount that has been said and acted on as regards the qualifications of pilots and engine drivers, a little attention might well be given to the qualifications of those who, in a minor way perhaps, are now freely assuming like responsibilities.

A PECULIAR TYPHOID SEQUEL.

A lay journal, basing its statements on some alleged statistics, says that when a bachelor is carried through an attack of typhoid fever under the care of a trained nurse the chances are two to three that he will make a proposition of marriage to her during his convalescence. It says further that if a bachelor is nursed through any illness the chances are one in six that he will make a proposal of marriage to his nurse, and if this rule fails the inference is that the nurse is aged or exceptionally plain. The trained nurse, it says, who has been in the business over ten years is a rarity. We are not advised as to the number of happy marriages thus brought about, but it might be in a certain way a salutary process in weeding out the sentimentally inclined trained nurses and preventing overcrowding of the occupation. The risks appear to be unevenly divided. The woman who takes care of a man during convalescence has a pretty fair chance to estimate his weak points properly, while the other party, aside from his possible mental disability due to the effect of his disease, has comparatively limited opportunities.

UNGRATUITOUS SERVICES TO FELLOW PHYSICIANS.

A recent lawsuit in which a prominent physician was the plaintiff and the estate of another prominent physician the defendant has excited much comment. The suit was for professional services from one physician to another and, we are pleased to say, was almost unique. The estate is said to be amply able to meet the bill, and in that case it was most unfortunate that the suit was allowed to be instituted, whatever one may think of the policy or motive that prompted the action. The result, favorable or otherwise, is of no benefit to the plaintiff. The testimony of some of the witnesses was certainly remarkable, if correctly reported. Physicians are reported as saying that they usually charged their brother physicians for professional services. One is said to have asserted that he never even heard of a custom in accordance with which one physician would not charge another! The proceeding as a whole, according to the news reports, gives evidence of a lack of true professional courtesy. We agree with the New York *Sun* that there are probably very few physicians who would have the hardihood to go into court for recovery in such cases. The same paper is complimentary and also just to the profession when it says that "there are very few physicians who would care to do so."

THE CALIFORNIA HORROR.

Several thousand copies of this issue of THE JOURNAL had been printed before information reached us of the awful results from the combination of earthquake and fire in California, especially in San Francisco. We have been trying to reach San Francisco by telegram, but have not been able thus far to do so. The newspapers have already recorded the deaths of two physicians, Dr. Stinson and Dr. Kelley. The Medical Society of the State of California was to have been in session on the 17th, 18th and 19th. While many of the members may have been in hotels that were more or less wrecked by the earthquake, it is hoped that all were able to escape. We fear that the Dr. Stinson mentioned in the newspapers may be Dr. J. C. Stinson, who has an article on page 1207 of this issue. The Dr. Kelley is probably Dr. Edwin Arthur Kelley, of the Agnews State Hospital. Our sympathies are extended to the people who are passing through this awful ordeal, and especially to the members of our profession in San Francisco. Further, we believe that the profession of the whole country will willingly extend more than sympathy if the slightest necessity arises.

Medical News

ALABAMA.

Resolutions Adopted.—The Jefferson County Medical Society, at a special meeting held in Birmingham, March 26, adopted resolutions testifying in a fitting manner to the high esteem in which the late Dr. John C. Le Grande was held by his professional associates.

Commencement.—The twelfth annual commencement exercises of Birmingham Medical College were held March 29. Rev. S. B. Culver delivered the annual address to the graduating class, in which he paid a tribute to the late Dr. John C. Le Grande, for many years secretary of the college. Degrees were conferred on a class of eight by Dr. Benjamin L. Wyman.

CONNECTICUT.

Communicable Diseases.—The smallpox situation in Putnam is reported to be serious.——The Plantsville, South Center and Middlesex schools, Southington, have been closed on account of the prevalence of scarlet fever, diphtheria and measles.

Health Board Moves Office.—The office of the State Board of Health, which, since the organization of that body has been located at the residence of the late Dr. Charles A. Lindsley, New Haven, was moved March 31 to Hartford, where it will be located henceforth.

Personal.—Dr. S. Burden Overlock, Pomfret, has been appointed a member of the State Board of Health, succeeding Dr. Joseph H. Townsend, New Haven, who became secretary of the board on the death of Dr. Charles A. Lindsley.——The International Congress of Physiotherapy, Liege, Belgium, has awarded a diploma of honor to Dr. Clarence E. Skinner, New Haven, for his book on the "Therapeutics of Dry Hot Air."

Annual Meeting.—At the annual meeting of the Hartford County Medical Association, April 3, the following officers were elected: President, Dr. Frederic S. Crossfield, Hartford; vice-president, Dr. Edward G. Fox, Wethersfield; clerk, Dr. Edward R. Lampson, Hartford; councilor, Dr. George R. Shepard, Hartford; delegates, Drs. Everett J. McKnight, Hartford; Ansel G. Cook, Hartford; George W. Lawrence, East Berlin; John B. Boucher, Hartford, and Kenneth E. Kellogg, New Britain, and censors, Drs. Robert M. Clark, New Britain; Oliver C. Smith, Hartford, and Thomas F. Kane, Hartford.

DELAWARE.

Will Prosecute Delinquents.—The board of health of Dover has issued a warning to local physicians that hereafter prosecution will follow the neglect promptly to report to the board all cases of infectious or contagious diseases.

Personal.—Drs. Napoleon B. Morrison, Thomas D. Cook, Haven B. Patton and George R. Faulk have been elected city vaccine physicians for Wilmington.——Dr. George W. K. Forrest, Wilmington, was severely hurt by being thrown from his carriage.

Wilmington Health.—The annual report of the local board of health of Wilmington shows a death rate for 1905 of 15.16 per 1,000. No smallpox reported during the year. The number of cases of diphtheria was cut in half as compared with 1904. There was a notable increase in scarlet fever, but without any increase in the deaths. Three times as many cases of typhoid fever were reported during the year, but with fewer deaths than in the previous year. Tuberculosis caused 152 deaths, and the board of health suggests that this disease be added to the list of diseases to be reported.

GEORGIA.

Senior Student Dies.—T. E. Lenier, a member of the senior class of the Atlanta School of Medicine, died at the Presbyterian Hospital, Atlanta, March 28.

Lay Cornerstone of College.—The cornerstone for the new building of the Atlanta College of Physicians and Surgeons was laid with appropriate ceremonies, April 6.

Donations to College.—Andrew Carnegie has donated $10,000, and Dr. A. W. Calhoun, Atlanta, $10,000, to the building fund of the Atlanta College of Physicians and Surgeons. The remaining $80,000 was subscribed by the faculty and citizens of Atlanta. The faculty and the board of trustees have decided to establish an Andrew Carnegie laboratory of pathology and an A. W. Calhoun chair of ophthalmology.

ILLINOIS.

Personal.—Dr. George A. Wash, Palmyra, was operated on April 7 in St. Anthony's Hospital, St. Louis, for appendicitis and is making satisfactory progress toward recovery.——Dr. William J. Huff, Mode, has been adjudged insane and committed to the Illinois Central Hospital for the Insane, Jacksonville.——Dr. and Mrs. William R. Parkes, Evanston, are visiting in Los Angeles, Cal.

Brainard District Society Meets.—At the thirtieth annual meeting of the Brainard District Medical Society, held in Lincoln, April 13, the principal address was given by Dr. J. N. McCormack, chairman of the Committee on Medical Organization of the American Medical Association. Dr. William E. Guthrie, Bloomington, was elected president, and Clinton was selected as the next place of meeting.

Anti-Tuberculosis Work in Peoria.—Through the efforts of the Peoria Association for the Prevention of Tuberculosis, an ordinance was passed by the city council, which became effective March 20, providing for the registration, disinfection or placarding of premises occupied by consumptives. The council also has appropriated $50 a month for a tuberculosis visiting nurse, who began her work April 12.

Society's Semi-Centennial.—The Jersey County Medical Society on April 4 celebrated the semi-centennial anniversary of its organization with a banquet. The society was organized April 4, 1856, at the office of Dr. White in Jerseyville. Dr. E. A. D'Arcy was first president and Dr. A. S. Brewster the first secretary and treasurer. Dr. Augustus K. Van Horne, Jerseyville, is the only living charter member of the organization.

Old-Time Violator in the Toils.—James M. Ferdon, better known to the public as "Brother Paul," or the "Great Paul," who has been engaging in the itinerant vending of drugs and illegal practice of medicine in various parts of the country, was arrested April 6, at Chicago, at the instance of the Illinois State Board of Health, and was taken to Freeport, where he is now incarcerated in the county jail. Ferdon was at Freeport in August, 1905, engaging in the sale of his so-called "Quaker remedies" and practicing medicine in violation of the statutes. Suit was brought against him at the instance of the State Board of Health and several judgments were obtained against him both as an itinerant vendor and for practicing medicine, the fines amounting to about $1,700. When mittimuses were issued Ferdon removed to Iowa, and since that time has been doing business in several western states. He returned to Chicago early in April and had made plans to take up his business at Rockford, when the state's attorney of Stephenson County ascertained his whereabouts. Ferdon was apprehended in his rooms at the Kaiserhof Hotel just as he was making plans to leave the city.

Chicago.

Deaths of the Week.—During the week ended April 14, 621 deaths were reported, equivalent to an annual death rate of 15.80 per 1,000. Pneumonia caused 133 deaths; consumption, 70; heart disease, 56; Bright's disease and violence, including suicide, each 41; scarlet fever, 17; diphtheria, 10, and whooping cough, 7.

Twice Fined in Two Weeks for Selling Cocain.—On April 13, for the second time within two weeks, A. Monaco, a druggist at Polk and Clark Streets, was fined $100 for selling cocain without a physician's prescription. A negro accused of buying cocain in Monaco's drug store for boys under age, was fined $100 for disorderly conduct.

Bogus Vaccination Certificates.—Two cases of smallpox have been discovered in the Brown school. It is reported that several hundred children attending the school have been exposed to smallpox through false vaccination certificates given to children who had not been successfully vaccinated. The health department is making a searching investigation into the matter.

Reduced Death Rate.—For the week ended April 14, 39 fewer deaths were reported than for the previous week, representing a decrease of nearly 6 per cent. in the annual rate. Almost all the important causes of death, and especially nephritis, bronchitis, cancer, consumption and typhoid fever, show a reduction in mortality. The mortality of the infectious diseases of childhood, diphtheria, scarlet fever and whooping cough, increased.

Comparative Mortality.—The statement of mortality for the week ended April 7 shows 78 more deaths than for the previous week and 148 more than reported in the corresponding week of 1905. The increase in the annual death rate is equivalent to 13.5 and 25.3 per cent., respectively. There was an abnormal increase in the deaths of those over 60 years of age. Pneumonia showed the highest figures of the season, 135, consumption following with 85 deaths.

Personal.—Dr. A. I. Bouffleur is visiting in California, and on March 28 addressed the Long Beach Medical Society on "Drainage, Surgical and Medical."——Dr. Max Reichmann has been appointed radiographer to the Alexian Brothers' Hospital. ——Dr. and Mrs. Lester Curtis sailed for Europe, April 14.—— Dr. and Mrs. C. Pruyn, Springfield, are taking a trip to Mexico.——Drs. Hugh T. Patrick and Henry Gradle have gone to Lisbon as delegates from the Northwestern University Medical School to the International Medical Congress.

INDIANA.

Free Dispensary Opened.—Hope Hospital, Fort Wayne, opened a dispensary for the free treatment of the poor, March 25. The dispensary is in charge of the staff of the hospital.

Physicians' Club Organized.—The physicians of Elwood organized the Elwood Physicians' Club, March 30, and elected the following officers: President, Dr. Tilmund O. Armfield; vice-president, Dr. John Q. Garner, and secretary and treasurer, Dr. Edward L. Wiggins.

Vanderburg County Election.—At the annual meeting of the Vanderburg County Medical Society, held in Evansville, March 27, the following officers were elected: President, Dr. John N. Baughman; vice-president, Dr. Marcus Ravdin; secretary and treasurer, Dr. William R. Davidson, and censor, Dr. George W. Varner, all of Evansville.

Resignations from Staff.—Owing to the recent change in the management of the Deaconess Hospital, Evansville, the following members of the medical staff have resigned: Drs. George P. Hodson, Joseph C. McClurkin, Philip Warter, Weller S. Pritchett, Henry F. McCool, William E. McCool, A. J. Knapp, Charles W. Hartloff, Jacob H. Kerth, Benoni S. Rose and Thomas Macer.

Epidemic Diseases.—The Carnegie library and Greensburg high and common schools have been closed by the board of health on account of the rapid spread of scarlet fever.—— Scarlet fever is far in the lead among communicable diseases. In Indianapolis 72 cases were reported in March, as compared with 61 in February.——An epidemic of scarlet fever is feared in Greenfield.——Dr. John N. Hurty, secretary of the State Board of Health, reports 6 cases of smallpox in Denver and 40 or more exposures to the disease.

Personal.—Dr. George W. McCaskey, Fort Wayne, goes abroad for a month.——Dr. Joseph W. Bowlby, Shelbyville, is seriously ill with cerebral hemorrhage.——The residence of Dr. John H. Hayden, Bethel, was totally destroyed by fire, March 20.——Dr. George D. Kahlo, Indianapolis, will become medical superintendent of the French Lick Springs Hotel, May 1.—— Dr. Job O. Ogburn, Green Hill, has been seriously ill with pneumonia, but is now improving. ——Dr. George D. Brannan, Crown Point, who has been seriously ill, is now convalescent. ——Dr. George Cassell, Hartford City, is seriously ill with septicemia.

New Medical Staff.—At a meeting held March 26 to elect a staff for the Fort Wayne Lutheran Hospital, Dr. Herman A. Duemling was appointed chief of staff; Dr. Henry G. Merz, chairman of the medical board; Dr. Eric A. Crull, secretary, and the following received staff appointments: Drs. George L. Greenawalt, Martin F. Schick, Charles E. Barnett, W. Wynn Barnett, Henry Ranke, Samuel H. Havice, Arthur L. Mikesell, Gustave G. Brudi, New Haven; Elmer E. Morgan, Samuel D. Sledd, Alpheus P. Buchman, Hiram Van Sweringen, George B. M. Bower, Charles R. Dancer, Henry O. Bruggeman, Adam L. Schneider and W. W. Carey.

Resignations from Faculty.—Dr. John F. Barnhill, clinical professor of diseases of the ear, nose and throat; Dr. E. O. Little, director of the physiologic laboratory and instructor in physiology; Dr. Frank F. Hutchins, assistant professor of nervous and mental diseases; Dr. Goethe Link, demonstrator in the anatomic laboratory; Dr. William H. Foreman, instructor in materia medica and therapeutics; Dr. Allison Maxwell, professor of practice of medicine; Dr. Robert O. Alexander, professor of pharmacology; Dr. Harvey A. Moore, clinical lecturer on genitourinary surgery, and Dr. Walter S. Given, lecturer on anatomy, have resigned from the faculty of the Medical College of Indiana, Indianapolis.

IOWA.

Complaining Witness Did Not Appear.—"Dr." Shipley, Madrid, who was arrested April 4, charged with practicing medicine without a license, appeared for trial April 9, and was discharged, as the complaining witness failed to appear.

Personal.—Dr. E. A. Bare, Ames, was attacked in his office building, March 24, stabbed and robbed of his pocketbook and watch.——Dr. Alfred Watkins, Des Moines, has returned from California.——Dr. Charles A. Delander, Des Moines, is critically ill with rheumatic fever.

Equal Rights.—Dr. Henry Young, state senator, presented an amendment to the bill authorizing cities of more than 12,000 population to build hospitals, requiring officials of hospitals to give an equal standing in such institutions to physicians of all schools of medicine.

Chiropractic Goes to Jail.—"Dr." D. D. Palmer, Davenport, discoverer and developer of "chiropractic," was committed to the county jail March 28, to serve out the sentence of 105 days' imprisonment imposed on him for practicing medicine without a license. Dr. Palmer could have been released after fifteen days' imprisonment on payment of a fine of $350, but decided to serve out his sentence and presumably pose as a martyr.

KENTUCKY.

Fire Loss.—The residence of Dr. A. C. Hagans, Langley, was destroyed by fire, March 26. No insurance was carried.

Meningitis Epidemic.—It is reported that cerebrospinal meningitis is epidemic in the vicinity of Alexandria. Out of one family of eight it is reported that three are dead and four are hopelessly ill with the disease. Two other deaths have been reported.

Personal.—Dr. John Price, Louisville, has returned from Vienna and will become an interne in a Philadelphia hospital the last of this month.——Dr. D. F. Reeder, Paducah, sails for Panama March 30.——Dr. Samuel H. Garvin, Louisville, celebrated the twenty-ninth anniversary of his election as jail physician, April 2.——Dr. L. Edwin Young, Paducah, has been elected physician of McCracken County, succeeding Dr. John W. Pendley.

Academy of Medicine Incorporated.—The Academy of Medicine of Jefferson County, Louisville, filed articles of incorporation April 3, with a capital stock of $20,000. The object of the organization is the fraternization and broadening of local practitioners. The following are the charter members: Drs. Ap Morgan Vance, William Bailey, L. S. McMurtry, W. H. Wathen, A. M. Cartledge, John T. Moran, C. G. Lucas, S. J. Meyers, L. Frank and John G. Cecil.

Trustees Vindicated.—For the last year and a half there has been a determined attempt to remove from office as trustees to Speers Hospital, Dayton, for alleged extravagance and mismanagement, Drs. James O. Jenkins and John L. Phythian, Newport, and Dr. W. E. Senour, Bellevue. Ouster proceedings were instituted by taxpayers and three times the case has gone to the Court of Appeals, and each time the phy-

sicians have won. The last trial before Special Judge W. B. Moody will probably end the matter for in his decision the judge paid a well-deserved compliment to the physicians for the splendid manner in which their onerous duties, without compensation, had been performed. The costs of the prosecution will amount to nearly $2,000.

MAINE.

Measles Epidemic.—Measles is reported as epidemic all over the state. Rural schools, school gatherings and public meetings are being deferred on this account.

Meeting Deferred.—The Maine Medical Association meeting will be held in Portland, June 13-15, instead of June 6-8, as formerly announced, in order to avoid conflict with the meeting of the American Medical Association at Boston.

Personal.—Dr. George H. Turner, Jr., Portland, has been appointed surgeon in the Maine Naval Reserves.——Dr. George L. Hilton, Bangor, has been elected a member of the local board of health, vice Dr. Harris J. Milligan, made city physician.

State Board Meeting.—At the annual meeting of the State Board of Health, April 2, Dr. Charles D. Smith, Portland, was unanimously re-elected president. The standing committees of the year were appointed and the secretary reported verbally the work of the board in stamping out smallpox.

Hospital Patients Should Pay When Possible.—At a recent meeting of the Penobscot County Medical Society resolutions were adopted embodying the idea that the public hospitals should make charge for services of physicians and surgeons to those who can afford to pay, that the hospital might be compensated for the service.

MARYLAND.

Smallpox.—Two cases of smallpox were reported at Cumberland on April 9.

Hospital Incorporated. Articles of incorporation have been filed by the Emergency Hospital, Easton.

County Society Election.—The Somerset County Medical Society held its regular meeting April 6 and elected Dr. Charles W. Wainwright, Princess Anne, president, and Dr. Ralph L. Hoyt, Oriole, secretary-treasurer.

Baltimore.

Personal.—Dr. Summerfield D. Bond has been appointed chief medical examiner of the Baltimore & Ohio System.

Gift for Hospital.—The trustees of Johns Hopkins Hospital have accepted a gift of $30,000 from Miss Helen F. Wilmer, to be used in the erection of a nurses' home in connection with the institution.

Early Days of Johns Hopkins.—On April 12 Mr. Daniel Gilman, ex-president of Johns Hopkins University, spoke before the Johns Hopkins Hospital Historical Club on "Early Days of the Johns Hopkins Medical School," and Dr. Howard A. Kelly spoke on "The First Medical Illustrations."

Society Discusses Variola.—The Allegany Medical Society, at its meeting in Cumberland, April 3, discussed the early diagnosis and treatment of variola. The society is reported to be in a flourishing condition and comprises in its membership almost all of the physicians of the county.

Eye, Ear and Throat Hospital Report.—The report of the Baltimore Eye, Ear and Throat Charity Hospital for 1905 shows that during the year 5,677 patients were treated, 5,590 of whom were charity patients. The total number of operations performed was 1,674. The number of patients increased 400 during the year, and the number of visits in the dispensary was nearly 5,000 greater than during the previous year.

Staff Changes at Infirmary.—The following changes will take place shortly at the Union Protestant Infirmary: Dr. Hugh H. Trout will retire as resident physician and will go to Vienna; Drs. George Tyler and Robert Nelson will also retire; Dr. Theodore F. Riggs, who has been a member of the resident staff, will succeed Dr. Trout. The following will be added to the staff: Drs. John Tarr, Baltimore; Sterry, New Orleans; Bell, Staunton, Va., and Dr. Wroth of Baltimore.

Health of the Week.—The death rate for the week ended April 14 was 21.53 per 1,000. Pneumonia was again in the lead with 29 deaths, to consumption, 24. It is interesting to note the variability without apparent cause of the former in the last several weeks, sometimes running far ahead of consumption and again falling much behind it. The large number of deaths due to violence was noticeable: Accidents, 12; suicides, 5, and homicides, 2. One case of smallpox was reported during the week.

Personal.—Dr. and Mrs. H. Barton Jacobs sailed for Europe, April 11.——Dr. A. R. L. Dohme has purchased the estate of 22 acres in the northern suburbs, formerly the country residence of Secretary of the Navy Bonaparte, and will reside there.——Dr. William S. Baer, chief of the orthopedic department of the Johns Hopkins University, was operated on for appendicitis at the Union Protestant Infirmary, April 8.——Dr. William H. Baltzell, who has been abroad for the last two years, is now in Paris and will not return to America at present.——Dr. Roland B. Whitridge is in Paris.

MISSOURI.

Health Department Appointments.—Mayor Wells of St. Louis has nominated Dr. H. Wheeler Bond, a member of the board of health, for health commissioner, to succeed Dr. Charles A. Snodgrass, deceased.

Symposium on Abortion.—The meeting of the St. Louis Medical Society of Missouri, April 21, will discuss criminal abortion. The subject will be dealt with from the medical standpoint by Dr. J. M. Grant; from the moral standpoint by Rev. James Hillem, and from the legal standpoint by Circuit Attorney A. N. Sager. This meeting is expected to be the beginning of a relentless campaign against abortionists of the city.

Memorial Services for Dr. Snodgrass.—Exercises in memory of the late Dr. Charles A. Snodgrass, health commissioner, were held by the St. Louis Medical Society, April 15. Dr. George Homan presided, and addresses were delivered by Dr. Homan, the mayor of St. Louis, Dr. W. G. Moore, Hon. Henry T. Kend, president of the Civic League; Dr. W. J. Miller, president of the Eclectic Medical Society, and John H. Matthews, of the board of health. At the close of the addresses a memorial to Dr. Snodgrass, prepared by a committee, was read by Dr. Sendebing and adopted by a rising vote. A memorial presented by Dr. Fred J. Taussig on behalf of the Medical Alumni Association of Washington University was also read and adopted.

NEW JERSEY.

Warning About an Agent.—In THE JOURNAL last week subscribers and members were cautioned against paying any money to Stein Josephs for the American Medical Association. When we last received information, his field of operations was in New Jersey. The Association is anxious to learn his whereabouts and will be glad to assist in his prosecution.

NEW YORK.

Ask for Milk Ordinance.—The physicians of Niagara Falls have petitioned the board of health asking that several changes be made in the sanitary code in regard to the distribution of milk in that city.

Dinner to Dr. Goffe.—Dr. J. Riddle Goffe, New York City, recently read a paper before the Buffalo Academy of Medicine on "The Etiology and Treatment of Cystocele." Before the meeting a dinner was given in his honor by Dr. Matthew D. Mann.

Bills Passed by the Senate.—Senator Saxe's bill authorizing New York City to establish and maintain a seaside park for the poor sick and convalescents was passed in the shape the New York City administration desired. The management of the new park will be under the control of the park board instead of the health department.

Antinarcotic Bill Reported.—This bill has been amended so as to practically exempt stocks of drugs now on hand, and to omit the provision that the analysis of the state chemist shall be presumptive evidence in criminal prosecution against a dealer. The bill would compel the labeling of all "patent medicines" and compounds containing more than a certain percentage of habit-forming drugs.

Higher Medical Standards.—There is now a bill called assembly bill No. 1715, which has for its purpose the exaction of a higher standard of education for all medical schools in the state and the establishment of one board of medical examiners, nine in number, in place of the board of seven each from each of the three schools of medicine. This bill would require colleges of osteopathy to exact a standard of preliminary education as high as that required by the regular colleges of medicine. It would also require students to attend sessions of nine months each in four calendar years. Power for the revocation of license of great scope would be vested in the examiners by the bill.

Personal.—Dr. W. F. Potter, Buffalo, has been appointed by Governor Higgins as a delegate to represent New York at the second annual conference of the Council on Medical Education of the American Medical Association, to be held in Chicago, May 12.——Dr. E. V. Stoddard, Rochester, was elected president, and Dr. Stephen Smith, New York City, vice-president, of the State Board of Charities for the ensuing year.——Dr. Horace M. Edmonds, Tonawanda, was reappointed health commissioner.——Dr. S. L. Higgins, Jr., physician at the Manhattan State Hospital, New York City, has been appointed assistant surgeon at the New York State Soldiers' Home Hospital, vice Dr. Laurance J. Gerold, deceased.

The Stevens-Wainwright Bill.—The New York State General Committee for Safeguarding the Sale of Narcotics has sent a letter to the physicians of New York State inclosing a booklet entitled "Has the Public a Right to Know"? containing the text of the Stevens-Wainwright bill now pending in Albany for the labeling of medicinal preparations which contain alcohol and certain other narcotic or potent drugs so as to disclose the presence and percentage of such ingredients. It is urged in the name of the poor and the sick in whose behalf this bill is being pressed, that every physician write to his senator and assemblyman urging the passage of the measure and also that he interest any influential friends and urge them to do the same. It is said that if the bill does not pass it will be for lack of public interest and demand for it, and it is impossible to bring facts before the public through the press, as it is silent on the question, owing to its advertising interests, excepting in a few instances.

Buffalo.

Restrict Sale of Poisons.—Because of the large number of suicides by carbolic acid, Health Commissioner Greene has prepared an ordinance restricting the sale of poisons, particularly carbolic acid and cocain.

Personal.—Dr. John H. Pryor, formerly superintendent of the New York State Hospital for Incipient Tuberculosis, has returned to Buffalo and resumed practice.——Dr. Charles G. Stockton has sailed for Europe.——Dr. Matthew D. Mann has returned from a visit to Jamaica.

Ordinance to License Criminals.—An ordinance is proposed by the Buffalo council which forbids clairvoyance, fortune telling, soothsaying, magic or sorcery without a license. It empowers the mayor to issue licenses to persons engaged in this "criminal business" who are of good moral character at a fee of $300 per year. It forbids the conduct of more than one place of business under one license and provides penalties of from $10 to $100 for its violation.

Tuberculosis Propaganda.—The tenement and tuberculosis committee of the Charity Organization Society has been reorganized and the tuberculosis section of the old committee has organized a new committee on tuberculosis, whose special work will be to spread the knowledge in destitute sections of the city that the disease is both curable and preventable. The following medical men will comprise this committee: Drs. John H. Pryor, Peter W. Van Peyma, De Lancey Rochester, De Witt H. Sherman, Irving P. Lyon, Julius Ullman and W. Harry Glenny.

New York City.

Bequest to St. Luke's.—Mrs. Sarah E. Sands has bequeathed $15,000 to St. Luke's Hospital. Three beds will be endowed in memory of her husband.

Hospital Ship Arrives.—The cruiser *Pennsylvania*, which is being used temporarily as a hospital ship, arrived from Guantanamo, Cuba, having on board the sick sailors and marines from the Atlantic fleet now in the Caribbean Sea. These men will be transfered to New York hospitals.

Tabulation of Sudden Deaths.—For the first time in the history of the coroner's office a complete list of the sudden deaths for the month has been issued. During March there were 546 cases of sudden death; 361 died from natural causes and 185 from burns, accidents and suicide.

Milk Below Standard.—Five dealers have been convicted of selling inferior milk. In one instance the milk was 32 per cent. below the required standard. The cases were brought into court by the inspectors, who based their complaints on samples taken from the milk offered for sale.

More Smallpox Imported.—The Hamburg-American liner *Amerika*, which arrived April 7, brought the second case of smallpox that has been imported within a week. The 260 passengers who occupied the same compartment were detained at quarantine for observation. The Red Star steamer *Noordland*, which arrived April 9, brought two cases in the steerage, where there were 1,150 passengers.

Consumptive Sanitarium Soon to Open.—The new Mount Hope Tuberculosis Sanitarium, Otisville, will be open in six weeks; when 100 patients will be chosen from the outdoor patients under treatment in the tuberculosis clinic which is conducted next to the board of health buildings on Sixth Avenue.

Hospital Fund Divided.—The Hospital Saturday and Sunday Association has apportioned the fund collected in 1906. This amounts to $81,000. Of this amount Montefiore and Mount Sinai hospitals receive the largest amounts, $8,100 each. St. Luke's and the German hospital each received over $1,500, while the remaining funds were apportioned among some thirty-four other institutions in lesser sums.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended April 7, 1,809 cases of measles, with 72 deaths; 386 cases of tuberculosis, with 185 deaths; 324 cases of diphtheria, with 39 deaths; 229 cases of scarlet fever, with 8 deaths; 29 cases of typhoid fever, with 6 deaths; 35 cases of cerebrospinal meningitis, with 27 deaths; 36 cases of whooping cough, with 4 deaths; 36 cases of varicella, and 2 cases of smallpox, making in all 2,986 cases, with 341 deaths.

How to Safeguard Marriage.—The Society of Sanitary and Moral Prophylaxis, which met at the Academy of Medicine, April 12, discussed methods of safeguarding the marriage relation from venereal diseases. The advisability of attempting to regulate this evil by law was discussed and it seemed to be the consensus of opinion that this would not be wise at present. Dr. John A. Wyeth was in favor of more general education through the medical profession. Senator Lindsay discussed the legal aspect of the question.

OHIO.

Measles Epidemic.—Springfield reports 120 cases of measles; Lorain, 100 cases.

Fire Damage.—The house of Dr. Charles Bonifeld, Avondale, was damaged to the extent of $500 by a fire supposed to have been started by rats gnawing matches, April 7.

Found Guilty of Arson.—Dr. G. W. Whitney, Alvordton, charged with setting fire to his house in 1901 and who then pleaded not guilty, changed his plea, April 2, to guilty and was sentenced to imprisonment for a year in the state penitentiary.

Eye, Ear, Nose and Throat Specialists Meet.—The eye, ear, nose and throat practitioners of Ohio have arranged to meet at the same time and place as the Ohio State Medical Association in Canton, May 9 and 10. An excellent program has been arranged. Dr. Mark D. Stevenson, Akron, will deliver an address, setting forth the need of state organizations of eye, ear, nose and throat practitioners.

State Hospital Physicians Meet.—The semi-annual meeting of the Association of Assistant Physicians of State Hospitals was held in the Cleveland State Hospital, April 4 and 5. The following officers were elected: President, Dr. P. W. Tappan, Dayton; vice-president, Dr. Kensie S. West, Cleveland; secretary, Dr. J. F. Harbottle, Dayton, and treasurer, Dr. Rose E. Williams, Toledo. The October meeting will be held in Athens.

Interne Elections.—The following have been elected internes to Christ's Hospital, Cincinnati: Drs. R. T. Gould, C. DuBois, J. L. Tuetcher and C. Runyan.——The eight successful contestants for interneships in the Cincinnati Hospital were as follows: Drs. C. R. Keller, Charles E. Doerr, W. D. Palmer, R. H. Butler, W. H. Lewis, M. H. Doughty, John T. Batte and E. G. Richter.——The following are the successful contestants for interneships in the Jewish Hospital, Cincinnati: Drs. E. A. North, H. Lusher, Millard Wallenstein and C. J. Broeman.

Personal.—Dr. D. S. Sampsell, Ashland, has resigned as president of the Ashland County Medical Association, and Dr. Abram L. Sherick, Ashland, has been elected in his stead.——Dr. David N. Hopkins, Friendship, has been appointed physician of Scioto County.——Dr. John H. Moody, Harlem Springs, who is 96 years of age, claims to be the oldest practitioner in the United States.——Dr. Floyd F. Swimley, Forest, was severely burned and may be permanently blinded by the explosion of an acetylene tank, April 5.——Dr. Edgar J. March and Dr. H. P. Pomerene, Canton, and Dr. and Mrs. George W. Ryall, Wooster, sailed for Europe, April 7.——Dr. Frank L. Ratterman has been elected a member of the staff of St. Mary's Hospital, Cincinnati, vice Dr. John L. Cleveland, deceased.——The Hamilton Academy of Medicine has presented Dr. Minor M. Jacobs a quarter-sawed oak desk, with chair to match.——Dr. William S. Bushnell and family will return to Mansfield, April 25, after a winter in California.

PENNSYLVANIA.

State to Fight Typhoid in Pittsburg.—Because of the epidemic of typhoid fever in Pittsburg and the surrounding country, which receive their water supply from the Allegheny River, the State Department of Health is making preparations to compel towns and cities along tributary streams to treat their sewage before it is allowed to reach the waterways.

Society Sustains Doctor.—The Delaware County Medical Society at its triennial meeting adopted a resolution of sympathy for and confidence in Dr. Daniel P. Maddux, Chester. The society pledged its support in the coming retrial of the suit instituted by the parents of a patient operated on by Dr. Maddux for appendicitis. He is charged with performing the operation without the parents' consent, and they ask $10,000 damages.

Typhoid at West Chester.—West Chester is again in the throes of an epidemic of typhoid fever. Three students of the State Normal School have died of the disease within the last two weeks. The disease is not widely prevalent throughout the school. It first made its appearance in the school in March, and since then the disease has been gradaully on the increase and now 26 cases have been reported. It is thought that the contagion has been carried to the institution in the milk supply, for thorough investigation of all other sources of possible infection has revealed nothing.

State Tuberculosis Society Election.—At the annual meeting of the Pennsylvania Society for the Prevention of Tuberculosis, held in Philadelphia, April 11, the following officers were elected: President, Dr. Joseph Walsh, Philadelphia; vice-presidents, Rev. Herman L. Duhring, Samuel Castner, Talcott Williams, Drs. Seneca Egbert, Lawrence F. Flick, Samuel G. Dixon, Benjamin Lee, Maczyk P. Ravenel, Leonard Pearson and W. D. Robinson; secretary, Dr. Ward Brinton; solicitor, James L. Stanton, and directors, Samuel Scoville, Jr., James L. Stanton, Drs. Howard S. Anders, Ward Brinton, J. Solis-Cohen, J. W. Irwin, D. J. McCarthy, G. W. Norris, R. N. Willson, M. P. Ravenel, W. B. Stanton, A. P. Francine, J. C Foltz, C, J. Hatfield and F. A. Craig.

Philadelphia.

Births and Deaths.—The report of the revision of vital statistics of the bureau of health for March shows that 2,435 deaths were reported and 2,590 births.

Dinner to Drs. Spitzka and McClellan.—Dr. Hobart Amory Hare and Dr. Francis Xavier Dercum entertained as guests of honor at dinner at the Art Club, Drs. E. Anthony Spitzka and George McClellan, recently appointed professors of anatomy in Jefferson Medical College. Many prominent physicians were present.

Innovation in Ambulance Service.—The first auto-ambulance to be used in this city was placed in service by the department of public safety, April 7. This innovation in the ambulance service of the city is looked on with favor, and it is intimated that the near future will find the city supplied generally with these vehicles.

Sterilizers for Schools.—The present system of supplying filtered water in the public schools is looked on with disfavor by the department of health and charities, and Dr. Coplin, director of the department, has recommended the use of sterilizers instead of filters. Dr. Coplin said that the present filters leak and, therefore, can not be germ-proof. He does not believe there is a trustworthy filter in any of the public schools.

Bacteriologic Laboratory Report.—The report of the bacteriologic laboratory of the bureau of health for March shows that 902 cultures were examined for diphtheria bacilli, and that 627 specimens of suspected typhoid blood were examined. The laboratory also examined 943 specimens of milk and 153 specimens of sputum; 4,596,500 units of antitoxin were supplied, and 8 disinfection tests were made and 130 analyses were performed. Under the revision of milk inspection 6,512 examinations were made, which included 128,626 quarts of milk. Of this number 360 quarts were condemned. Of these examinations 10 were chemical and 993 microscopic.

Philadelphia Health Report.—The total number of deaths reported for the week reached 588. This is a decrease of 37 from the number reported last week, and an increase of 71 over the number reported in the corresponding period of last year. The principal causes of death were: Typhoid fever, 24; pertussis, 8; meningitis, 4; cancer, 16; heart disease, 57; acute respiratory disease, 105; measles, 16; diphtheria, 14; consumption, 67; apoplexy, 21; marasmus, 6; enteritis, 25; Bright's disease, 52; accidents, 15, and suicide, 7. There were 272 cases of contagious disease reported, with 40 deaths, as compared with 290 cases and 43 deaths reported in the previous week.

Personal.—Dr. Robert C. Moon has returned to Philadelphia from the West Indies.——Dr. Montgomery H. Biggs, retiring chief resident of the Philadelphia Hospital, was tendered a testimonial reception at the University Club, April 9. Formal addresses were made by Drs. William Pepper, W. B. Stanton, C. Y. White and Charles Browne.

Medical Inspection for March.—The report of the revision of medical inspection of the bureau of health for March shows that for the month all inspections made, excluding schools, were 10,667; 2,158 fumigations were ordered, and 45 patients were examined for special diagnoses. Medical inspectors made 6,783 visits to the schools and excluded 1,124 children from attendance. The inspectors collected 323 cultures, made 283 injections of antitoxin and performed 460 vaccinations.

Bubonic Plague.—It has been demonstrated positively by the United States Public Health and Marine-Hospital Service that the cases of suspected plague on the British steamship *Burrsfield*, from Bombay, are bubonic plague. The men ill with the disease are confined in the United States Quarantine Hospital at Reedy Island, and the steamship is held at the quarantine station. One of the patients died April 11. Every effort is being made by the authorities to prevent the spread of the disease.

TENNESSEE.

The State Meeting.—The seventy-third annual meeting of the Tennessee State Medical Association was held in Memphis, April 10-12, and the following officers elected: President, Dr. L. A. Yarbrough, Covington; vice-presidents, Drs. J. L. Andrews, Memphis, A. B. Cooke, Nashville, and J. R. Rathmell, Chattanooga; secretary, Dr. George H. Price, Nashville (re-elected); treasurer, Dr. W. C. Bilbro, Murfreesboro (re-elected); delegate to the American Medical Association, Dr. T. J. Happel, Trenton; alternate delegate, Dr. Heber Jones, Memphis. Nashville was selected as the place for holding the next annual meeting in 1907. The following resolution was unanimously adopted:

Resolved, That the Tennessee State Medical Association recommends to all affiliated county societies to make no insurance examinations for old line life insurance companies for less than $5. This resolution is to have no bearing on those fraternal orders where the examinee pays for his own examination.

The report of the meeting will be continued next week.

GENERAL.

Spring Term of the Naval Medical School.—The spring term of the Naval Medical School, Washington, D. C., commenced April 14.

To Raise Standard of Immigrants. The house committee on immigration and naturalization has reported favorably on the immigration bill. This raises the head tax from $2 to $5, and provides an educational test for immigrants. Every person above the age of 16 years admitted to the United States must be able to read some language. It excludes imbeciles, the weak-minded, and manual laborers of poor physique.

Mosquito Extermination Society.—The third annual convention of this society was held in New York, April 11. William J. Matheson, president, in his opening address said that a large percentage of individuals in this country lose their lives or are incapacitated for work by disease caused by mosquitoes. He said that the society asks for the co-operation of every scientist and layman who desires to better his own or his neighbor's condition of existence. The "Mosquito Brief," otherwise known as the "confession of faith," is designed to convey to laymen information regarding these insects.

Sanitation in Cuba.—Minister Morgan, at Havana, reports that as an additional precautionary measure against yellow fever the sanitary department of that city has reapplied the regulations for house-cleaning enforced by General Ludlow in 1899, during the period of the American intervention, but which was discontinued in 1900. All buildings in the city are rigidly inspected and those found to be in an unsatisfactory condition are thoroughly cleaned by a sanitary brigade. Old clothes, paper and rubbish are carted away, loaded on large scows and dumped into the sea, five miles outside the harbor mouth. According to *Public Health Reports*, 120 men are at present engaged in this work under the direction of five inspectors. Thirty-five carts are in constant service, but the task has been so much heavier than was anticipated that it is proposed to enlarge the brigade in order that the city may be cleaned before the warm and damp season begins.

THE CHICAGO TUBERCULOSIS EXHIBITION.

Successful, Well-Attended Display of Statistics and Data on Tuberculosis Prophylaxis.

Objective demonstration of the causes and means for the prevention and cure of tuberculosis was the essential object which induced the National Association for the Study and Prevention of Tuberculosis to collect from all parts of the United States and from foreign countries whatever seemed to be illustrative of the progress made. Six cities have now seen the exhibition and there can not be any doubt that it has materially helped to arouse great public interest and to crystallize more or less spasmodic efforts. The Chicago Tuberculosis Institute secured the exhibition for a much longer time than the other cities (April 2 to 28) added to it, and arranged for conferences and lectures which, to judge by the profound interest taken in them, must have exerted a most salutary influence. Six conferences were held in the first two weeks, and also daily afternoon lectures, all of them bringing out crowded houses. A separate hall was set aside for them, with the banner of the international crusade against tuberculosis and many appropriate mottoes on the walls.

The formal opening on April 2 will remain a memorable occasion for Chicago. Dr. Frank Billings, as the president of the Chicago Tuberculosis Institute, introduced the principal speaker, Governor Charles S. Deneen, who outlined in his address the duties and limitations of the state's share in anti-tuberculosis efforts. Dr. Whalen, Chicago's commissioner of health, dwelt more particularly on milk supply and inspection as a factor of importance in the crusade. Dr. Webster, the president of the Illinois Board of Health, described the pioneer efforts made by the board. The great assistance to the maintenance of anti-tuberculosis efforts by a system of obligatory insurance for workingmen was lucidly shown by Prof. Charles R. Henderson of the University of Chicago. A touching demonstration of the pauperizing effects of the disease was given by Miss Jane Addams of Hull House. After addresses by Drs. Cigrand and Mix on other important phases of the problem this first conference adjourned.

Great interest was also manifested in the second conference of April 4, with Dr. H. B. Favill in the chair. Drs. Evans, Pettit, Sachs and Gray spoke on the subject of "Outdoor Treatment of Tuberculosis" from every point of view, and Miss Fulmer, head nurse of the Chicago Visiting Nurses' Association, presented the plans for a camp for tuberculous patients to be started immediately near Chicago. The announcement of the perfected plans for the establishment of a tuberculosis dispensary on novel lines by the Chicago Institute aroused considerable interest. The land has been given for it and funds for the building are accumulating. It is intended to play a rôle similar to that of the social settlement, with the difference that the medical and sanitary problems of the neighborhood will receive first consideration. A diet and milk kitchen, and a roof-garden school are the most distinct features of the plan.

Most interesting facts were brought out at the conference of April 6. The important subject of industrial workers and tuberculosis was discussed under the chairmanship of Prof. Graham Taylor. Particular interest was aroused by the statistics of Mr. Perkins, president of the cigarmakers' union. He demonstrated the tremendous tax levied by the disease on this one group of industrial workers. Dr. A. C. Klebs showed how preventive efforts and early treatment of tuberculous patients had effected great financial saving to organized labor and sick-benefit associations in other countries. He cited particularly the German insurance system, which had found of advantage a very considerable outlay of money for the establishment of sanatoria and healthy dwellings of the workingmen. Contrary to the usual conception of the subject, he showed that the system was not governmental and paternal, but socialistic in the broad sense of the word. Drs. Hamilton and Hedger gave interesting statistical data and also spoke of their experience in settlement work in various districts. Mr. Bisno gave the lay point of view on tuberculosis among garment workers.

The conference of April 9 took up the subject of "Charitable Organization and Tuberculosis," under Mr. S. C. Kingsley's chairmanship. The principal point brought out was the limitations of charity in dealing with the problem. The sustained, systematic effort necessary can not be maintained by charity, which has to concentrate on the care of the hopelessly advanced patients as its most legitimate field. Dr. Podstata's address forcibly dwelt on the inadequacy of institutional provisions for advanced consumptives in Cook County. The announcement by him of the establishment of a hospital for such cases within the city limits of Chicago was received with much satisfaction. Mr. Mullenbach told of the experience of the municipal lodging house with tuberculosis, demonstrating the great prevalence of consumption among the lodgers and the institution of preventive measures adopted for the safeguard of others. Mr. Bicknell of the Bureau of Charities and Mr. Riddle of Hull House told of their experience among the poor, and especially dwelt on the defective method of lodging house inspection in vogue in Chicago.

A most animated conference was the one held on the evening of April 12. Mr. Edwin G. Cooley, superintendent of schools, presided and outlined the various problems confronting the school management in dealing with tuberculous children and teachers. Rev. Mr. White of the board of education told of the plan adopted by the board to exclude such children, and other speakers insisted that such a plan was of great advantage, if proper provision could be made for such children. Drs. Churchill and Ryerson spoke of the medical aspects of this problem, and especially the difficulties encountered in the establishment of the diagnosis. Miss Addams described and recommended the establishment of garden schools, where children with early tuberculosis or those of tuberculous parentage could be taught out-of-doors in appropriate shelters. The results in such schools had been eminently satisfactory in Germany. Miss Fulmer told of the often deplorable condition among the poor children with tuberculosis of the glands, bones and joints, and the absolute lack of proper provisions for them. Dr. S. A. Knopf, New York, who had arrived earlier than expected, made a very forceful address on the deficiency of ventilation in public buildings, and especially that of the schools. This brought out a general discussion of this important subject in which several of the teachers present joined, showing the defects of systems of artificial ventilation and bringing many valuable suggestions for improvement in this as well as in the methods of cleaning of school rooms now employed.

Under the auspices of the Chicago Medical Society the Western Tuberculosis Conference convened April 14, Dr. H. B. Favill presiding. From Illinois and the neighboring states delegates had arrived in good numbers, and at the end resolutions were presented and adopted to make this conference an annual occasion, on which men and women interested and working in the cause could meet. It was the prevalent impression that this gathering is to become of the greatest importance to activity in this direction in the middle West. The principal addresses were made by the guests of honor, Dr. L. F. Flick, Philadelphia, the acting president of the national association, and by Dr. S. A. Knopf of New York. Both urged in eloquent language the great necessity of co-operation of both governmental and social elements in the crusade, which was so successfully inaugurated in this country by the National Association for the Study and Prevention of Tuberculosis and the Chicago Tuberculosis Institute.

The management of the Chicago Tuberculosis Institute can certainly congratulate itself for having inaugurated a campaign against the disease under the most favorable auspices. It has created not only a deep impression on the public mind, but it has brought together the most active workers and experts in the West for the one purpose of the eradication of that disease which most vitally affects the social welfare and health.

CANADA.

Outbreak of Smallpox Among Indians.—Consul Worman reports from Three Rivers that there is a serious outbreak of smallpox among the Indians and halfbreeds at Seven Islands, below Quebec. On account of the large number of laborers employed at Seven Islands in connection with the various industrial operations of Clarke City, the Dominion government and the provincial government have both taken steps to supply a staff of physicians and nurses, as well as medicine, and have ordered the icebreaker *Champlain* for service as a dispatch boat to this section of Quebec.

British Medical Association.—The honorary secretaries, Drs. J. N. G. Starr, D. J. Gibb, and Prof. J. J. MacKenzie, of the Medical Laboratories, University of Toronto, make the following announcement in connection with the seventy-fourth annual meeting of the British Medical Association, to be held at Toronto, Aug. 21-25, 1906:

MEETINGS OF SECTIONS.

The sections will meet on Tuesday, Wednesday, Thursday and Friday, August 21, 22, 23 and 24, at 9:30 a. m., adjourning at 12:30 p. m. each day.

SECTIONAL COMMITTEE OF REFERENCE.

The president, vice-presidents and secretaries of each section will form a committee of reference, and shall exercise the power of inviting, accepting, declining or postponing any paper and of arranging the order in which accepted papers shall be read.

GUESTS.

Papers by guests will be presented on invitation. If the committee of reference desires to invite persons to read papers in the section who are not eligible to become members of the association, their names should be submitted for the approval of the council. If it is desired to ask any such persons to attend the meetings of the section and to take part in the discussions a general permission to issue such invitation should be obtained.

All papers read are the property of the British Medical Association, and may not be published elsewhere than in the *British Medical Journal* without special permission.

DISCUSSIONS.

Secretaries are requested to communicate to the general secretary a preliminary statement of the arrangements made for the discussions in the section to be laid before the council at the earliest possible moment. This should consist of a statement of the subjects selected, together with the names, if possible, of the gentlemen who have undertaken to open the discussions.

PAPERS.

The offer of a paper should not be accepted on its title alone, and save under exceptional circumstances no paper should be accepted for reading until it has been sent to the secretaries.

The secretaries are requested to communicate to the general secretary of the association, 429 Strand, London, W. C., not later than June 15, a complete list of papers approved and accepted for reading.

It is suggested that the secretaries resident in the United Kingdom should collect papers from members on that side, and that the secretaries in Canada should deal with all papers in the Dominion and in the United States.

Only titles of papers which have been accepted, and which may be reasonably expected to be read, should be included in the program of sectional proceedings.

Offers of papers ought not to be accepted in excess of the number likely to be read. Failure to observe this condition leads to many inconveniences and gives rise to complaints of unfair preference.

REPORT IN THE BRITISH MEDICAL JOURNAL.

A report of the actual proceedings of the section will be published in the *British Medical Journal*, and in any communication addressed to persons who offered papers to be read in a section two things should be made clear:

1. Papers read are the property of the British Medical Association, and can not be published elsewhere than in the *British Medical Journal* without special permission.

2. The authors of papers not read have no claim for the publication of their papers in the *British Medical Journal*. Papers can not be "taken as read." If not read, they form no part of the proceedings of the section.

Secretaries are requested to co-operate in preparing the report of the proceedings of their section for publication in the *British Medical Journal*, with the reporter of the *British Medical Journal* appointed to the section, and to hand to him all matters for publication for transmission to the editor of the *British Medical Journal*, 2 Agar Street, Strand, London, W. C.

The attention of authors should be particularly directed to the time limit (see below), and the text of papers submitted for publication in the *British Medical Journal* as part of the report of the section should represent what is actually read to the section.

It is important that each author should hand the text of his paper in proper form for publication to one of the secretaries of the section immediately after it is read. It should be made clear that neglect to comply with this request may result in the omission of the paper in question from the proceedings of the section subsequently published in the *British Medical Journal*.

TIME LIMIT.

The attention of the council of the association has been called to the non-observance by readers of papers of the rule as to the time limit, which is as follows: "No paper must exceed fifteen minutes in reading and no subsequent speech must exceed ten minutes." The attention of presidents and secretaries of sections is particularly requested to this rule.

FOREIGN.

Oppression in Russia.—A St. Petersburg exchange states, March 31: "The dismissals from office and the arrest of medical men for participation in the political intrigues still continue. Dr. Fink, physician to the local prisons, has been dismissed because in his report to his superiors he called attention to the bad sanitary conditions of the political inmates of the prisons."

The Curable Tuberculous to Test African Climate.—The German authorities are discussing with favorable consideration the plan of sending a number of working people with mild forms of tuberculosis to German Southwest Africa instead of caring for them in sanatoria at home. The climatic conditions are said to be ideal, and by this plan they will be given a thorough test. The committee in charge of the temporary colony includes Kirschner and Katz of Berlin.

Bill to Regulate Marriage in Roumania. Dr. I. T. Thomescu and other senators have recently drawn up a bill which prohibits the marriage of the tuberculous, uncured syphilities, persons with heart disease, with general paralysis and infectious diseases of all kinds. A letter from Braila in the *Med. Klinik* states that some regulation of the kind is urgently needed in Roumania as an almost incredible disregard for such matters prevails and persons with florid syphilis now marry without the least restraint.

Proposed X-Ray Institute for India.—It is reported that the government of India has decided to establish an institution at Dehra Dun as a center for the practical instruction of medical officers in *x*-ray work, and as a depot for the storage of *x*-ray apparatus. The institution will be under the charge of an officer of the Indian Medical Service. Classes of instruction, according to the *Lancet*, will extend over a period of three months and facilities will be given officers who desire to acquire a knowledge of this special branch of medicine.

Progress in Enlightenment.—As a sign of the times we note a recent editorial in the Munich *Med. Wochft.* calling attention to the unprecedented way in which the national legislature voted appropriations for hospitals and hygienic measures. Heretofore these matters have received grudging attention with scant favor, but this year the comments were all favorable and commendatory. This transformation is due, the editorial hints, to the campaign of enlightenment which a committee from the Munich Medical Society (Aerztlicher Verein) has been quietly conducting for some months.

Glasgow Corporation and the Abuse of Alcohol.—The health committee of the Glasgow corporation recommended that a handbook be issued on "The Abuse of Alcohol and Its Results." The town council approved the recommendation and the pamphlet has been put in circulation. It consists of statements from the report of the Parliamentary Commission on Physicial Deterioration, and deals with the effect on adults and the effect of parental intemperance on the children. Emphasis is laid on two points: First, that the abuse of alcoholic stimulants is a most potent and deadly agent in producing physical deterioration, and second, that drinking habits are increasing among women of the working classes.

Central Sanitary Board for the Soudan.—Last October Sir R. Wingate, governor-general of the Soudan, approved the establishment of a board to advise the Soudan government on general medical and sanitary questions, including the treatment of epidemics. The president is Col. G. D. Hunter, D.S.O., R.A.M.C., and the members are eight in number, including the director of the Soudan Medical Department (Dr. J. B. Christopherson), the medical officer of health of Khartoum (Dr. A. Balfour), three medical officers of the Egyptian army, and a sanitary engineer. The *Lancet* states that this is a great advance, for the board will have to examine all schemes for medical and sanitary development, besides all legal ordinances and proposals connected with the public health.

Prizes Offered by Spanish Society of Hygiene.—Six prizes, the amounts ranging from $100 to $200, are offered by the Sociedad Española de Higiene. The competing articles can be written in Spanish, French or Italian, and must be sent in sealed envelopes. The Fernandez-Caro prize is for the best work on the hygiene of mines and means to enforce it. The Urgarte prize for the best on the subject of work and health, and their reciprocal influence on the duration of life; the Maura prize on sanitation of rural communities; the Guerra prize on Sunday rest and its relation to health; the Vadillo prize on hygiene and customs, and their mutual influence, and the Romanones prize on hygiene of the workingman's life in Spain. All communications must be addressed to the secretary-general, Sr. D. Mariano Belmas, Puerta del Sol, 9, Madrid, Spain, and be received before September 30 of the current year.

Sanitary Regulations for Hairdressers in Glasgow.—The Glasgow sanitary authorities and representatives of the hairdressers of the city, according to the *Glasgow Medical Journal*, have decided on certain regulations for the proper sanitary conduct of barber shops and hairdressing establishments. Shelves, fittings and tables on which instruments are placed must be of glass, marble, slate or other similar material. Clean towels must be placed on each headrest. No sponges or combs are to be used unless disinfected. Razors must be wiped on paper, and only clean hair brushes must be used. Shaving brushes are to be placed in a disinfecting solution after use, and only liquid or powdered soap or shaving cream is to be used. Other recommendations deal with rotary brushes, the cutting of hair in the case of skin affections, etc.

Smallpox and Yellow Fever in Ecuador.—Passed Assistant Surgeon Lloyd, of the Public Health and Marine-Hospital Service, reports that the situation in Guayaquil is very discouraging. From March 4 to 22, inclusive, there were thirteen deaths from smallpox and thirty-six from yellow fever. Local authorities give the present mortality at about 20 per cent. At the rate given for the nineteen days an estimate for March would be about 300 cases, with nearly sixty deaths. The actual number of deaths is probably, he states, a little under this figure, and the number of cases perhaps a little more than 300, because many mild cases are probably unrecognized. As there has never been a total of more than

twenty-six cases in the lazaretto at any one time, the indications are that perhaps two-thirds of the patients are not removed to the lazaretto. Inquiry among practicing physicians leads to the belief that this statement is not exaggerated. Many deaths are also inscribed in the records without specifying the nature of the fever, and Dr. Lloyd states that he has not considered these in the estimate given. Probably not half a dozen of the patients treated outside of the lazaretto have been protected from mosquitoes. He visited a number of patients who were suffering from typical attacks of yellow fever, and in not one case was any attempt made to screen the rooms. Should these conditions continue, Dr. Lloyd thinks that a longer quarantine would be justified or that passengers should be kept under observation before embarking, as contemplated in the regulations. Owing to the fact that adults who were born and reared in Guayaquil have recently been attacked by yellow fever, he is considering the advisability of recommending that the issuing of immune certificates be suspended.

Statistics in Regard to Adenoid Vegetations.—An examination was recently made of all the school children in Holland, between the ages of 6 and 12, for the discovery of adenoid vegetations. The minister of the interior issued an order that all the teachers should examine the children in their charge. To each teacher was sent a circular describing the principal external signs of adenoid vegetations. About 6 per cent. of the 800,000 children examined were reported as having them. As merely external signs were noted, this proportion is probably far below the real figures. In this and in other statistics on record the number of children with adenoid vegetations, discovered from the aspect of the face alone, was only 3.3 per cent. When the various external signs were noted it was 6 per cent., but when with the external signs the hearing also was examined, the proportion rose to 16 per cent., while local examination showed an average of 29.8 per cent. Although the statistics might not be reliable, yet the examination of the children, collecting of data and discussion of the subject aided materially in enlightening the public.

Cod Liver Oil in the Schools.—The gratuitous and compulsory administration of cod liver oil to all children for whom the school doctors prescribe it is included in the curriculum of the primary schools in parts of the district of Neufchatel, Switzerland. It is not stated whether the cod liver oil is prescribed for physical or moral degeneracy. In the latter case it might fill a long-felt want in the schools in this country as a substitute for the banished corporal punishment of our forefathers.

Remarkable Longevity.—A woman said to be 125 years old is now living in a Madrid hospital, in the service of Dr. H. Briz. She was born in Granada in 1780, her baptismal record being inscribed on the archives of a certain church. She entered the hospital thirteen years ago on account of a traumatism which left her blind.

LONDON LETTER.

The International Congress of School Hygiene.

The Duke of Northumberland presided over a preliminary meeting in connection with the Second International Congress of School Hygiene, which is to be held in London during August, 1907. Sir Lauder Brunton, president of the congress, in the course of a general statement on the arrangements said that the first congress was held in Nuremberg in 1904 and marked an epoch, because it was recognized then to a great extent that education should not be considered apart from physical conditions. The French are determined to do all in their power to make the congress in London a complete success, and other countries have also taken the matter up. He said that he was delighted with the reception that was accorded to the idea of an international congress in Canada and also in South Africa. He hoped that the congress would be a thoroughly representative gathering, not only of the colonies, but of every civilized country in the world. It is desired to see the important changes advocated in the physical education of children carried into practical effect. The congress, he said, promised to be one of the largest and most important ever held in London. Lord Reay then moved: "That in view of the importance of school hygiene in developing a strong and vigorous race, the necessity for scientific methods being followed in the training of the young, and for hygienic surroundings, being supplied in order to promote the health of the children during school life, this meeting consisting of representatives of educational authorities, medical men, teachers and others, is unanimously of opinion that it is desirable to hold the second international congress in London in August, 1907, to which representatives from India and the colonies should be invited in addition to representatives from other countries." He pointed out the enormous importance of hygiene in the elementary schools and particularly those in the poor districts of London. It is necessary, he said, that teachers should be trained to understand practical hygiene and that in this way great advantages would be reaped by the education given.

The Compulsory Medical Examination of School Children.

The question of the physical condition of the people has attracted much attention of late and considerable public alarm has been produced by the reiterated assertions of a number of faddists, who proclaim that the nation is physically deteriorating. As shown in former letters to THE JOURNAL, there are no grounds whatever for this pessimism. The council of the National League for Physical Education and Improvement has sent a deputation to the president of the board of education for the purpose of impressing on the government the importance of medical inspection of schools. This is to include the recording at least once every year of particulars of height, weight and chest girth of each child; the condition of eyes, ears, nose, throat; the detection of any disease, deformity or defect of general health, and the employment of all means possible to prevent the diffusion of offensive or infective diseases among children. The deputation urged that the examination should be compulsory and under the control of a central authority. The deputation was thoroughly representative and consisted of liberal and conservative members of parliament, the bishop of Southwark, Sir Lauder Brunton, Prof. Howard Marsh of Cambridge, the chief rabbi and Mr. Howard of the Salvation Army. Mr. Birrell, the president of the board of education, pointed out the difficulties arising from expense and from the possible prejudices of parents, but expressed his own sympathy with the general purposes of the league and his hope that they would be able to win that support of public opinion which would justify action. Professor Marsh pointed out that such an examination would do much to banish such ailments as measles, diphtheria and scarlet fever as completely as rabies has been banished by recent measures.

Fatal Accident to a Girl in Performing a Chemical Experiment.

A girl, aged 15, attending the Plymouth Technical School, met her death in a manner which should prove a warning to those responsible for the teaching of practical chemistry to children. In performing an experiment she had to suck a solution of caustic soda up into a pipette. Some of the solution entered her mouth and was swallowed. This experiment is provided for in the syllabus of the board of education and is carried out in practically all the technical schools of the country. The girl's mouth and throat were badly burned and she died a month later. The teacher who had conducted the experiment had included it in his instruction for the last ten years without accident. Now that this sad accident has happened, no doubt the authorities will insist that in future the experiment be conducted so as to make such an occurrence impossible. This could easily be done. At the inquest the father of the child pathetically asked: "Why was not a safety pipette used"? A pipette with a bulb would retain any excess of liquid which might be drawn up. A still safer and very ingenious invention has been introduced by Mr. Elias, who has called the attention of the authorities to it. It is termed a "fountain bulb." By compression of the bulb a burette or pipette can be accurately charged and all suction by the mouth is dispensed with.

Oysters and Sewage.

In the court of appeal an important case has been tried in which the urban district council of Warblington sought to have quashed a judgment of Mr. Justice Walton, who held that they as the sanitary authority were liable in damages for loss caused by the contamination of oyster beds situated on the foreshore of the manor of Emsworth. The council devised a scheme for the drainage of Warblington, the effect of which was to discharge the sewage just above the oyster beds. Dr. Bulstrode, a health officer of the local government board, visited the town and made a report in which he pointed out the danger that the oyster beds ran from contamination with sewage. Subsequently some oysters were supplied for a banquet, after which some of the guests were taken ill and died from typhoid fever. The result of an inquiry was to attribute the disease to the oysters. The trade of the proprietor of the beds being thus ruined, he brought an action to restrain the council from continuing to discharge sewage in the neighborhood of his oyster beds, so as to render the oysters liable to contamination and unfit for food. Mr. Justice Walton held that the plaintiff was not entitled to an injunction, but to damages, and ordered an inquiry. The defendants appealed, and the court affirmed the previous judgment.

The Invalid Children's Aid Association.

This association, which has been doing good work for seventeen years, now appeals for help. Its object is the care and relief of children suffering from tuberculous disease of the spine, bones, joints or glands, rickets, deformities, etc. These children require months and sometimes years of treatment, but they can not be retained in hospital indefinitely, and at home they are very liable to relapse even after successful operations. They are visited by women who are members of the association and, if possible, sent into the country; when this is impracticable they are provided with spinal couches or carriages, splints, crutches and the like, which the parents could not procure. Over $15,000 is spent yearly in the maintenance of beds constantly occupied in various homes in the country and at the seaside. About $2,500 is spent annually on surgical appliances, spinal carriages and other means of alleviation and physical improvement. A new departure in the association's work is an attempt to place children suffering from incipient phthisis under open-air and favorable conditions. Over 12,000 children have been under the care of the association, which works in co-operation with hospitals and other charitable agencies.

Pharmacology

A Hopeful Sign for Better Pharmacy.

A few weeks ago some of the progressive pharmacists of Chicago organized a local branch of the American Pharmaceutical Association; last week our news columns recorded the formation of a similar organization in Philadelphia. This movement is an encouraging sign and we certainly hope that it means that the retail druggists of the country have at last realized the position into which they have been gradually drifting.

For a number of years the efforts of a great number of retail druggists appear to have centered in obtaining better profits from "patent medicines." Evidently out of these efforts has developed a great, and in many respects a powerful organization, known as the N. A. R. D., with hundreds of affiliated local associations, the sole aim of which appears to be to aid "patent medicine" manufacturers to foist their wares on the public rather than to encourage its members to do better work as pharmaceutical chemists.

Largely through the efforts of this Association thousands of direct contracts have been entered into between "patent medicine" manufacturers and retail druggists by which the latter, in consideration of the additional profit promised them, voluntarily agree to refrain from discriminating in any way against the products of the manufacturer, and, while not so stated, to increase the sale of their articles.

It is largely due to the moral, or more correctly to the immoral, effect of this that retail druggists in all parts of the United States have apparently lost sight of the direct interests of the community at large and their true functions as pharmacists, and have not taken an active part in the agitation that is being waged against frauds in "patent medicines," but have, on the other hand, arrayed themselves against legislation that has been introduced in a number of state legislatures to eliminate secrecy, and with it the more evident possibilities of fraud, from the sale of popular nostrums.

The reawakening of pharmacists to the importance and need of higher ideals and higher aims in their vocation than the sale of nostrums at full prices, is indeed a promising one, and one that is worthy of our endorsement and support. To illustrate the objects and the aims of the new Philadelphia association we quote from the circular letter sent out as an invitation to pharmacists to attend the initial meeting:

"Among the more direct objects to be sought for and attained by the institution of a local branch, are:

"The development of a scientific spirit among the members of the profession.

"A more complete adherence to the Pharmacopeia of the United States and other generally accepted formularies in making the preparations to be used in the practice of medicine.

"The discovery and exposure of fraud and of fraudulent practices in connection with the materials used as medicine.

"The elimination of secrecy and fraud from the practice of pharmacy, and the cultivation of a proper appreciation, by members of the medical profession and others, of the ability, duty and position of an up-to-date pharmacist."

We physicians are in part responsible for the degradation of the retail pharmacy through our thoughtless prescribing of ready-made nostrums; and we should encourage this effort of the American Pharmaceutical Association to bring about better conditions. Undoubtedly a majority of the retail druggists of the country—certainly all the intelligent and educated among them—are opposed to the toadying to the "patent-medicine" men and will be glad of the promise of a better state of affairs which is becoming more and more evident. Pharmacy is to medicine what the ordnance department is to the army in the field; and the antagonism between the two, which has been developing in recent years, is destructive to the best interests of both, and, especially, of the public.

Deaths from Bromidia.

Dr. Horatio C. Wood, Jr., Philadelphia, writes:

One of the deleterious results of using proprietary mixtures even when the formula is known is that the physician gets in the habit of thinking of the mixture as a remedial entity, instead of a combination of active ingredients, and is thereby led to use this combination in cases in which he would have avoided the individual drugs making up the mixture. The following item is taken from the Philadelphia *Evening Telegraph*, February 13, and also appeared in several New York papers; it preaches an eloquent but pathetic sermon on this subject:

Within an hour after his father, a Brooklyn physician, had given him a dose of bromid, H. G. P., a prodigal son, died yesterday at his father's home in Brooklyn. Two years ago, when he appeared to have sown his wild oats, the father made him superintendent of his country place, near Grant's Mills, Delaware County. A week ago the son left his place, and at 1 o'clock yesterday morning appeared at his father's Brooklyn home. He was nervous, and at 9 a. m. begged for a sedative.

"I prescribed the usual quantity of bromidia," the young man's father told a reporter. "He was weak and had suffered from weak heart and kidney trouble for some time."

An hour later the father found the son dying and administered restoratives, but to no avail.

In an article published in THE JOURNAL, June 10, 1905, page 1836, I quoted in regard to bromidia the remarkable statement of the manufacturers that it is "the safest hypnotic known," and questioned how the addition of potassium bromid and tincture of hyoscyamus could overcome the depressant action of the chloral, which is the active ingredient of this nostrum. If the physician had thought of his bromidia as a solution of chloral rather than as a solution of bromid he probably would have hesitated before using it in an alcoholic case.

The following appeared in the Bangor (Me.) *Commercial*, March 8:

"Frank H. Perkins, a newspaper reporter of Plymouth, Mass., was found dead in a room in a hotel in Augusta, Sunday. The coroner stated that death was due to bromidia poisoning, but whether the drug was taken accidentally or with a suicide intent is a matter of conjecture. Perkins was a newspaper correspondent in Plymouth for 22 years. He left a few weeks ago to accept a position on the city desk of the Kennebec *Journal*. While a resident of Plymouth, he was correspondent for a number of Boston papers, and in recent years was connected with the Plymouth *Observer*. He was 55 years old and unmarried. It is understood that his nearest surviving relative is an aunt in Middleboro."

The above item was sent to Dr. O. C. S. Davies, Augusta, with a request that he send us a more complete report of the case. In his reply Dr. Davies stated that Mr. Perkins had at one time been an inmate of an inebriates' home and that he had gone to Augusta to do newspaper work, but had been unable to hold the position because of his condition. Dr. Davies, in his letter, says: "When the body was found, there were eleven one-ounce bromidia bottles about the room or on his person. Nine were entirely empty and the other two were about half full. None of these bottles indicated that they had been purchased on a physician's prescription, only the druggist's label marked 'bromidia' being on them."

Death from Headache Powders.

Dr. J. A. McCullum, Arkadelphia, Ark., reports a death from headache powders, self-administered: "Mrs. D. G. was subject to attacks of migraine, for which she had been in the habit of taking headache powders—the kind called 'Dixie pow-

ders.' She had taken at least three or four (possibly more) just preceding her death and while in a state of collapse from sick headache. Hypodermics of strychnin, digitalin and atropin with counterirritation with mustard plasters to inside of limbs and over spine, and hot water and mustard footbaths failed to revive her and she lived only a few hours."

Headache Powders and Deaths from Heart Disease.

Dr. W. H. Graves, Dodge City, Kas., writes:

"I was called to see a patient in a deplorable state of collapse from taking headache powders. I went to the drug store to investigate and found that the tablets were put up by a firm of high repute and long standing, but there was nothing on the label on the bottle or on the circulars to indicate the contents of the tablets. Neither was there any formula in the price list. I wrote to the firm in regard to the matter and learned what I suspected: that the tablets contained acetanilid. But the firm thought that as the average dose, according to the United States Dispensatory, was from five to fifteen grains, a tablet containing two grains could not do any harm unless it had been used recklessly. I protested that there was nothing on the package or in the price list to warn any one against the reckless use of an unknown and, therefore, doubly dangerous remedy. I called attention to the fact that in 1890, the first census since the use of coal-tar synthetics became at all general deaths from heart diseases were 38 per cent. more than in 1880, and in 1900 they were 72 per cent. more, allowing for the increase in population—this in the United States! They replied, expressing their astonishment and concern at the facts, to which their attention had never been called, and assuring me that they would at once take steps looking to a withdrawal of the preparation from the market.

"If the letter from one of whom they never heard before has such an effect on a manufacturing firm, surely letters of protest from old customers, known and esteemed for many years, will have decidedly beneficial influence."

Newspapers for "Patent-Medicine" Legislation.

One of the most encouraging developments of the past few months is the fact that many of the leading newspapers have come out in favor of regulating the "patent-medicine" business. The Chicago *Tribune*, one of the most influential newspapers of the country, is one of these, and we reproduce the following editorial from its issue of April 13:

RIDING THE SALE OF POISONS.

Protests continue to pour in against the proposed amendment to the regulations of the pure food bill relating to patent medicines, to which attention was called by the *Tribune* a few weeks ago. The bill as passed by the senate made it unlawful to sell a patent medicine containing certain dangerous drugs without a label stating their presence and the amount of them. The amendment permits proprietary preparations having less than two grains of opium or one-quarter of a grain of morphin to the ounce to be sold without such label to put the buyer on his guard.

There are two reasons why this should not be allowed. A quarter of a grain of morphin to the ounce may seem a trifle to the patent medicine manufacturer. The dose may be deadly for one who has never used morphin and is susceptible to its effects. The purchaser of a patent medicine which has been so heavily drugged may think an ounce is not too much to take at once and may put himself to sleep forever. There have been numerous instances lately of children killed by a patent medicine which was loaded with opium. There was nothing on the label to put the parents on their guard, and they unknowingly poisoned their children. That could not have occurred if there had been a decent law on the statute books.

In the next place the use of a patent medicine containing even an extremely small quantity of a drug like morphin may make him its slave. There is no question that thousands have become addicted to the use of narcotics in this way. If they had known what was in the nostrum they were taking they would not have touched it. Whenever a patent medicine contains such drugs as opium, morphin, or cocain, even in the smallest quantities, the label should set out the fact. Then the purchaser will buy at his own risk.

There would not be so many buyers as there are now. The patent medicine men are aware of it and that is the reason why they are lobbying so energetically in support of their dangerous amendment. It is strange that the members of the house committee are unable to see that they are co-operating in an attack on the life and health of the community. They are contributing to the spread of a baneful drug habit which it is so hard to cure. The amendment is said to have been accepted "tentatively." It should be rejected peremptorily by the committee, and if the amendment should be reported the house should make short work of it.

The proprietary medicine manufacturers have energetic agents at work in Washington. Organizations of physicians and other associations of citizens realizing the harm done by the indiscriminate and covert sale of poisons should bestir themselves to counteract their influence. Congress should be made aware that public sentiment is even more against the sale of unlabeled preparations containing poisons than it is against the sale of other fraudulent and deleterious commodities.

The Chicago *Evening Post*, April 12, has an editorial on the same subject, which we quote in part:

KILL THIS EVIL AMENDMENT.

It is the duty of every reputable physician and pharmacist in the United States, not only for his own sake but for the sake of his fellows, emphatically and formally to condemn one of the amendments to the pure food bill proposed by the United States Proprietary Association.

Briefly, this amendment provides that the maker of a patent medicine or proprietary article that is not prescribed by a physician, or one for which the formula does not appear in the United States Pharmacopeia or in the United States Dispensatory, shall not be required to print on the label the amount of poisons or narcotics it contains, provided this amount does not exceed two grains of opium or one-quarter grain of morphin to the ounce.

What druggist or doctor can read this amendment without being amazed at the blunted moral sense that could suggest it and shocked at the tremendous possibilities for evil that it so subtly aims to hide! * * * It was asserted that many patent preparations necessarily contained small quantities of narcotics and that when these were diluted as proposed in the amendment they would do no harm, "provided the patient did not know what he was taking."

Could ignorance or downright mendacity go further than this? No harm to give a person one grain of morphin in every four ounces of nostrum he swallows! No harm to make slaves to some drug habit, physical and moral wrecks, so long as the poor victims do not know the danger they are running! No harm to coin money at the expense of the health of thousands!

This amendment is utterly and absolutely bad. Yet it has been tacitly accepted by the committee and may become a feature of the pure food law. In that case it would legalize the selling of dangerous and harmful nostrums by anyone, for the sale of patent medicines is not restricted to druggists.

Let every physician, every druggist, every person who knows the awful dangers that lurk in the indiscriminate taking of narcotics, send his earnest protest against this amendment to his congressman and senators.

In this amendment lies unbounded power for harm; its mere proposal represents selfish commercialism at its lowest moral stage.

Even the Chicago *Daily News*, a paper which carries the most wretched "patent-medicine" advertisements, seems to be ready to defy the Proprietary Association of America, for in the issue of April 14 it too came out editorially against the "patent-medicine" men's amendment to the pure food bill, in an editorial entitled, "Another Attack on the Pure Food Bill." From this we quote:

Following the announcement that the makers of certain food preparations have succeeded in saddling the pending pure food bill with an amendment which threatens to render the measure nugatory comes the news of fresh opposition from another quarter. Deferring to the wishes of the makers of certain proprietary compounds, members of the House have given "tentative" adherence to an amendment which practically legalizes the sale of dangerous narcotics. . . . The person who consumes morphin in small doses without knowing what he is taking soon may find himself depending on the stimulant and developing a dangerous taste for the harmful drug. The very fact that he supposes the compound to be a medicine and regards its temporary quieting or exhilarating effect as beneficial, leads him to indulge in its unrestricted use, whereas he would resist vigorously any tendency toward becoming habituated to the use of opium or morphin sold by its proper name. In this as in the other features of the food bill, the consumer has a right to know whether he is getting something for his money that is likely to injure him. This is the principle adhered to in other countries, and it is the principle that should guide Congress unless this government is to go on record as legalizing a form of commercialism in which profits are sought at the risk of health and even of life.

We might quote similar expressions from newspapers in other parts of the country, but the above is sufficient to show that the Proprietary Association of America has "lost its grip" on papers of the town in which its headquarters are located.

Lay Resolutions Endorsing the Nostrum Campaign.

LEBANON, O., April 12, 1906.

To the Editor:—I enclose a copy of a memorial to the next general assembly of the Cumberland Presbyterian Church on the subject of medical advertisements, adopted by the Miami presbytery at its meeting in Lebanon, April 4, 1906. So far as I know this is the first instance of any religious body taking such action. It is to be hoped that many will follow the example. The work of THE JOURNAL on the nostrum question is heartily approved by all reputable physicians in Warren County.

B. H. BLAIR, M.D.

WHEREAS, There appear in the columns of our church paper and other periodicals, medical advertisements which are objectionable because of their misleading, deceptive, untrue, and fraudulent character; and

WHEREAS, The publication of such advertisements tends to suggest the presence of disease, which does not exist, to cause a postponement of early diagnosis and appropriate treatment of many serious maladies, and to injure the physical, mental and moral well-being of many readers who implicitly rely on what they have read in their church paper; and

WHEREAS, Our official church organ, by its course in admitting such advertisements is subjecting itself to ridicule while other periodicals of recognized standing are refusing all medical advertisements; and

WHEREAS, Many of the popular nostrums advertised contain alcohol, opium, chloral or cocain or other drugs in quantities, the indiscriminate use of which tends to produce drug fiends and inebriates and thereby to defeat the cause of temperance as presented and advocated by the same paper; and

WHEREAS, Reputable Christian physicians of unquestioned professional standing and eminent qualifications, on whose judgment we must rely on questions of medical character and whose labor and influence are exerted for the moral and physical betterment of humanity, it is to be observed, are a unit in condemnation of such advertisements; and

WHEREAS, The injuries wrought and evils perpetrated by the practice of charlatans and quacks are recognized, only in their fullest, by physicians and in part by intelligent laymen; and

WHEREAS, No amount of money received from such advertisements can right these wrongs; and

WHEREAS, We affirm our affection for the *Cumberland Presbyterian* and express our confidence in its management and editorial control and observe with pride its attainment. Therefore, be it

1. *Resolved*: That the General Assembly direct its board of publication, through its agents, to refuse all advertisements of a medical character unless said advertisements are first approved by the board to be hereinafter named. And

2. *Resolved*, That this special board be composed of three physicians, selected by the board of publication, for their known high professional standing, eminent qualifications, ripe experience, and unquestioned integrity.

Societies Take Action.

PHILADELPHIA, April 7, 1906.

To the Editor:—Will you kindly insert in the columns of THE JOURNAL the enclosed resolutions of the Medicolegal Society of Philadelphia?

These resolutions echo not only the sentiments of the members of this society, but of all the medical societies of Philadelphia. ALBERT M. EATON.

The Medicolegal Society of Philadelphia thanks the Board of Trustees of the American Medical Association for establishing a Council on Pharmacy and Chemistry. It considers this innovation of paramount importance to the general practitioner of medicine.

This work comes at the right time; is done in the right spirit, and should be received by the medical profession with real thankfulness.

To the editor of THE JOURNAL of the American Medical Association we owe a debt of gratitude; his policy has been plainly and fearlessly presented, every position he has taken against all degrees of quackery he has sustained, and he should be encouraged to hold to this high standard.

The Medicolegal Society feels that this good work can not be assumed and performed exclusively by the Board of Trustees of the Association nor by the editor of THE JOURNAL.

We believe that all members of the American Medical Association should dedicate themselves to the promotion of this propaganda to a successful issue, and that every physician who is eligible should become a member, thus bringing to the organized profession strength, influence and wealth; factors of inestimable value in increasing the influence of the American Medical Association to both physician and state and the upbuilding of scientific medicine in America.

W. T. HAMILTON, M.D., Secretary.
ROYAL W. BEMIS, M.D.
ALBERT M. EATON, M.D.

At the annual meeting of the Morris County (N. J.) Medical Society, held at Morristown, March 13, 1906, resolutions were adopted commending and endorsing the work of THE JOURNAL A. M. A., the *Ladies' Home Journal*, *Collier's Weekly*, the *Farm Journal*, and the Marine (Ill.) *Telegram* in enlightening the profession and the public regarding the nostrum evil, and especially commending THE JOURNAL A. M. A. for refusing to publish advertisements of medical agents the composition of which is concealed. The society also deprecated the fact that daily and weekly papers, periodicals representing religious denominations and organs engaged in reform work, including even some medical journals, accept advertisements of "patent medicines" a great percentage of which are rank frauds. The society also offered its aid and co-operation in any wise effort toward the enactment of legislation that will protect the public from the evils of "patent medicines."

The Cleveland County (Ark.) Medical Society at its March meeting adopted a resolution heartily endorsing the work which the American Medical Association has done and is doing in regard to the control of the "patent medicine" evil, and declared its intention of aiding the association in every way possible.

The Denver and Arapahoe County (Colo.) Medical Society, at a meeting held April 3, 1906, endorsed the resolutions on the nostrum evil which were passed by the Philadelphia County Medical Society January 10, and published in THE JOURNAL January 20; and the resolutions adopted by the New York Academy of Medicine, January 18, and published in THE JOURNAL January 27.

The society also adopted the following resolutions:

Resolved, That the secretary is hereby requested to tender the thanks of this society, especially to *Collier's Weekly*, the *Ladies' Home Journal*, and *Everybody's Magazine*, for their excellent work in behalf of the public health, in exposing impure drugs, impure foods and adulterated liquors.

Resolved, That we deeply appreciate the power and influence of the lay press in supporting the Pure Food Bill which recently passed the United States Senate and is now pending in the House of Representatives.

Resolved, That a copy of these resolutions be sent to each member of Congress of the State of Colorado with the request that they support the bill as it passed the Senate.

Resolved, That a copy of these resolutions be sent to the secretary of every county and district medical society in the state of Colorado with the request that they be presented to the respective societies for their consideration and their adoption urged.

Resolved, That a copy of these resolutions be sent to THE JOURNAL of the American Medical Association; and also to the daily press of Denver, requesting its co-operation in this endeavor to promote the public health and welfare.

W. W. GRANT,
GEORGE H. STOVER,
DANIEL S. NEUMAN
Committee

Madison County (Ky.) Medical Society at a recent meeting passed resolutions endorsing house bill No. 53, introduced by L. F. Johnson of Franklin County, the purpose of which is to regulate the sale of "patent medicines" in Kentucky.

At the regular meeting of the Dodge County (Neb.) Medical Society held at Fremont, March 8, 1906, resolutions were adopted endorsing the pure food bill as passed by the United States Senate during the session, and commending the policy of the *Ladies' Home Journal*, *Collier's Weekly* and THE JOURNAL of the American Medical Association in the fight against nostrums.

The society also ordered a copy of the resolutions sent to their representative in Congress requesting him to support the pure food bill on behalf of the physicians of Dodge County.

At a meeting of the St. James' Parish (La.) Medical Society, held December 7, 1905, resolutions offered by Dr. B. A. Colomb were adopted endorsing the movement against the "patent medicine" fraud and resolving to aid the lay journals and THE JOURNAL of the American Medical Association in this campaign by not prescribing such preparations. The Society also advised that the American Medical Association and its component societies distribute literature among the laity giving reliable information regarding the principal "patent medicines."

The Wayne County (Mich.) Medical Society at a meeting held March 5, passed resolutions endorsing the work of THE JOURNAL, the *Ladies' Home Journal*, *Collier's Weekly*, and the *Druggists' Circular* in the campaign against the proprietary and "patent" medicine evils, and asking members of the society not to use, or to sanction the use of remedies the nature and quantity of whose ingredients are unknown.

Similar resolutions were adopted by the Oakland County (Mich.) Medical Society, and by the Medical Society of the Borough of the Bronx (N. Y.). This last named society also commended the work of the Council on Pharmacy and Chemistry and urged each member to abide by the Council's reports and to prescribe nothing which the Council does not approve.

Letters of Commendation.

Dr. R. H. Ballard, Wheeling, W. Va., writes:

"I notice with much pleasure the position your JOURNAL takes regarding proprietary medicines. May the good work go on until the medical journals generally are forced to strike from their pages the 'thousand and one' advertisements the very existence of which is a cause for shame on the profession of medicine."

Dr. Walter W. Stebbins, Mount Horeb, Wis., writes:

"I wish to commend the fight you are making on nostrums. Keep up the good work."

Dr. W. J. Burdell, Lugoff, S. C., writes:

"Congratulations on the fight against nostrums and also congratulations to the editor for the splendid JOURNAL he is giving us."

Dr. W. K. McCoy, Gum Springs, W. Va., writes:

"I assure you of my unqualified endorsement of your fight against nostrums, whether 'ethical' or not."

The Methods of the Cheney Medicine Co.

Drs. Brown and Lenox, Rogers, Ark., send us an account of a case of catarrh which was not cured by Hall's Catarrh Cure. The patient, Mr. Robert Parks, consulted these physicians for catarrh and stated that he had just finished his twenty-sixth bottle of Hall's Catarrh Cure, but that instead of being benefited he was worse. Mr. Parks wrote to the Cheney Medicine Co., the makers of Hall's Catarrh Cure, giving his experience, and asking the firm to pay $100 in accordance with the advertisements: "$100 for any case of catarrh which it will not cure" or to refund the money he had paid.

The following is a copy of a letter which he received in reply:

TOLEDO, OHIO, March 30, 1906.

ROBERT PARK, Rogers, Ark.

DEAR SIR:—Yours of recent date received, and in reply will say, as we have already said, that many cases require much more than you have taken for a cure, and as this is the case and Hall's Catarrh Cure is not placed on the market on the "No cure, no pay" plan, we would not feel at all justified in refunding the money paid for this trial of the medicine. Will furtner say that you have failed to state much regarding your disease, symptoms of same, of how long standing, symptoms of the action of the medicine, etc. Had we more information concerning your case, we might have been able to make some helpful suggestions regarding the treatment. Yours very truly,

F. J. CHENEY & CO.

A. G. A.

The above is an example of the shrewdness and the unscrupulousness of nostrum vendors. Their brazen offers of reward are fortified by conditions impossible to fulfill. Of course, a patient should not expect to get results from simply twenty-six bottles! He should keep on until old age carries him off, or he must be very sure to inform the company of his slightest symptoms or he will fail to reap the benefits of their valuable remedy. It will be remembered that Mr. Cheney is the author of the "Red Clause," he is the man who bragged to his fellows at the last meeting of the American Proprietary Association, of which he was president, of having a lobbyist in the different state legislatures so as to be ready in case any untoward legislation should be introduced. He is too shrewd a business man to risk having to pay $100 to every individual with catarrh who tries his nostrum without being cured.

Medical Legislation

Medical Men in Congress.

The Committee on Medical Legislation, in its efforts to secure the enactment of medical legislation, has felt the need of more representation in the halls of Congress. For the first time in several years the medical profession is represented in the House, the following two physicians having taken their seats in the present Congress:

DR. HIRAM RODNEY BURTON, of Lewes, Sussex County, Delaware, is a Republican member of the Fifty-ninth Congress. Dr. Burton was born in Lewes, Sussex County, Delaware, Nov. 13, 1841, and attended the schools of his native town. He taught two years in Sussex County and engaged in the mercantile business in Washington from 1862 to 1865, after which he entered the Medical Department of the University of Pennsylvania and was graduated in 1868. He then began the practice of medicine at Lewes, where he has since resided. Dr. Burton has played a prominent part in the politics of his native state for the past thirty years. In 1877 he was appointed deputy collector of customs for the port of Lewes; during the years from 1890 to 1893 he served as acting assistant surgeon, United States Marine-Hospital Service; he was appointed delegate to the national Republican conventions of 1896 and 1900; ran for state senator from the fifth district of Delaware in 1898; is a director in the Queen Anne's Railroad and in the Lewes National bank, and was elected to the Fifty-ninth Congress.

DR. ANDREW JACKSON BARCHFELD, Republican representative from the Thirty-second Pennsylvania district, was born in Pittsburg, Pa., May 18, 1863. He received his education in the public schools and Pittsburg Central high school, and was graduated from Jefferson Medical College, Philadelphia, in 1884. He has been actively engaged in politics since attaining his majority; was elected school director in 1885; a member of the common council of Pittsburg in 1886 and 1887; was a delegate to the Republican state conventions in 1886, 1894 and 1901; for some years a member of the Republican state committee; ran for Congress in 1892 and was defeated; took an active interest in presidential and gubernatorial campaigns in his state. Dr. Barchfeld stands high in the medical profession of his state and country. He is a member of the Pittsburg South Side Medical Society, Allegheny County Medical Society, Pennsylvania State Medical Society and American Medical Association, is president of the board of directors of South Side Hospital, Pittsburg, and a member of the staff. He was elected to the Fifty-ninth Congress in 1904 by a large majority.

DR. JACOB H. GALLINGER, Republican, of Concord, N. H., has represented the medical profession in the Senate since March 4, 1891.

He was one of a family of twelve children, and was born in Cornwall, Ontario, March 28, 1839, of Dutch ancestry, his great-grandfather having emigrated from Holland before the War of the Revolution.

Receiving a common-school and academic education, he studied medicine and was graduated in 1869 from the New York Homeopathic Medical College and Hospital. He settled in Concord, where he resided, pursuing the practice of medicine and surgery until elected to Congress. Dr. Gallinger was identified with the leading medical organizations of his state and country, and was a frequent contributor to medical literature.

He began his political career in 1872 when he was elected a member of the House of Representatives of New Hampshire, since which time he has continuously played a prominent part in the affairs of his state and country. He served his state as a member of the constitutional convention in 1876, was a member of the State Senate in 1878, 1879 and 1880; in 1879 and 1880 was surgeon-general of New Hampshire; in 1885 he received the honorary degree of A.M. from Dartmouth College; is a trustee of the George Washington University of Washington, D. C. For eight years he was chairman of the Republican State Committee, resigned and was elected in 1898, 1900, 1902 and 1904; in 1888, as chairman of the delegation from the State of New Hampshire to the Republican National Convention, he made a speech seconding the nomination of Benjamin Harrison; in 1900, was also chairman of the New Hampshire delegation to the Republican National Convention at Philadelphia which nominated William McKinley. He was at one time a member of the National Republican Committee and was elected to the Forty-ninth and Fiftieth Congresses. He declined renomination to the Fifty-first Congress. He was elected United States Senator to succeed Henry W. Blair and took his seat March 4, 1891. In 1897 he was re-elected by a unanimous vote of the Republican members of the legislature and the votes of five Democratic members. He was re-elected in 1903, having the distinction of being the only man in his state who was elected United States Senator for three full terms. His term will expire March 3, 1909.

Correspondence

Dr. McCormack's Organization Work.

JACKSONVILLE, ILL., April 17, 1906.

To the Editor:—I write to ask if it would not be desirable to do something to secure for Dr. McCormack audiences somewhat in proportion to the importance and value of the great humanitarian work which he is doing. It seems to me a shame for him to go on from day to day making these important talks to little groups of doctors and citizens, when every person is so vitally involved in the subjects discussed.

No one, who may call on a physician for services, should fail to hear these topics considered. The patrons of physicians will be greatly benefited and will look on the physician with

an increased respect if he is worthy, and if not will set about to make him worthy or discard him as unworthy. It is impossible for the local medical men to do this work effectively without more detailed information as to what is to be expected.

Last Tuesday evening Dr. McCormack talked to our citizens and the room was filled with our best people. Everybody was delighted, but all united in saying that it was a great misfortune that only two or three hundred people should have had the privilege of being present.

This is what I hear every place Dr. McCormack has talked. They say, "If we had only known something of the character of his address beforehand there would have been two or three times as many present."

The fact is, Dr. McCormack is doing a great missionary work, probably the greatest missionary campaign by any individual to-day, and we should recognize it as such and give it the support and advance announcement which it deserves. The profession, as well as the people, should be better instructed in advance as to the field to be covered and the objects of these talks. If it could be made plain that the primary object is to help the people and give them a proper conception of what organized medicine stands for, it would go far toward securing the coöperation of all good citizens in doing away with the inherited antagonism to the medical profession, which has long existed among our people.

The profession, as well as the people, should learn from him that the basis of most of our professional difficulties and misunderstandings with the public are to be found in the jealousies and antagonisms within our own ranks, which we are making a great campaign to eliminate. The doctors of the past have kept themselves poor by hating each other and misleading the public. Everyone should understand that one of the purposes of this great work in which Dr. McCormack is engaged is to improve the condition of the profession by pointing out its poverty, brought about by envy, jealousy and poor business methods.

He most admirably brings about a frank and open discussion of these subjects among the doctors and between them and all classes of the public. He drives home the lesson that a jealous and envious doctor, and one kept in poverty, is a danger and menace to the community, and plainly advises the public against the employment of such. Neither the doctors nor the people realize the number or importance of these problems of mutual interest.

His statement of the poor business methods of many physicians, as well as their bad professional methods, attracts attention and does great good. The drug store evil, the social disease evil, and inattention to sanitary and health matters are a few of the subjects of mutual importance which receive attention in his addresses and never fail to arouse the public.

The remedy for these and other evils and antagonisms which exist he finds in a complete understanding (organization) among ourselves and a frank discussion of every interest of the profession with selected classes of the public, as well as the general public and patrons of the physicians. If physicians would realize the importance of these subjects they would soon see, what Dr. McCormack makes so plain, that the medical profession has no interest, including our financial condition, which is not of far more importance to the public than to the doctors.

If some plan could be devised by which at least the members of our county societies were informed in advance of the scope and importance of these addresses, it would certainly aid Dr. McCormack in his work. No man can do this effectively for himself. In order that the lawyers, bankers, editors, clergymen, teachers, druggists, legislators, commercial bodies, city and county officials, civic leagues, W. C. T. U. and Y. M. C. A. members, club women, farmers' organizations, labor unions, and all others, can be impressed with the importance of the subject, they must have some advance information as to the personality of the man as well as the character of his address. Each doctor should endeavor to have his patrons present. He will be amply rewarded by the better respect and better pay which they will give him, for they will certainly hear some of the most vital questions of the day presented in a most charming, effective and practical way. Dr. McCormack can tell the plain truth in a way which excites great interest and desire to do better, but never leads to bitterness or leaves a sting.

This work has such unlimited possibilities for good to the public, to the sister professions, and to our own profession, that it is unfortunate that we do not secure for our field worker in this great campaign of education a better hearing. Scores of my own citizens have expressed their regret at not being more carefully informed as to what was to be presented in order that they could have attended. The purposes, the evils to be corrected, the classes to be reached, the remedy to be applied, and the possibilities of the work should be understood in advance if the greatest good is to be accomplished by these addresses.

You cannot too strongly impress on the profession and on the public the value and importance of the subjects, and you may rest assured that there will be no disappointment on the part of either after hearing one of Dr. McCormack's most admirable and practical addresses.

I write you in the hope that some better plan may be devised by which the profession and the public may have more advance information in order that a greater number of people may have the privilege of this instruction.

CARL E. BLACK.

Need for Additional Nomenclature.

CHICAGO, April 14, 1906.

To the Editor:—In view of the recent laudable attempts to establish the functional diagnosis of the alimentary tract by means of minute examination of the feces on a systematic and trustworthy basis—an attempt which I firmly believe will eventually justify itself in the satisfactoriness of its methods and the value of its findings—it seems as though a suitable nomenclature should be adopted in order to clarify and simplify the literary features of the undertaking. This nomenclature should be uniform with that of the pathology of the urine, since both are concerned with excretory products.

The word "feces," which is universally, and I believe exclusively used to designate the excrement of the bowels, is the plural form of the Latin word, *fax*, meaning a sediment, of which the genitive form is *fæcis*, and in order to follow the nomenclature of the urine, I would suggest that the affix *sia* be applied to the root of the word, making *fæcia*, and this, in conjunction with the basic word, be used to express the pathologic condition in question. Thus, "hemafecia" would mean blood in the feces, "pyofecia" pus in the feces, "bilifecia" bile salts in the feces, and so on.

The question of nomenclature may seem to some a small and insignificant matter, but it is, I venture to think, by no means an unimportant factor in the orderly and systematic arrangement, and even in development, of a branch of applied science.

THOMAS G. ATKINSON.

The Association Button.

CHICAGO, April 11, 1906.

To the Editor:—While traveling in the south recently I was accosted one morning by an elderly gentleman who certainly would not have spoken to me had it not been that I had on the button of the American Medical Association. I found that he was a practitioner from Ohio, that he belonged to the American Medical Association, but he did not have on a button. We were on good terms at once, and I enjoyed meeting him very much. This brought to my mind the great advantage that I believe would accrue to the members of the American Medical Association if each one would wear his button all the time. There is a fraternal feeling among the profession, probably stronger than that among any of the fraternal societies; yet, without some badge when we meet a strange physician, we do not know whether he is a physician or not, and if he is not a member of the American Medical Association we have some question about his standing, even though he claims to be a physician. The button would be an introduction at once and would place physicians on a pleasant footing, even though they had never met before. If all the members would wear their buttons it would soon be discovered by other physicians that it was

very desirable to belong to this great organization. I hope some plan can be formulated which will induce the members of the Association to put on this badge. It is small, unobtrusive, and the laity do not even know its meaning; therefore, I can see no objection to it. But certainly none of us need be ashamed of belonging to the American Medical Association, even if the laity knew what the button meant.

E. Fletcher Ingals.

[Dr. Ingals' suggestion is a good one. There was a time when the doctor was known by his peculiar dress; his gold-headed cane was the insignia of his calling. But now there is no distinctive mark to separate him from his fellow mortals. Possibly some will say that it is not necessary, and probably this is true, but when traveling it is very pleasant, sometimes, to be able to go up to a man one has never met before, and with confidence extend the hand of greeting. The American Medical Association button is a means of introduction that will often bring two congenial souls together, to the pleasure of both.—Ed.]

Trip to China and Japan.

St. Paul, Minn., April 14, 1906.

To the Editor:—The Great Northern Railway Company has made me a very generous offer. If I can organize a party of 100, to include physicians, their families and their friends, it will give us round-trip rates from St. Paul to Japan and China and return for $700. This rate includes a double berth from St. Paul to Seattle and return, dining-car service to Seattle and return, first-class hotel in Seattle if necessary either way, first-class outside stateroom on the 28,000-ton steamship *Minnesota* from Seattle to China and return, with not more than two in a room, first-class hotel accommodations in Japan and China, jinrickishas, carriages or sedan chairs in Japan and China when desired, first-class railway transportation in Japan and boat transportation in China. For any one joining the party on the steamship in Seattle and leaving the party at Seattle on its return, a rate of $625 will be made. If any members of the party wish to remain in Japan at their own expense instead of going to China with the steamship a refund of $75 is made. The above rates also include guides. The party will leave St. Paul about July 21, sailing from Seattle on July 25, and reach Seattle on its return October 5 and St. Paul about October 9.

If any physicians wish further details it will afford me pleasure to answer any questions. Alexander J. Stone.

Hereditary Transmission of Yellow-Fever Parasite in the Mosquito.

Birmingham, Ala., April 14, 1906.

To the Editor:—I have just received a copy of "Yellow Fever Institute Bulletin No. 15," containing the account of an attempt to prove the "hereditary transmission of yellow-fever parasite in the mosquito."

In this experiment, fourteen mosquitoes, the progeny of three laboratory-grown mothers, were used, divided into three sets.

The mother of Set 1 was hatched in the laboratory. On October 3 she was allowed to sting a yellow-fever patient; again, on October 5, she stung same patient. On October 8, 10 and 12, she was allowed to feed to her fill on an immune. On October 17 she laid eggs for Set 1.

The mother of Set 2 was hatched from larva, "and for some time fed on immune blood." On October 4 she stung a yellow-fever patient. On October 6, 8, 10, 12 and 15 she fed on blood of an immune. On October 19 she laid eggs for Set 2.

The mother of Set 3 was raised from larva. On October 4 she stung a yellow-fever patient. On October 6, 8, 10, 12 and 14 she fed on blood of an immune. On October 18 and 19 and November 2 and November 13 to 18 she laid eggs for Set 3.

Now, let us suppose for a moment that hereditary transmission in the mosquito is a fact.

Immunity is supposed to be due to the presence in the blood of an immune of an antibody, and when the antibody disappears from the blood immunity ceases.

These mother mosquitoes were fed first on yellow-fever blood, then on immune blood, and afterward laid the eggs from which were hatched the experimental mosquitoes.

Is it not reasonable to suppose that the yellow-fever parasite taken with the yellow-fever blood, was destroyed by the antibody taken afterward in the immune blood, thus rendering it impossible to transmit the parasite by the eggs deposited at a later date?

And is not this experiment just as valuable in a positive way as the case of Marchoux and Simond, whose reported case was caused by mosquitoes hatched from eggs deposited by a mother fed only on syrup and yellow-fever blood?

J. M. Lowrey.

Tropical Gangrene in Guam.

Norfolk, Va., April 9, 1906.

To the Editor:—In The Journal, April 7, a paragraph appeared under the above heading, doubtless inspired by a Washington dispatch of the Associated Press which was published widely in the newspapers recently. The dispatch related to a report made by a lay official in the Island of Guam referring to a peculiar disease which is prevalent in that island and which has already been recognized by professional authority under the name rhinopharyngitis mutilans. (Report Surgeon-General of the Navy, 1905, et al.)

The Associated Press paragraph states that the report from Guam refers to the disease as *gangrosa*. It is not to be wondered at that the correspondent of The Journal did not know what this meant, but he was hardly justified in assuming from the form or sound of the word that it meant gangrene. As the heading and content of the paragraph convey an impression which is very far from the truth, I hope the explanation necessary to enable The Journal to set itself right will not be unacceptable.

The Spanish adjective *gangoso* (masculine), *gangosa* (feminine), means snuffling, nasal, catarrhal, ozenous. It is applied by the Spanish (and, after them, by the Chamorros of Guam) to any person who has a chronic nasal affection, and the word is entirely without special application or meaning in connection with the *rhinopharyngitis mutilans* prevalent in Guam. In Spain, or in Guam, *un hombre gangoso* or *un gangoso* is a snuffler, a man who has the snuffles. A woman so afflicted is *una gangosa*. Gang(r)osa is a misspelling of the feminine form of this adjective and not the name of a disease. No form of gangrene is prevalent in Guam.

I have recently served more than two years in Guam as a medical officer and as health officer of the island, a longer time than any other American medical man has ever spent there, and feeling, as I do, a keen interest in all that pertains to the island and its welfare, I venture to ask you to correct the wrong impression which you have inadvertently given in the paragraph referred to.

A prominent physician of Philadelphia, whose daughter happens to be living in Guam at the present time, was so alarmed by this "gang(r)osa" nonsense as published by the Associated Press that he sent me the paragraph and asked me what it meant.

I send you herewith a reprint, from the *Journal of Tropical Medicine*, Feb. 15, 1906, of the latest article I have published on the disease, *rhinopharyngitis mutilans*. As the *Journal of Tropical Medicine* reaches a very limited number of readers in America, as neither the article nor its substance has been offered to or has appeared in any American publication, as Guam is an American possession and as our American medical men are taking an increasing interest in tropical medicine, you may care to take some more extended notice of the subject than the mere correction of the misinforming paragraph to which I refer, and if you do the article I inclose is entirely at your disposal.

James Farquharson Leys,
Surgeon United States Navy.

[In the article referred to Dr. Leys describes the disease as beginning with sore throat and showing, on examination, a small ulcer on the back of the pharynx, on a posterior faucial pillar or on the free edge of the palate. The ulceration almost always extends upward, destroying the soft palate and

attacking the bones of the palate and nasal septum, finally destroying these entirely. While the disease is usually arrested at this stage, leaving the face of the victim deformed from the falling in of the nasal cartilage and skin, in less than 10 per cent. of the cases the skin of the nose and face are attacked. In such cases one can look through the anterior nares into the mouth and down the throat.

The disease appears to be infectious, and, although somewhat amenable to local surgical and antiseptic treatment, the infection is very difficult to eradicate and the affection is prone to recur. There are no constitutional symptoms, the general condition being in marked contrast to that in tuberculosis and secondary syphilis.

The disease is known in various parts of Polynesia and probably also in the West Indies. It has been attributed to leprosy, syphilis, tuberculosis, and has been considered as a sequel of yaws. The first opinion is not entertained by those conversant with leprosy; the second is negatived by the fact that it attacks adults who have been in good health and who show no signs of hereditary syphilis and also children who have had no opportunity of acquiring it. Its restricted geographical distribution is inconsistent with a syphilitic origin, and the absence of constitutional symptoms speaks against its syphilitic nature. The victims present no evidence of tuberculosis in other parts of the body, and the disease does not extend downward, the larynx remaining unaffected.

Most authors who have mentioned the affection, as Manson, Daniels, Maxwell, Rat and others, have regarded it as a sequel of yaws. Dr. Leys, after reviewing the published opinions and their reasons, comes to the conclusion that the disease is distinct from yaws and offers a problem in tropical medicine that will well repay the attempt to solve its etiology according to modern methods of investigation. The opinion that it is a sequel of yaws is based mainly on the coincidence of the two diseases, but it is easily seen that while yaws prevails wherever rhinopharyngitis is known, the same is also true of tuberculosis and syphilis, while rhinopharyngitis is limited to a few localities, yaws being prevalent over a much greater area.]

Pulmonic Second Sound in Health and Disease.

PHILADELPHIA, April 16, 1906.

To the Editor:—In THE JOURNAL, April 14, 1906, appears a clinical note on the pulmonic sound in health and disease. There is suggested the undoubted, and often overlooked fact, that an evidently accentuated pulmonic sound in certain normal persons can be rendered normal by exercise, as the result of an equal distribution of the blood volume of the body, so to speak. Dr. Hardy concluded: "If this be true, it would seem that too much stress has been laid on this sign as an early indication of pulmonary tuberculosis, thus giving an opportunity, at least, for misleading conclusions." It is needless to say that a constant and pathologic increase in the intensity of the pulmonic sound is a valuable aid in the diagnosis of early pulmonary lesions, indicating as it does an overtension in the pulmonary circulation, almost, if not always, due to mechanical causes (congestion, consolidation, etc.). This increase in intensity, however, must be constant enough and marked enough to be certainly pathologic, and just at this point enters the personal equation of experience and judgment that renders the pulmonic sign valuable to one observer, and a source of error to another. Certain medical men are better off, I am sure, without any teaching about the pulmonic sound, since ear and stethoscope fail to bring the proper result in the absence of a natural sense of discrimination.

The general rule may be laid down, none the less, that a truly pathologic increase in the intensity of the pulmonic sound will never disappear until its causal condition is removed; and that such an increase, when due to tuberculous infiltration or congestion, will remain constant in spite of exercise, and will, as a rule, become exaggerated thereby. Under such conditions there can be no approximation of the aortic and pulmonic systemic pressures short of a cure. This is equally true of mitral disease and every other pathologic process that tends to produce over tension in the pulmonic circulation.

ROBERT N. WILLSON.

Pauper Fees by Wealthy Corporations.

In THE JOURNAL, March 3, 1906, page 671, we referred to the absurdly low fees offered by the Maryland Casualty Company in their new schedule of fees. The subject came up for discussion at a meeting of the Jefferson County (Ky.) Medical Society, held March 27, 1906, at which Dr. Hugh R. Manning, Louisville, presented some letters from this company, and in discussing the matter said:

Much has been said and written of late about physicians' fees, especially the fees paid by various insurance companies for the examination of applicants for life insurance, and for first attention and services to "personal accident" and "employers' liability" insurance, all of which has been brought about by the action of practically all the companies in reducing the medical fees that were already so low as to be on a starvation ratio. . . . I maintain that no physician should make an examination of an applicant for life insurance for a fee less than $5, and that such examination should be made in a strictly honest and conscientious manner; whenever the policy to be issued the applicant is for a sum over $1,000, or whenever a microscopic examination of the urine is to be made, the fee should never be less than $10. Why, gentlemen, if you have a title company make an examination of the title of a piece of property you are about to purchase, that company will charge you a fee of $25 whenever the value of that property is $1,000 or less. Then is not the opinion of one of our profession as to whether a man is physically sound and a desirable risk for $1,000 of life insurance worth more than $2? If not, then it is not worth anything. The whole action of an insurance company must be based on the examination and report of the examiner, and the examiner should be paid for his expert knowledge or judgment in the matter. When you go to buy a horse you pay a veterinary $5 to look the animal over to ascertain whether he is sound, in which case you have $100 or $200 involved, and you think the money well spent; whereas, the insurance companies would have us make examination of their applicants for life insurance, requiring a great deal more technical training, where there is a thousand or several thousand dollars involved, and they offer us as remuneration for such services the miserable fee of $2. Just think the matter over. Aren't your services worth as much as a veterinary's? Isn't your time as valuable as that of a clerk's in a title company's office?

The remedy for these evils lies wholly in the united and concerted action of the profession. We will have to get together as lawyers have done, demand our rights—a reasonable compensation for the services we render—and we will secure them; but this end can not be secured without the united effort on the part of a majority of the profession. In other words, "The fault is not in our stars, but in ourselves, that we are underlings."

On receipt of the company's fee bill, which was published in the article above referred to, Dr. Manning wrote the company the following letter:

HAST BUILDING, Feb. 9, 1906.

Mr. Charles W. Maydwell, Manager Claim Division, the Maryland Casualty Company, Baltimore, Md.

Dear Sir:—I have to acknowledge the receipt of your communication of the 6th inst., inclosing new schedule of fees, effective March 1, 1906, and I regret the necessity of declining to accept such reduction in compensation as indicated therein.

In pursuing the course above indicated, of course, it is fully understood by me that my connection with your company terminates March 1, 1906, provided it is your determination to maintain such a schedule of fees, but I would like to be permitted to present to you some of my views as to why I do not consider it wise on your part and the part of the company to enforce it. No doubt you will find without great difficulty licensed and so-called doctors who will be glad of the opportunity of serving you for the miserable fees allowed by the schedule, and even then you will be paying them more than double what their services are worth; but no professional man of any intelligence, ability or reputation will serve your company or any individual for such remuneration as is offered by this new schedule. As to the increase in the volume of business and the "wedge by which you secure an entree into a new family" is concerned, it is a dream, a delusion and a snare; it should rather be stated that the increase in volume of "work" and consequent growth of "pauper practice" in many instances would make a doctor busy to serve you for less than a third of the fees paid by individuals of poor or moderate financial condition. Families into which it is desirable to have an entree always secure the services of higher-classed men than such of those who would be willing to accept such fees as indicated in your new schedule. If there is any particular department in your company where you need and demand, more than elsewhere, brains, intelligence, judgment and ability, it is in your field surgeon, for by his conservative and judicious action he saves you a hundred times the cost of his services, and incidentally prevents you many lawsuits and complications. You will pardon the personal allusion, but in the short time that I have been connected with the company I have saved the company many, many times the fees I have received. In one instance that I recall a doctor (who is of the class and kind whose services could doubtless be secured at the rate given in the new schedule) treated one of your policyholders for six weeks on account of an injury to the hand, without discovering the fact that the patient had a broken thumb. This little oversight on the part of the doctor, of course, had the effect of giving the policyholder double time for his total disability, to say the least. I merely recite this case to illustrate how it is possible that a cheap surgeon may be a very dear one. What would you think of a surgeon who would send you a bill of $2 for amputating your finger or a number of your fingers, furnishing his own anesthetic (Squibb's ether at $1 for eight ounces), his own dressings (at a cost of no less than from 25 to 50 cents), his own instruments, his time, his horse and buggy or automobile—all for the sum of $2? Further more, this was an emergency call, so must be answered at once regardless of office hours and everything else, and would require not less than from an hour to an hour and a half under the best

of conditions. I can imagine you would think, if you did not say, that that doctor had better get a job carrying a hod, for which he could get 50 cents an hour for eight hours every day and make a great deal more out of it. Likewise, I am certain that you would conclude that he can not have much more ability than the hod-carrier, and mentally resolve that in the future should you have to have anything of the kind done you would employ some one else to do it. Think of a surgeon in a city the size of Louisville performing an amputation at the hip-joint for $25. Compared with a hip-joint amputation, or even excision of the hip-joint, an abdominal section is a picnic, child's play, and the mortality of the former as compared with the latter is as one hundred is to one. A man would be nothing short of a fool who would take all this hazard, do all the work and neglect his private practice, which might pay him ten times the amount for the insignificant fee of $25; and I for one do not care for it.

Thanking you for past courtesies and kindnesses, and assuring you that I shall be glad to serve you at any time in the future at anything like a reasonable fee, or a minimum fee that may be collected from an individual, and hoping that you may be able to see my viewpoint, I am, Yours truly,

HUGH R. MANNING.

Following are the company's reply and Dr. Manning's answer:

BALTIMORE, Feb. 26, 1906.

Mr. Hugh R. Manning, Louisville, Ky.

Dear Sir:—You favor of the 9th inst., respecting our new schedule of fees, was received during my absence from the city, and a reply thereto has, for this reason, been delayed.

We have, as you suggest, found very many doctors willing to sign this schedule, and we know from experience that they are men fully qualified to perform the services required of them.

In view of the fact that such a large majority of our surgeons have agreed to be governed by the schedule in submitting their bills for services, I feel justified in asking you to give further consideration to the matter and advise us if you can not find it possible to give the schedule a fair trial, with the understanding that if it does not work out to your satisfaction the matter can be taken up for further discussion. Yours very truly,

CHARLES W. MAYDWELL,
Manager Claim Division.

HAST BUILDING, March 5, 1906.

Mr. Charles W. Maydwell, Manager Claim Division, Maryland Casualty Company, Baltimore, Md.

Dear Sir:—I thank you for the courtesy of your letter of the 26th ult., asking me to give further consideration to the matter of your new schedule of fees, with the understanding that should it not prove satisfactory after a fair trial to take up the matter for further discussion.

In reply I have to state that my action in declining to accept the new schedule of fees, under date of Feb. 9, 1906, was not taken without due consideration, and I still adhere to the views therein expressed, viz., that the fees allowed are inadequate and not acceptable to me. That there are others in the profession that share my opinion in this matter is evidenced by the clipping I have cut from THE JOURNAL of the American Medical Association, issue of March 3, 1906, herewith inclosed, which purports to have been written by Dr. C. H. Emery, of Bedford, Ind., a small town of about one-tenth the size of Louisville, Ky., and where the cost of living is much less. Doubtless you will hear from others along the same line, and I expect that you will find it a very unpopular measure.

There is a way in which a doctor may make a reasonable fee in all cases coming for first detention, provided he secures the "after-service." He can increase his charges against the patient, or make more visits than are warranted by the condition, or tell the patient that the insurance company pays only one-third fees and that he must make good for the balance—in short, by many dishonest and disreputable means, too numerous to mention; but I do not care to join the ranks of those who do this kind of work, and I imagine that it will, sooner or later, have a telling effect in the insurance field. A man who will practice deception to his patient will have no scruples in doing the same way by a corporation, and is a very unsafe man to deal with in any way. There is no field, unless it may be the insurance field, in which greater deception can be carried on without fear of detection than the practice of medicine; there is no professional field more full of shysters and charlatans, maintaining a degree of respectability unwarranted by their conduct. No respectable or self-respecting man can afford to work for the fees offered by the new schedule, unless he desires to put the "pauper Maryland Casualty Company" on his charity list and do their work for "glory." You can feel reasonably sure that the doctor has to have a living somehow, and you will have more "bogus" claims that will go through without a question, doubtless many others for which suit will be entered to enforce collection, and I verily believe that you will find small surgeon fees more expensive. Very truly yours,

HUGH R. MANNING.

Association News

Lodging-Houses and Boarding-Houses.

In the announcement in THE JOURNAL, April 7, it was stated that, in a future issue, a list of the boarding-houses and lodging-houses would be given; and the Committee on Hotels and Transportation volunteered to secure accommodations for all members who should request such service. It has been made clear, however, that great confusion and much annoyance are bound to result if any considerable proportion of those who attend the meeting negotiate directly with the proprietors of these houses while others are dealing with the same people through the committee. It has seemed best, therefore, to withdraw that part of the announcement and to simplify the work of placing members by having all applications and engagements pass through the hands of the committee. Members wishing the assistance of the committee will please specify the number of rooms desired, whether or not board is also desired, and the rate beyond which the committee shall make no engagements.

The committee advises early application, since, naturally, the most desirable accommodations in each class will be the first to be given out, on the principle of first come, best served. Members who delay action until arrival will be given the best that remains, but they should bear in mind the possibility of delay and disappointment.

The committee will spare no pains to place each applicant comfortably and satisfactorily, and will give to each its personal attention. CHARLES HARRINGTON, Chairman,
366 Commonwealth Avenue, Boston.

Excursion to Nova Scotia.

As on of the attractions following the Boston session a nine days' tour to New Brunswick, Nova Scotia, Maine and New Hampshire is being arranged. The party will visit a day or two in St. John, N. B., Digby, N. S., Bar Harbor, Me., and Portsmouth, N. H., and touch at the ports of Portland and Eastport, Me., and Lubec, N. B. A booklet fully describing the tour may be obtained from Dr. E. R. Campbell, Bellows Falls, Vt. As it will probably be necessary to limit the number of the party those desiring to go should write promptly.

Marriages

LESTER CURTIS, M.D., to Mrs. Mary B. Hibbard, both of Chicago, April 11.

FREDERICK H. LITTLE, M.D., to Miss Amelia Timm, both of Muscatine, Iowa, April 5.

S. D. LARGE, M.D., Hopkins, Mo., to Miss Sadie Musser, in St. Joseph, Mo., March 31.

CHARLES A. WORTHEN, M.D., to Miss Agnes L. Fitzgerald, both of Lynn, Mass., April 6.

JOHN B. SIMMS, M.D., Center, Texas, to Miss Julia A. Jordan of Neuville, Texas, April 8.

E. B. VAN ARSDEL, M.D., to Miss Marion Louise Farmer, both of Alamagordo, N. M., April 7.

W. HARRIMAN JONES, M.D., to Mrs. Ida Belle Musselman, both of Long Beach, Cal., March 29.

MAURICE OSTHEIMER, M.D., of Philadelphia, to Miss Martha S. McIlvaine of Downingtown, Pa., April 18.

WILLIAM HARRISON KENNEDY, M.D., Shelbyville, Ind., to Miss Effie Eleanor Burnham of Chicago, April 14.

SAMUEL MISLEY TRAVER, M.D., Steelton, Pa., to Miss Helen Elizabeth Harrison of Germantown, Pa., April 18.

NATHANIEL ORR, M.D., Charlotte, N. C., to Miss Susie Hales of Fredericksburg, Va., at Houston, Va., March 31.

GEORGE MONTGOMERY TUTTLE, M.D., New York City, to Mrs. Mabel Holden Kirkbride of St. Louis, in Florence, Italy, April 4.

Deaths

John Campbell, M.D. Albany (N. Y.) Medical College; a member of the medical department of the United States Army from 1847, when he joined as lieutenant, until 1886, when he retired as colonel, receiving in April, 1904, the rank of brigadier general retired; lieutenant-colonel and medical inspector, U. S. V. during the Civil War; a veteran of the Mexican War and of the various Indian campaigns, died at his home in Cold Spring, N. Y., Dec. 25, 1905, aged 84.

Edgar Allen Jones, M.D. Birmingham (Ala.) Medical College, 1898; professor of pathology in his alma mater; pathologist and bacteriologist to Hillman Hospital, Birmingham; secretary of the Jefferson County Medical Society, and a member of the Medical Association of the State of Alabama, died at the home of his uncle in Woodlawn, Ala., April 10, from tuberculosis, after an illness of more than two years, aged 29.

Jacob W. B. Wellcome, M.D. St. Louis College of Physicians and Surgeons, 1883; a pioneer of the Minnesota Valley; a member of the American Medical Association, Minnesota State Medical Society and Brown County Medical Society, died at his home in Sleepy Eye, April 8, after an illness of nearly a year, from malignant disease of the neck, aged 84.

Edward A. Crane, M.D. Harvard University Medical School, Boston, one of the organizers of the United States Sanitary Commission during the Civil War; a sanitary expert; for many years a resident of Paris, France, and editor of the *American Register*, died suddenly at his home in Paris, February 25, aged 73.

Archibell C. M. Moir, M.D. Tufts College Medical School, Boston, 1896; some-time house physician in the Cambridge Hospital; a member of the medical staff of Newton Hospital, and a member of the Newton Medical Improvement Society, died suddenly, March 29, at his home in Newton Highlands, Mass.

John Dickenson Curran, M.D. College of Physicians and Surgeons in the City of New York, 1901, of Binghamton, N. Y., for four years a member of the staff of the State Hospital in that city, died from typhoid fever at St. Augustine, Fla., April 7, after an illness of five weeks, aged 32.

Sanford Bert McClure, M.D. Medical College of Ohio, Cincinnati, for three years a contract surgeon in the United States Army, on duty in the Philippine Islands, died at his home in Walnut Hills, Cincinnati, April 6, from typhoid fever, after an illness of three months, aged 33.

Harry McKennan, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1889, secretary and treasurer of the Æsculapian Society of the Wabash Valley, and a member of the Illinois State Medical Society, died at his home in Paris, Ill., March 30.

T. Park Lewis, M.D. New York Homeopathic Medical College and Hospital, New York City, 1899, formerly of Waterville, N. Y., died recently while on his way home from Tucson, Ariz., where he had been living for two years on account of his health.

Andrew B. Stevens, M.D. University of Buffalo, Medical Department, 1873; the oldest practitioner of Watertown, N. Y.; a veteran of the Civil War, died at his home in Watertown, April 7, from heart disease, after a short illness, aged 66.

William W. Cozart, M.D. Medical College of the State of South Carolina, Charleston, 1866, a prominent practitioner of Granville County, N. C., died suddenly at his home, near Dutchville, N. C., April 7, from heart disease, aged 72.

Edward H. Kellers, M.D. Medical College of the State of South Carolina, Charleston, 1858, surgeon in the Confederate service during the Civil War, died suddenly from angina pectoris, at his house in Charleston, April 5, aged 70.

Thomas Beaver Wintersteen, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1899, formerly president of the Montour County Medical Society, died at his home in Danville, Pa., April 5, aged 33.

Andrew Jackson Smoot, M.D. University of Maryland School of Medicine, Baltimore, 1852, died from heart disease, April 11, at his home, Society Hill, Cooksey, Charles County, Md., after a lingering illness, aged 77.

Edgar A. Aikman, M.D. Rush Medical College, Chicago, 1891, a member of the American Medical Association and one of the best known physicians of Vermilion County, Ind., died at his home in Clinton, April 11.

Emmett Roberts, M.D. Geneva (N. Y.) Medical College, 1850, for many years a prominent practitioner of Berrien County, Mich., died at his home in St. Joseph, April 9, after an illness of one year.

Samuel B. Smale, M.D. Toronto University Medical Faculty, 1888, one of the oldest practitioners of Huron County, Ont., died at his home in Wroxeter, March 26, from pneumonia, after a short illness.

Hugh Cary, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1884, of Tenstrike, Minn., died in St. Anthony's Hospital, Bemidji, Minn., from nephritis, February 7.

Walter Alonzo Van Voorhis, M.D. Western Pennsylvania Medical College, Pittsburg, Pa., 1890, died at his home in Philadelphia, April 4, from the effects of a self inflicted gunshot wound.

George G. Palmer, M.D. Medical College of the State of South Carolina, Charleston, 1876, died at his home in Cartersville, S. C., from tuberculosis, after a prolonged illness, April 2, aged 52.

John S. Burridge, M.D. (Years of Practice, Illinois), formerly of Erie, Ill., died at the home of his daughter in Dyer, Tenn., February 18, from jaundice, after an illness of three weeks, aged 72.

Francis Elmer Fuller, M.D. College of Physicians and Surgeons of Chicago, 1902, died at his home in Adrian, Mich., January 25, from pneumonia, after an illness of four weeks, aged 43.

Samuel E. Winnemore, M.D. New York University, Medical Department, New York City, 1856, a Confederate veteran, died at his home in Benton, Ala., March 28, from heart disease, aged 72.

John Wesley Moak, M.D. College of Physicians and Surgeons of Ontario, Toronto, 1902, died at his home in McGregor, Ont., April 17, from nephritis, after an illness of six weeks, aged 31.

Frank B. Nailor, M.D. Transylvania University, Medical Department, Lexington, Ky., died at his home near Vicksburg, Miss., January 1, from cerebral hemorrhage, aged 69.

Jarvis U. Woods, M.D. Hahnemann Medical College, Philadelphia, 1868, died at his home in New Haven, Conn., April 1, from cerebral hemorrhage, after a short illness, aged 63.

John Hamilton Hissey, M.D. College of Physicians and Surgeons, Baltimore, 1878, died at his home, near Honesville, Md., March 29, after a long illness, aged 53.

Morris Rogers, M.D. University of Iowa, Medical Department, Iowa City, 1869, died at St. Joseph's Hospital, Deadwood, S. D., Aug. 19, 1905, aged 67.

W. H. M. Kyle, M.D. Trinity Medical College, Toronto, 1900, of Grosse Point, Mich., died at his father's home in Palmerston, Ont., April 7, after a short illness.

P. A. Letourneau, M.D. Chicago Medical College, 1881, died at his home in Frenchtown, Mont., April 8, after a long illness, from pulmonary abscess.

R. A. Hutcheson, M.D. Medical College of Georgia, Augusta, 1883, died at his home in Toccoa, Ga., from a self-inflicted gunshot wound, February 7.

J. B. Henion, M.D. Eclectic Medical College of the City of New York, 1883, died suddenly at the Quincy House, Boston, March 10, aged 67.

B. H. Leblanc, M.D. Laval University, Medical Department, Quebec, 1885, of Point St. Charles, Que., dropped dead in Montreal, April 3.

G. W. Kelly, M.D. (Years of Practice, West Virginia), died at his home in Glendale, W. Va., April 6, after a long illness, aged 79.

George H. Alway, M.D. Detroit College of Medicine, 1894, died recently at his home in Detroit.

William McIntyre, M.D. (Examination), Ohio, died at his home in Warrensburg, Ohio, April 7, aged 82.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

A SOUND OF WORDS.

A subscriber writes: "The other day, a bright young girl, who had lived in the country and knew something about the barnyard, was reading an article for me in which the word cachectic occurred several times. She had some trouble with its pronunciation. About the fourth time she met it she began, 'Cache-e, cachee-, cachectic,' and then in desperation looked up with the remark, 'Every time I say that word I feel like a hen that had just laid an egg.'"

SYRUP OF LACTUCARIUM.

NEWARK, N. J., April 8, 1906.

To the Editor:—1. Can you give me the formula of Aubergier's Syrup Lactucarii? A druggist dispensed this instead of the U. S. P. Syrup Lactucarii, claiming that it was no more potent but of better flavor. 2. In the National Standard Dispensatory the editors in discussing Antipyrin say it is incompatible with Natrium salicylas. I have seen these two drugs combined several times, and have always seen a clear white solution result. Will you explain in what way they are incompatible? J. L.

ANSWER.—1. Aubergier's Syrup of Lactucarium is a proprietary remedy, its exact composition, of course, is not known. It is generally believed to be a syrup flavored with orange flower water and containing very little of the active constituents of lactucarium. The following formula appears in Hager's "Pharmaceutische Praxis," vol. 1, p. 272

French extract of lactucarium	1|5
Hot water	500|
Sugar	1000|
Orange flower water	50|
Citric acid	1|5

The extract and 50 gm. sugar are dissolved in the hot water and the solution filtered. In the filtrate, after clarification with egg albumin, if needed, the remaining sugar is dissolved and then the orange-flower water and citric acid are added. The French extract of lactucarium referred to in the formula is not identical or even similar to the official lactucarium. 2. When antipyrin and sodium salicylate are triturated together a pasty mass results and such a mixture, therefore, can not be dispensed in powder form. A solution of antipyrin and sodium salicylate remains clear indefinitely and apparently no change occurs.

THE DOCTOR'S THREE FACES.

CLEVELAND, OHIO, April 9, 1906.

To the Editor:—The epigram quoted in your issue of March 31, 1906, page 979, seems to have been a favorite one among the old doctors. The following lines may be of interest to some of your readers. They may be found in a book entitled: "A Treatise of One Hundred and thirteene diseases of the Eyes and Eye-Liddes," by Richard Banister, Mr. in Chyrurgery, Oculift, and Practitioner in Phyficke. Imprinted in London, 1622.

"*The Surgeon divided into foure parts, or the Surgeon's Comment.*"

1. A Surgeon's like a God whom they adore:
   When death about the ficke man's bed doth fore,
   Then hath he great refpect, and high regard;
   Fed with the fmoaky promife of reward.

2. But as the Patient doth begin to mend,
   So doth the Surgeons God-head ftraighwayes ends
   Yet fush attendance on him ftill is giuen,
   As if he were an Angel comne from Heaven.

3. When health and ftrengh the Patients doth lofpire,
   To fleep, eate, walke, and fit up by the fire:
   Then ftrait the Surgeons ftate Angelicall,
   In their refpeft unto a man doth fall.

4. Laft, when the ficke or fore are heal'd agaone.
   And that the Surgeon feekes reward for's paine:
   Hee's neither counted God, nor Angel then,
   Nor is he intertained as a man.
   But (through ingratitude) that helleth euill,
   They bid the Surgeon, as welcome as the deuill.

The following lines, which I have seen credited—wrongly, I believe, to Pope, were doubtless inspired by the same sentiment:

"God and the doctor we alike adore,
But only when in danger, not before;
The danger o'er, both are alike requited,
God is forgotten, and the doctor slighted."

Pope who suffered from ill health during his entire life, always expressed the highest regard for the medical profession, and one time said, "They are in general the most amiable companions and the best friends, as well as the most learned men I know."

ALBERT REFUS BAKER, M.D.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending April 14, 1906:

Truby, W. F., asst.-surgeon, granted 30 days' leave of absence.

Moncrief, Wm. H., asst.-surgeon, granted 7 days' leave of absence.

Kneedler, Wm. L., surgeon, reported for treatment at Army General Hospital, Presidio of San Francisco, Cal.

Harvey, P. F., asst.-surgeon-general., left Chicago, Ill., on 21 days' leave of absence.

Childester, W. C., asst.-surgeon, reports on 30 days' leave of absence from duty in Philippines Division.

Gandy, Charles M., surgeon, relieved from duty at Fort Wayne, Mich., May 10, 1906, and ordered to surgeon general's office for temporary duty, and on completion of this duty will proceed to West Point, N. Y., as heretofore ordered.

Lewis, Wm. F., asst.-surgeon, reports in temporary charge of chief surgeon's office, Department of the Lakes, Chicago, Ill., in addition to his present duties.

Hallock, H. M., surgeon, sick leave further extended 30 days.

Richard, Charles, surgeon, granted 15 days' leave of absence, to take effect on the completion of his duties at Lisbon, Portugal.

Stone, John H., asst.-surgeon, granted 5 days' leave of absence, with permission to go beyond sea.

Usher, F. M. C., asst.-surgeon, granted 3 months' leave of absence, to take effect about May 1, 1906.

Banister, John M., deputy surgeon-general, promoted to the rank of lieutenant colonel, to rank from March 29, 1906.

Stark, Alexander N., surgeon, promoted to the rank of major, to rank from March 29, 1906.

Lynch, Charles, surgeon, promoted to the rank of major, to rank from April 2, 1906.

Truby, A. E., asst.-surgeon, granted 21 days' leave of absence about April 26, 1906.

Carswell, R. L., asst.-surgeon, leave of absence extended 30 days.

Blanchard, R. M., asst.-surgeon, relieved from duty in Philippines Division and ordered to proceed to and take station at Camp McKinley, Honolulu, Hawaii Territory.

Smart, William, asst.-surgeon, granted two months' leave of absence.

The following named assistant surgeons will report in person, on the dates specified, to Major William H. Arthur, surgeon, president of the examining board at the Army Medical Museum Building, Washington, D. C., appointed by Paragraph 7, Special Orders 219, War Department, Sept. 21, 1905, for examination to determine their fitness for advancement: April 24, 1906: Koerper, Conrad E., DeLaney, M. A., Halloran, Paul S., first lieutenants. May 7, 1906: Whitmore, Eugene R., Smart, Robert, first lieutenants. May 8, 1906: Buck, Carroll D., Nelson, Kent, first lieutenants. May 9, 1906, Allen, John H., Bevans, James L., first lieutenants. May 10, 1906: Ekwurzel, Geo. M., Whitcomb, Clement C., first lieutenants. May 11, 1906: Reno, William W., Roberts, William, first lieutenants. May 12, 1906: Sweazey, Verge E., Bloomburgh, Horace D., first lieutenants.

The following-named assistant-surgeons will report in person to Lieutenant-Colonel George H. Torney, deputy surgeon-general, president of the examining board at the General Hospital, Presidio of San Francisco, Cal., appointed by Paragraph 9, Special Orders No. 54, War Department, Oct. 17, 1906, at such time after April 30, 1906, as may be designated by him for examination to determine their fitness for advancement: Brownlee, Charles Y., Murtagh, John A., Patterson, Robert U., O'Connor, R. P., Heard, George P., Noble, Robert E., Brooke, Roger, Jr., Devereux, John R., Brechemin, Louis, Jr., Krebs, Lloyd Le R., Woodall, William P., first lieutenants.

Brown, Ire C., contract surgeon, left Fort Niobrara, Neb., with troops for Fort Washakie, Wyo.

Long, Stephen M., contract surgeon, order for Philippine service revoked; leave of absence extended two months.

McCallum, Francis M., contract surgeon, granted an extension of one month to his leave of absence.

Newton, Ralph W., contract surgeon, recently arrived at San Francisco, Cal., from Philippine service, ordered to temporary duty in the Department of California.

Adair, George F., contract surgeon, ordered from Fort Terry, N. Y., to Madison Barracks, N. Y., for temporary duty.

Purnell, Julius M., contract surgeon, relieved at Fort McDowell, Cal., and ordered to duty at Presidio of Monterey, Cal.

Marshall, John S., examining and supervising dental surgeon, returned to the Army General Hospital, Presidio of San Francisco, Cal., from temporary duty at Honolulu, H. T.

Stone, Frank P., dental surgeon, left Army General Hospital, Presidio of San Francisco, Cal., for duty at Fort Sam Houston, Texas.

Ware, William H., dental surgeon, left Fort Logan, Colo., and arrived at Fort Wingate, New Mexico.

Baker, Charles L., contract surgeon, granted leave of absence for three months.

Dillon, G. Parker, contract surgeon, relieved from further duty at Fort McDowell, Cal., and from treatment at Army and Navy General Hospital, Hot Springs, Ark., and ordered to duty at Fort Bliss, Texas.

Koyle, Fred T., contract surgeon, relieved from duty at Fort Bliss, Texas, and ordered to duty at Fort McDowell, Cal.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending April 14, 1906:

Warner, R. A., asst.-surgeon, ordered to the Naval Academy, April 10.

Schaller, W. F., asst.-surgeon, appointed assistant surgeon, with rank of lieutenant, junior grade, from March 21, 1906.

Kaufman, J. B., A. H. Robnett, M. H. Ames, C. K. Winn, W. S. Kuder, asst.-surgeons, appointed assistant surgeons, with rank of lieutenant, junior grade, from March 24, 1906.

Bucher, W. H., surgeon, ordered to Washington, D. C., April 14, for duty in attendance on course of instruction at the Naval Medical School.

Dorsey, B. H., asst.-surgeon, detached from duty with naval recruiting party No. 4, and ordered home to wait orders.

Winn, C. K., asst.-surgeon, ordered to duty with naval recruiting party No. 4, at Des Moines, Iowa, April 30.

Kuder, W. S., asst.-surgeon, ordered to the Naval Hospital, Boston, Mass.

Kaufman, J. B., and Ames, M. H., asst.-surgeons, ordered to the Naval Hospital, Norfolk, Va.

Robnett, A. H., asst.-surgeon, ordered to the Naval Hospital, New York, N. Y.

Farenholt, A., surgeon, detached from the *Oregon*, and ordered home to wait orders.

DeBruler, J. P., asst.-surgeon, detached from the *Oregon* and ordered home to wait orders.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending April 11, 1906:

Mead, F. W., surgeon, granted leave of absence for one day, April 16, 1906.

Guiteras, G. M., surgeon, granted leave of absence for two days, from April 16, 1906.

Wertenbaker, C. P., surgeon, relieved from duty at St. John, N. B., and directed to proceed to Quebec, Canada, with the commissioner of immigration.

Young, G. B., P. A. surgeon, granted leave of absence for three days from April 6, 1906.

Stimpson, W. G., P. A. surgeon, granted leave of absence for three days from April 11, 1906.

Blue, Rupert, P. A. surgeon, directed to report to the director of the Hygienic Laboratory, Washington, D. C., for temporary duty.

Blue, Rupert, P. A. surgeon, directed to proceed to Reedy Island Quarantine Station for temporary duty, on completion of which to rejoin station in Washington, D. C.

Anderson, J. F., P. A. surgeon, directed to proceed to Reedy Island Quarantine Station for special temporary duty, on completion of which to rejoin station in Washington, D. C.

White, M. J., P. A. surgeon, granted two months' leave of absence from July 15, 1906.

Lloyd, B. J., P. A. surgeon, granted leave of absence for fifteen days, from May 1, 1906.

McCoy, G. W., P. A. surgeon, granted leave of absence for one month, from April 8, 1906.

Frost, W. H., asst.-surgeon, temporarily relieved from duty at Baltimore, and directed to proceed to Ellis Island, New York, for temporary duty.

Bailey, G. W., acting asst.-surgeon, granted leave of absence for two days, from April 19, 1906.

Fogarty, J. N., acting asst.-surgeon, granted leave of absence for twenty-one days from April 13, 1906.

Griffitts, T. B. D., acting asst.-surgeon, granted leave of absence for thirty days from May 1, 1906.

Achenbach, John, pharmacist, granted leave of absence for thirty days, from April 3, 1906.

McKay, Malcolm, pharmacist, granted leave of absence for one day.

Scott, E. B., pharmacist, granted leave of absence for four days, from March 31, 1906, under Paragraph 210 of the Regulations.

Ryder, L. W., pharmacist, granted leave of absence for three days, from April 5, 1906.

Van Ness, Jr., Geo. L., pharmacist, granted leave of absence for thirty days, from April 25, 1906.

BOARD CONVENED.

A board of officers was convened to meet at San Francisco, on April 13, 1906, for the purpose of making a physical examination of an officer of the Revenue Cutter Service. Detail for the board: Surgeon H. W. Sawtelle, chairman; P. A. Surgeon J. M. Holt, recorder.

CASUALTY.

Acting Assistant Surgeon N. D. Richardson, died at San Francisco Quarantine Station, April 9, 1906.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, Public Health and Marine-Hospital Service during the week ended April 13, 1906:

SMALLPOX—UNITED STATES.

Arkansas: Fort Smith, March 24-31, 1 case.
California: Los Angeles, March 24-31, 15 cases; San Francisco, March 17-31, 27 cases, 4 deaths.
District of Columbia: Washington, March 31-April 7, 1 case.
Florida: Jacksonville, March 31-April 7, 1 case.
Georgia: Augusta, March 26-April 2, 4 cases.
Kentucky: Covington, March 31-April 7, 2 cases.
Louisiana: New Orleans, March 31-April 7, 5 cases.
Maryland: Baltimore, March 31-April 7, 3 cases.
Michigan: Detroit, March 24-April 6, 2 cases; Grand Rapids, March 31-April 7, 1 case.
Mississippi: Natchez, March 31-April 7, 1 case (on vessel).
Missouri: St. Louis, March 31-April 7, 2 cases.
New Jersey: Hudson County, April 1-8, 4 cases.
New York: Buffalo, March 24-31, 1 case; New York, March 31-April 7, 2 cases.
North Carolina: Greensboro, March 31-April 7, 3 cases.
Ohio: Cincinnati, March 30-April 6, 3 cases; Cleveland, 1 case.
Tennessee: Knoxville, March 31-April 7, 1 case.
Utah: Ogden, March 1-31, 3 cases.
West Virginia: Wheeling, March 30-April 6, 2 cases.
Wisconsin: Appleton, March 31-April 7, 4 cases.

SMALLPOX—FOREIGN.

Africa: Capetown, Feb. 24-March 3, 4 cases.
Austria: Gallicia (province), Feb. 18-March 3, 4 cases; Voralberg (district), 17 cases.
Canada: Seven Islands, March 21, present; Winnipeg, March 24-31, 1 case.
Chile: Iquique, March 3-10, present.
China: Hongkong, Feb. 10-24, 24 cases, 17 deaths.
Ecuador: Guayaquil, March 4-22, 13 cases.
Egypt: General, Dec. 17-31, 77 cases, 14 deaths.
France: Paris, March 17-24, 6 cases, 1 death.
Germany: Kehl, Jan. 1-31, 1 death.
Gibraltar: March 18-25, 4 cases.
Great Britain: London, March 17-24, 5 cases.
Greece: Patras, Feb. 27-March 6, 3 cases, 2 deaths.
India: Bombay, March 6-13, 8 deaths; Calcutta, Feb. 24-March 3, 189 deaths; Karachi, Feb. 25-March 11, 53 cases, 20 deaths; Madras: March 3-9, 48 deaths; Rangoon, Feb. 24-March 3, 83 deaths.
Italy: General, March 15-22, 35 cases.
The Netherlands: Rotterdam, March 24-31, 3 cases.
Russia: Moscow, March 3-17, 19 cases; Odessa, May 17-24, 6 cases.
Spain: Tarragona, March 17-24, 2 deaths.
Turkey: Constantinople, March 11-18, 2 deaths.

YELLOW FEVER—FOREIGN.

Ecuador: Guayaquil, March 4-22, 36 deaths.
Mexico: Merida, April 10, 1 case; Salina Cruz, March 18-24, 1 case (imported); Tehuantepec, March 18-24, 1 case (imported); Vera Cruz, April 7, 1 death (imported).

CHOLERA—FOREIGN.

India: Bombay, March 6-13, 2 deaths; Calcutta, Feb. 24-March 50 deaths; Rangoon, 2 deaths.

PLAGUE—FOREIGN.

China: Hongkong, Feb. 17-24, 17 cases, 16 deaths.
India: General, Feb. 24-March 3, 3,425 cases, 2,739 deaths; Bombay, March 6-13, 411 deaths; Calcutta, Feb. 24-March 3, 59 deaths; Karachi, Feb. 25-March 11, 67 cases, 58 deaths; Madras, March 3-9, 1 deaths; Rangoon, Feb. 24-March 3, 30 deaths.
Peru: Callao, Feb. 24-March 5, 1 case; Lima, 1 case, 1 death; Mollendo, 1 case; Paita, 2 cases, 2 deaths; Trujillo, 13 cases, 6 deaths.

Book Notices

THE AUTOMOBILE. A Practical Treatise on the Construction of Modern Motor Cars, Steam, Petrol, Electric and Petrol-Electric. Based on Lavergne's "L'Automobile sur Route." Edited by P. N. Hasluck. Special Edition, Enlarged, with 804 Illustrations, 8 Full-page Plates and an Addendum. Vols. 1 and 11. Cloth. Pp. 451-864. Price, $7.00 net. Chicago: W. T. Keener & Co.

If there is one thing more than another brought out in the automobile articles in this number of THE JOURNAL, it is that the physician who wishes to save himself from worry and expense should learn the details of the construction of his automobile. Some of this information may be had from books and some can only be had from actual, often painful, experience. Frequently it will be the cheapest and most satisfactory way to have a short course in instruction from a competent chauffeur or automobile machinist. The novice, however, should preface any such instruction by an understanding of the general principles of auto motors, etc., which he may gain from some good book on the subject. The work before us, in two handsome volumes, is well called a compendium of information, and it discusses every feature of the automobile with the details of construction, operation and repair. The first chapter is an interesting history of the evolution of the automobile, and then are taken up the various forms of motive power, steam, gasoline and electricity. The second volume takes up the details of wheels, tires, springs, frames, brakes, lubrications and then discusses the chief automobiles of England and the continent, as well as many American cars. The information about motors and motive power is of universal application and can be recommended for those who wish instruction. The illustrations are particularly valuable, being abundant and with full explanations, and will be much appreciated by the student.

SELF-PROPELLED VEHICLES. A Practical Treatise on the Theory, Construction, Operation, Care and Management of all Forms of Automobiles. By J. E. Homans, A.M., with Upward of 500 Illustrations and Diagrams, Giving the Essential Details of Construction and Many Important Points on the Successful Operation of the Various Types of Motor Carriages Driven by Steam, Gasoline and Electricity. Cloth. Pp. 652. Price, $2.00. New York: Theo. Audel & Co. 1905-1906.

This readable book discusses the entire subject from history through all the methods of application of power to the details of accessories. The illustrations are very good, clear and fully described. The subdivisions of the matter render reference from page to page easy. The book is written "for the practical information of such persons as have neither the time nor inclination to delve deeper into the subtleties of mechanics than the construction and the management of their machines require," and we can recommend it to anyone interested in the subject.

ORGANOTHERAPY, OR TREATMENT BY MEANS OF PREPARATIONS OF VARIOUS ORGANS. By H. B. Shaw, M.D., F.R.C.P. Illustrated. Cloth. Pp. 256. Price, $1.75 net. Chicago: W. T. Keener, 1905.

Almost one-third of Dr. Shaw's book is concerned with the thyroid and parathyroid glands. Other sections deal with the suprarenal glands, the alimentary tract, including the pancreas and liver, and genitourinary organs. A final section under the heading of "Other Organs and Tissues" considers the pituitary body, thymus, spleen, hemal lymphatic lymph glands, lymphatic glands, marrow, muscle, nerve tissue and placenta. A most commendable feature of the treatise and a most rational one is the fact that, in relation to each organ, the anatomy, physiology, chemistry and pathology are considered before the reader is introduced to the question of organotherapy. This is done without the too laborious citation of authorities, yet it could not be said that the author has omitted important references. Obscure questions in anatomy, etc., are dismissed satisfactorily with statements of the best opinions of the present time.

The same spirit of fairness and broad treatment is to be seen in the chapters dealing with organotherapy, which has been treated with sufficient thoroughness, considering the degree of chaos which manifestly exists in this field. In instances in which serum therapy, with specific cytotoxic serums, has been practiced and advocated, the results, which are largely negative, inconclusive and often misinterpreted, are given by the author. A reading of the book impresses one strongly with the great need of more physiologic knowledge, without which organotherapy, with one or two luminous exceptions, can be put to nothing more than empirical use.

Chemistry of the Proteids.. By G. Mann, M.D., B.Sc., University Demonstrator of Physiology, Oxford. Based on Prof. Otto Cohnheim's "Chemie der Eiweisskörper." Cloth. Pp. 606. Price, $3.25. New York: The MacMillan Co. 1906.

Recent Advances in Physiology and Bio-Chemistry. Edited by Leonard Hill, M.B., F.R.S. Contributors, B. Moore, M.A., D.Sc., J. J. R. Macleod, M.B., L. Hill, M.B., F.R.S., M. S. Pembrey, M.A., M.D., and A. P. Beddard, M.A., M.D., with Diagrams. Cloth, Pp. 740. Price, $5.00 net. New York: Longmans, Green & Co. 1906.

The appearance of these two books in the market is a striking evidence of the spirit of the times, and of the rapidly increasing interest and participation in the progress of biologic investigation in the English-speaking countries. They will be welcomed not only by students of the biologic sciences, but also by those practicing physicians who desire to keep abreast of the advances that are being made in the chemistry of living processes both in health and disease, and from which we must expect most of the progress that will be made along many lines of medical research for years to come.

Mann's "Chemistry of the Proteids" originated in a plan of the author to present to English-speaking students a translation of the standard work on the chemistry of the proteids, Cohnheim's "Chemie der Eiweisskörper"; but, being extremely full of original and independent ideas (as we have learned from his work on "Physiological Histology") Mann found himself unable to adhere to the production of a mere literal translation of another's work. As a result we have a book based on the work of Cohnheim, brought up to date from the second German edition, and so amplified that instead of the 308 pages of Cohnheim we have 584 pages of text in Mann's book. The increase in size represents partly the natural growth of the subject matter, partly an expansion of the consideration of certain topics that seemed of particular importance to the author, and partly the incorporation of his original ideas and their consideration. Thus we find much emphasis laid on the relation of the inorganic salts to the proteid molecule, a matter that those in this country who are familiar with J. Loeb's work will appreciate. As Mann said in his first book, salt-free proteids are dead proteids—it is the presence of salts that puts life into them. This view, of course, rests on an acceptance of the importance of electrical phenomena in chemical reactions and biologic processes, and Mann particularly urges the view that even the colloids are electrolytes that undergo dissociation to a certain degree. The work of Fischer and others on the synthesis of proteids is given quite fully. Taken all in all, this work is an important addition to the scientific literature in the English tongue.

The scope of the second book is indicated by its title, and we are promised that if this first effort meets with sufficient success it will be followed by further publications of like nature, an enterprise that is bound to be welcomed by all those who have the interests of medical science at heart. The book opens with a consideration of the chemical and physical principles underlying metabolism and enzyme action in general, which are then applied to a discussion of the problems of secretion. More specialized topics are then taken up, including the consideration of the atmosphere and the effects of increased and decreased atmospheric pressure. Separate chapters are given to the topics of carbohydrate, fat and purin metabolism; the relation of water to metabolism; the formation of urea and the secretion of urine; the formation of lymph and the mechanism of absorption from the small intestine. Recent work on hemolysins, cytotoxins, etc., as well as on the internal secretions, are also briefly summarized. The important question as to the amount of space that shall be given to bibliography has been compromised by putting at the end of each section references to the chief reviews on the topic, and also to most of the important papers. The book carries the impression that it is written for the advanced student, or perhaps better for the ordinary student who is not content with learning the fundamentals of the essentials of medicine, but wishes to know along which lines progress is being made, and what suggestions original minds have brought forth that will lead him into new fields for himself. The number of students of this type is growing, both among those who have graduated in medicine and among those who are at the beginning of their work, and the publication of such books is undoubtedly the greatest aid in the development of men who appreciate that medicine is a biologic science in the truest and broadest sense of the word.

Miscellany

Metabolism of Colds.—H. Wakefield (*Medical Record*), thinks that colds represent the results of disorders of metabolism due to local circulatory disturbances following the unequal exposure of some part of the body to cold. The degree of temperature is subordinate to the state of inequality produced, for a cold may be due to the extrinsic effect of either cold or heat if sufficiently pronounced or abrupt to insure a localized action of definite heterogeneity for the balance of the organism. The author has discovered that cold heightens and heat lowers the specific gravity of protoplasm in general, not excepting that of the parenchyma, that the molecular weight or density of our parenchyma and all the living protoplasm is increased by cold and decreased by heat. This is not a nervous effect but a direct responsive reaction of protoplasm, *per se*, as is attested by the fact that it is as marked in nerveless unicellular and multicellular organisms as in those of the highest types of nervous organizations. In a common cold the author says that primarily a condition of disequilibrium is produced. A subject, during a period of normal heat balance, gets wet, cold feet; a state of contraction of the tissues of the lower extremities is attained, the blood is ejected from the peripheral vascular areas to the more roomy reservoirs of the splanchnic veins, which readily dilate to receive it, with the result that a pernicious splanchnic venous stasis is produced, concurrent with a capillary and arterial blood deficiency in the extremities and with an inevitable suboxidation of the dependent tissues in the extremities. The author then describes the various stages through which such an affection passes. The usual treatment has been more or less successful in the past, but only with a vague idea of the pathology and etiology of the condition.

Anemia in Porto Rico.—The Anemia Commission reports further on its work in Porto Rico. The outdoor clinic was opened on June 1, 1905, at Aibonito. As soon as the principal station was thoroughly organized and in good running order, substations were opened at various other towns. The attendance of the patients at the clinics naturally fluctuated, but the majority attended regularly. Those from long distances were given enough medicine to last them for a longer interval than those patients who lived close at hand. A tent hospital of 60 beds was used for patients suffering from severe grades of the disease and for patients who had come great distances. This hospital also afforded opportunity to study and to keep under observation cases presenting symptoms of especial interest. The commission studied the effects of thymol and betanaphthol in the treatment of this disease, and their relative value is discussed. The commission states that the specific treatment of anemia in Porto Rico is beyond question. Both betanaphthol and thymol are excellent in their results and each, the commission states, has its special uses. The repeated use of these anthelmintics weekly for two or three months in cases in which there is intense anemia is not advised. Betanaphtbol in these cases, by adding an element of irritation to an already diseased kidney, may aggravate the existing process. Tbymol is less irritating, and the commission believes that consecutive doses of either drug is sufficient to bring the patient if not to a cure, at least to the assurance of a practical cure. The report refers at some length to the many "patent medicines," chiefly iron preparations, which are being sold in the island for the relief of this condition, and states that it should be remembered that these remedies are paid for from the earnings of a class said to be starving in poverty, and that the list of "snre cures," etc., is too long and too disgusting to contemplate without anger. The commission found that iron is of practically no value in the treatment of this condition except as it is of value in the after-treatment of malaria or of syphilis.

The Therapeutic Value of Alcohol.—A. D. Blackader (*Montreal Medical Journal*), does not consider alcohol an efficient cardiac or respiratory stimulant. In some conditions with a determination of blood to the interior of the body, the administration of alcohol by dilating the superficial vessels

and equalizing the circulation may be of considerable service. Alcohol is not a stimulant to the nervous system. Its action is that of a narcotic, relieving nervous strain, and promoting rest. No other narcotic can be used so freely with so few injurious by-effects. Alcohol in disease is a valuable food, replacing carbohydrates, and as a general rule saving proteid metabolism. It places no tax on the digestive organs; if used intelligently it increases their secretion. In low and asthenic conditions it may have also a favorable action on the hepatic cells, stimulating them to increased activity. In infections of all forms alcohol should be used cautiously. In large amounts it probably will do harm by destroying the resisting powers of the organism. The effect of alcohol varies much with the individual and its employment demands much discrimination and careful and frequent observation. Its prolonged use is liable to lead to degenerative changes in the heart, blood vessels, and secretory organs.

Profits from Dr. Pierce's Prescription.—At the trial in the libel suit brought by the World's Dispensary Association against the Curtis Publishing Company, the following figures were given by Lee H. Smith, vice president of the company, regarding the profits in the "Dr. Pierce's Favorite Prescription" business since 1899: 1899, $167,425.08; 1900, $188,607.09; 1901, $113,725.27; 1902, $143,731.86; 1903, $192,222.93; 1904, $78,241.72; 1905 (loss), $38,441.31. The sales from May, 1903, to May, 1904, amounted to $971,550.92; from May, 1904, to May, 1905, $752,935.97; decrease, $218,614.95. Sales from May, 1903, to December 31, 1903, were $585,735.41; and from May, 1905, to December 31, 1905, $447,655.98; decrease, $138,080.43. Total decrease in twenty months, $356,694.38.

Protection of Animals in Turkey.—The Constantinople correspondent of the *Lancet* states that the employment of senile, debilitated or diseased horses has been forbidden. The Turks, on the whole, are kind to animals, and at almost every house in Stamboul there is a receptacle of some kind which is kept full of water for the use of the innumerable street dogs. The *Lancet* states that a cabman who runs over one of these animals while it is taking a nap in the middle of the street is compelled to pay a fine, and that the Sultan is said to spend a large sum annually in feeding the numerous stray dogs round his kiosks and palaces.

Diagnosis of Liver Abscess.—Sexton says that more skill is required in diagnosing abscess of the liver than in diagnosing most other tropical diseases. The beginning of the abscess is often so obscure and its development so insidious that at times it is difficult to determine the presence of pus. Abscess of the liver, he states, may be confounded with intermittent malaria, typhoid fever, right sided pleurisy, cancer of the liver, gallstones, suppurating hydatid cyst, and many other diseases.

Spermaceti to Help in Removal of Cysts.—Pozzi has recently called attention anew to the advantages of filling a thin walled cyst with spermaceti as an aid in its removal. He first recommended it several years ago in his Handbook of Gynecology, and time has confirmed its value. The cyst is evacuated as usual and rinsed out. Melted spermaceti is then injected. By the next day the spermaceti inside the cyst has cooled into a hard ball so that the cyst can then be shelled out without the slightest difficulty.

Practice in Surgery.—Barbat, in the *California State Journal of Medicine*, states that no individual should attempt to operate who does not keep in constant training, either as an operator or an assistant, because his results will be bad, and he will bring legitimate surgery into disrepute.

Diet After Laparotomies.—Dr W. B. Chase, in the *American Journal of Obstetrics*, declares that the diet of patients after abdominal section calls for the greatest circumspection. He advises following the rule that nourishment, by the mouth, before the stomach retains or digests it, is positively harmful.

Survival of the Fittest.—Dr. S. M. Miller, Knoxville, Tenn., states that the influence of selection in the improvement of strains is clearly observed along the entire developmental line from the lowest visible organism to the highest order of physical perfection.—*Southern Med. and Surg.*

Climatology.—Dr. F. G. Byles, Denver, declares that a physician should not prescribe a drug or medicine the physiologic action of which is unknown to him, and that it is equally important that he understand the physiologic action of a climate before prescribing for a patient in this respect.—*Colorado Med. Journal.*

Prognosis in Alcoholic Insanity.—Dr. C. L. Hamilton says that in the more acute forms of alcoholic insanity it is always best to give a guarded prognosis to the patient's family; at the same time, he says, they should be encouraged by the statement that a large percentage of these patients recover.—*Illinois Med. Jour.*

AMERICAN SOCIETY OF TROPICAL MEDICINE.

Third Annual Meeting, held in Philadelphia, March 21, 1906.

DR. JAMES M. ANDERS in the Chair.

New Species of Parasite in Man.

DR. CHARLES WARDELL STILES, U. S. P. H. and M.-H. Service, described a parasite which is regarded as belonging to the family of filaria. It measures from 32 to 52 millimeters in length. It was found in Georgia and was taken from an ulceration of the leg. The only parasite which it most nearly approaches in similarity is one described for certain South American birds. He regards it as a tropical or subtropical parasite, of which Georgia will probably form the northern geographical border. It is immature as it occurs in man, and until the adult stage is observed he believes it impossible to say much concerning it. He regards the infection a surgical rather than a medical matter.

DR. JUDSON DALAND spoke of the prevalence of filaria on the eastern coast of India. The hospitals, however, do not show as many cases of filariasis as would be expected. This is because the patients do not apply promptly for aid.

DR. ALLAN G. SMITH questioned whether this new parasite should be regarded as definite for man and suggested the possibility of its presence in the local infection as accidental. He thought it probably is related to the hook worm species. Had it gotten into the general economy he thinks it would have grown to a larger size than that attained.

Malaria in the Tropics.

COL. WILLIAM C. GORGAS, Chief Sanitary Officer, Isthmus of Panama, contributed this paper, which was read by Dr

McFarland. Colonel Gorgas, since 1898, has served four years in Cuba and two years at Panama, part of the time with troops, but most of the time he has been connected with municipal sanitation. At Panama he is in charge of the yellow-fever wards, and all non-immunes with fever from any cause coming into Ancon Hospital are sent to these wards. The larger proportion of such cases are malaria, about 200 malaria being treated per month. His experience has shown that malaria in the tropics is by far the most important disease to which tropical populations are subjected. While the per cent. of fatalities is not nearly so great as from some other tropical disease, the degree of incapacity produced is much greater than that from all other diseases combined. At Santiago, while there were more deaths from yellow fever and typhoid than from malaria, it was the latter disease which prostrated the Army. Even at Havana, where malaria was by no means so general as would be expected, a greater number of persons died from malaria every year than from yellow fever. As a result of their mosquito work in Havana, the deaths from malaria, which for many years had averaged about 350, were 351 in 1901; 77 in 1902; about 50 in 1903; and since remained at about 40.

He regards Panama as favorable a place for the development of malaria as could be found. Three-fourths of the disability among the laborers are due to malaria. To correct this the greater effort was directed toward draining localities adjacent to towns and dwellings. In places that could not be drained oil was used very freely. An equally important measure is the giving of prophylactic doses of quinin. Thorough screening was also carried out. With 22,000 men on the payrolls during February, only 22 per 1,000 were incapacitated every day on account of sickness, three-fourths of which was due to malaria. In his wards at Ancon he has personally treated 1,055 cases of malaria in the last six months. In each case blood examinations were made and the character of the parasite recorded. The estivo-autumnal variety predominated, but the attacks, in general, were mild and yielded easily to treatment. Among the 1,055 cases there were only five deaths. There have been 20 cases of hemoglobinuric fever in the past eight months, with only three deaths. The treatment has been the persistent use of quinin, given for the first three or four days hypodermically, but as soon as vomiting ceases it is given by the mouth; 20 grains in the twenty-four hours, hypodermically, and 30 grains by the mouth, has been the ordinary course pursued. As sanitary conditions are improved, Colonel Gorgas believes it a rational hope that malaria will decrease in the same ratio.

Clinical Notes on a Recent Epidemic of Dengue Fever.

Dr. Aristides Agramonte, secretary of the Board of Infectious Diseases, Havana, Cuba, contributed this paper, which was read by Dr. John M. Swan. He said that the city of Havana and neighboring towns suffered from a well-marked epidemic of dengue fever during last year. From the middle of September to the first of December he personally attended 154 cases, and saw many others in consultation. He questions whether the disease may not be endemic there, assuming epidemic form at long intervals. During the period referred to he has seen but few children attacked and no infants. The degree of immunity conferred by an attack of dengue he believes is slight. He has seen four instances in which the disease reappeared in the same individual after an interval which excluded the possibility of relapses.

All efforts to infect individuals by the bites of mosquitoes previously applied to cases of dengue fever have been unsuccessful. Notwithstanding this, the circumstantial evidence is directly in favor of insect transmission, and he believes that mosquitoes are responsible for the extensive and rapid propagation of the disease, and that the inability to demonstrate this theory is due to incomplete technic. Finlay for twenty years defended the same theory regarding yellow fever before it was demonstrated. The spread of dengue fever occurs much like that of yellow fever, from house to house, along the same side of the street, attacking more frequently the members of a family than the transient visitors. Observation of many of the cases indicates an incubation period of from three to seven days, but in one special case cited, the period of incubation seemed to be from thirty-six to fifty-six hours.

Cephalalgia, rachialgia and fever usher in the attack, and the eruption may be observed in eight cases out of ten. Dr. Agramonte remarked on a few of the clinical features which, in his opinion, have been treated with undeserved disdain or entirely overlooked. Among these is the eruption, which is seen most frequently. The character of the eruption is modified by the patients' complexion and surface conditions. In the case of a plethoric, blonde German woman the eruption was like that of scarlatina. In the African it is most puzzling, and this race has a marked degree of resistance against dengue fever. Albuminuria in a slight degree has been found in almost every case, disappearing rapidly with defervescence. Exceptionally the albumin in the urine has been in considerable quantity, precipitating by the "heat-and-acid" test, but rarely containing casts or epithelium. The early appearance of albumin in dengue he suggested might be considered a differential sign between this disease and yellow fever. Observation of the epidemic shows that an attack of dengue leaves the individual a fit subject for the acquisition of other severe infections. The mortality is regarded as low, for in an estimated population of 266,000 only six or eight deaths were directly attributable to dengue.

The diagnosis is not difficult when it is known that an epidemic exists, but it is most easily mistaken for yellow fever during the first forty-eight or seventy-two hours. Faget's sign is a fairly constant differential index; in dengue the tendency is for the pulse to correspond with the variation in the degree of temperature, although there is sometimes a comparatively slow pulse as a result of the generally depressed condition. A most careful and painstaking examination of cases can only help to differentiate these diseases.

Officers Elected.

The following officers were elected: President, Dr. Roland G. Curtin, Philadelphia; vice-presidents, Dr. Abraham Jacobi, New York; Dr. Aristides Agramonte, Havana, Cuba; secretary, Dr. Joseph McFarland, Philadelphia; assistant secretary, Dr. John M. Swan, Philadelphia; treasurer, Dr. Wharton Sinkler, Philadelphia; councilors, Dr. James M. Anders, Dr. Judson Daland, Dr. Thomas H. Fenton and Dr. B. F. Stahl, all of Philadelphia.

CALIFORNIA ACADEMY OF MEDICINE.

Regular Meeting, held Feb. 27, 1906.

The President, Dr. P. K. Brown, in the Chair.

Personal Experiences with Football Injuries.

Dr. R. L. Wilbur described the football injuries that had come under his care for the past six years (omitting 1903), at the Leland Stanford, Jr., University. These included nearly all of the severe injuries and a large proportion of the minor ones. In the 88 individuals treated the most frequent injuries were the following: Fractures of the clavicle, 3; of both bones of the leg, 3; of the nose, 5; of the ribs, 5; sprained ankles, 6; severe knee injuries, 21; muscle tears, 5. The majority of the knee injuries were sufficiently severe to be followed by an effusion into the synovial sac. If seen within the first twenty-four hours these were treated by adhesive plaster tightly applied to the slightly flexed knee, and by rest in bed, elevation of the joint, cold locally, and a saline cathartic. After a few days a second bandage was applied, and if the knee appeared to be strong, a gap was left in the plaster posteriorly and the patient was allowed to walk with the aid of a cane. In ten days, in favorable cases, the player was able to do light work, but for three weeks or more the knee cap and the lateral portions of the joint were protected by adhesive plasters.

If the patient was not seen within the first twenty-four hours, a day elapsed before the adhesive bandage was applied, the treatment being otherwise practically the same as in the former case.

Sprains of other joints were treated on much the same lines as those of the knees. Muscle tears can be readily repaired by applying plaster in the direction of the muscle fibers and

binding them down with circular strips. After three to six days, active work can be resumed without removing the bandage. In the author's experience early rest and ambulatory treatment with adhesive bandages gives as good final results as where the injured muscles or joints are treated along more conservative lines. The injuries seemed to follow "open plays" about as frequently as "mass plays."

DR. A. B. SPALDING said that one reason why football injuries are so frequent is that the coaches urge the players to overlook injuries of all kinds. Furthermore, when an injury occurs, the coach does not allow the player to take proper care of himself. He mentioned a case in which a sarcoma developed in a subcutaneous clot, apparently on account of lack of care. The game should be more carefully supervised by physicians. The open game is quite as dangerous as the closed game.

Abdominal Exploration.

DR. C. M. COOPER stated that the mortality in diagnostic operations, even in large hospitals, is estimated at from one to two per cent., and that the mortality in private practice, by unskilled operators, is unquestionably higher. He believes that the peritoneal adhesions which sometimes follow these operations are less frequently due to the exploration itself than to some condition of sepsis that was already present before the operation. An exploratory operation should never be undertaken until all other diagnostic means have been exhausted. Many useless operations might thus be avoided. Furthermore the diagnosis may not be cleared up by the exploratory operation; and many patients have been closed up on account of supposed cancer, where the later developments showed that some other condition was present. In spite of these objections, exploratory operations are frequently indicated.

Examples of indications for operation are as follows: Stomach trouble with continued absence of free hydrochloric acid and the presence of lactic acid and the Oppler-Boas bacilli; or stomach trouble with continuous delay in emptying; or dyspepsia developing in middle life that does not yield to well-directed medical treatment, especially if anemia, wasting and occult blood in the stools are present.

DR. F. B. CARPENTER stated that continued pain is often an indication in itself for an exploratory operation. Adhesions may be found in such cases, and by breaking up these the pain may be relieved.

DR. TERRY advocated a long incision for exploratory operations long enough so that the operator may put his hand through with comfort. Sometimes continued pain is due to lesions of the solar plexus and surgical intervention is then of no avail.

DR. GEORGE B. SOMERS believes that the exact diagnosis is often of less moment as a guide to operation than are general indications. For example, it makes very little difference whether we operate on an ovarian or a tubal abscess. In either case the operation is indicated.

MEDICAL JURISPRUDENCE SOCIETY OF PHILADELPHIA.

Regular Meeting, held March 19, 1906.

The President, DR. HENRY W. CATTELL, in the Chair.

Quackery: What Are We Going to Do About It?

MR. CHAMPE S. ANDREWS, counsel of the Medical Society of the County of New York, described the laws of that state and their successful application against illegal practitioners in the metropolis, and gave suggestions for similar action in Philadelphia. A great cause of surprise, he said, is the fact of the different classes of society interested by the quack: The lawyer from one view; the doctor from an entirely different standpoint; the student of religions from a still different view. There is much to attract the sociologist and the criminologist. Among the different branches of the healing art which the quack takes up were mentioned those of the oculist, the hydropath the electropath the fraud pure and simple, who claims to be a physician; the osteopath, the vitapath; the fraud who practises on the consumptive poor; the so-called specialist in diseases of men, the patent medicine quack.

Mr. Andrews recounted specific instances of quackery and of arrests. One instance was that of a Mrs. Browning Weaverson, who belonged to a cult which claimed to cure disease by the application of human waste. The patient was a woman, 60 years of age, with cancer of the leg. For five days a plaster, composed of human waste of the patient, had been applied. Gangrene had set in and the patient was at the point of death. Another was that of a Jew named Benjamin, who practiced among the women of the East Side, claiming to have a drug which cured sterility. About 25 women had appeared in court who had taken the drug, the effect of which was to cause a swelling of the abdomen.

The midwives were said to be the most difficult class of quacks to convict. They are most effectively reached through the postoffice authorities. The water-cure fad seems to dominate the German section. A curious fact brought out in these trials is that almost every quack when brought into court has somebody who has been deceived into believing that they have been greatly benefited. Among the electropaths was one Rohrer, who had established a diploma mill operating chiefly among Swedish immigrants. Fifty of these graduates had been convicted. Rohrer was himself the head of what might be called the massage trust of New York. He is an example of the men who use electricity and claim that they are free from the medical law. In this class are the quacks who have the so-called electric chair, electric shoes, electric trusses, "magic boots," etc. An account was given of the quack who had represented himself as being associated with the celebrated Dr. Koch. Action has been brought against him which will make impossible the existence of the Koch lung institutes.

A case of special interest was that of a carpenter, rejected for life insurance on account of a slight condition of the kidneys, who had fallen into the hands of one Kane who was professing to cure by the use of radium. He greatly exaggerated the man's condition, but said that if he could afford to buy of him a certain quantity of radium, which would cost $10,000, he could cure him. The man actually did get together $9,872, which he paid the quack, being treated for about a year. An arrest followed for grand larceny and the man is now serving a term in the penitentiary. A vial filled with greenish colored fluid, claimed to be the so-called radium, and which had been taken from the safe of the quack, was shown. The vial was about an inch and a quarter in diameter, and the part which was said to cost $10,000 was about an inch in depth.

The professional abortionist will not give drugs because this makes his conviction easy. Mr. Andrews said that when every state shall have a comprehensive medical law the profession will have a medical instrument which will enable them to check the practice of almost every class of medical quackery, except the man who is a charlatan inside of his own profession. In referring to the attitude of the newspapers toward quackery, it was the opinion of Mr. Andrews that in their acceptance of the advertisements of the so-called specialists in diseases of men, abortionists and patent-medicine dealers, active assistance is given to the evil. He believes the time will come when the newspapers will be obliged to give up these advertisements, as some are now voluntarily doing. The President of the Board of Health of New York has sent to the County Society over 100 complaints against illegal practitioners. A police officer is detailed to the work of the society and does nothing else. The court sets aside a day in the week for the trial of these cases. There is the problem of much work to be done with but a small amount of money, but Mr. Andrews believes that the profession of New York will awake to the necessity of asking the general public to contribute toward the carrying on of the work which in reality affects the general public more than the profession. While much has been accomplished, Mr. Andrews believes that if the work were neglected for twelve months the city would be again overrun with quacks. He believes there should be some organized body behind the movement some concentric effort made to enforce the laws. He urges the formation of an organized body with a charter under the general corporation laws of one of the states. Should the American Medical Asso-

ciation, organized as it now is in every state of the Union, undertake the splendid work of suppressing the quack, he believes the effort would be attended with much success.

DISCUSSION.

Dr. Samuel G. Dixon, Health Commissioner of the State of Pennsylvania, thought the time has come when the members of the profession should present to the legislature a bill empowering the State Medical Examining Board to revoke the license of a physician practicing as a charlatan or a quack. Physicians should take as much pride in having a high standard of honesty and honor in the profession as do the members of the Bar. In his opinion the law-makers are ready to pass laws forbidding the sale of medicine unless the formula is printed in full.

Dr. John B. Roberts did not believe that the patent-medicine or quack evil is entirely a disease of the community, but a disease, to a certain extent, of the medical profession. The ease with which the public is duped by those whom intelligent men in general call quacks, is partly the result of quackish men in the professional ranks. The essence of quackery is a boastful assertion of skill and infallibility, and a desire to obtain large sums of money for treating disease. The sick often seek the advertising doctor and believe the false assertions of the patent-medicine label, because they have found the medical men known to them to be incapable, inefficient, or so exorbitant in fees that help seems impossible at their hands. The family which can obtain efficient medical aid for a moderate fee near its home does not often drift into the hands of the recognized quacks.

The college which graduates an ignoramus, the state examining board which gives a license to an unfit applicant, and the physician who places an unjust value on his services, or who deceives his confiding patient are potent agents in encouraging quackery. Some years ago, he said, the alumni of various medical schools were obliged to compel their alma maters to stop the output of half-educated graduates, and the profession has had need to be on the alert that medical examining boards do not permit improper men to obtain licenses to practice. These sources of supply of *quasi* physicians, Dr. Roberts said, have now been pretty satisfactorily checked. There remain, however, the secret remedy prescribers, the commission-giving consultant, and the big fee doctors to be disciplined by the medical profession itself.

Dr. Henry Beates said that the inability to successfully carry out the prosecution of quacks is due to the feebleness of the act of Assembly governing such matters. Efforts have been made to so amend the present law that to the usual fine there should be added a term in the penitentiary; also conferring the power to revoke the license of a practitioner who carries out quackish methods. These attempts to elevate the standard have met with opposition from every commercial medical college in the state of Pennsylvania. Dr. Beates strongly urged the organization of a movement to correct the evil of quackery.

Thomas W. Barlow, Esq., of the Philadelphia Bar, said that if an organized effort were made to prosecute offenders in Philadelphia as is being done in New York, there must of necessity be a change in the police rule; for, while in New York a day each week is given by the courts to the work of the society, in Philadelphia, were an arrest made, it would take from thirty to sixty days to secure an indictment and probably six months to obtain conviction.

Dr. S. Solis Cohen said that it is especially difficult to control the evil when men who are looked up to as leading lights, founders of colleges, etc., use their political influence against the effort. The medical profession, as a whole, and the medical press in particular, are not free from contamination with the patent-medicine evil. He expressed the hope that those interested, not of the medical profession, will point out to the newspapers the wrong they are doing in printing objectionable advertisements. Until the medical press is clean, the profession can not work in this direction. He doubts whether the American Medical Association is the body to lead in an organized movement against quackery, although it might properly co-operate with a national body, such as Mr. Andrews suggested, and that it would be quite proper for the Philadelphia County Medical and other bodies of physicians interested in the work to co-operate individually and collectively with such an organization. Regarding the suggestion of so amending the medical laws that a license may be revoked, he thought it would be injudicious to place such power in the hands of any other body than a court of law, and that a license should be revoked only by order of court after a full judicial hearing.

Dr. Persifor Frazer said that there are many quacks in geology and chemistry as in medicine. They are not, however, so well known. He endorsed the suggestions made by Mr. Andrews.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Scarlet Fever.

In the treatment of scarlet fever, C. F. Shollenberger, in the *Denver Medical Times*, states that there is no disease of infancy and childhood in which so much care is necessary in the treatment as scarlet fever. The important things to observe are to prevent complications and sequelæ, which so frequently arise during the convalescent period of scarlet fever unless exceedingly great care is observed. The patient should be instructed to remain in bed at least a week after the temperature has entirely subsided, and to continue on a liquid diet, preferably milk, for two weeks longer. During the active stage of the disease, whether mild or severe, the secretions from the nose, throat and mouth should be removed on pieces of linen and immediately burned. The fecal and urinary discharges should be disinfected, and any discharge from the ear after being removed by absorbent cotton should at once be destroyed. All linens, towels and bedding should receive thorough disinfection before being taken from the room. The feeding utensils should be properly sterilized, and after the removal of the patient the sickroom should be thoroughly disinfected by means of sulphur or formaldehyd gas. For the purpose of disinfecting the bed, furniture and feeding utensils, a strong solution of carbolic acid, 1 to 20, or corrosive sublimate, 1 to 200, should be used. All books and toys which have been in the sickroom should be thoroughly disinfected or destroyed. Failure to observe any or all of these precautions has produced a great many deaths.

The atmosphere of the sickroom should be kept pure and fresh and at a temperature of from 65 to 70 F., avoiding all exposure to draughts, either directly or indirectly. This author recommends that a sponge bath be given to the patient once or twice a day, and that during the period of desquamation or at any time when excessive pruritus is present, some soothing lotion should be applied to the entire body. For this purpose he recommends the following combination:

R. Menthol	gr. x	65
Unguenti zinci oxidi	ʒss	15
Lanolini q. s. ad to make	ʒi	30

M. Ft. unguentum. Sig.: Apply locally to the surface of the body.

The diet, of course, should be nutritious but mild, as has already been stated, consisting preferably of milk.

The medicinal treatment must be symptomatic, as no specific treatment has yet been discovered. Hydrotherapy is the best means of reducing the temperature, applied in the form of cold sponging, the cold wet pack or cold bath, depending on the individual case. Ice bags applied to the head are very serviceable. In giving the bath Shollenberger advises that the water be at first made lukewarm and gradually cooled until the desired temperature is reached. If active delirium is present and can not be controlled by hydrotherapy, potassium bromid or chloral hydrate may be given internally. In the treatment of the throat older children and adults may use some mild antiseptic gargle, while in young children spraying

should be employed. In the line of general treatment there is nothing better, he states, than the tincture of the chlorid of iron, especially when the stomach is in good condition. This preparation may be given in doses of from 3 to 10 minims each, and repeated every three hours, depending on the age of the patient. If the heart shows any signs of weakness, whisky, brandy or port wine is recommended as a stimulant, or strychnin sulphate in doses of 1 140 to 1 100 grain each, and repeated in from three to six hours.

COMPLICATIONS AND SEQUELÆ.

To prevent otitis media thorough irrigation of the fauces should be followed out. The younger patients will resist this irrigation of the fauces, and under such circumstances good judgment must be used as to the carrying out of this treatment. If the signs of otitis media arise, such as earache or pain referred to the ear, the instillation of hot water may be all that is necessary to relieve the distress. If this should not be sufficient, however, a solution similar to the following may be instilled into the ear:

℞ Tincturæ opii
Solutio cocainæ, 5 per cent., āā ..... ℥ss 2|

M. Sig.: Instill one or two drops into the affected ear.

The hot water bottle or hot salt bag should be applied externally. If pus is present the tympanic membrane must be incised. The ear should then be irrigated three times a day with a 5 per cent. solution of hydrogen peroxid, and if this discharge should persist after convalescence, irrigation must be continued at least twice a day until the pus has ceased to flow.

Enlargement of the glands of the neck is another very painful complication, and, according to this author, must be treated by the application of ice bags or cold cloths locally. If relief is not obtained within forty-eight hours hot poultices should be applied, and if there is any evidence of pus formation, a free incision, followed by sterilized irrigation and dressing, is necessary.

Arthritis as a complication frequently yields, without much stubbornness, to local treatment. For this purpose he recommends the following combination:

℞ Tincturæ aconiti ..... ℥ss 15|
Tincturæ opii
Spiritus chloroformi, āā ..... ʒvi 24|
Linimenti saponis q. s. ad to make ..... ℥iv 120|

M. Sig.: To be applied locally three or four times a day. The affected joints should be wrapped in absorbent cotton after the foregoing application has been made.

Although he does not regard this condition as a true rheumatic arthritis, he recommends small doses of sodium salicylate in such conditions.

When great gastric irritability is present, together with an accompanying enteritis, and the vomiting becomes excessive and continuous, he recommends large and frequent doses of bismuth subnitrate. In some cases minute doses of cocain may be given. The ice bag or mustard plaster applied to the epigastric region are of great service. Rectal feeding must be employed until the vomiting ceases, when the feeding by the stomach must be very gradually resumed.

Nephritis is the most severe and common complication of scarlet fever. Consequently, daily examination of the urine must be made for several days after convalescence has taken place. If there is any sign of disturbance of kidney secretion, diaphoresis may be employed by means of baths, hot packs, hot air, and hot drinks in small amounts. When marked dropsical effusion is present the free use of a hydragogue cathartic is indicated, and he recommends for this purpose the compound jalap powder. In order to render this more palatable for young children Shollenberger states that a cream of tartar lemonade may be substituted and sweetened and flavored with mild claret or wine. After the active congestion of the kidneys has been reduced, a stimulating diuretic should be given, and the following combination is recommended:

℞ Potassii acetatis ..... ʒii 8|
Infusi digitalis ..... ℥iii 90|

M. Sig.: One teaspoonful every four hours.

Flaxseed or mustard poultices placed over the region of the kidneys will often produce a stimulating effect, and assists in relieving the backache which is so frequently present. Some authorities recommend the local application of leeches over the kidneys, and others recommend dry cupping. Both of these are often objectionable to children.

If uremic convulsions should arise energetic diaphoresis must be procured. During the convulsion chloroform may be used to allay the violence of the attack; otherwise large doses of bromid or chloral hydrate will suffice.

D. R. Lucy, in the same periodical, recommends the following combination for general systemic treatment of scarlet fever, beginning about the second day:

℞ Tincturæ ferri chloridi ..... ʒii 60
Potassii chloratis ..... ʒi 4|
Glycerini
Aquæ, āā, q. s. ad to make ..... ℥iv 120|

M. Sig.: Take one teaspoonful in water every two hours.

Zinc Preparations.

In the treatment of herpes zoster the *American Journal of Clinical Medicine* recommends the use of zinc phosphid (U. S. P. 1890) as one of the most efficient remedies. As to its method of action, it is assumed that this preparation acts as a nutrient and relieves the condition by improving the deranged nutrition of the affected nerve tissue. Acting on this principle, the preparation has been used in numerous cases of stubborn neuralgia, in excessive hyperesthesia, and in other diseases of the peripheral nerve tracts, with marked success. It is suggested in this connection that the entire group of diseases following degeneration of the various tracts in the spinal cord, of which tabes dorsalis is one, the wet brain of alcoholics, general paresis, and neurasthenia are others, may be successfully treated by this preparation. As to the dosage one-sixth grain is the average dose for an adult, to be given one hour before each meal and just before retiring. The object of the time of administration is to avoid having the remedy broken up by the digestive fluids, with the evolution of phosphuretted hydrogen, and nauseous eructations, which are very unpleasant to the patient. In this size of dose it probably should not be continued for a longer period than one week at a time, each month.

In cases of epilepsy the zinc oxid pill is recommended by Gowers and Beevor when the bromids do not act properly.

In cases of heart complications with aortic regurgitation the following is recommended:

℞ Zinci phosphidi (U. S. P. 1890) ... gr. 1 s. .. 008
Ext. gentianæ q. s.
M. Ft. pillula No. i. Sig.: One such pill three times a day.

In hysterical affections the following is of value:

℞ Zinci valerianatis ..... gr. iii |20
Pil. asafetidæ co. (B. P.) ..... gr. ii |12
M. Ft. pil. No. i. Sig.: One such pill twice a day.

Medicolegal

Sudden Giving Way of Foot Not a Disease.

The Supreme Judicial Court of Massachusetts says, in the case of Noyes vs. Commercial Travelers' Eastern Accident Association, that the plaintiff, a man 76 years of age, was on the platform of a railroad station, about to take a train which was entering the station. He walked forward on the platform, near the side of the train, before it stopped, with a view to taking a forward car, when suddenly, without any apparent cause, "his right foot gave way," and he fell, coming in contact with the train, and his foot was crushed. On this description of the accident it could not be said as a matter of law that he was negligent. His foot had never before given way in a similar manner. So far as appeared, the injury was entirely accidental. In this particular the court could not rule that the accident prevented him from recovering on his contract with the association. Nor could it be said, as a matter of law, that such a disorder as the sudden giving way of his foot, without apparent cause, was a disease, within the meaning of the contract, such that he was precluded from recovery for that reason.

Condition of Family and Patients No Ground for Bail.

The Supreme Court of Mississippi says, in Winegarden vs. State, where the former was convicted of grand larceny, that, in an affidavit he made in support of an application for bail pending an appeal, he set forth, besides bad health in himself, that his family, a wife and daughter, were in poverty; that he was their only means of support; that his daughter had been an invalid for years, and needed his medical care, he being a physician who understood her case better than any one else; that he was in large practice as a doctor of medicine, making a specialty of diseases curable by medicine concocted by him from "native herbs and roots"; and that his large number of patients needed him very much at that time, and he thought that many of them would never be cured if they were deprived of his medical attention. The court says that it had deep sympathy for his family; but it was certain that their condition furnished no ground, under the law, on which to base an order of bail. The same was true of the deprivation of his services to his patients, to whom the court could extend its condolence only.

Power of Patient to Waive Statutory Privilege.

The Appellate Court of Indiana, Division No. 2, says, in Metropolitan Life Insurance Company vs. Willis, that in an application for insurance the insured "expressly agreed and stipulated that in any suit on the policy any physician who had attended him might disclose any information acquired by him in any wise affecting the declarations and warranties" made in the application. But when a physician was called as a witness objection was made that he was not competent to testify and answer the question as to the disease that the insured was afflicted with when he was called to visit him because it was a privileged communication between physician and patient. The court holds that it was error to exclude the evidence. It says that the Indiana statute which makes inviolate matters communicated by a patient to his physician in the course of his professional business has always been strictly construed, and the rule is that such confidential relations will be protected by the courts, except where the patient consents to their revelation by the physician. In Penn Mutual, etc., Company vs. Wiler, 100 Ind. 92, it was said: "Notwithstanding the absolutely prohibitory form of our present statute, we think it confers a privilege which the patient, for whose benefit the provision is made, may claim or waive it." Here the assured, by an agreement in writing, waived this statutory privilege, and this court has no doubt but that he had a right to do so. His waiver must operate as such to those claiming under him.

Corporations Barred from Doing Professional Business.

The Supreme Court of Ohio holds, in the case of State vs. Laylin, that a foreign corporation, the sole business of which, as authorized by its charter, is that of defending physicians and surgeons against civil prosecution for malpractice, which, in the prosecution and conduct of said business, issues and sells to members of the medical profession a contract whereby it undertakes and agrees to defend the holder of said contract against any suit for malpractice that may be brought against him during the term therein specified, but does not assume, or agree to assume or pay, any judgment that shall be rendered against him in such suit, is not engaged in the business of insurance, nor is the contract so issued and sold an insurance contract. But a foreign corporation, created for the purpose of engaging in and carrying on such business, is not entitled to have or receive from the Secretary of State of the State of Ohio a certificate authorizing it to transact such business in that state, for the reason that the business proposed is professional business, and as such is expressly prohibited to corporations by section 3235 of the Revised Statutes of 1903. It was urged that the company, being a corporation, an impersonal entity, could not and did not itself engage in the practice of law or the management and conduct of defenses in suits at law, but in what it did, or obligated itself to do, it undertook only "to act as the agent of the contract holder in retaining legal counsel, and in managing and maintaining the defense of the suit." But the court says that if this be not the engaging in or carrying on of professional business, then it would be difficult to conceive how professional business could be engaged in or carried on by a corporation. The conclusion reached, it further says, rendered it unnecessary to consider the question suggested that the contract issued and sold by the company was a contract, the making of which was against public policy, because of the stipulations and provisions therein contained, restricting the right to compromise.

Suggestion as to Instructions on Expert Testimony.

The Supreme Court of Missouri, Division No. 2, says, in the case of State vs. Wertz, a prosecution for rape, that part of the instruction given the jury was as follows: "Whether the hypothetical case on which the opinions of the experts are based corresponds to and coincides with the facts given in the evidence the jury alone must determine from the evidence produced in this case. And, if the jury finds such hypothetical questions supposed facts not given in evidence, they, together with the opinions of the experts based thereon, should be entirely disregarded by the jury in making up their verdict." It is clear that, if the hypothetical case on which the opinions of the experts were based did not correspond to and coincide with the facts given in evidence, the court should have excluded the questions and answers to such hypothetical questions; and this error was emphasized by the additional direction to the jury that they must determine whether there was any evidence upon which to base such hypothetical questions. This direction to the jury was manifestly erroneous and constituted reversible error.

Again the Supreme Court feels constrained to suggest to the trial court the propriety of following the old landmarks. The law on the subject of expert testimony has been repeatedly and correctly declared by the courts of Missouri, and such declarations have uniformly met the approval of this court and should be regarded as well-established precedents. Where medical experts testify in a case, it is usual and common for the court, in directing the jury as to the credit and weight to be given to such testimony, to simply say to the jury, by its instructions, that "the opinions given by the medical experts in this cause are testimony before you and subject to the same rules of credit or discredit as the testimony of other witnesses. The opinions neither establish nor tend to establish the truth of the facts upon which they are based. Whether the matters testified to by the witnesses in the cause as facts are true or false, is to be determined by the jury alone. Neither are the hypothetical questions put to the medical experts by the counsel in the cause evidence of the truth of the matters stated in these questions." An instruction substantially in this form would have covered the entire subject of the expert testimony given in this cause.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

Medical Record, New York.

April 7.

1 *Prevention and Treatment of Pneumonia. B. Robinson, New York.
2 *Synthetical Medicine. E. C. Savidge, New York.
3 The Hippocratic Era in Medicine. R. C. Newton, Montclair, N. J.
4 Plea for More Conservative Examination in Suspected Cases of Pulmonary Tuberculosis. C. C. Keeler, Denver, Colo.
5 *Intraligamentous Drainage for Non-suppurating Parametritis. L. F. Garrigues, New York.
6 Football and Moral Health. W. L. Howard, Baltimore.
7 Chorea and Some Disorders Simulating It. A. A. Fisher, Philadelphia.

1. **Prevention and Treatment of Pneumonia.**—Robinson claims that with the appearance of the first symptoms of pneumonia beechwood creosote should be vaporized more or less continuously in the patient's room. At frequent intervals the inhalations are stopped and the windows opened wide. Draughts must not be tolerated, although perfect ventilation is insisted on. Robinson regards creosote as the most useful single agent in the treatment of pneumonia, as a preventive and curative, if given properly and if continued for a sufficient length of time.

2. **Synthetical Medicine.**—The title of Savidge's paper is misleading inasmuch as it does not deal with synthetic remedies, as one naturally would suppose. The author says that synthetical medicine attempts to recognize and to postpone the future trouble which is menacing each individual.

3. **Intraligamentous Drainage for Parametritis.**—Garrigues made use of the following method in two cases of parametritis with very satisfactory results: After curetting the uterus, the cervix is drawn toward the healthy side, and a bullet forceps is inserted in the vagina to the side, and slightly posterior to the cervix, so as to put the vagina on the stretch. An incision, about three-fourths of an inch in length, is made through the vaginal wall, close to the uterus. Through this incision the forefinger is inserted, and, keeping close to the uterus, is pushed well up between the layers of the ligament into the hard parametrium, and then outward, so as to open up the mass freely for drainage. Should the Fallopian tube be much swollen it is opened by means of a blunt forceps under the guidance of the index finger. A good sized tube is introduced, either into the parametrium or into the tube, as the case may be, and the operation is complete. He advises against the use of sharp perforators, scissors, etc., the finger being the most accurate and harmless instrument that can be used. The operation is said to be not dangerous, usually not very difficult, and the results certain and satisfactory.

8 Mental Symptoms of Cerebral Tumor. P. C. Knapp, Boston.
9 Operation for Cataract. F. E. Cheney, Boston.
10 *The Early Diagnosis and Aggressive Treatment of Pulmonary Tuberculosis in a Large Out-patient Clinic. J. B. Hawes, Jr., Boston.
11 *A New Needle Holder. J. D. Barney, Boston.

10. **Treatment of Tuberculosis in the Out-Patient Clinic.**—Hawes directs attention to the harm done to patients with phthisis by the treatment ordinarily given in out-patient clinics. The great difficulty is not that there is any lack of willingness on the part of the physician, but that the patients will not co-operate with him in his efforts to get at the trouble. Sometimes, however, by waiting until the diagnosis of tuberculosis is proved by the demonstration of tubercle bacilli, those in charge of out-patient clinics are sometimes responsible for the death of the patient. Hawes emphasizes that there must be an aggressive personal interest on the part of the physician in charge; that he must himself take the initiative, educate and encourage the patient and hustle for his future good even when the patient is listless and indifferent. Every effort should be made to diagnose the disease early, before bacilli appear in the sputum, by careful temperature records kept by the patients themselves, by the use of tuberculin, and by mensuration and spirometry. By doing this much good can be done in the treatment of tuberculosis in the out patient department.

11. **New Needle Holder.** The particular advantages of the instrument devised by Barney are: 1, Curved needles are gripped too securely to turn over; 2, needles are not broken.

New York Medical Journal.

12 *Endothelial Spindle-Celled Sarcoma of the Dura Mater Penetrating the Brain. I. W. Blackburn and W. H. Hough, Washington, D. C.
13 Ascending Myelomalacia Caused by a Progressing Venous Thrombosis. M. G. Schlapp, New York.
14 Acute Intestinal Obstruction. H. Lilienthal, New York.
15 *The Vasomotor Factor in Asthma. F. Hare, London, England.
16 *What Causes the Pylorus to Relax? A. L. Benedict, Buffalo.
17 *Treatment of Diffuse and General Peritonitis, with Special Reference to the Murphy Method. J. B. Gibbon, Philadelphia.
18 Functional Heart Murmurs. R. Ellis, New York.
19 Motor Ocular Paralysis as a Complication of Acute Articular Rheumatism. L. Street, Kyoto, Japan.

12. **Sarcoma of Dura Mater.**—In the case described by Blackburn and Hough, the tumor originated from the dura mater just in advance of the sella turcica, and at the posterior inner angle of the orbital plate of the right frontal bone. As it grew upward it penetrated the brain and formed a large cavity in the base, mainly in the orbital surface of the right frontal lobe. In its invasion of the brain it destroyed both olfactory tracts, nearly destroyed the optic nerves and chiasm and thrust the cerebral structures before it, becoming almost wholly imbedded within the brain substance, yet the growth had no organic connection with the brain except slight incorporation with the leptomeninges.

15. **Vasomotor Factor in Asthma.**—Hare states that the meaning and mechanism of many asthmatic paroxysms may be summarized as follows: 1, Hyperpyremia; 2, widespread vasoconstriction compensated for by bronchial vasodilatation, or the converse; 3, vascular distension of the mucosa of the bronchioles; 4, obstructive dyspnea; 5, exaggerated combustion (catabolic expenditure); 6, gradual dispersion of hyperpyremia; 7, cessation of the vasomotor variation; 8, subsidence of vascular distension and asthmatic paroxysm.

16. **Relaxation of Pylorus.**—Benedict summarizes his objections to the acid theory of relaxation and closure of the pylorus as follows: 1. The local changes in reaction are physiologically inevitable. 2. The relative acidity of the chyme is not diminished by the passage onward of a small portion, yet the pylorus does not remain patulous. 3. While this failure of a continuous relaxation of the pylorus may be explained by the distal acidity, it is in close analogy with the action of other alimentary sphincters, which close without any exciting reflex that can be ascribed to differences in chemical reaction. 4. Fully half the stomach contents normally escape before it is conceivable that any great proportion of hydrochloric acid is present. 5. Clinical experience with dietaries shows that, other things being equal, meals that call for considerable hydrochloric acid secretion usually remain in the stomach longer than those which do not. 6. Clinical experience with stomach contents proves conclusively that deviation from the normal standard of hydrochloric acid secretion produces just the opposite effect to that which would be expected if this were the cause of pyloric relaxation. Even in achylia gastrica, there is no necessary abnormality of pyloric function, certainly not in the direction of retention.

17. **Treatment of Peritonitis.**—Gibbon subscribes to the value of the drainage treatment of peritonitis as outlined by Murphy. He believes that the Ochsner treatment of diffuse peritonitis is indicated in every case of appendicitis in which it is impossible to operate immediately, and after the removal of the appendix and the establishment of drainage.

24 *Metrorrhagia Myopathica. R. M. Anspach, Philadelphia.
25 Fractures of the Humerus by Muscular Violence. A. P. G. Ashhurst, Philadelphia.
26 Philip Syng Physick; A Sketch. R. H. Harte, Philadelphia

24. **Metrorrhagia Myopathica.**—Under this term Anspach describes a condition which hitherto has been variously and incorrectly grouped under apoplexia uteri, senile endometritis, and preclimacteric bleeding. It is a symptom dependent on an anatomic or physiologic lesion of the uterine muscle which has not yet been demonstrated. He thinks that the anatomic lesion will probably be found in the elastic tissue constituents of the vessel wall and the subserous and supravascular layers. The physiologic lesion is most likely an insufficient contractile power of the uterus. The condition does not occur in nulliparous women, and, therefore, it must have some connection with the child-bearing process. The uterus is enlarged and softened; the os is patulous. The diagnosis of the metrorrhagica myopathica is only justified when all other possible causes for uterine hemorrhages have been excluded. This is especially urgent in reference to carcinoma. While curettement, atmocausis, etc., have little effect in treatment Anspach states that palliative measures should always be tried before resorting to hysterectomy. Obliteration of the endometrial cavity by means of destructive atmocausis is the alternative of hysterectomy in these cases. It is harder to perform correctly, however, and is more dangerous than hysterectomy, which is the operation of choice.

33 Citrate of Soda In Infant Feeding. H. L. K. Shaw, Albany, N. Y.
34 Barlow's Disease (infantile scurvy) in the Island of Cuba. J. L. Duenas, Havana, Cuba.
35 *Hypertrophic Stenosis of the Pylorus, Operation, Recovery. J. Rogers and J. Howland, New York.
36 *Fat Problems and Goat's Milk in Infant Feeding. J. F. Bell, Englewood, N. J.
37 Diagnosis and Treatment of Chronic Polyarticular Diseases in Childhood. P. W. Nathan, New York.

35. **Hypertrophic Stenosis of Pylorus.**—Rogers and Howland report a successful operation on an infant three months of age, suffering from hypertrophic stenosis of the pylorus. The symptoms were typical. A posterior gastrojejunostomy, without a loop, was carried out with sutures. The length of the operation was twenty-five minutes.

36. **Fat Problems in Infant Feeding.**—As the result of clinical observation and experimentation Bell concludes that the digestion of fat retards the flow and diminishes the amount of gastric juice, at the same time lowering its digestive power. The ingestion of fluid oil increases the flow of pancreatic juice and probably the activity of its fat-splitting enzyme, steapsin. In case the fat is not fluid at body temperature, he states, it may still further retard and prevent the flow of gastric juice, coating over the gastric mucous membrane, thereby mechanically interfering with secretion. In the case of coagulable food, such as caseinogen, it may cover the curds with a layer of insoluble fat, thereby preventing the action of gastric juice on them, though the juice be secreted in sufficient amount and power, and also by preventing the action of the trypsin on them, though brought in contact with an increased supply of pancreatic juice, assuming that the action of the steapsin on the fats will be partially *nil*, or at least much impeded by the insolubility of their fat-covering permitting the curds to pass undigested. If goat's milk fat more closely approximates human milk fat than that of cow's milk, and if the proteid and sugar constituents are not more incompatible than in cow's milk and if there exists no serious commercial obstacle, goat's milk merits an extensive and thorough clinical trial in infant feeding.

March 15.

38 *Phases of Civil Liability of Physicians and Surgeons and Remedies Therefore. E. B. Kinkead, Columbus.
39 *Need of Patent Medicine Legislation. T. Sollmann, Cleveland.
40 Removal of Foreign Bodies. J. M. Leslie, Chillicothe.
41 A Type of Appendiceal Abscess. C. A. Hamann, Cleveland.
42 Direct Inspection of the Esophagus and the Bronchial Tubes. E. L. Stillman, Columbus.
43 Medical Organization. B. H. Blair, Lebanon.
44 Prostatic Hypertrophy. T. G. Youmans, Columbus.

38. **Civil Liability of Physicians.**—Kinkead discusses many legal questions and in closing speaks briefly of "patent medicine." He says that it is the duty of medical men to cast aside some of that modesty which pervades the profession, come out in the open, and make war on "patent medicines." They owe it, he declares, to the people as well as to themselves. He thinks that to require a license of physicians before they can practice and at the same time to permit irresponsible persons to flood the state with worthless and injurious "patent medicines" is not consistent. The idea of surrounding a remedy with secrecy and exclusiveness is ridiculous. To permit citizens to take medicines on the printed directions of some unknown person, or of some person who is dead, without knowing whether it is what they need, is unfortunate, he says, and should not be permitted.

39. **Need of "Patent-Medicine" Legislation.**—Sollmann urges that the medical profession support any measure tending to the improvement, regulation and enforcement of the poison laws. However, great caution is necessary to keep out all sort of restrictions and omissions which would greatly lessen the effectiveness of these laws. The only practical remedy is complete publicity as to all the active ingredients of a medicine. That takes the moral responsibility from the shoulders of the manufacturer and places it on the consumer, who will be the chief sufferer if he disregards the warning. Sollmann points out that the passage of a formula law would make the druggist a morally responsible agent in the "patent-medicine" traffic, a result which Sollmann considers is desirable.

Medical Fortnightly, St. Louis.
March 10.

45 Adenoids. H. Stolte, Milwaukee.

53 Public Health. D. C. Brockman, Ottumwa.
54 Diagnosis and Treatment of Diseases of the Right Upper Abdominal Cavity. B. M. Ricketts, Cincinnati.

46. **Rest Treatment.**—The use of this method in the treatment of over 400 patients has fully convinced Norbury of its value. He urges, however, that to be successful its technic must be carried out just as carefully as is the technic of the surgeon when he operates. Each factor of the treatment must be considered and none left out, for it is the treatment as a whole which accomplishes results. These factors are isolation, rest, massage, electricity, diet, an educated, tactful nurse, a hopeful, healthful, optimistic physician and a suitable, wholesome, restful environment.

50. **Stomach Drainage in Chronic Dyspepsia.**—Maxwell cites three cases as proof that certain cases of long continued dyspepsia are not amenable to internal medicine, but can be cured by gastroenterostomy, the choice of the operation being left to the physician in charge.

51. **Hydrotherapy in Chronic Nephritis.**—Croftan attempts to show that such simple measures as hot bathing, properly administered, and the application of heat or cold to various portions of the body, can accomplish much in the treatment of the nervous, metabolic, gastroenteric and cardiovascular manifestations of nephritis. A judicious selection of the diet, especially with the end in view of maintaining adequate nutrition, is an indispensable adjuvant to treatment, for otherwise the organism can not maintain those reactive and reconstructive powers that alone can bring about an amelioration of the disease, and, as far as that may be possible, a restitution to normal. Drugs, on the other hand, in Croftan's opinion, should be given very sparingly in chronic nephritis. They should always be reserved as an emergency measure and hydrotherapeutic means should replace them whenever possible.

55 *Significance of Albumin and Casts When Found in the Urine of Apparently Healthy Applicants for Life Insurance. E. W. Dwight, Boston.
56 Significance of the Commoner Microscopic Findings in Urinary Sediments. L. N. Boston, Philadelphia.
57 Albuminuria. P. F. Barbour, Louisville.

55. **Significance of Albumin and Casts in Healthy Individuals.**—Dwight believes that albumin in minute traces is not only frequently found in normal urine, but is a normal constituent of the urine. After severe exercise or mental strain, and under certain other conditions, it is constantly found in traces in

individuals who give every other positive evidence of being in good health. In 600 cases of so-called renal albuminuria, hyaline and finely granular casts were detected in 93.8 per cent. Dwight thinks that as we know there must be albumin to some extent in all cases which present renal casts, so we are justified in the assumption that in all cases in which the albumin is of renal origin, casts might be found if the search for them is prolonged and sufficiently accurate. He takes the position that the finding of a true renal hyaline cast indicates that the albumin in the urine, or at least a part of it, is of renal origin. A decision should not be based on the finding of albumin and casts in the urine.

62 Tuberculous Peritonitis. H. L. Wilson, Jordan.

61. **Veratrum Viride.**—Bates records his experiences with this drug, which he regards as the only remedy for continuous abnormal vascular tension. He has found it very satisfactory in the first stage of pneumonia, influenza, and bronchitis, in combination with morphin and sweet spirits of niter. In a very aggravated case of traumatic chorea from granular erosion of the cervix uteri which had resisted the usual routine remedies, fifteen drops of veratrum, at intervals of fifteen minutes, until three doses were given, afforded prompt relief. In the toxemia of eclampsia its use also was attended by success. After giving a good mercurial purge Bates injects from 25 to 30 drops of Norwood's tincture at intervals of thirty minutes until he secures complete muscular relaxation, when the convulsions generally cease in all cases unless there is cerebral traumatism. Shortly after the relaxation nausea and vomiting occur. He allows this to continue until he thinks the full physiologic effect of the veratrum has been exerted. Then he injects from ¼ to ½ grain of morphin to allay the vomiting.

75. **Surgical Treatment of Exophthalmic Goiter.**—In addition to the advice to divide the operation by performing preliminary ligation of the arteries and to use local anesthesia, Curtis adds that it is advantageous, if not absolutely necessary, to have the preliminary treatment by rest in bed, ice bag to the heart, bromids, etc., carried out at the hospital where the operation is to be done, in order that the patient may learn to know and trust the surgeon, to like the nurses, and to become familiar with her surroundings. This adds greatly to the efficiency of the control of the patient under local anesthesia. Of 14 patients operated on, 4 died, all from acute thyroidism. Of the 10 patients who recovered from the operation, one improved, but has not been seen since. One was improved for two years, relapsed, later had one artery tied on the other side with improvement, and again relapsed. Eight patients are said to be practically cured, having been followed for six months (two cases), eighteen months, two years, five years, seven years, eight years and twelve years, respectively. Two of the cases were slight, but the rest were serious, and some patients were in a dangerous condition. The four patients who died were all advanced cases. These results are encouraging, and partial thyroidectomy has apparently yielded better results than sympathectomy. In one of his cases the latter method has effected a practical cure after a relapse following thyroidectomy. On the other hand, a relapse, with fresh enlargement of the thyroid, occurred in one case after sympathectomy, and, perhaps, a thyroidectomy would have brought about a cure here had it been possible to get the patient's consent. A temporary improvement was obtained in one of the relapsed cases by ligation of one artery on the other side, the improvement lasting two years or more.

77. **Overlapping the Aponeurosis in Closure of Abdominal Wounds.**—Noble describes his method, which was first published in 1897, and directs attention to the fact that during the nine years in which the method has been in use but a single patient has presented herself with a postoperative hernia.

80. **Chylous Cysts of Mesentery.**—The basis of Porter's paper consists of a study of the literature on the subject, including the reports of 19 cases which he has been able to collect, together with one case which occurred in his own practice. A diagnosis of appendicitis had been made. On opening the abdomen through the right rectus muscle a group of chylous cysts was found together with a volvulus involving that portion of the ileum attached to the mesentery in which the cysts were found. The bowel and mesentery containing the cysts were excised and an end-to-end anastomosis was made with the aid of a Murphy button. The patient died on the morning of the seventh day. A postmortem examination showed leakage at the mesentery attachment at the point of anastomosis.

83. **Permanent Drainage of Kidneys.** The following article comprises the apparatus designed by Watson for draining the kidneys: 1. Two red-rubber drainage catheters. 2. Two bits of rubber drainage tube, each two and a half inches long more or less, according to the thickness of the patient's back), and of a size to fit tightly on the catheters and in the horizontal opening of the shield through which they are passed. 3. Two hard rubber shields about three inches in length, two inches wide, and curved to fit the back. There are three openings in each of the shields, two perpendicular and one horizontal; the latter should be a little narrower than the rubber tubing in order that it may compress the tubing firmly enough to prevent it, and the catheter which passes through it, from slipping to and fro. The former are long enough to admit tapes an inch wide. 4. Two pieces of strong

tape or elastic webbing. One end of this tape is attached to the outer of the two perpendicular openings in the plate. The tape should be long enough to pass around the body and is secured in the opening at the further end of the shield by a safety-pin, or such other device as may be preferred. Elastic bands have the advantage, as compared with tapes, of adapting themselves to the movements of the body and thus keeping the shield constantly apposed to the back. 5. A waistband long enough to go around the body and four inches wide. This band should be of stout material; its front ends are brought together by a couple of straps and buckles; on the lower border of the back of the waistband are attached four stout hooks, and there are two holes to allow the catheters to be led through the band. 6. Two flasks, 5 inches long by 4 inches high by 1½ inches wide, curved to fit the gluteal region; each having a nozzle projecting one inch above the middle of its top and just large enough to admit the ends of the catheters, and provided with a ring firmly soldered near either end of the inner side of the tops of the flasks. The flasks may be made of hard rubber, aluminum or any other suitable material having a surface that will not absorb urine. The *modus operandi* for employing the apparatus is given in detail, and for this part of the paper the reader is referred to the original article.

84. **Surgery of the Kidney.**—Barling reports six cases of disease of the kidney requiring nephrectomy. The six patients are alive and well. The conditions requiring the removal of the kidney were hypernephroma, pylonephritis and ureteritis, intermittent hydronephrosis, with extreme mobility of the kidney were hypernephroma, pyelonephritis and ureteritis, pyonephrosis simulating hepatic tumor, and pyonephrosis with large perinephritic suppuration due to renal calculus. The ages of the patients were 50, 26, 35, 25, 35 and 58 respectively. The first patient was operated on March 1, 1905, and the last Oct. 7, 1905.

85. **New Method of Excision of Knee Joints.**—Flint describes a method of excision of the knee joint which he thinks combines all the advantages of other methods without possessing any of their disadvantages. The skin incision should be rectangular, the two vertical cuts being well back at the sides of the leg, extending from a little above the level of the upper limit to the subcrural bursa to one inch below the joint line. These two vertical incisions are connected across the front of the tibia by a transverse incision. This rectangular skin flap with the subcutaneous tissue is reflected upward. The next incision is curved, the concavity upward. It starts in the vastus internus a little above the upper limit of the subcrural bursa and is carried down and outward in the direction of the muscle fibers to the tendon of the quadriceps extensor one-half inch above the patella, and from here upward and outward in the direction of the fibers of the vastus externus to a point corresponding to the beginning on the inner side. The muscle with the tendon is completely divided and turned upward, thus exposing to view the subcrural bursa. Two small incisions are made on either side of the femur, starting on each side of the patella in the incision just described, and carried downward and backward to the joint line. The one on the inner side divides the tendinous expansion of the quadriceps, the one on the outer side the tendinous expansion and part of the ilio-tibial band. After completing these incisions the subcrural bursa is separated from the femur with the knife and turned down, tilting the patella when not adherent.

The last incision in front is carried transversely across the front of the tibia down to the bone just below the joint line. On the inner side the sartorius and gracilis are pushed back; on the outer side of the biceps and peroneal nerve. A flat retractor, about one inch wide, is introduced on the inner side behind the head of the tibia close to the joint line. It is first introduced vertically between the gracilis and sartorius on one side and the tibia on the other. These muscles are pried off and the retractor is brought to a horizontal plane, the apex passing behind the tibia. This retractor is now pushed outward, always close to the bone, until it emerges at the outer side. All soft parts are thus held back.

The next step is to saw through the tibia as close to the joint as circumstances seem to warrant, the leg being still flat on the table; the retractor being in place protects the soft parts. The saw-cut through the head of the tibia is used as a joint. The femur is flexed on the body, the leg on the femur, and with a large knife the soft parts are quickly separated from the posterior structures of the joint. By a little downward traction on the leg, combined with the pull of its own weight, injury to the vessels is easily avoided. As soon as the posterior region of the condyles is exposed the femur is sawn through from behind forward and slightly downward at a level sufficient to clear the cartilage behind. This saw-cut is carried forward until it reaches the margin of the cartilage on the anterior surface of the femur, and the saw is then withdrawn. The direction of this cut should be downward and forward, so as to lose as little as possible of the femur and to obtain the desired slightly flexed position of the bones subsequently. After withdrawing the saw from the femur the leg is once more placed in a horizontal position. The saw is introduced behind the subcrural bursa at the upper margin of the articular cartilage on the front of the femur and a cut made which will meet the anterior limit of the horizontal saw-cut made from behind. This last cut is almost vertical, in the coronal plane, and allows the articular portion of the femur which extends upward in front to be removed with the joint. This is the last step of the incision proper, for it is now possible to lift out the joint with the patella and subcrural bursa, the articular surfaces of femur and tibia, all complete without having opened the joint. On removal of the tourniquet the bleeding points can be quickly clamped and tied, thereby reducing hemorrhage to a minimum. The subsequent steps of the operation differ in no way from those hitherto customary.

89. **Venous Transplantations.**—As a result of a series of experiments performed on dogs, Carrel and Guthrie found that uniterminal and biterminal transplantations of veins on arteries produce, from a functional point of view, the transformation of veins into arteries. These arteriovenous anastomoses adequately transmit the blood indefinitely. After seven months the circulation through such an anastomosis is apparently as active as on the day of the operation.

93. **Separation of Periosteum.** Beck calls attention to periosteal bands which often may be seen, if looked for with the radiograph, extending from a bone fragment after a fracture. These periosteal bands are likely to be the cause of much trouble, so that the process of healing may become in itself a disease. He advises the removal of all miniature fragments and of such portions of periosteum as protrude beyond the point of fracture.

95. **New Method of Lateral Anastomosis.**—This method is described in full in The Journal, Oct. 22, 1904, page 1230.

96. **Operation for Empyema.**—For the operation described by Richter local anesthesia is sufficient, preferably by the method of Schleich. The operation consists of a rib resection with the formation of a large opening for drainage of the pleural cavity. The device employed for this purpose consists of a Bunsen pump, a Woulf bottle to take up the discharge and to which a mercury manometer is attached to measure the degree of tension and to act as a safety valve against too strong tension, and a drainage tube passed through a sheet of rubber. The method is illustrated and described in detail.

2. **Anesthetics and Renal Activity.**—In this, the second part of his report, Thompson considers ether, the A. C. E. mixture, and the ether chloroform mixture. During ether narcosis the volume of urine secreted was diminished in the majority of his experiments. The depressing effect of ether, he states, is more marked than that of chlorform, and complete arrest of secretion occurs more readily. The after-effect is also similar to that of chloroform, but, as a rule, it is less marked. The maximum outflow of urine occurs about three hours after removal of the anesthetic. The effect of ether on the output of nitrogen corresponds more closely with its influence on the outflow of urine than is the case with chloroform. The urine when diminished in volume is, as a rule, more concentrated (contains more nitrogen). The converse was the case in the chloroform experiments. In ether narcosis, when the curves of urine outflow, kidney volume and blood pressure are compared there is found to be a closer correspondence than is the case with chloroform. The escape of leucocytes into the urine is also more marked with ether than with chloroform, probably indicating a higher degree of stasis in the glomerular capillaries. The excretion of chlorids is increased, but it is less and of shorter duration than in the case of chloroform.

During full narcosis with the A. C. E. mixture the outflow of urine is diminished, but to a less degree than with either chloroform or ether; the excretion of nitrogen is less depressed than the volume of urine; the effect on the concentration of urine alternated between those of chloroform and ether; the chlorids were increased to a less degree than with chloroform, but to a greater degree than with ether. The full influence of the ether-chloroform mixture produces a diminution of urine less than that of ether, but more than that of chloroform. The excretion of nitrogen is less influenced than that of urine. The urine of the anesthetic period was more concentrated than normal, and the chlorids were increased, but to a less degree than with any of the previous anesthetics. The effect of the mixture closely resembled that of ether.

3. **Electrolysis in Treatment of Cicatricial Strictures.**—After the dilatation of the stricture and a thorough and minute irrigation of the urethra with a solution of a mercuric preparation, Selhorst inserts an Oberlaender's urethroscopic tube, passing along the whole length of the stricture. In examining the urethra the tube is withdrawn slowly until the surface of the constriction is shown in the opening. The needle, ending in a strong platinum point from 1.5 cm. to 2 cm. in length, isolated almost quite close to its point, is forced to a depth of from 0.5 cm. to 1 cm. into the fibrous tissue according to the dimension, thickness, and hardness of the tissue. The needle is the negative pole of a galvanic battery, the positive pole of which, a large moistened, wetted disc, is placed on the thigh or on the abdomen. The electric current of from 4 to 6 milliamperes is turned on for three minutes. Before withdrawing the needle Selhorst interrupts the current, and drives the needle into another part. This operation may be repeated four or five times during a sitting, and, if executed by an expert hand, is said not to be very painful. During the whole period of treatment a bougie is introduced once a week, followed by an irrigation with a nitrate of silver solution to promote reabsorption, and to maintain the passage of the urethra at the size required. The number of the sittings depends on the extent of the stricture as well as on its thickness and hardness.

5. **Ascaris Lumbricoides and Appendicitis.**—Anley reports two cases, the history of which was typical of a catarrhal appendicitis. Both patients passed a round worm and from that moment began to improve, making an uninterrupted recovery.

The Lancet, London.

11 *Therapeutic Effects of Mercury in a Case of Tuberculous Meningitis. W. H. W. Brown.
12 *Treatment of Internal Hemorrhage by the Use of Drugs. W. E. Dixon.

7. **Biliary Calculi.** Bishop cites a number of cases which illustrate the difficulties of diagnosis encountered in actual practice, and the means which at the present time are most useful in differentiation.

8. **Hemorrhage from Superior Longitudinal Sinus without Fracture.**—Buzzard and Cunning attribute the hemorrhage in this case to the tearing away of a tributary vein, from its junction with the sinus, at the time of the accident. The search of the literature failed to reveal a similar case.

11. **Mercury in Tuberculous Meningitis.** Brown records the beneficent effect of munctions of mercurial ointment, and mercury, combined with the iodin and bromid of potassium, by the mouth in an unusually severe case of tuberculous meningitis. He is convinced that there are occasional cases of apparently genuine tuberculous meningitis that are cured by mercury, especially if the inunction is commenced early, if it is pushed, and if the patient's strength is maintained.

12. **Treatment of Internal Hemorrhage.** Dixon endeavors to show that the tannins, adrenalin, digitalis and its allies, ergot, veratrine, barium and lead are all worse than useless in the treatment of nosebleed or hemorrhage from the brain or the liver. Calcium, in his opinion, is the drug for that purpose, administered preferably in the form of the chlorid. In urgent cases the drug should be given subcutaneously. For this purpose the calcium chlorid should be neutral and injected deeply, in one or two grain doses, into subcutaneous tissue, so that the local irritant action of the drug may be avoided

14. **The French Yellow Fever Commission.**—This article is the third published by the French yellow-fever commission to Brazil. It describes experimental research in the biology of the *Stegomyia fasciata*. It was found that the female mosquito is capable of biting man from the first days of its adult existence, but that it very soon ceases to bite during the day, especially after it lays its first batch of eggs. The result is that under normal conditions the transmission of yellow fever does not occur during the day, that is, between 7 a. m. and 5 p. m. The ingestion of living blood is indispensable for the development of the eggs. The blood loses this property of favoring the development of the eggs if it stands even a short time. The stegomyia is capable of laying several batches of eggs, sometimes as many as seven, after a single coupling, on condition that blood be ingested anew after each laying. As a rule the stegomyia lays two or three times. It is this faculty of surviving to lay several batches of eggs which distinguishes the stegomyia and permits it to be the vehicle for the transmission of yellow fever. In children yellow fever runs a very mild course. The mortality is nearly zero during the first year of life, and is very low up to adult age. Abortive or "frustes" cases are noted at all ages, but are the rule in children. They confer immunity, however, although the durability and strength of this immunity vary with individuals. It may be re-enforced by recurrences. Recurrence of yellow-fever probably happens oftener than is generally recognized. It may escape observation on account of the extreme mildness of the symptoms, although a recurrence is liable sometimes to be a serious affair. Relapses are rare. When they occur they are generally very severe.

17. **Pain in the Liver in Asthmatics.**—Gilbert and Villaret call attention to the pain distinctly localized in the liver region which may be observed in some cases of asthma, the exacerbations of the pain corresponding with the attacks of asthma. This hepatalgia may occur at any stage of asthma, although less pronounced in its early phases. It may become so severe as seriously to incommode the patient. They relate the particulars of three cases of this kind; the patients had all reached the stage of emphysema. The pain in the liver region had been long observed; it was increased by pressure, but was not accompanied by any appreciable enlargement of the organ. They attribute the condition to congestion of the liver from impending asystelia. The cholemic condition of their patients, the persistence of the pain between the attacks of asthma, its resistance to all the usual therapeutic measures, and the prompt relief after blood-letting, are a train of symptoms revealing passive congestion on the part of the parenchyma of the liver. When the congestion has continued until there is destruction of part of the liver tissue and of the nerve terminals, the organ becomes less sensitive. In 2 cases the patients were relieved of the hepatalgia by absolute repose, a milk diet and venesection or wet-cupping. In one case the hepatalgia had been noted for fifteen years.

22. **Good Tubes for Radiotherapy.**—Noiré describes the requisites for a good tube in radiotherapy He remarks in conclusion that in Sabouraud's service, where more than six thousand sittings have been given the best results were invariably attained with an anticathode of platinum or some other metal, but always re-enforced, the glass very thin, and the tube not more than 8 cm. in diameter.

25. **Passive Congestion and Massage for Sprains and Contusions.**—De Gaulejac reports remarkably rapid healing of sprains treated with Bier's technic for artificial hyperemia. It relieved the pain much better than other measures and the after-results were unusually fine. Constriction of the limb induces dilatation of the vessels and a hyperphagocytosis which produces excellent conditions for massage to complete the cure. Constriction is applied for only from fifty to sixty minutes on the first day as it is liable to increase the pain at first. The sittings are prolonged to an hour or two on the following days. When the tourniquet is removed the injured member is massaged for ten or fifteen minutes and a flannel band wrapped lightly around it. When the lesion is on the trunk Gaulejac applies cupping around the lesion. Immobilization is imperative in all cases. He commends this combination of passive congestion and massage as a great advance in the treatment of sprains and of slight or moderate contusions.

26. **Signs of Hysteric Hemiplegia.**—Ingegnieros reports a case of hemiplegia, which presented all the signs of an organic affection, and yet the symptoms altered under hypnotic suggestion and finally yielded entirely to simple psychotherapy.

27. **Deep Injections of Alcohol in Treatment of Facial Neuralgia.**—Levy and Baudouin describe their technic for injecting the nerves at their emerging points and relate that this procedure is proving a perfectly harmless and effectual means of treating rebellious facial neuralgia. (See abstract 34, page 390.) After considerable experimental and clinical research they have adopted the following dosage: They inject 1 or 2 c.c. of alcohol, first at 70, then at 80, and then at 90 per cent., with or without cocain. They then add four drops of chloroform to each c.c. and repeat the procedure. They use a special needle which has a sharp point, but also has a blunt guide inside which can be adjusted to project beyond the sharp tip of the needle and to transform it into a blunt tip. This can be pushed into the tissues without danger of injury. They describe the technic for inserting the needle so as to reach the trunk of the inferior maxillary as it emerges from the foramen ovale, also the superior maxillary at its emerging point and the ophthalmic nerve. From six to eight injections are generally needed. They are given at intervals of three or four days. Experience has demonstrated that it is necessary to inject at least two of the branches of the trigeminal. These deep injections of alcohol have been used by these authors in six cases of extremely severe trigeminal neuralgia with almost continuous pains, accompanied by muscular twitchings, and of several years' duration. Medical treatment had long ceased to relieve and two operations on the peripheral nerves in one case had been unsuccessful. None of these patients has any further neuralgia. Four others still under treatment are very much improved. None of the cases in which the neuralgia was mild or of recent development is included in this report. The simplicity and harmlessness of the method commend it for general adoption, they say, even if recurrence should be observed later in some cases. Allaeys of Antwerp has been equally successful with 3 cases of old, rebellious neuralgia, while Ostwalt, Schlösser and others now number their cures by the hundreds.—Ed.]

29. **Danger from Ingestion of Tubercle Bacilli Killed by Heat.**—Calmette and Breton announce that guinea-pigs after experimental tuberculosis infection, either by the mouth or by intraperitoneal injection, succumbed much sooner than the controls under repeated ingestion of small amounts of tubercle bacilli killed by boiling. The repeated ingestion of tubercle

bacilli killed by boiling caused disturbances even in sound guinea-pigs, the symptoms observed resembling those induced by several small doses of tuberculin at intervals of a few days in non-tuberculous animals. Experiments are now under way to determine whether these same conclusions apply to larger animals, cattle and goats. Enough has already been learned, however, to warrant the statement that tuberculous products, even when sterilized by heat, are liable to be dangerous for persons already infected with tuberculosis, and may not be entirely harmless even for healthy persons. Milk from tuberculous cows, therefore, should not be used, even after thorough boiling, as this does not render it entirely harmless. Its use should be absolutely forbidden for children and for tuberculous adults. In conclusion Calmette and Breton add that these new facts should impel the powers that be to exercise still stricter supervision over dairy farms and to insist on the systematic use of the tuberculin test. Calmette published last October an announcement that experimental ingestion of bovine tubercle bacilli, even in small doses, repeated two or three times, entailed the tuberculization of the lungs, while the mesenteric glands were left intact. On the other hand, tuberculosis of the mesenteric glands invariably followed when kids were suckled by goats with tuberculous mammitis. The lungs rarely showed tuberculous lesions in this case. Tuberculous infection also invariably resulted when guinea pigs were given 1 or 2 c.c. of freshly dried bovine tubercle bacilli mixed with potatoes or carrots at a single meal. Young guinea-pigs, not more than ten or fifteen days old, died of the infection in about sixty-two days afterward. The mesenteric glands were the seat of advanced tuberculous lesions, and in most cases the peri-bronchial glands were also involved, but no tubercles were visible in the lungs. The adult guinea-pigs succumbed about twelve weeks after the single infecting meal (2 cg. of freshly dried bovine tubercle bacilli). When the infected animals were fed afterward with a few small doses of tubercle bacilli, killed by heat, the anatomic alterations found were identical with those observed in guinea-pigs treated with small, repeated doses of tuberculin, namely, discoloration and enlargement of the kidneys, with hypertrophy of the suprarenal capsules and liver and granular fatty degeneration of the latter.

32. **Appendicostomy.** Lanz says that he has never lost a patient in his 710 cases of appendicectomy out of 1,286 cases of appendicitis, and has never had but one fecal fistula after the operation. He attributes his success in part to the fact that he operates in two sittings in gangrenous cases. He brings the base of the appendix out and sutures the peritoneum carefully, and also the soft parts around it. This part of the appendix is then resected, merely the stump still projecting from the center of the sutured incision, with a catgut ligature around the base of the stump. The whole is covered with collodion, changed every few days, and removed on the tenth day, after which the stump is cauterized daily with silver nitrate. The tip of the appendix in his first case thus treated was imbedded in an abscess, and nothing was done to free it on account of the friable condition of the appendix and the complex adhesions. Nine months later the patient, a man of 56, experienced slight pains in the scar and a pulling sensation, with slight nausea. The appendix was easily extirpated this time, with an extra-appendicular abscess the size of a bean. No bacteria were found in the obliterated appendix nor in the abscess. In some later cases this operation in two sittings has proved remarkably successful. At the second sitting the appendix, which had been immovably fastened at the first operation, could be removed without the least difficulty. In appendicitis he operates if possible during the first or second day, but after this only when compelled by vital necessity, and then limits intervention to opening the abscess and draining the peritoneum. When the inflammation has subsided and the patient has entirely recovered he removes the appendix.

35. **Postoperative Ileus.**—Wilms describes the mechanism by which the paralysis of even a short stretch of intestine is able to form a kind of valve, closing the passage.

36. **The Leucocytes.**—Schridde's conclusion from much research is that in the postembryonal life the lymphocytes and leucocytes are two absolutely distinct races of cells. Lymphocytes can be produced only by the lymphoblasts, while the myeloblasts produce only leucocytes. The place of origin of the latter is exclusively the bone marrow, and that of the lymphocytes the lymph follicles.

37. **Intermediate Host of Cancer.**—Schmidt believes that he has discovered in a certain fungus the intermediate host of the protozoan parasite which he considers responsible for malignant tumor growth. He has previously announced in the "Communications from His Cancer Research Laboratory" (published by Hager of Bonn), his technic for showing these parasites. The fact that he was unable to cultivate them on the ordinary culture media convinced him that an intermediate host was involved. It might be an insect or a plant. He has found on the *Mucor racemosus* cultivated from malignant tumors certain formations which have nothing to do with the spores, sporangia, mycelium or buds of the fungus, while they are apparently identical in every respect with the protozoan parasite of cancer. They are spontaneously motile and grow by endogenous spore formation. In the parasites as observed in cancer, the ameboid, vegetative forms are most predominant, while on the fungus the sexual forms prevail and the ameboid forms are rare. Specimens of *Mucor racemosus* taken from cancers always developed these characteristic forms, while none was ever found on specimens of the mucor from other sources. In experiments on 80 animals, 6 true tumors developed after inoculation with the mucor containing the suspicious formations, 5 of the tumors of unmistakably malignant character. In one of the animals, a mouse, multiple metastasis was observed. Ehrlich has recently reported that the mice which spontaneously develop malignant tumors are almost invariably females and old. In Schmidt's researches he made a point of inoculating only just matured animals, and the malignant tumors developed in four males and two females. Microscopically the tumors seemed to be identical with Jensen's mouse tumors. Their malignant character was confirmed by the microscope, by their transmissibility, by transplantation of cells to other individuals of the same species, and by the development of metastases. These and other experiences convinced him of the specific nature of his parasite, and he proceeded to study the local and general reac-

tion that follows injection of killed pure cultures of the parasite, hoping to utilize the specific reaction as a means of curing cancer in the clinic. He describes the results observed in five out of a larger number of cases thus treated at Czerny's clinic. The general and local reaction was unmistakable, while no reaction was observed in healthy persons. The objection that possibly the mucor itself might be responsible for the tumor formation and reaction he answers by calling attention to the fact that this mucor never grows at the temperature of the body of warm-blooded animals, although the spores may remain in it for months and not lose their germinating power.

39. **House Series of Cases of Acute Articular Rheumatism.**—Schlbach states that he has had occasion to observe three cases of articular rheumatism occurring during February or April of three successive years in a two-story stone flat building. None of the three patients had ever suffered from tonsillitis, he says. The first case developed after the house had been built a year, and five years have now elapsed since the last case. The air seemed damp on entering the house during the first year or so after it was built.

43. **Elimination of Uric Acid, Etc., During Roentgen Treatment of Leukemia.**—Rosenberger summarizes his research in the statement that under Roentgen treatment the elimination of uric acid increases in leukemics. He was unable to detect any increase of this kind in other patients. If the proportion eliminated increases, the prognosis becomes less favorable, as the elimination diminishes as the patient shows other signs of recovery. The elimination of the xanthin bases increases during radiation and its after-effects.

47. **Precipitin for Cow's Milk in Infant's Blood.**—Moro and others were unable to find any traces of specific precipitins for cow's milk in the blood of infants with gastrointestinal troubles in their research a few years ago. They reasoned that if the injured lining of the intestines allowed the passage of albumin from the cow's milk into the blood, this fact would be revealed by the production of a precipitin, readily manifest in the biologic test. Their results were all negative, but resuming the research recently, Moro found intense precipitin action in the blood of an infant with general atrophy. The large amount of precipitin present indicated that albumin from the cow's milk must have been being absorbed for a long time. Albumin from cow's milk circulating in the blood can not be regarded as a harmless condition. Salge found that even 0.1 c.c. of cow serum, corresponding to 0.007 gm. cow albumin, caused the severest symptoms when injected subcutaneously into nurslings, in some instances inducing threatening collapse. Moro discusses the possibility of the atrophy being the result of the alien albumin in the blood.

49. **Infant Mortality and Survival of Fittest.**—Koeppe presents new statistics which confirm his previously published views that a high infant mortality does not indicate that the survivors are particularly well adapted for the struggle for existence. On the contrary, the same causes which induce a high infant mortality in the first year presumably still operate to induce high morbidity in the following years.

50. **Ovariotomy in Finland.**—This article opens with a reference to the "father of ovariotomy," Ephraim MacDowell, stating that the first ovariotomy in Finland was done in 1849, forty years after his pioneer work. Germany followed his lead in 1819, England in 1825, but France not until 1844. Out of the 424 ovariotomies performed at Helsingfors nine were done for recurrence of the lesion, requiring a second operation. Of the total number 385 patients were dismissed healthy, 2 only improved, 3 not benefited, and 34 had died, the majority cancer cases. Later information has been received from 303 patients after an interval of from a few months to twenty years. Among the 211 who were found healthy were 4 women who had been operated on for carcinoma, 35 for dermoid cystoma, 47 for pseudomucinous cystadenoma, 1 for adenocarcinoma, 3 for fibroma and 93 in which the character of the affection was not known.

Classifying the after-results according to the character of the affection for which the ovariotomy was performed, he found in 60 cases of pseudomucinous cystadenoma that 47 of the patients were entirely healthy, while 3 patients exhibited recurrence and one had nephritis a year afterward. In 20 cases of carcinoma or adenocarcinoma only 4 of the patients are free from recurrence after an interval of from one to four years. In 43 cases of dermoid cystoma, 35 patients are healthy (one month to 15 years); 6 have pains in the abdomen and general weakness, and 2 have died. The 3 patients with fibroma are all well; the 2 with endothelioma died not long after the operation, as also those with sarcoma.

51. **Sarcoma of Rectum.**—Key's first patient was a man in the fifties who had long suffered from hemorrhoids. A pedunculated tumor supposed to be a polyp was excised from the posterior wall of the rectum, and two years later another similar tumor was removed from the same site. It proved to be a melanoma, and a third recurrence required extirpation six months later. The patient succumbed to the affection in less than a year afterward. The case illustrates the peculiar malignancy of melanoma, and the importance of an early and radical operation. The second patient was a woman of 52, who had noticed slight discomfort and moisture at the anus for seven or eight weeks and finally felt a small tumor. There was no pain. The tumor resembled a hemorrhoidal varix, but examination showed ulceration and a little blackish secretion. A few lumps could also be felt a little higher up, and the inguinal glands were somewhat enlarged. The growths and glands were extirpated, and a recurrence took place five months later. The melanoma then recurred at various other points in four or five months. These tumors were also extirpated, but the patient began to lose strength a year after the first symptoms, and succumbed in the sixteenth month. The third tumor reported was a very vascular, round-celled sarcoma. There had been preceding hemorrhoidal troubles with considerable bleeding. A year before the operation the patient noticed that a plug about an inch long, the size of the little finger, protruded from the anus during defecation; this gradually increased in size, and there was pain and finally difficulty in urinating. The tumor was excised, but soon recurred, and the patient committed suicide. Key has been able to find only 60 cases of sarcoma of the rectum on record, omitting the dubious ones, and 38 of these were described as melanosarcoma. The youngest patient was 6 and the oldest 70 years of age. The ages of the patients with melanosarcoma ranged from 20 to 70. The average for 28 cases of melanosarcoma was 50.2 years. Males predominated. The symptoms are those of cancer in general. The feeling of a foreign body in the rectum is frequently a sign of a pedunculated tumor. In removing the growth mere excision is not enough; extensive resection is necessary.

54. **Otosclerosis.**—Möller's review of the literature can be summarized in the statement that otosclerosis is a special morbid entity with its own pathologic anatomic foundation, a characteristic new formation of bone in the interior of the labyrinth. It is a primary affection and does not depend on former affections of the ear. The characteristic syndrome includes progressive bilateral deafness, with an insidious course, occurring especially in young people in whose family similar cases already exist. The picture of the tympanic membrane is normal, or possibly showing redness shining through. There is also reduced bone conduction, restriction of lower and upper sound limits, and negative findings with the Gellé test. In treatment he warns against the air douche. Lucae's spring pressure catheter sometimes gives good results, but is liable to be painful. Vibration of the ear drum is a better measure, whether done with the Delstanche suction instrument or the Siegel, or merely by intermittent pressure on the tragus. Breitung's air pump is the most effectual. With the aid of

these the hearing can be improved in many cases, and in others can be kept from growing worse, while the subjective sounds are frequently cured. Operative measures do not offer much advantage, while they are inclined to be dangerous. Transient benefit has sometimes been obtained from administration of potassium iodid, quinin, sodium bromid, etc., but striking success need not be anticipated. Administration of phosphorus is more promising, and, he states, is certainly worth a trial, giving one or two tablespoonfuls a day of a 1 to 10,000 solution of phosphorus. Siebenmann has reported that the phosphorus arrested the progress of the affection in 50 per cent. of his cases. Much can be done in the way of prophylaxis. The affection shows a special tendency to run in families, and the younger members of such families should be guarded with special care. They should be kept from "catching cold," from exposure to sudden climatic changes, and from overexertion, both mental and physical. The diet and hygiene generally should be supervised, tobacco and alcohol avoided, and nervous, especially vasomotor disturbances, should be combated, while all nose and throat affections should be carefully treated. Members of these otosclerotic families, he adds, should be warned against matrimony. In 10 of the 36 cases a catarrhal affection of the eardrum was manifest, but it was so slight that it could not have been an important factor in the process. Only in one case was there a history of preceding suppuration in one ear.

55. **Encephalitis.**—Laache discusses the curability of encephalitis and describes 6 cases of the disease. One of his patients had suffered from a similar affection years before, with ten years of health before the fatal recurrence. Only one patient was a man; the symptoms of encephalitis in his case had been preceded by chronic hematuria from cystopyelitis. The process in the brain was in the right hemisphere and was very extensive, inducing numerous contractures of the muscles of the limbs and face and stupor suggesting chronic uremia. Tham has reported a somewhat similar case in which meningo-encephalitis caused a kind of sleeping sickness beside the convulsions, with normal intervals. One of Laache's patients presented symptoms suggesting tuberculous meningitis. The postmortem findings are shown in colored plates, the symmetrical hyperemia on each side of the longitudinal sinus being especially prominent, as also the thrombosis in the veins of this region. There was nothing in the history of the case of acute hemorrhagic, non-suppurative polioencephalitis to suggest a preceding infectious disease as responsible for the condition. The other patients were 5, 10 and 20 years old, respectively. There was nothing to indicate syphilis in any case.

62. **Recovery After Meningitic or Pseudomeningitic Conditions.** Laache reports 5 cases in which he was told by the patients that at some previous time they had passed through an illness, the symptoms of which, as related, seemed to have been those of meningitis (not the epidemic variety). Recovery from meningitis is so rare that he investigated the cases and has kept the patients under supervision since. The first patient was a girl of 4, tuberculous and psychopathic, with a tendency to rachitis. The acute cerebral affection had a sudden onset, but the child slowly regained her health. The second patient was a woman of 21, who suffered from diffuse headache, with rigidity of the neck, vomiting and slow pulse after a sun bath. This was possibly a case of sunstroke. Rapid improvement soon followed. The patient now shows signs of consumption. The third patient was a lad of 13 whose brother had recently died of tuberculous meningitis. The patient was addicted to cigarette smoking. He suddenly exhibited headache, rather slow pulse, slight temperature, rigidity of the neck, and a transient exanthem. He rapidly improved under iodoform salve externally and potassium iodid internally. The fourth patient was a young woman who recovered under Laache's eye from a second attack of serous meningitis, after an interval of nearly three years. The symptoms began abruptly the second time without a prodrome. The condition gradually improved to complete recovery after several weeks. The fifth patient was a young clerk who had an affection of the face, possibly erysipelas, followed by great prostration, headache, bradycardia, double vision and facial paralysis. Complete recovery followed after a protracted convalescence. Pseudomeningitic symptoms may be induced by febrile and infectious diseases, especially in young children and in the aged. Pneumonia in children frequently affects the brain. Cephalalgia may follow mumps and be accompanied by bradycardia, sometimes very pronounced. Laache has witnessed several instances of this. Pseudomeningitic symptoms may likewise be induced by disturbances in the circulation through the brain or may even be of merely nervous origin. In one male neurastheric he observed once an attack of prolonged and irregular migraine (intense headache with febrile states), the clinical picture strongly suggesting meningitis, but spontaneous recovery ensued in the course of a few weeks. An iodoform salve was rubbed into the shaved head in the 5 cases on which the article is based. Quincke has also obtained good results with mercury.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

ELLIS'S DEMONSTRATIONS OF ANATOMY. Being a Guide to the Knowledge of the Human Body by Dissection. Twelfth Edition. Revised and Edited by C. Addison, M.D., B.S., F.R.C.S., Lecturer on Anatomy, Charing Cross Hospital, Medical School; Formerly Hunterian Professor, Royal College of Surgeons, England. Illustrated by 306 Engravings on Wood, of which 75 are in color. Cloth. Pp. 851. Price, $3.50 net. New York: William Wood & Co.

THE PARASITISM OF THE TUBERCLE BACILLUS AND ITS BEARING ON INFECTION AND IMMUNITY.*

THEOBALD SMITH, M.D.

George Fabyan Professor of Comparative Pathology in the Harvard University Medical School.

BOSTON.

The present-day problems in tuberculosis which can be approached by experimental or at least by laboratory methods manifest themselves in three different ways:

1. In the somewhat chaotic condition of opinion concerning the avenues through which tubercle bacilli gain a foothold in the body.

2. In the wide divergence of opinion concerning the relation of bovine to human tuberculosis; and

3. In the general trend of studies toward the problem of specific immunity, with special reference to prevention and treatment.

These three problems, though distinct, are interrelated, and in a lecture of this kind, in which some freedom in the statement of theories and hypotheses and a rather broad treatment of the subject are not only permissible but desirable, it must be necessary to deal with each, to some extent at least. The most important of the three is the one dealing with immunity, and my statements will be grouped around and directed toward it as a focal point.

The method of treating the subject will be from a biologic standpoint which assumes as a basis for discussion a complex relationship established in time by a selective adaptation between two living organisms, of which one is a parasite of the other. Whatever pathologic processes of constant character are the expression of this parasitism, such as tubercle formation, for example, are regarded as the result of an interaction of two organisms rather than the work of one alone.

Viewed from this standpoint, this tendency toward a state of equilibrium between host and parasite is disturbed by any change of condition which influences either parasite or host. It varies with the species, race, nationality or even family of the host and many other accessory conditions. It depends on the race of tubercle bacilli. In experiments such conditions as age of culture, total period of cultivation, character of the culture medium, condition of aggregation of the bacilli, mode of application and dosage are of great importance in determining the outcome of the experiment. Similarly the outcome will vary according to the species of animal on which we are experimenting.

Much of the experimental inquiry of the past has been along too narrow lines and with the conditions too poorly defined. We have lost sight of the general relations of bacteria to animal life. Our haste to take the animal and bacterial mechanisms to pieces and to test the individual tissues and components have crowded out the broader view that the host fights more as a unit. We had almost forgotten to take into consideration the flexibility and adaptability of the micro-organisms themselves.

In a recent lecture I presented in a somewhat new aspect the relationship between host and parasite, by pointing out that in a stable parasitism the parasite is in command of a mode of exit from the body as well as one of entry. Both are necessary for the continued existence of the parasite as such. The evolution of this process has brought with it two related conditions: first, a lowered virulence or invasive power of the microbe, and, second, the tendency to attack mucous membranes, cutaneous surfaces or organs in direct communication with the exterior. The lowered virulence is only another expression for localization on the external surfaces among which mucous membranes and the respiratory tract may be placed for present purposes. As a result of this adaptation tuberculosis has taken largely the form of phthisis. That is, the parasite has become localized in an organ in direct communication with the exterior, yet largely protected from miscellaneous bacterial and other parasites. Its modes of exit and of entry are identical. The bacillus may vegetate in the lung tissue and it may be easily discharged outwardly.

Phthisis, however, is only one, even if the preponderating type, of tuberculosis. Much has been made of the other manifestations. Among these, disease of the lymph nodes, bones, kidney, brain and spinal cord must be considered aberrant from the standpoint of the bacillus, for in these situations, with the possible exception of tuberculosis of the kidneys, the bacillus is doomed to an ignominious destruction, because there is no exit. These aberrant forms of parasitism are most frequent in childhood, because, perhaps, the tubercle bacillus being, as it were, keyed to adult life, is for that reason more invasive for childhood.

To the biologist these types of disease are of interest as suggesting problems in susceptibility and resistance which, as stated above, are the problems through which experimental medicine may deal practically with this disease.

In order to bring out in relief certain general biologic phenomena of tuberculosis, I shall discuss, first, very briefly the mode of invasion of the body by the tubercle bacillus, then sketch a theory of the interaction of the body and the bacillus. I shall then discuss the tuberculin reaction and the action of dead tubercle bacilli and the procedures suggested or used for producing an increased resistance of the body.

I. THE INVASION OF THE BODY BY THE TUBERCLE BACILLUS.

Bearing on immunity, the problem which deals with the primary seat of tuberculosis and its relation to the

* Lecture delivered under the auspices of the Harvey Society of New York, at the Academy of Medicine.

portal of entry deserves consideration, since it is, to a certain degree, an index of susceptibility. The theories concerned with the mode of invasion of the tubercle bacillus may be classed under four heads:

1. The inhalation of dried sputa, as laid down by Koch and elaborated by Cornet and others.

2. The inhalation of moist particles, or spray infection, as formulated and worked out by Flügge and his pupils.

3. Congenital tuberculosis, resulting from infection *in utero*, as defended by Baumgarten.

4. The infection through milk in infancy associated with a greater or lesser degree of latency until puberty and even later, the theory recently championed by Behring.

In taking some definite stand as to which of these theories, if not all, should have our support, we may gain some evidence from a study of the primary seat of the disease, i. e., that place in the body where the presence of the bacillus is shown either by the existence of actual lesions or by animal inoculations.

In the largest number of cases of tuberculosis the lungs themselves have been regarded as the primary seat of the multiplying bacilli. In children, however, other conditions frequently prevail, and the primary seat of the active process may be in the cervical, the bronchial and the mesenteric lymph nodes; many authors have called attention to this fact. Weigert[1] referred to this over twenty years ago. He refers also to similar conditions for the bronchi, the mouth and the skin.

The most recent monograph of Harbitz[2] refers to it as follows: "The general rule in cases of children is that the lymph nodes are primarily attacked and that the lungs are infected from them. General experience teaches that isolated tuberculosis of bronchial nodes is quite common while isolated pulmonary tuberculosis, with or without a slight and plainly secondary lymph node tuberculosis, is a rarity in children."

Ribbert goes so far as to assume that pulmonary tuberculosis is mainly hematogenous in origin, the source of the infection being some lymph node primarily diseased.

Petruschky, in his various publications dealing with the curative power of tuberculin, has identified himself so thoroughly with this view as to regard and to classify lymph-node tuberculosis as the first stage in tuberculosis generally.

Baumgarten[3] has contended and still contends that tubercle bacilli always produce some lesion at the point of entry into the body. In taking this position he relies on animal experiments; but there are objections to animal experiments, inherent in the difficulty of approximating natural conditions. The local lesion in animals may be due to a variety of causes, among which are local trauma, dead and attenuated bacilli and chemotactic substances due to autolysis in the cultures, and the want of adaptation of the bacillus to the species of animal used. Compare these with the entry of a solitary bacillus or perhaps several bacilli in a dried condition, without producing trauma or any chemotactic response, and we see at once the difference between the natural and the experimental mode of invasion.

The invasion of tubercle bacilli into the lymph nodes without causing disease at the point of entry has interested me since I began the study of bovine tuberculosis, in which disease such invasion is the rule, and I shall take this opportunity, therefore, of describing this phenomenon in the cattle disease more in detail. I will premise my remarks on this subject by stating that mammalian tuberculosis appears in two independent types—human and bovine. If either human or bovine type were suppressed the other would still continue. The best evidence on this point was presented by Kitasato, who demonstrated that in Japan the human disease existed in its usual activity, though the cattle disease was absent and milk formed no appreciable element in the food of children. Most other mammals at times have been found infected, either from human or bovine sources. In these a satisfactory mechanism does not exist to perpetuate a porcine or canine or feline type of disease. The bovine disease is the best, therefore, for study, next to that of man himself.

Soon after the recognition of tuberculin as a valuable diagnostic agent, astonishment and consternation were created by the discovery that a very large percentage of the best dairy cattle of the world reacted to tuberculin. Under the influence of this discovery some ill-considered laws were passed to destroy all reacting cows and their flesh, for the purpose of eradicating the disease. During these few years of active warfare, beginning in 1893, I was able to make autopsies on about 350 head of cattle which has reacted to tuberculin. This enabled me to get a good composité picture, as it were, of the early stages of the disease and to determine the primary foci with considerable accuracy. A portion of the results of this investigation was published in 1894;[4] the rest has remained in manuscript form.

In cattle, tuberculosis is an exquisitely parasitic disease, in which the chief seat of the lesions is in the lymph nodes. Next in order come the lungs, then the liver and serous membranes. Furthermore, it may occasionally be encountered in almost any other organ and tissue.

There are three portals of entry, the upper respiratory tract (mouth and nose), the lungs themselves and the small intestines. Very rarely the skin or subcutis has given entrance. The infection through these portals is indicated chiefly by disease of the corresponding lymph nodes. In the head, for example, the pair of retropharyngeal glands are the chief indices of infection. They are situated close together under the mucous membrane covering the dorsal or posterior wall of the nasopharynx. The other lymph-nodes of the head are infrequently diseased and need not be considered here. The mucous membrane is free of disease; the tonsils are very rarely infected. The progress of the infection along the chain of nodes in the neck is slow, and the infection of the head glands has little, if anything, to do with the primary or secondary disease in the thorax.

Tuberculosis due to inhalation of tubercle bacilli is by far the most common. The lungs and associated lymph nodes may be infected or only the latter. The thoracic lymph nodes in cattle belong to three systems, the tracheal and bronchial nodes closely attached to the trachea and its branches, and draining the peribronchial and perivascular lymphatics, the dorsal mediastinal

1 Deutsche med. Wochft., 1903, p. 735. "In adults, for instance, we find so frequently the familiar tuberculous lymphatics issuing from ulcerations in the intestines while the lymph glands pertaining to them show comparatively slight changes. In children, on the contrary, we often encounter the reverse, pronounced caseous changes and swelling in the mesenteric glands while no morbid process can be detected in the afferent lymphatics, even into their trunk region."

3. Berliner klin. Wochft., 1905, p. 1329.

4 Bulletin No. 7, 1894, Bureau An. Ind. U. S. Dept. Agric.

chain or chains dorsal of and resting on the pillars of the diaphragm and on the esophagus, which probably drain the lymphatics of the lung tissue itself, and the interior mediastinal glands situated under the first rib; that is to say, in the apex of the thorax. That the bronchial and dorsal mediastinal glands drain the lungs is shown by their similar structure, pigmentation and contents of very fine particles of mineral matter coming from the air. The third group has no pigment and probably drains the pleural cavities only. It may also stand in some relation to the cervical nodes.

In all herds which were examined there was a considerable number of animals in which the pulmonary infection resulted in lymph-node disease only. In one herd of sixty animals, for example, of which fifty-three were infected, twenty-seven had tuberculosis of the thoracic lymph nodes, but no lesions in the lungs.

Next in frequency comes disease of the lungs themselves. The chief seat is in the large caudal lobes. In man the upper or cephalic lobes are the preferred seat. In cattle the invasion is just where one might suppose it to be when coming from bacilli suspended in air; it is in the direct line of the current and in the lobe which goes through the widest excursions. That most of the infection lodges here I also infer from the fact that the one mediastinal gland which evidently drains this portion of the lungs is the most frequently infected lymph node in the whole body. The infection through the intestines shows itself almost exclusively in tuberculosis of the mesenteric lymph nodes and in disease of the liver. Lesions of the mucous membrane are extremely rare.

This very hasty and imperfect sketch of the primary foci of tuberculosis in cattle shows that the bacilli usually enter the system, first, in the inspired air or in the food through the mucosa of the mouth or throat; secondly, through the lungs in the inspired air, and, thirdly, through the intestinal mucosa in bacilli swallowed in the food. The most striking fact is the passage of the bacilli through the mucous membrane or the air cells into the associated lymph nodes without leaving any trace visible to the naked eye or detected by manipulation. I am convinced, therefore, that Baumgarten's theory can not be maintained in the bovine disease and that tubercle bacilli may pass through at least one gateway of the body without being detained.

The tendency of the tubercle bacillus to settle down and to multiply in the lymph nodes in cattle is manifested in still another way. When the disease becomes generalized by the escape of bacilli from some primary focus into the general circulation, the secondary disease does not give rise to a miliary tuberculosis, but isolated foci may appear in various organs. Even these may be absent and the infection of the organ or the passage of bacilli through it indicated by marked affection of the corresponding lymph glands. Thus the evidence that bacilli have passed through the liver and kidneys is frequently indicated only by tuberculous portal and renal lymph nodes respectively. Evidence of udder infection is frequently presented only by tuberculous pubic lymph nodes. That submiliary tubercles may be found in these organs is not to be denied. I have found a few in the liver in an advanced stage of the disease, composed only of a giant cell and a few epithelioid cells around it. The fact remains that the lymph nodes act toward these organs very much as the lymph nodes of the lungs do in the primary infection.

There are a few other data derived from a study of the distribution of tuberculous lesions in cattle which are of interest here. In the disintegration of pulmonary foci the bacilli may pass in two directions, into the associated lymph node or outward by rupture into the air tubes, or both ways at the same time. Passage into the lymph channels is signalized by an enormous hyperplasia of the dorsal mediastinal and certain bronchial nodes. The bulk of these may be increased from twenty to thirty times. The tuberculous process is in the same stage throughout, which indicates a sudden flooding of the gland. When the discharge is outward, yellowish, caseous masses are found at the autopsy in the smaller air tubes. Ravenel has demonstrated that these masses are actually ejected during coughing. The mucosa of the air tubes themselves is not infected primarily, and eruptions, ulcers and catarrh are subsequent to the discharge of caseous matter. The latter acts both as an irritant and an infecting substance. Infection of other, notably the cephalic or smaller, lobes is brought about by aspiration of the caseous masses. These smaller lobes are more dependent and subject to the gravitation of fluids and semisolid matter.

The careful noting at the autopsy of the approximate age of the tuberculous lesions led me to conclude that infection through one of the avenues mentioned has, as a rule, nothing to do with the others. That is, there seemed to be no connection between tuberculosis of the mesenteric glands and pulmonary disease. It was noticed, however, that the stage of disease in the thoracic and abdominal lymph nodes was in many cases the same. The inference was that the animal was infected at the same time through two or even three different portals. The theory of Behring that tuberculosis starts in early life through the digestive tract is inapplicable as a rule to the bovine disease.

Concerning the mode of invasion of tubercle bacilli in rabbits and guinea-pigs through the natural portals, without the infliction of a trauma, as by subcutaneous inoculation, or the circumventing of certain channels, as by injections directly into the peritoneal cavity or the blood, I have no data of my own. There is evidence, however, to show that in these animals also the lymph nodes form the earliest foci of multiplication in feeding and inhalation experiments, and that the bacilli soon break away through this barrier and are diffused in the blood current over the body.

In the pig the ingestion of infected milk leads at first to tuberculosis of the head and cervical lymph nodes and those of the mesentery from which stations generalized infection by means of the blood takes place very soon.

A most important question is raised by this penetration of the tubercle bacilli to lymph nodes. How far may they penetrate before they settle down? Do they go beyond the first lymph node? Do they ever reach the blood directly from without? The conservative notions of twelve years ago would hardly admit the penetration of tubercle bacilli below the mucous membranes. To-day the extreme and radical notion of Behring that infection occurs early in life and may remain latent and that tuberculosis in later life largely dates from infancy is being seriously and widely discussed. This preparedness to receive and to discuss such a statement is partly due to the strides made in the study of parasitism. We have become accustomed to the complicated dual-host system of malarial and other blood parasites, the wanderings of the larvæ of uncinaria from skin to duodenum and of larvæ of certain flies from esophagus to skin. The revival of instructive studies in animal parasites brings back again the complicated life cycle of tape-

worms and flukes. Among the bacteria it seems well established that glanders bacilli may enter the body of horses through the digestive tract. Nicolas and Descos[5] showed that in the dog tubercle bacilli may appear in the thoracic duct after a meal of fatty substances impregnated with them. Ravenel[6] confirmed their observations. There is good reason, then, for anticipating discoveries or theories which might greatly simplify our view of infection.

In my studies of the bovine disease I was unable to see anything more than the localization in the lymph nodes of the invaded part or perhaps a very slow creeping along to the succeeding nodes. I am not inclined to accept the extreme view that tubercle bacilli may penetrate very far into the system at the start. The view that they may enter the blood during invasion is derived partly from artificial inoculations. In such experiments more or less injury is always inflicted and the bacilli may enter both blood vessels and lymphatics. In the spontaneous infection, the bacilli under the lymphatics only and the nodes act as a temporary or permanent barrier. The positive experiments with dogs quoted above can not very well be generalized to apply to the spontaneous disease until similar experiments have been made on other species with bacilli from various sources.

II. THE RECIPROCAL ACTION OF BACILLI AND THE INVADED ANIMAL TISSUES.

The passage of tubercle bacilli through mucous membranes and the alveoli of the lungs into the nearest lymph nodes is probably made in the same way and by means of the same agencies by which particles of soot, quartz and other mineral particles are conveyed, that is to say, as inert matter for the time being. The lodgment in the lymph nodes is probably due to mechanical agencies, the nodes acting as filters and barriers.

Here the bacilli begin to multiply and to set in motion that complex series of events leading to tubercle formation. Taking a tubercular focus in one of the thoracic lymph nodes of cattle, the first visible sign of the presence of the bacillus is the proliferation of epithelioid cells, with single nucleus or multiple nuclei. This new tissue undergoes central necrosis and caseation. The surrounding tissue proliferates to form a more or less dense capsule and the process comes to a standstill.

If we endeavor, with the aid and guidance of existing knowledge, to construct a sequence of the factors which are concerned in this process of tubercle formation, we shall find it extremely puzzling. It has occupied my attention for a number of years, yet even to-day with the help of the many currents of experimental data coming from so many laboratories I realize that we may choose several widely different interpretations without coming into violent collision with what we may regard as reliable experimental data.

At the outset it may be said that the tissue proliferation in tuberculosis is something specific in character, varying slightly from host to host. In man and cattle it is much the same. In the smaller animals, either spontaneously diseased or inoculated, the tuberculous tissue is still characteristic, but giant cells are rare or absent. These, as a rule, are absent when the process is very rapid. In those species to which the bacillus has adapted itself, man and cattle, the cell proliferation is most uniform and characteristic.

The tissue reaction leading to the quiescent focus above described I believe to be a mechanism of defense for the body, even though imperfect. I also believe that it is a mechanism of defense for the tubercle bacillus—a mutual product, as it were. The structure of the tubercle interferes with the further dissemination of the bacillus by clogging the channels of escape. The bacilli become embedded in the proliferating cells and the necrosis protects the surviving ones from further attack for the time being. We can conceive that if this cell proliferation is somewhat delayed, the final result is a much larger focus. If it is still more delayed, the bacilli may be carried into other lymph nodes of the series and may establish several foci. The stimulus for such proliferation rests somewhere with the bacillus. It was shown many years ago by Prudden and Hodenpyl, by Straus and by many others later that dead, even boiled and washed, bacilli stimulate cell proliferation of a more or less specific type. We know also that such proliferation goes on in the presence of living bacilli, for an indefinite number survive the whole process.

In view of the fact that living, though very attenuated, tubercle bacilli are far more effective in producing immunity than dead bacilli, a fact brought out by Behring, Koch, Trudeau and others, we are safe in granting that the formation of the tubercle is stimulated by something given off from the living bacilli and not destroyed by heat. The simple stimulation of cell growth by the multiplying bacilli, however, does not fully explain the matter. There is an additional element which enters here, and this probably resides in the blood and to a less degree in the lymph. The blood is evidently an unfavorable medium, as indicated by the location of tubercles in the various animal species.[7] In order to account for the facts as nearly as possible, the following theory has been evolved during the past seven or eight years:

The tubercle bacilli as they come directly from some discharging focus are provided with some protecting, more or less inert substance as an envelope. This envelope maintains a neutral chemotaxis until the bacillus reaches the connective and lymphatic tissue, where it settles down. The protecting envelope is slowly removed by the normal tissue fluids. When this has been accomplished the bacilli are able to multiply, but during multiplication they stimulate cell proliferation and, according to the activity of this process, the multiplication is checked. The bacilli are destroyed in part; the rest, through the protecting influence of caseation, remain latent, provide themselves with the protecting envelope, and if discharged outward are ready to infect another individual.

It will be noticed at once that the theory presented has much in common with the theory of opsonins which A. E. Wright has developed with so much skill and industry since 1902.[8] We may as well call the blood factor the opsonin, in deference to Wright, as the one who first called attention to it as a normal element. I do not agree with Wright, however, in attributing any special rôle to the blood leucocytes in body defense, for there is little or no evidence of this in the tissue reaction to the tubercle bacillus.

The many observations which refer to an early phagocytosis by leucocytes when bacilli are injected may be explained in two ways: First, as due to neglected fac-

6. Jour. Med. Research, vol. x, 1903, p. 460.

7. Maragliano states that he has been able to cultivate tubercle bacilli successfully only on guinea pigs' serum.
8. Bulloch: Practitioner, Nov. 1905; a general summary and bibliography of Wright's work.

tors inherent in the cultures used. These are the injection of too large numbers of bacilli, attenuated by long cultivation, and many of them dead, autolytic products, and the production of trauma during inoculation. The attenuated and dead bacilli fall a prey to the leucocytes, and as soon as these are disposed of the true tubercle appears. Second, it is possible that the virulent tubercle bacilli may be carried by leucocytes, as are inert particles of dust, pigment and mineral, and deposited in a favorable place. We should scarcely attribute much importance to the carrying of a particle of quartz dust from the alveolus of a cow's lung to a mediastinal gland as a protective measure.

Baumgarten justly calls attention to the errors lurking in the injection of large numbers of bacilli, and his theory that the elements of the tubercle are quite different from the wandering phagocytes has been fully sustained. The phagocytosis which appears to go on in the tubercle itself I regard as a hedging in, a suppression of multiplication rather than a destruction. Even the common appearance of bacilli in epithelioid and giant cells may be interpreted as a growing around the bacilli on the part of the proliferating elements rather than an actual ingestion. That destruction may finally occur is highly probable, but necrosis soon ensues to check this and protect the remaining bacilli. I am aware that this assumption of a protecting envelope which can be conceived of as a secretion may appear strained, but I have been unable to harmonize the facts with any other theory. In its support I presented in a recent paper facts observed in the cultivation of tubercle bacilli, some of which I quote here:

In the cultivation of tubercle bacilli the peculiar behavior of the bacilli first and last is best explained by assuming some change in the envelope or outer membrane of the bacilli. It is well known that it is very difficult and frequently impossible to obtain cultures of tubercle bacilli from tuberculous tissue in culture media in which they will grow readily after months or years of artificial cultivation. To obtain original cultures it is necessary to approximate as closely as possible the conditions obtaining in the animal body.

We can interpret this great change which the bacilli undergo in artificial cultures in two ways: 1. They make use of substances which at first could not be utilized as food. In other words, their metabolic functions have undergone a profound alteration. 2. The bacilli under artificial cultivation have eliminated something which has interfered with active absorption and assimilation.

I am inclined to accept the second theory and to assume that in the course of artificial cultivation a relatively impervious protective capsule has been gradually eliminated or modified, and, as a result, the growth and multiplication has become freer and more rapid. This elimination or modification of the envelope may go on by a selective growth of those bacilli which are most easily affected, or else the membrane may become modified in all bacilli because the active struggle with living tissue is in abeyance.

This theory also voices a condition which, I think, should be considered in any theory of immunity. I refer to the latency of tubercle and other bacteria in tissues. This latency of tubercle bacilli in lymph nodes has been demonstrated by not a few experimenters (Loomis, Pizzini, Harbitz and others).[9] According to theory here proposed, the tubercle bacilli are unable to multiply in the system when the opsonic power is too low, for the reason that the protecting capsules are not removed. Under such conditions the body is apparently immune, but really is in a state of hypersusceptibility. When the opsonic power rises the multiplication begins. This theory would also explain more rationally the greater activity of tuberculosis in certain decades of life.

It is far from my purpose to apply this theory to all invasive bacteria. Each group or species possesses certain morphologic and physiologic peculiarities which are overdeveloped or suppressed in the evolution of parasitism. The work of Denys, of A. E. Wright and of Neufeld has shown that, while lytic forces may control typhoid and cholera bacteria, they do not govern streptococcus and other infections, in which cellular activity in the form of phagocytosis plays an important part. The more rapidly growing bacteria may possess quite a different mechanism of defense. As pointed out by Dr. W. H. Welch, they may secrete substances in the body which we do not sense in the culture tube. These he calls toxins, while I should prefer to call them protective substances of the bacteria. According to either conception, they would be harmful, the toxin directly, the protective substance indirectly by neutralizing the protective substances of the animal body. Finally, the theory here presented holds only for the spontaneous disease of man and cattle, attacked by their own specifically adapted races of bacilli. In experimental work this mutual relationship is disturbed by the foreign character of the bacilli used, by the crude methods of causing infection and by the use of artificial cultures more or less modified.

III. THE PRODUCTION OF SPECIFIC ARTIFICIAL IMMUNITY TOWARD TUBERCLE BACILLI.

The overshadowing problem before society to-day is that relating to acquired immunity to tuberculosis in the individual and its influence on future generations. Can immunity be induced artificially and will the survivors transmit anything of value to their offspring? The relative mildness of endemic diseases has been at times referred to as indicating the inheritance of acquired immunity, but the increased resistance of the population to endemic diseases can be explained as a result of weeding out or selection. In a recent lecture I pointed out that, with the weeding out of the host, there goes on a weeding out of the parasite as well until two are eventually selected which maintain a kind of equilibrium toward each other. During the weeding out of the host the parasite must gain in power to keep up with the former. This selected race of bacteria or other parasites attacking a population hitherto unexposed to it may cause serious epidemics and lead to the belief that the permanently infected population had gradually inherited an acquired immunity, whereas selection may have done it. In spite of these discouraging possibilities, the face of medicine and of society in general is determinedly set toward the prevention and cure of consumption and every possible means will be tried to raise the resistance of the individual. To experimental medicine has fallen the task of seeing what can be done to raise the specific immunity artificially by making use of the tubercle bacillus, or any of its component substances, or even of hypothetical antibodies.

Historically the most important factor in the study of immunity is Koch's old tuberculin. From this, logically and illogically, all other methods of inducing immunity have radiated. It will be necessary, therefore, to deal with this first of all. The administration

9. This conception of a hypersusceptibility in the form given here is, I think, new. There are several other diseases in which this conception may prove explanatory and stimulating, and I hope to return to this subject in a later paper.

of this substance demonstrated three remarkable phenomena: 1. The great sensitiveness of the tuberculous individual and the comparative indifference of the healthy body to it. 2. A distinct thermal reaction of the tuberculous individual, that is to say, a general effect, and 3, a hyperemia of the tuberculous focus. These can be readily demonstrated on tuberculous guinea-pigs.

My interest in the tuberculin reaction was aroused in 1898, when I was giving considerable attention to the immunizing effect of tubercle bacilli, killed at the low temperature of 60 degrees centigrade. I was very much surprised to find that some of the guinea-pigs which had been inoculated with heated bacilli and in which there were no signs of active tuberculosis after eight weeks succumbed promptly to small doses of tuberculin. Others lost considerable weight, but survived.

This tuberculin reaction is closely allied to another brought out by dead bacilli, injected into an animal which has already received a dose of dead bacilli. In other words, the first dose of dead bacilli sensitizes the animal to such a degree that the second arouses a violent reaction and may even prove fatal. This had already been pointed out by Straus. Since making these experiments I have asked myself the question again and again, Why does a single dose of the dead bacilli sensitize the animal, and why does not a corresponding dose of tuberculin do likewise? So far as I was able to examine the literature, no one had succeeded in making animals hypersensitive by the use of tuberculin alone.

This hypersensitiveness I looked on as an immune reaction. The animal had been taken out of a condition of neutrality or indifference into one of irritability and defense, however imperfect. In seeking an explanation of this peculiar difference between heated bacilli and tuberculin, it became necessary to determine what the tuberculin reaction means. It is well known to the special student that there are about nine or ten theories of the action of tuberculin in print, and it seems perhaps folly to add another. Fortunately the one I believe accounts best for the facts observed by others and myself is very much like one of these nine or ten as I shall point out.

In the tubercular tissue and its immediate vicinity the tubercle bacilli have induced certain tissue changes, and with them certain new functions of the tissue have been aroused which are the result of immunization. These new properties are concentrated in the immediate neighborhood of the focus. The specific resistance is, as it were, chiefly focal and only secondarily generalized. When the tuberculin comes in contact with this focus, the former is acted on, with the result that the originally innocuous tuberculin becomes poisonous perhaps by the splitting off of some poisonous substance. An incomplete digestion I should prefer to call it. As a result of this action we have, first, the local hyperemia and, second, the constitutional effect. In other words, the tuberculin becomes poisonous by an immune reaction directed toward the tubercle bacillus. This reaction is defective and in so far dangerous to the host. The only way in which the danger can be met is for the body to produce an antibody to this second substance. So far there is little evidence to show that the body is able to produce this in any amount. The animal body has learned to protect itself by suppressing multiplication rather than by attempting to neutralize such poisons.[10]

10. This secondary poison is probably of the same nature as the aggressins recently brought forward by Ball.

This theory of the tuberculin reaction as stated above is similar to the one proposed by A. Eber[11] nearly ten years ago. According to him the action of the tubercle bacillus raises the physiologic activity of the tissue involved in disease to such a height that it becomes capable of acting on the tuberculin and splitting off from it a toxic pyrogenic substance called by him tuberculopyrin.

My own interest in the tuberculin reaction was aroused by the query why a dose of dead tubercle bacilli can make the body sensitive while a corresponding amount of tuberculin does not. The reason why the injection of tuberculin as such does not lead to a subsequent tuberculin reaction as a result of one or several doses lies in the fact that tuberculin after injection is distributed throughout the body. Each cell receives but a brief exposure to a very minute quantity and probably much is eliminated unused. When dead bacilli (or even living ones) are introduced they soon settle down, and, the process of disintegration being very gradual, the tissues in which they are deposited receive a continuous, even though infinitesimal amount of tuberculin from the bacilli, and as a result of this persistent stimulus over a small area the tissue becomes focally active.

If this theory be true, the effect of the old tuberculin in establishing resistance appears in a new light. It would, first of all, exercise its chief function of being converted into a poison. During this conversion it uses up the antibody of the tuberculous focus. The benefit to be derived from it would be, first, in stimulating the reproduction of this antibody in the focus and around it, and, secondly, to accustom the body gradually to the action of the secondary poison set free from it. According to Koch, it would be antitoxic, but in a very roundabout way. Nevertheless, the use of the very minute doses now generally advocated may accomplish a kind of one-sided resistance, which large doses, as given in the past, might strain and even injure. This view would also oppose doses of tuberculin which set free enough toxin to cause fever, and this mode of administration has been interdicted.

This theory, furthermore, harmonizes with certain recent experiments which show that tuberculin reactions are diminished in severity when accessible foci are removed before injecting the tuberculin.

The gradual loss of the tuberculin reaction may be accounted for in one case by the tissues becoming gradually accustomed to the secondary tuberculin poison, in one another by the subsidence of the active process and the gradual loss of the antibody production on the part of the healed or quiescent focus, in a third by a temporary exhaustion of the antibody which activates the tuberculin in the focus. It is well known that in cattle the tuberculin injection following another similar one at a short interval appears earlier and is weaker and shorter in duration than the first or it may not appear at all. If twenty times the initial dose be injected reaction does occur, but here we may have other substances enter which were present in the small dose in insignificant amount. Just as in diphtheria toxin the toxon elements began to appear when we gave up the ten-minimum fatal dose for the fifty or one hundred in testing the strength of antitoxins.

That I should have given preference to heated tubercle bacilli as immunizing agents rather than to the old tuberculin is obvious from the theory of action of the latter which I have formulated. Fully a year before I

11. Deuts. Ztschr. f. Tiermed. XXI, p. 31.

began my experiments with tuberculin Koch, in 1897, had issued his new tuberculin T.R., which consisted of the ground, unheated bodies of tubercle bacilli. This was a distinct theoretical advance on the old tuberculin and was abreast of the new views of immunity. The old conception of the direct curative action of tuberculin had been abandoned. The issuing of the bacilli *in toto* tacitly acknowledged that the body must become immune to the entire bacillus and its metabolic products, for as long as we do not know which substance of the bacillus plays the most important and decisive rôle in arousing the defensive reaction of the body we must inject all of them.

There have been many other investigators working along similar lines. Some have kept us regularly informed of their forward and backward movements in this puzzling territory; others have kept to themselves their wanderings. The literature has grown to stupendous proportions, and any one who enters this field with any suggestions or theories is certain to do injustice to some precursor, for almost every possible interpretation has been stated somewhere before.

Among the more thorough and distinguished investigators a few may be mentioned. Maragliano has essayed immunity with the watery extract of tubercle bacilli and has studied assiduously the various toxins of the bacillus. Denys has tried to immunize with the bacteria-free filtrate of cultures. There have been notable contributions to the chemistry of the tubercle bacillus by Kühne, Ruppel, Levene, de Schweinitz and others. The noteworthy work of Trudeau, Baldwin and their associates has greatly contributed to the steadying of our advance in the knowledge of immunity and its bearing on clinical medicine. These observers have also been untiring in separating the wheat from the chaff of that which has come to us from abroad. Very recently Behring announced the use of tubercle bacilli for immunization or treatment which, according to brief reports, have been extracted with water, 10 per cent. salt solution and, finally, alcohol, ether and chloroform. With this bacillar skeleton, as it were, he expects to obtain better results. The details of the process are not yet generally known.

The attempts at the preparation of a therapeutic serum I shall pass over, since there does not yet appear to be a very satisfactory experimental basis for estimating its efficiency. It will in any case remain of merely theoretical interest in the cure of tuberculosis, owing to the difficulty of preparation and the probable cost.

In spite of this array of painstaking contributions to the biochemistry of the tubercle bacillus and the relation of its various component elements, secretions and metabolic products to the production of immunity, we still appear to be at the beginning. The recent studies of Koch, Behring and Pearson in bovine immunity produced by the intravenous injection of living human bacilli, and the same experiments of Trudeau on smaller animals, bring us back to the old principle first brought out by Pasteur in 1880 in his studies of protective inoculation toward fowl cholera. We have not only retraced our steps to the whole bacillus, but even to the living attenuated bacillus.

A very pertinent question, one which has undoubtedly been put by every physician and experimenter dealing with tuberculosis, suggests itself here: If immunity does not appear in the course of tuberculosis, why should we expect to produce it by artificial means? An answer to this question involves many factors, on only one of which I shall touch.

Immunity in tuberculosis consists of two elements, the focal or local immunity due to the multiplication of tubercle bacilli in a given territory, and a less pronounced general immunity due to the biochemical activities of the local process. If the general immunity becomes quite strong, or if the original resistance is so great that a little impulse makes it complete, then a second attack is not likely to occur. This, alas, is not ordinarily the case.

Granted that the first infection manifests itself, as a rule, in certain lymph nodes, two different results may be looked for. Either it leaves an immunity which promptly fixes the next invader, closes in on him so that multiplication is speedily checked, or else in the less responsive the second invaders, lodging in the lungs themselves, may prove disastrous, owing to the destructibility of the lung tissue itself and the chance for secondary infections. This would mean that in the first type of individual the early infection protects against a second; in the second type, the first apparently, but not really, predisposes toward a second, the distinction being due to a difference in the rousing of immunizing factors.

In cattle the short life of the individual does not enable us to realize much from a study of primary and subsequent infections, but the impression that I have gained from a careful repeated study of the autopsy notes is that old lymph-node tuberculosis is rarely associated with fresh pulmonary disease. Cattle, I believe, are nearly immune and it requires but a little to tip the scales in favor of the host.

The acquired general immunity following the first attack is shown in a variety of ways. Experimentally the second local lesion in the guinea-pig, as pointed out by Koch, is a different process from the first. Clinically, the lymph-node tuberculosis of childhood later becomes an organ tuberculosis. The bacilli are literally held up in the portal of entry, and pulmonary disease becomes the type of the second stage or of later life. The first infection of the intestines lodges and multiplies in the mesenteric lymph nodes. When lung disease is established and the sputum is swallowed, tuberculous lesions of the mucous membrane are very common; those of the lymph nodes, slight or absent. Behring is quoted by some one as stating that this infection is due to a hypersensitiveness. I should say a partial immunity, for here also the bacilli are held up at the place of entry. These facts were noted long ago, but not explained, by Weigert,[1] as stated at the beginning of the article.

To the physician this phenomenon of repeated infection meant no immunity. And, indeed, so far as the patient is concerned, it is as good as none. It is more dangerous owing to secondary infection, but it carries in it the germ of possibilities, namely, the immunization to a degree which will totally prevent the second attack. In the meantime it may not be amiss to point out here the true significance of protecting patients from repeated infection. I should place this among the most important of the details of treatment, and it is not to be denied that the careful protection afforded tuberculous patients nowadays in sanatoria may have a powerful influence in raising the percentage of recoveries. To this opportunity for repeated infection on which I would place much more responsibility than on diffusion of early or latent infection in the body itself, there must be added the chance of acquiring tubercle bacilli of much higher invasive powers and, therefore, more dangerous.

At this point I may be permitted to digress a moment to refer to the peculiar localization of tuberculosis in the upper or cephalic lobes of the lungs. Numerous attempts at explanation have been made chiefly on anatomic bases. Some would make pulmonary disease hematogenous in origin, the infection coming from some disrupted primary focus, probably a caseous lymph node. The following evidence offered by experimental and comparative pathology on this puzzling phenomenon is somewhat contradictory, but suggestive.

I have already stated that in the spontaneous disease of cattle the largest or caudal lobes are most frequently diseased primarily or else those lymph nodes associated with them. The smaller cephalic lobes are more often secondarily diseased from aspirated caseous matter. This is as we should expect to find it if the germ lodges and multiplies where we should expect most bacilli to lodge.

Some years ago I noticed in several rabbits which had been inoculated into the ear vein with human tubercle bacilli and kept a long time the following peculiar condition: The bacilli which ordinarily are deposited in every part of the lungs and which, if virulent, fill the entire lung tissue with tubercles, had been suppressed and destroyed excepting along the thin border of both cephalic lobes, which were solid and tuberculous. It is probable that this condition can be frequently induced if the tubercle bacilli are very finely ground before injection so that large masses may not lodge and inevitably produce foci anywhere. These two facts, the spontaneous disease in cattle and the induced disease in rabbits, both favor, one negatively, the other positively, the hematogenic origin of tuberculosis of the upper lobes in man; but there is a third element in the form of a general principle which, to my mind, holds the balance. This may be briefly stated as follows:

Bacteria multiplying by preference in certain localities as *loci minoris resistentiæ* will reach these places if they have access to them through the blood or through natural openings. For example, typhoid bacilli injected into the blood will probably cause ulceration of the intestinal lymph apparatus just the same as if ingested. Applying these various data to pulmonary disease, there is no more reason to assume the suppression of tubercle bacilli entering by one route, the air, than by the other, the blood. I am myself inclined to believe that the bacilli inhaled are suppressed and destroyed except in the apices in susceptible individuals.

(To be continued.)

A PLEA FOR THE INTERNATIONAL STUDY OF CARCINOMA.*

NICHOLAS SENN, M.D.

Professor of Surgery in the University of Chicago; Professor and Head of the Surgical Department, Rush Medical College.

CHICAGO.

"Sed opertet privatis utilitatibus publicas, morbis eternas anteferre; multoque diligentius muneri [illegible] consulere, quam facultatibus."

INTRODUCTORY REMARKS.

Humanitarian Service.—From time immemorial the medical profession has been in search of ways and means to reduce the sum of human suffering in its efforts to prevent and treat disease.

The physicians of all times, more than any other class of men, have devoted a large part of their time, talents and energies to promote the happiness, welfare and usefulness of their fellow-beings without any expectation of a pecuniary gain for their unselfish, self-imposed and often arduous task.

The philanthropic spirit has always animated medical men and their organizations, large and small. A liberal part of the transactions of the medical societies throughout the entire civilized world is devoted to subjects which have a bearing on the prophylaxis of disease. The public will never realize the vast amount of work that has been done in this direction by the mass of the profession inspired by men of the highest scientific attainments. The growing knowledge of the real cause and nature of disease, the outgrowth of original research and accurate scientific investigation by a host of earnest students the world over has already resulted in erasing from our nomenclature a number of formidable diseases and in limiting the spread of deadly epidemics.

Preventive Medicine.—The crowning glory of our profession in the future will be preventive medicine. The sphere of the general practitioner will become more and more circumscribed; that of the scientist will expand and keep step with the progress and advancements of preventive medicine. Rational preventive medicine had its origin contemporaneously with the foundation of the new science of bacteriology, and its further development and sphere of usefulness must necessarily depend on the progress and expansion of the latter. We may confidently look to the near future for more men like Jenner, Haffkine, Lister, Pasteur and Koch, who will do their good share in blotting out preventable diseases.

Surgery has not been idle and has contributed its liberal part toward reducing the death rate and diminishing human suffering. Based on the teachings of Pasteur and Lister, a system of aseptic and antiseptic precautions has been gradually perfected which is now in force wherever modern surgery is practiced and which has been the means of almost entirely eliminating from wound complications the disastrous affections due to infection and has greatly increased the range of operative procedures. Primary healing of wounds is now the rule, instead of the exception, as was the case only a quarter of a century ago. Hospital gangrene, the black monster of military and civil hospitals less than half a century ago, has disappeared from the face of the earth never to return. Erysipelas and pyemia have become pathologic curiosities. Secondary hemorrhage, such a frequent and dangerous occurrence formerly, seldom now disturbs the peace of mind of the operating surgeon since he has come in possession of the aseptic absorbable ligature.

CARCINOMA A MYSTERY.

There is one dark chapter in surgery to which I wish to call your attention on this occasion, and in which I desire to enlist the interest of the medical profession throughout the entire world—it is carcinoma. It is an old, old subject, which has interested the profession for centuries and, which, notwithstanding the prodigious efforts which have been made to solve the mystery of its real cause and nature, remains unexplained. Carcinoma is so common and, according to recent statistics, unquestionably on the increase that it behooves our profession to make use of every possible means and avenue to discover its real cause and nature and, having accomplished this, to open up the way for its prevention and more successful treatment.

* Oration for the United States, delivered before one of the general sections of the Lisbon International Medical Congress, April 19-26, 1906.

The prevalence of this disease, its relentless course and obstinacy to all known methods of treatment surround it with the gloom of fear and hopelessness to the public. By hearsay and observation the masses of the people are firmly impressed with the idea that carcinoma is a fatal disease, and when such a diagnosis is made it is regarded as a death sentence. The medical profession is equally aware of the painful fact that in the great majority of patients afflicted with this disease it proves fatal within three to five years, and that the only cases which recover permanently are those in which an early radical operation is performed.

A LOCAL DISEASE.

One feature of this dreadful disease has been definitely settled, and that is that it begins as a local affection, and it is in this stage that it is amenable to successful treatment by an early radical operation, and it is safe to state that not more than 25 per cent. of all the patients who apply for surgical aid are within reach of successful operative intervention. Left to itself, the intrinsic tendency of the disease is to destroy life. Its malignant course is not influenced by any kind of internal medication or local treatment short of complete destruction or removal of every vestige of carcinoma tissue. The prevention and successful treatment of any disease depend on the neutralization or removal of its cause. Material progress in the treatment of carcinoma can only be hoped for after we have succeeded in demonstrating its essential cause.

NON-PARASITIC.

The most intense interest in the study of carcinoma was awakened with the origin and rapid growth of the modern science of bacteriology. As soon as it became known that all inflammatory processes are caused by specific pathogenic micro-organisms it was very natural that, by reasoning from analogy, the conclusion was reached that carcinoma must be a parasitic disease. There are so many similarities between chronic infective diseases, notably tuberculosis and carcinoma, that we can readily appreciate the motives that led to the investigations in all parts of the civilized world concerning the microbic origin of carcinoma. Various methods of tissue staining, cultivation and inoculation experiments have all been utilized by thousands of earnest investigators in their strenuous efforts to discover and prove the essential microbic cause of carcinoma. A number of intracellular and extracellular bodies have been found and described as the specific parasitic cause of carcinoma, but for none of them has the claim been substantiated by crucial impartial laboratory and clinical tests. Searching criticisms from different reliable sources have disarmed all such claims.

From an etiologic standpoint, very little has been added to our knowledge of the nature of carcinoma since the epoch-making researches of Virchow, Cohnheim, Thiersch and Waldeyer. The pathology of carcinoma has been materially advanced by the most painstaking and accurate microscopic work concerning the origin, growth, multiplication and life history of the carcinoma cell and its manner of local and general dissemination. The atypical, irregular mitotic figures which are seen in the segmenting carcinoma cell are in strong contrast with the regular, symmetric, karyokinetic processes observed in direct division in normal tissue cells. The metastatic processes have been traced, step by step, through the lymphatic channels and the systemic circulation, and it has been demonstrated beyond all doubt that the secondary tumors are the direct offspring of migrating carcinoma cells from the primary tumor, and that the pre-existing mature tissues take no active part in the tumor formation, primary or metastatic.

This tends to prove that the histology and histogenesis of carcinoma speak against the parasitic origin of this disease and in favor of a disease of the epithelial cells independent of infection. The mass of tumor tissue, the parenchyma of carcinoma, is invariably made up of epithelial cells in the primary, as well as in all metastatic tumors, regardless of their anatomic location. Inflammatory products, on the other hand, present the same histologic structure independent of their anatomic location or character of the tissue involved. Infective processes are caused by the pathogenic action of micro-organisms on pre-existing tissue, and the inflammatory swelling is made up of the products of effusion and cell migration through the damaged capillary walls plus new tissue cells generated by the pre-existing tissues acted on by the microbic cause of the inflammation.

Carcinoma is a tumor that invariably starts from a matrix of embryonic epithelial cells of prenatal or postnatal origin, and in its growth only epithelial cells take an active part; hence, if its microbic nature should ever be demonstrated, it will be a microbe which has a special predilection for epithelial cells, a very unlikely, exceptional phase in the vast field of bacteriology. The failure to discover the microbic origin of carcinoma, together with the histology and histogenesis of the tumor, speaks strongly against the parasitic origin of the disease. Inoculation experiments have so far only proved the negative side of the question. As an additional proof of the truth of this statement I will mention an experiment which has confirmed me in the belief of the non-parasitic nature of carcinoma.

Author's Experiment.—On May 4, 1901, I inoculated myself with carcinoma tissue immediately after I had completed a radical operation for advanced carcinoma of the lower lip. The patient from whom the malignant graft was obtained was an Irishman, 60 years of age. The submental and submaxillary lymphatic glands were involved. The excised glands were immersed in a warm saline solution, and from one of them a fragment, the size of a split pea, was used for implantation. A small incision was made about the middle of the forearm, over the supinator muscles, under strict aseptic precautions. One of the margins of the skin wound was undermined sufficiently to make a pocket large enough to receive the graft. After implantation of the carcinoma graft the wound was closed with a horsehair suture and iodoform collodium. The carcinomatous nature of the glandular affection was proved by microscopic examination of the gland from which the tissue was taken. In the course of a week a subcutaneous nodule, the size of a pea, made its appearance, which remained stationary for two weeks, when it gradually disappeared. At the present time a faint linear scar remains, indicating the site of the incision. This, as well as a few similar experiments made by Alibert, furnish strong, if not convincing, proof of the non-parasitic nature of carcinoma. The bacteriologic search for the supposed microbic cause of carcinoma will continue in the future but undoubtedly will be as devoid of positive results as it has been in the past.

INTERNATIONAL CO-OPERATION INVITED.

It seems to me that the time has come when it is necessary, by joint and persistent action, to study the

etiology of carcinoma from other standpoints, and it is for this reason that I have chosen as the subject for my oration "A Plea for the International Study of Carcinoma." The vast importance of this subject merits united systematic efforts, in which representatives of all nations should take a willing active part. It is only by such concerted action that we may expect to reach the final solution concerning the true nature of this strange disease, and in doing so prepare the way for a rational and more successful treatment.

So far as our present knowledge goes, carcinoma must be regarded as a tumor caused by an atypical proliferation of epithelial cells from a matrix of embryonic cells of congenital or postnatal origin. The epithelial proliferation takes place in vascular tissue where epithelial cells are never found in a normal condition. The heterotopic location of these cells distinguishes carcinoma from all benign epithelial tumors. Atypical proliferation of epithelial cells signifies their growth and multiplication in a locality where they have no legitimate citizenship.

The malignancy of carcinoma is due to the fact that the epithelial cells remain in their embryonic state, fail to reach maturity, retain their abnormal vegetative capacity until degeneration sets in, and by virtue of their ameboid movements invade the neighboring tissues, enter the lymphatic channels and finally give rise to regional and general metastasis. It is this abnormal behavior of the epithelial cells, their prodigious vegetative capacity and their migration into all adjacent tissues, irrespective of their histologic structure, that characterizes their life history and intrinsic pathologic tendencies. What are the general influences or local conditions productive of such a morbid erratic cellular life? The disease in its incipiency being local, it would be natural to search for local causes. If this be the case, where do the first textural changes take place? Are they to be found in the epithelial cells or in the tissues in their immediate environment? These are questions that must be answered before the etiology of carcinoma is definitely settled.

FACTORS IN THE ETIOLOGY OF CARCINOMA.

That the general condition of the organism, an aptitude, has some influence in determining the disease there can be no question, but that it is entirely responsible for it is more than doubtful. If a general predisposition were the principal agent in causing the disease, autoinoculation experiments ought to have proved successful. In the case of an inoperable carcinoma of the leg, a few years ago, I implanted subcutaneously fragments of carcinoma tissue from the same patient at two points on the affected limb. A little nodule formed at the seat of inoculation, remained stationary for about two weeks, and then disappeared entirely. The same experiment has been made by several other surgeons, with a similar negative result. The microscope has proved an invaluable aid in the study of the histology and histogenesis of carcinoma, but so far it has been powerless in demonstrating its cause. Future microscopic researches may yield unexpected results, but it appears to me that the time is at hand to extend our inquiries regarding the etiology of carcinoma beyond the confines of laboratories and explore other fields less cultivated in search for its cause or causes. United action on a large scale, embracing enthusiastic investigators of all nations, concerning the influence of heredity, age, race, climate, diet, habits, trauma, prolonged irritation, chronic inflammation, scar tissue and benign tumors in the causation of the disease, could not fail in bringing more light on this perplexing subject.

Heredity.—The influence of heredity in the etiology of carcinoma is unquestionable. Every surgeon of large experience has observed cases in which the disease could be traced through several successive generations. The percentage of cases in which carcinoma has been shown to be hereditary is estimated at from 12 to 33 per cent. by different authors. More extensive and accurate statistics from all available sources are needed to prove the influence of heredity in the etiology of carcinoma. In studying the influence of heredity, it is not fair to exclude from the statistics distant cancerous relatives, as has been done by Cripps and others, because it is well known that congenital deformities, physiognomy and mental peculiarities frequently reappear several generations apart and in distant relatives. There is no reason to doubt that at least a predisposition or aptitude for carcinoma is transmitted in a similar manner.

Age.—It is a familiar fact that advanced age plays an important rôle in the etiology of carcinoma. Of the 9,906 cases collected by De la Camp, there were only 19 less than 20 years of age. I have seen a carcinoma of the mammary gland in a girl, 21 years of age; a carcinoma of the rectum in a boy of 17, and several cases of carcinoma of the stomach in persons between 25 and 30 years of age. There appear to be conditions, local or general, antagonistic to carcinoma during the most active physiologic processes concerned in the growth and development of the body, and the disease manifests a special predilection for the aged when all the active processes in tissue formation are on the decline. Age has also a decided influence on the clinical course of carcinoma, as it is well known that its malignancy diminishes with advancing age. The senile state favors the development of the disease, but exercises an inhibitory influence on its progress, while, on the other hand, the juvenile tissues are antagonistic to it, but when it does occur in young subjects it pursues an unusually malignant course. The influence of age on the prevalence and malignancy of carcinoma merits more careful study in searching for the key that will eventually unlock the mystery of its etiology.

Racial and Social Influences.—It is a well-known fact, confirmed by reliable and extensive statistics, that some races are much more predisposed to carcinoma than others. The black and yellow races are not as susceptible to the disease as the whites. Our North American Indians have been and still are peculiarly exempt from this disease. As a rule, to which there are few exceptions, it may be stated, without fear of contradiction, that the primitive races, as long as they remain true to their original habits, customs and manner of living, seldom suffer from carcinoma; on the other hand, the disease is most prevalent where civilization has reached its climax. This difference in the prevalence of carcinoma among the ignorant and educated, the savage and the highly civilized, is undoubtedly due, to a large extent, to diet, brain rest on one side and a strenuous life, worry and discontent on the other. That the state of the nervous system plays a part in the etiology of carcinoma I am satisfied and have seen it repeatedly demonstrated in my practice. Future statistics based on racial and social influences will bring out many important facts that may forge the connecting link in the long chain of evidence necessary to reach the final aim of etiologic research.

Climate and Topography.—The very unequal geographic distribution of carcinoma over the surface of the earth points to local conditions, climatic, racial and dietetic, which favor or inhibit the development of the disease. Like lepra, carcinoma has its favorite geographic haunts. A careful study of the local conditions where carcinoma is most prevalent should form an important part of future researches relating to the etiology of this disease, and, if done on a large scale by the most competent men in such localities, may lead to important results.

Legrain makes the statement that carcinoma is unknown in Algeria, except as it appears in the European. Behla has made a study of the geographic influences in the causation of carcinoma. According to his observations, it is very rare in the extreme northern and southern countries. It occurs with greatest frequency in the temperate zones of Europe, Asia and America. It is very rare in Central Africa, the South Sea Islands, Central America, and almost unknown in New Guinea. Haviland, in his researches, found the disease in the same latitude most prevalent along river courses and in localities subjected to periodic floods, while it is less frequent in high altitudes and in the spring districts at the river sources. It was a noteworthy fact that geologically the alluvial soil appeared to constitute a local cause, while a chalky or lime soil exercised the opposite effect. Heimann made similar inquiries and came to the same conclusions.

Diet.—For a long time popular belief has accused certain articles of food, such as meats, tomatoes, condiments, as causes of carcinoma. Verneuil and Reclus long ago called attention to the fact that herbivora were much less liable to carcinoma than the carnivora, and they ascribed the great increase in the number of patients suffering from carcinoma that came under their observation during forty years to the increased consumption of meat by the laboring classes. That diet may have some influence as a predisposing influence there can be no doubt, but to assume that it is the sole or even the principal cause of carcinoma would be a position which is not sustained by facts.

During my trip last summer to the very heart of the Arctics to within 650 miles of the North Pole, I made special observations and inquiries in reference to the occurrence of tumors among the aborigines. These people have lived for unknown centuries on an exclusive animal diet, blubber and meat; they do not know the taste of a single article of vegetable diet; they are the filthiest people in the world, as they never wash themselves, and wear fur throughout the entire year, and yet they appear to be immune to tumor formation of any kind. The idea occurred to me that this immunity might be due to the iodin contained in the food obtained from the sea animals.

The North American Indians, who in their primitive state lived largely on an animal diet, were likewise singularly free from tumor formation, more especially carcinoma. The subject of diet as a causative element of carcinoma deserves further and more thorough and systematic investigation.

Habits.—Certain habits appear to be conducive to the occurrence of carcinoma. Habits and occupations which expose certain parts to repeated and prolonged irritation deserve special mention here. I will refer to two only as most striking illustrations, smoking and betel chewing. Justly or unjustly, smoking has been accused for a long time as being a frequent cause of carcinoma of the lower lip, tongue and tonsils. The clay pipe has an unenviable reputation in this respect in cases of carcinoma of the lower lip, and probably deservedly so. It is singular, however, that in many countries where cigarette smoking is practiced to the greatest excess, like Turkey, Palestine, Algeria and Morocco, carcinoma of the lip and mouth is of rare occurrence. The vice of betel chewing, so generally practiced in Ceylon and all through India, is unquestionably responsible for the frequency with which carcinoma of the mucous lining of the mouth is met with in those countries. The principal constituents of "betel" are the betel leaf, areca nut, caustic lime and some sort of a strong condiment, all powerful irritants of the mucous membrane. The disease effects the buccal surface of the cheek, generally commencing opposite the teeth of the lower jaw and spreading with varying rapidity according to the pathologic type of the tumor.

Trauma.—The influence of traumatism in the etiology of carcinoma is variously estimated by different authors. Trauma exercises a more important rôle in the causation of sarcoma than carcinoma. In most cases in which an alleged single trauma has been charged with having caused the disease, the carcinoma was present when the injury was received, the injury having called the patient's or physician's attention to it. Carcinoma seldom, if ever, follows a single injury, but develops more frequently in consequence of

Prolonged Irritation.—Frequently repeated and long-continued irritation is a generally recognized exciting, if not the principal, cause of carcinoma. Certain occupations, habits, malposition and diseases of teeth and displacement of organs due to abnormal sources of irritation must be included under this category as agencies which so often precede carcinoma and which must be regarded at least in the light of determining causes, as without such local harmful action the disease might not have made its appearance. The local irritation effects tissue changes conducive to carcinoma formation in persons who are the subjects of a hereditary or acquired predisposition or aptitude to the disease. It would be well to study more thoroughly and on a larger scale, experimentally and clinically, the effect of chronic irritation on the etiology of carcinoma.

Chronic Inflammation.—While the histologic processes observed in inflammation have nothing in common with carcinoma, clinical observations appear to prove that carcinoma not infrequently develops in an organ or part which is the seat of a chronic inflammation. It is not at all uncommon to find a carcinoma take its starting point in ulcers of the stomach and chronic ulcers of the lower extremities, in tubercular lesions of the skin, and in chronic inflammatory affections of the mucous membrane of the tongue and other organs. Goodhart has called special attention to ichthyosis of the tongue as a cause of carcinoma. It has been well known for a long time that this superficial inflammation of the tongue frequently precedes carcinoma.

Another inflammatory product, very often the starting point of carcinoma, is the wart. Warts on the forehead, cheeks and hands of aged persons, "verruca senilis," most frequently undergo such malignant transition. The inflammatory process is undoubtedly concerned in laying the histologic foundation for carcinoma by causing the penetration of embryonic epithelial cells into the inflammatory product, where they are brought in contact with vascular tissue, which in-

creases their vegetative activity and alters their habits of life.

The influence of chronic inflammatory processes involving the epithelial cells of glandular organs and the surface of the skin and mucous membranes as one of the causes of carcinoma should receive more careful attention than has been devoted to it. Extensive and reliable statistics on this phase of the etiology of carcinoma is what is needed in the further elucidation of this subject.

Scar Tissue.—The origin of carcinoma in scar tissue has been so often observed that German surgeons designate it as "Narbenkrebs." The tumor almost invariably begins as a subepidermal nodule from a matrix of embryonic epithelial cells buried in the mesoblastic tissues during the process of healing by granulation of the injury or lesion which gave rise to the tissue defect.

Trauma, irritation, inflammation and cicatrization as causes of carcinoma undoubtedly play a double rôle in lighting up the disease in persons predisposed to it, as any of them may be the means of transporting the essential tumor elements, epithelial cells, from their normal vascular physiologic habitat into a vascular district and may likewise be concerned in stimulating their vegetative life by diminishing the normal physiologic resistance of the adjacent tissues.

Benign Tumors.—The frequency with which benign epithelial tumors undergo transformation into carcinoma remains a matter of individual opinion and isolated experience. In papilloma and adenoma the epithelial cells which make up the parenchyma of the tumors are not in touch with the blood vessels. Any and all influences, local and general, which are capable of stimulating cell growth beyond the limits observed in benign tumors, and which result in penetration of the membrana propria by embryonic epithelial cells, are the causes on which depends the transition of a benign epithelial tumor into a carcinoma.

Among the local causes which bring about such a malignant transformation may be enumerated trauma, prolonged or repeated irritation, and incomplete removal of the benign tumor by excision or the employment of caustics. Benign tumors on exposed surfaces of the body are most prone to become malignant, because they are most subjected to injuries and irritations which result in histologic changes favorable to the development and growth of carcinoma. From a scientific as well as a practical point of view, it is extremely important that by concerted action more light should be shed on the frequency with which benign epithelial tumors become the starting point of carcinoma and the influences which determine such transition.

CONCLUDING REMARKS.

I have only briefly alluded to a number of the most familiar conditions, influences and lesions which are known to favor the origin and growth of carcinoma, with a view of inciting a more general and concerted interest in the study of the etiology of this disease outside of laboratory methods. Laboratory research will be carried on until the real cause of carcinoma has been discovered, but this method of investigation will receive material, if not essential, aid by a more careful and extended inquiry concerning the relations of what might be designated as some of the exciting or predisposing causes of the true nature of carcinoma.

I would like to see this congress take the initiative for the international study of carcinoma in all its phases, but with special reference to its etiology as influenced by the agencies which I have enumerated. For this purpose a committee should be appointed representing all nations who have sent delegates to this international gathering, and this committee should be requested to report the results of their investigations at the next meeting of the Congress.

I am confident that earnest, united work on such a large scale, representing practically the entire inhabited surface of the earth, would contribute invaluable material for the final discovery of the essential cause of carcinoma. Investigations on such a basis may finally lead to a successful treatment of carcinoma, without resort to the knife, by the employment of remedies which will either destroy the abnormal cells or cause them to reach maturity, either removing the tumor or rendering it stationary.

It is the duty of the medical profession to lend every effort toward accomplishing this object, as the old sentiment ever remains true:

"Salus populi lex suprema est."

SIXTEEN YEARS' EXPERIENCE WITH FORMIC ACID AS A THERAPEUTIC AGENT.*

HEINRICH STERN, M.D.
NEW YORK.

My attention was first drawn to the medicinal qualities of formic acid by a semi-secret preparation styled by its manufacturer, Hensel, "Ferrum formicarum oxidatum oxydulatum." This was in 1888. The same or a similar preparation is now sold by a homeopathic drug house under the name of "Hensel's tonicum."

HISTORICAL REVIEW.

There is no doubt in my mind that Hensel's formic acid compound is a latter-day transformation of Hoffmann's "Vinegar of Magnanimity," in which a preparation of ants played the leading rôle. In the seventeenth century this famous vinegar had found entrance in all European courts and was employed by men and women as a general tonic, stomachic and diuretic, and probably also as an aphrodisiac. For formic acid seems to possess certain qualities stimulating sexual appetite (in South America a species of large ants are consumed), and the proprietary tonics demanding a good sale, as a general rule, are those which increase sexual desire.

Otto Braunfels, a German botanist and physician (1188-1534), to whom Linnæus refers to as "the father of botany," already drew attention to the fact that an acid fume reddening blue vegetable colors emanated from ant hills. Formic acid, however, was first isolated and discovered by J. Wray or Rey in 1670 by distilling red ants with water; others ascribe the first isolation of this substance to Samuel Fischer (1670). Marggraf, in 1749, experimentally proved the dissimilarity of formic and acetic acids. Döbereiner, in 1822, produced formic acid artificially by the oxidation of tartaric acid with manganese dioxid and sulphuric acid thus:

$$\begin{matrix} CH(OH)\,CO.OH \\ | \\ CH(OH)\,CO.OH \end{matrix} + MnO_2 + H_2SO_4 = 2H.CO.OH + 2H_2O + 2CO_2$$

Tartaric acid + Manganese dioxid + Sulphuric acid = Formic acid + Water + Carbon dioxid.

Berzelius and Liebig devoted much time to the minute study of formic acid.

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

PREPARATION OF FORMIC ACID.

Formic acid is prepared in different ways. The best mode of obtaining it is by heating equal weights of oxalic acid and glycerin to a temperature of 100 to 110 C. for about fifteen hours, when carbon dioxid is given off and dilute formic acid distils over. The dilute acid may be concentrated by saturating it with lead carbonate or lead oxid, after which the mixture is filtered and evaporated to a small bulk (complete dryness). The dry lead formate, reduced to a fine powder, is then heated in a glass tube connected with a condensing apparatus, through which a current of sulphureted hydrogen is passed. The glycerin apparently exerts no chemical action, but seems to bring about decomposition of oxalic acid at a lower temperature than would otherwise be necessary. At a temperature above 110 C. decomposition of the formic acid would ensue.

The name formic acid is an appropriate one, for, as is well known, the ant, especially the red ant, *Formica rufa,* ejects, when irritated, a secretion, the greater part of which is composed of formic acid. Ants, however, are not the only insects which produce the acid. This substance is produced or accumulated in a special gland from which, by means of the sting, it finds its way under the skin, where it gives rise to a local inflammatory process. Bees impart some of their formic acid to the honey. The acidity is particularly noticeable in fresh honey of wild bees. In domestic medicine, honey at one time was considered to be a good preventive of diphtheria. The formic acid contained in it is said to inhibit the growth of the Klebs-Loeffler bacillus. The diuretic qualities of certain isopoda, like *Armadillo officinalis* and *Oniscus asellus,* have also been ascribed to the formic acid which they contain. Free formic acid is also contained in the leaves of the stinging nettle, *Urtica urens,* and in other plants, and it has been demonstrated in unripe grapes. Being a decomposition product of vegetable débris, it is very likely the potent medicinal constituent of mud baths. The mud bath acts as a local rubefacient.

REVIEW OF LITERATURE.

The effect of formic acid or the formates on the animal organism has not been studied exhaustively. Mitscherlich was the first[1] to bestow more than casual attention on this question. He reported the following:

Rabbits were poisoned with lethal doses of free formic acid. The autopsy revealed pronounced thickening of the outer layer of the gastric mucosa without marked cellular changes; the capillary vessels and veins were engorged and showed extravasation of blood; in short, the lining of the stomach and the upper part of the small intestines was violently inflamed. The dilute acid produced the same effect but, of course, in a less pronounced degree. That the acid was absorbed was evinced by the acid reaction of the urine which in rabbits is normally alkaline. The blood appeared to be little altered. The kidneys were discolored dark red brown, and contained a large amount of blood. The urine exhibited blood and numerous cylindrical bodies. This evinced that formic acid like other acrid substances exerted a specific influence on the kidneys. In this respect they acted in a similar manner to cantharides.

The toxic state due to formic acid, according to Mitscherlich, is different from that due to any of the other acids he had experimented with. The experiment-animals become restless and excited. Asthenia supervenes only after some hours. Death ensues after a period of mild convulsions and difficult respiration.

According to the same author, formic acid is a very violent poison, as half an ounce of a liquid containing in 100 parts 7 parts of the acid caused death after twenty-four hours, and two drams even called forth marked poisonous symptoms. The acid in the same dilution applied on the skin of various individuals caused but a slight burning sensation; the pure acid, on the other hand, gave rise to a severe inflammatory process which only subsided after a number of weeks.

Rabuteau,[2] in experimenting with formic acid and sodium formate, came to different results. He showed that the acid is again eliminated by the urine as a carbonate (combined with alkali), and that it has no deleterious effect on the organism if administered as free diluted acid or if combined with sodium. He took 3.5 gm. of sodium formate without experiencing any undue effects.

Arloing[3] observed the action of sodium formate in dogs and horses, and found that it diminishes cardiac activity and lowers the blood pressure and the temperature. Massive doses, as one gram per kilogram body weight, cause death by cardiac paralysis.

Hoffmann[4] studied the influence of formic acid on the lower organisms. Infusoria became immediately paralyzed in dilutions of the acid down to 0.1 per cent. Their body-contents were rendered dark and granulated and finally the enveloping membrane burst in most organisms. Bursting of the infusoria could not be observed in a 0.01 per cent. solution of the acid, although all other phenomena were still well marked.

A leech put into a beaker containing formic acid in 0.25 per cent. dilution immediately contracts its body and relaxes it again and makes vain attempts to escape from the vessel. Its movements, at first lively, gradually become weaker and after twenty-five minutes the leech is dead. The same phenomena occur in the 0.1 per cent. solution of the acid, but death ensues only after fifty minutes. Placed in a 0.05 per cent. solution of formic acid, the leech immediately fastens itself on the glass and performs moderate movements with the free end of his body. After five minutes it tries to get out of the fluid; again placed in the solution, the animal fastens itself again, renewing at the same time its movements, and attempts to escape. The leech becomes gradually weaker, and after fifty minutes the sucking discs no longer work. The movements cease temporarily while the animal lies on its side contracting its body vehemently. After two hours neither spontaneous nor reactive movements are perceptible. In a 0.01 per cent. solution of the acid the leech apparently was not disturbed, but twenty-four hours after it was found dead at the bottom of the vessel. A leech put for control purposes into a 0.05 per cent. solution of acetic acid fastened itself at once on the wall of the vessel and remained in a quiescent state. The animal was found in the position after twenty-four hours, although means to escape were offered it. In the same dilution formic acid caused the death of the leech in two hours.

Frogs placed in a beaker containing 100 c.c. of a 0.5 per cent. solution of formic acid at once make attempts

to escape; after fifteen minutes the animal suddenly falls on its abdomen, holding its head above the fluid and making violent motions with its hind legs. Soon it becomes unable to rise and its head droops down. The extremities are moderately rigid after twenty-five minutes. This rigidity slowly increases and becomes more general, so that in fifty minutes the animal gives the impression as if it were frozen; an hour and a half after starting the experiment it is lifeless. The blood spectroscopically examined exhibits the bands of oxyhemoglobin. In a 0.5 per cent. solution of acetic acid a frog lived for two hours and a half. In this frog muscular rigidity did not ensue.

Hoffmann also inquired into the antiseptic and antifermentative properties of formic acid. He found that free formic acid in a solution of 1 per cent. prevented even the slightest degree of putrefaction; that a 0.5 per cent. solution averted putrefaction of Buchholtz's nutrient (distilled water 100 c.c., commercial rock candy 10 gm., ammonium tartrate 1 gm., and potassium phosphate 0.5 gm), and that a 0.25 per cent. solution exerted a definite but limited preventive influence on putrefaction. He showed that the conversion of albumin by pepsin and hydrochloric acid is not prevented if as much as 1 per cent. of formic acid is contained in the digestive fluid, and that formic acid can not replace hydrochloric acid in proteid digestion.

Sodium formate inhibits proteid digestion by combining with the hydrochloric acid to form sodium chlorid, setting free thereby formic acid. Fermentation, of course, is also inhibited when the liquid to be fermented contains formic acid in rather large proportion; in greater dilution, however, as demonstrated by the same observer, formic acid exerts a stimulating influence on the process of fermentation. It appears that the activity of the yeast cell is enhanced when high dilutions of formic acid are added to the glucose solution.

The latter observation I am able to corroborate to a certain extent. I found that while in dilution of 1 to 3000 formic acid suppresses the development of bacteria in weakly acid media like beer, and while in dilutions of 1:7000 and 1:10000 the bacteria are rendered more or less inactive; culture, as well as wild yeasts, thrive very well and often times become even more active in these dilutions.[5]

During the last few years a number of investigators (notably French) have studied the antiseptic, antifermentative and clinical possibilities of formic acid. Concerning its antiputrefactive and antifermentative qualities, they have, in substance, not gone far beyond Hoffmann's experiments; concerning its clinical value they have said nothing. We owe thanks, however, to the French clinicians for having resuscitated from oblivion this very potent remedial agent.

The effect of formic acid on the healthy human organism as studied by me is as follows: In doses of two drops, well diluted, it gives rise to no symptoms besides an occasional irritation in the throat and a feeling of warmth and emptiness in the stomach. In doses of five drops it causes a slight irritation in the pharynx and larynx; in 10-drop doses it exerts mild diuretic and diaphoretic influence; in 20-drop doses it produces the same phenomenon, but in a more pronounced degree and gives rise to contracting sensations in the pyloric region when the stomach is empty. Administered to the amount of from 3 to 4 c.c., very well diluted, and when the stomach is empty, it causes dryness in the throat, ringing in the ears, slight vertigo, burning sensation in the gastric organ and sometimes mild pyloric spasms, lassitude, slight motor disturbances and elevation of temperature of from one-half to two degrees, which latter is followed after half an hour or an hour by marked perspiration and increased micturition. In doses of 0.5 to 1 c.c., repeated three or four times a day for some weeks, it acts as a muscular excitant in some instances. Clement[6] states that formic acid augments muscular force, activity and resistance. By its action on the muscular structure of the bladder it facilitates emission of the urine and enhances the contractility of the muscles of the larynx.

There is no authentic case of fatal formic-acid poisoning on record. In very massive doses as recommended by Clement (2 to 3 gm. a few times during the day), we find not infrequently toxic symptoms, as vertigo, nausea and vomiting, albuminuria, hematuria, vesical tenesmus, dyspnea and lowered temperature. According to Lewin,[7] 1 gr. of sodium formate per kilogram of animal weight is a lethal dose.

THERAPEUTICS OF FORMIC ACID.

The therapeutics of formic acid are manifold, but indefinite. It has been employed, as we have already seen, in a similar way as cantharides to increase sexual desire. At present the people of Paris, as I have learned from a trustworthy source, are again beginning to utilize it for the same purpose. Formic acid has been turned to practical account—in years gone-by especially—in the treatment of atonic conditions of the urinary organs, vesical weakness, dropsy, paralysis and gouty and rheumatic affections, in general when a stimulant of the mucous membranes or a diaphoretic and diuretic agent was indicated.

It was often used as an external remedy, especially in the form of the *Spiritus formicarum*. This is prepared by mixing four parts of formic acid, seventy parts of alcohol and twenty-six parts of water. Topically this was employed alone or with other rubefacients, as compound spirit of angelica, spirits of camphor, etc. Internally it was prescribed in doses of from 0.5 to 2.0 c.c. several times a day. Popular medicine made use of the ants and of formic acid. Placed in little linen bags and crushed therein, the ants were pressed against the portion of the body affected with paralysis, neuralgia, gout or rheumatism, or their juice was employed by rubbing it directly into the diseased joint or muscle. At other times the ants were used for local or general baths or for inhalation (diseases of the respiratory organs) or finally in the form of fomentations. The Russian peasant prepares his ant bath in the following way: Finding an ant's nest, he puts into a linen bag the ants, their eggs and necessarily considerable dirt. Returning to his home, he plunges his bag of ants, which he has previously fastened tightly at the mouth, into the hot water of the bath. After several minutes the water gives off a very strong penetrating odor of formic acid. The bath is now ready and the invalid is put

5. Formaldehyd is partially oxidized to formic acid in the organism and excreted as such by the urine. I have repeatedly observed that the urine of diabetic patients, when these had taken urinary antiseptics (so called) which liberate formaldehyd and consequently formic acid, had no inhibiting influence on distiller's yeast which was added in order to perform the fermentation test for urinary glucose. Again, Effront, of Brussels, has lately demonstrated that yeast which has become accustomed to gradually increased amount of formol, is capable of decomposing the latter even before it attacks maltose or glucose contained in the liquid.

into it. In certain diseases of the respiratory organs the fumes emanating from the decoction are inhaled by the patient.

Looking over the field of formic-acid therapeutics we find that it was and still is chiefly employed as an epispastic. It has been generally utilized on account of its vesicatory, rubefacient and irritating qualities and not on account of a well-defined chemical or constitutional action. Its employment even as an aphrodisiac or as a diuretic must be ascribed to its irritating influence. Applied to a paralyzed limb or to a rheumatic joint, its beneficial influence is solely due to its power of exciting the circulation and setting up a somewhat enduring counter-irritation. Hypodermic injection of the dilute acid into limbs affected with rheumatic conditions as practiced by Couch[8] may effect beneficial results by reason of its antiseptic qualities if a septic state underlies the local manifestation. In the majority of instances, however, it is the epispastic property of this substance which brings about an amelioration of the painful condition.

My experience with formic acid as a therapeutic agent has been obtained by its internal administration mostly, or at least in conditions in which its rubefacient qualities seemed to play an unimportant or secondary rôle. Besides using this remedy in a variety of other affections, I have tested its therapeutic efficacy in a comparatively large number of cases of gout, acute articular rheumatism, muscular pain, cancer, diphtheria, intestinal toxicoses, syphilis and phthisis.

Gout.—Internally administered in doses of from two to ten drops, formic acid does not seem to reduce the gouty state. Employed hypodermically (not in the lesion itself) in from 0.5 to 1.5 c.c. of a 2 per cent. solution, it proved equally ineffective even when it was injected three times daily for from three to five consecutive days.

Acute Articular Rheumatism.—Administered alone internally, formic acid in my hands proved of no avail in ameliorating rheumatic fever. The same must be said of its hypodermic introduction when injected into non-affected parts for eventual constitutional effects. Combined with citric acid, however, as in the following formula, I have employed it with a certain degree of satisfaction, although its efficacy can not be compared with that of sodium salicylate:

R. Acidi formici
Acidi citrici, āā ..... 5 parts
Glycerini ..... 40 parts
Tinct. cardamoni ..... 1 part
Aquæ ..... 49 parts
M. Sig.: Teaspoonful doses every two to four hours.

Muscular Pain.—Muscular pain of vague character which ceases when an ointment of salicylic acid and methyl salicylate or dry hot air is applied is not relieved by the internal continued administration of formic acid in the usual doses.

Cancer.—The internal administration of formic acid has certainly averted a quick fatal issue in a number of inoperable cases of cancer. In such cases I have usually given it in essence of pepsin which makes an excellent vehicle for its administration. A saturated formic-acid-iodin solution (about 0.5 gram iodin in 60 c.c. formic acid) has given similar results, either when administered by the mouth or hypodermically. Injected in and around the edges of the cancerous tumor (epithelioma, etc.), the iodin-formic-acid solution has given very gratifying results to some of my surgical colleagues in New York (Dr. Daniel Lewis, the late Dr. Thomas H. Manley). The advent of Roentgen-ray therapy by which similarly located cancerous growths are successfully treated prompted us to discontinue our experiments in this particular field.

Diphtheria.—Before the days of the diphtheria antitoxin I used nothing but formic acid, both locally and internally, in the treatment of diphtheritic affections. I do not remember having lost a single case of diphtheria so treated. Internally in this condition I usually gave formic acid in drop doses well diluted in water, with the occasional addition of some whisky. This dose was repeated every one, two or three hours according to the severity of the attack. When the disease was well under control the medication was continued three times a day for from four to eight days. Locally, that is to the faucial mucosa or to any other affected area of the mucous membrane, a 5 per cent. formic-acid-glycerin solution was at once applied and this was followed by swabbing with a 1 or 2 per cent. glycerin solution every few hours. To prevent the spreading of diphtheria in a family I employed locally the 1 per cent. glycerin solution, which was applied once daily to the nares and three times a day to the fauces of the healthy members.

Intestinal Toxicoses.—In toxicoses of supposedly intestinal origin I have made use of formic acid very frequently. I have already dwelt on this point.[9] Formic acid exerts a distinct antidotal value in certain forms of enterotoxicosis and even autotoxicosis. It may be taken before or after removal of the gastric and colonic contents in doses of from two to five drops, well diluted, every hour. Besides its pronounced antiseptic qualities, which it has no occasion to exhibit in genuine intrabiontic toxicosis, formic acid undoubtedly exerts a specific influence on the enteric secretion, a property which sodium formate and the other formates, ingested as such, do not seem to possess.

Syphilis.—In the secondary and tertiary stages of syphilis the iodin-formic acid solution, internally administered, has been well borne in most of the instances in which I employed it, and has been productive of splendid results in almost every case. It does not, as a rule, call forth the same degree of depression of the nervous system as potassium iodid, neither does it occasion muscular asthenia or lowered tone of the heart, which will invariably follow the prolonged administration of iodin or any of its therapeutically active salts.

The iodin-formic acid solution, which some of my chemical and medical colleagues have styled "Stern's solution," for the treatment of syphilitic manifestations is best prescribed in gradually increasing doses and in a menstruum like essence of pepsin. I had a patient who took as much as 3 c.c. of the solution three times a day. Such large doses, however, are hardly called for and may prove injurious to the gastrointestinal mucosa. Applied locally in syphilitic (and gonorrheal) rheumatism, so-called, some of the iodin, probably on account of the vesicatory action of the formic acid, penetrates into the deeper structures, frequently affording relief of the symptoms. The local application, undiluted, is rather a painful expedient and the diluted solution is of but little, if any, therapeutic value. Hypodermically administered, it will improve the symptoms in a comparatively short time. Still, for obvious reasons, I would

8 Medical Record, June 24, 1905.

9. Medical Standard, September, 1904.

prefer the internal administration of this remedy. The solution is especially indicated in the treatment of the syphilitic manifestations of the nervous system, preeminently in those conditions which are the result of syphilitic nodes or gummata.

Pulmonary Phthisis.—Formic acid, and more particularly the iodin-formic acid solution, which must be prepared without heating, as the latter would cause decomposition of the formic acid, in my hands has proved the most valuable medicinal agent thus far advanced for the treatment and cure of—let me call it by the old names—chronic ulcerative and chronic fibrous phthisis. It would lead me too far to state on this occasion my experience with these medicinal agents in detail. A more thorough study of the subject will be published in a separate article in the near future. I only wish to state that I have employed it in the treatment of pulmonary phthisis ever since the monumental tuberculin failure, both in private and hospital practice, in more than 800 cases.

Of course, neither formic acid nor the iodin solution, which latter I have used exclusively in phthisis in the last ten years, is an infallible remedy in this affection. If this were the case I would have given to the world my experience with the drug long ago. I am sorry to say that the solution did not cure all of these 800 patients, neither do I wish to maintain at the present moment that it is even a rational remedial agent in the treatment of phthisis, but I wish to state that thus far it is the only drug which has given me positive results, that is, in improving or curing the condition in over 70 per cent. of all of my cases.

It is certainly a much more rational agent than creosote and its preparations and all other symptomatic makeshifts, including rest cure, open air and dietary treatment, devised to this day for the amelioration of this, the most common of all the chronic pathologic conditions.

DISCUSSION.

DR. W. C. ABBOTT, Chicago, asked: Taking formic acid as a remedial agent, what does it do physiologically? Clinically, he said, the result has been demonstrated, but he asked how the result is obtained.

DR. W. F. WAUGH, Chicago, called attention to the fact that formic acid has been said to stimulate the growth of plants, so much so that it has been alleged that the Hindoo fakir who shows a plant growing before one's eyes employs an earth that contains formic acid. If this be true, Dr. Waugh said that it would be exceedingly interesting to know whether or not formic acid stimulates any of the tissues or organs of the body, or its cells, so as to increase their power of resisting noxious agents such as tubercle bacilli, or the possible germ of cancer.

DR. H. STERN, New York, said that he had tried to give all the real pharmacodynamics of formic acid and that he did not succeed because formic acid is produced constantly in the human body, as it is one of the members of the fatty acid series found in every organism, healthy or diseased. When formic acid as such is taken by the mouth it combines to form sodium formate in the stomach, but it is again excreted as formic acid, provided it is taken in medicinal doses. Therefore, there is a double conversion, into sodium formate and then back into formic acid. Dr. Stern said he does not know how it acts. Whether or not it exerts a specific action on the tubercle he does not know, but in combination with iodin, he said, it has healing virtues and facilitates the production of fibrous tissue. In other words, in most of the patients who have taken the iodin preparation a chronic fibrosis has been produced.

A PRACTICAL METHOD OF ABOLISHING THE CAUSE OF ONE-QUARTER OF THE UNNECESSARY BLINDNESS IN THE UNITED STATES.

F. PARK LEWIS, M.D.

President New York State Commission for Improving the Condition of the Blind, 1903-1904.

BUFFALO, N. Y.

When an enlightened, civilized and progressive nation quietly and passively, year after year, permits a multitude of its people unnecessarily to become blind, and more especially when one-quarter of these are infants, the reason for such a startling condition of affairs demands explanation. That such is the fact practically all reliable ophthalmologists agree.

From a summary of carefully tabulated statistics it has been demonstrated that at least four-tenths of all existing blindness might have been avoided had proper preventative or curative measures been employed, while one-quarter of this, or one-tenth of the whole, is due to ophthalmia neonatorum, an infectious, preventable and almost absolutely curable disease. Perhaps this statement will take on a new meaning when it is added that there are in the State of New York alone more than six thousand and in the United States more than fifty thousand blind people; of these, six hundred in the one state and five thousand in the country would have been saved from lives of darkness and unhappiness, in having lost all the joys that come through sight, and of more or less complete dependence, for no individual can be as self-sufficient without as with eyes—if a simple, safe and easily applied precautionary measure had been taken at the right time and in the right way to prevent this affliction. The following three vital facts are not questioned, but are universally accepted by those qualified to know:

1. The ophthalmia of infancy is an infectious germ disease.

2. By the instillation of a silver salt in the eyes of a new-born infant the disease is prevented from developing in all but an exceedingly small number of the cases in which it would otherwise have appeared.

3. In practically all those few exceptional cases the disease is absolutely curable if like treatment is employed at a sufficiently early period.

Since these facts are no longer subjects of discussion, but are universally accepted by all educated medical men, the natural inquiry follows: Why, as a commonsense proposition, are not these simple, harmless, preventive measures invariably employed, and why, in consequence of this neglect, does a nation sit quietly and indifferently by, making no attempt to prevent this enormous and needless waste of human eyes?

The reasons are threefold and lie, first, with the medical profession; second, with the lay public; third, with the state.

The medical profession, great as have been its advances during recent years and strenuous as have been the efforts of its teachers and leaders to promulgate the fundamental importance of germs in disease, is by no means yet universally familiar with the facts concerning infantile ophthalmia, as to its prevalence, its dangers, its prevention and the measures that may be successfully instituted for its treatment. While the total number of cases is large, the disease may occur very rarely in the experience of any individual physician, even though he may have had an extensive general practice. When it does occur, unless the physician is fully informed, he

does not anticipate it and is unprepared to meet it. He thinks, in many cases, if his attention is called to the baby's eyes, as, indeed, it may not be at all, that the redness and watering is caused by a trifling catarrhal conjunctivitis, and prescribes some simple collyrium or external wash for the lids. He may not see the child again for a week, when perhaps the disease is fully developed, the cornea broken down and irreparable damage done; or, as sometimes happens, he does not know of the special value of the silver salts or fears to employ them because of their possible danger to the delicate eye of the child, and prevention is omitted and correct treatment neglected. It has been shown that the larger proportion of cases of blindness resulting from infantile ophthalmia occurs in the more remote country districts where the parturient patient is infrequently seen and where preventive measures are most imperative. It may not seem possible to the progressive up-to-date practitioner that many physicians are not familiar with this common disease, but the large number of cases of infantile ophthalmia that are constantly occurring, with the clinical histories accompanying them, together with the immense number of blind eyes as a direct sequence, prove beyond question that this is a fact.

The second reason for this apparent indifference lies with the lay public. The young mother has no conception of the danger which an inflammation of the eyes means to her baby. She has probably never heard that such a condition can threaten an infant's eyes. It is but one of the many new problems which maternity has for her, and only when the truth is told to her that the child, in whom all her hopes had been centered, is hopelessly, irrecoverably blind, does she begin to realize the extent of this frightful affliction. If she chance to learn, as she may, that this calamity was a needless one and might have been avoided by simple precautionary measures which were not taken, to her anguish is added indignation and censure of the physician by whom she considers her trust to have been betrayed.

The third agent concerned is the commonwealth. The loss of sight on the part of an infant makes the individual a state care in some measure for life. For the education of its blind children annually New York alone pays per capita at least three hundred and fifty dollars and a yearly gross sum amounting to much more than one hundred thousand dollars. If, as sometimes happens, the blind citizen is a dependent throughout a long life, the cost of maintenance is not less than ten thousand dollars, and the mere cost in money will be multiplied many times in that a productive factor, in reason of blindness, has been removed from the community.

If, therefore, as an economic proposition, it were realized how vitally it concerns the state that not one child shall needlessly become blind, thereby increasing the public financial burden, there is no doubt that early and effective measures would be instituted to protect the state from this unnecessary and extravagant expenditure of public funds.

It would seem that there are but two reasons why a generally recognized and effective measure for the prevention of a widespread and common cause of blindness is not invariably employed: First, because the dangers of the disease and the value of prevention are not universally known, and, second, because a safe, sterile, simple and free preparation in which the profession and the public have absolute confidence is not always at hand when needed. Concerning the first, various sporadic efforts have been made to inform midwives, who in large cities preside over half at least of the births, of the dangers of sore eyes in the new-born, and eleven states have passed legislative enactments requiring that the midwife shall report each case to the proper health authority and affixing a penalty for the failure to do so. As has been intimated, however, it is not by any means always under the ministration of midwives that these cases occur, and, like all laws behind which is not a strong and well-informed public sentiment, this law is rarely enforced. A more effective method must be devised. Every physician having to do with the parturient woman, every obstetrician, every midwife, must be frequently and constantly advised of the dangers and possibilities of this disease, the necessity of prevention and the value of early and correct treatment. They must then have placed in their hands ready for instant use a safe and efficient preparation issued by the health authorities as a guarantee as to its quality and efficiency.

An important step was taken in this direction when a resolution was passed by the House of Delegates, at the annual meeting of the New York State Medical Society, requesting the various health officers of the state to include ophthalmia neonatorum among contagious diseases which must be reported to the local boards of health.

This is, indeed, only a beginning; not only should every case be reported, but the conditions of each eye should be described in the report and accurate records made as to the result. If, then, the sight in one or both eyes is lost, inquiry as to the reason should be instituted. The assurance that such an investigation will certainly follow will inevitably cause a degree of care to be exercised that will immediately lessen the number of cases of blindness due to this cause.
