of some children to frequent outbreaks in one family or another. This is due to a lessened resistance, either hereditary or acquired. The protection of the heart and the prevention of fresh attacks should be the main object of treatment. The former is secured by rest and counteracting of poisons, while the latter is obtained by hygienic management, especially of clothing, exercise and bathing.

The Attitude of the Physician Toward the Nostrum Evil.

DR. CHARLES SPENCER WILLIAMSON, Chicago, said that a very small part of the knowledge and energy which every physician is constantly giving to his work would, if applied to the eradication of the nostrum evil, do away with it in a very short time. Already there are signs of improvement. In another city where the nostrum evil had reached a year or so ago even a worse stage than in Chicago, he finds from the last 200 prescriptions taken consecutively but 21 calling for proprietaries. This number is, of course, still many times in excess of the justifiable proportion, and yet it shows the diminution to one-half or one-third of what should be readily obtained. All that is necessary is to arouse the profession thoroughly to the exact situation, and it will do as it always has done before—act promptly and efficiently, and wipe out this blot on its fair name.

Diseases in the Aged.

DR. W. H. CURTIS, Wilmington, drew the following conclusions: 1. While the first requisite for longevity may, perhaps, be deemed to be an inborn, perhaps inherited quality of tissue structure wherein one part shall be just as strong as another, like the materials of the famous "One Hoss Shay," it is still manifestly possible and sometime practicable to detect the onset of those pathologic processes frequently originating in middle life, and whose development is synonymous with that symptom-complex known as old age. And, further, when a diagnosis is thus made, it is possible and frequently practicable to institute therapeutic measures that will insure the prolongation of the individual life. 2. The study of the processes of disease in the aged, together with their appropriate therapeutics, offers a rich field for individual research, and one that deserves more thorough cultivation. In this connection present knowledge of the subject needs thorough revision, amplification and systematization at competent hands, and to be made more accessible. 3. It is requisite to the successful study of disease in the aged, and certainly almost essential to the one who undertakes their management, that he be possessed of a peculiar mentality, combining not only a liberal education, but great resourcefulness in tact, patience and sympathy.

Treatment of Obesity.

DR. ALFRED C. CROFTAN, Chicago, presented some newer ideas on the treatment of this condition. He discussed the science and art of reduction cures, the calorimetric method, the three degrees of obesity and their management, the restriction of liquids, the element of exercise, the treatment of complications, thyroid therapy and results.

Significance of Hydrochloric Acid Variation in the Stomach Contents.

DR. E. J. BROWN, Decatur, spoke of the relative importance of HCl determination to other chemical findings, and to the physical examination of the stomach. Errors in diagnosis are made by placing too much reliance on HCl tests. He spoke of the relations of HCl excess to so called bilious attacks, muscular rheumatism, gout, eczema, etc. He emphasized, too, the value of HCl tests in hyperchlorhydria, achylia gastrica, gastritis, cancer, ulcer and neurasthenic gastrica.

The Opium Habit and Its Treatment.

DR. GEORGE F. BUTLER, Chicago, said that there is no systematic routine specific treatment for this disease. The patient and not the disease, here as in all cases, is first to be considered. He first ascertains the maximum dose and the total daily amount of the drug the patient is taking. Then he begins the gradual or more rapid withdrawal of the morphin, the method employed being governed entirely by the character of the case. Under no circumstances must the patient know the amount he is given at any stage of the treatment. If the patient is taking it hypodermically, Butler endeavors to abandon the use of the needle as soon as possible, without detriment to the patient, substituting deodorized tincture of opium or codein in some vehicle, preferably non-alcoholic, which will completely disguise the taste of the opium. The patient is invariably encouraged to abandon the use of the hypodermic syringe. The opium in the mixture for internal use can be diminished as required. Free elimination by the bowels, skin and kidneys must be maintained. He believes morphinism can be cured in the great majority of cases if the physician can have the confidence and entire control of the patient, and have him in an institution where all the facilities for proper treatment are at hand, and provided he can keep the patient under observation a sufficient length of time and will treat the patient mentally and physically, and not merely the disease, according to some routine method.

Serum Therapy.

DR. E. R. LARNED, Chicago, classified sera as to their being efficient or inefficient. He spoke of efforts to produce new sera; also of the attempts made to improve sera which have been inefficient for the purposes intended. He spoke of the investigations that have been carried on with reference to making anti-gonorrheal and anti-syphilitic serum. Attention was directed to modifications of the Widal test for the diagnosis of typhoid fever, and of Wassermann's serum in the treatment of diphtheria.

Crime as a Social Disease.

GOV. CHARLES S. DENEEN confined his remarks mostly to crime in Cook County, where for eight years he was state's attorney, and was brought face to face with some of the worst criminals and criminal cases in the world. While crime has existed in the world almost from the beginning, it is only comparatively recently that it is being unearthed by modern methods, and it is only within the past 25 years that criminal procedure has been directed at the source of crime. The criminal court of Cook County is the greatest in the world. This court has a record of 4,000 prosecutions annually by the state's attorney of Cook County. He closed by saying that crime offered one of the widest fields for medical opportunity in the country.

Popular Diffusion of Medical Knowledge.

DR. H. C. MITCHELL, Carbondale, in his presidential address, brought forth the fact that the educated are the best class of people with whom the doctors have to deal; that there is less disease as the people advance in the educational scale, and that the educated are the most reasonable to deal with. He also stated that the society should advocate the passage of a law compelling people who wish to marry to undergo a physical and mental examination before entering on matrimony, and thus allay much of the suffering caused by immature marriage and consequent evil and sickness. Such a measure, he said, would cheat the divorce courts and the jails of their patrons.

Perirectal Abscess.

DR. CHARLES J. DRUECK, Chicago, emphasized the frequently overlooked details in the treatment of perirectal abscess, and took up the pathology, symptoms and diagnosis. Under treatment he considered the necessity of immediate evacuation. He referred to the facts and fallacies of the different methods of obtaining drainage, and made a few remarks relative to the method employed by him. He spoke of the danger of autointoxication and pelvic congestion during the postoperative treatment, and how to prevent it.

The Brain a Good Field for Surgery.

DR. CHARLES D. CENTER, Quincy, attempted to show by numerous well-authenticated cases of traumatism, that many portions of the brain need not be considered vital parts; that less reluctance should be shown by surgeons in invading the brain under antiseptic precautions, the argument being based on the insensitivenes of the brain to injury. The reason for much unsatisfactory brain surgery in the past is that operative measures have been used too much as a last resort instead

of a first resort, and operation has been done in the presence of inflammation, sepsis, or both. He reported a case of gunshot wound of the brain where the ball traversed the brain once in antero-posterior diameter, and partially traversed again in ricochet. Skiagraphs of the head of the patient at the present time were exhibited, and some interesting phenomena were noticed during the progress of the case.

Renal Diagnosis.

DR. FREDERICK LEUSMAN, Chicago, submitted the following conclusions: 1. Functional tests are helpful in causing us to study the kidney more accurately before operation. Their findings are not without value, but experience shows we can do as well without as with their assistance. When employing them in order to save life, we must at times operate, despite their findings. 2. The cystoscope and ureteral catheter have come to stay, and familiarity with their use is becoming more general every day. They are indispensable diagnostic aids. 3. Time will show the practical value or worthlessness of other diagnostic methods. 4. A chemical, microscopic and bacteriologic examination of the urine obtained from the ureteral catheter frequently means much to the patient. 5. The *x*-ray is desirable, if obtainable. 6. An early incision into the kidney in the presence of symptoms pointing to renal surgery is the safest thing for the patient. 7. Do not explore during suppurating conditions. 8. Most kidney operations demand probing to test ureteral patency. 8. Experience demands early nephrolithotomy as soon as the existence of stone is established; early nephrectomy in renal tuberculosis, and early nephrotomy or nephrectomy in acute renal abscess. 10. Nephrotomy is safer than nephrectomy in calculus, especially multiple; also in nephritis and cystic kidney. 11. In doing renal surgery we must not neglect to take care of the associated abdominal pathology—stomach ulcer, duodenal ulcer, cholelithiasis and cholecystitis, appendicitis, intestinal stricture or tumor, intestinal tuberculosis, uterine and pelvic adnexa disease.

(To be continued.)

THE MEDICAL SOCIETY OF THE CITY HOSPITAL ALUMNI.

Meeting held at the St. Louis Female Hospital, May 17, 1906.

Lymphangioma of the Hand.

DR. C. G. WRIGHT presented a case of this affection occurring in a negro child. Family history was not obtained; physical examination showed a well-nourished child; palpation and auscultation were negative. The skin showed numerous small scars; the inguinal lymph glands were enlarged. There was multiple dactylitis of the right hand, the dorsal surface of the fingers being involved. The bones were palpable in the mass, the enlargement being hard and nodular. The left hand was in good condition. The condition had existed since birth.

DR. JOHN GREEN, JR., thought that the condition of the eyes suggested struma. There was a phlyctenular keratitis with some marginal trouble of the lids. Yet he understood that the tuberculous nature of the condition was denied.

A Case of Complete Prolapse of Uterus.

DR. O. H. ELBRECHT'S patient was a washerwoman with a family and personal history negative. She has had three children. The prolapse had existed for eighteen years. There was pain and tenderness in the groin and in the uterus, and the bladder protruded through the labia majora.

DISCUSSION.

DR. F. J. TAUSSIG said that the question of therapy in these cases is puzzling to the profession. The first thing to be considered is whether or not the patient will consent to an operation. If not, the cup and bell supporting pessary may be tried, but it is not usually successful. Another form of pessary that is not so well known is the Menge pessary, which is a modification of the ordinary hard-rubber ring, with a stem which points outward. The main objection to the ordinary hard-rubber ring is that it is easily expelled, because it tilts. The idea of the bulb stem in the Menge pessary is to keep the round part transversely in the pelvis. The bulb end is short. He said that he had tried it in two cases with good results, both being cases of complete prolapse. Operation was suggested, but was refused. As regards the operative side of the case, Dr. Taussig said that he favors the operation of inverting the uterus in the vagina. If the tubes are resected, conception is prevented. By complete hysterectomy the chance of cystocele forming must always be remembered. Furthermore, in such an operation the vagina is obliterated, which is objectionable in married women. The danger of hernia likewise must not be overlooked.

DR. ELBRECHT said that the prolapsus did not bother this patient except when she was working. He did not think the use of pessaries practicable in women who have to do manual labor. They produce excoriations of the vagina. He said that he has yet to see a pessary that will last. They irritate and produce inflammation. He does not like the operation of inversion. He believes the ideal operation is to remove the uterus by the abdominal route and to sew the broad ligaments together. This gives the intestines something on which to rest. This is accomplished in the Fruend-Wertheim operation. When the possibility of pregnancy can not be excluded it is not right to do this.

Aneurism of Thoracic Aorta with Ulcer of Esophagus and Perigastritis.

DR. W. H. RUSH'S patient was a male, aged 56. He had no specific history. Nine years ago he had some caseous lymphatic glands of the neck excised. He presented himself on two different occasions with pains in the pectoral muscles, cough, no chill, but with decided pains in the epigastrium and symptoms suggestive of ulcer of the stomach. He left the hospital and returned some few months later with diminished weight, pain under the scapula and behind the sternum, also exaggeration of the stomach pains. Analysis of stomach contents after a test meal showed free hydrochloric acid, but no blood. He displayed marked tenderness on the left of the spinal column from the third to the ninth dorsal vertebræ. There was extreme tenderness in the entire epigastrium and left hypochondrium, the point of greatest tenderness being to the left of the median line, about two inches below the ensiform cartilage. A diagnosis of ulcer of the stomach and perigastritis was made and the patient was given potassium iodid and mercury in view of the possibility of existing syphilis. Improvement followed for about two weeks, when he was suddenly seized with hemorrhage and in thirty minutes was dead. The autopsy showed the left pleural cavity filled with blood, the lower lobe of left lung filled with blood, the tissue soft and friable. The entire arch of the aorta and the thoracic aorta were atheromatous and projecting from the outer curve of the arch and from the outer side of the upper part of the thoracic aorta was a group of several small sacculated aneurisms, the smallest no larger than a pea. The largest, very thin-walled, about two inches long and irregularly cylindrical in shape, had ruptured into the left pleural cavity and into the left lung. The bodies of the fifth and sixth dorsal vertebræ were eroded. There was no ulcer of the stomach, but in the esophagus, on a level with the upper and smaller of the aneurisms, was an irregular shallow ulcer about 2 cm. in diameter. There was some perigastritis. Rush did not believe that the ulcer of the esophagus caused any of the pain, which was probably due to the pressure of the aneurism.

DR. C. H. SHUTT referred to the case of a man who presented symptoms of a chest disorder. The diagnosis was made of old pleuritis with dense adhesions. One day while walking about the ward he fell over and died. The autopsy showed a rupture of an aneurism into the chest. The dorsal and lumbar vertebræ were eroded from the eleventh dorsal to the third lumbar. The posterior wall of the aorta had entirely disappeared. Pieces of bone projected into the sac.

Ventral Hernia with Gangrenous Ulceration Over Sac.

DR. CORPEDGE'S patient was a very fat subject, a female. She acquired a hernia in the median line. An operation had been performed a few months previously, but the protrusion recurred. There are now three protruding areas. Each pre-

rusion is about the size of an orange. The abdominal walls are very lax. There is a gangrenous ulcer over one side.

DISCUSSION.

DR. DEUTSCH said that no operation would be justifiable in such a case, but he thought the ulcer could be excised so as to prevent the death of the patient from gangrene.

DR. ELBRECHT stated that the patient's condition had improved since entering the hospital. The ulcer was healing. The operation that had previously been performed was the overlapping operation of Mayo, made in this case by Dr. Brown of the City Hospital. He did not believe that any surgical procedure would avail at this time. He did not think that the ulcer should be healed by grafts, but rather preferred the method of healing by scar tissue, thus strengthening the abdominal walls.

Case of Spina Bifida.

DR. GIVEN CAMPBELL presented this patient, a girl of 12. Ever since birth she has been unable to use the lower extremities, bladder and rectum. This condition, he stated, was undoubtedly a meningo-myelocele, with projection of the lower part of the spinal cord into the tumor. Part of the nervous tissue was defective and produced the paralysis and the paralytic clubfoot.

Case of Insular Sclerosis.

DR. CAMPBELL also presented this patient, a woman of 28. The trouble began two years ago. The practical point to be deduced from the case is that when there is nervous trouble of an organic nature in a person of this age it is apt to be multiple sclerosis. Dr. Campbell then presented another case which he was inclined to believe was also multiple sclerosis. The history of the first patient (aged 28 years) was that she noticed a numbness four months ago. She can not use the right hand in eating. The knee-jerks are increased; Babinski reflex increased. The pupils react to light. Nystagmus is present. There were no signs of mental disturbance. The feet sometimes swell. She has a distinct nervous disturbance of the bladder. The ankle clonus present stamps the organic nature of the trouble. Campbell said that the most common diffuse organic condition that occurs in young women is multiple sclerosis. Among the symptoms are intention tremor, being a trembling in the hands when the individual attempts to perform some voluntary act that requires precision. In this case there is a distinct jerk of the eyeball. Among the important symptoms which this patient shows are spastic condition of the lower limbs and the ankle clonus. If the condition were due to a specific trouble there would be sluggishness to light reaction. In the two temporal halves of the optic discs there was a tendency to atrophy, which is symptomatic of multiple sclerosis. The other patient presented showed the phenomenon of "scanning speech," that is to say, an accentuation of words in talking much as one accentuates in scanning poetry. The intention tremor was very pronounced in the second case. The author believes rest cure the best treatment. The salicylates, iron and quinin help in some cases. The tendency of the disease, however, is to progress, although some patients hold their own for twenty years with this condition.

DISCUSSION.

DR. JOHN GREEN, JR., stated that he had examined the eyes of the first patient presented last November. There were some suggestive symptoms of insular sclerosis. Her vision was good. The left pupil was larger than the right. The reaction to light was sharp. The visual fields were apparently quite normal. He was only able to apply the rough finger tests at the time of the examination at the hospital. He said that in the differential diagnosis between hysteria and multiple sclerosis it is of great importance to get a careful estimation of the color fields. There did not appear to be any true nystagmus, but toward the end of the lateral excursions to the right and to the left there was a slight twitching. This is characteristic of the nystagmus of multiple sclerosis, this condition being more marked than the physiologic nystagmus. There was no ocular paralysis. Mobility was free in all directions. The patient never "saw double." The ophthalmoscope revealed pallor of the discs. The atrophy of multiple sclerosis is a postneuritic atrophy. Dr. Green called attention to the fact that ocular examination is often of the greatest assistance in estimating the differential diagnosis between multiple sclerosis and hysteria. Last year Dr. Schwab and Dr. Green reported such a case. There was slight ocular atrophy. Another sign was contraction of the fields for form and color. The fields were contracted in the usual way, not inverted. There was no evidence of tube-shaped fields. It is said that certain of these cases present eye symptoms years before the other symptoms of multiple sclerosis appear, and therefore it behooves the neurologist in any doubtful case to have the eyes examined.

DR. ELBRECHT said that most patients with spina bifida die within the first week of life. Operations for their cure are not successful. In view of the high mortality of the operation he did not approve of operation. Dennis has reported 57 cases, 25 operations, 15 deaths, 7 recoveries, 3 recoveries with no improvement. These cases often occur in bunches, and he has seen four at the Female Hospital in six weeks. The contraindications for operation are involvement of the bladder, hydrocephalus, clubfoot and marasmus. Deaths after operation occur from meningitis through infection.

AMERICAN GYNECOLOGICAL SOCIETY.

Thirty-first Annual Meeting, held at Hot Springs, Va., May 22-24, 1906.

The President, DR. RICHARD B. MAURY, Memphis, Tenn., in the Chair.

Officers Elected.

The following officers were elected for the ensuing year: President, Dr. Clement Cleveland, New York; vice-presidents, Dr. J. Clifton Edgar, New York, and Dr. Willis E. Ford, Utica, N. Y.; secretary, Dr. J. Riddle Goffe, New York (re-elected); treasurer, Dr. J. Montgomery Baldy, Philadelphia (re-elected); member of the council, Dr. Richard D. Maury, Memphis, Tenn.

The next annual meeting of the society will be held in Washington, D. C., 1907, in connection with the Congress of Physicians and Surgeons.

Is Gynecology Dead? Or Gynecology Against Overdone and Misapplied Surgery.

DR. E. C. GEHRUNG, St. Louis, Mo., protested against unnecessary, if not criminal, surgery that has been and is still being practiced in cases that can not be benefited by the knife, and in others that can be as well or better treated by other and less radical means. In many of the latter the knife may obtain a quicker and, perhaps, just as good result, yet at the cost of mutilation. Many women complain of various kinds and degrees of suffering, yet a most careful examination does not disclose anything on which to operate. Such women may be treated gynecologically with good results. All uterine displacements should be considered in the light of ptoses and herniæ. When the keystone between the pelvis and abdomen is displaced, abdominal ptosis must follow. These enteroptoses may be of minor degree only, or may extend to the kidney or other abdominal organs, and thus produce symptoms for which the simple uterine displacement will not account satisfactorily. The replacement of the pelvic organs frequently relieves the symptoms.

Concerning forward displacements, the situation is altogether different. Since anatomists say that anteversion and anteflexion are the normal positions of the uterus, the pathologist denies pathologic effects to antedisplacements, and the practitioner is only too happy to ignore a state of affairs for which the means of relief are so imperfect, apparently, and so difficult to apply, with so little or no results in prospect. Many of these displacements get well within a comparatively short time, while in others the support or pessary must be worn a long time. The wearing of a pessary he considered as much a cure as the wearing of a cicatrix. The author has obtained excellent results in the relief and cure of symptoms and diseases which have been declared utterly incurable by many gynecologists, by mechanical and other means. His results in cases

of antedisplacements and retrodisplacements have been extremely satisfactory.

DISCUSSION.

DR. GEORGE M. EDEBOHLS, New York, said that his views in regard to anteversion and anteflexion of the uterus have undergone radical changes since he began to practice gynecology. When he finds the uterus anteverted or antellexed, it leads him to suspect that he has to deal with excessive mobility of the organ; in other words, it is the therapeutic equivalent of retroversion of the uterus, and he treats it like a case of retroversion, and invariably his efforts have been crowned with success.

DR. J. RIDDLE GOFFE, New York, expressed himself as having been convinced for many years that anteversion is a normal position of the uterus, and teaches that anteversion should be stricken out of the list of pathologic positions of the fundus of the uterus. He has not found in later years any occasion whatever to interfere with a fundus that lies well to the front. He believes the symptoms of which patients complain can be accounted for by other conditions, and he invariably finds some pathologic condition to account for the symptoms. He does not try to manipulate the fundus in any way with a view of fixing it, or to interfere with its mobility. Anteflexion he regards in a different light and believes that the anteflexed uterus is, as a rule, unless the flexion is acquired, an undeveloped uterus, and he treats it by improving its nutrition, stimulating its circulation, and developing the organ. If the case is one of acquired anteflexion, he treats it very much in the same way, but does not interfere with it surgically by shortening its ligaments or by attaching the fundus to abnormal tissue.

Enteroptosis.

DR. RICHARD R. SMITH, Grand Rapids, Mich., said that the subject is of especial importance to the gynecologist since the majority of the patients who come to him for relief show more or less signs of this condition. It may form merely the background of the picture which the physician has before him, or it may be the complete picture without other pathology. It can be left out of consideration, so far as treatment goes, in patients presenting neoplasms or pelvic inflammatory diseases. It is of great importance in considering lacerations, the various displacements of the uterus, as well as that large class of patients presenting pelvic symptoms, so-called, with slight or undemonstrable lesion. One should consider the matter of operation in such cases with great care, and be most guarded in his prognosis. Above all, in case operation is done, it is very necessary that a proper course of treatment be carried out afterward if one expects to get results. Enteroptosis and fair health are not incompatible. The enteroptosis may be of a decided degree and still the woman go through life comfortably and accomplish her work.

The treatment of enteroptosis should really begin in childhood, and it means all that proper hygiene can do for children. The outdoor life, the exercise and school work should be carefully balanced. The child should be encouraged in the various sports which develop the chest and the muscles of the trunk. If a woman comes suffering from the symptoms which accompany enteroptosis, she should be put to bed. She should be given an abundant, easily digested diet, massage, and any necessary indications as to the bowels and digestion should be met. Pain usually decreases rapidly under this plan. He emphasized the great good that may be obtained from an outdoor life. He advises many of his patients practically as he would a patient suffering from tuberculosis. If the abdomen is prominent or very flabby, and the woman has general abdominal tenderness, and more especially if he finds that by standing behind her and placing the hands over the lower abdomen (the patient standing) and lifting up, relief is obtained, he advises a well-fitting abdominal bandage. If the patient is young, the thorax more or less mobile, he has often given a system of breathing exercises with the idea of increasing the lung capacity and the size of the upper abdomen.

DISCUSSION.

DR. CHARLES P. NOBLE, Philadelphia, thinks that it is a mistake to teach that all patients who have loose kidneys have enteroptosis. It is only in a minority of cases that a loose kidney is complicated with enteroptosis. Many patients who have enteroptosis have loose kidneys; but the converse, in his judgment, is not true. He has seen a few cases of loose kidney due to traumatism, but the number is very small. The great majority of women who have loose kidneys are unmarried; therefore the question of child-bearing is a very small factor in these subjects. It has much more to do with enteroptosis by causing a flaccid condition of the abdominal muscles; but so far as the kidney is concerned, it is a small factor.

DR. MATTHEW D. MANN, Buffalo, New York, said that the all-pervading style among civilized women of constricting the waist line is an important causal factor of enteroptosis. The universality of this mode of dress has a great deal to do with the condition mentioned as it is more commonly found in women than in men. Men who wear tight belts, like blacksmiths, and men who constrict their waists with bands, are the subjects of enteroptoses. He condemned the use of corsets as worn by young women, and said the thorax can never attain its proper shape; the abdominal muscles lacked supportive power, and the contents of the abdomen would be forced down into an abnormal position. He has not been satisfied with operative procedures for the relief of the conditions mentioned.

DR. JOHN G. CLARK, Philadelphia, has had twenty-one cases of various ptoses of the viscera, chief among which have been ptoses of the transverse colon, especially of the sigmoid flexure. He recalls several cases of ptosis of the sigmoid flexure, where a loop of bowel has been caught, in which there was alternating constipation and diarrhea, which is not infrequently seen. He demonstrated a method which he has resorted to for the relief of this condition. He believes that in many of these cases inattention to the bowels is one material factor in the etiology.

DR. GOFFE asked what percentage of these cases came to operation?

DR. CLARK replied, a very small percentage, as medical men relieve the great majority of them.

DR. J. CLIFTON EDGAR, New York, called attention to the too early getting up of women after confinement as a causal factor of enteroptoses. Women, when they get up too early after confinement, complain of stomach trouble, and drift into the hands of a stomach specialist, who finds dropping of the stomach or intestines, yet they did not complain before. Such women are prone to attribute their discomfort to uterine trouble, to uterine displacement, etc. Constipation, alternating with relaxation of the bowels, produced by the constant administration of cathartics given during pregnancy, is one of many causal factors. There is a faulty involution of the intestinal supports. Involution of the abdomen should be complete before a woman gets up after confinement. Massage is a valuable means of prophylaxis. He believes in women, especially primipara, wearing an abdominal support for three months after confinement.

DR. J. RIDDLE GOFFE, in referring to the corset as a part of woman's dress, said he believes the new-fashioned straight front corset is an improvement over those previously worn. He thinks it is a beneficial garment to women. Instead of using abdominal supports, as was formerly his custom after laparotomy, he puts a woman in a straight-front corset, which is carefully made by a woman who carries out his idea. This corset supports the abdomen well. Women like it very much, and continue to wear it for years. He has also recommended this corset to be worn by women with pendulous abdomens.

DR. SMITH, in closing, said that a tight corset will exaggerate such conditions as he had referred to; but it must be remembered that enteroptosis is not due to the wearing of a tight corset nor to tight lacing. Enteroptosis is quite common in Arabian women, who never wear corsets.

Thrombosis and Embolism Following Abdominal Operation.

DR. JOSEPH TABER JOHNSON, Washington, D. C., said that these complications occur most frequently after supravaginal hysterectomies for fibroid tumors; although they may follow any abdominal section, notably after suspension of the uterus. The left leg is most frequently affected; both legs may be affected alternately. The symptoms generally appear between

the second and third weeks. Suppuration is rare. Recovery is the rule, although convalescence is protracted. Pulmonary, cardiac, or cerebral embolism may result, and prove rapidly fatal. He reported two such cases, and gave the histories of six cases of thrombophlebitis with slow recoveries.

Postoperative Embolism.

DR. EUGENE BOISE, Grand Rapids, Mich., said that this condition affects the pulmonary artery and its branches in the great majority of cases. An embolus presupposes a thrombus. For the formation of a thrombus three elements are necessary, fibrinogen and calcium salts, which exist normally in the blood, and nucleoproteid, which is never found in normal blood. Nucleoproteid is formed by the degeneration of the blood plates and leucocytes. Certain conditions of the blood and blood vessels predispose to thrombosis, as anemia or chlorosis, sepsis, excess of calcium salts, retardation of rate of blood current, traumatism, inflammation of coats of vessels, pressure, etc. Conditions calling for operation often involve one or more of these conditions. Fibroid tumors, which show the greatest percentage of postoperative emboli, are coincident with excess of calcium salts in the blood and degeneration of the musculature of the heart, with consequent imperfect contractions, and residual blood, with retardation of blood flow, predisposing to heart clot. Indications for treatment are mostly looking toward prevention. When pulmonary embolism occurs nothing is of much avail except the administration of oxygen.

DISCUSSION.

DR. CHARLES P. NOBLE, Philadelphia, said that of 7,130 women operated on in the Johns Hopkins Hospital, phlebitis occurred in 48. After perineorrhaphy, 4 times; after myomectomy, 19 times; after the removal of ovarian cystoma, 9 times; after hysterectomy for carcinoma, 5 times; after suspension of the uterus, 3 times; after suspensio-uteri and perineorrhaphy, 4 times; after hysterectomy for pelvic inflammatory disease, once, and after miscellaneous operations, 3 times. He has had embolism and phlebitis of the left crural vein occur twice after right nephrorrhaphies. He has had these conditions occur after hysterorrhaphy and after operations on the cervix and perineum.

DR. REUBEN PETERSON, Ann Arbor, Mich., said that the mystery in the etiology of thrombosis and embolism makes it doubly interesting. These conditions come on not only immediately after operation, but a month or six weeks afterward. He has a patient with an aggravated form of femoral thrombophlebitis, which appeared in the third week after operation. The operation consisted of the removal of non-purulent, nonadherent appendages. There was not enough sepsis connected with the case to warrant one in thinking that any such condition would develop. During the third week the woman developed thrombophlebitis of the left side of a severe type, in that it extended not only in the femoral region, but also up over the buttocks. Swelling was very intense. Very soon a dark area appeared over the left femoral vein and gradually this developed into a necrosis.

He has taken statistics from his clinic for the last four and a half years, but which do not include the case mentioned. Of 3,000 operations performed during this period there were 6 cases of femoral thrombosis. There were 1,050 women operated on. Of these, 3 came for removal of the appendages; one for hysterectomy for fibroid, although there were 80 or 100 cases in which fibroids were removed; one came for simple dilatation and curettement of the uterus, and in one case the record was not available. The left femoral vein was affected four times, and in one case the left groin and right leg were affected. As regards its occurrence after operation, in one case it occurred eleven days after operation, in two cases fourteen days, in two cases nineteen days and in one case twenty-one days.

DR. EDWARD REYNOLDS, Boston, said that thrombosis has occurred most frequently in his experience in patients treated for the correction of retrodeviations of the uterus, in which there has been a great deal of congestion before operation. He is inclined to believe that thromboses are more frequent now than they were a dozen or fifteen years ago.

DR. ANDREW F. CURRIER, New York, said that the tendency of surgeons in these days to get patients up in a hurry after the performance of serious operations has doubtless something to do with the production of thrombosis.

DR. SETH C. GORDON, Portland, Me., agreed with Dr. Currier and expressed the belief that too early getting up of patients after operation is causative of phlebitis.

DR. T. J. WATKINS, Chicago, said that evidence has been brought forth to show that thromboses are in some cases due to infection. Thromboses are common in infectious diseases where there is no traumatism. They also are common after typhoid fever. He believes that thromboses are nearly as frequent after typhoid as after abdominal section.

DR. J. MONTGOMERY BALDY, Philadelphia, said that while sepsis, pressure by retractors and traumatism of the pelvic veins are possible causal factors, yet none of the explanations so far offered seemed sufficiently feasible to explain a large number of cases.

SYMPOSIUM ON DILATATION VERSUS INCISION OF THE PREGNANT UTERUS.

Artificial Dilatation of the Cervix Uteri.

DR. GEORGE TUCKER HARRISON, New York, said that some indications for the artificial dilatation of the cervix are local morbid conditions which interfere to such an extent with the dilatability of the os uteri and cervix that the natural forces are inadequate to the end to be attained. In addition, direct danger to mother and child might furnish an indication for the artificial dilatation of the cervix, a danger only to be averted by a speedy delivery of the child. Of the local diseases, he referred especially to those which make a rigid, unyielding condition of the cervix, namely, chronic inflammations, syphilitic induration, carcinoma or hypertrophy of the infravaginal and supravaginal portions. Of the pathologic conditions which demand active intervention in the interests of both mother and child, to effect a speedy delivery he mentioned eclampsia, prolapse of the umbilical cord, placenta prævia portialis, asphyxia of the fetus, and beginning sapremic intoxication consequent on a dead fetus or retention of placental parts. Furthermore, the premature detachment of the placenta attended by internal or external hemorrhage is a grave and dangerous accident which demands prompt delivery. Artificial dilatation is indicated when in an obstetric operation (forceps, version, perforation) the passage of the head or breech meets with difficulty in consequence of an insufficiently dilated os uteri. Finally, an indication is furnished in cases of transverse presentation with premature rupture of the membranes, when version, according to Braxton-Hicks method, is not yet possible, and also in certain cases of narrow pelvis, with the head at the brim, in order to make the prophylactic version.

An indication for the incision of the os uteri is given when immediate delivery is a matter of paramount importance, the os uteri not being sufficiently dilated and the cervical canal, on the contrary, unfolded. Deep incisions of the cervix, usually combined with deep vaginal and perineal incisions, open up a wider field of operative intervention. The advantages of this procedure were pointed out. Mechanical dilatation of the cervical canal and external os uteri can be effected by distension with the fetal body after bringing down a foot, by the hand, by the use of expanding foreign bodies, such as tents, dilators, iodoform gauze, rubber bags or balloons.

Dilatation of the Parturient Uterus.

DR. PHILANDER A. HARRIS, Paterson, N. J., referred to a method of manual dilatation which he has employed for the past twenty-two years, and first described in 1893. By this method a far greater tonic strain can be applied on the musculature of the cervical ring than by any other manual method. It is also far less fatiguing than other methods. It relies mainly on the flexor muscles of the fingers and hands. Not all cervices are dilatable. Cancer of the cervix may render it undilatable. A cervix which has been partly cut away and amputated or sewn, or resewn, may contain so much white fibrous tissue that it is undilatable. The average time required safely to dilate the cervical ring to a circumference of eleven or twelve inches should be forty-five minutes. If the cervix is not effaced the average time of ninety minutes will be necessary safely to dilate the cervical ring to a circumference of eleven or twelve inches. The special advantage of knowing how to dilate man-

nally is that the operator always has his hands with him, and they scarcely ever fail to dilate the cervix if properly used. The disadvantages of the method are the fatigue incident to the task and the frequent changing of hands from left to right and from right to left is liable to carry septic matter into the vagina from the rectum or some unwatched area.

The advantages of instrumental dilatation, as accomplished by the instrument which the author presented, are that it will dilate any cervix that is dilatable. It is easy of introduction. It does not have to be withdrawn and reintroduced over and over again, as in the long operation when done by the hand. It is provided with a dynamometer which shows not only the number of pounds pressure which are being exerted on the cervical ring, but it also shows whether the ring is dilating under the pressure. The instrument has a safety device, so that extensive laceration can not occur if the instrument is used properly. Laceration, however, rarely occurs, except in the hands of impatient and unskilled operators. The instrument is made of steel and can be sterilized. No one should use it who has not previously and practically studied its behavior.

Advantages of Bimanual Dilatation of the Pregnant and Parturient Uterus.

DR. J. CLIFTON EDGAR, New York, said that no method of manual dilatation can ever entirely supplant instrumental dilatation and incision. The uterine and vaginal tampon, graduated hard dilators, branched rectal dilators, hydrostatic dilators, superficial and deep incisions and vaginal Cesarean section are all applicable in appropriate cases. Dilatation by hydrostatic bags, the fingers of one or both hands, and branched rectal dilators are feasible in most instances and are to be preferred to methods by incision. Incision of the uterus for purposes of dilatation is rarely indicated. The best method of cervical dilatation is the one which most closely imitates Nature's method of dilatation, hence the advantages of hydrostatic and manual dilatation. The bimanual method is a closer imitation of the natural process than any other method of manual dilatation, being in this respect analogous to the bag of membranes or the hydrostatic bag, because the force used for dilating the cervical ring is directed from above downward. Far greater force can be brought to bear on the cervical ring, if need be, by the bimanual method than by any other, because the fingers of both hands are brought into play, and the stronger flexor muscles of the fingers and hand are the ones made use of. There is no danger of prematurely rupturing the membranes, as there is when the fingers of one hand are passed through the cervix. There is no interference with the original presentation or position, since the finger ends closely hug the lateral uterine wall; this can not be said of any other manual method of dilatation nor even of hydrostatic bags. The bimanual method is far less fatiguing than any other method, because the strain is distributed in both hands and the sense of touch of the operator's fingers is unimpaired, as there is no constriction of the hands, as happens when one hand is used.

(To be continued.)

ASSOCIATION OF AMERICAN PHYSICIANS.

Twenty-first Annual Meeting, held at Washington, D. C., May 15-16, 1906.

(Concluded from page 1723.)

Therapeutic Advantages of a Refined and Concentrated Diphtheria Antitoxin.

DR. W. H. PARK, New York, described a method of refining this antitoxin by precipitating and eliminating the serum albumin and non-proteid constituents by means of ammonium sulphate, afterward precipitating other materials by sodium chlorid, and finally by dialysis rendering it very similar to the blood. This also gives it two and one-half times the concentration of the original. Nine months' use of antitoxin thus prepared seems to show that it is preferable to that formerly employed. Rashes following its use are milder, and constitutional symptoms practically do not appear. The results indicate that the proteid substances thus eliminated are deleterious.

A Case of Bacillus Coli Septicemia with Hemolysis.

DRS. A. D. BLACKADER and B. D. GILLIES, Montreal, reported this case, apparently uterine in origin, which occurred in a woman of 27. Hemoglobin was 48 per cent. and marked hemolysis was shown microscopically and by the presence in the blood of methemoglobin. Cultures from the blood, urine and uterus showed purely the colon bacillus.

DISCUSSION.

DR. T. G. JANEWAY, New York, said that in such cases one must think of one other thing, although that was not suggested by the autopsy in this instance, and that is the possibility of bichlorid poisoning. He has seen four cases within six months, and not one of them presented salivation. In the urinary passages bacillus coli infections often pass off and the patients recover.

DR. G. M. STERNBERG, Washington, said the injection of *Bacillus coli communis* into animals gives results similar to those described by Dr. Blackader. From the fatty changes in certain tissues Sternberg was led in some instances to suspect yellow fever, and when he was studying yellow fever he obtained from those subjects a pathogenic variety of the colon bacillus. It produced fatal results in dogs, but there was not such marked hemoglobinuria as that described.

Hemachromatosis and Diabetes Mellitus.

DR. THOMAS B. FUTCHER, Baltimore, said that hemachromatosis is distinguished by a triad of symptoms, pigmentation of the skin and viscera, hypertrophic cirrhosis of the liver, and, in advanced stages, persistent diabetes. He reported two fatal cases in which diabetes was a terminal event. The first was in a man of 45, an alcoholic, who died 20 months after onset of symptoms, diabetes being present during 15 months. The second patient was a man of 53, with striking pigmentation and acidosis, who had diabetes six weeks before death. In both, microscopic examination of the skin showed the characteristic iron reaction in the sweat glands and ducts. The disease has been called bronze diabetes. The cases should not be reported as such unless the pigment is found histologically. The pigment is of two kinds, one iron-containing, the other iron-free or hemofuscin.

DR. JAMES B. HERRICK, Chicago, mentioned a case giving a clinical picture somewhat like those reported, with also tuberculosis of the lung. Autopsy revealed atrophic cirrhosis of the liver, pulmonary tuberculosis, and absence of pigment in the viscera. The sequence of events in this case ought to have ruled out the idea of hemachromatosis, as for seven years there were indications of cirrhosis, for four years glycosuria, and lastly, pigmentation of the skin developed. With these three symptoms present one may be misled unless they are carefully analyzed.

Universal Skin Itching without Skin Lesion; Hematogenous Urobilinuria; Peculiar Erythrocytolysis.

DRS. JOHN K. MITCHELL and A. R. ALLEN, Philadelphia, reported the case of a man who for seven or eight years had chronic malaria, followed by Raynaud's disease, and finally itching of the whole body. The particular interest lay in the urinary and blood findings. To the urobilinuria a hematogenous rather than a hepatogenous origin was ascribed because: 1. No bile acids were present. 2. The liver function was always good. 3. There was no increase in the indican. The blood showed non-staining granular bodies, in or partly in or outside the red cells; they could not be stained by any method tried, appearing more like the endoglobular degenerative bodies which have been described than any other condition. Eosinophilia was conspicuous, reaching as high as 13 per cent. Treatment by hot baths and intermittent courses of the iodids and mercury diminished the itching and caused improved condition of the blood and urine; there is, however, a constant tendency to relapse.

Two Cases of Essential Pentosuria.

DR. T. W. JANEWAY, New York, said that these cases occurred in brothers. One had been mildly diabetic for a year, but the constant presence of sugar, notwithstanding change in diet, raised the suspicion of pentosuria, and tests confirmed its presence. It was also shown to be present in the second case.

The diagnosis requires several steps. The substance reduces Fehling's solution only after several minutes' boiling, when there is a sudden change to a greenish or orange-yellow throughout the specimen. This phenomenon should lead to the suspicion of pentose. The urine should then be tested by orcein, then by the spectroscope, and finally by ozosone prepared by a chemist. The clinical significance of the condition is mainly negative; that is, it should not be confounded with diabetes and the diet so modified. The real nature is not known, but it has no connection with decreased sugar combustion. It is analogous to cystinuria and alkaptonuria rather than to diabetes.

Aplastic Anemia with Report of a Case.

DR. R. S. LAVENSON, Philadelphia, reported the case of a woman of 35, previously healthy, who without apparent cause developed a profound, rapidly fatal anemia. The blood showed marked reduction of red cells and hemoglobin, a few normoblasts, no megaloblasts, and leukopenia with relative lymphocytosis. Autopsy showed complete aplasia of the bone marrow.

DISCUSSION.

DR. R. C. CABOT, Boston, has seen two cases believed to be of this type, but which were not confirmed by autopsy. The practical point is the prognosis. All these patients go progressively and rapidly to death in a few months. In cases of pernicious anemia there are usually waves of improvement.

DR. A. C. WARTHIN, Ann Arbor, took issue with the statements as to the rarity of the condition in question. In Michigan this is the most common form of pernicious anemia, most cases showing no changes in the bone marrow. These cases might well be called hemolytic anemias. The name aplastic is better applied to the megaloblastic type.

DR. ALFRED STENGEL, Philadelphia, does not agree with Dr. Warthin as to the absence of bone marrow changes in pernicious anemia. As to aplastic anemia being an independent disease, his views have changed somewhat, and he thinks there is, after all, a primary hemolysis in these cases. He does not believe there is aplasia of bone marrow before the symptoms of the disease develop.

DR. E. O. OPIE, New York, said that as the polynuclear cells are replaced by lymphocytes, and the former arise only from the bone marrow, this is an indication that the disease is primary in the marrow.

Exophthalmus in Leukemia.

DR. JAMES B. HERRICK, Chicago, reported the case of an Italian, aged 26, who had been ill for 32 days. He saw him during 10 or 12 days, the case running the typical course of acute lymphatic leukemia. Bilateral exophthalmus was a striking feature. Autopsy showed hyperplasia of the spleen and other lymphoid structures, and leucocytic infiltration of the lungs, liver and other organs. Exophthalmus was explained by a retrobulbar leukemic infiltration of the fatty tissue.

Leucolytic Action of Roentgen Rays and Injection of Leucolytic Serum in Leukemia.

DRS. J. A. CAPPS and J. F. SMITH, Chicago, showed that the serum of a leukemic patient under treatment by the Roentgen ray caused leukopenia in animals into which it was injected, and also caused destruction of the leucocytes in a hanging drop of human blood, the destruction of the lymphocytes being greater than that of the polynuclears. Serum from such a patient was injected into a person who had lymphatic leukemia and had been for three months without treatment. Four c.c. were injected with a drop in leucocytes during 48 hours from 160,000 to 104,000. The leucocytes then increased gradually until at the end of 13 days the original number had been reached. A second injection of 5 c.c. caused a drop less marked than the first, and the number was regained in nine days. After this the count went up to 320,000. A third injection of 10 c.c., when the count was 300,000, brought it down to 215,000, but the number was again attained in seven days. Since the treatment the leucocytes have been more variable than they were before. The points emphasized were: 1. The immediate drops of the leucocytes in all the experiments and the selective action of the serum on the mononuclear forms; 2, recovery of number was more quick after each of the injections, suggesting a partial immunity against the serum. The same immunity is also noted in cases being treated by the Roentgen ray.

DR. A. S. WARTHIN, Ann Arbor, did not regard the leucolyses reported as being very striking; many serums produce the same effect. There are also striking falls in the leucocytes in cases of leukemia not so treated, the cells in this disease being very unstable. In one case pneumonia caused a fall from 750,000 to 4,000. The improvement noted in cases of leukemia treated by the Roentgen ray is due to the destruction of leucocytes, but the disease itself goes on.

The Nucleus Test in Pancreatic Disease.

DR. J. DUTTON STEELE, Philadelphia, confirmed Schmidt's and Wallenfang's experiments on dogs and studied two cases of pancreatic disease and nine of other affections in human beings. In one of the cases of pancreatic disease, muscle nuclei in ingested meat were not digested. The chief fault with the test is that it does not show the reaction until the pancreas is far gone. Further experiments indicate, however, that a modification of Schmidt's method may be made to show partial as well as complete lesions of the organ. One case in contrast showed lack of digestion of muscle fiber when chronic appendicitis was the lesion.

Experiments on the Digestive Activity of Pepsin in the Gastric Contents.

DRS. JOSEPH SAILER and C. F. FARR, Philadelphia, spoke particularly on the advantages and disadvantages of Mett's method of estimating peptic activity; they find it reliable. The elaborate details of using it described by some they do not find necessary. Two essential points are that the albumin must be coagulated by boiling and that five minutes must be allowed for the test. Experiments indicate that the inhibitory factors in peptic digestion depend on the products of peptic activity on albumins. The effects of various foods and food preservatives on peptic digestion were given in detail. Boric acid did not appear to inhibit, and alcohol and formalin exercised but very little inhibitory action on digestion by pepsin. Benzoic acid and sodium sulphid caused strong inhibition and sodium chlorid a considerable degree.

Glandular Fever with Dermal Lesions Suggesting Syphilis.

DRS. ALFRED STENGEL, J. W. WHITE and J. S. EVANS, Philadelphia, detailed this case, which occurred in a physician of 26 years. He had anal fistula when a child, and later suffered from neurasthenia, which was relieved by glasses. The onset of the condition reported was sudden, as an itching of the skin and a tendency to urticaria. An icteroid condition then appeared and finally sore throat, there being vague pains in the body, the joints, and finally substernal. Fever then developed and the eruption became more marked. The lymphatic glands of the neck, axillæ, inguinal regions and finally in all the superficial groups, became enlarged. The eruption can best be described as an atypical erythema multiforme. Some leucocytosis was present, at one time reaching 22,000. The juice from massage glands and also some removed glands were examined for the *Treponema pallidum* and found negative. Cultures from the blood, enlarged glands, and from the tonsils showed a streptococcus resembling the *S. equi* found in the epidemic coryza and glandular fever of horses. The patient has gradually improved without specific treatment.

Experimental Study of Cerebrospinal Meningitis.

DR. SIMON FLEXNER, New York, described experiments carried out at the request of the New York health department. The experiments were made on 30 or 40 monkeys of the rhesus type. When culture of the meningococcus is injected into the spinal canal symptoms identical with those in man appear. They develop quickly, beginning in two or three hours, and when severe prove rapidly fatal, the animal dying within fourteen hours. If it survives forty-eight hours recovery usually occurs. Microscopically the organisms are found at first extracellular in the fluid, and the fluid is clear. In from two to six hours emigration of leucocytes and englobulation of cocci may be observed. The phagocytosis of cocci increases, except in

the rapidly fatal cases, and at the end of twelve hours most of the cocci are within leucocytes. Dr. Flexner has reached the conclusion that the cocci do not multiply in the cerebrospinal canal, the effect depending on the amount of material injected. By grading the amount of the cocci and by multiple injections of small amounts of culture, there can be induced a subinfection lasting a week or more. A serious infection can then be caused in the ordinary manner. The lesions found are not only those of an acute inflammation, but there is also dilatation of the cerebral ventricles. An interesting point in the condition is the localization of the disease. The exudate on the base of the brain has been ascribed to the fact that the infection comes from the nose, but it is also said that the monkey can not be infected through the nose. In the monkey, however, the sites of the lesions are the same as in man, even when the cocci are introduced into the lower end of the spinal canal. Some explanation other than that of the point of entrance is then needed. The upper nasal passages in some of the monkeys became inflamed and suggested that the coccus came down from the brain into the nose. In one instance careful examination left no doubt that this extension had actually occurred. Without throwing doubt on the possibility of infection through the nose, it appears probable that reinfection of the nose occurs from above. It remains yet to work out the poison and find how it acts. Some problems of immunity have also been investigated during the studies summarized.

Internal Hydrocephalus Complicating and Following Cerebrospinal Meningitis.

Dr. Henry Koplik, New York, described three forms, the acute, subacute and chronic. The first may come very suddenly at the end of twenty-four hours, and is dangerous to life unless quickly relieved. The subacute and chronic are the forms usually mentioned. The cause is commonly said to be the matting together of the structures at the base of the brain and occluding the ventricles. This is regarded by Dr. Koplik as only one cause, as in some cases the narrow ventricles are open. Hence, more than the mechanical factor must be active. The diagnosis of hydrocephalus is best determined by percussion of the skull by MacEwen's method or a modification of it. By this means can be told whether or not lumbar puncture is justified at the outset. Some cases get well without interference. Others will recover if pressure from hydrocephalus be relieved early. In chronic cases puncture is of no use, even the repeated punctures advised by some being valueless.

Nature of Spirochetes.

Dr. F. G. Novy, Ann Arbor, showed numerous lantern slides illustrating his views regarding the nature of spirochetes, based on his work with *Spirochæta obermeieri*. He does not agree with Schaudinn that they are protozoa. In the first place they have no structure as do other protozoa; they possess neither nucleus, micronucleus, flagellum or undulating membrane. Secondly, tests of resistance show that under adverse conditions they are not destroyed as are protozoa, but they approach the bacteria in resisting qualities.

Prevention and Cure of Relapsing Fever.

Dr. F. G. Novy immunizes rats and uses the serum from them, devising a unit for its measurement. By injecting this serum in conjunction with cultures of spirilla, he has reached the conclusion that the serum treatment, or prevention, of relapsing fever in human beings is a possibility. He regards the tick fever of Africa as distinct from the relapsing fever of Europe.

Thrombophlebitis of Splenic and Portal Veins and Its Relation to Splenic Anemia.

Dr. A. S. Warthin, Ann Arbor, reported an additional case of this lesion, supplementing the three previously put on record by Dock and Warthin, and illustrated the histology by lantern slides. The fourth case is one of relatively acute splenic thrombophlebitis following pneumonia, and presenting features of secondary anemia and splenic fibrosis. Many of the cases of this condition reported followed typhoid fever, the patient never fully recovering from that disease. The cases indicate that certain forms of Banti's disease have primarily nothing to do with the spleen. The advisability of the term splenic anemia for them is doubtful. Those in which thrombophlebitis is present had better be put in a separate class under that name. The sequence appears to be thrombosis, fibrosis of the spleen, and passive congestion of the liver and other structures. Apparently old infections underlie the condition.

Two Cases of Sudden Death Associated with Hypertrophy of the Thymus.

Dr. Warthin also presented slides of these cases. Both concerned boys of 6 years. One had enlargement of the glands simulating Hodgkin's disease; in the other the glands were not enlarged. Both died the so-called thymic death. In each the thymus was 17 cm. long, reaching from the floor of the mouth to the apex of the heart, and causing tracheal stenosis. In both the lymph nodes showed the same changes, atrophy and disappearance of the lymphoid elements, with hyperplasia of the endothelial and fibrous hyperplasia. Similar changes were also found in the spleen and bone marrow. The thymus showed lymphoid hyperplasia and an eosinophilia. The findings are taken to indicate the action of toxemia which resulted in lymphoid exhaustion of the lymph nodes, bone marrow and spleen, and a compensatory hypertrophy of the thymus. The cases suggest a relationship between Hodgkin's disease and thymic hypertrophy.

Clinical Notes on Eighty Cases of Exophthalmic Goiter.

Dr. W. Gilman Thompson, New York, spoke particularly of three features of the disease: 1. The large number of cases in which an acute febrile toxemia develops. In addition to the cardinal symptoms there appear fever, acute dilatation of the heart, cardiac murmurs, dyspnea, precordial, thoracic or abdominal pain, edema of the legs, erythema and sweating. The temperature not infrequently reaches 104 or more, and may persist for weeks. These toxic exacerbations are particularly favorable for treatment by the new cytotoxic serum. 2. The cause of these toxic attacks appear often to be intercurrent mild infections, as tonsillitis, influenza, bronchitis or gastrointestinal disturbance. 3. The close resemblance of these cases when aggravated to malignant endocarditis. In the hospital at one time was a case of each, and they were interchangeable, as far as clinical symptoms were concerned, for teaching purposes. Dr. Thompson has never seen a case of this condition end in recovery with the exception of two or three treated by the serum described by Dr. Rogers.

Treatment of Exophthalmic Goiter by a Specific Cytotoxin.

Dr. John Rogers, New York, described the results of treatment with the serum prepared by Dr. Beebe and himself. Of 41 personal cases, 8 patients were cured, 25 improved, 6 gave no result, and 2 died. Of 28 patients treated by others, 3 were cured, 16 improved, and 9 unimproved. Two types of serum are employed—the pathologic, obtained by injecting rabbits with the products of diseased glands, and the normal, obtained by the use of normal glands. There is not a great distinction between the two, but they differ in activity. The serum is given subcutaneously by hypodermatic injection. Reaction follows the injection, usually according to the benefit derived in severity. Swelling after a few hours appears, the part becoming not unlike erysipelas in appearance. Constitutional disturbance also accompanies the swelling. A reaction that is alarming occurs occasionally. No patients have died from this, but Dr. Rogers believes they might. The reaction is believed to be due to the entrance of the serum into a vein. The dosage varies. Usually 1 c.c. is given every other day, with the patient in bed; if reaction occurs, no more is given until it subsides. Regarding the limitations of the serum, if the goiter is small and soft the chances for improvement or cure are good, by the normal serum. If the thyroid be large and hard, the case is doubtful. Cases may respond to pathologic serum when they do not to normal serum. The acute toxic are the most amenable; the chronic toxic the most refractory. Improvement in the chronic or subacute cases is usually slow. Dr. Rogers recognizes these forms of the disease: 1. The simple subacute or chronic; 2. the acute toxic; 3. the chronic toxic; 4. the atypical. Under the last are included the simple adeno-

natous or cystic goiter with subsequent Graves' symptoms, the cases without goiter, and the psychopathic cases.

Preparation of a Specific Cytotoxin for Exophthalmic Goiter.

DR. S. P. BEEBE, New York, gave in detail the principles underlying the serum referred to by Dr. Rogers. It had its basis in serums cytolytic for other organs, as the liver and kidney. The nucleoproteids alone or in combination with the thyroglobulin of the gland are employed, as it is believed, to produce higher specificity than when the whole gland is employed. The serum is based on the assumption that in the disease in question there is hyperactivity of the thyroid. The serum possesses both cytolytic and antitoxic properties. The presence of the latter is shown particularly in the acute toxic cases which are so amenable to treatment.

Pathology of Exophthalmic Goiter.

DR. JAMES EWING, New York, gave a lantern slide demonstration of the changes in the thyroid in the disease in question. He believes the change is one of functional hypertrophy. To establish this theory it is not necessary that a specific change be found in the gland. Histologic studies favor the theory of hypersecretion, though the structure need not differ essentially from that found in simple goiter. Clinical data offer a definite basis for serum therapy in uncomplicated cases. The possible implication of other organs and the permanent lesions in many organs in prolonged cases seem to preclude the possibility of securing any agent that will be curative in all cases.

DISCUSSION.

DR. S. J. MELTZER, New York, showed photographs of a case of exophthalmic goiter cured by treatment with thymus gland, and afterward the administration of sodium phosphate. As to the work of Rogers and Beebe, it is a remarkable discovery. They should see, however, if the serum attacks the thyroid in animals as did the hepatolysins the liver in their experiments.

DR. F. FORCHHEIMER, Cincinnati, reported 31 cases of exophthalmic goiter treated in an empirical manner by giving 5 grains of hydrobromate of quinin and 1 grain of ergotin three or four times daily. There was a decided improvement in the patients, beginning in some in six weeks, in others only after fifteen months. In four of the cases the method failed, and four are still under treatment. The remaining 23 patients have been comparatively restored to health.

Enzymes in Phagocytic Cells of Inflammatory Exudate.

DR. EUGENE L. OPIE, New York, described the technic for determining the ferments in leucocytes by which he arrived at the proof of two, one in the polynuclear and the other in the large mononuclear. The former digests actively in an alkaline medium and to it he has given the name leukoprotase. That of the mononuclear cells digests only in an acid medium and has been named lymphoprotase. The importance of the ferments in the progress of pathologic processes is very great. He has also found in the blood in a case of myelogenous leukemia a proteolytic substance capable of digesting fibrin.

Experiments in Psychotherapy.

DR. L. F. BARKER, Baltimore, was much impressed by the methods of Dejerine, who isolated certain patients and impressed on them the fact that they ought to get well. He has tried the plan on a small scale in the Johns Hopkins Hospital with results that are distinctly gratifying. Only the simpler methods of isolation, persuasion and re-education or suggestion, have been used as a rule, hypnotism being used only in special cases. Neurasthenics and that class of subjects do best under this mode of treatment.

Effect of the Roentgen Ray on Unresolved Pneumonia; Nature of Toxic Reaction to Roentgen Ray.

DR. D. L. EDSALL, Philadelphia, reported observations on two cases of unresolved pneumonia. Under the action of the rays one case cleared up in five days and the other in ten days. The changes in metabolism during this time showed a remarkable increase in the output, just as occurs in ordinary pneumonia at the time of the crisis. In the three cases in which he used the rays response was prompt. It appears worth while to try this agent farther in cases of unresolved pneumonia. As to the nature of the toxic reaction to the Roentgen ray, a case of pernicious anemia was instructive. A slight exposure was followed in a few hours by a violent reaction. The patient improved somewhat at first, but died within a week or two. A second patient suffering from polyarthritis was given a slight exposure. He was evidently ill that night and next day was worse, and death was feared. He finally slowly returned to the original condition before the exposure was given. In both these cases the excretion was diminished. The indications are that the Roentgen ray causes a remarkable breakdown of tissue already toxic and this sudden change causes metabolism to halt. The experiments confirm Dr. Edsall's previous views that the action of the rays is on something already in the body and not the production of a new substance. The best explanation is that it acts as a ferment accelerator.

Officers Elected.

The officers for the ensuing year are: President, Dr. F. P. Kinnicutt, New York; vice-president, Dr. James Tyson, Philadelphia; secretary, Dr. Henry Hun, Albany; recorder, Dr. S. Solis-Cohen, Philadelphia; treasurer, Dr. J. P. Crozer Griffith, Philadelphia; member of council, Dr. L. F. Barker, Baltimore.

Active members elected are: Dr. W. M. L. Coplin, Philadelphia; Dr. S. W. Lambert, New York; Dr. G. H. Weaver, Chicago. Associate members elected are: Dr. A. A. Eshner, Philadelphia; Drs. R. G. Freeman and J. S. Billings, Jr., New York; Dr. I. P. Lyon, Buffalo; Dr. M. J. Rosenau, Washington; Dr. E. R. Baldwin, Saranac Lake; Dr. H. C. Moffitt, San Francisco.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Nocturnal Enuresis.

In considering the most common causes of nocturnal enuresis V. Chastel de Boinville, in an article in the *Practitioner*, states that nocturnal enuresis is commonly found in weak, excitable children. It occurs, however, in every class of life. It is more common in boys than in girls, but among adults women are more frequently affected. It is very frequently associated with some local irritative process, such as thread worms, and it also occurs more frequently in those who are in the habit of lying on the back during sleep, as the weight of the urine presses on the trigone of the bladder. He mentions the fact also that pressure exerted between the bedclothes and the sacrum may reflexly be a contributing cause. He speaks of the pernicious habit of overloading the stomach at the evening meal, also flatulence of the stomach or bowels from any cause as etiologic factors. A bed which is too hot or, on the other hand, one which is too cold, as may be the case in the winter months, also contributes to this condition. Children born in warmer climates, such as in India, may acquire the habit on coming to a colder climate. In a great many instances it is the symptom of organic disease of a serious nature, many of which he enumerates in his article. The treatment, according to this author, must pertain to removing any conditions or group of conditions which may be found to contribute to this malady, as nocturnal enuresis is not in itself a disease, but a symptom. Any sources of general debility must be checked, if possible, and every means taken to strengthen the patient. Exercise in the open air is of great value, and in some cases change of air is very beneficial. Cool baths and, in obstinate cases, general massage along with suitable tonics, are advised. Any source of local irritation, the most frequent of which is thread worms, must be promptly removed. The urine in any case should be thoroughly tested, and if any irritating combinations are found, they should be properly corrected. The

time of eating should be carefully regulated, and special attention should be given to the evening meal, which should consist of easily digestible food, and tea and coffee, on account of their diuretic action, should be avoided. As a rule, he advises against a strong animal diet, and against those articles of food which are liable to produce flatulency. Inquiry should be made as to whether or not nocturnal fits have been overlooked by the nurse or parents, and if these fits should be found to be present, bromids in proper doses should be administered. In hysterical and mentally weak patients strict discipline should be installed, avoiding, however, scolding or punishing the child. The child should be encouraged to use all his will power to overcome the trouble. The urine should be passed the last thing before going to bed, and it is a good plan to accustom the patient to emptying the bowels in the evening rather than in the morning. By this means the evil effects of the full rectum are disposed of, pelvic congestion is relieved, and the gradually enlarging bladder meets with a minimum amount of resistance during sleep. The writer speaks of this simple precaution alone as having cured the habit. The tendency to lie on the back during sleep may be overcome by attaching a bobbin or some other hard body to the patient in such a position that during his sleep, if he lies in this attitude, the pressure of the bobbin will disturb him and cause him to turn on his side. The night clothing should be properly regulated so as not to allow the child to get too hot or too cold when asleep. The bed should have a moderately hard mattress, and the clothing should not be too heavy. It is sometimes well in these cases to awaken the patient at least once during the night to empty the bladder.

DRUGS.

Of the medicinal preparations employed, the author recommends belladonna or atropin and nux vomica or strychnin as the best preparations, although these drugs differ widely in their general effects, they each directly or indirectly have control over the sphincters. Belladonna acts probably by producing a paresis of the inhibitory nerve fibers of the sympathetic, and also by depressing the peripheral nerve endings of the sensory nerves. In ordinary medicinal quantities its action is not very powerful, and as children bear the drug well, it is recommended administered in large doses, beginning, however, with moderate-sized doses, such as perhaps 2 minims of the tincture for a child of 5 years. The dose may be gradually increased until some effects are shown on the pupils, and after ten days or two weeks the quantity may be gradually diminished. He advises the administration of two doses daily, one just before the evening meal and the other just before retiring. In this way the maximum action of the preparation is obtained at the desired period. In the administration of atropin it should be injected subcutaneously, the doses ranging to suit the age of the child, and increased to the point of tolerance. The injection should be given about one hour previous to retiring. For a child of 5 years he recommends a dose of 1 minim of a 1 per cent. solution to begin with. Nux vomica and its alkaloid, strychnin, act by stimulating the motor nerves in the spinal cord, and are of value because of their tonic effects. Care must be observed in the administration of these drugs to avoid any cumulative action, for in such instances more harm than good may be done by their tendency to set up intermittent contraction in the muscular walls of the bladder. Consequently the object is to administer such quantities as will maintain the tone of the sphincter muscle and strengthen the patient generally. For a child of 5 years he recommends 1½-minim doses of the tincture of nux vomica, given three times daily after meals, and continued for several weeks. If desirable, the nux vomica may be combined with belladonna without fear of decreasing the influence of either preparation over the condition present. For this purpose he recommends the following combination:

R.	Tincturæ belladonnæ	.m. xxxii	2|12
	Tincturæ nucis vomicæ	.m. xxiv	1|55
	Syrupi aurantii floris	.3iiss	|15
	Aquæ q. s. ad	.....℥iv	120|

M. Sig.: Two teaspoonfuls three times a day for a child of 5 years.

If for any reason it is desirable, the tincture of belladonna may be provided in a separate bottle and added to the nux vomica preparation in increasing quantities, as the physician may see fit. The author mentions urotropin (hexamethylenamin) as sometimes of value when the urine is at fault; and the alkalies, he states, are invaluable for a patient having highly acid urine. Potassium bromid, chloral hydrate, opium, codein, morphin, cannabis indica, and other narcotics should, as a rule, be avoided.

LOCAL MEASURES.

When medicinal preparations do not succeed local methods may be resorted to. For this purpose he recommends cold douches applied to the perineum as being very efficacious; they should be given the last thing before retiring. Counter-irritation by means of fly blisters applied to the spinal column has not proven of much benefit in his experience, and, indeed, in some cases it has aggravated the condition. Good results, however, have in some instances followed the passage of a sound into the urethra. Where this method is employed, it must be carried out daily for several days to obtain proper results. In other cases good results have followed cauterization of the urethra in females, and has been more successful when the cauterization is carried well back toward the neck of the bladder. In males the catheter may be passed down to the prostatic portion of the urethra, and a solution of silver nitrate, 10 grains to the ounce, may be injected.

ELECTRICITY.

As regards electricity, its effects, according to this author, are, as a rule, only transient in character. The constant and faradic current both have been used. One pole may be placed over the pubes or over the lumbar spine, and the other in the perineum or even in the urethra. The current should be reasonably strong, without producing any unusual symptoms on the part of the patient. It should be kept in mind, however, that nocturnal enuresis in children usually ceases of its own accord about the period of puberty, and consequently heroic measures are not advisable, nor is it wise to introduce electric or other sounds into the genital orifices of children approaching this age. If necessary, local massage may be applied in connection with cold douches to the perineum, and the sphincter itself may be massaged by means of a probe introduced into the neck of the bladder. But in cases of children, again, there is always great danger of producing the habit of masturbation. In adults, nocturnal enuresis often depends on conditions more serious, such as tumors in the pelvis, or organic disease of the nervous system. In such cases, of course, but little can be done in the way of a cure.

OTHER CAUSES AND THEIR TREATMENT.

R. T. Morris, in New York *Med. Jour.*, states that preputial adhesions are predominantly the cause of enuresis, particularly among girls, and recommends that no treatment be outlined until that trouble has been disposed of. This disturbance is more frequent in girls than in boys.

J. Ullman, in an abstract in "Practical Medicine Series", summarizes the following outline of treatment: 1, Hygiene; 2, psychical and suggestive; 3, physical or mechanical. He emphasizes the importance of massage combined with the administration of atropin internally. The object of the massage is to remedy the insufficient action of the detrusors and sphincter vesicæ. He, therefore, recommends that:

1. The rectum be freed of fecal matter and massage applied, by means of the index finger, to the sphincter vesicæ, gently tapping it for one-half to one minute.

2. A deep circular massage should be applied over the hypogastric region for two or three minutes.

3. The patient should be placed in the dorsal position, with the knees tightly drawn together, and instructed to resist while the knees are drawn apart; and with the knees wide apart he should be told to resist while they are drawn together. Adduction and abduction of the limbs should be carried out in the same manner. These movements should occupy about two minutes.

4. The patient should be instructed to stand against the wall or a door and cross and recross one thigh over the other for a period of five minutes.

5. Vibratory massage may be applied to the lumbar and sacral regions for one or two minutes.

Percy Lewis, in *Med. Record*, has noticed that infants fed on starchy foods always pass a larger amount of urine than normal, and that a decrease in the amount takes place when this form of food is cut off. Starchy food, however, may be allowed for breakfast as a rule when the nocturnal enuresis has stopped. At the same time tonic treatment should be instituted and pushed for a period of four weeks, when a normal diet may be resumed.

Medicolegal

Physician's Account Book May be Used to Show Birth.

The Court of Criminal Appeals of Texas says that in Neill vs. State, a prosecution for rape, the state introduced a physician, who testified that he waited on the mother at the time the prosecutrix was born, as shown by his memorandum in medical accounts made at the time. The accused objected on the ground "that the same was not admissible for any purpose. There is only one kind of book admissible in evidence; that is, an account book between the parties, where there is a suit between the parties connected with the account. It is hearsay testimony and improper." But the court holds that these objections were not tenable. It says that it has heretofore held that books kept by a physician, when proper predicate was laid, as the record here showed, are admissible to show the birth of children.

Privilege Not Waived by Mere Taking of Deposition.

The First Appellate Division of the Supreme Court of New York says that the plaintiff in the personal injury case of Clifford vs. Denver & Rio Grande Railroad Co. took the deposition of a physician in Colorado, but she did not use same at the trial. When the defendant then proposed to use it, she objected to certain portions thereof involving disclosures by the physician. Thus was raised the question of whether the plaintiff, by procuring this testimony to be taken, waived the prohibition contained in section 834 of the New York Code of Civil Procedure, which prevents a physician from disclosing any information which he acquired in attending a patient in his professional capacity. The court holds that she did not. It says that a waiver, by section 836, must be made in open court, on the trial of the action, and that it certainly could not be said that the proceeding to take the testimony by commission before the trial was a proceeding in open court on the trial of the action. After the testimony was taken and the deposition returned to the court, the plaintiff was not bound to read it. Not having read it, when the defendant offered to read same, it made the physician its witness, and the competency of the witness to testify was to be determined by the trial judge. Nothing that the plaintiff had done before and nothing that had happened in the course of the action could be a waiver of the right to prevent a disclosure to the jury of the facts acquired by this physician in attending the plaintiff except a waiver in open court or a written stipulation signed by the attorneys. The prohibition being absolute, unless waived, and the only method by which it could be waived, namely, a waiver in open court on the trial, or a written stipulation signed by the attorneys, not appearing, the court thinks that it was rightly held that the evidence was not competent.

Insurance of Physician and Septicemia—"Operation."

The Supreme Court of Illinois says, in Central Accident Insurance Co. vs. Rembe, that a practicing physician and surgeon having agreed to take an accident policy, was tendered one containing the clause: "This policy does not cover . . . death . . . resulting wholly or partially from any of the following causes: . . . voluntary or involuntary taking of poison or contact with poisoned substance." He declined to accept it, and insisted on an additional clause to cover blood poisoning or septicemia. The policy then had a slip attached which read: "Policy No. 75,719 is hereby extended to cover that class of injuries known as septic wounds, caused by accident while performing any operation pertaining to the business of the insured, the poison matter being injected into the wound at the time of the accident and resulting in disability or death under the conditions of the policy." This was accepted.

Thereafter, during the treatment, in his office, of a patient afflicted with syphilis in a virulent form, of several weeks' duration, the physician, while in the act of preparing medicine to be administered to the patient, attempted to remove the cork from a glass bottle, and the top or neck of it was accidentally broken, cutting a small wound in one of the fingers of his right hand. He immediately dressed the cut, binding it up in gauze cloth and rubber tissue. On the afternoon of the same day, and again on the next day, he treated a child suffering from an abscess in the ear, which was discharging pus. On the next morning after breaking the bottle the wound on his finger began to pain him and swell, and on the second day a well-defined case of septicemia, or blood poisoning, manifested itself. Skilled physicians were called, who, by operation and other means, made every effort to save his life, but failed, his death occurring in about three weeks after the accident.

The insurance company refused to pay the policy, and the beneficiaries brought suit, recovering a judgment, which is affirmed. The court says that the facts not only tended to prove, but established, the fact that the death of the insured resulted from the accidental injury to his finger. And it is unable to see how it could be seriously contended that under these facts and the law applicable to the case his beneficiaries were not entitled to recover under the first count of their declaration, which declared on the policy as it was first tendered without the attached slip and averred that while the insured was in pursuit of his avocation as a physician and surgeon, and while undertaking to remove the cork from a bottle, his finger was injured, and the wound caused blood poisoning, resulting in his death. The policy without the slip provided that on the death of the insured caused by external violence and accidental means the company would pay the beneficiaries therein named $5,000. The cause of the death, as the court understands it, was the wound in the finger, by means of which blood poisoning intervened. Without the accidental wounding of the finger blood poisoning would not have ensued, and, therefore, that disease was only incidental to the wound.

The claim, not seriously insisted on, that the inoculation was caused by the pus discharged from the child's ear, was wholly unsupported by the evidence.

Again, with regard to the contention that the death of the insured was caused by the wound coming in contact with virus from the syphilitic patient, either on the hands of the insured or on the neck of the bottle which was broken, the court says that if poisonous germs entered the wound, causing blood poisoning, that wound would not be, within the fair meaning of the policy, "coming in contact with poisonous substance," causing death. Even if the germs were a poisonous substance within the meaning of the policy, those germs, according to the testimony, would have produced no injurious effect, but for the wound in the finger. They only became poisonous when allowed to mingle with the blood.

The court is also satisfied that the evidence justified the verdict in favor of the beneficiaries under the second count of the declaration, which declared on the policy as amended by the attached slip, and averred the injury from the broken bottle, and that poison matter from the patient suffering from syphilis became injected into the wound at the time of the accident, resulting in death. It says that it seemed to be contended on behalf of the company that the provision in the slip only covered cases where a surgeon or physician was in the act of performing an operation or administering treatment on a patient, and in the act met with some accident which caused a wound, while the wound in this case was not inflicted while the insured was so engaged in performing an

operation or administering treatment to the patient. But in the court's opinion this was too narrow a construction of the language of the policy.

Suppose the insured had cut his finger by accident while preparing instruments with which to perform a surgical operation, or if, after the operation, in disinfecting the instrument used he had accidentally wounded himself and blood poisoning had in either case intervened, would it be claimed there was no right of recovery under the conditions of this policy? The court hardly thinks it would be seriously so contended. The clause was, "caused by accident while performing any operation pertaining to the business of the insured." His business was both that of a surgeon and physician. His treatment of the patient was a continuing service, and should not be limited to any particular act in such treatment. The preparation of medicine to be taken internally at the very time the patient was in his office, or subsequently, according to directions, was, the court thinks, administering treatment pertaining to the business of the insured, within the meaning of this clause of the policy. "Operation" meant treatment pertaining to the business of the insured.

Furthermore, the court says that if the accidental cutting of the finger caused the death, then, under the proof in this case, it was clearly independent of all other causes.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

6 Gigli's Operation. J. A. Schmitt, New York.
7 *Occurrence and Prognosis of Pneumonia as Studied at the Lincoln Hospital. L. F. Bishop, New York.

1. **Heart Failure as Result of Deficient Food.** Haig says that he has seen many instances in which deficient nourishment had led directly to more or less marked heart failure. If there is a condition of slow, steady, and constant deficiency of food there comes a time when not only do the less important tissues suffer, but the heart, muscles and brain cells begin to suffer with them to some extent. The signs of heart failure are perfectly definite and distinct, and those who know how to look for them can scarcely miss them. The three chief objects of treatment are: The diminishing of the work of the heart, the increase of its nourishment, and for a time the administration of a tonic. In practice he gives all such adults who consult him nine grains of albumin a day for each pound of body weight. He declares that although this is only a rough guide it is decidedly better than none. He also watches the temperature of the body, the condition of the blood, the ratio of the capillary reflux to blood pressure, and the other circulatory signs, and looks on these taken together as safe and certain guides to a condition of satisfactory nourishment and nutrition.

4. **Conservatism in Treatment of Senile Hypertrophy of Prostate.** Van der Poel believes that catheterism properly applied and at the right time renders unnecessary many operations. Modern technic and advance in the knowlege of prostatectomy now make operations justifiable which would not have been so according to former statistics. Operation must be considered much earlier in poorer patients or when aseptic catheterism is practically impossible than in other cases. Prophylactic prostatectomy can not be recommended. In acute retentions the catheter should be given a full trial before intervention. In certain cases catheterism will reestablish the urinary function for many years, no matter what may be the condition of the prostate. In chronic retentions, if the case is septic and has been so for some time, clean catheterism seems to be powerless to eradicate its effects and operation is indicated.

5. **Gonococcal Infection in Women.** Grandin declares that fully 60 per cent. of his operative work among women would not exist if it were not for the gonococcus. About 45 per cent. of sterile marriages are due to the gonococcus. It is said that about 75 per cent. of males have had gonorrhea at least once, while fully 30 per cent. carry the latent germ to the nuptial couch. It has been estimated that about 30 per cent. of blindness is traceable to this disease. The disease is tolerated on account of ignorance on the part of the laity. The code of morals should be the same for both man and woman. The author believes that in time public opinion will make itself heard and that boards of health will be obliged to place gonorrhea in the class of acute infectious diseases.

7. **Occurrence and Prognosis of Pneumonia.**—Bishop states that pneumonia, in a measure, ranks with the degenerative diseases. If people live long enough and become feeble from age, and escape death from epidemics, or any of the infections, the contraction of pneumonia is one of the things particularly liable to occur. Damage to the kidneys and circulation, such as comes from high living or overwork, predisposes to fatal pneumonia. The writer declares that clinically it does not seem to him that the infectiousness of pneumonia is very marked. It has not at all been proved, he thinks, that a particular germ is the cause of pneumonia. The prognosis depends to a great extent on the previous life history of the patient, as well as on the cause of pneumonia. Pneumonias that occur as terminal conditions are necessarily extremely fatal. The prognosis in a case of mild pneumonia affecting one lobe in a previously healthy and robust person is very good indeed. The prognosis of those patients who are in a class between these extremes is doubtful. Blood examination is a matter of much importance in prognosis.

16 Bilateral Empyema in Children. H. Heiman, New York

8. **Bacteriology of Conjunctivitis.** Duane and Hastings report on the findings in 132 unselected cases of conjunctivitis. The following tentative conclusions are drawn, pending a further investigation:

1. There is no special type of conjunctivitis associated with any special germ. The clinical picture, therefore, affords no clue to the germ causing the conjunctivitis.

2. While certain organisms, like the gonococcus, diphtheria bacillus, and streptococcus, usually cause severe reaction, and the other germs regularly produce much slighter effects, this rule has many exceptions, and no sure deductions can be drawn from the intensity of the inflammation as to the germ causing it.

3. Membranous conjunctivitis, as is well known, may be caused by a variety of organisms. It does not necessarily indicate a severe inflammation, nor one that will always produce other evidences of excessive reaction besides the false membrane.

4. In trachoma, particularly trachoma in the stage of acute exacerbation, a variety of organisms may be present. These do not, of course, cause the trachoma, but they are of importance in that they do produce an intercurrent acute conjunctivitis with secretion, which latter serves as a carrier of contagion and thus disseminates not only the conjunctivitis, but the trachoma as well.

5. The *Staphylococcus albus* and particularly the *Staphylococcus aureus* when occurring in the conjunctival sac are sometimes at least pathogenic, and distinctly predispose to the production of corneal lesions. The fact that the *Staphylococcus albus* is probably an almost constant inhabitant of the conjunctival sac, does not invalidate this conclusion.

6. Very mixed infections seem, if anything, to be rather less severe than those in which one germ is the predominant infecting agent.

10. **Liability of Contracting Tuberculosis in Sanatoria.** After a careful investigation of the danger of visiting places frequented by tuberculous patients, Way has come to the conclusion that non-tuberculous individuals necessarily incur no danger of infection with tuberculosis in visiting or residing at modern health resorts frequented by patients with pulmonary tuberculosis. There is less danger of contracting pulmonary

tuberculosis in a well-regulated modern health resort than elsewhere. Health resorts for tuberculosis are almost invariably places where it has been originally noted that the average of deaths from tuberculosis among the natives was remarkably small. The climatic and other local conditions which originally permitted so small a development of tuberculosis among the natives continues to render them relatively (not absolutely) immune, and as well to beneficially impress the visitors to such resort. Considered in the light of most recent scientific knowledge, it is doubtful if the infective dangers of street expectoration are so great as we have previously believed. The average greater degree of sanitary knowledge and practice prevailing to an extent among all classes at a modern health resort is also highly conducive to the physical improvement and gain shown by the immense majority of visitors to our mountain resorts. The most careful attention to sputum indoors, thorough ventilation, and open air life so much in vogue at the modern health resort for tuberculosis render them safer and should be continued.

24 Case of Pernicious Vomiting in Pregnancy. J. W. Markoe, New York.
25 Case of Benign Goiter Complicating Pregnancy. W. A. Morgan, New York.

22. **Unusual Hemorrhage in Eclampsia.**—Welch reports the findings in a case diagnosed clinically as eclampsia which exhibited hemorrhagic lesions in the skin and serous membranes, congestion of all the meninges, distension of all the ventricles by fluid blood, a large clot in the left corpus striatum which projected into the left lateral ventricle causing extensive laceration in the substance of the left frontal, parietal and occipital regions. The patient died four hours after admission to the hospital. The autopsy report is published in full.

23. **Maternal Mortality in 32,000 Confinements.**—In the series of cases reported by Harrar the maternal mortality was 0.357 per cent., or about 1 death in every 280 deliveries. The chief causes of death were sepsis, rupture of the uterus, eclampsia and placenta prævia, in the order named. Twenty-seven women, or about 1 in 1,200, succumbed to septic infection. The next most frequent cause of death after sepsis was rupture of the uterus, 15 women having died as the result of this accident. In 5 of these cases rupture occurred as the result of an internal version; in one woman, in whom the cervix had been amputated a year previously, it was produced during a forceps delivery; and in 2 others it was traced to severe falls sustained several days before delivery. Thirteen deaths are accredited to eclampsia, and it may also be noted in passing that this complication occurred 50 times in the series of cases here reported, with a mortality of 26 per cent. Placenta prævia ranks fourth on the list as a mortality factor, there having been 12 deaths from this condition. The 4 cases alluded to account for 67 of the total of 114 deaths from all causes. Lobar pneumonia was fatal in 6 cases, postpartum hemorrhage in 5, premature detachment of the placenta in 4, chronic endocarditis in 4, and phthisis in 4. Four deaths are ascribed to shock and 4 to uremia. Three women died after Cesarean section had been performed. Other causes of death were pulmonary edema, which claimed 3 patients, and embolism and thrombosis, which was fatal in 3 cases. Toxic albuminuria and puerperal toxemia account for 2 deaths. One death was due to chloroform and one each to carcinoma and erysipelas.

31 *Cystinuria with Formation of Calculi. H. A. Fowler, Washington, D. C.
32 Case of Adenocarcinoma of Lachrymal Gland. E. O. Belt, Washington, D. C.

31. **Cystinuria.**—The patient in the case reported by Fowler was a male, aged 67, whose family and personal history were absolutely negative, except for an attack of malaria and one of typhoid, about 30 years previously. His present trouble began about a year ago, when he first noticed a slight increase in the frequency of urination, associated with precipitency. Six months later he began to have sharp pains at the end of micturition. Cystoscopic examination revealed a single large oval calculus with a coarsely granular surface lying on the right side of the trigone. This calculus was removed by a perineal prostatectomy, and a smaller one was passed spontaneously later. Chemical examination showed the calculi to be composed of pure cystin.

36 *Study of the Blood in Lead Poisoning, with Description of Bone-marrow of one Fatal Case. W. B. Cadwalader, Philadelphia.

36. **Blood in Lead Poisoning.**—Cadwalader made total and differential blood counts in 37 cases of lead poisoning, all the patients presenting typical symptoms and a clear history of having worked in lead for periods of from a few weeks to many months. The hemoglobin and the erythrocytes were reduced to about one-fourth of the normal in most cases, giving an average of about 65 per cent. hemoglobin and 3,850,000 red cells per 1 cm. In every instance there was a marked increase in the number of granular red blood corpuscles. Macrocytes and microcytes were occasionally met with, but poikilocytosis was, as a rule, not marked. One or more normoblasts were found in all but four cases, and megaloblasts in two instances, while in one case 130 normoblasts and 13 megaloblasts were found, while counting 500 white cells, notwithstanding the fact that the total number of erythrocytes was scarcely one-fourth less than the normal. After convalescence was established the nucleated red cells disappeared from the circulating blood before the granular erythrocytes, which slowly decreased in numbers. The total number of red cells very gradually approached the normal. In one case, in which the blood was studied during some length of time, the red cells had only increased 40,000 in four weeks after all symptoms had disappeared, while granular erythrocytes were still easily demonstrated. It would seem as if the intense pallor so characteristic of this condition could not be wholly dependent on so slight an anemia, and may possibly be caused in part by a contraction of the peripheral capillaries, as has been suggested. The leucocytes showed no morphologic changes. The greatest number per 1 cm. was found to be 12,550, while the lowest was 4,700, giving an average of 7,568.

42. **Detection of Occult Blood in Feces.**—Benedict employs the following modification of the Boas test. Any convenient quantity of feces is used, say 2 to 5 c.c. of liquid feces, or of more or less solid feces reduced to a diarrheal consistency with water. (Distilled water is not a necessity.) For every 5 parts of liquid feces about one part each of fresh tincture of guaiac and old oil of turpentine is used, and from one to five parts of gasoline. On shaking the blue tint of the positive reaction—or it may be a greenish blue—is communicated to the gasoline. Fats do not interfere with the test, so that no preliminary extraction is necessary. It seems to make no difference in what order the ingredients are added. Ordinarily, to conceal the fecal odor, gasoline is added immediately to the feces, then the guaiac, and finally, the oil of turpentine are poured in and the whole is shaken. The test may be performed perfectly well in an ordinary bottle, even at the house of the patient. Unless several suspicious cases are under observation, the tincture of guaiac is best made fresh, by adding alcohol or wood alcohol to a few whittlings of gum guaiac, so as to produce a yellow solution.

54 Abscess of the Liver—Successful Cases in Point. W. Bartlett, St. Louis.

49. **Chorionepithelioma in a Male.** Fisch reports the twenty-first case of this kind recorded in the literature. The patient, a male, 26 years old, applied for relief of an enlarged right testicle that had begun to grow for a period of about 6 months. There was no pain connected with the enlargement, only mechanical inconvenience. The testicle was removed and a microscopic examination showed a typical chorionepithelioma. The patient died about five weeks after the operation, and the autopsy disclosed extensive metastases of the tumor in the lungs, kidney, subperitoneal, bronchial and tracheal glands, one tumor under the scalp of the forehead, and a large metastasis in the white substance of the left posterior frontal lobe, encroaching on the gray matter of the posterior or third frontal convolution. A small tumor was found in the neighborhood of the opening of the carotid canal on the right petrosum. Symptoms of brain tumor were present shortly before the death of the patient.

51. **Abnormal Retention of Dead Ovum.**—In the first case reported by Ehrenfest the dead fetus was retained for about six weeks. In the second case it was retained for about six months.

53 **Treatment of Epididymitis.**—Johnson describes a method which he has employed extensively and with most gratifying results. The parts should first be shaved. With the patient lying on the back one end of a strap of zinc oxid adhesive plaster, two and a half to three inches wide, is applied to the lower abdomen, from one and one half to two inches from the median line. The strap, face upward, is taken around and under the scrotum, elevating the testicles to a level at least as high as the peno pubic angle, and forming, as it were a sling. The other end of the plaster passes up on the opposite side of the median line of the abdomen. A second strap is applied in the same manner as the first, overlapping the latter at its median border by about one inch. The straps are now neatly adjusted about the scrotum. A few short straps are gently passed crosswise over the anterior portion of the scrotum, just below the peno-scrotal angle, completely to cover in the testicles and to enclose them by the plaster, and one crosswise above the penis to aid in holding the longitudinal straps in place. It is intended to make no pressure whatever, and care should be taken that none is made. Both testicles are included in the bandage whether both or one are inflamed. The bandage may be applied at any stage of the attack, but it is especially applicable in the beginning often cutting short the swelling. If the testicle should swell after this dressing is put on—which, thus far, has not happened in the author's cases—there is ample room toward the penis and perineum to allow of swelling without undue pressure, thus relieving any fear of strangulation. The testicle is thus put in a splint, so to speak, and at the same time the plaster retains the heat and moisture. Patients who come with an epididymis much swollen, saying that they can scarcely walk for the pain, after the application of the bandage, express themselves as much more comfortable. They go about in comfort, attending to their ordinary duties, provided the occupation is not one calling for unusual exercise. The swelling subsides rather rapidly so that within a week or ten days the plaster may be removed and suspensory bandage worn instead.

56. **Interstitial Hernia.**—Halstead reports one case of strangulated inguino-properitoneal hernia in which reduction was accomplished *en masse*, followed by herniotomy. The second case was one of inguino-interstitial hernia (left-sided) in which a herniotomy was done. Both patients recovered. Halstead urges that operative treatment be instituted in all cases of interstitial hernia, including the properitoneal type, because the wearing of a truss can do nothing but harm.

58. See abstract in The Journal, Jan. 13, 1906, p. 146.

62. **Chronic Dilatation of Stomach.**—In the case cited, Donaldson performed, with slight modifications, the operation which is known as Weir's modification of Bircher's operation. The surfaces were brought together with Lembert sutures, the opposing surfaces scarified, and the sutures tied and reinforced by a continuous gut suture. Lastly, in the bottom of the first fold which forms the largest dead space a continuous gut suture was introduced, bringing the surfaces together and making a submucous stitch after the first row was tied. By means of the first row of sutures Donaldson enfolded three inches of stomach wall, and by the second row two inches, bringing the two curvatures within about four inches of each other. After two years the stomach apparently is normal in capacity, there has been no return of the gastric symptoms, and the patient is well.

Donaldson emphasizes the following points on which he believes the success of the operation depends: The catgut suture, obliterating the large fold and dead space and pulling up the fold, flattens it out against the surface of the stomach, preventing it from hanging down into the cavity of the stomach, making, by its firmer and broader contact with the opposing serous surfaces, that giving increased nutrition, less danger of ulcer formation. By two rows of Lembert sutures, reinforced by continuous suture, there is absolutely no danger of any gaping of the wound, even if one or more sutures prove defective. The careful scarification between the sutures insures excellent and immediate union. The multiplicity of

sutures gives so much strength and firmness that fluids can be given in twelve hours after the operation without fear of injuring the wound.

63. Operative Treatment of Osteomyelitis.—The operation referred to by Huntington is one which has been described by him before. A trephine opening about one-half inch in diameter is made on the outer aspect of the thigh, at the lower border of the great trochanter. Through this opening, with a small bone curette, the neck of the femur is tunneled to a depth of from two to two and a half inches. At this depth the epiphyseal cartilage connecting the head and neck will be encountered. If there be any evidence of the focal lesion external to the epiphyseal cartilage, further efforts may be suspended. It is extremely desirable not to interfere with this cartilage, if possible to avoid it, for the reason that such interference will materially affect future development. If it be necessary to enter the head of the bone, either at the time of the initial undertaking or at a later period, this should be accomplished by a small instrument, thereby establishing a channel of communication between the head and neck through which, as a line of resistance, a liquefied focus may find exit.

64. Arterial Anastomosis by Invagination.—Brougham reports the case of a boy who received a penetrating wound of the axillary artery, almost severing this vessel, and of the axillary vein. After freeing the ends of the artery from the sheath for about half an inch, the proximal end of the artery was invaginated into the distal end by means of three fine silk sutures. Five additional sutures taken in the overlapping edge of the distal part sufficed to bind it securely to the external surface of the proximal end. The sheath was adjusted over the invagination for double security. The operation wound was packed with iodoform gauze and the entire arm enveloped in cotton. Late in the evening the radial pulse returned. The patient made an uninterrupted recovery. At no time was there edema of the arm or any evident disturbance of the circulation. The axillary vein was ligated.

78 Hysteric Hemiplegia. A. Gordon, Philadelphia.

70. Action of Quinin on Malarial Plasmodia.—The study undertaken by Craig for the purpose of determining the actual effect of quinin on the various forms of the malarial plasmodia, and the best time for the administration of the drug, show that quinin acts on every stage in the growth of all the varieties of the plasmodia, but that its action is most marked on the free spores and on the young intracorpuscular forms, in the latter often not preventing entirely the development but producing very marked developmental changes. In tertian malaria quinin is effective on all but the segmental bodies, and therefore exercises its curative action whenever given, whether in one large dose just prior to segmentation, or in undivided doses. The effect of quinin on the quartam plasmodium is practically the same as its effects on the tertian in all stages of its development, hence the effect of the drug is most apparent when it is administered in divided doses given at regular intervals, thus keeping the blood full of quinin all the time. Craig's observations on the estivo-autumnal parasite have not yet been completed.

73. End Results in Appendicitis Work.—Balloch believes: (1) The appendix is a rudimentary organ, a part of the cecum, undergoing obliteration, and so far has not been shown to be in any way a necessary part of the human economy. (2) Reasoning from the results of operation in cases of chronic and quiescent appendicitis, the removal of the appendix in the course of operations for other conditions is justifiable. (3) The difficulty of determining from microscopic examination whether an appendix is diseased or not, is an argument in favor of the removal of the organ. (4) The fact that deaths have occurred that might have been avoided had the appendix been removed at the first operation is an unanswerable argument in favor of the practice advocated in this communication, viz., that the appendix should be removed as a routine measure in abdominal work, provided always, that its removal will not prejudice the chances of the patient for a smooth recovery.

76. Spirochaeta Pallida.—Schultz reports a case of hereditary syphilis in which this organism was found in sections from the various organs. The case from which the material was derived was a female infant which died on the fourth day after birth of acute lobar pneumonia. The mother gave an indefinite, but probable, history of syphilitic affection contracted after the beginning of her pregnancy.

91 Etiology and Treatment of Mastoiditis. S. M. Smith, Philadelphia.

90. Calomel in Eclampsia.—Wilson reports 6 cases of eclampsia in which the use of calomel was attended by good results, except in 1 case. In the first case 10 grains were given immediately after delivery. There were no further convulsions and the urine became normal in quantity in less than 48 hours after delivery. There was no salivation. In the second case, 20 grains of calomel were given in 2-grain doses, frequently repeated, with the same result as in the previous case. The third patient had her first convulsions during the third stage. There were 11 convulsions in all. The patient was given 15 grains of calomel within 30 hours. The fourth patient was given 20 grains of calomel after the first convulsion, which occurred during the third stage. There were no more convulsions, nor was there any need for the use of sedatives. The fifth patient had convulsions immediately after labor began. Following a podalic version and extraction she had two more convulsions, with increasing coma, and after an interval of three days another convulsion occurred. (No mention is made of the amount of calomel administered in this case.) The sixth patient, an alcoholic, was first seen in coma which followed three convulsions. Death occurred 30 hours after delivery from pulmonary edema. Thirty-five grains of calomel had been given in doses of 5 and 10 grains.

Wilson urges that calomel should be energetically administered both in the pre-eclamptic stage and in the stage of convulsions. An initial dose of 10 grains, followed in 46 hours by an equal dose, is indicated in the first instance. In the convulsive stage an initial dose of 20 grains, followed by half this amount in the intervals between convulsions, as the opportunity arises, or in accordance with the ability of the patient to swallow, is indicated. If the patient is somnolent or if the convulsions follow each other in quick succession, the maximum dose, 25 grains, should be administered at the first opportunity. In cases in which a pre existing kidney lesion is present smaller doses may be given frequently—two grains every six hours.

7 Local Anesthetic Action of Stovain. D. McKenzie.

4. **Spirochaeta Pallida.**—Maclennan is of the opinion that the name *Spirochæta pallida* denotes only one stage in the history of an organism, while *Cytorrhyctes luis* probably denotes another, so that another name will be required for the protozoan found with, or as the cause of, syphilis. He suggests that it is also possible—if not, indeed, probable—that there is more than one organism responsible for the series of symptoms included in syphilis. It is a striking fact, he says, that the symptoms of syphilis during the roseolar stage are so slight, yet the blood and tissues are more or less contaminated by hordes of micro-organisms. Such symptoms as are present are not likely, therefore, to be due to a toxin elaborated by these germs, but to the germs themselves.

5. **Acute Cardiac Beriberi.**—A postmortem examination was held on the case reported by Wright, and careful culture experiments were conducted. A very suspicious bacillus was found, similar to one recovered from the stools in other cases of acute beriberi. A full report of these findings is given. All the media inoculated from the contents and scrapings of the stomach and duodenum showed growth by the end of twenty-four hours. Plates were made from all surface colonies, but no organism was seen which corresponded with that found in the mucosa of the stomach and duodenum. In the glucose-agar stabs there was found, in almost pure culture, a bacillus which corresponded morphologically and in staining reaction with that found in the gastric and duodenal mucosa. At twenty-four hours the bacillus ranged from 4 to 8 or 9 microns in length, and was 1.05 microns in breadth. The ends were almost square and the sides regular, but slightly curved. Older cultures were longer, stouter, and tended to become clubbed. The patient died in the seventh week of the disease from cardiac failure. The train of events during life were an acute onset with complaint of gastrointestinal symptoms, followed or accompanied by other symptoms that marked the effect of the beriberi virus on the cardiac and vasomotor nervous systems.

12 *Invisible Surgery. J. L. A. Aymard.
13 Bronchopneumonia and Pyemia. I. McKenzie.

9. **Primary Intestinal Anthrax.** Clinically the case reported by Teacher was one of an acute illness terminating fatally within twenty-four hours, the prominent features of which

were headache, cerebral irritation manifesting itself in restlessness, delirium, and finally convulsions. There was also slight abdominal tenderness which might have suggested peritonitis, but there was no pyrexia. The history afforded no hint as to the nature of the disease. At the postmortem examination the case presented the features of an acute septicemia and early peritonitis which appeared to spread from a hemorrhagic lesion of the small intestine with ulceration and necrosis internally and signs of an infective process extending up the mesentery. The nervous phenomena were explained by the discovery of a diffuse hemorrhagic condition of the pia-arachnoid, which microscopic examination demonstrated to be an early meningitis due to the anthrax itself. The identity of the organism was proved by cultivation and inoculation experiments. The intestinal lesion was clearly the oldest, and the conclusion appears warranted that the case was one of anthrax septicemia due to intestinal infection caused most probably by the ingestion of a quantity of anthrax bacilli or spores in the stools.

12. **Invisible Surgery.**—Aymard describes a skin incision for which he claims that a permanent visible scar is not left. His method consists in dividing the skin on the slant in contradistinction to the present method of dividing it at right angles to the surface. The scar is present, but is hidden away. The knife should make one clean sweep down to the fascia, which in turn should be divided as far under the face of the upper flap as possible, and on no account should the lower flap be dissected off this fascia. The upper flap is enclosed in a warm, dry, sterile link and secured far back with tissue forceps. The lower flap being retracted, the fascia is treated in a similar manner and the operation for which the incision is made is proceeded with in the usual way. Aymard seldom uses a suture, but when he does he passes a lance-shaped, slightly curved needle threaded with horsehair through the skin on a slant at a little distance from one extremity of the wound; it then passes through the base of the upper and the apex of the lower flap continuously, its point of exit being through the skin on the slant at the other extremity of the wound. The suture is not tied and is removed at the end of forty-eight hours.

The object is to stretch the delicate apex of the upper flap, and the best plan is to press this edge gently between the finger and thumb, the lower flap at the same time being stretched and placed in position with suitable forceps. The accuracy of the apposition should be tested with a magnifying glass. The subsequent object of dressing is to keep this edge, together with the rest of the flap, in accurate flat apposition, remembering that undue pressure may cause damage. Sometimes he secures the wound by placing across it a few strips of china silk and collodion, at others by merely placing collodion on the curved or flat glass dressing. He prefers glass to celluloid or mica because it is rigid and prevents contraction of the flap.

19 *Three Cases of (So-called) Double Uterus. G. S. MacGregor.

19. **Double Uterus.**—Macgregor reports 3 cases of this kind seen by him and makes an analysis of 100 cases occurring in the literature. Of these 100 patients 30 were unmarried, while 70 were married women. Two out of the 30 unmarried women had had abortions. Of the 70 married women, 14 were non-parous, while 56 were parous; of these 56, 14 aborted and 44 went to full time. From these 44 women there were 96 children, while out of the labors of these there were 2 Cesarean sections, 2 hysterectomies, 4 forceps cases and 36 normal labors. In only 71 cases is there any reference to menstruation; 58 patients were regular, 8 were irregular, while 5 had amenorrhea and 13 dysmenorrhea. In 38 cases there is noted the size of each uterine horn; in 17 cases the left was the larger, the right was the larger in 13 cases, in 8 they were equal, while one was an infantile uterus didelphys. It is evident that the presence of such malformations does not materially lessen the chances of impregnation, except when the genital canal is completely occluded at some point, and that delivery usually occurs without any special danger or difficulty, except when the fetus is held in the rudimentary horn of a markedly double uterus. In such a case there is danger of rupture of the uterine wall; or there may be no dilatation of the imperfectly developed cervical canal; or, again, it may be a powerless labor from the lack of sufficient contractile force in the uterus itself.

23. **The Senile Heart.**—Létienne remarks that the heart is the organ which is generally most affected by senility, but the symptoms suggesting its inferiority are usually masked by others which seem foreign to this organ. It may struggle along for years handicapped by the unsuspected senile changes, and succumb at last abruptly. The fulminating end is apparently very sudden, but the struggle has been going on for years. The most common signs of senile changes in the heart are shortness of breath and fatigue. There is no real pain, but merely a disinclination to make an effort. If the effort is made it is followed by rheumatoid pains in the muscles involved. Rest banishes the pains, but they return at the next effort and may become permanent in time. They may be accompanied by slight dizziness, unstable balance, possibly even ocular troubles or actual angor, which cease during rest but recur at the slightest fatigue. General nervous troubles may be observed, taking the form of indolence or disinclination for the accustomed brain work. The nervous system requires rest like the muscles and demands it imperiously by recurring periods of somnolence. On the other hand, sleep at night is interrupted by waking frequently, or there may be actual insomnia. Slight gastric disturbances may also be observed. None of these symptoms points to the heart, and the only sign of the underlying trouble is possibly slight swelling of the ankles at night or after a long walk, and the composition of the urine. All the constituents of the urine will be found notably reduced in amount, although generally retaining their proportional values.

24. **Syphilitic Aortitis.**—Dieulafoy relates 3 striking examples of syphilitic angina pectoris of extreme severity and persistence for years rapidly cured by daily injections of from 0.5 to 2 c.c. of mercury biniodid in an aqueous solution. He keeps up the injections for ten or twelve days at a time, with intervals of two weeks or a month. Mercurial inunctions had failed to relieve in one case and the patient was in a condition similar to the *état de mal* of epilepsy, the attacks being practically continuous. The biniodid seems to have a remarkably prompt and efficient action on the symptoms. One patient was so much improved that he is now—seven years later—working on a farm, no one in the district being able to compete with him in endurance, although the physical signs of aortic insufficiency still persist.

26. **Early Sign of Tendency to Nervous and "Rheumatic" Affections.**—Landouzy refers to an irreducible inward flexion of the ring and little fingers, generally of the right hand. It is impossible to straighten them out voluntarily. This little sign, he says, permits the physician to divine the past of his patient, to judge of his temperament, and to augur his future. It is a sign of "neuro-arthritism"—nutritional sluggishness—

and may be observed early in life or may develop later, especially after some infection. It reveals the kind of defensive reactions that may be anticipated in case of disease. It has led Landouzy in many instances to prophesy congestive or nervous troubles at puberty, and in case of incipient tuberculosis in such young people, to announce that the disease would probably assume more of a bronchitic form, with spasmodic asthma, or slight recurring hemoptyses or attacks of tachycardia. The course of the disease in such individuals is more inclined to be inflammatory.

27. Technic of Nephropexy.—Albarran gives an illustrated description of the technic with which he fastens the kidney to the lower rib and muscle wall.

32. Spasmodic Contraction of the Cardia.—Brüning describes a case in detail, with the resulting disturbances and the benefit derived from operative treatment. The patient was a young man and as the disturbances from the dilated esophagus were serious, the cardia was stretched with Mikulicz forceps introduced through an opening into the stomach. It required some force to conquer the spasmodic contraction, but it was finally stretched to a diameter of 6 cm. A tube had been passed into the stomach through the mouth and out through the opening made in the stomach. The lower end of the tube was slit into halves for a short distance, and one of these halves was tied to each branch of the forceps. The forceps could then be drawn up into the cardia as the tube was drawn up through the mouth. The single stretching answered the purpose. In acute cardiospasm, painting the mucosa of the cardia with a 3 per cent. solution of cocain has proved effectual in some instances. In the chronic cases the cocain has given only transient benefit, not affecting the purely functional spasm. It is sometimes possible to cure an incipient tendency by changing the diet, restricting the patient to fluid foods for a time. No benefit has been derived to date from electricity. Feeding through the stomach sound has benefited many patients. In the case described this was kept up for two months, supplemented by rinsing out the esophagus and application of electricity. This improved the patient to such an extent that he felt comparatively free from disturbances for two years, but then they returned in a more serious form than before. The spasmodic contraction never returned after the cardia was finally stretched.

34. Treatment of Acute Inflammation with Passive Congestion. Rubritius reports the experience at Wölfler's clinic at Prague with Bier's method of passive congestion. Nearly 125 patients were thus treated and the results were highly satisfactory, in cases of suppuration in a tendon sheath, abscess, furuncle and especially so in mastitis. The final verdict is that Bier's method of "congestive hyperemia" is extremely useful in the treatment of acute suppurative processes, but is liable to do harm in case of existing general infection. In an experience with 3 cases of this kind and in 3 reported in the literature, existing general infection seemed to be aggravated by the passive congestion. Symptoms of general infection or the finding of bacteria in the blood should contraindicate this method of treatment. [The second edition of Bier's book, "Hyperemia as a Curative Agent," 1905, is already exhausted and a third edition is now being prepared. He states that

Figure 1.

from lack of space in the new edition he refrains from touching on the value of artificial hyperemia in the treatment of cutaneous affections, although his experiences in this line have been remarkably favorable. The various devices used to induce passive congestion at his clinic have recently been described and illustrated anew in the *Zeitft. f. aerztliche Fort-*

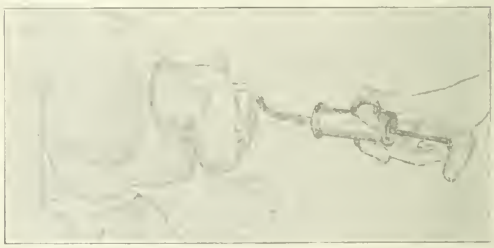

Figure 2.

bildung, Nos. 7 to 9. The article is by R. Klapp of his clinic, who reiterates that the constricting band should not cause any discomfort in itself, and that the sensations in the congested area should be merely those of congestion without any prickling or "going to sleep" in the part. The limb should feel warm, even warmer than the sound side. The skin should

Figure 3.

look bluish red, and the pulse should be distinctly felt. In case of acute inflammation the limb flushes up to the constricting band and generally swells considerably, while the pre existing pain gradually subsides. In case of a chronic affection, or with merely brief artificial hyperemia, the congested area does not swell much and it does not grow much if any

warmer. Bier has always advocated the use of simple, generally home-made devices, for application of superheated air, for the elastic constricting bands and for his suction cups. Figure 1 shows the constricting bands as applied to the arm, shoulder and neck. For the shoulder a rubber tube is sewed into a ring. Figure 2 shows the suction cup used for mastitis with a syringe pump or rubber bulb. Figure 3 shows the cup used for boils, abscesses, etc. At the Hamburg surgical clinic the constricting bands are applied on out-patients, without medical supervision. They are told to take them off at once if they begin to hurt.—ED.]

35. **Splenectomy for Injured Spleen.**—Noetzel reviews the history of 6 patients whose spleens were removed on account of injury of the organ. He did not notice any symptom specially characteristic of such injury, but signs of irritation of the peritoneum from effusion of blood demanded prompt intervention. He also found that severe pain at the point of injury invariably accompanied serious damage within. In one of the cases the early intraperitoneal hemorrhage stopped spontaneously, but commenced again the third day, requiring operative measures. He discusses the best technic for splenectomy judging by the outcome of his cases. It is the only means of arresting hemorrhage from the injured spleen. Suture and tamponing may arrest it for a time, but there is always great danger of recurrence of the hemorrhage, as occurred in some of his cases.

36. **Operative Treatment for Injuries of Liver.**—Noetzel here describes 8 cases of injury of the liver in which an operation was performed in less than four hours in all but one, in which the interval was ten hours. His experience shows the advantage of suturing the wound in the liver whenever it is at all possible. He sutures through a tampon to prevent bleeding later. He has recently examined 3 of the patients after an interval of from several months to two and a quarter years, and found them all entirely well and free from disturbances of any kind.

37. **Roentgen Treatment of Goiter.**—Pfeiffer describes the experiences with Roentgen treatment of goiter at von Bruns' clinic at Tübingen. The particulars of 51 cases are given and the histologic findings in 8, with the results of experimental research. The general conclusion is to the effect that Roentgen treatment of goiter is ineffectual as a rule and should not supplant the better tried methods.

41. **Cause of Death in Acute Pancreatitis.**—Doberauer analyzes the clinical histories of 6 cases of acute pancreatitis and summarizes his experiments on 35 dogs. The course of the clinical cases and the findings in the dogs indicate that the diseased pancreas generates toxins which are extremely injurious. He was able to cause the same symptoms in dogs as those observed in human acute pancreatitis by tying off the vessels in the pancreas and isolating it. The pancreas soon showed signs of fat necrosis, subserous hemorrhage and hemorrhagic effusion into the peritoneal cavity, and the animals rapidly succumbed. Injection of fragments of the diseased pancreas into healthy animals caused the same fatal syndrome in the latter. The diseased pancreas evidently undergoes an autodigestion with the generation of extremely toxic elements which are rapidly absorbed by the peritoneum irritated by the presence of the digestive juices. His experiences further suggest the possibility of rendering dogs immune to this toxin by injections of normal and then of small amounts of the diseased pancreas.

43. **Traumatic Bright's Disease.**—Posner discusses the questions suggested by the case described. A girl of 11 had scarlet fever, but was otherwise healthy until she reached her twenty-third year. She then fell from a horse car and immediately experienced violent pain in the right side which recurred repeatedly. A tumor became evident and was recognized as the displaced kidney. Two years passed without essential improvement from the supporting bandage ordered. Six months later, while the pains still continued, albuminuria was observed. It was of the cyclic type at first, but after another six months pains developed also on the left side, the albuminuria became constant and signs of chronic inflammation of both kidneys became apparent.

44. **Early Diagnosis and Treatment of Laryngeal Cancer.**—This article is a postgraduate lecture and outlines the present status of the subject. Total extirpation, Baginsky says, has become a less dangerous operation than it used to be, and the after-treatment has been much improved, but, even at the best, the mutilation is great. The physician must bend all his efforts to early diagnosis and exert his influence to have the growth removed in its incipiency.

45. **Premenstrual Increase of Temperature.**—Riebold calls attention to the fact that in many women, just before the menstrual discharge appears, the process of ripening of the follicle is accompanied by an increased activity in all the vital processes, so that at this time a violent storm sweeps over the organism. In healthy women there does not seem to be any special disposition to acquire disease during this period, although digestive disturbances are frequent. An already diseased organism is especially liable to contract new infections at this time. Any disease already present may become aggravated during the premenstrual period. There is frequently a rise in temperature at this time, generally due to absorption from some old infectious focus or to exacerbation of the underlying affection. This premenstrual fever is observed frequently but not exclusively in tuberculous women, and never in entirely healthy women. Franck has recently asserted that premenstrual fever is an indication that something is wrong somewhere in the organism. It may be necessary to take the rectal temperature in order to detect minimal premenstrual fever.

48. **Test for Santonin in Urine.**—Fehling's solution turns the urine dark green and, in larger amounts, dark purple, in case of the presence of santonin.

52. **Artificial Pneumothorax in Treatment of Pulmonary Tuberculosis.**—Schmidt describes a combined trocar and cannula with which he has been injecting gases or fluids into the pleural cavity. He does not yet publish his therapeutic results, but merely describes his technic. He evidently thinks it promises well.

53. **Transmission of Syphilis to Monkeys.**—Neisser's experiments on monkeys have been frequently mentioned in these columns. In this fourth part of his official report he states that fresh syphilitic growths, even the tertiary, induce primary sores when inoculated into monkeys. It is immaterial whether these tertiary manifestations occur in an early or at a very late stage of the syphilitic infection. The inoculations are always positive so long as the growths are not destroyed by necrosis or suppuration. When there is specific gummatous degeneration of the tissues or suppuration then the inoculations are never successful. He warns that every tertiary man-

festation should be regarded as contagious even although the danger of infection is much less than in case of the primary and secondary manifestations. His findings also suggest the necessity for several thorough, intermittent courses of mercurial treatment for every syphilitic in the tertiary stage. The primary and secondary lesions are particularly dangerous, as they are located at the points which are most liable to come into close contact was other individuals. These points are, also, particularly liable to excoriation (lips, interior of the mouth, etc.). On account of the latter fact, the lesions are especially liable to be mistaken for harmless excoriations. The tertiary lesions from which the positive inoculations were made were always those with intact skin above them. Some were on patients who had acquired their syphilis from ten to fifteen years before. Neisser's examinations of children with inherited syphilis have convinced him that their bodies swarm with parasites which can pass by way of the blood into the organs. Inoculation with mucus from the nose of such a child produced a primary sore on a monkey in one case. Inoculation with the blood and tissues from various organs was also always positive. In 2 of the 3 cases described in detail the children were apparently healthy for several weeks before anything suspicious of syphilis developed. Nothing in the history of the parents suggested any suspicion of the disease. It may be possible to detect the syphilis in such cases much earlier by examination of the blood or secretions for spirochetes.

54. **Contagiousness of Syphilitic Blood.**—Hoffmann also reports experiments with monkeys which have confirmed the contagiousness of the blood during the early stage of syphilis. The virus is present in the blood in an attenuated form, probably, as only part of the experiments resulted positively.

55. **Radium Treatment of Cutaneous Affections.**—Wichmann reports the experience at the Hamburg Lupus Institute with radium. He found that the larger part of the rays are absorbed in the cutis and that pathologic tissues absorb more than the sound. The action on the surface is too intense, while the underlying tissues do not feel the effect of the radiation enough. He suggests that it might be possible to overcome this difficulty by filtering the rays and increasing their deep action by supplementing them with injections of radioactivated fluids. He has found radioactive barium sulphate excellent for the latter purpose.

59. **Volvulus of Sigmoid Flexure in Children.**—Tschernow reports 3 cases. Two were in lads of 10 and one in a girl of 4. The condition is very rare in children under 15, but is so frequent after 20 that Treves is cited to the effect that 2,000 persons die annually from this cause in England alone. One of Tschernow's 3 patients succumbed to the ileus. The girl was relieved of the acute symptoms of occlusion, but the trouble was evidently due mainly to a congenital dilatation of the colon. The sigmoid flexure and mesentery were unusually long allowing the flexure to form a loop which caused trouble in the passage of feces but no occlusion, as the loop was rounding and not a sharp peak. In Boeckel's case the round loop was twisted a quarter around on its axis. The symptoms are those of ileus in general. Indicanuria indicates obstruction in the intestines and may aid in the diagnosis. Other symptoms are due to the resulting autointoxication.

60. **Osmotic Concentration of Infants' Foods.**—Stoeltzner urges study of the osmotic concentration of the foods and stomach content of infants. It is almost certain that osmotic processes play an important part in the digestive processes.

62. **Sudden Death from Enlarged Thymus in Infants.**—Hedinger's previous communications on "thymus deaths" were recently reviewed in these columns, page 1484. He has found evidences of hyperplasia of the thymus in the cadavers of 17 infants. In some the thymus alone was unusually large, while in the others there was also thyroid hyperplasia, although not to such a degree as to have suffocated the child. In all these cases, as also in those on record, the children either did not recover from their asphyxia after birth or else, after a few hours of apparently normal breathing, respiration ceased abruptly. In the cases reported by Somma the children did not succumb until the third or fourth day, after several attacks of suffocation. Hedinger gives an illustration of a deformed, hemicephalous child who lived twenty-four hours. The thymus was extremely large, measuring 7.5 by 6.5 cm. and 4 cm. thick. The suprarenals were extraordinarily small. The findings in all these cases differed in several important respects from those characteristic of the status lymphaticus.

66. **Idiopathic Atrophy in Infants.**—Bloch supplements his former communications on this subject by reporting the pathologic anatomic findings in 6 cases of idiopathic atrophy of infants under 8 months. They demonstrate that the primary cause of this condition, as also of certain forms of chronic dyspepsia (without catarrh of the intestines), is defective functioning of the serous digestive glands.

67. **Pneumococcus Arthritis.**—Herzog remarks that the 3 cases of this condition which he has had occasion to observe in infants certainly demonstrate that the joints at this early age are predisposed to pneumococcus infection the same as other serous membranes, the pleura, peritoneum, pericardium and meninges. Without a preceding lung affection, it is rare in adults. Only 4 are known in 55 cases in adults; 11 in 28 cases in infants under 2, and 5 in 8 children from 2 to 14. The only effectual treatment is by extensive arthrotomy, carefully saving the ligament apparatus. The tendency to multiple abscesses must not be forgotten. The deposits of fibrin—"nests for the pneumococci"—must be carefully removed. Defects in the cartilage and bone must be curetted and the wound drained for two or three days. The function of the joint is seldom permanently impaired. Detachment of the epiphysis has been observed in neglected cases, but there is no actual sequestrum formation. The clinical picture observed in Herzog's 3 cases included extreme pallor of the skin, especially of the face, notwithstanding the irregular fever. The appetite, digestion and sleep did not seem to suffer much. The joint was swollen, sometimes the entire limb, and it was hot and sensitive to pressure. Sometimes the joint was abnormally movable. A characteristic feature is the absence of circumscribed redness when all other signs point to an inflammatory process. He based his diagnosis on this feature in one instance. When there is redness it indicates that the process has involved the tissues around the joint. The pneumococcus pus is generally a greenish yellow, not fetid, but creamy, with a tendency to fibrin formation. Endocarditis has never been observed in connection with the arthritis in infants. The general symptoms are much milder than in case of staphylococcus arthritis. Exploratory puncture will differentiate the affection from tuberculosis, etc. Gonorrheal arthritis in infants resembles more the pneumococcus affection, but other signs of gonorrheal infection are seldom lacking. There is little edema and the pus is thin and serous. The article concludes with a bibliography of 108 titles on pneumococcus arthritis.

69. **Diffuse Eczema; Heart Failure.**—An apparently healthy child of 16 months, with diffuse eczema with much exudation, was brought to Rehn for relief from the itching. He prescribed a 2 per cent. ichthyol salve and in a week the eczema had improved to such an extent that there was no more itching, and the child's appetite and sleep were good. This improvement lasted for two weeks, when the eczema flared up again with fever. It subsided under cool compresses and aluminum acetate with 0.1 gm. phenacetin internally morning

and evening. These measures were followed by application of a 5 per cent. ichthyol salve, under which the eczema and the general health rapidly improved. The mother reported five days later that the child had no appetite. There was no fever and no edema. The lymph glands around the right ear were enlarged, evidently the result of suppurating eczematous patches in the outer ear. The next morning Rehn was hastily summoned to the child, who was in collapse; the heart action was weak and irregular. The child died in less than two hours. There were no evidences of status lymphaticus, but there was fatty degeneration of the heart, liver and kidneys. Streptococci and staphylococci were found in the blood of the heart.

70. **Right of Child to Life at Birth.**—Krönig discusses the question of how far obstetricians are justified in imperiling the mother to save the child. He quotes Zangemeister to the effect that the obstetrician is justified in performing operations in the interests of the child if they have generally a mortality of not over 2 per cent. He analyzes the 135 cases in his own experience in which children died during delivery, out of a total of 3,133 births. In 40 instances death was due to protracted birth and consequent asphyxia of the child, the soft parts being contracted and the head twisted. In 23 cases there was placenta prævia, in 18 prolapse of the cord and strangling, and in 22 cases the mother's pelvis was contracted. He is convinced that with more active measures some of these children might have been saved. Reviewing his own and the experience of others, he has found that the prognosis for the mother of symphyseotomy and Cesarean section is scarcely any more unfavorable than that of craniotomy, granted good technic and asepsis. The maternal morbidity of craniotomy is also higher than is generally assumed. Prophylactic version and artificial premature delivery have a larger mortality for the mother than is generally recognized, and they reduce the mortality of the children very little if at all. He advocates more extensive resort to pelvis-enlarging operations or Cesarean section, provided the birth canal can still be regarded as aseptic. If the mother is already infected, Cesarean section is almost inevitably fatal, unless infection of the peritoneal cavity can be prevented. During 1905, 440 children weighing over 2,500 gm. were delivered at his clinic, with 11 deaths. Two at least of these children might possibly have been saved if an operation to enlarge the pelvis had been undertaken earlier. One of the children succumbed during the serious collapse of the mother in consequence of lumbar anesthesia.

71. **Past and Present Mortality in Case of Contracted Pelvis.**—Baisch compares statistics from various clinics to learn the causes of the mortality for mothers and children when the pelvis is deformed. The practical conclusions of his study are that it is a grave mistake to suppose that artificial premature delivery, prophylactic version and high forceps will accomplish the desired purpose when the pelvis is too much contracted to allow the passage of a living child. The mortality from expectant treatment in such cases is not so high as from these operative measures. Zweifel and Döderlein have abandoned them altogether, and yet their mortality is lower than that of others who still cling to these measures. In conclusion Baisch asks if it might not be advisable to substitute external cephalic version in case of transverse presentation, for the classic podalic version. He advises against trusting too long to expectant treatment in case of too protracted delivery. The widespread dread of the forceps is perhaps exaggerated. Forceps and version are contraindicated, however, when the head has failed to move downward at all. The entrance of the head into the pelvis might be favored by hebotomy (pubiotomy or extramedian symphyseotomy).

72. **Lactation and Menstruation.**—Heil's article is based on 200 cases. His experience has been that about half of all nursing women menstruate regularly. He is almost tempted to believe, for reasons which he cites, that the menstruating nursing women represent the normal healthy type.

74. **Hebotomy or Symphyseotomy.**—Sellheim contributes anatomic, clinical and experimental researches to aid in deciding the question as to the superior advantages of these two operations. The balance is still undecided.

75. **Anatomic Bases for Secretion of Milk.**—Engel points out that the defective development of the specific glandular parenchyma of the mamma may be responsible for the inability of certain women to nurse their babies. The external form and palpation findings do not permit of reliable conclusions as to the functional capacity of the mammary glands. Every breast, even the defectively developed ones, contain more or less of the secreting parenchyma, and in every case it should be pressed into service for the feeding of the infant. The mothers with little of this secreting parenchyma should be encouraged to keep it continuously at work so that their infants can at least profit by partial breast feeding if the mothers are not able to feed them entirely.

76. **Reduction of Salt in Treatment of Dropsy of Pregnancy.**—Cramer regards the edema that develops in the course of pregnancy, and also the varices, as a manifestation of the autointoxication of pregnancy. The walls of the vessels are affected by some disturbance in metabolism, the result of autointoxication. The dropsical tendency can be successfully combated by reduction of the intake of salt, as his experience in 5 typical cases has demonstrated. The patients did not eat salted foods, the bread was baked without salt, and all food containing salt was avoided, including milk and meat. On a diet of eggs, puddings, cereals, vegetables and fruits the existing dropsy rapidly retrogressed and the patients lost weight constantly until their normal weight was reached. One of his patients had a fetus in each half of a double uterus, delivery proceeding nearly simultaneously in each but quite independently, although requiring some help. This patient exhibited symptoms toward the end of the pregnancy which indicated the existence of eclampsia, although there were no convulsions. He thinks that we must accept the existence of eclampsia without convulsions as a well-defined morbid entity, and even without edema or albuminuria. His experience further demonstrates that the edema of the legs observed during pregnancy is a static accumulation of fluid when the dropsy has reached a certain degree. He was unable to detect any injurious influence from the "salt starvation" treatment on the development of the children, and regards the benefit observed after reduction of salt in the diet in the dropsy of pregnancy as a very promising fact. The measures ordinarily applied, sweats, diuretics, etc., have more or less of an effect on the heart or general health of the patient, while reduction of salt in the food is harmless, simple and easy, even for the poorest.

79. **Postoperative Ventral Hernia.**—Schütze declares that a well-made suture of the fascia after a laparotomy ensures positively against postoperative hernia. The best technic for the suture is what he calls the "Vienna suture," with an antiseptic (Turner) silk. In case of postoperative hernia, he has found the Karewski technic of treating it harmless and extremely satisfactory. The earlier it is done the better the results. The Karewski technic was briefly described in THE JOURNAL, xliv, page 665, 1905.

81. **Statistical and Anatomic Study of Results of Operations for Uterine Cancer.** Schindler's extensive article re-

views what has been written on the results of the Freund-Wertheim radical operation for carcinoma of the uterus. He presents all the evidence and the results of 117 operations at Gratz.

94 Historisches zur Frage des Einzelkelches beim Abendmahl (individual communion cup). A. Martin.

83. **Carbolic Acid and Camphor in Treatment of Acute and Chronic Suppuration.**—Ehrlich has adopted Chlumsky's method of treating suppuration with a mixture of 30 parts carbolic acid, 60 parts camphor, and alcohol to 100 parts. It was described in The Journal, Nov. 4, 1905, page 1453. Ehrlich confirms all Chlumsky's assertions in regard to the simplicity, harmlessness and effectiveness of this method of treating all kinds of inflammations. It does not require trained assistance, and his experience in 96 cases of felons, phlegmons, leg ulcers, furunculosis, erysipelas, tuberculous fistulas and infected wounds of all kinds, was extremely favorable. He applies the mixture on a loose tampon, without an impermeable covering, and found the length of treatment very much shorter than by other methods. There were no disagreeable by-effects. Among the examples cited was the case of a soldier with a tuberculous fistula in his neck which had resisted treatment for months. Under phenol-camphor treatment the fistula healed in twelve days. In another case an old leg ulcer on a soldier healed under three applications. The relief from pain and the feeling of warmth suggest that the benefit may be due to artificial hyperemia as in Bier's passive congestion, but the latter technic requires trained supervision, which is unnecessary with the phenol-camphor dressings. A folded mull compress impregnated with the phenol-camphor is placed around the focus and dry cotton over it, the whole held by a loose bandage. When the focus is incised a strip of mull impregnated with the mixture is introduced into the opening.

85. **Sensitive Reaction for Bile Pigments.**—Krokiewicz reports that later experience has confirmed more and more the extreme delicacy of his test for bile pigments. The reagents used are 1 per cent. aqueous solution of sulphanilic acid and also of sodium nitrite, and pure hydrochloric acid. He mixes 1 c.c. each of the two solutions together and then pours out all but 0.5 c.c. The same amount of the fluid to be examined is added. In case of the presence of bile pigments it turns red and, on addition of a drop or two of hydrochloric acid, a permanent violet. In 1,000 different tests with urine after ingestion of various drugs and in other conditions the reaction was never positive except in the presence of bile pigments. The reaction also can be obtained with as little as from 2 to 10 drops of the fluid to be examined.

88 **Spontaneous Cure of Perforation of Stomach.** The patient described was an artist of 46 who had complained for some time of symptoms suggesting a possible ulcer in the stomach. Indications of perforation developed, treated by absolute rest, very hot applications to the region for several hours, and then ice. Although the high temperature and the serious condition of the patient seemed to impose surgical intervention, yet his constitution and a family history of tuberculosis, and signs that the peritonitis was becoming circumscribed justified delay and recovery proceeded smoothly. A year later there were evidences of fixation of the transverse colon and of its adhesion to the abdominal wall and liver.

89. **Vaccine Affection of Eye.**—Alexander reviews the literature on the subject of vaccine affections of the eyes, mouth, genitals, etc. He reports a case in which a child had probably scratched a vaccination pustule and inoculated itself on the face, eyelids, right hand and arm so that other pustules developed. He urges prophylaxis of such occurrences.

91. **Pregnancy and Delivery After Vaginal Cesarean Section.**—Rühl relates the details of 4 cases in which he delivered women in a pregnancy subsequent to vaginal Cesarean section. No disturbing influence from the operation could be discovered. In one case the rigidity of the cervix had been the reason for the obstetric operation, and this rigidity interfered also with the later delivery. In another case a cicatricial adhesion fastened the uterus to the broad ligament, and this had to be severed before the uterus was able to enlarge normally, but this band was the result of old inflammation, not of the obstetric operation.

97 *Die Cytologie der Pleura- und Peritoneal-Ergüsse (effusions). H. Köster.
98 Traitement de la tuberculose par le sérum antituberculeux de Marmorek. E. Levin.

96. **Experimental Leucocytosis.**—Kier asserts that in rabbits there are always more leucocytes proportionately in the peripheral vessels than in the central, except that the portal vein always contains a large proportion of leucocytes. The fastening of the animals, the anesthetic, and any slight operation affects the number of leucocytes, and the leucocytosis of digestion, in rabbits, is always very pronounced. These facts must be borne in mind in experimental studies of leucocytosis in these animals.

97. **Cytology of Pleural and Peritoneal Effusions.**—Among the results of this extensive study of the subject may be mentioned the fact that lymphocytes predominated in 80 per cent. of the tuberculous effusions, while in the inflammatory exudates of other than tuberculous or rheumatic origin, the polynuclear leucocytes predominated in 80 per cent. and the lymphocytes were comparatively rare. In cases of carcinoma the endothelial cells predominated in 63.4 per cent., but lymphocytes were also present in large numbers in 11 out of the 41 cases.

NEW PATENTS.

Recent patents of interest to physicians:

$18814. Vaginal syringe. Martin L. Bosworth, Bristol, R. I.

Addresses

THE ASSAULT ON TROPICAL DISEASE.*

LEWELLYS F. BARKER, M.D.

Professor of Medicine, Johns Hopkins University, Baltimore.

BALTIMORE.

INTRODUCTION.

Tropical pathology is rapidly becoming recognized as a special field in medicine, a field worthy of cultivation by itself and for its own sake. Indeed a number of the energetic and able men of our profession have already made the decision to devote themselves to it as a life work.

Though it was my rare good fortune some years ago to travel as a member of a commission for the special study of tropical diseases, and I had the opportunity in Hongkong, in the Philippines and in India to observe some of the more prevalent maladies occurring there, it was less this fleeting experience, I imagine, which prompted you to ask me to speak on the subject allotted to me, than, in the first place, a desire to extend a courtesy to the appointee to a dignified office, and, in the second place, the conviction that one whose life is devoted to teaching and research in inner medicine might have some qualifications for judging of progress in one of its special fields. For after all the problems and difficulties of disease in warm climates do not differ fundamentally from those of disease in the cooler countries of the earth; they can scarcely be solved without enlightenment by the principles which are true for pathology here as well as there.

THE GROWTH OF INTEREST IN TROPICAL MEDICINE.

A survey of the history of medicine will reveal many examples of stimulation to medical research the outgrowth of changes in the political and economic movements in the world. Perhaps none is more striking, however, than the impulse to medical research excited comparatively recently by the struggle of the nations for the control of the tropics. A great impetus to American interest was given by the Spanish-American war and the relations necessarily established with Cuba, Porto Rico and the Philippines. That experience taught us on the one hand how ultimately the problems of tropical pathology and colonial medicine are bound up with those of military and naval hygiene, and, on the other, how indispensable a knowledge of tropical diseases is for a home country that has to deal with tropical possessions. The proximity of Mexico to the United States, the large volume of trade with South American ports and with the Orient, the increasing number of American inhabitants in the Philippines and West Indies, clearly emphasize the importance of the study of tropical diseases for the people of the United States; this importance is decidedly augmented as we consider the construction of the Panama Canal and the results that inevitably will follow it.

Europeans are no less interested in the problems of tropical medicine. England with India, the Malay States and its African territories is, wisely, greatly concerned. Germany's investigations in tropical pathology are as aggressive as are her political tactics in the hot countries. France, though in a smaller way perhaps, is making notable contributions. Italy, Portugal and even Russia are taking part in the movement to increase our knowledge of tropical diseases, to improve the hygienic conditions in warm climates and to make effective the sanitary engines of modern prophylaxis.

THE PRINCIPAL DISEASES OF THE TROPICS.

The people in hot countries suffer from the "cosmopolitan" diseases, as well as from those peculiar to their lands. The study of these universal maladies as they occur in the warmest climates is a problem by itself, well worthy of serious investigation. The difference in climatic relations, the various races affected, and the peculiar economic and cultural conditions, give in the tropics an especial stamp to types of disease well known all over the world. Typhoid fever, relapsing fever, cholera, dysentery, smallpox, tetanus, tuberculosis, syphilis, diabetes, arteriosclerosis, nephritis and neurasthenia ought to be understood by the physicians of Manila, Singapore, Bombay, Khartoum and Havana as well as by the doctors in Baltimore, London and Berlin. But there is a large group of diseases which occur almost exclusively in tropical and sub-tropical climates and only rarely in the more temperate regions of the earth. A surprisingly large number of them are due to bacteria or to animal parasites. Some of them are infections or toxic diseases of unknown origin. A large number of them are cutaneous diseases presenting peculiar characters. Of the better known infectious diseases you will recall bubonic plague, dengue, yellow fever, Malta fever, tropical malaria, beriberi and leprosy. Of the intoxications I may remind you of pellagra, lathyrism and snake poisoning. Of the diseases due to animal parasites, the distomal, the bilharzial, the filarial, the uncinarial, the amebic, the piroplasmal, the malarial, and the trypanosomal appear to be the most widespread and important.

INSTITUTES FOR INSTRUCTION IN TROPICAL MEDICINE.

Coincident with the recognition of the momentousness of tropical disease there has developed a series of institutes for its special investigation, a group of hospitals in which cases may be observed, and a number of courses of instruction in tropical medicine, some of them in separately organized schools.

Here in the United States, we are far behind other countries in the foundation of such institutes and in the planning and realizing of such courses of instruction. American contributions to tropical medicine have been great, but they have been along other lines. There is

* An address delivered by invitation before the Medical and Chirurgical Faculty of Maryland, Baltimore, April, 1906.

one notable exception and that is not in the United States, but in a dependency. Thanks to the liberal mindedness of the Hon. Dean C. Worcester of the Philippine Department of the Interior, a biologic laboratory has been established as a part of the Bureau of Government Laboratories in Manila, with Dr. Richard P. Strong as director; it has been admirably equipped, has a fine library and other exceptional facilities, and is attracting a high type of trained investigators. This laboratory and its management guarantee the thorough investigation of tropical pathology in the Philippine Islands; that it will continue to reflect credit (as it has already done) upon American medicine as a whole there can be no doubt. For an account of the organization and equipment of this Institute I would refer you to an article by the superintendent of the government laboratories in Manila, Dr. Paul Freer.[1]

But within home territory, despite the excellent work carried on in tropical pathology by our University laboratories, the Army, Navy and Marine-Hospital service, so far as I know, no institute especially set apart for the study of tropical disease has thus far been endowed or planned. A choice opportunity thus lies open to some wealthy person who wishes to benefit humanity.

There has been a good deal of discussion as to whether the institutes for tropical research should be situated in the home countries or in the tropical lands themselves. As noted, America thus far utilizes only laboratories established for more general purposes at home, and has set up one permanent laboratory in the tropics. The advantage of a permanent station in Manila must be obvious to all; with abundant materials and facilities for work on the spot, investigators avoid those difficulties which so often rob travelling commissions both of valuable time and of rare opportunity. Much can be said, however, for the more generally accepted view that special institutes should be organized at home, one or more for each great nation. Germany, for example, set up in 1900 an Institute for Naval and Tropical Hygiene (*Seemanskrankenhaus und Institut für Schiffs- und Tropenkrankeiten*) in Hamburg, which serves as a sort of central institute for all her many scattered colonies. It has the advantage of economy on the one hand and of contact with home science on the other. The Germans fit out expeditions to the tropics instead of establishing stations there, though these expeditions frequently spend large sums of money in setting up temporary laboratories in the tropical regions where they work. In Hamburg the institute has a hospital connected with it; it contains a fine library. Regular courses of instruction in tropical diseases, six weeks in duration, are given two or three times a year. There is no examination at the end of the course. A good description of the institute and its work will be found in an article by Dr. Nocht, its director.[2]

In England, too, the tendency is toward the establishment of home institutes for the study of tropical diseases, though certain laboratories, usually temporary, such as the plague laboratories in India, the beriberi laboratory in the Malay States, the Burroughs Wellcome laboratory at Khartoum, have been set up nearer the equator. Largely through the far-sightedness of the Hon. Joseph Chamberlain, there has been founded at Albert Dock in London as a branch of the Dreadnaught Seaman's Hospital, the now well-known London School of Tropical Medicine (Director S. C. Low), where Sir Patrick Manson and other lecturers, including Hewlett, Duncan, Cantlie, Simpson and Sambon, are at work. It has an income of some ten thousand dollars per annum, and gives several courses yearly to physicians entering the Colonial service or to others interested in tropical diseases.[3]

The Liverpool School of Tropical Medicine was founded in 1899 and is supported by voluntary contributions. Its aims are first to train physicians in tropical hygiene; secondly, to make original investigations of tropical diseases; and thirdly, to organize preventive measures for the tropics. It gives many shorter and longer courses of instruction and issues certificates of proficiency. Dr. R. Boyce is the dean of the school, and Major Ronald Ross is the principal professor with tropical experience. The special laboratory for Tropical Medicine and Parasitology forms a part of the magnificently equipped Thompson-Yates and Johnston laboratories in Liverpool.

In France there is the Institute of Colonial Medicine (*Institut de medicine coloniale de Paris*); in Italy special instruction is given in "exotic pathology" and "naval hygiene" by Rho and Pasquale. Even Portugal, I am told, has a school of tropical medicine.

EXPEDITIONS AND COMMISSIONS FOR THE STUDY OF TROPICAL DISEASES.

Most fruitful in results has been the promotion of expeditions and commissions to the tropics for the study of particular diseases. The wealth of information we now possess concerning plague and Asiatic cholera is largely due to the work of such commissions. The Yellow Fever Commission of the United States Army, with Walter Reed at its head, carried out in Cuba the remarkable series of experiments well known to us all. The Johns Hopkins Medical Commission to the Philippines gave Flexner the opportunity to begin his important studies on dysentery; the light recently thrown on the summer diarrheas of infants may be regarded as a direct sequel to his investigations.

The Liverpool School of Tropical Medicine has sent out nearly twenty different expeditions to the tropics, among them commissions which have greatly increased our knowledge of malaria and sleeping sickness. The German government is very liberal in the financing of expeditions. R. Koch, who has already been sent on a number of costly excursions, has left again this month for Entebbe in British Uganda. He has been sent for eighteen months to continue the study of sleeping sickness, and has been allotted some $30,000 for his expenses during the first year.

THE BIBLIOGRAPHY OF TROPICAL DISEASES.

A subject of such rapidly extending significance, and one which has to be taught to an increasing number of medical men, could not go long without its text-books. Sir Patrick Manson's "Tropical Diseases,"[4] is widely read in English speaking countries. His "Lane Lectures" given in San Francisco last year also afford an easy approach to the subject.[5]

Of German books, Scheube's "Diseases of Warm

5. Manson (Sir P.): Lectures on Tropical Diseases. Lane Lectures for 1905. London, 1905, pp. 230.

Countries"[6] is excellent. The references at the ends of the individual chapters permit of quickly getting at the original sources. The book has been translated into English.[7] Just recently the first volume of a new handbook has appeared in Germany.[8] I have not yet had the opportunity to study it. The books of Rho, Le Dantec, Brault and Muzio may be mentioned without exhausting the list from other countries.

Original articles on tropical disease appear in various scientific periodicals. Recently several journals have been established which are devoted either wholly or largely to the subject. Prominent among these are the *Journal of Tropical Medicine* issued twice a month in London, the *Archiv für Schiffs- und Tropenhygiene* in Hamburg, *Janus* in Amsterdam and the *Philippine Journal of Science* in Manila.

Almost every conceivable phase of the subject is being dealt with in special articles in the general medical journals. A glance through the Index Medicus under the caption "Tropical Medicine" will give an idea of the activity prevailing. There are papers dealing, for instance, with diet in the tropics, the influence of the acquisition of tropical territory on American medicine, the effects of tropical diseases on commerce, the care of the aged and infirm in the tropics, and the particular diseases which occur in various localities such as the Panama Canal zone.

RECENT ADVANCES IN THE STUDY OF PARTICULAR DISEASES.

So avid are medical men to-day of knowledge of tropical diseases that reviews of progress are demanded at brief intervals. The Journal of Tropical Medicine, for instance, has recently reviewed the work of 1905[9] and in the articles by McCrae,[10] Blumer,[11] and Boyce,[12] a great deal of newer work is referred to. I dare not in the time allotted to me do more than call your attention most briefly to some of the more interesting advances.

Bubonic Plague.—This disease, interesting especially to me on account of the opportunities I had for observing it, first in Hongkong, later in Bombay and Poona and still later as a member of the Federal Commission in San Francisco, continues its ravages in some countries, especially in India, unabated. It may surprise you, as it did me, to learn that the mortality from plague, in India alone, during the first six months of 1905 amounted to 878,602, the highest record for a half year thus far made in the epidemic. In the latter half of the year the disease was less prevalent, though the number of deaths even then was enormous.

Workers in Hongkong assert that they have shown that plague is in most instances set up by infection in the alimentary canal, an opinion in which pathologists will I believe be slow to concur. The opinion of Cantlie (1897), so often spoken of nowadays, that the black rats (*Mus rattus*) and brown rats (*Mus decumanus*) play a different part in the spread of the disease, needs farther confirmation before it is accepted.

In countries where plague is rampant, preventive inoculation is gaining ground. Haffkine's method is followed as a rule; it is desirable that the new autolytic prophylactic worked out by R. P. Strong be tried on a large scale, since theoretically it should be very serviceable.

Dengue.—The most important new observation on the disease is that of Sutton and Carpenter in the Isthmus of Panama, which shows it to be one of the diseases in which the white corpuscles are diminished in number and there is a relative preponderance of the small mononuclear variety.

Yellow Fever.—The fundamental experiments of Reed, Lazear, Carroll, and Agramonte, which demonstrated the rôle of a particular form of mosquito, *Stegomyia fasciata,* in the transmission of yellow fever, a conception first formed by Finlay of Havana, has been manifoldly confirmed by other observers, in Cuba, in Mexico and in South America. The brilliant application of the discovery to yellow fever prophyiaxis in Havana by Gorgas is well known to all. After last year's experience with yellow fever in New Orleans, everyone is wondering as to what will happen there this year. The death rate in the epidemic in New Orleans and adjacent places last autumn was exceptionally low; of 3,400 attacked only some 451 died (13.20 per cent). In Pensacola there were 80 deaths in some 560 cases (14.28 per cent). It is rather strange, as a recent commentator points out, to see Havana turning the tables on New Orleans and establishing a rigid quarantine against that city! It is asserted that the few cases which occurred in Havana last year were all imported.

Malta Fever, Mediterranean Fever, or Undulant Fever.—An occasional soldier or sailor returns to the United States suffering from this disease (Curry, Craig), and it is known to occur in Porto Rico (Musser and Sailer), and in the Philippines (Strong and Musgrave). This disease, which in some respects resembles typhoid fever, is separable from it clinically by its more protracted course, the more marked remissions in the fever, the sweating, the frequency of joint pains and neuralgias and the orchitis and epididymitis which frequently complicate it. The disease is due to infection with the *Micrococcus melitensis* (Bruce, Hughes). It is not contagious. The diagnosis is easily made by means of the serum reaction introduced by Wright.

Some very important work has been done during 1905 by the so-called Mediterranean Fever Commission, consisting of Colonel Bruce, Major Horrocks, and Drs. Shaw, Zammit and Johnstone. It is regarded by some as the best piece of work of the year in tropical medicine. This commission studied the duration of life of the causative micrococcus outside the body, and made investigations concerning its occurrence in the blood, urine, feces and sweat of patients suffering from the disease; they also studied the disease experimentally in monkeys. It appears that the milk supply in Malta is derived chiefly from goats, and in June of last year Zammit made the important discovery that the Maltese goats are infected with *M. melitensis*; the coccus was isolated from the milk and from the urine of these animals.

Malaria.—This disease, of paramount interest to physicians in Maryland, is still being assiduously studied and its ravages are being curtailed. The diagnosis has been rendered more rapid and certain by the introduction of the dehemoglobinized-thick-blood-film method

and of the Jenner and Hastings stains. The studies of Craig on latent or masked malarial infections, from which 25 per cent. of the soldiers returning from the Philippines suffered, should teach us a salutary lesson.

The distribution of the mosquito which transmits malaria is becoming better known. Hirshberg and Dohme's studies here in Baltimore were supplemented last year by Coffin's careful search. The various methods for the prevention of malaria—the prophylactic administration of quinin, the use of mosquito netting, the destruction of the breeding places of the mosquito—are being tried, one method being favored in one place, another in another. That the annihilation of the mosquito is not an impossible, nor even an impracticable task is the conviction gained by many who listened to the interesting address recently delivered here by Dr. Smith of Connecticut. In Italy the destruction of breeding places has thus far seemed too formidable a task, but in the Malay States (at Klang and Port Swettenham) Watson has applied the method successfully. Celli's report of the great anti-malarial campaign in Italy makes most interesting reading. There is no longer any doubt that malaria is a preventable disease; the only question is, when shall we prevent it?

Beriberi.—This disease, the *Kakke* of Japan, continues to interest and to puzzle medical scientists. The etiology is still obscure. Dr. Hamilton Wright[13] believes that it is an acute or subacute infectious disease, due to a specific but as yet undiscovered micro-organism. He thinks that the germs may be taken in with food of various kinds, and his theory is that the micro-organism, whatever it is, multiplies chiefly in the pyloric end of the stomach and duodenum, and that it produces a toxin which is immediately absorbed and affects first the terminals of the vagi in the stomach and heart, and later on other nerves. Wright thinks the disease is spread by the feces, and regards this view as of great importance for prophylaxis. His practical results at the jail in Knale Lumper appear to lend some support to his view.

The recent Japanese announcement of the discovery of a specific bacterium in Kakke does not seem to be well founded, as may be read between the lines of the conservative report of Herzog, who went from Manila to Japan to investigate the matter.

Tick Fever.—The tick fever of Africa, first observed by Livingstone, was definitely proved in 1904 to be due to the bite of a tick, the *Ornithodorus moubata* of Murray. The disease has been carefully studied recently by Todd, of McGill, and the late Dr. Dutton, as well as by Ross and Milne in the Congo Free State. Koch thinks that the disease is identical, clinically, with relapsing fever, and that it is due to a spirochete which is probably the *Spirochæte obermeieri.*[14] It has been shown that the tick can transmit it, and it seems likely that the transmission is not merely mechanical, but that there is a special phase of development in the tick. Koch has studied the disease in East Africa.[15] He states that the tick lives in the floors of native huts and sucks blood at night. The spirochete does not multiply in the tick's stomach; it leaves the alimentary tract of the tick in a few days, and is later found in the ovary, multiplying in the eggs. Koch advises travelers to pitch their tents on ground not previously used for camps.

Uncinariasis.—Since Ashford's discovery of the prevalence of hook-worm disease in Porto Rico in 1900 and the stimulus exerted by Stiles' excellent monograph, the physicians in the Southern States, especially in North Carolina, Georgia and Alabama, have reported a large number of cases of the disease. We meet with it not infrequently in the wards of the Johns Hopkins Hospital. The theory that the parasite enters through the skin has received much support just lately from the experimental work of Looss.[16]

Sleeping Sickness.—One of the most interesting advances of the time is the clearing up of the causation of that remarkable disease known as the sleeping sickness of West Africa, or negro lethargy. In November, 1902, Castellani, while examining the cerebrospinal fluid obtained by lumbar puncture from a case of sleeping sickness, found a trypanosome in the microscopic field. He seems to have attached no especial significance to the observation, but on mentioning his finding to Lieutenant-Colonel Bruce some time later, the latter initiated and carried out an investigation which demonstrates that sleeping sickness is due to a trypanosomal infection of the nervous system. In 1903 it was shown that in at least 70 per cent. of the cases of sleeping sickness the trypanosoma can be found in the cerebrospinal fluid. It had been supposed earlier that a special fly—the so-called Uganda tsetse-fly, *Glossina palpalis*—might transmit the disease, and Bruce found (1) that its distribution corresponds to that of sleeping sickness, and (2) that it can and does carry the parasite.

In 1901, at Bathurst, Gambia, Forde found a trypanosome in a case of anomalous fever, an observation confirmed later in the year by Dutton. This human trypanosoma fever is due to an especial trypanosome, called by Dutton the *Trypanosoma gambiense.* In 1903 Manson and Mott, studying a case of trypanosoma fever in a European lady, were surprised to find the symptoms of sleeping sickness developing in their patient. The idea occurred to them that "trypanosoma fever" is merely the first stage of sleeping sickness, and this idea has been shown by Laveran and other workers to be correct. The Royal Society appointed a sleeping sickness commission, which has recently reported. Its members find that sleeping sickness begins as a specific polyadenitis caused by the *Trypanosoma gambiense.* Besides the enlargement of the glands, there is an increase in the small mononuclear white corpuscles in the blood. The sleeping symptoms develop in a late stage, and the disease is then invariably fatal. Cases in the stage of polyadenitis, before the lymph spaces of the nervous system are invaded, may recover, especially if arsenical preparations be given. The bacteria occasionally found in the blood and tissues at autopsy have no relation to the disease proper, but are secondary invaders. While the Uganda tsetse-fly (*Glossina palpalis*) is capable of transmitting the disease, other biting flies, such as *Stomoxys*, can not do so.

In this connection the work of Novy of Ann Arbor and his associates assumes the greatest importance. These American parasitologists have succeeded in grow-

14. Since the above was written Dr. F. G. Novy, Ann Arbor, has reported at the Association of American Physicians in Washington, his studies on the spirochete of tick fever. His investigations appear to demonstrate conclusively that this spirochete is not identical with that of ordinary relapsing fever, but is a distinct species. There may be, therefore, several varieties of relapsing fever, each with a special causative spiral organism. Novy names the micro-organism of African tick fever the *Spirochæte du Boni.*

ing trypanosomata on artificial media in the laboratory, and their work is helping to differentiate clearly the various forms of trypanosomiasis. Africa has no less than six different trypanosomal diseases, all of them very important, including nagana, dourine, galziekte, zonsfana, Gambian horse disease and human trypanosomiasis.

The recent memoirs of the Liverpool School of Tropical Medicine contain important papers on trypanosomiasis and sleeping sickness, especially on the method of diagnosis by aspiration of enlarged lymph glands.

AMERICA'S OPPORTUNITIES AND OBLIGATIONS.

That America is alive to the importance of research in tropical medicine the records of the last few years clearly show. But that in the immediate future she must do more than she has yet done is also clear. Strong appeals for work in tropical medicine are being made by medical men in various parts of this country, especially by those who live near the Gulf of Mexico.[17] Nothing is truer than the statement of one of them that "opportunity and obligation are indissolubly bound together," and he urges appropriations by the state both for instruction and research. The problems to be solved are large in their scope, the difficulties to be overcome are tremendous, but we may say with safety that they are not too great for American energy.

THE NEW HYGIENE.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON HYGIENE AND SANITARY SCIENCE, AT THE FIFTY-SEVENTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, BOSTON, JUNE 5-8, 1906.

DENSLOW LEWIS, M.D.
CHICAGO.

A real advancement of our civilization must imply additional knowledge and increased altruism. A progressive evolution should mean a new and more comprehensive understanding of the truth, a more thorough realization of responsibility and opportunity, a more earnest desire for achievement, a more rational endeavor to secure definite results, and, at the same time, a more consistent appreciation of the value of exact justice. Man changes by virtue of development and environment, but the primitive impulses are subject to but slight modifications in the course of ages, and the animal part of his nature remains essentially what it has always been. This fact is not necessarily deplorable. No victory is possible without an adversary, no success is worthy without struggle.

BIRTH OF THE NEW HYGIENE.

Notwithstanding all philosophic inquiry, the great scheme of life still remains unknown and perhaps unknowable, but the accumulation of knowledge and experience makes possible a readjustment of preconceived ideas, so that we understand, perhaps now better than ever before, the relative value of events which pertain to individual life and to the community at large. We are learning the truth; our estimate is becoming more exact of the real worth of character, of honesty, of wealth, of labor, of peace of mind, of freedom from care, of safety from danger, of relief from pain and of immunity from disease. We are also learning many new things, and in the light of recent developments in science and in experience our understanding of many well-known facts is acquiring a new significance which necessitates changes both of appreciation and of administration. Thus the new hygiene comes into being.

INTERDEPENDENCE OF ALL MEN.

In the science of hygiene the advance, both actual and potential, is most practical and effective. Sanitary science was called into existence when nomadic tribes coalesced and when primitive law determined that individual liberty does not permit the injury of another even inadvertently. This principle is the essence of the science. Sovereigns have sought to suppress it, capitalists have disregarded it. The poor, in their ignorance, have suffered as all must suffer who transgress the immutable law of Nature, and the rich, only too often, have fallen victims to the pestilence which originated in the slums and which a timely consideration might have prevented. Thus is demonstrated the interdependence of all men, and from a knowledge of the relations we bear, even unconsciously and in some instances unwillingly, one to the other, is evolved a true humanitarianism and a real religion.

THE NEED OF THE TRUTH.

The new hygiene is an exponent of the necessities of modern civilization in all details that relate to the health and happiness of the human race. To be effective it must be practical and to secure definite results it must, above all things, teach the truth. Here is the first matter of importance, the first essential of success, the chief object of all earnest endeavor. We must know the truth which shall make us free, and we must teach what we know. Just here, too, is encountered the first obstacle to an advance that has for its aim the amelioration of the human race, and in many instances in the past this obstacle has proved insuperable.

THE EXERCISE OF TOLERATION.

History shows that in the beginning of government might was right, in the beginning of religion the progress from phallic worship was gradual, and invariably the domination of ruler and priest was selfish, and often oppressive and tyrannical. It has taken centuries for the development of the idea of equity. It is only of late years that we begin to understand the meaning of human brotherhood and to appreciate in its full significance the necessity of liberty, the inadequacy of repression and the inestimable value of true education as a real measure of prophylaxis and as a practical means of right living. The tendency of the times is liberalizing. Our religion is not the only religion, nor does it embody all the truth. Our government is not perfect, nor are all other governments faulty. Indeed, it has been well said, and the present position of Mexico would seem to verify the statement, that a beneficent despotism is at times an admirable form of government. A great step in advance is taken when we are able to see beyond the confines of our individual methods of worship and government and are willing to acknowledge good in the methods of others. It needs no sect to prove the beauty of integrity, sobriety and decency of life. A true morality is the basis of every true religion; dogmas, creeds and ceremonials are but paths leading to a common goal. The welfare of the people should be the chief object of every government; the methods in use are but expressions of the average intelligence of the community applied to existing conditions. Our boast is that our form of government is truly representative. Alarming in the

17. Moore, J. T.: Tropical Diseases; Their Importance and the Opportunity for Their Study in Texas Imposes the Obligation to Provide the Facilities for Training Medical Men in Their Prevention, Diagnosis and Treatment. Texas Med. News, Austin, 1902-3, xii, pp. 437-444.

extreme are statements made by prominent statesmen that the accumulation of wealth and power in the hands of a few is a menace to our system of government, because it tends to permit the exercise of a despotism which subserves selfish ends and militates against the well-being of the great mass of our population. The new hygiene, taking cognizance of this important factor in our present-day civilization, as indeed it is bound to do in the case of all conditions that affect the welfare of humanity, gives evidence from its point of view and is prepared to show that the accumulation of great wealth is too often effected at the sacrifice of health, that the possession of millions is an incentive to dissipation, that morality, decency and probity apparently are cast aside when financial independence is assured, that disease and disgrace are not infrequently the sequelæ of affluence.

FUNCTION AND DUTY OF THE NEW HYGIENE.

What is to-day the function and the duty of the new hygiene? It should study the past to appreciate the necessities of the present and the possibilities of the future. To be most truly effective it will consider man in his entirety as he is, and not as preconceived notions would imagine him to be. It must be broad in its philanthropy, liberal in its charity, comprehensive in its effort. It must be an active, sensitizing force in the community. It must be more than a name or an abstract proposition. It must become a part—a most important part—of every life, for it has to do with the health and happiness of humanity, without which no life is satisfactory. The practitioners of medicine are the exponents of this philanthropy, the priests of this religion of health. To direct the destiny of mankind is their sacred privilege and their high office. Their influence more than that of any other element in our society must determine the future of the race. The greed of avariee must be restrained. The outbreaks of lawlessness must be condemned. The conditions of every community must receive thoughtful and serious consideration to the end that the beneficent influence of the new hygiene may prevail for the good of all humanity.

PHYSICIANS AND HYGIENE.

The profession is now organized. All petty differences are forgotten. The reunion is complete. Medical men can not be classed together as a unit to be extolled, maligned or condemned. They are human like other men, and there are among them examples of all types of the genus homo. They are subject to the same temptations and influences as other men, and they furnish their share—which is, I believe, a relatively small share—of the perverts and criminals of our society. Nevertheless, the great mass of the profession is honest and active in philanthropic endeavor. They must live, and usually the exercise of their professional talents must furnish the means of livelihood. But the spirit of modern commercialism has ensnared a comparatively insignificant contingent. The great majority remain members of a profession which is not primarily a business. They remain true to their principles and their ideals. They are servants of the people, striving to aid the ill and the injured, trying to protect the ignorant and innocent if need be even against themselves. Others receive their reward in the accumulation of property, the glory of renown, the acclaim of the public. The true physician has the approval of his conscience, the satisfaction of duty performed, the opportunity to do good. Who shall say that his recompense is inadequate?

SCOPE OF THE PROGRAM.

The program of this meeting of the Section on Hygiene and Sanitary Science shows to what an extent the profession of to-day realizes its opportunity to contribute its share toward the solution of the live topics of the times. Gathered together here from all parts of this great country are representative men and women, whose lives have been devoted to the cause of philanthropy. Some are active and energetic with the impulse of youth to excite to continued effort; others have passed the heat of the day, have borne the burden of the past, have known the indignity of misrepresentation, and have been privileged to suffer in the interests of humanity for the good of the cause. From Berlin, the great medical center of the world, come two distinguished and honored guests whose fame is international and whose teachings have done much to advance American gynecology and dermatology. From France and from New South Wales come highly valued contributions. From universities, from kindred professions, from the ranks of true philanthropy, and from the army and navy have come others, actuated by a common purpose—the desire to benefit mankind. Now shall we forget at this time the many men and women who in the past struggled and sometimes died for what they believed to be the truth. They did what they could, but in many instances even their names are now forgotten. Nevertheless their work has been effective, their influence remains. Their unselfish devotion to duty, their steadfastness in the faith, their demonstrated love for humanity will for centuries to come inspire the earnest worker along the lines of philanthropic endeavor to ever increased effort. Their work is done, but they did not live and die in vain.

WORK OF THE UNITED STATES.

In the great cause of humanity the United States has assumed a new responsibility and most cheerfully has taken up a share of the white man's burden. Our duty to the Filipinos is finding expression in determined educational effort, and in the exploitation of a new hygiene which will result in increased health and happiness for those in our charge. Our commercial interests with the far East become more intimate. It is our duty to see to it that the residents of the Pacific coast be not subjected to increased danger from bubonic plague in consequence of an increase in our business relations with the Orient. This subject is to-day presented for your thoughtful consideration.

PREVENTIVE MEDICINE.

The great white plague—tuberculosis—will also be considered at our meeting. The past few years have witnessed a wonderful effort along the lines of prevention and the results have been extremely satisfactory. If any one factor has exerted the greatest effect I believe it can truthfully be said that publicity regarding etiology, transmission of disease and rational hygiene is chiefly responsible for the enthusiastic desire of the public to know the truth and for the universal co-operation in prophylaxis which has prevailed and which has produced such wonderfully beneficent results.

PUBLICITY REGARDING THE VENEREAL PLAGUE.

There is another plague, which has been called the great black plague. It is the venereal plague. In some respects this is the most serious of all, for it produces among adults the greatest morbidity and as a disturbing element in our society it takes front rank. Originating, as it does usually but not always, from extramarital sexual congress, its consideration in the past has been

tabooed because a false modesty has prevented an exposition of the truth. With the success that has attended publicity regarding tuberculosis the past few years there has arisen in this country among eminent venereal specialists and true philanthropists the conviction that maudlin sentimentality no longer can prevent a consistent study of all etiologic factors and a dissemination among the public of the knowledge we already possess. In an earnest endeavor to produce definite results—that is, to limit venereal infection—facts must be recognized and the truth must be told. If this is done we must, first of all, admit the dominating influence of the sexual instinct which determines the perpetuation of the race. Why should we not admit this fact? This is the twentieth century, and education is said to be the palladium of our liberty. From the ignorant immigrant there is evolved in the second generation a real American. In appearance, in thought, in subjection to the law, in respect for our institutions, in love for our country, the child of the anarchist becomes one of us. If such a transformation as this can take place, how wonderful, then, are the possibilities if a true education will teach the dangers that confront the young and the ignorant, if the physiology of the whole body may be taught, if the study of man be made of chief importance in every curriculum.

THE CRIMES AGAINST WOMANKIND.

Intertwined with venereal disease and a result of perverted, premature or misdirected extramarital congress are the many crimes against womankind. The subject in its entirety is the most important that can engage the attention of the humanitarian. Here, also, we now believe, the policy of silence is responsible for the desolation of many a home and the ruin of many a girl. Ignorance, an etiologic factor in criminal abortion, illegitimacy and infanticide, must no longer be permitted to expose the innocent girl to unknown danger, but the new hygiene must intervene to protect her against the passion of the man and, if need be, even against herself.

I favor, as I have done for years, the teaching of the truth regarding ovulation, menstruation and conception. These subjects are among the most important matters the girl can know. I believe in teaching the boy regarding the sexual instinct, the possibility of continence, the dignity of virility, and his duty as a man, worthy of the name, toward woman. I believe in the advocacy of decency and the inculcation of principles of honor. This can not be done by keeping silent. It is only possible by speaking out plainly, by telling the truth.

INFLUENCE OF ALCOHOL.

In connection with the venereal plague and the crimes against womankind, affecting humanity in many important details, is the use of alcohol. It is necessary to know in no spirit of fanaticism, but scientifically and truthfully, to what extent the indulgence in alcohol is a disturber of our social conditions and an etiologic factor in disease. Moreover, we must know how and to what extent the young should be taught regarding the influence of alcohol on the health and happiness of our citizens. Extravagant statements will be received with mistrust. Prohibitory assertions will not often be heeded. Even the child knows that men who use alcohol may live to enjoy old age and may remain honorable citizens. The truth must be disclosed in a spirit of fairness.

To the solution of these momentous problems of our present civilization the new hygiene consecrates itself in all earnestness. We shall not to-day give the final answer nor say the last word. We will, however, do something. We will say what we think. We will express our ideas, but we will not deny others the right to differ with us. In a spirit of charity and toleration the new hygiene, through the kindly co-operation of distinguished and honest workers, whose experience entitles them to speak with authority, now offers, in the interest of humanity, a consideration of these most important topics.

92 State Street.

TUBERCULOSIS A SOCIAL DISEASE.*

S. A. KNOPF, M.D.

Associate Director of the Clinic for Pulmonary Diseases of the Health Department of New York City; Visiting Physician to the Riverside Sanatorium of the City of New York; Consulting Physician to the Sanatoria at Gabriels, N. Y., Scranton, Pa., and Binghampton, N. Y.

NEW YORK.

Were our great Osler in my place, he would probably in his own inimitable way, treat the subject as if it were a clinical case. He would begin with the etiology, then describe the symptoms, then the prevention and the curative measures, and lastly, the prognosis, the outlook. I will endeavor to carry out this idea as well as I can in my present address, also beginning at the bottom of the social ladder with the children.

Tuberculosis in infancy is indirectly due, on the one hand, to either a hereditary or an acquired predisposition, and directly, on the other hand, to a postnatal infection. Direct hereditary transmission of the tuberculous germ from parent to child is of exceedingly rare occurrence. When the father or mother is tuberculous the child may inherit a predisposition, which I like to describe as a physiologic poverty, giving the child less resisting power to the invasion of tuberculous diseases. The same condition may be produced when the child, instead of being raised at the breast of a healthy mother or wetnurse, is fed from a bottle. Such a child, unless the greatest care is bestowed on the artificial feeding, will almost invariably remain below par in health. The earliest postnatal infection takes place if a tuberculous mother or tuberculous wetnurse is allowed to give the breast to the child, or if she carelessly coughs over the child, kisses it on the mouth, or if, when feeding it, she puts the nipple of the milk bottle or the spoon alternately into her mouth and then into the baby's, in order to test temperature or sweetness. Furthermore, we must not forget the very probable source of infection through milk from tuberculous cows used as food for the infant.

Lastly, there is another source of infant infection, threatening particularly infant foundlings or deserted little ones, who have, at first, been inmates of foundling asylums or infant hospitals, and because of their not having done very well, have been given to the care of families residing in the country. In institution life there is, of course, always some danger of infection from a tuberculous infant to a healthy one; secondly, from tuberculous milk supply; and, thirdly, though more rarely, from tuberculous attendants. To my mind, the danger to the little ones given out to families living in the country is far greater than in an institution. Do you know that the majority of families, who make boarding babies a business, confide them to the care of

* Address delivered by invitation before the Laennec Society for the Study of Tuberculosis of Johns Hopkins Hospital, Baltimore, Nov. 23, 1905. Revised for publication in THE JOURNAL A. M. A., May 1, 1906.

the invalid of the family, who, perhaps, nine times out of ten, is a consumptive? The danger which arises to these little ones from such a consumptive attendant is obvious, particularly when we consider the usually inferior hygiene in such homes and the ignorance of the inmates of the nature and prevention of tuberculosis.

Before going any further, let us see what we may be able to suggest in order to combat these various sources of tuberculous predisposition and actual infection. The prophylaxis regarding the transmission of a predisposition to tuberculosis lies, of course, in preventing tuberculous individuals from marrying and procreating a predisposed race. It is not always easy to prevent the marriage of tuberculous individuals, for some marry without knowing that they are tuberculous, and some, who even know they are so, marry anyhow, no matter what the physician says, and there is no law to prevent them from doing so. In such instances, unfortunate as they are, the physician has a divine mission to perform in preserving the life of the tuberculous mother, which is always endangered by pregnancy, and preventing the transmission of a tuberculous diathesis to an innocent child. His mission is thus teaching prevention. I feel very strongly on this subject, but I know that there are many worthy men and women, inside and outside of the medical profession who differ with me. However this may be, I am willing to take the responsibility before the law and my God for each time I have taught a consumptive husband and wife not to procreate a tuberculous race.

Certain authors have made the statement that tuberculous parents confer on their children an immunity against the contraction of the disease. In twenty years of labor, exclusively devoted to tuberculous patients, I have not found the slightest evidence for this deduction; on the contrary, I have found children of tuberculous parents owing to their inherited physiologic poverty, anything but immune.

What can we do to have more breastfed and vigorous babies and thus a more vigorous race, a healthier type of American men and women, strong enough to resist a tuberculous invasion, or, for that matter, any other infectious disease, to which a weakened organism easily falls prey? For, after all, with all due respect to our beloved President, let me say that as a physician with, I may modestly claim, a somewhat large experience among the poor and poorest of the poor, the middle classes and also among the well-to-do, and as a student of sociology, as well as of preventive medicine, I am not for quantity but for quality.

I know I am in the presence of earnest students, who by careful study of the social, as well as the medical aspect of tuberculosis, are anxious to better the condition of their fellowmen. For this reason I speak plainly and am willing to give you the result of some interesting observations from my own practice which, I think, justify me in taking this position. It is invariably my custom when examining a patient to take down the family history, and one of the questions asked is, "how many children were in your family and were you born the first, second, or third, etc.?" In the majority of cases, when there is a large family, it is the 5th, 6th, 7th, 8th or 9th born who has contracted tuberculosis. This is to be explained, on the one hand, by physiologic reasons, the parents being in advanced life and less vigorous; on the other, by economic reasons, the later born children can not, because of increased expense, receive that particular care and that good and ample nourishment which was the privilege of the first ones to receive when the family was still small. No amount of wealth, no family prestige or social connection can give the child that inheritance which it receives when born of vigorous parents, nursed by its own mother and tenderly cared for until able to care for itself.

Let the mothers who, for the sake of pleasure and convenience, abandon the divine privilege of nursing their own children, change this unnatural practice. I feel certain that if they but knew the difference in the physical and intellectual makeup of their sons and daughters, if tenderly nursed by themselves, or when handed over to strangers to become bottle-fed babies, they surely would do differently. I know it will be said that not every mother can nurse her infant. This is true in some instances; but to the women, the future mothers of mothers, I like to say that it has been statistically demonstrated that if one generation of mothers fails to give their infants, and particularly female infants, food from the source which nature has designed, the next generation of mothers will have great difficulty in the natural feeding of their infants. The reverse has also been demonstrated and it has even been shown that when mothers, not fully able to supply the infant with food, have supplemented the artificial feeding as best they could with their own breast, their daughters have been able to fulfill the divine duty of nursing their infants, if not always entirely, at least to a much larger degree than the preceding generation.

Let us draw a lesson from this scientific fact which is corroborated by Nature's own laws. This lesson, once learned, the coming generation of American men and women may yet surpass all other nations in physical beauty, intellectual attainments, and moral strength.

Against postnatal infection, arising as aforesaid, from a careless mother, father or attendant, there is but one remedy, and that is education. Education of the prospective mother, education in all that appertains to the prevention of tuberculosis and other infections and preventable diseases, in schools, high schools, colleges, etc. Against the contraction of tuberculosis from infected milk our sanitary authorities should protect us. Regular tuberculin tests of all milch cows, inspection of stables, milk transportation and milk depots, should be practiced in all well-regulated communities. But we, ourselves, can protect our babies from infected milk by boiling or sterilizing the milk whenever we are not certain of its absolute purity. In this connection I can not help paying a tribute to Mr. Nathan Straus, of New York, who has done such grand and life-saving work by presenting to several communities large plants for sterilizing milk, to be distributed to the poor at cost.

In institutions for infants, isolation of tuberculous children should be practiced as far as possible. No tuberculous individual should be employed in a hospital to take care of infants, and no child should be given into the care of a family unless the hospital authorities are absolutely certain that the infant will not be attended by a consumptive.

We come now to tuberculosis in childhood, which may likewise be contracted from either tuberculous parents, tuberculous relatives, friends or boarders. A tuberculous individual living in such a home, particularly if it is small and unhygienic, need only be careless with his expectoration, and the little child, crawling on the floor, is sure to come in contact with it, touching everything with its fingers, which are often put into its mouth afterwards, or scratching its delicate skin with the infected nails. If the tuberculous sputum has had a chance to dry and become pulverized, the bacilli-laden

atmosphere, always heavier in the lower strata of the air, is sure to be inhaled by the little one. You have thus a source of infection which may cause a tuberculosis from ingestion, from inhalation, and from inoculation; in other words, the child has a chance of having its intestines, its lungs and its skin tuberculously infected at the same time.

The remedy for this lies again in education—education of the tuberculous and education of those living with them.

There is one more source of infection arising in children of which I must speak and which is often overlooked by our hygienists and social workers. I refer to the life of little ones in day nurseries. These institutions should be most carefully watched and supervised, in fact, I firmly believe that not only tuberculosis, but diphtheria, measles, and other children's diseases would be greatly diminished if our sanitary authorities would insist on a daily medical inspection of the children in these nurseries. The isolation and particular watching of tuberculous children could then be easily accomplished.

Before taking up the third phase, "tuberculosis during the school age," I would like to say one word more in regard to the management of the predisposed child, when it no longer receives the healthy mother's or foster mother's breast. In the eyes of the utilitarian or materialist, or, perhaps, also in the eyes of a certain class of sociologists, the question, how to raise a child predisposed to tuberculosis, might seem a paradox. In defense of our views in this respect, let me repeat, that while in my humble opinion it belongs to the highest mission of the physician to prevent the procreation of a tuberculous race, when in spite of his warnings and teachings, a child is born of tuberculous parents, it is his most sacred duty to do all in his power to save the child's life and, if at all possible, make it strong, healthy and vigorous; and we physicians should use the clinical experience of the best authorities to guide us in this respect.

Predisposed children are almost all born bad eaters. They will have a disinclination to many kinds of food and be often unwilling to eat when they should. Only by beginning at the earliest possible period, with a firm discipline, can these children be made to eat as other healthy children would. The old practice of folding our hands, resigning ourselves to fate, and saying that because the father or mother had tuberculosis the child must also be doomed, with our present knowledge of phthisiology, is thoroughly reprehensible. Sensible parents, even if tuberculous, can often be very helpful in combating a hereditary predisposition in their children, if able to give them proper physical and intellectual care and training, combined with good food, much outdoor life and sensible dress.

In the homes of the poor such an ideal training of the child is not always easy. French phthisiotherapeutists and philanthropists have realized the importance of caring for the offspring of tuberculous parents who would have to live in a *milieu tuberculeaux*, and have a special organization, called "Oeuvre de Prevention de l'Enfance contre la Tuberculose." This work was started by my esteemed master and teacher, the great children's physician, Professor Grancher, of Paris, in November, 1903, by a large personal gift from Mrs. Grancher and himself. It consists, in the main, in removing the children of poor tuberculous parents from the center of infection, either to good, sanitary private homes in the country or to seaside or inland sanatoria. There is no time limit; the children may stay away until, in the opinion of the supervising physician, they are strong enough to resist a tuberculous invasion. The removal of these children is, of course, always done with the consent of the parents. The first complete report of the work of this society was given out at the recent Tuberculosis Congress at Paris, and showed most gratifying results.

What are the predisposing causes of tuberculosis during the school age? Badly ventilated school rooms, overtaxing of the child's brain to the detriment of its physical development, unhygienic dress, particularly of school girls and in the poor, underfeeding, insufficient clothing and bad housing, often combined with child labor in workshop, factory and even at home.

What are the direct causes of tuberculous infection during school life? Close association with tuberculous fellow pupils; very much more rarely the carelessness of a tuberculous teacher.

To describe the various sources of infection during school life I believe I can not do better than to repeat here the little list of rules[1] which I like to see school teachers give to their pupils, and which might serve as an alphabet in the prevention of tuberculosis.

1. Every child and adult can be helpful in fighting consumption. School children can help by complying with the following rules:

2. Do not spit except in a spittoon or a piece of cloth or a handkerchief used for that purpose alone. On your return home have the cloth burned by your mother or the handkerchief put in water until ready for the wash.

3. Never spit on a slate, floor, sidewalk or playground.

4. Do not put your fingers in your mouth.

5. Do not pick your nose or wipe it on your hand or sleeve.

6. Do not wet your finger in your mouth when turning the leaves of books.

7. Do not put pencils in your mouth or wet them with your lips.

8. Do not hold money in your mouth.

9. Do not put pins in your mouth.

10. Do not put anything in your mouth except food and drink.

11. Do not swap apple cores, candy, chewing gum, half-eaten food, whistles, bean blowers or anything that is put in the mouth.

12. Peel or wash your fruit before eating it.

13. Never cough or sneeze in a person's face. Turn your face to one side or hold a handkerchief before your mouth.

14. Keep your face and hands and finger-nails clean; wash your hands with soap and water before each meal.

15. Do not kiss any one on the mouth or allow anybody to do so to you.

16. When you don't feel well, have cut yourself or have been hurt by others, do not be afraid to report to the teacher.

17. Be just as careful and cleanly about your person at home as in school.

18. Clean your teeth with toothbrush and water, if possible, after each meal, but at least on getting up in the morning and on going to bed at night.

19. Learn to love fresh air and learn to breathe deeply and do it often.

Another good method of teaching school children the prevention of tuberculosis has been inaugurated in France, in a most ingenious way. My distinguished teacher, Professor Letulle, suggested to the minister of education of France that the coverings of the books used by school children might serve as a means of instructing the pupils concerning the prevention of tuberculosis. He, himself, wrote two pages of instructions for the pur-

1. My inspiration to compile this set of rules I received from a little leaflet which I came across during my visit at Providence. I have since learned that they were written by Prof. Theobald Smith of Harvard, who wrote them at the suggestion of Dr. Chapin of Providence, R. I., and I am anxious to give these gentlemen credit for their work. I have ventured to make some additions and some changes in order to cover the entire ground of first principles in the prevention of tuberculosis.

pose. The outside cover represents the exterior of a sanatorium, and the text is illustrated by a number of pictures. Permit me to give you here the translation of the subjects which are treated in a most concise and comprehensible way on these two pages:

"The air we breathe and the respiratory organs."
"Tuberculosis decimates humanity."
"Tuberculosis is contagious."
"Tuberculosis and its microbe."
"Robert Koch, the discoverer of the microbe of tuberculosis (consumption)."
"Tuberculous infection from man to animal and from animal to man."
"Tuberculosis can be prevented."
"Sure way to prevent consumption."
"Never use strong drinks."
"Tuberculosis can be cured."
"Tuberculosis is a social disease."

To remove all possible causes which might render a child susceptible to the invasion of tuberculosis during school life, we must appeal to school boards, superintendents, teachers, and school physicians to do all in their power. Permit me to quote here what I said on this subject in an address delivered last year before the American Academy of Medicine. The school board, or board of education, as it is called in some localities, should, in choosing a sight for a school, bear in mind that, whenever possible, a somewhat elevated region, where the streets are wide and the surrounding houses not too high and not too close together, and where the traffic is not too heavy, should be selected in building a public school. About the construction of a modern and model school house much could be said. The essentials of such construction are well known to all sanitarians and up-to-date architects. In relation to the prevention of tuberculosis, I would suggest only a few points. Where the site or locality does not permit of having a large playground, a roof garden, which can be covered in winter, is absolutely necessary. Instead of our American windows, which can only be opened to one-half of their extent, I should wish to see French windows in every school house, or windows sliding in the wall, or those that turn on a pivot, all of which permit twice the amount of foul air to go out and of good air to come in, that our ordinary windows do. Heating and general ventilation of school rooms should, of course, be of the most improved kind. The walls and woodwork of school rooms should be plain, to make the accumulation of dust virtually impossible and the cleansing easy. All corners should be rounded off and the walls painted. The interior equipment—that is to say, the school furniture, benches and desks—should be so arranged that they can be easily moved or folded together, so that a thorough cleaning of the floors is made possible after each daily session. It goes without saying that the drinking cup should be replaced by the hygienic drinking fountain, which makes the use of a cup unnecessary, and thus eliminates one method of transmission of microbic diseases.

Every public school should have a well equipped gymnasium and a swimming tank with constantly running fresh and salt water, warmed to a suitable temperature in winter. Each pupil should be given the opportunity to bathe several times during the week. To learn to swim should be made obligatory and every class should be supervised by a competent swimming master. Leaving aside the great hygienic gain to be derived from such an installation, especially when the pupils are recruited from homes where bath rooms are rare and where regular bathing is considered superfluous, the swimming lessons would be of value to every boy and girl, and in case of such disaster as the recent Slocum tragedy there would be a much smaller loss of life. There is hardly a college in existence in America where the gymnasium and the swimming tank do not form an important part of the equipments, and a college without them would surely suffer in prestige. The public school, where the children of the masses receive their education, should not be behind the private college in its equipments.

I am convinced not only that the public school, which has a well-equipped swimming establishment and which makes regular bathing and instruction in swimming obligatory for every pupil, will have fewer cases of infectious and contagious diseases, particularly scrofula and tuberculosis, but that the intellectual and moral status of its pupils will also be higher.

The duties of the superintendent of a public school in the prevention of tuberculosis are manifold. In arranging the curriculm he should bear in mind never to push the intellectual training to the detriment of the bodily development or physical welfare of the children in his school. There has been, and is yet, altogether too much overtaxing of the brain and the nervous system of our boys and girls in public and also in private schools. Our gynecologists and nerve specialists have given us enough illustrations of the detrimental effects of the overtaxing and overstraining of the mind and the nervous system of young girls at the age of their development into womanhood. Many of our college pupils, male and female, do not get enough rest, they are overworked and underslept. Those of us who have given tuberculosis a somewhat closer study also know that it is often at the period of entering puberty that the predisposed individual becomes most susceptible to the invasion of the bacillus, particularly when additional strain is put on the physical or mental system. This holds good of both sexes. A judiciously divided curriculum, intercepted with gymnastics, swimming and as much outdoor instruction as possible, would seem to me a most important factor in the prevention, not only of tuberculosis, but of all indoor diseases and nervous troubles.

By outdoor instruction I mean not only botanizing tours and geological excursions, but also outdoor singing and outdoor recitation. In my textbook on tuberculosis[2] (as well as in my article on the subject in the Twentieth Century Practice of Medicine[3]), I quoted Barth, of Koslin, who had made a careful study of the effects of singing on the action of the lungs, on diseases of the heart, on the pulmonary circulation, on the blood, the vocal apparatus, the upper air passages, the ear, the general health, the development of the chest, and the activity of the digestive organs. As a result of his studies he came to the conclusion that singing should be considered one of the exercises most conducive to health. I am willing to go even further and say that outdoor singing and outdoor recitation, when the weather is neither too windy nor too cold, is a most excellent means of preventing the development of pulmonary diseases. You have all heard of the numerous cases of open-air speakers, such as political campaigners, evangelists, etc., having developed their respiratory capacities and strengthened their lungs as a result of their peculiar profession. Some even profess to have been cured of consumption as a result of

2. "Pulmonary Tuberculosis, Its Modern Prophylaxis and the Treatment in Special Institutions and at Home." P. Blakiston's Son & Co., Philadelphia.
3. Twentieth Century Practice of Medicine, Vol. xx, p. 230

their outdoor speaking. The German military authorities, who have the reputation of instituting all exercises which tend to prevent disease and invigorate the soldiers, have of late much encouraged singing during the marching of the troops.

To every class in the public school opportunity should be given in fairly good weather to have recitation and singing at least once a day in the playground, adjoining garden, or roof garden. Breathing exercises should, of course, be instituted for at least a few minutes at a time during recess for all classes. This should be done either in the open air or when the windows are wide open, and a number of times each day. The simple breathing exercises which I recommended as a prevention of pulmonary diseases, I have published and illustrated in my books, as well as in various articles, and also in my popular essay on tuberculosis,[4] and I do not feel that it will be necessary to describe them here again. The selection of rational textbooks on physiology and general hygiene must be left to the good judgment of the board of education and the superintendent.

The duties of the superintendent and those of the school teacher are, of course, interdependent. The former makes out and supervises the curriculum, the latter carries it out. The lessions in physiology and hygiene must be adapted to the age and understanding of the pupils. The school teacher should, of course, be familiar with all the practical and feasible methods in vogue in regard to the prevention of tuberculosis as an infectious and communicable disease.

Before closing the paragraph on the prevention of tuberculosis during school age, I must call your attention to the term scrofulosis, which really means tuberculosis in a milder form, and which is particularly frequent among school children in the districts of the poor and is the result of bad housing and particularly of underfeeding. To prevent scrofulosis—the milder form of tuberculosis—I must revert once more to the duties of the school board, for what can the teacher or superintendent do with the underfed children of the poor attending our public schools? Breathing exercises will not supplement their lack of food, but, if anything, they will increase the appetite of the pupil, and an apple and a cracker are not enough for a growing boy or girl and altogether too little to make their cheeks red. I would, therefore, suggest to the board of education a philanthropic enterprise in which the generous and goodhearted people of every city would most gladly join. It may thus become possible to provide these halfstarved little ones with a luncheon of a few meat sandwiches and one or two glasses of good milk, and I am convinced that fewer will develop tuberculosis and scrofulosis, and they will do better work at school and at home. To avoid a pauperizing tendency a few pennies may be charged for these lunches. If I have been well informed, I believe this practice is in vogue in Boston, Milwaukee and a few other cities. I do not know whether statistics have been kept regarding the results, but I know that in some European cities the persistent administration of a nutritious luncheon resulted in the physical and intellectual improvement of the children and a considerable gain in weight. You see thus that in school children, tuberculosis has a very decided social aspect.

One more word on the duties of the school physician, and, of course, every school should have one or several. These duties should consist in the constaut supervision of the sanitary condition of the school buildings; regular visits to the gymnasium and the swimming school, and, lastly, the most important function of all, the monthly weighing of the pupils and the periodic examination of the chests of all pupils, teachers and employés of the school. The weeding out of all such individuals as might constitute a source of infection, or those whose treatment becomes an imperative necessity, and the advice to be given to parents of a tuberculous child, will make the school physician a most important factor in the solution of the tuberculosis problem.

It goes without saying that the school physician, who must devote so much time to this duty in order to do it faithfully, should receive ample remuneration for his service.

I do not wish to have it understood that our public schools and kindergartens are the only institutions which need sanitary supervisions. Boarding schools, parochial schools, seminaries, etc., need often the watchful eye and frequent visits of a trained sanitarian just as much, if not more, in order to prevent the spread of tuberculosis and other infectious diseases.

Before leaving the subject of tuberculosis in schools it is but right that we should devote a few earnest words to the subject of "What to Do with the Tuberculous School Child and the Tuberculous School Teacher." Permit me to quote here from a recent address which I delivered before the teachers of the public schools of New York at the occasion of the American Tuberculosis Exhibition held under the auspices of our national and our New York anti-tuberculosis associations. A number of states have taken very radical measures in this respect. My interest in the subject was first aroused by a letter received last February from my friend, Dr. Herbert Maxon King, the physician-in-chief of the Loomis Sanatorium at Liberty. He sent me a clipping announcing the decision of the board of education of Jersey City that no teacher having consumption would hereafter be allowed to teach in a public school. In commenting on this decision, Dr. King said: "It occurs to me that if such action shall be taken on the part of the various boards of education throughout the country much injustice is going to be done." Since then the states of Iowa[5] and Illinois[6] have joined the list of those that exclude tuberculosis from the public schools, and these boards have issued an order notifying the superintendents of schools throughout the state to exclude all teachers, pupils and employés suffering from the malady. They exclude the teacher, and they exclude the child, and I approve of this decision, but I must ask, Have those states which exclude the tuberculous teacher, who nine times out of ten has contracted this disease in the performance of his or her duty, provided a pension for her, so that she can devote a year, perhaps more, to doing nothing but getting well? Or has she been able to accumulate enough means to live the rest of her life without care in case she is not entirely cured and readmitted in the school? I doubt if this will be the case in many instances.

A French commission was recently appointed to look into this matter and they recommended that all tuberculous school teachers employed in the Republic of France should receive for at least three years a sum sufficiently large to provide for proper sanatorium treatment at home, and this without losing the right to be pensioned later on.

4. "Tuberculosis as a Disease of the Masses and How to Combat It." M. Firestack, 139 East Seventeenth St., New York, Publisher.

5. According to the Med. Record, Nov. 25, 1905.

6. According to the Med. News, Dec. 30, 1905.

And what is done in our American schools for the children who are tuberculous? How many seaside or inland sanatoria for tuberculous children have we where the child can become cured of its infirmity and concomitant with its physical improvement receive its intellectual education? We in the great city of New York have just one seaside sanatorium for tuberculous children which fulfills this mission, but its capacity is limited to 54 beds, and we have in New York about six thousand tuberculous children needing sanatorium treatment.

I approve of weeding out tuberculous children and the tuberculous teacher from our public schools, but I also believe that it is our most sacred duty to provide for these tuberculous teachers and tuberculous children. Let us multiply our sanatoria for children and employ in them as many teachers as we can from the unfortunate ones who have contracted tuberculosis.

Now, what are we to do with the rest, who can not find employment in these institutions? One of our most beloved, large-hearted and generous philanthropists and distinguished fellow-townsman, Mr. Andrew Carnegie, recently created a fund to pension teachers in academic schools who are beyond a certain age and no longer able to earn their livelihood. Mr. Carnegie very justly surmised that our college professors are, as a rule, too poorly paid to accumulate a sufficient fortune to live in comfort during their reclining years. This is a grand and beautiful philanthropy, and I sincerely hope that the example of Mr. Carnegie may be emulated by other philanthropists; but I hope and pray that in the future gifts for pensioning educators our ordinary school teachers will not be forgotten. They must have served at least twenty years before they are entitled to any pension, and then it is but small.

Then they, too, have often very little chance to accumulate enough to enable them to live in comfort during old age; and I am certain that when misfortune strikes one in the prime of life, when the school teacher contracts tuberculosis and must leave the school, nine times out of ten she will have very little or no money saved. Yet it costs money to provide for at least a year in which to cure a tuberculous patient, and it requires even more to make him comfortable when he is not curable, but is forced to live in idleness for two years or more. Let the municipality which excludes the tuberculous teacher and the tuberculous child provide school sanatoria for the children and, whenever possible, employ therein the tuberculous teachers in the earlier stages of the disease. Let our good and generous fellow citizens who love to devote part of their wealth to the relief of the suffering and misery of their fellowmen remember in their benefaction the school teacher who has had the misfortune to contract consumption. Whether such a benefaction be in the shape of a special sanatorium for tuberculous school teachers or a special fund whereby these school teachers can be sent to existing sanatoria, or be treated at home, is immaterial.

What need have I, before an audience of this kind, to speak of the baneful influence of child labor? A few states of the Union have endeavored to do their best in enacting and enforcing laws against this shameful practice. But there is yet much to be done. Let all American legislatures understand that nothing predisposes a child's delicate and growing organism to tuberculosis more than the great physical strain produced by hours, and often long hours, of indoor labor, which time the child should spend in play outdoors. Child labor makes physical and nervous wrecks of normal children, and because of its influence on the nervous system of the growing boy and girl I hold child labor responsible for a good deal of alcoholism among our young people.

President Roosevelt, in his recent message at the opening of the last session of Congress, recommended in strong terms a model child labor law, in order that Congress might set a worthy example to the states in which it has no power to legislate on this subject, by wise and discriminating legislation for the District of Columbia, over which it has the necessary power.

Permit me to read to you a few suggestions from an appeal issued recently by the National Child Labor Committee,[7] which, I think, speak for themselves:

> We request the friends of the 29,000,000 children under 16 years of age in the United States, for whose industrial guardianship and for the protection of whose rights to healthy physical development, education and leisure the national committee is organized, to co-operate in recommending this bill to the favorable attention of their members in Congress. It will mean much for our cause in every state to have at the national capital a reasonably strong and fair law on the subject of child labor. Members and friends of local child-labor committees, of educational, charitable and philanthropic societies, of women's clubs and all other organizations interested in this movement are earnestly requested to write at once to their respective senators and members of Congress, sending them, if possible, the inclosed copy of the bill to be presented and urging the passage of this bill.

There is, of course, also a kind of child labor at home for which school superintendents, teachers or parents are alone responsible. When the child is given too many lessons to study at home so that it must rise very early or can only retire at a late hour, the result on its nervous and general system is the same as child labor performed in a factory or shop. Like the overworked college student above referred to, those children do not sleep enough. They are habitually in the want of sleep. Children up to the age of 16 should have nine hours' sleep in summer and nine to ten in winter. This certainly offers a field for reform in arranging the curricula of our public schools.

One of the saddest forms of child labor is the one imposed on the child of thoughtless parents who, in addition to the school lessons at home, expect their children to devote nearly all their time, which should be spent in play or recreation, to helping in the household.

I have seen so-called "little mothers" in our New York tenement homes who were veritable heroines and who sacrificed their little lives on the altar of devotion to their little brothers and sisters and in obedience to their thoughtless and often cruel parents. I have seen a widower leaving a 10-year-old daughter to take care of three smaller children, one a babe, and expecting her to do the cooking besides. Is it a wonder that such a child can not resist the invasion of the tubercle bacilli so prevalent in the crowded tenement districts of our large cities?

To treat the children of the poor when they are afflicted with tuberculous and scrofulous diseases, the seaside sanatorium, as has been said, is the ideal place, but inland sanatoria will also answer the purpose if the coast is at too great a distance. It goes without saying that a school should be attached to every sanatorium for children so that the intellectual training keeps pace with the physical improvement of the sanatorium inmate. The results obtained in these children's sanatoria are surprisingly good; they vary from 50 to 75 per cent. of cures.

7. This appeal was accompanied by a copy of a most excellent bill proposed to regulate the employment of child labor in the District of Columbia.

The great social and economic advantage resulting to a community which takes care of the tuberculous and scrofulous children of the poor must be obvious. Such a sanatorium not only spares the community the expense of taking care of more consumptive adults, because of the cures accomplished among the children, but it lessens the number of crippled, deformed and helpless individuals. Every case of Pott's disease cured, means a hunchback less in the world; every case of tuberculous hip or knee joint cured means a well person and a bread winner, instead of a cripple who is likely to become a pauper.

The dangers of contracting tuberculosis during the age of adolescence in college or high school are about the same as those during the school age. I have already referred to the detrimental effects of overtaxing and overstraining the mind and nervous system of young girls. The young man choosing a college career should bear in mind that, while a reasonable amount of athletics are conducive to health, physical overtaxing is a strong predisposing factor to tuberculosis, and, strange as it may seem, when the overtrained athletic contracts tuberculosis, the disease more frequently takes an unfavorable turn than in other instances. I have examined a number of men, recently from college, who had distinguished themselves as athletes, and, as a rule, I had the painful experience of finding them in worse condition to battle with the disease than individuals who had never practiced athletics. The remedy for all this lies, of course, with the college authorities who should regulate the sports so that they may become a benefit and not a detriment to the students.

The young man or woman who is obliged to go to work in a shop, factory, office or store in order to make a living has the same risk of contracting tuberculosis as the adult. However, even close contact with a tuberculous individual is not dangerous if the latter is trained to take care of his tuberculous sputum and is careful to hold his hand or handkerchief before his mouth when coughing, even when he does not expectorate, so as to prevent the droplets or the possibly infectious spray from doing any harm. Right here I wish to state distinctly that the conscientious consumptive is as safe an individual to associate with as any healthy person. To treat the conscientious consumptive as an outcast is cruel and most inhumane, and phthisiophobia, that is to say, the exaggerated fear of the presence of the consumptive, is a disease which all, social workers and physicians, must combat. Let us teach the masses and the individual consumptive the effective and yet so simple means of preventing the dissemination of consumption through carelessness. Teach them never to expectorate except in a proper receptacle, never to cough unless it is really necessary, and then always to hold the handkerchief or the hand before the mouth. Let our sanitary authorities, our railway and street car companies see to it that in every public place where people congregate a sufficient number of well-kept spittoons are provided. Let them, furthermore, change the wording of the formula. "Don't spit," which, as we know only too well, is frequently disobeyed, to the formula, "Spit here."

Our factories, workshops, the notorious sweatshops, our offices and department stores, and smaller ones also, our railroad stations and trains should receive the visits of sanitary inspectors so that it may be assured that the men and women employed or congregating in them are reasonably protected from the diseases arising through bad ventilation and other insanitary conditions.

To improve the hygiene in the homes of the poor and prevent as far as possible the propagation of tuberculosis through dust, I beg leave to reproduce here some rules which, on the suggestion of our distinguished co-worker, Prof. T. Mitchel Prudden, were issued by our New York Committee on the Prevention of Tuberculosis.

SWEEPING AND DUSTING.

When you sweep a room raise as little dust as possible, because this dust when breathed irritates the nose and throat and may set up catarrh. Some of the dust breathed in dusty air reaches the lungs, making parts of them black and hard and useless.

If the dust in the air you breathe contains germs of consumption—tubercle bacilli—which have come from consumptives spitting on the floors, you run the risk of getting consumption yourself. If consumptives use proper spit-cups and are careful in coughing or sneezing to hold the hand or handkerchief over the nose and mouth so as not to scatter spittle about in the air, the risk of getting the disease by living in the same rooms is mostly removed.

To prevent making a great dust in sweeping, use moist sawdust on bare floors. When the room is carpeted, moisten a newspaper and tear it into small scraps and scatter these over the carpet when you begin sweeping. As you sweep, brush the paper along by the broom and they will catch most of the dust and hold it fast, just as the sawdust does on bare floors. Do not have either the paper or the sawdust dripping wet, only moist.

In dusting a room do not use a feather duster, because this does not remove the dust from the room, but only brushes it into the air so that you breathe it in, or it settles down and then you have to do the work over again.

Use soft, dry cloths to dust with, and shake them frequently out of the window, or use slightly moistened cloths and rinse them out in water when you have finished. In this way you get the dust out of the room.

In cleaning rooms you should remember that dust settles on the floors as well as on the furniture, and is stirred into the air we breathe by walking over them. You can easily remove all this dust in rooms which have bare floors, in houses, stores, shops, schoolrooms, etc., after the dust has settled, by passing over the floor a mop which has been wrung out so as to be only moist, not dripping wet.

One of the strong predisposing factors to an acquired tuberculosis in adult life is always the fearful scourge, alcoholism. How to combat this is in itself a problem. I confess that, to my mind, the only rational way is to follow the example of Norway and some of the Cantons of Switzerland by making the manufacture and sale of alcohol a government affair. Experience in these countries has shown that through such means alone have they been able to reduce alcoholism and its consequent evils—disease, crime, poverty, misery, and want.

Educational propaganda regarding alcoholism will also be helpful. Concerning tuberculosis it should be impressed on the masses that alcohol, in whatever form it may have been administered, has never been either a prevention or a cure for consumption. Since we have not yet any laws prohibiting the sale of patent preparations and proprietary medicine containing a large percentage of alcohol and other deleterious substances under the guise of medicine, we must educate the people to the true state of affairs.

For the benefit of the statesman, legislator and the clergyman who recommend, the public press which lends its columns to advertise, and the people who consume, "patent medicines," I would like to make a few quotations from important authorities on the subject:

Mr. Adams, in his second article[8] on "The Great American Fraud," entitled "Peruna and the Bracers," has this to say on the manufacture of Peruna:

8. Collier's Weekly, Oct. 28, 1905.

Any one wishing to make Peruna for home consumption may do so by mixing half a pint of cologne spirits, 190 proof, with a pint and a half of water, adding thereto a little cubebs for flavor and a little burned sugar for color. Manufactured in bulk, so a former Peruna agent estimates, its cost, including bottle and wrapper, is between 15 and 18 cents a bottle. Its price is $1.00. Because of this handsome margin of profit, and by way of making hay in the stolen sunshine of Peruna advertising, many imitations have sprung up to harass the proprietors of the alcohol-and-water product. Pe-ru-vi-na, P-ru-na, Purina, Anurep (an obvious inversion), these bottled and labeled to resemble Peruna, are self-confessed imitations. From what the Peruna people tell me, I gather that they are dangerous and damnable frauds and that they cure nothing.

What does Peruna cure? Catarrh. That is the modest claim for it—nothing but catarrh. To be sure, a careful study of its literature will suggest its value as a tonic and a preventive of lassitude. But its reputation rests on catarrh. What is catarrh? Whatever ails you. No matter what you've got, you will be not only enabled, but compelled, after reading Dr. Hartman's Peruna book, "The Ills of Life," to diagnose your illness as catarrh and to realize that Peruna alone will save you. Pneumonia is catarrh of the lungs; so is consumption. Dyspepsia is catarrh of the stomach. Enteritis is catarrh of the intestines. Appendicitis—surgeons, please note before operating—is catarrh of the appendix. Bright's disease is catarrh of the kidneys. Heart disease is catarrh of the heart. Canker sores are catarrh of the mouth. Measles is, perhaps, catarrh of the skin, since "a teaspoonful of Peruna thrice daily or oftener is an effectual cure."

Prof. A. Jacobi of New York City, my venerable friend and the teacher of thousands of American physicians for the past fifty years, has come to the conclusion, from a careful estimate, that the American people spend an average of $200,000,000 a year for "patent medicines."

Prof. Oliver T. Osborne of Yale, in his address[9] on "The Scourge of Nostrums, Etc.," expresses himself regarding the public press and "patent medicines" as follows:

> Were it not for the daily papers and periodicals this enormous sale of "patent medicines" could not take place. This autosuggestion of disease and disease symptoms, and then the positive promise of cure causes frail human nature to give the stuff a trial, and as is expected, the narcotic and the alcohol gives a taste for more.

According to a statement published in connection with Mr. Adams' article, Dr. Ashbel P. Grinnell of New York City, who has made a statistical study of "patent medicines," asserts as a provable fact that "more alcohol is consumed in this country in 'patent medicines' than is dispensed in a legal way by licensed liquor venders, barring the sale of ale and beer."

Next to alcoholism, insanitary tenements and lack of air and light are the strongest predisposing factors to tuberculosis. The building of model tenement houses where the honest laborer may have a cheerful home at a reasonable rate, the creating of tenement house commissions in large and smaller cities to compel greedy contractors to remodel insanitary tenement houses and build only sanitary ones is one way of combating this evil. Not enough praise can be bestowed on men like Mr. Phipps and others who devote their wealth to the building of sanitary homes for laborers. These are certainly more needed than monuments, libraries, general hospitals, and even churches. To me the man who builds such homes which render thousands of American laborers and their families happy serves his Creator better than the builder of cathedrals and churches, for the former serves God by serving his fellowmen, and if we are to believe the beautiful story told us of Abu ben Adhem

> 'Midst those whom love of God has blessed
> The lover of his kind leads all the rest.

I have always maintained that if we can give the honest laborer a cheerful home and a wife who knows how to cook a good, plain but appetizing meal the saloon with its bright lights will have less attraction to him and alcoholism will be indirectly combated. When duty calls me into the houses of the poor, and I see the dingy, untidy rooms of the laborers and the woman unskilled in the plainest household duties, getting the meals from the nearest delicatessen store instead of preparing them herself, I do not blame the laborer when, instead of returning directly home from his occupation, he enters the saloon to take a drink, thinking it will cheer him up. The laborer's wife who, after leaving school, had to enter the workshop or store, and thus never had a chance to learn to cook or learn the first principles of housekeeping, is not to blame for her ignorance, but society is, and we should seek to remedy such conditions by not allowing our girls to leave the public school without having learned to be housekeepers and cooks.

It would, furthermore, pay economically and socially if our philanthropists and communities would establish places of amusement where a man might go with his family to sepnd his leisure time, partake of non-alcoholic drinks and enjoy good music or other healthful amusement. All this will help to strengthen family ties, prevent alcoholism, and indirectly prevent tuberculosis and other diseases.

In most of our cities we need more parks, large and small, more playgrounds, more recreation piers and public roof gardens. These places represent the lungs of a great city; without them a city can not be in a healthy condition. Sanitary houses, public baths and healthful places for amusement are, however, not only necessary for our city population, but are equally important for people living in the country. Home sanitation, love for fresh air, general and personal hygiene, must be taught to the country people as well. They have the good air of the country, but how often do they shut themselves up in badly ventilated rooms, being more afraid of fresh air than even city people, fearing the little draught—the only way of purifying foul air—as if it was disease producing. The lack of healthful amusement in the country is the cause of so many young people migrating to the cities. Here is a new field of philanthropy. The man who, by creating a system of healthful amusements for country people, can stop the ever-increasing migration to the cities, or perhaps even induce laboring families to migrate from on crowded cities to the country, will bestow a lasting benefit on present and future generations.

If we wish to diminish tuberculosis among the masses, we must pay our laborers in city and country reasonable wages so that they can live decently, eat sufficient good and nourishing food, and provide food and shelter for themselves and families for a time when work is lacking. Labor bureaus should be established everywhere by states, cities and smaller communities. There should be constant interchange between all of them so as to regulate the demand and supply as far as practicable. Then the abnormality that one section of the country suffers from the want of laborers while another has an army of "the unemployed" will be a thing of the past. Some man or woman having been cured of pulmonary tuberculosis may find outdoor employment through such an

9. "The Scourge of Nostrums and Irregular Practitioners," The Journal A. M. A., July 2, 1904

exchange which will insure his or her recovery and guard against a relapse which often follows from a return to insanitary environments. Our federal government could materially help these labor exchanges in their grand work by arranging for cheap transportation whenever it seems expedient to do so.

In relation to employment, travel and transportation, there comes to my mind another means of contagion which I consider dangerous, and that is dust. We are in the habit of calling tuberculosis a house disease, and well it deserves this name, but it might also be called a dust disease, and we will not be able to eradicate tuberculosis if we do not find means to lessen the amount of dust we breathe. Even so-called non-infectious dust is apt to irritate the pulmonary surface and thus make the respiratory system more receptive to the invasion of the bacillus. The dust uselessly raised in our factories and workshops could be materially lessened by automatic dust-collectors. The cleaning of such establishments, and also department stores, churches, theaters, concert halls, offices, schools, railway stations and railroad and street cars, should not be done in the old-fashioned way with a broom, but by the modern electric-exhaustion process now in use in some establishments, which is certainly far superior and thoroughly hygienic. The same process of cleaning should be employed for carpets in preference to beating them in the back yards in closely settled communities. Sweeping a street in its dry state should be considered a municipal crime, and the same holds good of the collecting of ashes in uncovered carts.

What to do to prevent the dust raised by speeding electric street cars and automobiles is indeed a difficult problem. Our fellow citizens on the Pacific Coast have used an oily substance to allay the dust. I submit this problem to the street-cleaning commissioners and city engineers of our great Eastern cities in the hope that their ingenuity may find a solution.

The dust in a railway car could be greatly minimized by proper ventilation and the more simple construction and equipment of sleepers and passenger coaches. But in addition to this a regulation should be enforced which will make it punishable by dismissal for any colored porter to brush a passenger about to leave the car in the presence of the others. To my mind it is an unpardonable offense on the part of any company not to prevent this practice of their employés who, as we all know, resort to it in order to solicit a gratuity. I have been told that the wages of colored porters on Pullman and parlor cars are so small that they must rely on an additional source of income from "tips." I do not know whether this is so or not, or whether the companies, the porters or the passengers are to blame, but tipping the colored porter has become habit with the American public and would probably be difficult to stop. However, I think a rule that brushing garments should only be allowed in the vestibule of the cars should be enforced.

Dust-collectors should be an obligatory equipment in the workshops of our prisons. In a recent investigation of some of our penal institutions I found a deplorable state of affairs in regard to this, besides the many other unhygienic conditions tending to propagate tuberculosis which I had occasion to observe.[10]

No matter how serious a crime the individual may have committed, society has no right to add to years of imprisonment additional punishment by giving the individual tuberculosis through unhygienic prisons and workshops.

In speaking of the social aspect of tuberculosis we can not overlook the tuberculosis situation in prisons and reformatories. Isolation and treatment of tuberculous prisoners in special wards or agricultural colonies are some of the means which must be resorted to to diminish consumption among this class of people. Some prisoners return to their families, and this would be undesirable had they become tuberculous or had they not been treated and cured of the disease. The practice of discharging prisoners in the last stage of tuberculosis, often virtually dying, without previous investigation to see that the freed individual will find a home where he will not constitute a source of infection and receive proper medical care, is thoroughly reprehensible.

What is the social duty, the duty of a community in regard to the average individual afflicted with tuberculosis? The rich consumptive will be able to take care of himself; he can be cured at home, in health resorts, or private sanatoria; but for the comparatively poor, or middle classes, there should be institutions where, for a moderate price, equally good chances for cure can be offered. No community has a right to pauperize its citizens; many are willing to pay, and he who can pay but will not should be made to pay. We have in this country a number of high-priced institutions and a number of purely charitable institutions, while for the middle classes and for the more advanced cases of consumption we have virtually nothing. There should be a sufficient number of city and county sanatoria to take in the moderately and absolutely poor consumptives in all stages of the disease. That it is cheaper to take care of a consumptive at the right time and in the right place until he is well, instead of taking care of him at the wrong time (in the advanced stage) and at the wrong place (general hospital) until he is dead has been often enough demonstrated not to need any further proof.[11]

But how are we to discover a patient at the right time? By educating the public in the early signs of tuberculosis, by establishing special tuberculosis dispensaries, by having periodic examinations of the chests of all public employés, pupils of public and private schools, colleges, etc., by urging the well-to-do to employ a family physician not only to take care of them when they are ill, but to watch over them while well and examine every member of the family from time to time so as to discover an early tuberculosis if such is developing. The special tuberculosis dispensary will serve the poor for the purpose of seeking early advice. Although I hope that at not too distant a time communities will realize that it will pay them to pay physicians, each one to be assigned to a number of poor families as a healer and a teacher, that is to say, to cure and to prevent disease.

If, furthermore, we could imitate the German state invalidity insurance companies, I think we would make a good step forward toward the betterment of the lot of our working population and make a wonderful stride toward the solution of the tuberculosis problem. Every laborer and employé in the German empire earning less than 800 marks must be insured against accident, old age and disease, including tuberculosis. The German insurance companies, under state supervision, soon realized that the earlier they took care of the policy holders who happened to become tuberculous the greater was the chance of their cure and the smaller the expense to the company. They urge their policy holders, at the slightest indication of pulmonary trouble, to go to the physi-

11. John H. Pryor, M.D.: "What Shall the State Do for the Consumptive?" Medical News, October, 1900.

cian paid by the company, for examination, and tuberculosis is thus discovered very often in the most incipient and consequently the most curable stage. The patient is then sent to a sanatorium, very often built and maintained by the insurance company, near large centers of population and independent of climatic conditions. Nevertheless the absolute and lasting cures often amount to 75 and 85 per cent. In the meantime the family of the consumptive laborer is looked after so that they may not be in want.

What is the social aspect, the social advantage of such an institution, which the Germans very justly call a *Volksheilanstalt*—a people's healing institution, or sanatorium? Time does not permit me to dwell at length on all that is accomplished by the sanatorium in regard to the social aspect of the disease under consideration. I had the honor, a few months ago, to address the Tuberculosis Congress in Paris on the subject of "The Sanatorium for Tuberculous Patients and Its Medical and Social Mission." Let me recapitulate rapidly the essential points of the latter, that is to say, the social mission, which I enumerated in that address.

By the admission of a patient to a sanatorium a frequently dangerous center of infection is made inoffensive and the patient is given the greatest possible chance of cure. If he is in the advanced stage he is made as comfortable as lies in the power of human skill with all the modern therapeutic means at command. The statistics of sanatoria show that the careful and trained consumptive is no danger to his immediate surroundings and the sanatorium no danger to the neighborhood. The contraction of tuberculosis by physicians, nurses and employés in sanatoria is of the rarest occurrence. The tuberculosis mortality in villages surrounding well-conducted sanatoria decreases because of the imitation by the inhabitants of the example in cleanly habits set before them by the inmates of the sanatorium.[12] The sanatorium cures the consumptive whenever he is curable and thus demonstrates the curability of the disease independent of climatic conditions. This is important when we consider that the majority of patients must be treated and cured in the same, or nearly the same, climate, in which they have to live and labor after their restoration to health. This cure is not established by quacks, "patent medicines," faith cure, or other mysterious means, but simply by the judicious use of God's fresh air, sunshine, good food, pure water, and sometimes a little medicine, and all under the careful guidance of a competent physician. The sanatorium makes the patient a hygienic factor when he returns to his former environments and thus demonstrates the preventability of tuberculous diseases. The patient has been taught the love of fresh air by day and by night, taught to shun vitiated atmosphere and the air of the saloon and of crowded meeting places. He has learned the value of simple, pure and good food, and how much more advantageous it is for him and his family to spend his money for food instead of for intoxicating liquors.

In the private as well as in the people's sanatorium there is much opportunity for cultivating compassion, benevolence and true democracy. It was my good fortune, ten years ago, when serving as assistant to my immortal teacher, Professor Dettweiler at Falkenstein, to see the birth of the first sanatorium for the consumptive poor. The wealthy and aristocratic patients at Falkenstein, being so much benefited by their sojourn there, manifested a deep feeling for the sufferings of the consumptive poor, deprived of the care and comfort of institutional treatment. They collected a large fund which became the nucleus of the largest people's institution in Germany, now located at Ruppertshain.

Many of these people's sanatoria give their patients educational advantages through lectures and regular classes of instruction. Some of our American sanatoria, I am happy to say, have imitated this good practice.[13] The young medical man, entering the sanatorium as assistant, is given an opportunity to become a trained diagnostician of incipient tuberculosis. The addition of such a physician to a community means a great step toward the solution of the tuberculosis problem. Do not consider me too sanguine if I say the sanatorium teaches true democracy, compassion and benevolence to the aristocratic, the rich and indifferent. It teaches the intemperate to become temperate, the disorderly to become orderly. It offers opportunity for education to the uneducated, and by teaching its inmates personal and general cleanliness and hygiene and love for fresh air it not only indirectly prevents tuberculosis, but also many other diseases whose origin must be traced to lack of fresh air, to filth, bad food, insanitary habitation, and bad habits.

Let me conclude this altogether too lengthy paper by saying that, to my mind, the solution of the tuberculosis problem means the solution of the social problem. Whatever prevents the development of tuberculosis will prevent social misery, whatever cures it will help to cure the social ills. Inasmuch as we diminish tuberculosis among the masses we will diminish suffering, misery and social discontent, and when the problem of tuberculosis shall have been solved we shall be nearer the millennium than we have ever been before.

BENNETT'S FRACTURE.

RAYMOND RUSS, M.D.
Instructor in Surgery in the University of California.
SAN FRANCISCO.

In the president's address before the Section on Surgery of the British Medical Association, 1885, Edward H. Bennett, professor of surgery in Trinity College, Dublin, drew attention to a fracture at the base of the first metacarpal bone, the first note on which he had published in 1881.[1] In a series of museum specimens he had found six of these lesions; in all the injury was the same, an oblique fracture in which the palmar half or more of the surface articulating with the trapezium was detached, the shaft of the bone slipping upward past this detached fragment, thus simulating in the living a backward subluxation. Bennett described the injury as a "Stave of the Thumb," and this name is particularly appropriate.

My attention was first called to this fracture a little more than a year ago, and, from the paucity of literature at my command on the subject, and my own limited experience, I was led to believe that it was very

1. Bennett: Dublin Journal of Medical Science, vol. lxxiii, p. 72; British Med. Jour., Aug. 1, 1885, p. 200; ibid., July, 1886, p. 13.

uncommon. In an article[2] lately published, I reviewed my two cases and stated my conclusions. During the past year we have been on the lookout for Bennett's fracture, with the result that I here report eight cases of this interesting lesion, nearly all of which have been observed in the surgical dispensary of the University of California. With the increase in our cases of Bennett's fracture there has been a marked decrease in our diagnoses of sprains of the thumb and of subluxations at the metacarpal-trapezial joint.

It is perhaps not surprising that this fracture, which I now believe to be the most common as well as the most important fracture of the metacarpals, should go so long unrecognized. Its diagnosis is sometimes very difficult. Those who are not familiar with the lesion will generally have their attention first directed to it by a radiogram. It is to Bennett's remarkable clinical acumen that we owe the recognition of this fracture long before the days of the Roentgen ray. By careful and pains-taking observation, together with an examination of bone specimens, he succeeded in eliciting the truth. Bennett's work is no less remarkable than that of Colles who published the first accurate description of the fracture which now bears his name in 1814. Like Colles, several years were to elapse before the true value of his observations were to be recognized. Beatson[3] published a single case of Bennett's fracture in 1900, and a month later Prichard[4] reported the fracture occurring in his own hand. Beatson's case was republished by Roberts[5] in this country in 1901. Oberst[6] has reported but two cases out of his great clinical material and more recently Aulhorn[7] has collected and published three cases, one occurring in Friedrich's clinic, one in Perthes' and the third in his own service. He states the fracture does not appear to be as frequent as Bennett had supposed. The only series of cases thus far reported is by Miles and Struthers,[8] and unfortunately but an abstract of their communication has been published.

The difficulties attending the recognition of this fracture have given the general impression that it is rare. Indeed, in my first communication on this subject, read before the California Academy of Medicine, a prominent surgeon, whose scholarly attainments are generally recognized, stated that he had never heard of Bennett's fracture. In any large out-patient service sprained thumbs pass as trifling affairs and receive but slight attention from the clinician, yet if the histories of these so-called sprains were to be followed, we would find that many give rise to prolonged periods of disability. The patient is not able to use his hand freely and his wage earning capacity is either nil or materially lessened. The long period of disuse and the rapid healing of the fracture after reduction has been made and a suitable dressing applied, are shown in several of our cases.

As a knowledge of the anatomy of the part is essential to a thorough understanding of this fracture, a brief consideration of this subject will not be out of place. The first metacarpal bone is shorter and wider than its fellows; the shaft is flatter and its distal end does not present so great a rotundity. The shaft narrows slightly as it approaches the carpal extremity or base, and then suddenly widens into a marked palmar projection, which carries a large part of the articulating surface. This surface is concavo-convex for articulation with the carpal bone, the metarcapal resting on the trapezium much as a rider rests in his saddle. But section through the joint has shown that the metacarpal articulation does not rest equally on the trapezium in all positions. In extension of the metacarpal it rests more on the dorsal portion of the trapezium while in flexion it rests more on the palmar portion. The saddle joint is more noticeable in the first than in the other metacarpal bones. The first metacarpal possesses two inherent points of weakness, the narrow portion just below the base, which we may term the neck, and the anterior basal projection which suddenly bulges from the shaft of the bone to increase the articulating surface. When, therefore, a sudden and a considerable force is received on the distal end of the first metacarpal, as in striking a blow with the clinched fist, or when a sudden force is received indirectly, as in a fall on the tip of the outstretched thumb, the first metacarpal is most generally fractured transversely at its neck, or longitudinally, the anterior basal projection being broken off. In some cases both these lesions are found. A continuation of the vulnerating force would drive the shaft of the bone on to the back of the trapezium.

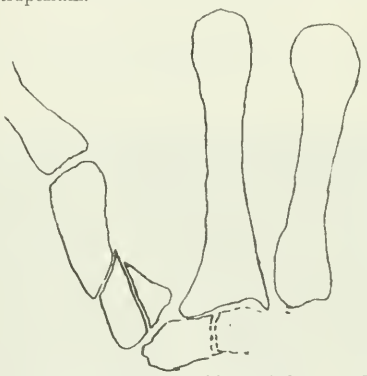

Fig. 1.—Tracing from radiogram of Bennett's fracture. Case 1.

A better idea of the mechanism of the injury can be gained from the following histories of our cases:

CASE 1.—J. B., a railroad engineer, aged 41, while adjusting the headlight on his engine, slipped and fell. He remained unconscious twenty-five minutes. He resumed work soon after the accident, but his left hand was very painful. Eight hours later, when he reached the city, his glove had to be cut off. The whole hand was much swollen. Careful palpation of the metacarpal and phalangeal bones revealed no fracture. The hand was treated as a simple contusion and hot applications made. One month later the patient again reported. The thumb was still very painful, especially when adduction was attempted. The patient had not been able to resume work since the receipt of the injury. There was considerable fluid in the flexor tendon sheath. Outside of the thenar eminence there was little swelling. The maximum tenderness was at the base of the first metacarpal bone. A tracing of the fracture is here given (Fig. 1), the radiogram being too faint to permit of reproduction. This shows a transverse fracture at the metacarpal neck, and a longitudinal fracture running into the joint between the metacarpal bone and the trapezium, the anterior projection at the base of the bone having been broken off. A subluxation is also present, although this was not demonstrated in the patient on account of the swelling. The thumb was put up in strong abduction, being held in this position by an internal rectangular cardboard splint. One month later the joint was somewhat stiff, but the patient had been able to resume work.

CASE 2.—T. D., aged 27, an oiler by occupation, took part in a street fight two days before he presented himself to me. He reported that he struck a heavy blow with his left fist tightly clinched, the force being received on the head of the first metacarpal. He went immediately to the City Receiving Hospital, where a diagnosis of backward dislocation of the first

Fig. 2. Bennett's fracture. Case 2.

metacarpal was made and a pasteboard splint applied. On examination I found great swelling over the thenar eminence. Posteriorly there was a prominence at the base of the first metacarpal. The thumb appeared slightly shortened. Profiting by my first case I succeeded in eliciting crepitus at the

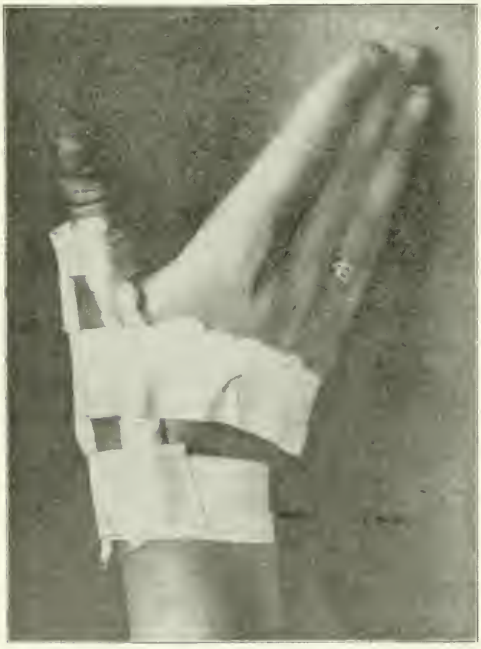

Fig. 3.—Author's coaptation-traction splint.

metacarpal base. The accompanying radiogram of this case (Fig. 2), shows a displacement of the distal fragment upward. The line of cleavage is the same as that described by Bennett. Function was restored at the end of three weeks.

The following coaptation and traction splint was applied (Fig. 3), this being a modification of the splint which I had previously generally employed for fractures of the metacarpal bones. The thumb was put in strong abduction and three wooden skewers—butcher's—neatly padded, were placed about the metacarpal, one posteriorly in the interosseous space, one along the outer border, and the third over the thenar eminence. These extended from well above the metacarpal bone to the first phalangeal joint. They were fastened tightly in place by two strips of adhesive plaster. Traction was then exerted on the thumb and maintained by strips of adhesive plaster passing about the first phalanx and the projecting ends of the three skewers. This dressing was reinforced by a rectangular cardboard splint. Accurate coaptation and sufficient traction to overcome the deformity and muscular action are most necessary in the treatment of this fracture. Slate pencils or small lead pencils can be used in place of the wooden skewers. The soapstone slate pencils are less brittle than the ordinary kind.

CASE 3.—T. D., a waiter, aged 26, struck a man with his right fist tightly clinched, three weeks before presenting himself at the clinic. He stated that immediately after the blow was struck he noticed that the metacarpal bone was displaced backward and that a friend "pulled it into place for him." He had not been able to use the thumb since the receipt of the injury; considerable swelling was present. Crepitus was easily elicited at the metacarpal base, but there was no tendency toward a repetition of the displacement. The coaptation-traction splint was applied and the fracture made an uneventful recovery. Full function was restored at the end of seventeen days.

Fig. 4.—Bennett's fracture. Case 4.

CASE 4.—J. W. C., a laborer, aged 27, while attempting to move a heavy box three weeks before presenting himself at the clinic, struck the tip of the right thumb very forcibly against the edge of the box. He at first regarded the injury as trifling, but found that he was unable to use his right hand in manual labor. He had had no treatment. On examination there appeared to be a subluxation at the trapezial-metacarpal joint, accompanied by considerable shortening. There was little swelling in the vicinity of the bone. Crepitus was determined near the base. The radiogram (Fig. 4) shows the presence of a transverse fracture at the narrow portion of the bone, with an overriding of the distal fragment. With the thumb in traction and strongly abducted, a tightly fitting plaster-of-Paris dressing was applied. Twelve days later the dressing was removed. There was slight exuberant callus, but the alignment was perfect. There was good function and the bone seemed to be firmly united. As a matter of precaution, however, the dressing was reapplied for five days longer, and the patient resumed his work the following day.

CASE 5.—G. B., a laborer, aged 35, was hit with a heavy lead pipe across the palmar surface of the metacarpal bones of the left hand, the force being largely expended on the first metacarpal. There was great pain and swelling of the whole hand when we saw him shortly after the injury had been inflicted. He had motion in the fingers, but was unable to move

the thumb. Crepitus was determined near the base of the first metacarpal. The upper end of the distal fragment appeared prominent, although this is not shown in the radiogram. The radiogram (Fig. 5), shows, however, a transverse fracture just below the palmar projection at the base of the bone. A coaptation-traction splint was applied. This was removed at the end of twelve days. There was a slight callus deformity at the point of fracture, but a good functional result.

CASE 6.—P. F., laborer, aged 33, had injured his left hand six days before I saw him. He stated that he tripped and fell with thumb extended, the force of the fall being received on the tip of the thumb. Since then he had not been able to use his left hand. There was no laceration, but slight discoloration and much swelling were present about the first metacarpal, especially noticeable in the flexor tendon sheath on the thenar eminence. There was some shortening of the thumb and the clinical picture of a subluxation. Pain was localized at a point just below the metacarpal base and crepitus was easily determined here. The thumb was placed in a coaptation-traction

Fig. 5.—Bennett's fracture. Case 5.

splint and the dressing removed at the end of seven days. The alignment was good and no crepitus was determined. The splint was reapplied and removed on the fourteenth day. There was perfect functional result and no deformity.

CASE 7.—T. D., a kitchen helper, aged 56, had injured the thumb of left hand four months before he applied at the clinic. He stated that he had fallen, striking the palmar surface of the ungual phalanx of the thumb very forcibly. On examination there was considerable prominence at base of the first metacarpal, giving the appearance of a backward subluxation. On comparison of the two thumbs slight shortening on the injured side was observed. Crepitation was elicited just below the base of the metacarpal. The patient was able to execute slight movements in all directions, but free movement gave him pain. There was slight swelling over the thenar eminence. A coaptation-traction splint was applied and a radiogram then taken. This showed a transverse fracture similar to that in Case 4. The alignment was good. The patient was discharged three weeks later with full restoration of function.

CASE 8.—H. K., a solicitor, aged 45, had fallen three days before, striking his right thumb forcibly against a wall. There was some swelling and great deformity, the lesion appearing like a complete dislocation backward of the first metacarpal. The trapezium could not, however, be felt in the palm of the hand, as is usually the case in these luxations.

With considerable traction on the abducted thumb reduction was made and crepitus was elicited. The point of fracture was found to be just below the joint. The overriding of the distal fragment had been great and there was a strong tendency for a repetition of the deformity. A coaptation-traction splint was applied, but when examined three days later it was found that the deformity had recurred. The deformity was corrected and a plaster-of-Paris bandage applied very tightly, pressure being exerted at the point of fracture until the plaster had set. The dressing was taken off at the end of twelve days. The patient had free movement of the thumb. He returned to the clinic one month later, complaining of a general tenderness over the first metacarpal. There was slight deformity, but motion was not limited. Massage was advised and the patient has not reported since that time.

It will thus be seen that the left first metacarpal was fractured in five cases, the right in three. In all cases the fracture resulted from a considerable force; from direct violence in two cases, striking a heavy blow with the clinched fist. In four the fracture resulted from indirect violence, striking the thumb forcibly, the tip of the thumb being specified in two cases. The exact manner in which the accident took place could not be elicited in the first case. In the fifth case the fracture resulted from an injury inflicted on the palmar surface by a heavy lead pipe. While in point of etiology this injury does not correspond with the others, nevertheless the displacement was characteristic of Bennett's fracture and it has therefore been included in the series.

All the cases have occurred in men ranging in age from 26 to 56 years. Cases 1 and 5 alone reported for treatment immediately after the injury and it is noticeable in these instances that considerable trauma of the hand accompanied the fracture. The other patients at first considered the injury too trifling to warrant surgical attention, but, after periods of disability ranging from two days to four months, consulted us.

The diagnosis between this fracture and backward subluxation is a matter of the greatest importance, for it will be remembered that surgeons have for years failed to determine the true lesion. Bennett has made the statement that "when we bear in mind the form of the articulation, it is difficult to conceive the idea of a partial dislocation occurring in it and remaining as a permanent deformity. If we apply the analogy of a rider and his saddle to this perfect saddle-shaped joint, the difficulty will, I think, be evident. A rider, thrown on to the pommel, must, as we know, adopt one of two courses; make his dislocation complete, or get back into his seat. There is no permanent partial displacement possible."

Partial displacement does occur, however, and the following case, seen by me in consultation with Dr. John C. Newton, is given in proof of this statement.

CASE 9.—H. F. C., a stevedore, aged 32, engaged in a street fight on Jan. 2, 1906. He reported that he struck his adversary a heavy blow with his clinched fist. When seen by Dr. Newton the next day the vicinity of the first metacarpal of the left hand was much swollen and discolored. There was a hard swelling near the metacarpal-trapezial joint and distinct crepitation could be heard. A moulded plaster-of-Paris splint was applied, but the deformity showed a great tendency to recur.

I saw patient on Jan. 14. At that time the swelling had largely disappeared but the least movement was very painful. The proximal end of the first metacarpal was prominent, giv

ing the picture of a backward subluxation. Reduction was easily made and was accompanied by a decided crepitation, but the deformity recurred immediately when the pressure was relieved. With the metacarpal reduced and the index finger on the metacarpal-trapezial articulation, I carefully palpated the shaft of the bone with the second and ring fingers, at the same time manipulating the distal end of the metacarpal with the other hand. No fracture of the bone could be made out and the crepitus which was elicited when reduction was made, was distinctly wanting. It was evident that we were dealing with a backward subluxation of the first metacarpal, and a radiogram taken the following day showed that the bone was intact. The metacarpal was placed in abduction and a plaster-of-Paris roller bandage applied. Dr. Newton tells me that the patient resumed work on March 2. He examined the hand four days later; the patient had free movement of the thumb, but the base of the metacarpal was still prominent.

This case exhibits the main points which are to be borne in mind in the differential diagnosis. In obscure cases the Roentgen ray must be depended on to make a diagnosis, but the clinician will generally be able to arrive at a correct conclusion after a careful examination. We have found the dressing here described useful, although it failed in case 8. After reduction has been made and maintained the fracture heals very readily, even in old cases. Our shortest period of disability was twelve days, our longest one month.[9]

THE FORMATION OF CONNECTIVE TISSUE IN THE ANTERIOR PART OF THE VITREOUS BODY IN YOUNG GIRLS.

CHARLES J. KIPP, M.D.
NEWARK, N. J.

Hirschberg[1] says: "Enigmatical to me is also the white tissue formation in the lower anterior part of the vitreous body, which I have seen a few times in young girls, ending in some in some damage to, in others in total loss of vision. In these cases tuberculosis could be excluded. He quotes briefly two cases.

CASE 1.—A healthy girl, aged 16, was first seen Nov. 29, 1897. The right eye began to lacrimate two and one half months previously. The lacrimation lasted two days and was accompanied by pain for a day only. There was obscuration of right eye; the left eye was normal. Right eye: fingers at 4′ V. F. intact. There was a large dark spot which surrounded the blind spot, and which sent a broad offshoot toward the point of fixation. There was no irritation. Tn. Brownish dots in the cornea. The pupil was of medium size but irregular in form. There were brownish dots on anterior capsule, bluish spiderweb-like opacity immediately behind lens which is transparent. Flaky opacities were in the vitreous. An extensive white opacity, greenish-white in daylight, was situated outward and downward close behind the lens. The fundus was not visible.

Treatment.—Moderate inunction treatment was followed by slow but steady improvement. Jan. 11, 1898, counts fingers at 6′; February 28, fingers at 8′; March 22, fingers at 10′; June 9, 1898, S. 1/25; August 25, S. 1/10. V. F. good, but with a large longitudinal scotoma, which includes Mariotte's spot. Posterior synechia. The bluish-white mass behind the lens is still present but smaller. Disc visible with a staphyloma-like focus adjoining lower margin, and a thick floating opacity in vitreous immediately in front of disc. uly 9, 1900, no change. Robust health.

CASE 2.—A girl, aged 26. Was first seen Oct. 1, 1890.

History.—In January of same year she noticed suddenly a grayish-white veil before right eye. This lasted but two days, but returned intensified in March. Vision improved again, but for some weeks past it had failed again. She was anemic and weak, but free from organic disease. Left eye normal (M. 3, 5. D.). Right eye, fingers at 5′. V. F. defective upward, defect wedge-shaped, extends up to point of fixation. Bluish flocculent opacities were in vitreous. Outward and below was a bluish connective tissue formation connected with a peripheric detachment of the retina.

Treatment.—Tannin and secale, iron and hydrastis were used in treatment. Nov. 19, 1890, an iritis had developed; the fresh exudation extended close up to the lens. April 15, 1891, the eyeball was deformed and there was a grayish-white reflex from behind pupil. With oblique illumination a grayish-white wall was seen behind lower half of lens. On Nov. 28, 1891, the V. F. was contracted to an island below the point of fixation.

Cases like the ones here reported, in which only one eye is the seat of disease, are not very rare and have doubtless been seen by most ophthalmologists. In Case 3 both eyes were affected in almost the same manner simultaneously and although the patient was practically blind for some time, and the improvement very slow, the outcome was complete restoration of vision in both eyes. The case seems to me to be worthy of recording also, as I have had the opportunity of seeing the patient during the subsequent twenty-five years, and therefore can testify to the permanency of the cure.

CASE 3.—Miss S. R., aged 20, was first seen by me May 2, 1875.

History.—She was in very good health. Her family history was good. Parents were in good health. Had never had a serious disease. Had noticed some impairment of vision for last three years. For six days past she was almost totally blind in left eye. Both eyes were perfectly normal in appearance, and the mobility of either was unimpaired in all directions.

Examination.—Both eyes are E. R. S. 18/50. L. S. 2/200 Ophthalmoscopic examination showed in right eye vitreous body very cloudy with floating membranous opacities. Disc and retina were veiled. Retinal veins were very large. Tn. V. F. intact. Left eye vitreous was so opaque that disc and retina could not be seen. Dense floating opacities in anterior part of vitreous. Tn. V. F. intact.

Further inquiry revealed that she menstruated regularly and no evidence of disease of other organs could be discovered. Urine was free from albumin and sugar. I ordered two leeches to each temple and prescribed potassium iodid in 5-grain doses three times daily.

Clinical Course.—May 15. No change, except that in right eye there are now visible several small bluish-white globular masses in lowest part of vitreous. In the left eye there is now apparently a slight contraction of the V. F. downward.

May 22: Right eye; bluish-white plaques are now also seen in lower part of vitreous of this eye. In both eyes there are now semi-transparent membranes in anterior portion of lower part of vitreous, resembling detached retina, but they are distinctly circumscribed. There is apparently an increase in the opacity of the vitreous in both eyes. R. S. 18/40. L. S. 6/50.

June 6: Right eye as before. Left eye, vitreous is much clearer. The disc is now visible and seems normal. Retinal veins are much enlarged. There is no apparent change in the choroid.

Aug. 8: Both eyes are in about the condition last described. Jan. 25, 1876. In both eyes the vitreous is much clearer, otherwise as before. R. S. 18/25. L. S. 18/25.

July 6: For the last three months, vitreous has been almost clear in both eyes. Now there are again visible in the left eye, several of the bluish white globular masses in the lower part of the vitreous. In the right eye, the semi-transparent membrane in lower part of vitreous is now of a distinctly convex outline, and protrudes toward the axis of the eye, from in front and below. Arterial vessels pass over it and diminish in caliber as they approach most convex portion of prominence, while veins gain in size as they approach the periphery. No connection between these vessels and the retinal vessels can be

9. Further literature may be found as follows: Bähr: Monats. f. Unfallhk., 1897, No. 4; Blenke: Ibid., 1901, No. 4; Lauf: Deuts. militärärztliche Zeits., 1902, No. 4.

1. Hirschberg: "Einführung in die Augenheilkunde," second half, division 1, p. 211.

made out. Opacity of vitreous is again somewhat increased in both eyes. R. S. 18/25. L. S. 18/25.

Nov. 4: Right eye. The membrane in lower part of vitreous is no longer visible and the vessels that were seen on it are now indistinctly seen at a greater distance from the anterior part of vitreous than formerly. In the place of the membrane there are now many small fixed membranous opacities. In lowest part of vitreous apparently immediately behind lens are seen two small bluish-white glistening bodies of globular form and in outer region closely behind or on posterior capsule of lens are several very dark opacities. A diffuse opacity of vitreous still veils the disc in both eyes. R. S. 18/25. L. S. 18/25.

Feb. 21, 1877: Right eye: the interior portion of the vitreous is again full of floating membranous opacities. The semi-globular protrusion previously noticed, is again visible. The veins on it have changed their course somewhat. They now run downward instead of forward. The left eye is now free from floating opacities. R. S. 18/20. L. S. 18/15. Patient is still taking potassium iodid in 10 grain doses, three times daily.

March 16: Right eye: The floating membranous opacities have largely disappeared. The convex protrusion is now distinctly seen as a grayish membrane, over which vessels pass from behind forward.

Left Eye: A grayish membrane, convex in form, has made its appearance also in this eye. It is situated in lower outer portion of vitreous, apparently not far behind lens, and protrudes toward the axis of the eye. Vessels are seen on it, but no connection between them and the retinal vessels can be made out. It looks very much like a detached retina. The membrane is sufficiently translucent to allow floating opacities to be seen behind it. In both eyes the V. F. is intact. R. S. 18/20. L. S. 18/15.

June 22: In both eyes the convex protrusion has apparently become larger, and its outline is more opaque.

Dec. 14: Right eye: There is an increase in floating membranous opacities in anterior portion of the vitreous. The convex protrusion is hidden by them.

Left Eye: The convex protrusion seems larger than at last visit.

Jan. 26, 1878: Right eye: Vitreous opacities have nearly all disappeared. The protrusion previously noted, is no longer seen. S. 18/20.

Left Eye: The convex membrane seems to have become loose anteriorly, as it now floats slightly on movements of eye. Several bluish-white, brilliant globular bodies are again visible in lower part of vitreous, not far behind lens.

December 1: Right eye: There is still diffuse haziness of vitreous, but no floating opacities are present. The apparent detachment of the retina is no longer visible. S. 18/20.

Left Eye: The same as right; the membranous protrusion is not visible. There are no vessels in vitreous. S. 18/20.

June 7, 1879: Right eye: No change since last entry.

Left Eye: An increase in the number of floating opacities. The semi-globular protrusion in lower outer part of vitreous is again visible and in addition there is now seen a similar protrusion with vessels on it, in lower inner portion, not far behind lens. S. 18/20. V. F. intact.

April 14, 1880: Right eye: Media are perfectly clear; fundus is normal. S. 18/15.

Left Eye: Large floating membranous opacities. The semi-globular protrusion in anterior lower portion of retina remains as before. S. 18/20.

Nov. 22, 1881: Right eye: Diffuse haziness of vitreous, otherwise normal. S. 18/20.

Left Eye: Haziness of vitreous. The protrusions in lower part of vitreous are no longer visible.

Feb. 2, 1882: Right eye: Vitreous not quite clear. S. 18/15.

Left Eye: Membranous floating opacities in vitreous. Two small atrophic patches are now visible in outer periphery of choroid. S. 18/30.

During the following five years she lived in the tropics. She married and had one child. On her return to this country I examined her eyes and found both free from opacities in the vitreous and fundi normal. During the last few years, the lens of this left eye has become cataractous, and more lately the lens of the right eye has become somewhat opaque at posterior pole. On Dec. 14, 1905, I found her vision as follows: R. Hm. 1.50; S. 6/6; L. Hm. 1.5; D. S. 6/12. With the exception of the opacities of the lenses the eyes are apparently normal.

As to the pathology of this affection I have nothing new to offer. Although I did not see any actual extravasation of blood in the vitreous body in this case, I have seen it in others with similar membranous formation in the anterior parts of the vitreous, and think that in this case also, hemorrhages from the ciliary body were present before I first saw the case. The resemblance of the membranes with the vessels on them to a detached retina, was so great that one of my most experienced colleagues, who saw the case, urged me to make a scleral puncture, but having watched the development of these membranes for months, I felt sure that they were not the retina and, therefore, did not follow his advice. The gradual disappearance of the connective tissue formation was followed by the complete absorption of all the floating opacities in the vitreous. The participation of the choroid in the morbid process was shown by the appearance of an atrophic spot near its periphery.

SPINAL AMYOTROPHY WITH PUPILLARY INEQUALITY, AND JUVENILE DYSTROPHY.*

L. HARRISON METTLER, A.M., M.D.

Professor of Mental and Nervous Diseases in the Chicago Clinical School; Associate Professor of Neurology in the College of Medicine of the University of Illinois; Neurologist to the Cook County Hospital; Norwegian Lutheran Deaconness' Home and Hospital.

CHICAGO.

The following case, seen in consultation with Dr. Alexander C. Wiener, is reported not as such an extraordinary case, for it is one of amyotrophic lateral sclerosis, but on account of the association with it of inequality of the pupils. This association is exceptional.

CASE I.—Mrs. J. P., aged 49, twice married, has two healthy children by her first husband. During the nine years of married life with her second husband she has borne no children, but has had four or five early abortions.

Family History.—Her father died of consumption when the patient was six years old. Her mother died of paralysis of the heart at the age of 56. She has a half brother and a sister in perfect health. Nothing further of interest is in the family history. She had the usual children's diseases, and a severe attack of inflammation of the bowels twelve years ago. Menstrual life began at 13 years of age, is regular and painless. Ten years ago the patient worked hard, so hard that men refused to do the work, kneading bread all day in a bakery. This she continued for about five years. She would use a barrel and a half of flour a day. As a strong, healthful, farmer's daughter, she had worked hard pitching hay in her early life.

History of Disease.—Her present trouble commenced about three years ago. The middle finger of the right hand began to be stiff, especially when she was sewing. It seemed like "a steel spring at times, and flew back." There was absolutely no pain, soreness or other sensory manifestation with it. Then the wrist became weak and dropped on the right side. Still there was no pain or soreness whatever, no numbness or tingling either. About four months later the same phenomena took place, in about the same way, in the left hand. When she would pull out the middle finger it flew back like a steel spring. Then the wrist became weak and dropped on the left side as it had done on the right. No sensory phenomena of any sort, however, appeared at this time anywhere. This condition remained more or less stationary until last Christmas, when the trouble seemed to pass to the arms and shoulder.

* The patients were shown to the Chicago Neurological Society, March 29, 1906.

At present she can raise her left arm to the head, but not the right arm. There is wasting to a considerable degree in the deltoids, and to a lesser degree in the other shoulder and neck muscles. All of this is more pronounced on the right than on the left side. There is a distinct reaction of degeneration on electrical examination of the right deltoid, and partial reaction in the supraspinati and infraspinati, interosseal, and thenar muscles of the right side; and a very slight reaction in the corresponding parts of the left side. There seems to be no wasting of the latissimus dorsi and rhomboids and very slight, if any, in the pectorals. The left arm is somewhat softer and smaller than the right. The thumb muscles are slightly wasted. The hands seem to her swollen and somewhat larger generally than normal. They are feebly rigid and tend to assume the *main en griffe* attitude. The muscles of the neck, "the cords" she calls them, feel a little stiff and "seem to crack." She does not think she is any thinner about the neck. There have been creeping, fibrillary twitchings in the muscles of the right arm at times, but not in those of the left. The collar bone feels sore and slightly depressed.

There are no symptoms whatever in the legs; but the knee jerks are very decidedly exaggerated. No ankle clonus or Babinski could be elicited.

Until last Christmas there were no notable sensory symptoms in any part of the body or extremities: no local tenderness anywhere now or referred to in the past. Under the left shoulder there is now a little soreness, and under the right collar bone she feels a slight degree of soreness. There is absolutely no spinal tenderness on vigorous percussion; no tenderness along the course of any of the spinal nerves. There have been no neuralgic manifestations. There have been no bowel or bladder troubles of any sort.

The right pupil is markedly dilated, but contracts slightly, quickly and sharply on accommodation and light stimulation. This condition is probably due to ciliospinal irritation and not to a sympathetic lesion.

Differential Diagnosis.—There are some suggestions of syringomyelia in this case; but the latter disease is ruled out by the absence of the syringomyelic syndrome, for the pain and heat sense, as well as the tactile sense, are normal everywhere. Peripheral neuritis is excluded by the absence of all sensory symptoms; and for the same reason pachymeningitis cervicalis hypertrophica is also ruled out. The latter disease, were there present any sensory symptoms at all, might be well considered, in view of the fact that the patient has had two healthy children with her first husband, but a number of suspicious abortions with her second. The closest inquiry in regard to any specific trouble elicited continued denial.

Treatment.—The treatment consists of the daily injection hypodermatically of nitrate of strichnia gm. 0.003. After four weeks of this treatment, without any improvement in the paralysis, there seems to have been a little improvement in the appearance of the atrophied muscles around the right shoulder. The patient and her husband are very positive of this, though imagination may have something to do with it, I suspect.

The case of juvenile myopathy may be diagnosed as such clinically, though there is some question as to its being a pure example of Erb's type. The case is from the Cook County Hospital, where I was asked to see it in consultation, in the service of Dr. H. V. Halbert.

CASE 2.—G. H., aged 19, German, unmarried, watchman and laborer. Patient has indulged in beer, whisky and tobacco, but not to excess. Had measles in childhood and says that when young he was "deathly sick" several times, but from what cause or disease he does not know. He has never had typhoid fever or diarrhea prior to Christmas, 1905, when the present trouble seems to have begun. He had an attack of gonorrhea, July, 1905; syphilis is denied.

History of Disease.—On Dec. 28, 1905, the patient entered the Cook County Hospital, in the service of Dr. W. S. Harpole, and gave the following history: About two weeks previously he commenced to have diarrheal attacks, obliging him to go to stool three or four times a day and the same number of times at night. He formed no opinion of his own as to the cause of this trouble. The stools increased to five or six a day and the same number at night. At one time they decreased in frequency and severity, but increased again, for which reason he entered the hospital. The stools, according to the patient's own account, were thin and watery, yellowish, sometimes odorless and at other times "putrid." Prior to coming to the hospital this condition existed for one week, during which time he ate no solid food whatever. He never saw any blood in the discharges. Vomiting began with the onset of diarrhea, and during the week prior to entering the hospital, occurred every day. Whenever he took a bite of food he became nauseated and immediately began to vomit. During the last two or three days of the week he vomited two or three times during the day and as often during the night. He thirsted keenly for cold water, but the drinking of it would set up an attack of emesis.

Fig. 1.—Juvenile myopathy.

He had no appetite for food and he believed he had lost ten pounds at least in two weeks. A slight cough was present. There was tenderness in the region of the stomach, and occasionally for a few minutes he would experience a dull pain in the stomach itself. He never had had night sweats; never had had any difficulty in urination.

Examination.—The record of the physical examination of the patient, made Dec. 28, 1905, shows no abnormality about the head. There were prominences of the intercostal, supraclavicular and infraclavicular spaces; winged scapulæ; narrow and emaciated thorax; no pulmonary, cardiac or pericardiac signs; no disturbance of the pulse, except a slight retardation and reduced tension; no abdominal tenderness, but a somewhat

scaphoid abdomen. Liver and spleen were impalpable; there were no evidences of fluid or tumor in the abdomen. Nothing of note was discovered in connection with the genitalia, the nervous and glandular systems, the extremities or the skin. Urinalysis revealed; color yellow, cloudy, acid reaction, sp. gr. 1,020, trace of albumin, no casts, no sugar, abundant deposit of urates. Examination of feces was negative.

Examination of the blood showed white corpuscles, 8,200; reds, 4,500,000 or 90 per cent.; hemoglobin, 90 per cent.; color index, 90/90-1. Differential—polymorphonuclears, 67 per cent.; large mononuclears, 20 per cent.; small mononuclears, 11 per cent.; basophiles, 2 per cent.; eosinophiles, 0; emucleated reds, 0; transitional forms, a few. The blood stained well and

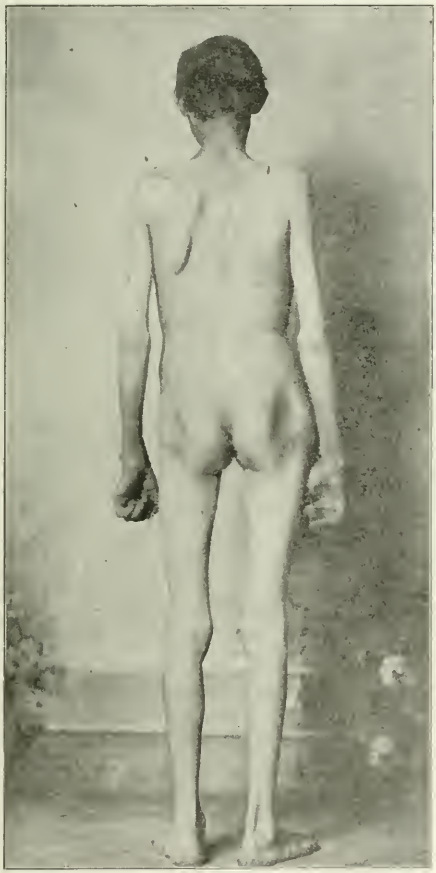

Fig. 2.—Juvenile myopathy.

coagulated rapidly. There was slight crenation and poikilocytosis of red blood corpuscles. Widal reaction, solution, 1-40, was not positive in 35 minutes. The temperature remained at all times practically normal, while the pulse ran a little subnormal. An antityphoid régime was adopted, and the patient left the hospital Jan. 6, 1906, recovered.

On March 13, 1906, the patient returned to the hospital. He says that almost immediately after he had gone out as cured he began to notice some pain and stiffness in his legs. The pain increased on walking. The muscles seemed to swell up and then grow small. Similar phenomena appeared in the thighs. After an interval of about ten days the same thing, or something like it, occurred in the shoulder and advanced down the arm to the elbow. In the upper limbs these manifestations did not seem so marked to him as in the lower limbs. Finally, the neck muscles became gradually involved, so that he had difficulty in holding up his head. He could walk when he entered the hospital, but he complained of pains of a dull aching character in the right leg when he exerted it. According to the patient's own testimony, the left leg has made an almost complete recovery. He feels that he has lost 20 pounds or more in weight the last three months. The marked atrophy of the shoulder and pelvic girdle muscles is obvious. In the upper extremities, the deltoid, and infraspinati and supraspinati, the pectorals, and the muscles of the arm down to the elbow are decidedly wasted. The forearm is very little wasted, if any, and the hand is practically normal. The glutei muscles, the muscles extending the hip joint, and those of the thigh are wasted. The legs below the knee and the feet are practically normal. The appearance of the face is characteristic. The knee jerks are present but much reduced. There have never been any fibrillary contractions at any time.

On electrical examination the wasted muscles show a quantitative reduction in excitability to both Faradic and Galvanic currents. No reaction of degeneration or inversion of normal formulæ have I ever been able to detect. There are no sensory disturbances, nor any recorded except for the slight dull pains in the beginning. There are no disturbances of the sphincters.

A few words of interest may be said in regard to the etiology of the myopathies, and especially of this case. As we all know, heredity plays a dominant rôle, but cases have been reported by Erb himself, Gowers and others, in which no heredity could be traced, hardly even a neuropathic tendency. In our case certainly no heredity could be elicited. Other cases are on record in which infection, such as diphtheria, rheumatism, measles, scarlatina, played a very possible and even probable rôle. Gowers says, "As a rule no exciting cause can be traced. In a few instances the onset has succeeded some other morbid process, such as chlorosis, acute disease, rheumatic affections due to exposure to cold, and the depression of general health resulting from these may have determined the time of onset." In a case reported by Gowers the patient died from diarrhea. In connection with the history of infection that appears in this case it is to be noted that the winged scapulæ and marked depression about the shoulder girdle were made note of when the patient entered the hospital in December on account of diarrhea. The diarrhea may have been a mere incident, and the muscular wasting, unnoted, may have already begun.

In the next place a polymyositis of mild degree has been reported as occurring before these myopathies, and is suggested, in our case, in the soreness, transient swelling of the muscles of the leg, and other characteristics of the disease. The view has been put forth that some of these myopathies, if not all of them, are due to a transient mild degree of polymyositis. Jacoby[1] of New York reports an interesting case with many features like those of our own, and discusses most interestingly and plausibly the possible relationship between his case and cases like his and primary progressive muscular atrophy. He asks:

> In short, is our case, perhaps, a case of progressive muscular atrophy in which the inflammatory stage is more marked clinically than usual, due to the myositis being more of a parenchymatous character? . . . Are not some cases of primary progressive muscular atrophy the resultants of light cases of polymyositis parenchymatosis? We believe that there is considerable evidence in favor of these views and we do not stand entirely alone in possessing this opinion.

Wagner insisted, and Unverricht admitted the possibility of their cases being acute cases of primary progressive muscular atrophy. Wagner's cases showed a

1. Jour. of Nervous and Mental Disease, vol. xlii, No. 11.

duration respectively of three and eight weeks; Unverricht's a duration of six weeks. Gowers, Beevor and most authors believe that the pathologic change in the myopathies in the muscles is interstitial, that is, overgrowth of fat, proliferation of nucleated fibrous tissue between muscle fiber, with secondarily changes in the muscle fibers themselves, causing the narrowing and distortion of the fibers and their wasting.

A transient infectious polymyositis may, therefore, in our case, as has been suggested in many if not all cases of primary myopathy, have been present. The evidence, at all events, points away from a primary cord or nerve degeneration, and toward a primary muscular change.

But again, in these cases of myopathy there may be both a neural and a muscular process going on at the same time. In one case[2] the cord was normal except at the last dorsal segment, where there was found an area of granular disintegration in the intermediate substance on each side, but the cells of the anterior cornua were never atrophied, according to Beevor. Barsicow's cases and Zimmerlin's show that different, so-called types, of primary myopathy occur in the same family; and other cases have been reported wherein clinically neural disease was suspected and yet only myopathic changes were discovered and *vice versa*. Such cases lend color to the contention of Erb, who holds in contradistinction to Gowers and others, that the change in the muscle is primarily in the muscular substance itself, and secondarily in the interstitial tissue, and that the whole process is a functional disturbance in the trophic centers of the cord; thus, according to Erb, making of a myopathy both a muscle and a neural disease. These transitional cases, such as Barsicow's and Zimmerlin's, give support to the contention of many of our latter day physiologists that the lower motor neuron, with its associated muscle, constitutes a physiologic unit, a neuro-muscular apparatus. Grasset has even gone so far, in declaring for the solidarity of the lower neuron, as to affirm that an anterior poliomyelitis can not be differentiated from an inferior motor polyneuritis, because they are both but expressions of an inferior motor neuronitis.

The etiology and pathology of our case are such as not to exclude it entirely from the class of juvenile myopathies, though they do not give it the frank, clear-cut position demanded by the average text-book.

The symptomatology, especially in regard to the distribution of the atrophy involving as it does the shoulder and pelvic girdles, favors the diagnosis of juvenile dystrophy for our case.

cord; thus, according to Erb, making of a myopathy

In differentiating in doubtful cases between a dystrophy insists on the great importance of the grouping of the atrophied muscles. Thus, in spinal cases, he finds that the deltoid, infraspinati and supraspinati, clavicular part of the pectoral, biceps, brachialis anticus and supinator longus are in one group involved (fifth cervical root); the latissimus dorsi, sternal part of the pectoralis and triceps being involved in another group (sixth cervical root). In the myopathies, the biceps, triceps and supinator longus are wasted, while the deltoids and spinati muscles escape. In other words, he finds in the spinal atrophies that there is a physiologic grouping of the muscles according to the center of the cord involved; while in the myopathies there is no evidence of such spinal grouping. This, I think, is a little too rigid. Gowers has stated, in his description of the myopathies, that occasionally hardly any muscle of the body escapes. He reports the case of a man, 27 years of age at the time of his death, with no history of any analogous case in the patient's family. The affection began at the age of 14, when the feet began to turn in so that he walked on the outer side of the foot. He soon noticed a gradual wasting of the legs, which slowly progressed, and at about the age of 24 involved the arms. When the patient was first seen, a few months before his death, the muscular atrophy was universal and the subcutaneous fat had completely disappeared. Even the hands were greatly wasted. There was a hollowing in the position of the thenar eminence, just as one sees in progressive muscular atrophy of the spinal type, and wasting in the interosseal muscles. There had been slight fibrillation in this case. The intercostal muscles were paralyzed. The wasting of the legs was extreme and the patient ultimately died with diarrhea. The muscles were found to be small and pale, the chief microscopic change being intense granular fatty degeneration of the fibers. A very few normal fibers were seen in some muscles. There was no increase of interstitial tissue. Careful microscopic examination revealed no morbid changes whatever in the spinal cord.

I am convinced that the mere distribution of the atrophy is not a sufficient basis whereon to distinguish special types of this disease. If, as it is believed, the primary trouble is some neural effect, the distribution of the atrophy would have to follow along physiologic lines represented in central functions. It is difficult to understand why certain areas for the atrophy should be selected as the prominent manifestation of a disease which is so generalized as an hereditary or infectious etiology would presuppose. On the other hand, if these primary myopathies are nothing but the late results of a transient polymyositis, as has been contended by some, it is also difficult to understand why there should be so much uniformity in the distribution of the atrophy in the so-called types. As a matter of fact, the types, as such, are exceedingly rare. The mixed or obscure cases are much more frequent and give strength to the view that these types, as such, do not really exist, but are the mere accidental clinical illustrations of a much larger pathologic process than they would presuppose or represent. In the myopathies there is partial preservation of the deep reflexes. In our case the reflexes were neither increased nor absolutely lost.

In the differentiation between spinal atrophy and primary dystrophy much has been made of the presence and absence, respectively, of muscular fibrillation. In our case, fibrillation seems to have been totally wanting, and it is usually regarded that absence of fibrillation is a cardinal sign of primary dystrophy. Gowers says that fibrillation is absent and that this is almost the invariable rule; and yet in his own case, referred to above, he mentions that there was slight fibrillation. Another point of value in the differentiation between progressive muscular atrophy of the spinal type and primary dystrophy is the absence in the latter of the reaction of degeneration or qualitative change in the electrical excitability. As in our case, only a quantitative loss of excitability to both faradic and galvanic currents was observed. On this point Gowers says very emphatically that in a primary dystrophy there is no trace of the reaction of degeneration.

In both progressive muscular atrophy of the spinal type and in the primary dystrophies, the sensibility remains practically normal. There may be in both slight transient pains of a dull character, possibly due in the former to irritation of the sensory elements, and in the

2. Clarke and Gowers, Med. Chir. Trans., vol. lvii, p. 247.

latter to the initial transient polymyositis, if, indeed, the dystrophies are at all myositic in origin.

As a result of my own observations, I feel like seconding Gowers when he remarks that "it seems, therefore, undesirable to form a separate variety of juvenile muscular atrophy, as Erb has proposed. Spinal atrophies may also be juvenile." So also may myositic atrophies.

100 State Street.

PRETUBERCULAR CONDITIONS AND THE TREATMENT OF ASSOCIATED ANEMIA BY HYPODERMIC INJECTIONS OF IRON AND ARSENIC.*

B. R. SHURLY, M.D.

Lecturer on Laryngology, Detroit College of Medicine; Laryngologist, Harper and Childrens' Free Hospitals; Attending Physician, Woman's Hospital.

DETROIT.

It is a well-recognized fact that pulmonary tuberculosis is the cause of more deaths than any other one disease, except pneumonia. In the state of Michigan our mortality record for some years has averaged above 2,500, while in Detroit our last report shows that 327 individuals died from this cause. We are all familiar with the fact that nearly one-seventh of all persons die of tuberculosis, and more than 50 per cent. of the remainder give postmortem evidences of tuberculous foci that had remained dormant or succumbed entirely to the antitoxic properties of our cells.

If this latter astounding and well-conceded fact is true, seven out of ten individuals that reach late adult life have been infected with tuberculosis.

The profession and the laity are awakened to the stupendous problem at hand. Many of us appreciate our inefficiency in battling with the ravages of this disease. We are especially apt to become therapeutic nihilists in the treatment of tuberculosis and to keep most prominently in mind the phenomena of hopeless advanced cases where all therapy has proved unsuccessful. It is with a hope of re-establishing an enthusiasm along the brighter and more encouraging fields of so-called pretubercular and early tuberculous conditions that I present this subject for your consideration.

Our daily routine work in the examination of the chest will divide our patients into five distinct degrees of disease.

First.—The acute miliary or the advanced chronic cases of pulmonary tuberculosis, generally incurable in any climate.

Second.—The moderately severe tuberculosis, a considerable number of whom will recover under proper treatment.

Third.—Early or incipient phthisis, 70 per cent. of whom it is estimated can be cured under favorable conditions.

Fourth.—Bronchopneumonitis and other non-tubercular lung diseases.

Fifth.—Cases with hereditary or acquired predisposition presenting prominent nutritional or constitutional changes, which we may classify for convenience as pretubercular conditions.

Every consumptive of the moderately or advanced type is putting up a fight for life, and we are helping him as best we can. The symptoms of hemoptysis or the chills and fever of the mixed infections are usually signals for a change of physicians or a consultation. It is at these times that the relatives and the physicians become thoroughly alarmed, and no financial or physical effort can be too great to satisfy the anxious minds at these crises.

A most conclusive demonstration of the ravages of the disease up to the time of hemoptysis or when the evidences of mixed infection become pronounced is offered us by the *x*-ray. Two facts are at once apparent. First, phthisis pulmonalis progresses to small cavity formation usually before ordinary skill in percussion and auscultation reveals it; second, *x*-ray examination at the period of hemoptysis or at the onset of fever frequently demonstrates extensive tubercular disease all out of proportion to the physical signs. A keen knowledge of the diagnosis and treatment of the so-called pretubercular stage, which antedates outward tubercular manifestations, is exceedingly important from all points of view.

Those who take careful histories of chest cases and carefully analyze a series of them will most certainly be impressed with the great number of persons who report a prevailing impoverishment or morbid state of the whole system for a considerable period before the apparent development of the local lesions. The general practitioner finds a deep problem in the relations of hereditary and acquired predisposition to pulmonary tuberculosis, and his therapeutic indications must be promptly met.

If I were to state that pretubercular phthisis pulmonalis was as distinctly a stage of phthisis as phthisis incipiens, with prominent fixed diagnostic signs and manifestations, I am confident many would assent. How many of us vigorously supply the therapeutic indications in this curable onsetting stage of tuberculosis? Are we justified in terming this condition tuberculosis from postmortem findings in individuals of this type? No, but the patients should have the benefit of our suspicions. It is impossible to overestimate the value to the patient or the state of timely applied hygiene and treatment in the pretubercular stages.

Some very interesting questions arise along this line of thought. First, where does the so-called pretubercular stage of phthisis end and incipient phthisis begin? Second, what methods of diagnosis have we that differentiate the stages and what treatment must be applied? Third, how much tuberculosis of the lungs may exist before ordinary skill in physical diagnosis can detect it? If we can successfully thresh out these problems and throw the brunt of our efforts on patients exhibiting the phenomena of the pretubercular or the incipient stages, the mortality from consumption would certainly be lowered. The maxim of Tyndale is certainly logical: "that localized tuberculosis does not endanger life of itself so long as the general nutrition begets a reasonable resisting power of the pulmonary tissues." And especially the pulmonary gland tissues, I might add. This is demonstrated to us daily in the postmortem findings in accidental deaths.

We may divide our tuberculous cases into two grand classes. First, the infections that have taken place in strong healthy individuals, who have no evidences of predisposition, acquired or hereditary, such as renowned athletes or prize cattle. Second, those cases which present a prodromal period of impaired general condition from all causes. It is this latter class that I wish to consider.

It is my belief that the pretubercular stage of phthisis, as we now classify it, is, in the vast majority of cases, nothing more than a latent unrecognized tuber-

* Read before the Wayne County (Mich.) Medical Society.

culosis, and the development of the bacillus tuberculosis in many is a problem in cell nutrition, the biochemic phenomena of which we do not understand. The examination of recruits for the armies and navies of the world, performed by men eminently fitted for this work, reveals the fact that many cases of latent or incipient tuberculosis are admitted. The French army shows a record of 7.2 per cent. who soon develop phthisis, while the percentage is higher in the Austrian, German and American armies.

In the light of our present knowledge, we are unable to draw sharp lines of distinction between the pretubercular and incipient stages. There is no tuberculosis without the tubercle bacilli. It is the province of this paper, then, to classify all phenomena that predispose or lead up to the actual demonstration of incipient phthisis. For convenience in arrangement I have adopted and modified the classification of Loomis:

1. Corpulence, viz., the relation of the body weight in pounds to height in feet.
2. Chest conditions. A—Conformation of the Chest. B—Chest measurements. C—Vital capacity.
3. Constitutional conditions. A—Lymphatism. B—Digestive disturbances. C—Chloro-anemia.
4. Character of pulse.

Allow me to exclude from consideration the factors of sex, age, race, previous or present disease of the lungs, septicemia or other thoroughly appreciated etiologic factors.

Corpulence is taken from the French, and it is used to express mathematically any departure from a standard of ratio between weight and height. According to the military tables, a man, at height five feet eight inches, should weigh 150 pounds, having an average corpulence of 26.47. The ratio shown by dividing the weight by the height is 26½ as a standard. We appreciate entirely the important significance in progressive loss of weight without a demonstrable cause as a very constant symptom of onsetting phthisis. This fact of a continued loss in body weight is usually recognized as of importance only when it is followed by a hacking dry cough some months later. Accurate scales and a measurement of height in this class of patients are much more necessary than is generally admitted. A record is certainly as valuable in determining the nutrition of tuberculosis as the weight chart is in infant feeding. A majority of my patients have given a history of steadily increasing loss of weight before the lesions were diagnosed. Loomis reports 50 per cent. in a series of forty cases. Many thousand military observations have established a normal standard of corpulence for men as 26, while the observations of Bonchard show that women should have a normal of 23. A corpulence of 21 is considered abnormally thin.

Associated with steadily increasing loss of tissue is the prominent symptom of general malaise. The daily routine is marked by a substitution of will power for natural automatic power. We may note increasing motor debility, the patient may complain of being "sawed off at the legs," or a weakness in the knees. Sensations become abnormally accentuated or dulled; sleep becomes broken or profound; digestion, changeable respiration, superficial and slightly hurried, as 22 or 24. Many cases show acceleration of the heart with relative falling off of arterial pressure. When these symptoms of disturbance are present, and after the exclusion of acute and chronic diseases, we thoroughly examine the chest and nothing definite can be determined; a true latent tubercular condition exists.

When this complex of symptoms arise, we should give additional attention to the predisposing group of conditions previously enumerated. We are well aware that a single tubercle requires two to four weeks in its process of evolution, and the foci must break down and infect often numerous areas before clinical symptoms appear. Let us consider, further, what danger signals of a possible onsetting tuberculosis are reliable aids to diagnosis.

Our insurance companies are particularly interested in all observations of dangerous chest conditions. We are well aware that there may be many deviations from the normal standard of chest conformation without in any special manner increasing the liability to phthisis. The postures of childhood or occupation may lead to faulty conformations without increasing the tendency to the invasion of the tubercle bacilli. Our suspicions are aroused when we have presented for examination the lean, hollow chest, with marked subclavicular depressions, with prominent spaces between the ribs, with projecting scapulæ, and decided diminution of the antero-posterior diameter.

Considerable and more valuable evidence may be obtained by scientific measurement of a chest. French military observers have placed much importance on what is called a determination of "the vigor of constitution." It is taken successfully in this manner: "Two ordinary measuring tapes are sewed together and the point of juncture rests in the center of the spine. In men the estimations are made at the nipple level, while in women the line of the ensiform cartilage is preferred. The double tape aids in measuring the difference in expansion of the right and left sides, as well as the total chest mobility. The right is usually at least a half-inch larger, although both lungs should show almost equal expansion." A circular measurement below 35 inches is abnormal. The average of measurements taken at the end of forced expiration and at the moment of forced inspiration is defined as the thoracic perimeter. The vigor of constitution is the relation between the perimeter and the height. The thoracic perimeter of a person, according to the French, should never be lower than one-half the height.

The question of vital capacity is important, but the deductions are more subject to error. Considered from its own standpoint alone, it is of little value. Much depends on the previous education of the patient and the experience which the physician may have had in the use of the spirometer. When considered in relation to age, weight and particularly height, important data on respiratory capacity may be obtained. Standards have been made from a great number of cases, and we find that the relation between the height and the capacity should be one to three inches in men and one to two and six-tenths in women. A man of five feet eight inches should not fall under 204 cu. inches. The interrelation of corpulence, thoracic perimeter and vital capacity should be considered valuable aids to a determination of genuine predisposition to pulmonary tuberculosis.

We are well aware that pneumonia, pleuritis, infectious diseases, occupations, direct exposure, etc., are the great etiologic factors, but these are eliminated, as I have previously stated, because they are centers of infection from local causes that can be demonstrated. They do not constitute the true pretubercular conditions. The pretubercular stage in some individuals is marked by a constitutional condition called lymphatism. Pathologic adenoids, tonsils, or hypertrophies interfere

with nasal and nasopharyngeal drainage, the cervical lymphatic chains are taking in septic material and the bronchial glands are involved in like pathologic processes. A latent tuberculosis which it is impossible to diagnose may exist at this time or this type of glandular hypertrophy may take on infection and become a glandular tuberculosis of the lungs.

Another class of individuals may show a series of digestive disturbances prior to tubercular infections. There is a genuine relation between so-called indigestion that exists for months or years antecedent to phthisis. The malnutrition attending disorders or digestion renders the system much more vulnerable to invasion by the bacilli. Over-indulgence in indigestible food has increased this symptom.

It is especially the relation of chloroanemias to the development of phthisis that I wished to discuss and present for your consideration. Some investigators have claimed that an actual antagonism exists between tuberculosis and chlorosis. Some consider chlorotics well under way in the destructive processes of phthisis. However this may be, we can certainly be impressed with the constant attendance of anemic blood changes in cases that show imperfect chest development and continuous loss of weight for which no cause is apparent. It is especially a danger signal in men of tubercular age. Chlorosis ordinarily is not accompanied by loss of weight nor abnormal chest conditions. While the examination of the blood in the late stages of consumption is of no practical value, except that the absence of eosinophiles may be looked on as an unfavorable prognostic sign, examinations in the pretubercular conditions all show that the hemoglobin is diminished out of all proportion to the loss in red cells. Henocque, an extensive observer, says that a diminished supply of oxyhemoglobin characterizes tubercular chloroanemia. The hemoglobin never falls as low as in chlorosis. Early phthisis is usually marked by a slight leucocytosis, slight diminution of the red blood corpuscles, and a moderate reduction in hemoglobin.

Laache has found 29 per cent. of tubercular chloroanemias in the early stages with a diminished hemoglobin. Labbe, who has investigated extensively, regards chlorosis as a symptom of some other affection often as a first manifestation of a latent tuberculosis. If we should consider chlorosis or the simple anemias just as a pleuritis to be many times nothing more than the initial evidence of a slumbering tuberculosis, the proper hygienic and medicinal treatment can produce a complete recovery. A number of cases of anemias showing with many of the other symptoms of impaired resistances enumerated have come under my observations during the last year or two. The method of treatment has proved so successful that the plan may be of interest.

I have selected only a few cases as a preliminary report, as it is necessary that six months or a year should elapse before we can determine our results. Even the therapeutic nihilist will admit that iron, arsenic and the hyphophosphites have a wide field of usefulness, and as these are used hypodermically the effects are more pronounced, more rapid and permanent. Wherever iron is indicated, it can be administered in the form of the green ammoniated citrate, while arsenic can be given as the arsenate of soda or the arsenate of iron. The injections are given deeply into the muscles of the buttocks or back. There is almost no pain attending the operation and in indicated cases the general feeling of well-being which follows the proper dosage allows the treatment to speak for itself. A blood examination should be made, after which punctures may be given daily. An increase of 5 to 10 per cent. hemoglobin a week can be expected.

It is unnecessary to consume time with a consideration of the therapeutic action of these substances. Nothing, however, has been written in English on the subject of the hypodermic use of these medicinals. Italian and French literature since 1890 has had much to say on the method, and the fact that it remains to-day as the usual treatment is sufficient recommendation for its usefulness.

The green ammonio-citrate can be introduced into the system without danger in doses ranging from .05 to .1 gram, while the arsenate of soda is given in .001 to .002 gram. The treatment should be started with the smaller dosage. A full dose of iron by this method produces a reaction within five minutes. A feeling of tension in the head is experienced, the face flushes and tingling sensations are noticed. There may be waves of nausea or sudden vomiting if a larger dose than 1½ grain is administered. A full dose gives a sensation of a warm flush or glow over the entire body. The pulse quickens and a general feeling of well-being follows the proper dose. The arsenate shows its usefulness as a general reconstructive and stimulant to nutrition. The hypodermic method obviates all injury to the teeth or stomach and constipation is not produced. It is contraindicated in fever and active hemorrhage. Iron and arsenic are too well known to need any argument in their favor. The hypodermic method produces all the good effects more promptly and without the serious results produced when these remedies are taken by the stomach.

The character of the pulse in determining the pretubercular stage of consumption is quite important. Dr. Wells, of Chicago, and Dr. H. P. Loomis have made excellent reports in regard to their findings along this line. Two prominent characteristics are noted. A change in position has but little influence on the very thin. The examination must be made some hours after eating and when the patient is free from excitement. Ordinarily the pulse is found to vary on an average of fifteen beats in a healthy man. I am unable to make practical use of this observation, as few patients under examination are not subject to the pulse effects of excitement. The relative feebleness of arterial pressure is an important sign. The normal arterial pressure of 15 to 18 is found by French investigators to be always less than thirteen and often only ten. The lessened arterial pressure may be nothing more than a factor in the problem of increased susceptibility. The pulse of lowered pressure is usually tense and hurried, 100 to 120. In the early stages of phthisis the sphygmograph shows a sudden ascent and descent of the curve. The arterial pressure can be readily taken in the office with a Gärtner's or preferably a Cook's pressure apparatus.

In conclusion, it is evident that no one or two signs can be relied on as conclusive proof of an approaching phthisis. Yet, taken together, we are given enough danger signals to warn us. Active measures may be enforced at this stage with the best results. If the strenuous fight against the ravages of tuberculosis was advanced to the latent tubercular stages, the stages of lowered resistance, consumption would not attain its high mortality. Hypodermic medication with iron, arsenic, hyphophosphites and strychnin offers a prompt and powerful reconstructive adjunct to the necessary pure air, good food and sensible hygiene.

HYDATID CYST OF THE LIVER IN CHILDREN.*

WILLIAM FITCH CHENEY, M.D.

Professor of Principles and Practice of Medicine, Cooper Medical College; Physician to Lane Hospital.

SAN FRANCISCO, CAL.

In children, hydatid cyst of the liver appears to be a very rare disease, especially in the United States. Our text books on pediatrics dismiss the subject with but few words. Koplik, so far as I can find, makes no reference to it at all in the last edition of his work. Rotch says "Echinococcus cysts are so rare in early life that they need merely be mentioned as of possible occurrence." Holt says "Echinococcus disease of the liver, while rare among adults in this country, is almost unknown in children. I have been able to find but two recorded cases in America." American medical journals likewise pass the matter by without comment. In the Index Catalogue of the Library of the Surgeon-General's Office, brought up to 1903, there are but four references to the subject of hydatids in children, two in Italian literature, one in Russian, and one in French, but none at all in American journals.

This infrequency of the affection in children is not, however, a peculiarity of the United States. Peiper[1] says: "The number of children infected appears very small when we consider the fact that at this period of life, in consequence of close association with dogs, they are particularly endangered. This observation is confirmed by all statisties. In the Pomeranian investigation, among 139 patients, only 13 were under 15 years of age." It seems odd, therefore, that within ten years, with a comparatively small material falling under my observation, I have seen two cases of hydatid cyst of the liver in children. Because of the rarity of the affection at this time of life, it has seemed that reports of these cases deserve to be published in detail, and I present them with the hope that their publication may lead to the discovery of others on this coast.

CASE 1.—An Italian boy, aged 7, was brought to the children's clinic at Cooper Medical College, March 31, 1897.

History.—His symptoms were vague; occasional pain in the right side, head ache now and then, and during the week previous occasional vomiting spells. His appetite was fair, he slept well at night and his bowels moved regularly. The mother had noticed a swelling in the boy's right side about two years previous, that had never disappeared since its discovery, but rather had grown a little larger as time went by; and it was this that induced her to bring the child for examination.

Examination.—He was a bright, intelligent looking little fellow; his face indicated perfect health, but his body and limbs were somewhat emaciated. There was no icteric hue to be detected in skin or conjunctivæ. The tongue was heavily coated with a yellowish fur. In the region of the liver a swelling was perceptible on inspection, extending downward to the level of the anterior superior spine, and inward to the median line. On palpation this swelling was evidently somewhat tender; it was smooth in outline, not nodular; hard throughout most of its extent, but in one part, about three inches below the border of the ribs, was distinctly fluctuating; there was a sulcus or groove, perceptible to touch and to sight, running across the swelling just below the border of the ribs, apparently separating the mass below from the liver above. Finally, the lower border of the tumor was sharp and distinct, so that the examining fingers could easily be inserted beneath it; and the tumor moved on deep inspiration.

On percussion, there was dullness over the area of swelling, directly continuous with the liver dullness above, but not extending to the lower edge of the tumor as perceptible on palpation; for tympany replaced the dull note across the lowest portion of the tumor, over a zone about two inches in width. The dullness extended to the median line internally and to the axillary line externally. Directly back of the axillary line and posteriorly a tympanitic note was found, the dullness not extending in that region below the normal liver dullness. The urine was examined and found normal; the heart and lungs likewise gave no evidence of disease.

Ordinary means of examination were supplemented by the use of the *x*-ray, at that time still a novelty. The fluorescent screen showed the upper border of the liver, rounded and distinct, rising and falling with each respiration; but it failed to give any idea of the relation of the parts below the level of the ribs, and, therefore, left the character of the tumor as much in the dark as before. It was next decided to resort to diagnostic aspiration with a needle at the point where fluctuation had been found. By this means a fluid was obtained that was turbid and looked like thin pus. Under the microscope it showed broken down pus cells but no hooklets of hydatids.

Diagnosis.—Plainly the differential diagnosis concerned two organs: the liver and the right kidney. With regard to the liver, was this a malignant tumor, an abscess or a hydatid cyst of this organ? With regard to the kidney, was it a sarcoma or a pyonephrosis? Malignant tumor of the liver was excluded by the smooth contour of the swelling, the normal upper border as shown by the *x*-ray, the slow growth of the mass and the moderate emaciation and constitutional disturbance of the child. Liver abscess could not be positively excluded; it is rare in children, but its main signs are those that were present in this case, viz.: enlargement of the liver, usually downward, with tenderness over the swelling; and its chief symptoms are gastrointestinal—coated tongue, loss of appetite and occasional vomiting. The symptom lacking from the clinical picture of liver abscess was fever, which was never found in this boy during the time he was under observation. Nevertheless this condition was looked on as one of the possibilities, especially after the hypodermic needle showed the presence of pus in the swelling. As for hydatid cyst of the liver, there was nothing to speak for it, after the microscope failed to show hooklets in the fluid withdrawn by the needle. If this fluid had been clear, chemical examination would have been made for albumin and sodium chlorid, even though no hooklets were found with the microscope; but its turbidity misled us and this chemical examination was not made. There was no characteristic fremitus present, such as is supposed to be a diagnostic sign of hydatid cyst, and nothing in the clinical history pointed to this affection more than to another.

The argument in favor of the kidney as the point of origin of the tumor, rather than the liver, was the apparent line of demarcation between the lower surface of the liver and the tumor proper; for there was a depression across the swelling, just below the lower border of the ribs, which could be both seen and felt. In favor of a diagnosis of sarcoma of the kidney was the fact that the tumor had pushed the bowel in front of it, and, therefore, came probably from behind the peritoneum. The condition is not uncommon in childhood and the character of the tumor it produces is not unlike that which was presented here. The point against sarcoma was the absence of bloody urine at any time. The diagnosis of pyonephrosis had as its basis the pus found on aspiration, and the chemical examination made of the fluid obtained, to determine whether it was urine. The addition of nitric acid to this fluid after partial evaporation gave crystals, which under the microscope strongly resembled those of nitrate of urea.

Operation.—In any case it was evident that operation was necessary, and that an exploratory incision would reveal the exact nature of the swelling and determine the proper plan of procedure. This was, therefore, advised, the parents consented and the boy was sent to Lane Hospital, where he was operated on by Dr. Emmet Rixford, April 11. When the abdomen was opened it was seen at once that the tumor involved the structure of the liver; but it was thought, from the surface appearance, to be an abscess of the liver, and the organ was, therefore, stitched to the edges of the incision, the wound packed with gauze and the boy put back to bed to await the formation of adhesions before opening the abscess.

* Read before the California Academy of Medicine, March 29, 1906.

1 Peiper: "Echinococcus Disease," Deuts. Klin.,

The secondary operation was performed April 14, 1897. On incising the tumor, instead of a gush of pus, as was expected, there came out a thin turbid fluid and numerous transparent, glistening cysts, the size of small grapes, that at once settled the diagnosis as hydatids. The cavity was washed out and the wall of the mother cyst removed. This cyst when distended must have measured between 4 and 6 inches in diameter. After its removal, there still seemed to be too much liver left for so small a boy. A long hypodermic needle was, therefore, passed from the cyst cavity upward into the liver beneath the ribs, and with this there was withdrawn perfectly clear, transparent fluid. An incision was then made in the track of the needle, and another cyst, equally as large as the first, evacuated of its contents of fluid and daughter cysts. Drainage tubes were inserted, the wound dressed and the boy put back to bed. He made a slow but perfect recovery. The purulent fluid obtained with the hypodermic needle before operation came from the lower cyst, which had begun to suppurate. The upper cyst, lying beneath the ribs, contained the characteristic clear fluid of hydatids. The groove across the swelling, which had proved such a stumbling block in diagnosis, was the depression between the upper and the lower cysts. The two were separate and perfectly distinct.

CASE 2.—A boy, aged 10, was brought to the children's clinic on Jan. 4, 1906. He was born of Italian parents in Buenos Ayres, Argentine Republic. In May, 1903, the family had moved to Oregon, and again one year later to the San Joaquin valley, California, where the boy lived until he was brought to San Francisco in November, 1905, on account of his health.

History of Disease.—His illness dated back two years to an attack diagnosed typhoid fever, which lasted for only three weeks. Following that attack he remained weak and complained much of pain and fullness in the right side, especially on stooping to pick up objects from the floor. It was then discovered that he had an enlargement in the right side of his abdomen, which never subsequently disappeared. In October, 1905, he had an attack of fever, with increased pain in his right side, this attack lasting three days. He was then brought to San Francisco, on the advice of a Fresno physician, and taken to the Children's Hospital. He remained under observation in that hospital for six weeks. His parents were finally told that the boy had an enlargement of the liver, but that the case was not one for operation. Then in the search for further advice his parents brought him to the Cooper College Dispensary.

For two years the boy had persistently complained of a sense of weight and fullness and frequently of sharp pain in his right side; but during this time had gained in flesh and had never seemed ill except for the feverish attack in October, 1905. He had always had a good appetite, there was no vomiting, his bowels were regular, there had never been any jaundice, and never any edema of feet or limbs.

Examination.—On physical examination he was found to be a well-nourished, healthy-looking boy. The heart and lungs showed no disease, the urine analysis was normal. The feces showed no abnormalities. In the region of the liver a rounded mass was visible, extending as low as the navel and as far internally as the median line. This mass was smooth, rounded and elastic. Manifestly it took its origin from the under surface of the liver, because the sharp lower edge of the liver could be felt projecting from the tumor's upper surface, just below the border of the ribs. The mass did not seem to be at all tender. No hydatid fremitus could be elicited. Percussion dullness was found over the mass, continuous above with the normal liver dullness, the total extent in the mammary line being 19 c.m.

Blood Examinations.—Numerous blood examinations were made by Dr. H. R. Oliver. On January 4 the hemoglobin was 80 per cent., the red corpuscles 4,250,000, the white corpuscles 25,000; and the differential count showed: polymorphonuclears 68 per cent., large lymphocytes 8, small lymphocytes 24, eosinophiles 2. January 6 the leucocytes numbered 14,000; January 14, 15,000. January 22 the hemoglobin was 70 per cent., the red corpuscles 3,750,000, the white corpuscles 16,000, and the differential count as follows: Polymorphonuclears 70 per cent., large lymphocytes 3 per cent., small lymphocytes 25 per cent., eosinophiles 2 per cent. From these reports it will be seen that while a leucocytosis of moderate grade was constantly present, there was never any marked increase in the eosinophiles.

Diagnosis.—From the physical examinations repeatedly made it seemed clear that the liver was the organ concerned, that the tumor originated from it, that this tumor contained fluid of some sort, and was not simply the liver of chronic passive congestion, fatty infiltration, or hypertrophic cirrhosis. Malignancy was excluded by the boy's state of blood and nutrition, and specific disease by the lack of history or signs. The conclusion was therefore inevitable that we had to do with either hydatid cyst or abscess. In favor of hydatid cyst was a history of constant intimacy with dogs, with which pets the boy had been closely associated in Buenos Ayres, with the absence of chills, recurring fever, emaciation, or constitutional disturbance during the two years that the enlarged liver had obviously been present. In favor of abscess there was nothing except the leucocytosis, which was not so high as it should have been, with sepsis, and lacked the characteristic predominance of polymorphonuclears. To settle the diagnosis an aspirating needle was introduced through the abdominal wall January 20, directly over the lower portion of the tumor, where elasticity seemed most definite. The needle at the first puncture withdrew the clear, water-like fluid diagnostic of hydatid cyst, and in this fluid hydatid booklets were at once found with the microscope. The diagnosis thus being positively settled, the case was transferred to the surgical clinic for treatment.

Operation.—On January 23 the boy's abdomen was opened by Dr. Stanley Stillman at Lane Hospital. The cyst was found to originate from the under surface of the liver. It was aspirated, and when empty the wall was peeled from its bed and so removed intact. No daughter cysts were found within its cavity. When distended, it measured about 5 inches in diameter. The wound was drained and the boy made a good recovery, except for a fistulous track that healed slowly.

DISCUSSION OF THE DISEASE.

The points bearing on the diagnosis of hydatid cyst of the liver in children, as brought out by the preceding cases, are the following:

1. *History.*—Inquiry should always be directed to the child's intimacy with dogs. The second child lived with dogs in Buenos Ayres, played with them, slept with them, ate with them, and kissed them. As the *Tænia echinococcus* is a parasite of the dog family, such a history is extremely suggestive of the possibility of infection of the child. The history of illness is mainly one of symptoms due to mechanical pressure by the cyst: pain, fullness, weight, dragging and interference with movements such as stooping, together with gradual enlargement, visible to parents and to child. The general health—digestion, nutrition, strength—is interfered with slightly or not at all, even though the symptoms last for months or even years. Fever is not a symptom unless the cyst has suppurated, and then the clinical history may become one of sepsis, as from any other collection of pus.

2. *Physical Examination.*—It is usually easy to determine that the tumor is situated in the liver, though the problem is not always a simple one, as the first case reported proves. The fact that the tumor contains fluid of some sort is also usually apparent from its rounded outline and the elastic feel of it. But the peculiar thrill described as the hydatid fremitus is not always present—it was certainly absent in both the cases reported, and therefore can not always be depended on for diagnosis.

The aspirating needle best answers the question as to what the cyst contains; and the clear, transparent fluid of a hydatid cyst is diagnostic even to the naked eye. It must not be forgotten, however, that the introduction of an aspirating needle into a hydatid cyst is not without

danger. In addition to the possibility of damage to blood vessels or to intestines, such as exists with any puncture of the abdominal cavity, there are in this instance two other dangers: (a), autosemination, or the scattering of hooklets in the abdominal cavity by subsequent oozing from the cyst at the site of the puncture; or, (b), symptoms of poisoning such as fever, nausea, vomiting and collapse, due to the toxicity of the fluid and its absorption after leaking out at the site of puncture. These dangers must be borne in mind and diagnostic puncture should not be looked on as a procedure without risk.

3. Laboratory Examination.—Under the microscope the sediment from hydatid fluid usually shows the peculiar bodies called hooklets, found in no other fluid but this; but their absence does not negative the diagnosis. The blood usually shows a moderate leucocytosis, persistent so long as the cyst remains; but the eosinophiles are not necessarily increased here, though Cabot says: "Eosinophilia is the rule in hydatid disease without suppuration."

Except for the examination of the hydatid fluid obtained by diagnostic puncture, and except for the blood count, there are no methods of laboratory diagnosis available in these cases.

BACTERIURIA.

REPORT OF A UNIQUE CASE.

G. PAUL LA ROQUE, M.D.

Lecturer and Bedside Instructor in Surgery, University College of Medicine; Clinical Assistant St. Luke's and Virginia Hospitals, Etc.

RICHMOND, VA.

I believe the importance of this affection to be generally underestimated and am positive that the condition is vastly more common than is generally supposed.

The term bacteriuria implies the presence of bacteria in the urinary tract above the compressor urethræ muscle. Micro-organisms are always present in the normal male urethra, certainly its anterior portion, and may be found in the urine of most people provided it is voided through this structure. Aside, however, from the trivial urethral discharge occasionally provoked by certain of these organisms, their presence in the anterior urethra causes no symptoms. Apart from the bacteriuria, which always exists as a part of pyuria, there is a simple bacteriuria, without pus, or at least such small quantities of this as to be of minor clinical significance. There is this difference regarding the etiology of the two affections: Pyuria always indicates suppuration in some part of the urogenital apparatus; simple bacteriuria may indicate the earliest or terminal phenomenon of true inflammation with little or no pus formation, or an eliminative process, the bacteria being deposited in the urinary conducting apparatus from the blood and lymph, or having gained entrance to these organs, through continuity or contiguity from anatomically related structures.

The organisms most frequently deposited in the urine from the circulation include the typhoid bacillus in cases of typhoid fever, the tubercle bacillus in miliary tuberculosis, staphylococci and streptococci in general septicemia and pyemia, rarely the pneumococcus, and the undetermined organisms of scarlatina and smallpox, as manifested by the urinary phenomena of these infections.

From continuity and contiguity of structure, the most frequent causes of bacteriuria include urethritis, prostatitis, seminal vesiculitis, colitis, enteritis, perinephric abscess, peritonitis and any focus of inflammation in the female generative organs. Every case of spinal cord disease with paralysis of the sphincter vesicæ is attended by bacteriuria.

MICRO-ORGANISMS CAUSING THE CONDITION.

By far the most frequent organism causative of simple bacteriuria is the *Bacillus coli communis*. These organisms readily gain entrance from the intestine in cases of chronic constipation, acute enteritis, dysentery, colitis, typhoid fever; or from the prostate, seminal vesicles and urethra, where they are abundant in chronic inflammatory processes involving these structures. They frequently enter along the ducts leading to the bladder and are carried by instruments from the urethra. In women with unclean habits, relaxed sphincters, fistulous communications or even slight wounds of the genito-urinary organs, bacteriuria is common. Ascending vulvovaginitis is a common cause. From perinephric abscess, the colon bacillus and other organisms penetrate the kidneys. From the intestine and all retroperitoneal sources they may enter the ureters. Many cases of bacteriuria are consecutive to colitis and frequently a history of dysentery may be elicited.

Generally, the colon bacillus is found in all forms of bacteriuria, often in pure culture. In the typhoid form of the disease they may be associated, but often the typhoid bacillus is present alone. Of 132 cases reported by Elliott, the *Bacillus coli communis* was the infective agent in 75. Other bacteria found were streptococci, staphylococci, bacillus proteus, bacillus subtilis, sarcinæ and undetermined bacteria, alone and in combination.

FREQUENCY OF THE AFFECTION.

The frequency of the affection can scarcely be even approximately estimated. A single intravesical instrumentation practically always carries with it bacteria from the urethra. Such bacteriuria is generally transient in duration. Should the bladder or posterior urethra be traumatized by the operation it will almost certainly result in inflammation.

Proctitis, hemorrhoids and other lesions in the rectum are attended by bacteriuria so frequently as to make it safe to believe that this complication exists in nearly every case. Its frequency in old women and as an eliminative process in cases of typhoid and many other infectious fevers have been mentioned. Typhoid bacilli exist in the urine in from 20 to 30 per cent. of cases of typhoid fever usually in pure culture, appearing generally in from the second to the third week of the disease, commonly associated with albuminuria, without pus, and rarely producing the morbid changes of cystitis, even though they persist for years. Young, however, reports two cases of true chronic cystitis due to the typhoid bacillus.

PATHOLOGY.

With the exception of hyperemia and excessive mucous secretion along the whole urinary tract and generally slight albuminuria, simple bacteriuria in a healthy, well-drained urinary apparatus produces none of the changes of true inflammation. In the presence of partial or complete obstruction or diminished vital resistance in these structures, it is easy for a simple bacteriuria to cause the phenomena of true inflammation with pus formation.

SYMPTOMS.

When first voided, the urine is cloudy, generally acid in reaction and of a penetrating, offensive odor. The turbidity is diffuse, does not settle on standing, and can

not be removed by acidulation, filtration or sedimentation. The bacteria may be sedimented by centrifugation after the addition of alcohol. There may or may not be a trace of albumin. Microscopic examination shows a field swarming with actively motile bacteria.

The local symptoms when present are: Generally slight frequency of micturition, mild *ardor urinæ,* occasionally incontinence, and in children there may be nervous disturbances. Rarely a slight mucoid urethral discharge may be noted. So long as the epithelium of the urinary tract remains healthy there is no absorption of bacterial toxins. If abrasions exist, or if from the imperfect drainage incident to prostatic hypertrophy or urethral stricture, the bladder epithelium from prolonged contact with the concentrated toxins loses its vitality, absorption occurs, and mild fever, with lassitude and digestive and nervous disturbances, may be noted. In many cases there are no subjective signs.

DIAGNOSIS.

It is essential to distinguish simple bacteriuria from that in combination with pus. In the latter there is always positive pyuria, in the former never so. Pyuria implies an area of suppuration in some part of the genito-urinary tract and is generally associated with symptoms referable to its location.

As to the point of entrance of the micro-organisms into the urinary tract, it may be said that whenever they enter through the kidneys as in septicemia, typhoid or scarlet fever, there is always a positive albuminuria. When they enter below the renal pelvis, as from the genitalia and from the lower intestinal tract, from instrumentation, ascending inflammation, pelvic disease, colitis or proctitis, the presence of albuminuria is dependent on the previous condition of the kidneys

As to the nature of infection, alkalinity of the urine always means infection by either the staphylococcus or bacillus proteus vulgaris. All other organisms, save when mixed with these, produce an acid urine. The history of the case will suggest the probable causative organism, though it must be remembered that the colon bacillus is by far the most frequently found germ.

TREATMENT.

Treatment has for its purpose removal of the cause, prevention of true inflammation and elimination of the organism.

Intestinal and urinary antiseptics, such as urotropin salol or boric acid, with large amounts of drinking water, are indicated. Vesical instrumentation and (unless cystitis is actually present) irrigations are to be avoided. The traumatism incident to these procedures is apt so to diminish local resistance as almost certainly to result in true inflammation. Many cases of postoperative cystitis can be avoided by judicious efforts to avoid catheterization. In patients with spinal cord lesions associated with paralysis of the compressor urethræ muscle, bacteriuria is a constant attendant affection; and when, in addition to this, ammoniacal urine is allowed to be retained, cystitis is sure to result. Since in these patients the cause of death is so commonly ascending urinary infection, the dangers of bacteriuria should be recognized. Every one knows the importance of thorough, gentle and rigidly aseptic bladder drainage as a part of the treatment of these cases.

For the cases so frequently dependent, especially in old people, on colitis and constipation, free purgation, with regulation of diet and intestinal antiseptics, are essential. Janet often practices, in addition, colonic lavage for two or three months.

REPORT OF A UNIQUE CASE.

History.—An obese, slightly sclerotic, ignorant, partially deaf maiden, aged 55, suffered during the summer of 1905, a a rather severe attack of dysentery. Within a month after this, she began to notice frequent burning urination and the passage of foul, intensely turbid urine, the act of micturition being followed by a sensation of having incompletely emptied the bladder, but at no time did she pass blood or gravel. These signs became progressively but gradually more marked and caused her great mental anxiety, fearing that she was suffering from some dreadful disease. She consulted her local physician, who at once made a vaginal examination. She was told that there was a peculiar "growth" in her vagina, and the physician removed a piece of this and sent it to a pathologist for microscopic examination. The latter reported the tissue to be fibroid in character. Ever since the tissue was removed she has concentrated her mind on the genital apparatus and has been in constant fear of cancer.

She was referred for treatment to Dr. Stuart McGuire, to whom I am indebted for the privilege of studying and reporting the case.

Examination.—Vaginal examination showed a small, rigid canal with the hymen present and save in the upper portion intact. In the upper portion there was a wedge-shaped deficiency of about one-half inch. When she stands erect, there is slight bulging of the anterior vaginal wall.

Cystoscopic examination showed slight general redness of the mucous membrane of the bladder, but no real sign of disease.

Urine.—The first specimen was so extremely turbid as to give at first sight the appearance of chyluria. This material, however, was not present. The turbidity was diffuse and did not precipitate on long standing. The urine was foul and penetrating in odor, acid in reaction and contained no albumin. Microscopic examination showed amorphous acid urates, and every field was swarming with motile bacteria, but pus was absent.

REMARKS.

A diagnosis of bacteriuria was positive and this was the source of all the trouble. The growth in the vagina was the hymen, from which a wedge-shaped piece had been removed. The slight bulging of the anterior vaginal wall which was not sufficiently marked to be called cystocele was doubtless due to the incision in this structure produced for removing the wedge-shaped piece of hymen. The woman was the victim of pronounced cancerophobia.

The bacteriuria in this case definitely followed dysentery; the organisms entered the urinary apparatus below the kidney, as shown by the absence of albumin.

THE STRENUOUS LIFE AND ITS EFFECTS IN DISEASE.*

S. T. RUCKER, M.D.

MEMPHIS, TENN.

At the outset I desire to state that I am not opposed to the strenuous life when it is safeguarded by proper diversion and sufficient rest; but there is a wrong way to live the strenuous life, and it is of this I desire to speak. Work, *per se,* never kills, but it is the way one works. A bank account kept by continuous deposits in excess of the checks drawn is a good business method. It is when the account is overdrawn that one receives notice to make good the deficit. Mental and physical exercise in legitimate channels is good. It promotes health, happiness and a long life, but when by prolonged endeavor under high pressure an individual overdraws

* Read at the Seventy-third Annual Meeting of the Tennessee State Medical Association, Memphis, Tenn., April 10-13, 1906.

his supply of energy he must replenish it or suffer the consequence. The temperate life, the systematic methods of diversion and relaxation as practiced by Mr. Gladstone, the great English statesman, and Grover Cleveland, twice president of the United States, is well known and will serve to illustrate the proper way to live the strenuous life and to succeed without sacrificing health and strength. Mr. Gladstone not only had regular times for diversion and recreation, but when the affairs of state became too onerous and tiresome he would turn loose all duties and go to his country home to rest. There he would walk, run, chop wood and do other exercises to divert the mind and to invigorate the body. At 85 years of age he retired from the premiership of England in good health and with a clear, active mind. We are all familiar with Mr. Cleveland's fondness for fishing and hunting, and remember while he was president how often he would lay aside official duties and go to the bays of Virginia or North Carolina to indulge in his favorite sport. At 70 years of age he is still in active life, hale and hearty. The quality of a man's thought, energy and ideals depends largely on the condition of his health. The now famous saying credited to Dr. Osler that a man is practically useless after 60 years of age is true of most men, but it should not be, and would not be, if we would remember that "all work and no play makes Jack a dull boy." Every busy man should have a hobby to which he can devote his leisure; he should also have seasons for sport in the country, like hunting and fishing. A married man should spend more time with his family and in reading wholesome literature. Sunday, the best day of all for rest and recreation, is perhaps the most neglected. It is not only a religious duty to cease all labor every seventh day, but it is essential to the health and well-being of man. He will do better work and live longer.

HIGH PRESSURE OF EDUCATION.

The physiologic functions of the human economy are governed by the simple law of demand and supply. The executor of this law is the cell. It contains a life principle called the nucleus. The nucleus gives the cells energy and the power to reproduce themselves rapidly and manifold, when supplied with the proper food, as found in the healthy blood current. Every tissue and part of the body is an aggregation of cells, like the bricks that make up a wall. The process called metabolism is cellular activity. By thought and muscular action tissues are consumed; by cell proliferation they are replenished. In order that the proper equilibrium be maintained in this process and the cells be not consumed faster than they multiply, it is decreed that we must take time to eat, rest and sleep. Prolonged endeavor, overwork and worry, with insufficient food and rest, break the equilibrium, exhaust vitality and invite disease. This condition is too prevalent in our American life. We go under high pressure and our pace is too rapid. Our schools and colleges, where we should be taught how to live, are not free from this spirit of stress and strain. Students are goaded to tasks beyond their powers, and, being anxious to stand at the head of their classes, they hurry their meals, overstudy, take little time for rest and, as a natural consequence, many become nervous wrecks. I have under observation now a patient who is a sad illustration of this forcing method of pedagogy. He had an active mind and bright prospects ahead for a useful career. He studied hard and was cramming for his final examinations before graduating from college, when a collapse came, and his mind was left a chaotic wreck. There is a mental incoordination and an inability to concentrate his thoughts. His talking and writing are centrifugal and erratic. I have undertaken the task of re-educating him into mental co-ordination and concentration, with probabilities of never succeeding.

Analyze the graduating classes of the best female colleges, and the crop of neurasthenic girls will out-number those who are able to enter on the duties of married life. I have under treatment now one of these unfortunate girls. She is anemic and her brain is not properly nourished. Her mind is unstable and her ideas are erratic. She has overdrawn her account and is now trying to make good the deficit by rest and forced feeding.

BUSINESS LIFE TOO STRENUOUS.

In business and professional life the conditions are even worse. The average business man is always worried and overworked. He has no leisure. He sees so little of his family they scarcely know him. He is chained to commercialism of thought and taste. He worships it by day and dreams of it by night. His business methods become questionable and pernicious. He takes all the law allows, and does the other fellow if he can. He makes money, makes it honestly if he can, but makes it. After all, it does not pay. It is like chasing a phantom. He pursues his business to a certain point, then his business pursues him. He is no longer in control. He thinks in a circle and acts like an automaton. He is a slave to his business and can't turn loose—until perhaps he is released by sudden death or is sent to a sanitarium, broken in health, to die without enjoying the pleasures of a long life that is due him.

A striking coincidence is that as our strenuous civilization progresses the number of cases of mental and nervous diseases increases. There is hardly a state institution that is not overcrowded. Texas is just completing additional buildings to accommodate the increasing number of insane patients, and applications now on file show more than 600 patients seeking admission that can not be accommodated when the hospital is completed. Besides these state institutions, there are scores of private sanitariums for treating the milder cases of these unfortunate patients. Nervous breakdown has been called our national disease, and not without good reason. Arteriosclerosis, a disease largely due to nervous strain and hyperarterial tension, formerly a rare disease, is now prominently and extensively treated of in leading text-books on practice.

Another striking illustration of the effect of our strenuous civilization in producing disease is the rapid increase in the number of deaths from heart disease. One hundred and twenty-five persons died recently in one week in New York City from heart disease, while the deaths for the corresponding week in 1904 were 56.

Another phase of this subject I would like to treat of at length, but for lack of time I will only say enough to provoke discussion or start you to thinking. The stress and strain, worry and anxiety attendant on fierce competition in business and professional life is enervating and devitalizing. It embarrasses or suspends organic function and lessens resistance to morbid influences. As a consequence we fall easy victims to almost any disease, such as pneumonia, tuberculosis, typhoid fever, cancer and grave kidney lesions. If a man who lives this kind of life undergoes a surgical operation of any consequence, it is exceedingly hard for him to recover. His vitality is so lessened that any traumatic lesion will probably undergo necrosis or gangrene instead of healing.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN.

CHAPTER XXV.

GENERAL ANESTHETICS.

The subject of general anesthesia concerns the surgeon much more than it does the physician, but, as in the matter of antisepsis, the physician must have some knowledge of this subject, and we shall, therefore, briefly consider the more important members of the group of general anesthetics, their uses and their probable limitations.

Narcotics have been used from time immemorial, for producing unconsciousness during surgical operations, but nitrous oxid has been in use longer than any other agent now employed for inducing general anesthesia. It is more than 100 years since Sir Humphrey Davy first suggested this use for nitrous oxid, but his suggestion met with no response, and it was not until many years later, in 1844, that Horace Wells, a dentist of Hartford, Conn., employed it for that purpose and thus introduced what he was pleased to term "a new era in tooth-pulling."

It was at one time supposed that nitrous oxid caused unconsciousness merely through asphyxia, and while this is a very important factor, it has been shown that nitrous oxid also causes a depression of the central nervous system resembling that of the methane derivatives such as chloroform and ether, and complete anesthesia has been produced without asphyxia by using a mixture of oxygen and nitrous oxid under pressure. This would probably constitute an ideal method of inducing anesthesia were it not for the mechanical difficulties and the expense that it necessarily involves.

Nitrous oxid is usually administered only for a short time, it being necessary to discontinue it so soon as marked cyanosis of the face occurs, after which the anesthesia lasts for about a minute or two. It is the safest agent which we possess for general anesthesia, the death rate being approximately one in half a million cases, but aside from its use in dentistry and for inducing unconsciousness, preliminary to other anesthetics, its application is extremely limited.

It is impossible to estimate the value to mankind, and to surgery in particular, of the introduction of anesthetization with ether by Morton and Jackson just fifty years ago. Its use by Dr. Crawford W. Long, in Georgia, antedates by more than two years the real work of Morton and Jackson in introducing the method, but the greatest credit is due those men for their splendid achievement in gaining general recognition for this boon to humanity.

Shortly after the introduction of general anesthesia by the use of ether Sir J. Y. Simpson announced his discovery of the use of chloroform as an anesthetic, and this latter agent soon displaced ether almost entirely in many parts of the world. Even at present chloroform is used almost exclusively in England and in several other European countries.

From time to time other agents have been proposed as substitutes for chloroform and ether, and some of them have enjoyed a greater or less popularity for a time, only to sink into obscurity.

In this connection we may mention a few of those which will be remembered even by the younger generation of physicians, and which have not yet fallen into complete disuse.

Ethyl bromid and bromoform have been used to some extent as general anesthetics, and it has been suggested that the typical bromid action might be obtained from them, but the action is that of the entire molecule. Both of these have passed almost completely from use as general anesthetics, largely, perhaps, because of the unstable character of the substances themselves and the accompanying uncertainty of the action of the decomposition products.

Petroleum ether, or benzin, because of its cheapness, is sometimes used in vivisection experiments, but not on man.

The use of mixtures of varying composition appears to offer a peculiarly interesting field for experimentation in connection with general anesthesia.

Of the several mixtures that have been used from time to time, that popularly known as the A. C. E. mixture, containing 1 part of alcohol, 2 parts of chloroform and 3 parts of ether, is perhaps the one that has been used most widely. This also referred to occasionally as the one-two-three mixture, was, at one time at least, quite popular in England. While it has been urged against this mixture that the differences in volatility of the three substances prevents the anesthetist knowing just what he is administering, it is a fact that the vapors of all three tend to pass off together, and, furthermore, the object is to induce anesthesia and to avoid an excess of the anesthetic and the action of the mixture seems to be as easily controlled as that of chloroform, while not so much is required as of ether alone. The alcohol and chloroform raise the boiling point of the mixture above the temperature of the lungs and this probably secures some of the advantages claimed by Schleich for the mixture of ether, chloroform and benzin.

A mixture containing 57 parts of ether and 43 parts of chloroform has been suggested as having some advantages over either of its component parts. It was at one time quite widely recommended under the title of M. S. mixture, but appears to have fallen into disuse, having probably no advantage over the better known A. C. E. mixture mentioned above.

Dr. Carl Ludwig Schleich of Berlin some years ago recommended the admixture of 5 per cent. of petroleum ether, or benzin, with ether and chloroform, as a general anesthetic. This preparation had been used by Schleich in nearly 500 cases in which he obtained excellent results, such as absence of excitement and of the excessive salivary discharge so frequently seen with ether, while the depressing effect of chloroform on the heart was not observed. Despite these and other advantages, which he cited at the time, the mixture never attained much popularity, and even Schleich himself appears to have discontinued its use in favor of an ethyl chlorid mixture.

The mixture of ether, chloroform and ethyl chlorid has been proposed at different times and in varying proportions; the one proposed by Schleich contains 2 parts of ethyl chlorid, 4 parts of chloroform and 12 parts of ether, and is fairly representative of this class.

The advisability of using mixtures of any kind, for general anesthesia is still an open question, particularly in view of the fact that the several chemical substances themselves are far from being absolutely stable, even under the most favorable conditions, chloroform particularly being readily decomposed and forming, as one of the possible decomposition products, the really dangerous substance known as phosgene.

Magnesium Sulphate.

S. J. Meltzer has recently suggested the use of a solution of magnesium sulphate for inducing general anesthesia. For this purpose he advised the intraspinal injection of 1 c.c. (15 minims) of a 25 per cent. sterilized solution of magnesium sulphate for each 25 pounds of body weight. This method possesses no advantage over cocain used in the same way for producing anesthesia of the lower parts of the body, but general anesthesia is induced and persists for some hours, and the method, therefore, may possibly prove serviceable in controlling the convulsions of tetanus.

Marked depression of the respiration occurs, and Maury and Teague, working with guinea-pigs and injecting the solution intraperitoneally have found that the repetition of the primary anesthetic dose, on the following day, sometimes causes death. It must, therefore, be used only with extreme caution. The sudden introduction of a small quantity of this solution into the blood vessels will immediately prove fatal.

Scopolamin-Morphin and Similar Solutions.

Reference has been made to the use of scopolamin-morphin for producing anesthesia, and while a number of deaths are reported as having attended its use, the combination is still being recommended by some as constituting a satisfactory method.

Morphin sulphate alone or in combination with atropin sulphate is very commonly employed preliminary to chloroform or ether narcosis, and appears to have well established uses in this connection.

E. Fraenkel reported some ten years ago that he had habitually used a mixture of morphin, atropin and chloral for hypo-

dermic injections, preliminary to narcosis, for twenty-two years, without an accident. He claimed that this procedure lessened to an extraordinary degree the amount of chloroform or ether used to maintain anesthesia.[1]

1. The solution used by Fraenkel was made as follows:

Morphin muriate	gr. iiss	15
Atropin sulphate	gr. ¼	015
Hydrated chloral	gr. iv	25
Distilled water	ʒss	15

He injected hypodermically from 1 c.c. to 1.25 c.c. (15 to 19 minims) fifteen minutes before the commencement of the ether or chloroform administration.

Fraenkel further asserts that this mixture is free from the objectionable side actions of morphin, being well borne by patients who could not take morphin by the mouth or hypodermically.

Ethyl Chlorid.

A substance which bids fair to rival chloroform and ether as a general anesthetic, under certain conditions at least, is ethyl chlorid.

This substance is extremely volatile, boiling at from 12.5 to 13 C. (54.5 to 55.4 F.), and it is necessary, therefore, to keep it in sealed tubes. The ends of the tubes are drawn out to fine capillary tubes which are then sealed, or the capillary opening is closed by a metal cap which may be replaced when a part of the contents of the tube has been used. When required for use the glass tip is broken off, or the metal cap unscrewed, when the heat of the hand causes the ethyl chlorid to volatilize, forcing out a fine stream which may be directed against the surface which is to be frozen for local anesthesia, or the stream may supply the vapor for inhalation to produce general anesthesia.

Ethyl chlorid induces anesthesia more rapidly than ether does, and when it is withdrawn the patient recovers more quickly, thus saving an average of some twelve minutes on each operation, hence it is likely to prove useful on the battlefield and in great calamities when a number of operations must be performed with a minimum loss of time.

Figures purporting to give relative degrees of danger for various anesthetics are notoriously unreliable, but it seems probable that ethyl chlorid is less dangerous than chloroform and somewhat more dangerous than ether. Among the objectionable features of ethyl chlorid are increased cost, the explosive character of the vapor, extreme volatility, the accompanying waste of material and the difficulty of administration.

Action of Chloroform and Ether.

It would hardly be profitable to discuss here in detail the actions of chloroform and ether, but there are certain important points concerning them which are so frequently overlooked that we will consider them briefly.

While there are records of as many as 40,000 consecutive anesthetizations with chloroform without a fatality, this is only possible in the case of skilled anesthetists working with carefully selected cases. Certainly no such results are possible in ordinary practice, and with that alone are we concerned at present.

We must always remember that the production of general anesthesia is a grave matter in which death is an ever present possibility despite the utmost care, and of which there is actual danger unless caution is observed. The possibility of fatal complications in all cases of general anesthesia would appear to make it necessary that the patient or his friends be informed of this fact, if for no other reason than to protect the physician administering the anesthetic.

Each case must be carefully considered when selecting the anesthetic, and neither chloroform nor ether should be used exclusively. Ether being the safer, however, should have the preference, when it is not contraindicated, and chloroform should not be used unless the anesthetist is experienced and is reasonably skilled in the use of it.

The following are some of the principal advantages and contraindications of both of these agents:

The vapor of ether is inflammable, that of chloroform is not, and the latter is to be preferred when operations are to be performed by gas or lamplight. In this connection, however, we must not forget that chloroform vapor coming in contact with an open flame is readily decomposed into chlorin and hydrochloric acid, and that it will be necessary, therefore, to provide for free ventilation to eliminate these decomposition products. If ether must be used under such circumstances, the light should be placed as high above the level of the mask as practicable, since ether vapor is heavier than air. The thermocautery, of course, can also ignite the vapor of ether.

An acute cold is a contraindication to the use of any anesthetic, but more particularly to the use of ether. Ether is also contraindicated in bronchitis, because of the great irritation caused by the relatively large amount necessary to maintain anesthesia; it is likewise contraindicated in nephritis, since the kidneys take part in the excretion, and, of course, suffer from the irritant action.

In extremely hot weather, that is, when the thermometer is above 93 to 95 F. (34 to 35 C.), ether is volatilized so rapidly that the atmosphere contains amounts which may prove objectionable, and it often becomes very difficult to maintain complete anesthesia.

When it is absolutely imperative to reduce the stage of excitement to the minimum, or when it becomes necessary to secure complete anesthesia rapidly, ether is contraindicated and chloroform is to be preferred when it is not specifically contraindicated for other and more important reasons. In the latter event ethyl chlorid may be used, or preliminary unconsciousness may be induced by nitrous oxid, and this followed up by the use of ether.

Chloroform is very commonly preferred by obstetricians, but deep anesthesia is not usually induced in such cases.

In fatty disease of the heart chloroform is contraindicated because it also induces fatty degeneration of that organ, and for this reason it is not advisable to use it repeatedly on the same person in succeeding operations.

Chloroform is much more toxic to the heart than ether, and there is a much narrower margin of safety between the amount necessary to induce anesthesia and that which causes death, chloroform being thirty-six times as active as ether in inducing anesthesia, but forty-eight times as toxic.

A matter of the greatest practical importance, especially for the unskilled anesthetist, is the very brief interval between the cessation of respiration and the stopping of the heart beat with chloroform, giving very little chance to resuscitate the patient after respiration has stopped. With ether the interval is much longer, and the prompt resort to artificial respiration, while the body is raised higher than the head, very commonly results in saving the patient.

This variation in the action of anesthetics and also the fact that the condition of anesthesia is a dangerous one, according to the degree to which it is carried, will be more fully appreciated if we have a clear conception of the several stages of anesthesia and the rapidity with which a patient may pass from one stage into the other.

These several stages are usually designated as: 1, the stage of excitement; 2, the narcotic and anodyne stage; 3, complete anesthesia; 4, paralysis and death.

The acceleration of the circulation noticed in the first stage is similar to that produced by the ingestion of alcohol or alcoholic beverages, and the production of this stage was one of the uses to which ether was put long before it was used as an anesthetic in surgical operations. From this stage the patient usually passes quite gradually into the second or narcotic stage.

In the narcotic stage sensibility becomes impaired, but there is not infrequently a persistence of reflex action which manifests itself in a form of delirium or wild excitement. This is usually an indication of faulty anesthetization and is a complication that can be avoided in many instances by the more careful preparation of the patient for the anesthetic. In the majority of instances, however, the patient passes rapidly into the third stage, that of complete anesthesia.

This third stage differs from the second in that there is complete absence of reflex action, even of the conjunctiva, which is usually, though erroneously, advocated as the most satisfactory test for complete anesthesia. A satisfactory surgical anesthesia is indicated by complete relaxation of all of the muscles of the body, regular breathing, deep inspirations and a fully relaxed lower jaw. The widely prevailing though barbarous habit of touching the conjunctiva should never be resorted to.

By the careful administration of the anesthetic this stage of surgical anesthesia may be continued for a considerable period of time, but we must never forget that it is ever bordering on, and may at any moment pass into, the fourth or paralytic stage, when respiration ceases, the heart beats become feebler, and, unless vigorous and prompt restorative measures can be resorted to, may cease entirely.

The Administration of Ether.

While it has been asserted that the administration of anesthetics is an art that can not be taught or learned but must be acquired, it is also true that there are certain points or rules that have been sufficiently well established to warrant their being heeded, and the general conduct of anesthetization can best be illustrated, perhaps, by giving the method pursued by an ordinarily careful anesthetist.

The patient is made thoroughly comfortable, in a recumbent position, on a table or wheel stretcher, if in a hospital, with a pillow just sufficient to raise his head but slightly.

The mouth is freed from false teeth and other foreign materials, and the lips and nose are anointed with petrolatum to avoid the accompanying irritation from contact with the anesthetic.

A pad of moistened gauze is then placed over the eyes to avoid irritation by the fumes of the anesthetic.

All these several stages should be carefully explained to the patient so as to assure him that every possible precaution is being taken to provide for his comfort and well-being, and to gain his confidence, for the more important feature of administering the anesthetic itself.

After the patient has been prepared and his confidence gained by explanation of the several stages of the preparation, he is allowed to accustom himself somewhat gradually to the taste and smell of the ether. To accomplish this the cone or gauze containing the anesthetic is held some slight distance from his face, gradually brought closer as the patient becomes more and more accustomed to the inhalation. If the anesthetist has been successful in gaining the confidence of the patient he will find that the latter will pass through the preliminary stages of anesthesia without a struggle, and that complete relaxation will be secured with a minimum of the anesthetic.

When a patient has been completely anesthetized very little of the anesthetic will suffice to maintain the condition and the further efforts of the anesthetist can be devoted to observing the respiration and the surface reflexes of the patient in order to prevent his reverting to the second stage of anesthesia, or passing on into the much-to-be-dreaded stage of paralysis of the respiratory center.

With chloroform the passing from one stage of anesthesia to the next is much more rapid than with ether, less of the anesthetic is used, more air must be allowed, and there is, of course, a correspondingly smaller margin of safety in the stage of complete surgical anesthesia.

Since all of us can not become expert anesthetists and yet must at times perform that office, this advantage of ether is well worth consideration.

The greatest immediate danger from the inhalation of ether or chloroform, but more especially of the latter, is the administration of the vapor in too great concentration. One hundred volumes of air require approximately from three to four volumes of ether vapor, and 100 volumes of air require about one volume of the vapor of chloroform to induce anesthesia, but an increase of from two to three volumes in the concentration of the ether, or only one volume of chloroform to 200 of air will prove fatal in a short time.

While we do not actually measure the relative volumes of air and vapor, as a rule, these figures will serve to show the comparative danger of the two substances, for it is many times more difficult to avoid overstepping narrow boundaries than broad ones.

When a perfectly safe ratio is maintained the delay in inducing anesthesia often proves vexatious, and the anesthetist may be urged to expedite the operation by increasing the concentration, but he should never forget the grave responsibility which he has assumed and should never permit the impatience of others to induce him to exceed the limits of caution, save only in those grave emergencies where delay in operation may mean death to others who are awaiting their turn.

Official Anesthetics.

ÆTHYLIS CHLORIDUM.—U. S.—Ethyl chlorid occurs as a colorless, transparent, very volatile liquid, having a characteristic, rather agreeable odor and a burning taste. It is only slightly soluble in water, but is readily miscible with alcohol.

Ethyl chlorid is a haloid derivative, and is prepared by the action of hydrochloric acid gas on absolute ethyl alcohol. It is usually marketed in hermetically sealed glass tubes, and when liberated at ordinary room temperature volatilizes almost instantly. The resulting gas is very inflammable and the substance itself should never be used in proximity to an open flame or fire.

For local anesthesia the liquid in a fine spray is applied to the surface to be anesthetized.

The average amount necessary to induce general anesthesia is from 5 to 10 c.c. (75 to 100 minims).

ÆTHER.—U. S.—Ether is a transparent, colorless, volatile liquid having a characteristic odor and a pungent, sweetish taste. It should contain 96 per cent. by weight of absolute ether or ethyl oxid and about 4 per cent. of alcohol containing a little water.

The per cent. content of ethyl oxid or absolute ether in a given specimen is a matter of considerable importance when the substance is to be used for anesthesia. The official ether, when exposed to air, appears to absorb moisture, thus materially reducing the anesthetic value of the ether. The practice that has long been followed of sending out ether in hermetically sealed cans is an efficient safeguard against this absorption of moisture.

CHLOROFORMUM.—U. S.—Chloroform is a heavy, clear, colorless liquid having a characteristic ethereal odor and a burning, sweet taste. It should contain not less than 99 per cent. by weight of absolute chloroform and from 0.6 to 1 per cent. by weight of alcohol.

Chloroform when not pure is readily decomposed, forming chlorin compounds that may prove to be extremely dangerous to the patient. Even chloroform that corresponds to the requirements of the Pharmacopeia may be decomposed in the presence of damp air and heat, and the substance should, therefore, be carefully preserved in small, well-stoppered bottles.

The Army Medical Bill.—How much we have learned from our Oriental friends, says *Collier's Weekly*, will be indicated by the disposition of the Army Medical Bill, now before Congress, which might be described as a measure to make the United States Army fit to fight in time of war. If the Japanese triumph taught the military world anything, it was the importance of keeping soldiers healthy. That a sound man will fight better than a sick man, that an army in good physical condition will beat an army depleted by disease, seem truisms. Yet, until the little yellow men achieved their unbroken record of victories no military authority had ever given due weight to the hygienic problem. Our Army is now officered for a strength of 100,000 men, except the medical department, which is officered for a strength of less than 50,000 men. This bill seeks to increase the medical faculty to a strength sufficient to care for the health of the fighting men. In our late war with Spain the medical department lacked numbers, equipment and authority. The result was fourteen soldiers dead from disease (mostly preventable) to one from wounds. In the recent war in the Far East the Japanese lost one soldier from sickness to four from shell, bullet and bayonet. Their medical department was sufficient, and, in its own province, paramount. Only 5 per cent. of our forces escaped the hospital. In an equal length of time, and under more trying conditions, so reckons Dr. L. L. Seaman, in his recent book, but 15 per cent. of the Japanese army reported sick. Fighting strength depends not more on the number of soldiers on the roster than on the proportion able to bear arms when the time of action comes. Painful though it be to our national pride, the inference is inevitable, that with equal forces enlisted, a Japanese army with a hospital record of only 15 per cent. would defeat an American army with a hospital record of 95 per cent. An adequate medical force is as essential to an army as a skillful trainer to a pugilist.

SATURDAY, JUNE 16, 1906.

To give our readers the complete proceedings of the House of Delegates and of the General Meetings at Boston, we omit some departments from this issue and curtail others.

THE SUCCESS OF THE BOSTON SESSION.

The Boston session of the American Medical Association was a remarkable success in every way. In numbers it exceeded any previous gathering of medical men anywhere, unless it be the Moscow International Medical Congress. Over four thousand seven hundred registered, exceeding by eighteen hundred the largest previous registration—that of Atlantic City in 1904. A large number of physicians were present who did not register, besides invited guests and associate members who are not included in the above figures. It is not an exaggeration to say that at least six thousand physicians were in attendance. An unusual number were accompanied by their wives and friends, so that one local newspaper's statement that fifteen thousand visitors were in Boston as a result of the American Medical Association session was probably true.

In spite of the unusually large attendance, the accommodations were most ample, and the fear that Boston could not take care of the Association was not realized. The hotel committee had done its work well. Good rooms in first-class boarding houses and hotels were still on the list when the last comer had been satisfactorily located.

The local Committee of Arrangements deserves the highest commendation for the magnificent manner in which the Association was entertained. Never before in the history of the organization have the plans for its care and entertainment been conceived and executed on such a grand scale and with such attention to the minutest detail. With it all there was not the slightest attempt at ostentatious display. Not a single offensive advertisement was to be seen, but throughout the entire meeting everything from the greatest to the least was carried out with precision and with that dignity and graciousness which are so characteristic of this famous city.

The scientific exhibits, the clinical exhibits, and the practical clinical demonstrations at the hospitals and elsewhere provided sufficient scientific entertainment to have well repaid attendance at the session, even had there been no section work—indeed, this elaborate clinical feast might have detracted from the section work had not the attendance been so phenomenally large. As it was, the overflow at some of the section meetings found ample opportunity to be both entertained and enlightened by these exhibits.

The session of 1906 will be a memorable one in the history of the organization on account of the perfect unity of feeling which developed throughout the entire profession and from all sections of the country. Never before has it been so apparent that the end and aims of the profession are not limited to personal and individual benefits nor to local conditions, but are coextensive in philanthropy and beneficence with the welfare of the entire community, and that when the great interests of the public are concerned all individual differences are at once lost in that altruism which so characterizes the true physician.

PHOTODYNAMIC ACTION.

H. von Tappeiner originated the term photodynamic action to designate the toxic effects exerted by fluorescent substances in the light. He first worked with certain chemical substances, the chinin derivatives, and showed that the toxic action was due to a definite nucleus in the molecule. Grethe and later Raab studied the marked toxic effect that certain fluorescent substances have on the paramecium; and Raab traced this to the action of light on these chemicals since in the dark they were quite ineffective. The sunlight does not affect non-fluorescent poisons in this way. The fluorescent substance must be in solution and in order to obtain the toxic effect the living cells must be immersed in the fluid as fluorescent light itself has no effect; further, light passing through one fluorescent solution has lost its power to cause a second solution to fluoresce. Photodynamic action and absorption of light are not identical, for it has been shown that many actively absorbing substances show no increased toxicity following the absorption.

The fluorescent substances include a large number of chemicals belonging to the anilins. As examples may be mentioned eosin, magdala red, erythrosin, fluorescein and acridin. All fluorescent substances exert some photodynamic action but they vary a great deal in their intensity. Weaker solutions are more active in proportion to their concentration than strong solutions, and the intensity of action also bears a direct relation to the intensity of the light. Both sunlight and artificial light are effective, the former being the more powerful.

The first work carried out by Raab, v. Tappeiner and others on the effect of fluorescent substances in light

was principally on infusoria. More recently, the effect of fluorescent fluids has been studied on many other substances, including such bodies as bacteria, toxins, antitoxins, ferments of various kinds, parasitic conditions of the skin and neoplasms.

Bacteria and fungi, as a rule, are susceptible to the photodynamic action of many fluorescent substances. Some ferments show a decided susceptibility to this action, others much less. Diastase, trypsin, invertin and chymosin are affected especially by eosin and magdala red, while other fluorescent bodies do not affect them. Katalase is not affected by any fluorescent body, so far tested.

Jodlbauer and v. Tappeiner discovered the interesting fact that in the presence of oxygen the photodynamic action on enzymes is very much stronger than in its absence. There is undoubtedly an important relation existing between oxidation and this action, but from the work already done it appears that they are not identical and not always parallel. Oxygen, however, seems to be an important condition for the development of this activity.

An interesting field is opened up by the work on bacterial and other toxins. Eosin and other anilins act injuriously on diphtheria and tetanus toxin, diphtheria and tetanus antitoxin, ricin and snake venoms. Guinea pigs, for instance, can be protected from one minimum lethal dose of diphtheria toxin by the injection of eosin with subsequent exposure to sunlight. The protective action is not great, however. The activity of the agglutinin of ricin and of the interesting bodies in snake venoms (neurotoxins, hemolysins, agglutinins) is more or less diminished by eosin and erythrosin in sunlight. In the dark no effect is noted. It has also been found that complements and precipitins are acted on by these fluorescent substances, but the immune body or amboceptor is not affected.

If one injects a fluorescent body such as eosin, under the skin of an animal and then exposes this part to the sunlight, a marked reaction occurs, which consists essentially in the formation of areas of necrosis and sloughing. v. Tappeiner and others have applied this observation to the treatment of superficial tumors, lupus and other skin lesions which are injected with eosin and exposed to sunlight or artificial light. This, apparently, has met with some success, but the data thus far obtained are hardly sufficient to draw any definite conclusions.

Summing up, we see that photodynamic action is a form of destructive activity which acts on various bodies much as do the usual chemical and physical agents. On the whole, substances which are highly resistant to the latter, also conduct themselves in a similar manner to this action, while the more labile bodies show a corresponding susceptibility. From a practical standpoint, it furnishes us with another means whereby the properties of various complex bodies may be studied and compared, and it may become of real value as a therapeutic agent in the field of phototherapy.

THE EMOTIONS AS FACTORS IN THE ETIOLOGY OF DISEASE.

Although the mechanism may not be clear, it is generally recognized that emotional states constitute a distinct and definite factor in the etiology of a number of morbid affections. This relation is observed more especially, though not exclusively, in connection with disorders involving the nervous system. Even apart from disease, various phenomena appear in the train of emotional influences. Among the more common of these are tremor or muscular twitching, vasomotor spasm (pallor) or paresis (blushing), cardiac inhibition (syncope) or release of normal cardiac inhibition (tachycardia, palpitation), horripilation, secretory disturbances (hyperidrosis, anidrosis, involuntary discharges). No definite and constant relation exists between the character of the emotional disturbance and the resulting manifestations. An interesting presentation of some effects of fright is contained in a communication read recently before the Bristol Medico-Chirurgical Society by Dr. J. R. Charles,[1] but many of the statements made therein are applicable also to other forms of emotion.

Emotional influences constitute one of the most important factors in the etiology of hysteria, with its protean manifestations, and not rarely they act as potent therapeutic factors. A similar causative relation has been observed also in some cases of exophthalmic goiter. Emotional perturbations, particularly fright, are included among the classic causes of chorea, and they have been noted as antecedent in some cases of paralysis agitans. Not rarely they are assigned as causes of the attacks of epilepsy. They may precipitate enuresis in a child previously continent and they may give rise to night terrors in an impressionable subject. Attacks of asthma and of migraine are said sometimes to be superinduced by emotional influences. Attacks of gout may be excited in a similar manner, and sugar may be made to appear in the urine as a result of profound mental strain. Depressing emotions appear to lower the bodily resistance and thus to facilitate, if not to invite, bacterial invasion, and the impression prevails that fear predisposes to infection in times of epidemic.

In what manner emotional influences operate under the conditions discussed must for the present remain a matter for speculation. It may be surmised in a general way, however, that they result in a disturbance of functional balance and merely precipitate conditions for the development of which the necessary factors are already present.

THE SURGICAL VALUE OF THE DIFFERENTIAL LEUCOCYTE COUNT.

Enumeration of the corpuscular elements of the blood, both red and colorless cells, is so well established a procedure as to require no special advocacy at the present time. It must be borne in mind, however, that the information acquired in this way will prove of greatest

1. Bristol Medico-Chirurgical Jour., March, 1906, p. 23.

value according as it is weighed in connection with the other clinical phenomena present. Alteration in the number of blood corpuscles is due to so many different causes that a careful study of all the signs and symptoms will often be necessary, and is always to be advised, in order to determine the particular cause in any given case. A determination of the relative number of the several varieties of leucocytes, besides, will often yield valuable information, sometimes even when the number of colorless corpuscles is not increased. Decisive as is at times the information thus gained in the diagnosis of affections ordinarily requiring only medicinal treatment, it may be of vital significance in the recognition and treatment of disorders requiring surgical intervention, and more especially with regard to the severity and prognosis. As the result of a careful and extended study of the subject Dr. Chas. Langdon Gibson[1] arrives at the opinion that the differential blood count and its relation to the total leucocytosis constitute the most valuable diagnostic and prognostic aid in acute surgical diseases furnished by any of the methods of blood examination. Its chief value consists in indicating the existence of suppuration or gangrene, the increase in the number of polynuclear cells under such circumstances being disproportionately great as compared to the leucocytosis. The normal number of leucocytes is placed at between 5,000 and 10,000 and the normal proportion of polynuclear cells at 75 per cent. An increase beyond these figures may be accepted as an indication of the presence of some morbid process in the body, but especial significance is to be attached to a disproportionate increase in the number of polynuclear cells. When the latter is present it will be found that the lesion is a severe one, or that absorption is active, or that both of these conditions prevail. In order to record graphically the varying degrees of disproportion between the two factors mentioned, and to make comparisons from day to day, Dr. Gibson has devised a chart in which the horizontal base line corresponds to 10,000 leucocytes on the one hand and 75 per cent. of polynuclear cells on the other hand. The greater the disproportion between the two will be the vertical distance between a point on the leucocyte level and another point on the polynuclear level. The greater this distance the more severe is the lesion, the less the bodily resistance to the infection present and the graver, therefore, the prognosis. We appear to have here not only a guide to diagnosis and in prognosis, but also an indication for or against surgical intervention.

1. Annals of Surgery April, 1905, p. 485.

Medical News

CALIFORNIA.

Medical College Will Rebuild.—The College of Physicians and Surgeons, San Francisco, expects to have its new building open and ready for work by the beginning of the fall term.

Hospital at Gilroy to be Built.—In spite of the fact that Mr. Henry Miller is a heavy loser in the recent earthquake and fire, he will allow no change to be made in the plans for the Gilroy Hospital, which he is having erected at a cost of $100,000.

New Hospital.—The Angelus Hospital, Los Angeles, was formally opened for inspection May 14. The building represents an outlay of more than $200,000 and has incorporated in it the latest ideas in hospital construction. It is a four-story structure, and as nearly fireproof as possible.

Postgraduate School in Los Angeles.—The Los Angeles Postgraduate School has been organized and will be affiliated with the medical department of the University of Southern California. The officers of the institution are: Dr. Walter Lindley, president; Dr. Ernest W. Fleming, vice-president; Dr. W. W. Richardson, secretary, and Dr. John C. Ferbert, treasurer.

Commencement.—The Oakland College of Medicine and Surgery held its first graduating exercises June 1. A class of four was graduated, and the addresses of the evening were made by Mayor Mott of Oakland, and the Rev. Charles R. Brown, and the degrees were conferred by Dr. Frank L. Adams, president of the college.——Cooper Medical College held its annual commencement exercises May 9. Mr. Horace Davis and Dr. Charles N. Ellinwood delivered the addresses, and a class of 30 was graduated.

ILLINOIS.

Personal.—Dr. Philip F. Gillette, Elgin, has been appointed a member of the medical staff of the Illinois Hospital for the Incurable Insane, Bartonville.——Dr. W. T. Lynn of Shelby County celebrated his ninety-first birthday anniversary May 28.——Dr. Frank S. Whitman, superintendent of the Illinois Northern Hospital for the Insane, Elgin, has resigned, to take effect July 1.——Dr. Thomas W. Keys, Leroy, left for a three months' visit to Great Britain, June 2.

Chicago.

Deaths of the Week.—The total deaths from all causes for the week ended June 9 were 523, 58 more than those reported for the preceding week. This is equivalent to an annual death rate of 13.31 per 1,000. Pneumonia caused the greatest number of deaths, 77; consumption caused 45; nephritis and violence (including suicide), each 43; heart diseases, 42; cancer, 32; nervous diseases, 31, and acute intestinal diseases, 27.

Commencement.—The twenty-fourth annual commencement exercises of the College of Physicians and Surgeons, the College of Medicine of the University of Illinois, were held June 5, when degrees were conferred on a class of 226 by President Edward J. James, of the University of Illinois. The doctorate address was delivered by Dr. William E. Quine, dean of the college.

NEW YORK.

New York City.

Personal. Dr. Albert M. Judd, Brooklyn, was caught between his own and another automobile on June 1 and severely bruised.

Quarantine Inspected.—The consulting board of health officers of the port of New York, after making a tour of inspection, reported very favorably on the administration of the service during the past year. The duties of the station were discharged with little interference with commerce or the welfare of passengers. The new buildings on Swinburne Island, which have been erected during the past year, were also inspected and approved.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended June 2, 931 cases of measles, with 38 deaths; 351 cases of tuberculosis, with 179 deaths; 347 cases of diphtheria, with 57 deaths; 192 cases of scarlet fever, with 18 deaths; 49 cases of whooping cough, with 6 deaths; 85 cases of varicella, with 1 death; 25 cases of typhoid fever, with 6 deaths, and 22 cases of cerebrospinal meningitis, with 17 deaths, making in all 2,012 cases, with 325 deaths.

Coroner Arraigns Hospital System.—At a meeting of superintendents of hospitals throughout the city on June 7, the subject of transferring patients from one hospital to another was discussed and the reasons set forth for the impracticability of Coroner Harburg's ordinance fixing a penalty of $100 in every case where a superintendent refuses admission to a sick person in an ambulance or orders the transfer of a patient who is dangerously ill. Under such an ordinance all hospitals would have to admit contagious diseases and insane patients, as well as those suffering from insomnia or old age. Dr. Armstrong of Bellevue refuted the accusations that moribund patients had been transferred to keep down the death rate of the hospital.

NORTH CAROLINA.

April Deaths. During April 242 deaths were reported, equivalent to an annual death rate of 14.4 per 1,000. The principal causes of death were: Consumption, 36; pneumonia, 33; heart disease, 28; diarrheal diseases, 19, and violence (including suicide), 14.

Graduating Exercises.—At the graduating exercises of the North Carolina Medical College, Davidson, April 3, degrees were conferred on a class of 24. Dr. Benjamin K. Hays, Oxford, delivered the address.——The fourth annual commencement exercises of the University of North Carolina, Medical Department, were held at Chapel Hill, May 11. The address of the evening was delivered by Dr. Robert Lee Payne, Norfolk, Va., and a class of 11 received diplomas.

State Society Meeting.—The fifty-third annual meeting of the Medical Society of the State of North Carolina was held in Charlotte, May 29, 30 and 31. The meeting was called to order by Dr. Robert L. Gibbon, Charlotte, who introduced the new president, Dr. Edward C. Register, Charlotte. The welcome to the delegates was extended by Hon. C. T. Guthrie, and the response was made by Dr. Benjamin K. Hays, Oxford. The president, in his address, "Higher Standard Preliminary Education for Medical Students," made a strong appeal for better and higher standards for entrance into the ranks of the profession of the state, and pointed out where the state fell below the standard of other states in this particular. He urged strongly the better literary and practical training of students before entry to medical college. The chief topics of discussion during the meeting were the pure-food movement and the nostrum evil, and resolutions were adopted urging on the state representatives in congress the necessity of radical action on both subjects. On the evening of May 30 the society met with the State Board of Health and discussed matters pertaining to the health of the commonwealth. The following officers were elected: President, Stephen D. Booth, Oxford; vice-presidents, Drs. Charles M. Strong, Charlotte, John E. McLaughlin, Statesville, and William F. Hargrove, Kinston; secretary, Dr. David A. Stanton, High Point, and treasurer, H. McKee Tucker, Raleigh. Morehead City was chosen as the place for the next annual meeting.

PENNSYLVANIA.

Philadelphia.

Jefferson Commencement.—Jefferson Medical College celebrated its eighty-first annual commencement June 4. The class was composed of 213 men, and the diplomas were awarded by Hon. William Potter, president of the board of trustees. The total number of graduates is now 12,019.

Personal.—Dr. Richard Sharpless Davis was appointed resident physician to the Medico-Chirurgical Hospital.——Dr. and Mrs. George McClellan sailed for Europe June 16.——Dr. S. I. Eber, resident physician in Mount Sinai Hospital since its opening, was tendered a farewell reception June 3.

Health Report.—The total number of deaths reported for last week reached 496, an increase of 52 over the week previous and an increase of 74 over the number for the corresponding week of last year. The principal causes of death were: Typhoid fever, 24; measles, 3; pertussis, 9; diphtheria, 7; meningitis, 3; consumption, 57; cancer, 21; apoplexy, 21; heart disease, 41; acute respiratory disease, 50; gastritis, 7; enteritis, 26; Bright's disease, 40; suicide, 6; accidents, 23, and marasmus, 9. There were 282 cases of contagious disease reported, with 32 deaths, as compared with 309 cases and 39 deaths reported in the preceding week, and 189 new cases of typhoid fever were reported, as compared with 170 in the previous week.

VIRGINIA.

Commencements.—The University College of Medicine held its annual commencement exercises at Richmond, May 17. Dr. Stuart McGuire, president of the college, delivered the commencement address, after which the diplomas were awarded.——The faculty of the Medical College of Virginia, at its meeting, May 9, declared 45 students of the graduating class of that institution to be doctors of medicine.

Amalgamation of Medical Colleges.—Committees of the Medical College of Virginia and the University College of Medicine, Richmond, are at work with the view to consolidation of the two institutions. The propositions under consideration are that the two colleges should be consolidated under the name of the Medical College of Virginia, with Dr. Stuart McGuire as president of the consolidated colleges; that the corporation of the University College of Medicine cease to exist and its board of trustees be abolished; that the faculty of the present two colleges have equal representation in the faculty of the consolidated institution, and that the buildings of the Medical College of Virginia become the home of the amalgamated institution.

WASHINGTON.

Fever Closes College.—An epidemic of typhoid fever at Gonzaga College, Spokane, has caused the authorities of the institution to close the institution for six weeks.

State Board Appointed.—The governor has announced on May 24 the following appointments on the State Medical Board: Dr. Casper W. Sharples, Seattle, to succeed himself; Dr. H. A. Wright, Wilbur, to succeed himself, and Dr. Kenneth B. Turner, Seattle, to succeed Dr. Ellsworth E. Shaw, Walla Walla.

Damage Suits Won and Lost.—The Supreme Court decided against Dr. H. E. Ayers, Mohler, who appealed from the decision of the lower court in the damage suit brought by Thomas Froman, Spokane, in which a judgment for $5,000 was rendered against the appellant.——The suit of Roy Millis, Spokane, against Drs. Donald G. Russell, Henry B. Luhn and James B. Munly for $20,000 damages for alleged malpractice in the setting of a broken leg three years ago, was decided in favor of the defendants, April 17.

Personal.—Drs. Frank J. Vankirk and William D. Kirkpatrick, Bellingham, are spending the summer in Europe.——Dr. William B. McCreery, Tacoma, has been appointed physician of Pierce County, vice Dr. Thomas B. Curran, Tacoma, resigned.——Dr. Daniel M. Angus has resigned from the Prosser city council.—Dr. J. L. Lane, Redmond, has been made physician at the state penitentiary, Walla Walla, succeeding Dr. John C. Mack.——Drs. Ellsworth E. Shaw and Yancey C. Blalock, Walla Walla, have been appointed assistant surgeons for the Oregon Railway and Navigation Company.——Dr. William L. Ludlow, health officer of Seattle, has resigned, to take effect August 1.

WEST VIRGINIA.

Personal.—Dr. D. E. Stephan, traveling medical examiner for the Baltimore & Ohio, has been appointed medical examiner, with headquarters at Fairmont.——Dr. and Mrs. Frank L. Hupp, Wheeling, left for Europe June 10.——Dr. B. B. Wheeler, Clay, has been elected assistant physician of the McKendree Hospital, Fayetteville.

Ill and Injured.—Dr. Samuel E. Bailey, Parkersburg, who has been seriously ill with pneumonia, is now securely convalescent.——Dr. Joseph E. Robins, Claremont, was seriously injured in a collision between his buggy and a street car in Charleston, April 5. His companion, Dr. Timothy L. Barber, Charleston, had several ribs broken.——Dr. Emery W. Strickler, Shinnston, was thrown from his horse May 7 and sustained painful injuries.——Dr. Charles A. Barlow, Benwood, was kicked in the abdomen by a horse April 4, and seriously injured.

WISCONSIN.

Smallpox.—The village of Roscoe has been alarmed by the appearance of smallpox; 27 cases have been reported, and the village schools have been closed.——Five cases of smallpox are reported in one house in Madison.

Commencement Exercises.—The Milwaukee Medical College held its annual graduation exercises May 31, when a class of 30 received diplomas from the president, Dr. William H. Earles. The valedictory for the medical department was delivered by Dr. A. D. Hoyer.

Personal.—Dr. William M. Farr, Kenosha, has resigned as local surgeon for the Chicago & Northwestern Railway Company, and Dr. Herbert A. Robinson has been named as his successor.——Dr. Frederick S. Luhmann, Manitowoc, has been re-elected county physician of Manitowoc County.

The Value of a Stomach.—In the case of Robert Koerber against Dr. Arthur J. Patek, Milwaukee, in which the defendant demands $5,000 damages, claiming that the physician, after a postmortem examination of the plaintiff's mother, four years ago, carried away the stomach and refused to return it, the jury rendered a verdict awarding $833.45 to the plaintiff. Dr. Patek has appealed from the verdict.

GENERAL.

Gastroenterologists Elect.—At the ninth annual meeting of the American Gastroenterological Association, held in Boston, June 4 and 5, the following officers were elected for the ensuing year: President, Dr. Henry W. Bettmann, Cincinnati; vice-presidents, Drs. Julius Friedenwald, Baltimore, and Frank H. Murdock, Pittsburg, and secretary and treasurer, Dr. Charles D. Aaron, Detroit.

FOREIGN.

Measles in Mexico.—Measles has been epidemic for the last few months in Santa Rosalia, in the state of Chihuahua. The

children of the poorer classes are chiefly affected. Sequelæ are unusually frequent, bronchopneumonia oftener than anything else. In many cases the measles is followed by stomatitis, exhausting diarrhea, etc. The uncleanly habits of the peons, the class chiefly affected, are responsible for many of the complications.

Deaths

Charles Henry Alden, M.D. Pennsylvania Medical College, Philadelphia, 1858, brigadier general United States Army, retired, died at his home in Pasadena, Cal., June 9, aged 70. General Alden was born in Philadelphia, April 28, 1836, received his preliminary academic education at Brown University, Providence, graduating in 1856, and afterward received the degree of A.M. from that institution. He also received the honorary degree of Doctor of Medicine from the University of Pennsylvania in 1901. He entered the medical department of the Army as lieutenant and assistant surgeon in June, 1860; was made captain and assistant surgeon five years later; was breveted lieutenant-colonel March 13, 1865; was promoted to major and surgeon in 1866, to lieutenant-colonel and deputy surgeon general in 1888, and to colonel and assistant surgeon general in 1892. When General Sternberg became surgeon general in 1893, Colonel Alden, who was then chief surgeon of the department of Dakota, was ordered to Washington for duty as principal assistant in the office of the surgeon general, and retained this position until his retirement in April, 1900. He was the first president of the Army Medical School, Washington, and retained this position for several years. Just prior to his retirement Colonel Alden was tendered a dinner at the Raleigh Hotel by the medical officers stationed in and around Washington, to testify to the high esteem and affection in which he was held. Colonel Alden was retired in April, 1900, and four years later was made brigadier general, United States Army, retired. On his retirement he moved to Newtonville, Mass., and thence to Pasadena, where he died. He was a member for many years of the American Medical Association, a member and once president of the Association of Military Surgeons of the United States, a fellow of the New York Academy of Medicine, a member of the American Public Health Association, American Climatological Association, American Academy of Medicine, the Military Order of the Loyal Legion and the Order of Foreign Wars. General Alden was a man of charming personality, and a medical officer of distinguished ability, esteemed and beloved by his associates.

William Reginald Purvis, M.D. Jefferson Medical College, Philadelphia, 1886, of Alexandria, Va.; for many years health officer of that place, and at the time of his death coroner of Alexandria County, and one of the city physicians of Alexandria, died at the Alexandria Hospital, June 1, aged 45. The Alexandria Medical Society at a special meeting, June 2, passed suitable resolutions regarding the death of Dr. Purvis.

Peter L. Horne, M.D. Medical College of the State of South Carolina, Charleston, 1860; assistant surgeon in the Confederate service during the Civil War; once vice-president of the state medical society; and president of the Dorchester County Medical Association from the time of its organization, died at his home in St. George, S. C., April 21, aged 69.

Samuel Rush Sayers, Jr., M.D. University of Virginia, Medical Department, Charlottesville, 1900, of Wytheville, Va., a member of the Medical Society of Virginia, was found dead in his room in the Gault House, Chicago, May 29, aged 30. The coroner's jury found that he died from a gunshot wound inflicted with suicidal intent while despondent.

William Christie, M.D. Jefferson Medical College, Philadelphia, 1861; a member of the city council of St. John, N. B.; at one time president of the city medical society, and a member of the medical council, the executive of the provincial society, and a member of the hospital staff for 20 years, died at his home in St. John, February 8, aged 71.

Edgar Adolph Fischer, M.D. Long Island College Hospital, Brooklyn, N. Y., 1868; formerly of Watertown, S. D.; a member of the American Medical Association, and of the Baldwin County (Ala.) Medical Society, died at his home in Robertsdale, Ala., January 30, from meningitis, after an illness of three months, aged 61.

William C. J. Smith, M.D. College of Physicians and Surgeons in the City of New York, 1866, a veteran of the Civil War, and for many years a practitioner of Pottsville, Pa., but more recently a resident of St. Clair, died at the Pottsville Hospital, May 31, from cerebral hemorrhage, after a short illness, aged 68.

John Eugene Tremaine, M.D. Hahnemann Medical College and Hospital, Chicago, 1891, professor of materia medica in his alma mater, died at his home in Chicago, June 7, from septicemia attributable to infection received while attending an obstetric case, after an illness of two weeks, aged 37.

Thomas Henry Brinker, M.D. Jefferson Medical College, Philadelphia, 1846, one of the oldest practitioners of Westmoreland County, Pa., died at his home in Pleasant Unity, Pa., April 27, after an illness of ten days, from disease of the kidney and bladder, aged 87.

Alvin R. Bills, M.D. University Medical College of Kansas City, Mo., 1882; a member of the American Medical Association; for many years a practitioner of Bentonville, Ark., died at his home in Sulphur Springs, Ark., May 24, from asthma, aged 50.

James C. M. Rankin, M.D. Medical Department of the University of Nashville, Tenn., 1858, for four years in the Confederate service during the Civil War, died at his home in Bella Mina, Ala., February 18, aged 72.

William E. Morrison, M.D. Hospital Medical College, Louisville, 1884, for 20 years a prominent physician of Cumberland Gap, Tenn., died June 9, at his home in that place, from cerebral hemorrhage, aged 45.

Charles Wilson Lewis, M.D. Vanderbilt University, Medical Department, Nashville, Tenn., 1886, died at the home of his son in Birmingham, Ala., May 2, from heart disease, after an illness of two years, aged 67.

Clark B. Provins, M.D. Rush Medical College, Chicago, 1882, a specialist on diseases of the eye and ear, died at his home in Ottawa, Ill., June 4, from pernicious anemia, after an illness of three years, aged [illegible].

Thomas B. Watkins, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1868, a Confederate veteran, died at his home in Memphis, Tenn., May 31, aged 65.

W. O. Williams, M.D. Medical College of Indiana, Indianapolis, 1890, died at his home in Indianapolis, March 30, from pneumonia, aged 38.

George E. Willard, M.D. Chicago Medical College, 1874, died at his home in Chicago, June 9, after an illness of seven years, aged 51.

A. M. Watson, M.D. University of Edinboro, Scotland, 1864, died at his home at Alberni, B. C., March 24.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending June 9, 1906:

Rand, J. W., Fuller, L. A. Skinner, George A., asst.-surgeons, ordered to report in person, June 25, 1906, to Lieut.-Col. George H. Torney, deputy surgeon general, president examining board, Army General Hospital, Presidio, San Francisco, Cal., for examination to determine their fitness for promotion.

Stone, John H., Wilson, James S., Fauntleroy, P. C., Dutcher, Basil H., Darnall, Carl R., asst.-surgeons, ordered to report in person, June 25 and 26, 1906, to Major William H. Arthur, surgeon, president examining board, Army Medical Museum Building, Washington, D. C., for examination to determine their fitness for promotion.

Hutton, Paul C., asst.-surgeon, granted ten days' leave of absence, with permission to apply for 21 days' extension.

Yost, John D., asst.-surgeon, relieved from duty at Honolulu, H. T., and ordered to proceed to Manila and report in person to the commanding general, Philippines Division, for duty.

Richard, Charles, surgeon, in addition to his other duties is announced as attending surgeon at Headquarters, Department of the East, Governor's Island, N. Y.

Hutton, Paul C., asst.-surgeon, leave of absence extended 21 days.

Swenzey, Verge E., asst.-surgeon, relieved from further treatment at the General Hospital, Washington Barracks, D. C., and ordered to Fort Williams, Me., for duty.

Duval, Douglas F., asst.-surgeon, relieved from duty at Fort Williams, Me., and ordered to Fort Snelling, Minn., for duty.

Grissinger, J. W., asst.-surgeon, left Fort Jay, N. Y., on leave of absence, to include July 1, 1906.

Appel, D. M., deputy surgeon general, reported for temporary duty in the office of the chief surgeon, Headquarters Department of California, San Francisco, Cal.

Ware, William H., dental surgeon, left Fort Wingate, N. M., and arrived at Fort Apache, Ariz., for duty.

Kelly, John P., contract surgeon, left Presidio of Monterey, Cal., for duty with troops in Sequoia National Park, Cal.

Thorp, Charles W., contract surgeon, left Fort Ethan Allen, Vt., on sick leave of absence for three months.

Burkhart, John L., contract surgeon, relieved from duty in the Philippines Division, and ordered to the United States on first transport after August 1.

Hess, John H., examining and supervising dental surgeon, granted leave of absence for two months.

Rhoades, Rex H., dental surgeon, ordered from San Francisco, Cal., to Fort Sheridan, Ill., for duty.

Rietz, Hugo C., dental surgeon, relieved from duty in the Department of the Lakes, and ordered to the Philippines Division for duty

AMERICAN MEDICAL ASSOCIATION

PROCEEDINGS OF THE FIFTY-SEVENTH ANNUAL SESSION HELD AT BOSTON, JUNE, 5-8, 1906.

INDEX TO OFFICIAL MINUTES

OFFICIAL MINUTES—HOUSE OF DELEGATES

First Meeting Monday, June 4

The House of Delegates convened in the Assembly Hall of the Boston Medical Library, and was called to order at 10:30 p. m. by the President, Dr. Lewis S. McMurtry, Louisville, Ky.

The report of the Committee on Credentials was read by the Chairman, Dr. W. B. Dorsett, St. Louis, Mo.

The President then delivered his Address.

President's Address.

READ AND REFERRED TO COMMITTEE (see page 1872).

To the Members of the House of Delegates of the American Medical Association:

Gentlemen:—On July 13, 1905, this House of Delegates adjourned in Portland, Oregon, to convene this day in Boston. From the beautiful city within sight of Mount Hood to the historic city of Boston is a transition which well typifies the broad scope and truly national character of the American Medical Association.

I see before me many delegates who participated in our work at Portland, and also a goodly number who are entering on the duties of this House for the first time. To all I extend a cordial greeting.

The second annual session of the American Medical Association was held in Boston in 1849. Sixteen years later, in 1865, at the close of the great civil war, the Association convened in this city for the second time; so that the present meeting marks the third convention of the Association here. We have come on the cordial invitation of the Massachusetts Medical Society, and we doubt not that the meeting will strengthen the bonds of sympathy and fraternity between the profession of the other states and our brethren in New England.

I would suggest that this House of Delegates extend to our hosts, the members of the Massachusetts Medical Society, a cordial invitation to attend the various proceedings of the Association and to take part in the same.

This session is made marked and memorable by the return to the Association of a full representation of the united profession of the great state of New York. After many years of disagreement and separation, all differences have been adjusted with mutual respect and honor, and the national association once more claims for its own the society by which it was founded and fostered. And the crowning triumph of this achievement is that the reunion of our New York brethren has been accomplished with perfect harmony and unanimity. Time and progress have removed every vestige of former disagreement, and the members of the profession of the Empire State have exhibited a noble spirit of moderation and consideration with one another. Some of the leaders in this great achievement are sitting in this House as delegates. All

honor to them. I know that I voice the sentiment of the profession of the constituent societies of this House when I extend to the delegates from New York a welcome, a most cordial welcome, to the fellowship of this Association.

During the year which has elapsed since I became President of the Association, I have had ample opportunity to become familiar with the work of the Association as it is conducted in the several directions you have authorized and ordered. Last year my distinguished predecessor in this chair, Dr. Musser of Philadelphia, mentioned in his address the fact that the President of the Association represents in our organization the great body of the profession as separate and distinct from the organization composed of officials whose tenure of office extends over several years. Such a relation imposes on your President the duty of reporting to you his impressions of the organization, with such suggestions as he may believe will be useful, and conducive to the better accomplishment of the great and noble purposes to which this Association is dedicated, and which are set forth in Article 2 of our Constitution.

Following this suggestion, it is a pleasing duty for me to bear testimony to the fidelity, honor and devotion of those officials who compose the established organization of this Association.

During my term of office I have been in constant official relations with the Secretary-Editor, and I would be remiss in my duty did I not publicly attest his ability, his conscientious devotion to his duty, his entire self-effacement in the discharge of his onerous, exacting and often disagreeable duties. I know whereof I speak when I say that, week in and week out, while we go our way in pursuit of our daily duties, he is laboring unselfishly to carry out the purposes of this House of Delegates, to elevate our profession on a higher plane of scientific achievement and professional advancement. Under the direction of the Board of Trustees, and with the resources provided by the Association, he has made THE JOURNAL the foremost medical weekly periodical in the world; and, as chairman of one of your most important committees, he is doing work of transcendent importance to scientific medicine and the welfare of humanity. These words of commendation are spoken as a duty I owe to the Association and must not be construed as a tribute of friendship or the commonplace eulogium of public occasion.

In the same spirit, I desire to bear testimony to the faithful work of the Board of Trustees. No more honorable men have ever discharged a high public duty and trust than those who have hitherto and who now compose that board. Their responsibilities are great, and with altruistic motives they have discharged their duties faithfully and without thought of self-interest.

From my intercourse with the members of our profession in the various states, as also from my correspondence during the year of my Presidency, it is apparent that the impression is very general that the President and Secretary are the chief and most authoritative officials of this Association. Permit me to call your attention to the fact that the combined powers vested in the President, Vice-Presidents, Secretary, the Judicial Council, and all committees, are trivial in comparison with the power concentrated in the Board of Trustees. Under our organization, the Board of Trustees has sole charge of the extensive property and controls all the financial and business affairs of the Association. This Board also has sole control of the disbursement of all funds in carrying on the publications of the Association—to supply funds for standing committees, to direct scientific investigations—and can mould the policy of the Association at will during the interim of the annual sessions. The present prosperous condition of the financial affairs of the Association, the splendid position and high standard of THE JOURNAL, and the efficiency with which the work of the several standing committees is being prosecuted, all compose a superb tribute to the ability, good judgment and professional devotion of the present Board. Indeed, the profession is honored by their service, and they deserve the grateful appreciation of the members of the medical profession.

In view of the fact that the Association's membership is increasing with great rapidity, and that its property interests and financial resources are also rapidly growing, it is of the highest importance that the efficiency of a board entrusted with such vital interests should be properly safe-guarded by careful selection of its members. Under our Constitution, three trustees are elected annually, each to serve for three years. It is inimical to a deliberate and discriminating choice to elect these responsible officers as is habitually done by the House of Delegates. I allude to the custom of voting on three names at once. When you consider that these officers are vested with more power and responsibility than are placed in all the other officers, certainly they deserve to be carefully chosen, one at a time, as obtains in the selection of the other officers. While the Constitution and By-laws make no specific direction as to the method of balloting, but prescribe the same course for the election of all officers (except that the Treasurer is to be nominated by the Board of Trustees), it is apparent that the intention is that the three trustees are to be elected by the same method of nomination and balloting as are the four Vice-Presidents. I would respectfully recommend that a motion be adopted which will guarantee a free and deliberate choice in the selection of these most important officers, by electing one at a time.

In Article 5, Section 1 of the Constitution it is prescribed that "the trustees shall be members of the House of Delegates, without the right to vote." This is eminently proper, and is intended to afford the trustees opportunity to give the House of Delegates information on all matters arising in the course of the proceedings over which the Board of Trustees has control and especial cognizance. That it would be an abuse of office, fraught with danger, to invest officers of such supreme power with the delegate's ballot was apparent when the Constitution was framed and adopted. Therefore, no member of the Board of Trustees should be eligible to membership in the House of Delegates, since such a delegate would be a trustee with the right to vote, a condition expressly forbidden in the Constitution. He would become a voter in the House before which his own name and the names of his colleagues of the Board of Trustees are to be submitted in competing ballot.

The Constitution, Article 9, Section 3, declares: "No member of the House of Delegates shall be eligible to the office of President or Vice-President." Such a protection of the interests of the Association against undue influence is so just, and the precaution is so necessary, that it needs no comment for proper appreciation. If such doubling of office in one individual is forbidden by the Constitution as to the President and Vice-President, how much more essential is it that the same precaution should be prescribed and enforced as to the trustees, whose power and responsibilities are so much greater? I shall have occasion presently to allude to the attacks now being made on the Association's JOURNAL and the Association's management. These attacks, which you will readily recognize as the result of sinister motives and altogether unjustified in fact, are directed toward work entirely within the control and direction of the Board of Trustees. As the strength and influence of the Association grows, and pressing evils are exposed and corrected, such attacks will naturally increase. Under such circumstances, the Board of Trustees should command the confidence of the profession at large, all members of the board should sustain the same relation to this House of Delegates, which selects them, and they should also be on the same footing with each other. Hence, I would recommend that the Constitution be so amended that no member of the board can occupy the double office of trustee and delegate.

So long as the meetings of the American Medical Association consisted almost wholly of section work, with a large general session every day for the adoption of resolutions, with no systematic or persistent work along definite lines, the commendation of the medical press was generally and freely bestowed on the organization. But since the reorganization, when this House of Delegates was established, and the membership has increased, and the power of a great organization comes to be intelligently directed toward improving the resources of scientific medicine and advancing the welfare of the

profession by organization, certain interests have been interfered with, and the natural course of misrepresentation and abuse has been resorted to by the interests involved. First, and most naturally, THE JOURNAL, owned and controlled by the Association and ably edited and published under the direction of the Board of Trustees, was the object of attack and misrepresentation. For years publishing firms have grown rich by the patronage of the medical profession, and these same firms owned medical journals liberally supported by the profession. That the medical profession should own and publish a journal of its own, and that this journal should attain great popularity and influence, has provoked hostile criticism and misrepresentation. That this hostility, abuse and misrepresentation should be directed against the editor of THE JOURNAL is natural, since he is in the direct line of fire, and, from one standpoint, is the chief offender. That you may appreciate the ridiculous character of these charges, I would refer you to the leading editorial in the last issue but one of a New York weekly, which has for years enjoyed the liberal patronage of the profession, and which is owned by a wealthy publisher of medical books. The editorial is entitled, "The American Medical Directory." After stating that the issuance of a medical directory by the American Medical Association is absolutely without excuse, although mentioning that the Medical Society of the State of New York had advantageously issued a directory of that state, the editor says:

"The Editor-Secretary has also gone into the business of publishing medical books—he might as well drag the Association into the making of shoes. We do not know who authorized this venture—perhaps the managers will take us into their confidence at the Boston meeting in June—but, whether authorized or not, if the Association publishes books it should give them without price to its members."* Comment on this is unnecessary. The allusion to Dr. Simmons and the feigned ignorance of the fact that the publication of a medical directory was authorized by a vote of this House of Delegates at Portland last year, shows the unfair methods and animus of the editor who wrote the lines quoted.

But there is another interest which has been offended and which is equally unfair and far more abusive in its attacks on THE JOURNAL and the Association. This is the interest of the manufacturers of "patent" and proprietary medicines. This House of Delegates established a Council on Pharmacy and Chemistry, which, with the co-operation of the Board of Trustees, has secured the services of expert chemists and pharmacists to analyze the various nostrums and proprietary medicines in popular use. Many remedies, widely advertised under a plausible name, were found to be composed of cheap and familiar drugs, and sold at a ridiculously high price. The Board of Trustees, by direction of this House of Delegates, excluded from the advertising pages of THE JOURNAL all preparations which did not make public with the advertisement the formula showing accurately the composition of the products advertised. Many of these manufacturers of proprietary medicines have grown rich and they saw here a serious menace to their interests. Their avenue of assault is through the editorial columns of the medical journals they have subsidized, and their press committee has been very active of late. Here, as in the instance I have cited from the medical publishers, the editor of THE JOURNAL is made the special object of abuse and criticism. In the meantime, the editor's unpardonable offense is that he is doing his duty faithfully, as he is appointed to do, and at all times under the direction of this House of Delegates.

The far-reaching labors of the chairman of your committee on organization, Dr. J. N. McCormack, which have done so much to build up this great organization, have likewise brought on that distinguished physician a goodly share of unjust criticism and abuse.

These attacks on the Association, its work and its officers, abound with allusions to "clique" and "ring" in the organization, which "clique" or "ring" is alleged to be surreptitiously and treacherously running the affairs of the Association. I know not to whom these epithets are intended to apply, but this I do know, that there is no officer or board, or committee of the Association which is not directly created by this House of Delegates. Hence, if there be a clique or ring entrenched in power anywhere in this great organization, the responsibility for its existence rests on this House of Delegates and the means for its immediate destruction are in your hands. You represent a constituency of more than 60,000 physicians, and it devolves on you to discharge faithfully the trust you have assumed.

Craving your pardon for detaining you so long, and bespeaking your indulgence and co-operation in the work before us, I now declare the House of Delegates open for the transaction of business.

On motion of Dr. Frank Billings, Chicago, the Address was referred to the Reference Committee on Reports of Officers.

Method of Election of Trustees.

AMENDMENT REFERRED TO COMMITTEE.

In harmony with the suggestions contained in the President's Address, Dr. E. Eliot Harris, New York, offered the following resolution, which was likewise referred to the Reference Committee on Reports of Officers:

Resolved, That the Trustees of the American Medical Association be nominated orally and elected by ballot of the House of Delegates in separate order.

Reference Committees Announced.

The President then announced the reference committees:

COMMITTEE ON REAPPORTIONMENT.

President and Secretary (*ex-officio*).
G. W. Guthrie, Pennsylvania. F. D. Bain, Ohio.
W. J. Miller, Tennessee.

COMMITTEE ON CREDENTIALS.

W. B. Dorsett, Missouri, Chairman.
W. R. Townsend, New York. H. Bert Ellis, California.
Thomas McDavitt, Minnesota. J. H. Hamilton, South Carolina.

COMMITTEE ON AMENDMENTS TO CONSTITUTION AND BY-LAWS.

Alexander R. Craig, Pennsylvania, Chairman.
H. Bert Ellis, California. D. C. Brockman, Iowa.
William N. Wishard, Indiana. C. E. Cantrell, Texas.

REFERENCE COMMITTEE ON MISCELLANEOUS BUSINESS.

E. Eliot Harris, New York, Chairman.
W. D. Haggard, Tennessee. R. C. Moore, Nebraska.
Frank Paschal, Texas. A. D. Price, Kentucky.

COMMITTEE ON REPORTS OF OFFICERS.

Philip Mills Jones, California, Chairman.
Donald Campbell, Montana. A. Jacobi, New York.
Edwin Walker, Indiana. A. F. Jonas, Nebraska.

COMMITTEE ON MEDICAL LEGISLATION AND POLITICAL ACTION.

The Standing Committees, members (*ex-officio*).
J. F. Percy, Illinois, Chairman.
W. T. Sarles, Wisconsin. W. E. Anderson, Virginia.
J. R. Kean, United States Army. Hiram Burton, Delaware.

COMMITTEE ON MEDICAL EDUCATION.

Stuart McGuire, Virginia, Chairman.
John T. Rogers, Minnesota. J. N. MacCormack, Kentucky.
Henry L. Elsner, New York. L. C. Morris, Alabama.

COMMITTEE ON SECTIONS AND SECTION WORK.

C. L. Bonifield, Ohio, Chairman.
Charles Chassaignac, Louisiana. Jos. McFarland, Pennsylvania.
G. B. Ross, Vermont. H. W. Dewey, Washington.

COMMITTEE ON RULES AND ORDERS.

J. Garland Sherrill, Kentucky, Chairman.
Edwin M. Fuller, Maine. H. M. Workman, Minnesota.
D. T. Coleman, Georgia. L. D. Wilson, West Virginia.

COMMITTEE ON HYGIENE AND PUBLIC HEALTH.

Reginald H. Fitz, Massachusetts, Chairman.
H. F. Harris, Georgia. L. M. Halsey, New Jersey.
George W. Webster, Illinois. John T. Wilson, Texas.

Report of the General Secretary.

READ AND REFERRED TO COMMITTEE.

The Secretary read his report, which was referred to the Reference Committee on Reports of Officers (see page 1873), and that portion of it relating to the Constitution and By-Laws was referred to the Reference Committee on Constitution and By-Laws (see page 1871).

MEMBERSHIP.

To the Members of the House of Delegates:

Gentlemen:—The membership on the date of the Secretary's last report, June 1, 1905, was 19,285. From June 1, 1905, to May 1, 1906, 5,559 were added to the list of members, and 1,208 were dropped from the list, making a net gain for the 11

*I would state that the weekly New York journal quoted here is not the New York Medical Journal, edited by that veteran medical editor and scholar, Dr. Frank P. Foster.

months of 4,351, or a total membership on May 1, 1906, of 23,636. The discontinuances were: 171 from death, 153 not eligible, 226 for non-payment of dues, 619 resigned, and 38 not found; total, 1,208. Of the 5,559 added to the list, 1,802 were new members, joining the Association direct, while 3,757 had been subscribers to THE JOURNAL and were transferred from the subscription list to the membership list. (On May 1, 1906, there were approximately 18,700 subscribers to THE JOURNAL not members of the Association.)

AMALGAMATED CONSTITUENT ASSOCIATIONS.

Since the last session of the Association two changes have occurred among the constituent state associations. All the legal details for the amalgamation of the New York State Medical Association with the Medical Society of the State of New York under the name of the Medical Society of the State of New York were completed last October and the consolidation was officially recognized by Dr. Lewis S. McMurtry, President of the American Medical Association, December 22.

We have been unofficially informed that on May 8, 1906, a joint meeting of the Oklahoma State Medical Association and the Indian Territory Medical Association was held at Oklahoma City, Oklahoma, at which it was voted to unite the two organizations under the name of the Oklahoma State Medical Association. Dr. B. F. Fortner of Vinita, Indian Territory, was elected as President, with Dr. E. O. Barker, of Guthrie, Oklahoma, as Secretary.

SECTION ON TROPICAL MEDICINE.

The following letter was received May 5, 1906:

DEPARTMENT OF THE INTERIOR, BUREAU OF HEALTH,
MANILA, March 30, 1906.

Dr. George H. Simmons, General Secretary, American Medical Association:

Sir:—By direction of the Committee on Public Policy and Legislation of the Philippine Islands Medical Association, I have the honor to recommend through you that the American Medical Association establish at its next annual meeting, a permanent section on Tropical Medicine. This movement will be gratifying not only to the Philippine Islands, but to Porto Rico, Hawaii and Panama as well. Very respectfully,

R. E. L. NEWBERNE,
Ex-officio, Sec., Committee on Public Policy and Legislation
Philippine Islands Medical Association.

AMERICAN PHARMACEUTICAL ASSOCIATION.

A letter received from the General Secretary of the American Pharmaceutical Association, Mr. Charles Caspari, Jr., dated "Baltimore, May 14, 1906," says:

I have the honor of informing you that President Lemberger has appointed the following gentlemen delegates to attend the next annual meeting of the American Medical Association, to be held at Boston in June, for the purpose of extending cordial fraternal greetings from the American Pharmaceutical Association, and especially to attend the sessions of the Section on Pharmacology and Therapeutics:

Henry P. Hynson, chairman; John F. Hancock; Thomas P. Cook; Henry Kraemer; S. A. D. Sheppard; Charles Caspari, Jr.; C. S. N. Hallberg; E. L. Patch; Chas. F. Nixon; E. H. LaPierre; James H. Beal; S. P. Sadtler

ASSOCIATE MEMBERS.

I respectfully suggest that Section 5 of Chapter III of Book I of the By-Laws be made more definite. This year there have been certain misunderstandings in regard to the admission to the Official Program of "associate" members.

In 1901 a provision was made by which section officers could invite to take part in the scientific work those who were working in the allied sciences and who were not eligible to membership in the American Medical Association. The provision made in 1901 was as indefinite as the present by-law. I beg to quote from the minutes of the meeting of the House of Delegates, held June 11, 1902:

Dr. Victor C. Vaughan, a member of the Committee on Sections and Section Work, asked for an interpretation of Section 5 of the Constitution as to associate members, which reads as follows:

"Representative teachers and students of the allied sciences, not physicians, may become associate members by vote of the House of Delegates."

He said a gentleman, a distinguished physiologist, who is not a member of the Association, is to read a paper before one of the sections this afternoon, and he wanted to know whether the committee was barred from electing such men as associate members. He asked an interpretation of the two words, "not physicians," and suggested that such men be designated as "unregistered or uncensed practitioners." If this were done, some of the best men, who were doing good scientific work, could be elected associate members.

Dr. John B. Roberts moved that the words suggested by the committee be incorporated and the committee so instructed. Carried.

As a result the section was modified to read as follows:

Section 7. Associate Members.—Representative teachers and students of the allied sciences, not registered or licensed physicians, may become Associate Members by the vote of the House of Delegates.

Section 3, Article II, of the Constitution, adopted in 1903, provided for "members by invitation" as follows:

Members by Invitation.—Members by invitation shall consist of distinguished physicians of foreign countries who may be invited by the officers of Sections or of the Association. They shall hold their connection with this Association until the close of the annual session to which they are invited, and shall be entitled to participate in all of its affairs, as in the case of members, but they shall not be assessed the annual dues.

The committee appointed by the House of Delegates in 1904 for codifying the Constitution and By-laws, combined these two sections—"Members by Invitation" and "Associate Members"—in one section, transferred it from the Constitution to the By-laws, and it is now Section 5, Chapter III, Book I, as follows:

Associate Members.—Representative teachers and students of the allied sciences, and distinguished physicians of foreign countries, may be invited by the general officers or by the officers of a section, to attend the annual session and to take part in the scientific work. They shall be designated associate members. They shall hold their connection with this Association until the close of the annual session to which they are invited and shall be entitled to participate in the scientific and social functions of the Association.

I at first took it for granted that the same general principles were intended to be incorporated in this section as was indicated by the action of the House of Delegates on previous occasions, namely, that the provision was made to admit those who are not eligible to come in as regular members. The opposite view was taken by some, i. e., that teachers who were not in active practice, even though they had been licensed to practice and were members of their constituent state association, were eligible to come in as "associate" members.

My understanding is that originally it was intended that those once elected to "associate" membership should be continued as such members, but in the section adopted in 1904, quoted above, it is stated that "they shall hold their connection with this Association until the close of the annual session to which they are invited," carrying the idea that they are "associate" members only for that meeting. The trouble comes from the fact that the two sections above quoted were combined, and this provision just quoted, while it originally referred to "members by invitation" is made to apply to "associate" members also.

I would respectfully suggest that the matter be given consideration and the by-law made sufficiently definite as to both of these points to avoid any misunderstanding hereafter.

ALTERNATE DELEGATES FOR SECTIONS.

I respectfully suggest that provision be made for the appointment of an alternate from a Section to the House of Delegates when the duly elected delegate is not able to be present to represent the Section. No provision is made for such a contingency. The present provision is as follows, and is from Section 2, Chapter XII, devoted to "Sections": "Each Section shall also elect annually one representative to the House of Delegates of the American Medical Association to serve one year." There is no provision for the appointment of a delegate when the one elected can not serve.

DELEGATES FROM GOVERNMENT SERVICE.

Section 1, Chapter IV, Book II, of the By-laws specifies that no one shall serve as a member of the House of Delegates who has not been a member of the American Medical Association for at least two years. Surgeon-General P. M. Rixey, of the United States Navy, has called attention to the fact that in appointing a representative from the Navy to the House of Delegates his choice is greatly limited, as only medical officers who happen at the time to be stationed near the place of meeting are available. It sometimes happens that these surgeons have only recently become members of the American Medical Association. This also applies to medical officers of the Army and of the United States Public Health and Marine-Hospital Service. I would, therefore, suggest the advisability of adding to Section 1, Chapter IV, Book II of the By-laws the following: "Provided that this shall not apply to delegates appointed to represent the medical departments

of the United States Army, of the United States Navy or of the United States Public Health and Marine-Hospital Service."

SYSTEM OF REPORTING.

In my report for last year the advisability of establishing a system of reporting for county and state secretaries was suggested, which suggestion met the approval of the House of Delegates. Accordingly, a system of report blanks was devised, after consultation with the various state secretaries. Of these a sufficient number was printed to supply all state secretaries desiring them. These blanks consisted of a card for the use of county secretaries in reporting changes and additions to the membership of county societies to the state secretary, and a large blank form for the use of secretaries of constituent state associations in making monthly reports to the office of the General Secretary. They were readily adopted by 43 state associations, or all except Alabama, District of Columbia, Florida, Maine, Mississippi, New Hampshire, Tennessee, Virginia and Wyoming. Monthly or quarterly reports are made, whereby the card index of members of the constituent state associations is kept corrected up to date. This index now consists of approximately 60,000 names entered alphabetically by state and county societies, and furnishes information regarding the membership of any individual physician in his constituent association.

THE COUNCILOR'S BULLETIN.

The advisability of establishing a Bulletin for the consideration of organization matters was also recommended in the report for last year and was approved by the House of Delegates at the Portland session. Accordingly the publication of such a bulletin was begun last fall, and numbers were issued in November, January, March and May. It has been sent to all county secretaries, officers of constituted state associations, including the Councilors, members of the House of Delegates, members of the Board of Trustees, officers of the Sections, etc., in short, to all persons interested in the work along the line of medical organization. The reception which the Bulletin has received has been most gratifying and the matter contained has been of interest and value to organization workers.

BIOGRAPHICAL CARD INDEX.

The establishment and maintenance of a biographical card index of the physicians of the United States was also recommended and approved last year. The work of collecting and arranging biographical matter for such an index was begun immediately after the Portland session, the plan being to accumulate all information possible regarding members of the profession, preserving it in permanent form and using such portions of it as might be required for the American Medical Directory. Beside sending out large quantities of personal information blanks to the profession throughout the country, data have been obtained from state licensing boards, medical colleges, as well as from secretaries of state societies. There are at present on file between 50,000 and 60,000 biographical blanks, filled out by the physicians themselves, containing full biographical data. These blanks are arranged alphabetically, so that they are readily accessible. The work is being carried on and in a short time the Association will have practically complete biographical data regarding every member of the profession and, as time goes on, this accumulation of material will become of immense value in obtaining any information regarding the personnel of the profession.

Respectfully submitted,

GEORGE H. SIMMONS, *General Secretary.*

Report of Board of Trustees Distributed.

The President then called for the report of the Board of Trustees.

The Chairman of the Board, Dr. T. J. Happel, suggested that a copy of the report be distributed to each member of the House of Delegates, without being read, and that a time be set Monday afternoon or Tuesday morning for its consideration.

Dr. E. D. Ferguson, Troy, N. Y., moved that the report be referred to the Committee on Reports of Officers without being read and that Tuesday at 2 p. m., be set for its consideration. Seconded.

Dr. Frank Billings moved as an amendment that the report be made the first order of business Monday afternoon. Seconded (see page 1861).

The original motion as amended was accepted and carried.

Report of the Council on Medical Education.

READ AND REFERRED TO COMMITTEE (see page 1875).

Dr. Arthur D. Bevan, Chicago, Chairman, presented the report of the Council on Medical Education.

Mr. President and Members of the House of Delegates:—The Council on Medical Education desires to call your attention to the report of the work of the Council as given at our second annual conference, May 12, 1906, copies of which have been handed you. This report is as follows:

The purpose of the Council during the last year has been and shall continue to be until accomplished the securing of the general adoption of the standards now recommended.

In order to obtain the general adoption of these basic principles the co-operation of the state licensing boards and the state medical societies must be secured. It has been gratifying to note the very general approval of these basic principles by these bodies, and it is believed that within two years the standard which we recommended as a result of the last conference will be practically universally adopted.

The work of the Council during the last year has been devoted to obtaining data of the existing state of facts in regard to medical education under the following heads:

First, the medical laws of the states and territories and foreign countries; second, the standing of medical schools, as shown by the results of examinations before the various state boards; third, the work of the state boards; fourth, the character of the medical schools, their courses, equipment, facilities, etc.

There can be no doubt but that the most important function of the Council of Education will be the careful collecting of all the facts on medical education and giving publicity to these facts, so that the state licensing bodies, the state medical societies and the medical colleges may be given an accurate presentation of existing conditions. Such publicity is bound to lead to correction and improvement. As an example, let us review briefly the work of the state licensing boards, and the standing of the medical colleges in this country, as determined by the percentage of their graduates passing such examinations.

We have divided the schools of the country into four classes, according to the percentage of failures before the different state boards. Table 1 gives the percentage of failures from 0 to 10; Table 2, the percentage of failures from 10 to 20; Table 3, the percentage of failures over 20 per cent.

In addition to that, we have an unclassified list in Table 4, in which are placed the schools which have not enough data upon which to warrant their being classified. For instance, schools with less than ten students applying for examinations and schools where students have applied simply for examination in one state. I think it is rather interesting to note that the schools which we might expect would be in the first class are largely in the first class, with such a school as Harvard leading the list with the smallest number of failures. In Class 2 the failures are from 10 to 20 per cent. There are a number of good schools in Class 2. I am rather inclined to believe that by directing the attention of the faculties of these schools to the fact that they are in Table 2, it will surely be of value to the schools themselves and will, I think, lead to improvement. I know from my own personal experience that by having our attention called to the number of candidates rejected during this year has placed the faculty with which I am connected upon its mettle. They all feel that it must be within their power to pay more careful attention to the final examinations to prevent the graduation of those students who later fail before state boards.

In Class 3 we will find some thirty-eight schools, with a percentage of failures of more than 20 per cent. It is evident from a study of the medical schools in this country and their work that there are five specially rotten spots which are responsible for most of the bad medical instruction. They are Illinois, Missouri, Maryland, Kentucky and Tennessee. In Table 3 this fact is very well shown. Beginning, for example, with these five states, you will find in Illinois a group of colleges, with 36.8 per cent., 21.5 per cent., and 30 per cent. of failures. You find in Kentucky, for instance, a group of five colleges, with

44 per cent., 30 per cent., 25 per cent., 37 per cent. and 25 per cent. of failures. You find in Maryland a group of five colleges with 24 per cent., 69.2 per cent., 26.2 per cent., 22.7 per cent., and 29.5 per cent. of failures.

You find in Missouri in a group of five colleges the following percentage of failures: 48.4 per cent., 52.4 per cent., 60 per cent., 25 per cent., 30.8 per cent.

Lastly, you find in Tennessee a group of six colleges the percentages of failures 60 per cent., 41.8 per cent., 30.4 per cent., 36.7 per cent., 51.4 per cent., and 34.1 per cent.

The principal cause for this bad work is found in the existence of medical schools which are conducted for profit. At our last conference we called attention to the fact that the time had arrived when a medical school could not be properly conducted from the fees of students and pay a profit to its faculty as a business investment. If we are to raise the standard of medical education in this country to a point where it ranks with the other great countries of the world, the medical school for profit must cease to exist.

Tables 5 and 6, which are also taken from the large tables published in THE JOURNAL of the American Medical Association, May 6, 1905, show comparatively: (1) the severity of examinations conducted by the various state examining boards and (2) the apparent leniency shown to colleges of the home state as compared with colleges of other states.

In these tables we find evidence that is of interest and may prove to be of service to the state boards themselves. The general proposition is that the percentage of rejections by state boards varies from 76 per cent. to 0 per cent. These tables, however, have but a comparative value. In making comparisons a number of other points must be considered. Some states (New York, for example) scrutinize the credentials of and reject many candidates before they come to the examination, thereby reducing the percentage of rejections by examination. States allowing non-graduates to come up for examination would have and should have a large percentage of failures. Colorado leads the list with 70 per cent. of rejections. However, in this state there were only thirteen men who submitted to a written examination, most of the applicants being granted license after a careful inspection of their credentials. The candidates whose credentials were not accepted were offered the opportunity to take a state board examination, but when they found an examination was necessary many refused to come up for it. In the general result, given at the foot of the columns, we find there were 7,035 students from all colleges examined before state boards with an average percentage of failures of 19.3.

An interesting point, too, is found in the separation of failures into two classes: one, the failures by students from colleges of the home state, and the other from colleges of outside states. I think there is food for reflection in these figures. Of 3,129 students examined by the state boards of the same states in which colleges were located, there was 9.2 per cent. failures; from outside colleges some 27.4 per cent. of failures. This is a comparative statement, but one of some value, and it is one which should be carefully analyzed. Undoubtedly one reason for the greater percentage of failures of students from colleges without the state is that the recent graduate usually appears before his own state board at a time when he is best prepared to pass a written examination. Many practitioners moving from one state to another ap

The following tables are based on the reports of State Examining Boards for the year 1904, published in the *Journal of the American Medical Association*, May, 6, 1905.

In making comparisons, besides the percentage, one must consider also the total number examined and the number of State Boards before which representatives of the college appeared.

pear before the state board years after their graduation at a period when they are not as well qualified to take such an examination. Then some states (New York, for example) having a high class of medical colleges would naturally have a smaller percentage of rejections from their own colleges than from colleges outside the state.

The more the subject of medical education in this country is studied, the clearer it becomes that the two agencies which must be relied on to elevate the standard of medical education are:

1. The state licensing boards, which have the legal power to enforce the laws regulating the practice of medicine.

2. The medical profession of each state, which must see to it that the state possesses efficient medical legislation, and, what is even more important, that the right sort of men are placed on the state board.

Acting in harmony, these two agencies can demand and secure satisfactory standards practically at once. The power to control medical practice is and always will be exercised by the state governments.

A national body, such as the American Medical Association, can only be of service in this movement by acting as a central bureau of information, which will collect all the evidence of existing conditions and furnish this evidence to the state boards and to the medical profession of the various states and to the medical schools. Publicity is often the best cure of an evil. Such a central body can be of service by formulating on the basis of this evidence a minimum standard as to preliminary requirements, medical curriculum, etc., the general adoption of which would result in higher requirements and greater uniformity.

In order to ascertain just what conditions prevailed in the various states and territories, a circular letter was sent to the president and secretary of each state examining board, asking definite questions regarding (1) the standard of preliminary education; (2) whether such preliminary education is passed on by a state official or not; (3) who this official should be; (4) the standard medical curriculum held by the state, and (5) whether or not lists of colleges are kept showing which were recognized and which not. Answers to this letter were received from all but six states and from these six the conditions have been since learned through other reliable sources, so that our data is practically complete. From these replies the following facts have been deducted: (See also table 7)

VARIATION IN LAWS.

In the wording of the laws regarding the standards of preliminary education required in the various states, there is a great variety of statements, some of them being quite indefinite, so that it is difficult to deduct positive conclusions. There are nine states, Colorado, Illinois, Indiana, Iowa, Michigan, New Jersey, New York, Ohio and Vermont, which require a four-year high-school diploma or equivalent as a minimum standard. There are five states which apparently hold the same requirements since they have adopted the standard of the Association of American Medical Colleges; these are California, Maryland, Nevada, North Dakota and Virginia. The laws of Connecticut, Kentucky, Missouri, New Hampshire and Wisconsin recognize a "diploma from an accredited (or registered, commissioned or approved) high school"; Nebraska requires a diploma from "a high school or college entrance standing"; and Minnesota, New Mexico and South Dakota require "a high-school diploma" or "a high school educa

tion." Undoubtedly, some of these mean a four-year high-school course, but just how many it is impossible to determine without further correspondence. Pennsylvania's law requires only a three-year high-school education, although the board of examiners states that a four-year high-school education is practically insisted on. Three states, Arizona, Maine and Washington, require "preliminary education satisfactory to the board"; Delaware and Indian Territory require "a common school education" and South Carolina requires "a first-grade teacher's certificate." We can find no mention of preliminary requirements in the laws and regulations of 29 states.

PRELIMINARY REQUIREMENTS.

Eleven states have taken some steps toward having the entrance credentials passed on by a state board or state official. In eight of these states, Indiana, Iowa, Kentucky, Michigan, New Jersey, New York, Ohio and Pennsylvania, all preliminary credentials are passed on not by the college, but by the board of examiners or state official, while in three states, Colorado, Illinois and Wisconsin, it is clear entrance examinations are conducted by the state official, but it is not clear whether other entrance credentials are inspected by this state official or by the medical college. The states in which credentials are all carefully scrutinized by the board or state official and a "certificate of qualification" is issued at the time of matriculation, are to this extent on a similar footing with British requirements where registration of every medical student before or at the time of matriculation is required. There are twelve states which still allow undergraduates to take the licensing examination. These are Alabama, Arkansas, Colorado, Indian Territory, Massachusetts, Mississippi, Missouri, Nevada, Oregon, Tennessee, Texas and West Virginia. Of these, Colorado, Indian Territory and Missouri require that the applicant must have studied four full years, while in the others there is no statement as to whether there is any requirement, so long as the applicant can pass the examination.

ADVANCED STANDING FOR A.B., B.S.

Four states, Iowa, Kentucky, Minnesota and New York, do not sanction the giving of advanced standing to graduates of colleges of liberal arts. Minnesota and Iowa refuse to recognize any diploma from a medical school which gives such advanced standing. New York and Kentucky allow the medical school to do as it pleases, but rejects the applicant in case he has not had the full four years' course in a medical college. In 34 states provision is made requiring four full courses in separate years, three states, Delaware, Georgia and North Carolina have three years as the minimum, while 15 make no statement. Twenty-three states, or 27 if we include California, Maryland, Nevada and Virginia, have endeavored to regulate the length of the college year either by the requirements of a definite number of weeks or months. Seven of these place the minimum at 6 months, Georgia, Indian Territory, Kansas, Montana, Nebraska, New Hampshire and New York; four, Connecticut, Minnesota, South Carolina and South Dakota require 26 weeks (6½ months); eight, Iowa, Missouri, Ohio, New Jersey and Wisconsin, require 7 months; seven, California, Illinois, Indiana, Kentucky, Maryland, Nevada and Virginia, require 7½ months; North Dakota requires 8, Michigan 8½ an Colorado 9 months.

MEDICAL CURRICULUM.

Only one state, Michigan, has adopted the medical curriculum setting forth a definite number of hours in definite subjects, unless we include

TABLE 4.—UNCLASSIFIED COLLEGES.

In this table are all colleges having less than 10 graduates examined, having all examined in the home state, or otherwise showing insufficient data to allow comparison.

* Non-graduates allowed to take examinations.

California, Maryland, Nevada, North Dakota and Virginia, which appear to have adopted the standard of the Association of American Medical Colleges. This, if enforced, would give these states the same standard curriculum as Michigan. Five other states have endeavored in a way, to fix a curriculum requirement, 2, Connecticut and Indiana, by stating the minimum hours per week, for a definite number of weeks each year, and 3, Colorado, Illinois and Vermont, by requiring a minimum number of hours each year. Therefore, only 6 states have arranged in any way for a medical curriculum on a basis of hours required unless we may add the 5 states named above which have adopted the standard of the Association of American Medical Colleges. Therefore, before the standard of the American Medical Association shall become the standard throughout this country, at least 29 states must provide for higher entrance requirements; 40 must provide for registration of medical students before a board of entrance examiners, or a state official, at the time of matriculation; 36 should require higher requirements as to the length of year and 4 should require an examination.

PRELIMINARY EXAMINERS.

As to the official who should pass on the entrance credentials, the majority seem to favor a board rather than an individual; first, because to do the work thoroughly requires more than one, and again, the decisions are less apt to be criticised or to be open to suspicion. Indiana, New York and Michigan have boards. In Illinois, New Jersey, Pennsylvania and Wisconsin entrance requirements are inspected by the State Superintendent of Public Instruction (or in Illinois, superintendent of public schools); in Kentucky by an examiner certified by the state board, while in Ohio there are four different examiners at the four seats of medical education. In Colorado, the law states that the entrance examination shall "not be conducted by the medical college." Classified lists are kept by several states, notably New York and Michigan.

To sum up, the work of the Council for the past year has been:

1. The publication of the standards adopted by the American Medical Association, by printed circulars, by letter and by requesting presidents of state associations to make the subject of medical education a portion of their annual address.

2. Ascertaining the conditions actually existing as regards licensure to practice medicine in the various states.

3. Working for the appointment of committees on medical education in connection with the state medical societies.

4. Laying plans for work through the state examining boards and through the committees on medical education to secure the adoption of the minimum standard in the various states.

5. Collecting, tabulating and publishing the results of state board examinations, showing how many passed and how many failed of the graduates of various medical colleges.

6. Compiling and publishing abstracts of the laws and board rulings governing medical licensure in the various states and territories, as well as extracts from requirements in foreign countries.

7. Compiling of facts regarding medical colleges to be issued in book form, giving the seat, history, hospitals, dispensaries, buildings, equipment, teaching force, preliminary requirements, admission to advanced standing, medical curriculum, requirements for graduation, fees, number of graduates for the current year, length of college year and the name of the dean of each medical college in the United States.

8. Preparation of a list of all medical colleges which have ceased to exist under their original names, whether through merging with other colleges, or otherwise becoming extinct.

7. We believe that for the present every effort of the Association should be made to secure the adoption of the standards recommended by the House of Delegates at the Portland session, and which we believe can be accomplished as planned by Jan. 1, 1908.

The next advance in medical education in this country must be the addition of a year between the high school course and the present four-year course in the medical school, this year to be devoted to chemistry, physics and biology. When this is secured our standards will be equal to those of Great Britain and other European nations.

That this desirable advance is not far off is shown by the fact that a resolution embodying this provision has just been unanimously adopted by the National Confederation of Examining Boards at their meeting in Boston. It is probable that during the year a number of state licensing boards will agree to this recommendation. If in addition to this, the thirty or forty medical schools which are doing the best work publicly announce that all students admitted after 1910 must possess these scientific requirements, this advance will be assured.

On motion, the report was referred to the Reference Committee on Medical Education (see page 1875).

Report of Committee on Medical Legislation.

READ AND REFERRED TO COMMITTEE (see page 1875).

Dr. Charles A. L. Reed, Cincinnati, Ohio, presented the report of the Committee on Medical Legislation.

The past year has been characterized by a great diversity of demands on the legislative organization of the American Medical Association. This diversity grows out of the fact that a larger number of bills covering a greater number of subjects and subjects of greater importance, have been presented to Congress, than during any year since the Association has undertaken to look after legislative questions in a systematic manner. This fact was set forth in detail in the report of the conference held between the Committee on Medical Legislation and the National Legislative Council, which took place at Washington, January 9-11, which report was published in THE JOURNAL, Jan. 20, 1906. It is unnecessary in this connection to discuss these various measures in detail, but merely to call attention to the fact that they embrace the following subjects—namely:

(a) A Department of Public Health, with Representation in the Cabinet.
(b) The Army Medical Reorganization Bill.
(c) The Pure Food and Drug Bill.
(d) Amendment of the Lunacy Laws of the District of Columbia.
(e) Governmental Regulation of Indigent Consumptives.
(f) Anti-nostrum Crusade.
(g) Government Recognition of the Services of Dr. James Carroll.
(h) Regulation of Medical Practice in the Government Reservation of Hot Springs.
(i) Bill for the Relief of the Widow of the Late Surgeon-General Wm. A. Hammond.
(j) Bill to Restore the Canteen in the Army.
(k) Bill Regulating the Treatment of Inebriates in the District of Columbia.
(l) The Postoffice Attitude Toward Nostrums.

These various measures were submitted to committees of the conference and were acted on in the light of the reports of such committees. Several measures of minor importance were brought to the attention of the conference, but from the fact that the energies of the legislative organization were already too much divided, it was thought inexpedient to take them up at this juncture. In this same connection it was urged that even those measures that received affirmative action at the hands of the legislative council were too numerous to enable either the legislative council or the National Auxiliary Legislative committee to give sufficient attention to any one of them to awake the influence that the profession most effectively felt at Washington. It is recommended, therefore, that in future the action of the legislative council be restricted only to measures of paramount importance. By this it is not meant to exclude from consideration bills of special or minor importance—for to do so would be to open again the floodgates of Congress to a lot of measures that lack any merit, but that from their very nature would be charged to the medical profession. Such minor and special measures ought to be considered in conference, and, when meritorious, formally endorsed and thereafter left to the labors of their respective champions. Only meas-

* Law proposed but not adopted as yet.

† Law provides for standards of the Association of American Medical Colleges.

9. Securing, tabulating and publishing of statistics regarding medical students in the medical colleges of the United States and the graduating classes for the last year.

10. Collecting and filing any other obtainable information bearing upon medical education.

Besides the work as outlined in the foregoing report the Council desires to add the following statement:

1. The Council is more and more impressed with the possibility of elevating the standards of medical education through the efforts of the organized profession.

2. That the two most important factors which must be considered in this movement are the state examining and licensing boards and the state medical societies.

3. The state licensing boards represent the power to execute and the state medical societies represent the best means of securing the state laws, which must be secured and executed before proper standards can be established and maintained.

4. The higher class medical schools will of their own volition adopt and maintain proper standards.

5. The lower class medical schools, "the schools for profit," must be compelled by the law executed by the state licensing boards to live up to proper standards.

6. The problem before us therefore resolves itself at present into, first: The securing of efficient medical legislation in each state through the efforts of the organized profession in each state; and, second, the securing of efficient medical men to serve on the state examining and licensing boards.

ERROR.

On page 1858 the two columns are transposed. Table 7 and the matter below it should be first on the page.

vide means for defraying their expenses. The state associations should realize the responsibility that rests with them in promoting legislation by Congress and the extreme importance of providing active representation in the National Legislative Council.

NATIONAL AUXILIARY LEGISLATIVE COMMITTEE.

This committee, consisting theoretically of one member in each county of the United States, actually of 2,130 members, is of extreme importance in bringing the influence of the medical profession to bear on members of Congress. It is, indeed, an effective arm of our legislative organization. On the National Legislative committee devolves, and must continue to devolve, the responsibility of maintaining in number and character, the personnel of this extensive organization. Without this auxiliary committee your National Legislative committee, technically your Committee on Medical Legislation, would find itself reduced to the mere function of making verbal representations to the Congress.

But by this large committee we appeal very effectively to all of the members of Congress, through either the local district societies or through the avenue of their actual constituents.

Too much praise can not be given to the faithfulness and efficiency of this large auxiliary committee, which has at all times responded promptly and faithfully to the demands of the central organization.

THE QUESTION OF ESPRIT DU CORPS.

This leads your committee to observe with extreme satisfaction that the profession as reflected through the national auxiliary committee, and as represented in the various local organizations, state and national, has manifested a most wholesome *esprit du corps*. In times past every member of the profession who had any opinion on any subject, however immature that opinion might be, felt it incumbent on himself to communicate his views directly to his representatives at Washington. Now, however, under the influence of organization, these views are expressed in county and state associations, are developed with a reasonable degree of maturity, and are then communicated to Congress through the recognized channels of the profession. In this way, as never before, the medical profession of the United States is enabled to bring its influence to bear on public questions. The most hopeful sign of the times in this particular has been a general acquiescence on the part of the profession in this program. In only a single instance have influential members of the profession seen fit to ignore the consensus of opinion of the great national body by appearing in person before the committees of Congress to make personal representations that were inimical to the interests of the legislation desired and demanded by the general profession. This instance occurred in connection with the hearings in the pure food and drug bill. The suggestions were seized on by the enemies of that measure to weaken the force and effectiveness of the proposed measure. It is to be hoped that the future will fail to reveal any instance in which any physician, otherwise in good standing in the medical profession, will so far forget his obligations to his profession as to become the representative of the interests engaged in the manufacture and sale of spurious drugs and adulterated foods, as against the carefully determined and justly thought out demands of his profession.

BUREAU OF MEDICAL LEGISLATION.

In the report of the Committee on Medical Legislation presented at Portland a year ago the recommendation was made that a Bureau of Medical Legislation be established in the office of the Association at Chicago. This recommendation was concurred in, but for practical reasons it was found inex-

y out the provision. The recommendation is ar, with the belief that the contemplated step efficiency of the legislative organization. This he fact that the work of the Association has several departments, which departments could rative in carrying on the work of this commit- Information Bureau of the American Medical at all times be made available in determining rsonnel in connection with the large auxiliary e general correspondence of the office is con- g in information that can be referred with ad- vantage to the Bureau of Legislation; the news department of THE JOURNAL could be furnished with items from all over the country, gleaned from the extensive correspondence with the auxiliary committee; but above all, proximity to the printing facilities of the Association would enable the bureau to get out its own large volume of correspondence with greater expedition. This is often a matter of vital importance—particularly in instances in which a pending measure has been assigned for final hearing on short notice by the committee on rules, necessitating an almost immediate issuance of a general referendum. At such times a single day is of extreme importance in getting out an appeal to the Auxiliary Legislative committee. It is to be hoped, therefore, that the previous action of the House of Delegates in creating a Bureau of Legislation will be reaffirmed, and that effective steps will be taken to carry it into operation.

These effective steps should consist in placing the work of the bureau in the hands of a representative located in Chicago, invested with executive authority to conduct the necessary correspondence. The mere fact that your chairman, on whom this work has devolved during the past and the several preceding years, resided at a considerable distance from Chicago, has made it inexpedient for him to assume direct charge of the proposed bureau. This condition of affairs should be corrected, either by selecting an executive for the committee who resides in Chicago, or providing for the committee a secretary with authority to proceed with the work.

AN APPROPRIATION TO DEFRAY EXPENSES INCIDENT TO FORMULATING A BILL FOR A DEPARTMENT OF PUBLIC HEALTH.

The American Medical Association has stood committed to a National Department of Public Health, with representation in the Cabinet, ever since it took affirmative action on this question at Washington in 1891. The gradual evolution of the Bureau of Public Health, known technically as the Bureau of Public Health and Marine-Hospital Service, has been viewed with extreme satisfaction by the American Medical Association, as expressed in a resolution adopted last year at Portland. The matter had reached that point when it was taken up by the conference with the National Legislative Council at Washington in January, resulting in the adoption of the following:

WHEREAS, The medical profession at the Portland Session of the American Medical Association had good reason for endorsing the excellent work done by the Public Health and Marine-Hospital Service during the preceding ten years, has now better reason for asking for an amplification of its powers in view of the valuable services rendered commerce and the most vital interests of this country during the recent epidemic of yellow fever in the south and realizing that the national public health service should be placed on an independent basis; therefore be it

Resolved, That it is the sense of the American Medical Association that a Department of Public Health, with representation in the Cabinet of the President, ought to be established, such department to embrace an expansion of the present Public Health and Marine-Hospital Service, with the addition of other public health agencies now existing and in operation in other departments of the government, together with such additional agencies and functions as may best subserve the public welfare.

Resolved, That the National Committee on Legislation be and is hereby instructed to proceed at once with the preparation of a bill for this purpose to be presented to Congress at the earliest practicable date, if possible during the present session.

Resolved, That the Trustees of the Association be and are hereby requested to appropriate one thousand dollars ($1,000.00), or so much of the same as may be required to defray the expenses of the Committee on Legislation in employing a competent constitutional lawyer to draft a bill for a Department of Public Health contemplated by these proceedings.

The purposes of this resolution have not been carried into effect because the necessary funds have not been provided with which to defray the expenses in connection with the preparation of the bill. This question is brought to the attention of the House of Delegates with the request that the necessary action be taken in the premises.

THE PURE FOOD AND DRUG BILL.

The National Legislative Council reaffirmed its previous action in favor of the pure food and drug bill and renewed its representations to Congress touching this very important measure. This measure has passed the Senate in its original and effective form. It has been reported favorably from the committee of the House, with two amendments, which weaken, but do not entirely destroy its salutary provisions. It is now awaiting the pleasure of the speaker and of the committee on rules for consideration by the House.

It seems that there is a disposition on the part of the speaker and of some members of the committee on rules, arbitrarily to exclude this measure from consideration by the House. It is urged, therefore, that the House of Delegates during its present session, adopt a resolution urging the speaker, in connection with the committee on rules, to provide for the early consideration of the measure by the House, and that such resolution be telegraphed in duplicate to the speaker of the House of Representatives and to the chairman of the committee on rules.

ORGANIZATION FOR THE SUPPRESSION OF QUACKERY.

Your committee has had referred to it the question of organizing a movement whose sole object shall be to deal with the question of quackery as represented not only in the manufacture and purveying of poisonous or otherwise deleterious proprietary medicines, but in the dishonest representations that are made by unscrupulous pretenders through the advertising medium of periodical publications and through the United States mails. The fact that the American Medical Association is interested in any endeavor to safeguard the public health and morals and that it is in consequence opposed to the depredations of medical quacks and charlatans in continually robbing their helpless victims and endangering the public health, and the fact that it is likewise antagonistic to the manufacturers of so-called "patent medicines," who are debauching the public health and morals by the sale of alcohol and narcotics under the guise of medicines—it seems important that for these and other reasons, the House of Delegates should take some action to co operate with non-professional elements of society in correcting these evils. With this object in view it might be well for the House of Delegates to instruct its Committee on Medical Legislation to attend a proposed conference of delegates from other societies and organizations, lay and professional, to be held in the City of New York on November 15 next, for the purpose of effecting a national organization whose specific object shall be to deal with this very perplexing question. The mere fact that medical societies when taking individual action on this question are supposed to be actuated by personal and selfish motives makes it highly important to remember that the initiative in this proposed movement comes from influences entirely outside of the medical profession. It is this fact which points with peculiar significance to the probable efficiency of the movement.

GENERAL EXPENSES OF THE COMMITTEE.

It is urged on the House of Delegates that a generous appropriation for the expenses of the committee be directed. Efficient work can not be undertaken unless the officer in charge of the executive work of the Legislative committee can feel that he has reasonable leeway in the matter of expense. The policy adopted during the last year has not been one of cordial support of the committee. As a result, instead of issuing individual referenda, all the subjects were sent to the profession under cover of one referendum. This is a far less effective way of carrying on the work than by asking for individual action in individual instances. An appropriation of not less than $2,000 ought to be devoted to the current expenses of this committee. The House of Delegates is respectfully urged to take action on this question.

COMPENSATION OF OFFICERS.

In submitting this report of the Committee on Medical Legislation, the chairman urges on the House of Delegates consideration of the following facts:

1. The work of the committee demands the attention of an executive officer for a very considerable time, practically every day in the year

2. This time must be taken from the usually remunerative labors of his profession.

3. Identification with this branch of the work does not bring any indirect remuneration, but becomes a source of additional expense by diverting attention from the strictly professional work of the executive officer.

4. The Association ought not, therefore, to expect or accept such service without some measure of pecuniary compensation.

The House of Delegates is urged seriously to take this matter under consideration. The matter is brought to their attention with all the less hesitancy because your present chairman can not longer serve in the capacity of executive of your committee, and can not, therefore, in any sense be a beneficiary of the foregoing recommendations. Respectfully submitted,

CHARLES A. L. REED, *Chairman.*
WM. H. WELCH,
WM. L. ROHMAN.

NATIONAL INCORPORATION.

Dr. Reed referred to the matter of national incorporation, which, he said, was not mentioned in the report, as the committee desired further conference and would make a supplementary report later.

ARMY REORGANIZATION BILL.

He said there ought to be adopted a resolution urging prompt action with reference to Army medical reorganization, and as Chairman of the committee he wished to confer with members of the Army medical service.

PURE FOOD AND DRUG BILL.

With regard to the Pure Food and Drug Bill Dr. Reed said: "No legislator can explain his opposition to the measure on any theory consistent with either intelligence or honesty. This fact becomes all the more important, all the more significant, when the character of the opposition is taken into account, an opposition which, without exception, is made up of people interested in manufacturing and selling rotten and poisonous foods and liquors with which to make the well sick, and adulterated medicines with which to make the sick sicker. These people, the very vultures of society, possessed of enormous sums of ill-gotten money, are organized into a powerful lobby whose methods stop with no scheme of corruption. Their boast, unblushingly made under the roof of the Capitol at Washington, is that they represent over a hundred millions of capital and that the Pure Food and Drug Bill shall not pass. Yet this bill is simply a safeguard such as the government of every other civilized country has provided for the necessary protection of society. There is no doubt but that the people at large demand a reasonable protection to their health and lives. The Senate has passed the bill. There is no doubt but that a large majority of the House favor it if they can only be given a chance to vote on it. Why is this chance not given? Where is the responsibility for the holdup? At this moment it lies between the chairman of the subcommittee having it in charge, the Committee on Rules, and the Speaker—if, indeed, the order ought not to be reversed. The whole House owes it to itself to take the matter by unanimous action into its own hands. Therefore, I ask for the immediate adoption of the following resolutions:

WHEREAS, The revolting methods recently revealed by both private and governmental inquiry to exist in connection with the selection and preparation of meat for the American and foreign markets are a serious menace to the public health, and,

WHEREAS, The impurities demonstrated by government experts and by the Bureau of Chemistry and Pharmacy of the American Medical Association to exist in numerous other food products, in nostrums purveyed to the public and in remedies prescribed to the sick comprise even more serious menaces to the public welfare; therefore, be it

Resolved, That the American Medical Association, with an affiliated membership of more than sixty thousand physicians and representing the organized medical profession in twenty-four hundred of the twenty-eight hundred and thirty counties of the United States, views with satisfaction the efforts of the administration and of the Congress to protect the American public against adulterated foods and impure drugs and to purge our commerce, domestic and foreign, of fraudulent products.

Resolved, That the National House of Representatives be and is hereby earnestly petitioned to place the pending Pure Food and Drug Bill on its passage during the present week

Resolved, That Honorable W. P. Hepburn, author of the House Bill, be and is hereby requested to lay this petition before the House of Representatives at the earliest practicable moment, and to present a copy of these proceedings to the Speaker of the House and to the Committee on Rules.

Resolved, That the President and Secretary of this Association are hereby instructed officially to telegraph the foregoing preamble and resolutions to Honorable W. P. Hepburn.

NOSTRUMS AND QUACKERY.

Dr. Reed read the following resolutions in regard to quackery and charlatanism:

WHEREAS, The ..... is interested in any endeavor to safeguard and improve the public health and morals, and

WHEREAS, The medical quack and charlatan, by their outrageous practices, are continually robbing their helpless victims and undermining the public health, and

WHEREAS, Many manufacturers of so-called "patent medicines" are debauching the public health and morals by the sale of alcohol and narcotics and many dangerous poisons under the guise of medicines, and by following the most pernicious customs and practices in the conduct of their business and the exploitation of the public, and

WHEREAS, Many manufacturers of drugs and food substances are persistently treating their wares with harmful adulterants and other vicious substances, to the great detriment of health and danger to life, and

WHEREAS, Many newspapers entering American homes contain alluringly false advertisements of adulterated foods and vicious "patent medicines," and criminal quacks and charlatans. Now, therefore, be it

Resolved, By ..... that by reason of the foregoing conditions some concerted action against these evil conditions by public-spirited men and women is necessary for the preservation of the public health and morals and the purity of the American home. Be it further

Resolved, That for the co-ordination and co-operation of the forces willing and able to combat these frightful abuses, the..... does hereby appoint ..... as a delegate to attend a conference of other delegates from other societies and organizations to be held in the City of New York on the 15th of November, 1906, for the purpose of devising ways and means to combat the dangerous attacks now being made from such powerful sources on the public health and morals. Be it further

Resolved, That we approve of the formation of a national Society for the Preservation of the Public Health, whose objects shall be as follows:

(*a*) To obtain and disseminate accurate information concerning practices and conditions of every kind that are dangerous to the public health and morals, and to work for the enlightenment of the public on all matters affecting these subjects.

(*b*) To work for the enactment of laws in the United States, Territories and colonial possessions, for the protection and preservation of the public health and morals, including those matters mentioned in subdivision *c* thereof.

(*c*) To assist the constituted authorities in the enforcement of all laws affecting the public health, including those laws for the prevention of quackery, charlatanism and criminal practices in the healing art, whether by licensed or unlicensed practitioners; the prevention of adulteration and substitution of drugs and food substances; the prevention of the sale of narcotics, alcohol and dangerous substances of every kind, whether under the guise of proprietary remedies and so-called "patent-medicines" and nostrums and remedies, or whether sold as narcotics in violation of law; the prevention of the admission to the United States mails of all newspapers and printed matter of every sort advertising any business injurious to the public health or morals, and to prohibit the advertising of such business in any way. The mention of any one or more particular words or terms in the foregoing paragraph shall not be construed as limiting or qualifying the general terms "public health" or "public morals." Be it further

Resolved, That a copy of these resolutions be furnished the delegate to said conference, and that an additional copy be filed by the delegate with the secretary of the conference of delegates.

Dr. Reed asked that these resolutions be referred at once to the Reference Committee on Medical Legislation and Political Action, with the request that the committee report back to the House of Delegates this afternoon, so that a telegram embodying the resolutions could be sent promptly to the Hon. W. P. Hepburn.

On motion, the report of the committee and resolutions were so referred (see next column).

Report of Committee on Senn Medal.

The report of the Committee on Award of Senn Medal was called for.

Dr. A. F. Jonas, Omaha, Chairman, stated that the committee had only received one paper, consequently it had made no award. The committee submitted its report without definite action.

On motion, the report was adopted.

The reports of the committees on Scientific Research and on Recording the Minutes were called for, and passed in the absence of the chairmen.

On motion, the House of Delegates then adjourned until 2 p. m.

Second Meeting—Monday, June 4

The House of Delegates reassembled at 2 p. m. and was called to order by the President.

The Secretary read the minutes of the previous meeting, which were approved.

Report of Reference Committee on Legislation.

Dr. J. F. Percy, Illinois, Chairman, presented the following report:

The Reference Committee on Medical Legislation and Political Action hereby endorses the preamble and resolutions of the Committee on Medical Legislation and recommends their immediate adoption.

On motion, the recommendations of the committee were concurred in.

Report of the Board of Trustees.

For the Year Ending Dec. 31, 1905.

REFERRED TO COMMITTEE (see page 1873).

Dr. T. J. Happel, Tennessee, presented the report of the Board of Trustees.

To the Officers, the Members, and the House of Delegates of the American Medical Association:

We herewith present our annual report for the current year ending Dec. 31, 1905, as required by our Charter and By-Laws. We desire to make this report so clear that every member, not only of the House of Delegates, but also of the Association, may fully comprehend it.

We present the financial part of the report in the form of the Auditors' report made to the Board after a careful examination of the books, accounts and vouchers of THE JOURNAL office and of the Treasurer of the Association.

EXHIBIT A gives you the letter of the auditing company to the Board of Trustees, calling attention, among other things, to the "Directory Investment," and the net revenue as compared with that of the preceding year.

EXHIBIT B gives you the balance sheet of the Association on Dec. 31, 1905, showing what is called "surplus," and carried forward as such as the basis of the annual report for 1906. This surplus is $237,746.79, as compared with $212,055.18 for Dec. 31, 1904. That account ought to furnish each member of the Association a clear insight into the present status of the Association property on Dec. 31, 1905. In it you will find the value of your real estate and buildings (under-estimated rather than over-estimated), your machinery, furniture and fixtures, bonds, etc.

EXHIBIT C, "Revenue Account as per Books for the Year ending Dec. 31, 1905," shows you the inventory of stock on hand Dec. 31 of that year incurred in "publication" and "general" expenses, showing an aggregate of $249,723.71, and then giving your revenue account itemized, together with your inventory, summing up $275,415.32, the net gain for the year being $25,691.61.

EXHIBIT D shows the "Disposition of Net Revenue for the Year Ending Dec. 31, 1905." From this you will find that your real estate and buildings have increased $21,920.15; your machinery, after deducting "wear," $5,808.75; and that your new account, "Net Investment in Directory," is $10,868.39. You will observe that owing to our new building expense account we have less cash on hand.

EXHIBIT E, Treasurer's Report, shows the money in your Treasurer's hands and the bonds which go to make up the reserve fund of the Association. To this report reference will be made later. Suffice it to say here that you own bonds which cost $40,199.39, the par value of which is $39,000.

The exhibits are worthy of the careful study of every officer and member of the Association.

EXHIBIT F is a comparison of some of the larger items of revenue for the year 1905 with those of 1904, given by the Board, not being the work of the auditing company.

EXHIBIT G, appended to this report, is the "Report of the Council on Pharmacy and Chemistry," made to the Board of Trustees of the American Medical Association at their meet-

ing Feb. 2 and 3, 1906. Although this report has been published in THE JOURNAL, we feel that a matter of so much importance will bear repetition and re-reading.

These examinations are made by a paid auditing company which has no interest in misrepresenting anything. The business of the Association has grown to such an extent that we feel that this is the only business-like method of procedure.

The following is a copy of the Auditors' report:

EXHIBIT A.

THE INVESTORS' AUDIT COMPANY.

CHICAGO, JAN. 31, 1906.

To the Board of Trustees of the American Medical Association, Chicago.

Gentlemen:

In accordance with your instructions, we have examined the books and vouchers of the American Medical Association for the year ending Dec. 31, 1905, and hand you herewith the following statements:

Balance Sheet as at Dec. 31, 1905.
Revenue Account for the year ending Dec. 31, 1905.
Disposition of Net Revenue for the year ending Dec. 31, 1904.

The Association, following its usual custom, has charged against the profits a liberal reserve for depreciation of new building, machinery and furniture and fixtures.

During the year there have been several important improvements made, consisting of a large addition to the building occupied by the Association, considerable new printing equipment, and the equipment of the extension with fixtures, etc.

We would call your attention to an item shown on the balance sheet: "Net Investment in Directory to date $10,858.39." This is made up as follows.

Cost of directory property		$ 6,035.50
Expenditures for salaries, labor and material in preparing first edition		5,042.89
		$11,078.39
Less:		
Directory advance sales	$165.00	
Directory advance advertisements	45.00	210.00
		$10,868.39

We are informed that the first edition of the Directory published by the Association will not appear until about June 1, 1906. Therefore, it is proper to carry the expense incurred as an asset until such time as an income from the Directory shall be realized.

The net revenue, as shown in our last report for the year ending Dec. 31, 1904, was	$43,465.03
And for the year ending Dec. 31, 1905, as per account annexed	25,691.61
Or a decrease of	$17,773.42

We shall be glad to report in detail on this decrease if you desire.

We have examined, properly approved and receipted vouchers for all expenditures, with the exception of a few which had not been returned by the bank at the time of our visit. We shall audit same on our next visit to the office of the Association. We counted the cash on hand and verified the cash in bank with statements furnished us by the bankers. The securities in possession of the Trust Company were examined and found to be intact. In addition to the above, we have verified the footings of the cash book and made such other checks as in our opinion were deemed necessary for the protection of the Association.

Considering the amount of detail handled by the Accounting Department, we found the work to be in excellent condition. There appears to be a continued improvement in the manner of handling the accounts and office work.

We will be pleased to furnish you with any other information that you may desire. Yours faithfully,

E. M. MILLS, Manager.

EXHIBIT B.

BALANCE SHEET AS AT DEC. 31, 1905.

ASSETS.

Real estate and buildings		$114,323.61
Machinery		33,422.45

	$256,961.21	$239,062.85	$17,888.12

A glance at the above table shows from whence has come the larger portion of our profits.

ADVERTISING DEPARTMENT.

The receipts from advertising last year (1905) were $95,600.36—showing a net gain over 1904 of $654.76, but it must be remembered that this gain was made in spite of the fact that in 1904 $15,000 of advertising matter was either rejected or discontinued from THE JOURNAL, and in 1905 at least $10,000 more was rejected, making in all $25,000. The higher rates obtained alone saved us from showing a decrease from this source. A further loss will no doubt result in 1906, from the application of the Rules of the Council on Pharmacy and Chemistry. The Editor and General Manager estimates that the gross loss may amount to nearly $20,000. As the circulation of THE JOURNAL increases, however, its advertising pages become more valuable to ethical advertisers and new matter will take the place of much that has been eliminated by the expiration of contracts, etc. In fact, to sum up the whole matter, your Board of Trustees and your Editor intend to free the pages of THE JOURNAL from everything about which any question can be raised. A glance at the advertising pages of THE JOURNAL shows even now a long stride in that direction.

At the present time things are in a very chaotic condition as regards what is acceptable and non-acceptable advertising for the reason that the Council on Pharmacy and Chemistry has many preparations under consideration, and whether they will be finally recognized as acceptable, depends on the result of the deliberation of the Council. We believe, however, that when this matter has been thoroughly worked out and we get on a solid basis, we shall be able to make up for lost advertising by getting a larger patronage from the more reputable houses. As the circulation of THE JOURNAL increases it becomes more valuable as a medium for general advertisers, not necessarily medical, and these advertisers we think will soon begin to realize it.

By far the greatest number of members and subscribers is obtained by representatives calling on the profession. Over 6,000 names were secured from this source. These special representatives not only secure orders, but some of them are doing excellent work building up the organization and calling attention to its benefits.

Of course, our loss each year is great, and the larger the number of subscribers and members, the greater the loss. There is no way of estimating the loss from deaths and retirement on account of old age, but the number is not inconsiderable. A considerable number, of course, are dropped for nonpayment of dues or subscription, besides those who voluntarily give up their membership or subscription from various causes.

CIRCULATION.

The weekly issue of THE JOURNAL of the American Medical Association from Jan. 7, 1905, to Dec. 30, 1905, inclusive, 52 issues, was as follows:

Weekly Edition. 1905.			Weekly Edition. 1905		
Jan. 7	35,319		July 1	39,182

Grand Total .....1,976,316 Weekly Average 38,006

The total number of copies issued during 1905 was 1,976,316.

The total number of copies issued during 1904 was 1,718,402.

An increase of 257,914, or 15 per cent.

The following is a detailed count of mailing list of members and subscribers by states on Jan. 1, 1906. It also indicates the loss or gain in each state during 1905. Copies to the U. S. Army, Marine-Hospital Service, etc., omitted:

State.	Members.	Subscribers.	Totals.	Gain for Year.	Loss for Year.
Alabama	229	198	427	89	...
Arkansas	287	199	486	36	...

The figures below indicate the count of the mailing list, Jan. 1, 1906, compared with that of Jan. 1, 1905:

	Jan. 1, 1905.	Jan. 1, 1906.
Copies to members	17,570	20,826
Copies to subscribers	15,698	17,669
Copies to exchanges	178	216
Copies to advertisers	248	310
Copies to medical colleges and libraries	98	114
Copies to subscription agents	90	96
Complimentary copies to members of Council on Pharmacy and Chemistry, etc.	.....	30
	33,882	39,261

This shows an increase of 5,379.

PERCENTAGE OF PHYSICIANS RECEIVING THE JOURNAL.

This table gives the number of physicians (based on Polk's and Standard directories, 1904 editions) in each state, and the number receiving THE JOURNAL and the percentage in each state. Copies to physicians in the U. S. Army, Marine-Hospital Service, etc., are omitted.

State	Physicians in State.	Number receiving Journal.	Approximate Per cent.
Alabama	2,114	427	20.1
Arkansas	2,382	486	20.4
Arizona	210	90	42.8
Alaska	55	4	7.2
California	3,921	1,463	37.3
Colorado	1,506	616	40.9
Connecticut	1,361	533	39.1
Delaware	227	51	22.4
District of Columbia	1,030	417	40.4
Florida	660	264	40
Georgia	2,769	467	16.8
Idaho	227	125	55
Illinois	8,517	3,811	44.7
Indiana	4,902	1,517	30.9
Indian Territory	801	166	20.7
Iowa	3,791	1,387	36.5
Kansas	2,566	716	27.8
Kentucky	3,387	894	26
Louisiana	1,462	603	41.2
Maine	1,229	287	23.3
Maryland	1,922	741	38.5
Massachusetts	5,150	1,665	32.3
Michigan	4,274	1,448	33.8
Minnesota	1,960	904	46.1
Missouri	6,089	1,457	25.2
Mississippi	1,663	458	27.5
Montana	356	171	48
Nebraska	1,647	612	37.1
New Hampshire	705	220	31.2
Nevada	84	49	58.3
New Jersey	2,302	774	33.6
New York	13,316	2,813	21.1
North Carolina	1,607	257	15.9
North Dakota	340	249	73.2
New Mexico	203	104	51.2
Ohio	8,112	2,351	28.9
Oklahoma	1,027	207	20.1
Oregon	692	358	51.7
Pennsylvania	9,714	3,156	32.5
Rhode Island	680	185	27.2
South Carolina	1,160	263	22.7
South Dakota	523	258	49.3
Tennessee	3,450	610	17.7
Texas	4,935	1,160	23.5
Utah	301	141	46.9
Vermont	701	189	26.9
Virginia	2,063	487	23.1
Washington	910	532	58.4
West Virginia	1,410	418	29.6
Wisconsin	2,500	1,202	48.1
Wyoming	133	62	46.6

The following table shows the number of members and of subscribers for each year, commencing with 1899, at about which time our present editor took charge of THE JOURNAL:

	Members.	Subscribers.
Jan. 1, 1899	7,997	2,453
Jan. 1, 1900	8,445	4,633
Jan. 1, 1901	9,881	8,339
Jan. 1, 1902	11,107	10,795
Jan. 1, 1903	12,553	12,378
Jan. 1, 1904	13,899	14,674
Jan. 1, 1905	17,570	15,698
Jan. 1, 1906	20,826	17,669

It will be noticed from the above that the membership increased 3,256, but most of these were in the "subscribers" column last year and were transferred to membership during the past year.

This last table presented shows that not enough members of the various state societies are becoming members of the American Medical Association. There are only 3,157 more members than subscribers, showing plainly that many who could become members are not availing themselves of the privilege so to do. In Alabama, for example, 229 of her 2,114 physicians are members of the American Medical Association and receive THE JOURNAL as members, while there are 198 non-members who are subscribers to THE JOURNAL. Tennessee, with her 3,430 physicians, shows only 350 members to whom THE JOURNAL is sent as such, and 260 who take it as subscribers; North Dakota leads all the states in percentage of her physicians who get THE JOURNAL—this being 73.2 per cent.; Washington next with 58.4 per cent.; coming on down to North Carolina with 15.9 per cent. and Alaska with 7.2 per cent. The sparsely settled western states show the greatest appreciation of the efforts of the American Medical Association to furnish a first-class medical journal by heartily supporting it—the lowest percentage being Nebraska, with 37.1 per cent., and the highest being North Dakota with her 73.2 per cent. This is easily accounted by the fact that, outside of the cities, the physicians are so far removed from each other that they are forced to depend on themselves and on the best literature that they can obtain: hence they take THE JOURNAL.

Work done among the physicians by canvassing agents on this point would accomplish much good. They would reach more of the country physicians, who constitute the majority of the practitioners in every state, and could easily induce all who are members of the state society to subscribe for THE JOURNAL. In our opinion much growth in membership must be made through direct contact with the members of the county societies: and frequently the canvasser will be able to induce a physician subscribing for THE JOURNAL to become a member of the county society, which makes him a member of his state society, and hence eligible for membership in the American Medical Association.

PAPER STOCK.

The Editor reports to us that he was able, last November, to make the best contract for paper for 1906 that he has ever made. This is due to the fact that the paper required for THE JOURNAL is a very large order, and is sought after by many mills, which can make it at their convenience, and which is paid for as delivered.

The following table gives the amount of paper stock used, in reams, pounds and tons, and is merely carrying on the statement made to you in previous reports:

	Reams.	Lbs. of paper.	Tons
1898	3,395	321,525	157
1899	4,832	461,420	230
1900	6,747	607,230	303.5
1901	9,052	814,680	407
1902	10,230	938,700	469.3
1903	12,368	1,113,100	586.5
1904	14,399	1,295,910	648
1905	17,783	1,576,530	788

MACHINERY.

During the year we bought another linotype machine. In the very near future a new printing press, modern in every respect, will have to be bought.

INCREASED EXPENSES.

We submit below the various tables illustrating the gradual increase in expenses. This is merely a continuation of the tables of previous years and shows how rapidly this account grows as the number of copies of THE JOURNAL increases.

PAY ROLL AND SALARY.

1899	$31,448.69	1903	$57,067.34
1900	37,359.49	1904	64,471.26
1901	40,416.01	1905	78,874.79
1902	46,316.65		

PAPER STOCK.

1900	$27,598.00	1903	$43,966.57
1901	29,825.00	1904	51,190.05
1902	35,675.06	1905	57,526.69

POSTAGE ON JOURNAL.

1899	$3,905.65	1903	$9,828.41
1900	5,616.06	1904	11,773.44
1901	7,591.37	1905	14,360.28
1902	8,595.63		

INK.

1899	$718.44	1903	$2,055.95
1900	1,145.45	1904	2,225.58
1901	1,753.31	1905	2,765.64
1902	1,930.65		

DIRECTORY.

The Secretary, Dr. Simmons, presents to us the following report in regard to the Directory:

"The editorial work on the Directory is in charge of Dr. Frederick R. Green. The publication of such a directory by the Association has been considered from the first years of the organization of the Association. On several occasions the Association has voted to establish such a Directory and has even appointed committees with full power to act, but owing to the lack of funds and of an organization sufficiently adequate, nothing was accomplished. It will be remembered that the report of the Committee on Organization, adopted at St. Paul, mentioned the Directory as one of the objects to be accomplished by an organized profession.

"The fundamental and most important work has been that of securing an official list of those legally entitled to practice medicine in each state, i. e., those who hold a license from the licensing board. As there are 52 states and territories with 70 licensing boards, the amount of work along this line has necessarily been very large, but it must be remembered that it will not have to be done hereafter. The Association now has a list recorded on the card-index system of the legally qualified physicians of the United States. Arrangements have been made with each of the licensing bodies to keep this information up to date by furnishing a list of newly licensed physicians, subsequent to each examination. The secretaries of the licensing boards have heartily and enthusiastically aided in the work and deserve the thanks of the Association.

"In some of the states, owing to the unsatisfactory condition of the records, it has been exceedingly difficult to obtain the desired information. In Pennsylvania, for instance, there is no complete list of legally qualified physicians in the hands of any of the state boards. The present medical practice law requires registration in the office of the county clerk. It was, therefore, necessary to obtain a copy of the list of registered physicians from the prothonotaries of the 67 counties in Pennsylvania. In New Jersey the same procedure was necessary, owing to the fact that the medical practice act in force from 1880 to 1890 only required registration in the county clerk's office. This necessitated obtaining transcripts of the records from each of the 21 county clerks, in addition to the list of the secretary of the State Board of Medical Examiners, of physicians licensed from 1880 to date. In Texas, the fact that four successive practice acts have been in force during the last 20 years, each one with different requirements regarding registration, as well as the vast size of the state and the fact that the profession is widely scattered, made it difficult to compile an accurate list of practitioners. This problem has been solved in a more or less satisfactory manner, however.

"It should be constantly borne in mind that the Directory will be a compilation of only a portion of the personal and professional information contained in the biographical card index. It is manifestly impossible, owing to lack of space, to publish full and complete information regarding each physician. All the data obtained, however, is made a matter of permanent record and is preserved in the card records. We have now on file over 50,000 personal information blanks, beside large amounts of data obtained from medical colleges, societies, etc. As stated above, the most important work is the compilation of a list of legally qualified physicians. The result of this work has been that, in nearly all the states, the secretaries have realized more than ever before the importance of accurate registration. The Association is co-operating with them in this effort and, in some instances, will probably print alphabetical rosters for individual state boards. The value to the boards themselves, is that all of the information on file at this office is placed at their disposal.

"Medical college statistics have been secured in the same manner. We have obtained a list of graduates for the years 1902, 1903, 1904 and 1905 from every medical college now in existence with the exception of two. This completes and brings up to date the list of college graduates already in our possession. Arrangements have been made with the medical colleges to supply us with a list of graduates each year. Thus we shall have a list of those licensed in each state and a list of graduates of all schools.

"At this time—May 15—the matter for 35 of the states is in type. The preliminary matter, including medical practice laws, state boards, officers of the county and state medical societies, medical colleges, etc., is complete and in type for all states."

BUILDING.

The addition to THE JOURNAL building, when completed, as suggested in the annual report made at Portland, increased the floor space about 50 per cent. For the present there is no crowding and work can be carried on much more rapidly and conveniently. The fourth story has been left without partitions, which will be put in as needed, under the supervision of the resident Trustee and the Editor and General Manager, Dr. Simmons. At the February meeting of the Board of Trustees they were directed to arrange for the installation of a chemical laboratory outfit on this floor. Reference will be made to this matter again under the head of appropriations. Until this fourth floor is partitioned off, the room called the Library, and used also as a meeting place for the Board of Trustees, is utilized for various purposes. There will soon be no spare space in the building if the business grows as it has in the years 1904 and 1905. In using the term "building," reference is made to THE JOURNAL home alone. The balance of the property is spoken of as real estate.

REAL ESTATE.

You have, in addition to THE JOURNAL office, five houses—two of three stories and basement and three of two stories and basement. These have all been kept in first-class repair. Three of these houses front on Dearborn Avenue and two on Indiana Street. The double house on Indiana Street has been continuously rented during the past year for $130 a month. The corner house on Dearborn Avenue is renting for $60 a month, and the two next to this building are now rented to one party at $80 per month, making a total of $270 per month for rents. The gross income from this source was $3,447.04. The excess of receipts as given in the total amount is accounted for by the fact that the agents who originally looked after the matter always kept back a month's rent, which was paid in full last March at the time the management of the property was taken on by THE JOURNAL office.

Assuming that the cost of the property occupied by the houses is three-fifths of the original cost, we should estimate its value as being $34,558.26, which will make a net income of 3.3 per cent.

To show more plainly the conservatism of our auditing company, your attention is called to Exhibit C, where there is charged against the Association "Depreciation of buildings, $1,742.32." This is a charge that is made under their business rules, while the whole real estate is worth more than it originally cost the Association.

PROFITS.

The profits from the business for the year 1905 are $17,773.42 less than last year. Perhaps an explanation of this decrease is due the House of Delegates and the Association. The receipts from dues for 1904 were abnormally large by reason of a special offer made in September of that year, and continued to the end of the year to send THE JOURNAL from date of subscription or application for membership until Dec. 31, 1905. By virtue of this offer 1,100 new members paid their 1905 dues in 1904, increasing the receipts of 1904 by $5,500, which could be properly deducted from the receipts of 1904 and added to those of 1905, thus making a difference of $11,000. Again the expiration of the contracts of many medical advertisements in 1905, which could not be renewed for the present, has been another source of loss of revenue. The estimated value of these advertisements, together with those rejected, as stated elsewhere, amounts to about $10,000. Thus it can be readily

seen that the difference in profits can be accounted for. This shrinkage may continue through another year, but it is expected that all rejected ads will soon be replaced by others to which no objection can be offered.

As stated in each of our previous reports, the true profits of THE JOURNAL should be kept separate and distinct from the profits of the Association, for the reason that the expenses incurred by the Association are liable to vary greatly in different years. The Association expenses for 1905 exceeded those for 1904 by $4,172.70. This is offset to a slight extent by an increase in receipts from interest on bonds, $400, and from rents, $702.70, a total of $1,102.70. This, therefore, will account for a decrease in profits of about $3,000.

We can estimate the approximate profits of THE JOURNAL as follows:

Association net profits	$25,391.61	
Association expenses	21,596.27	
Journal profit		$47,287.88
Interest	$2,057.54	
Rents	1,466.75	3,524.29
		$43,763.59

The following table shows the profits made by THE JOURNAL, the true profits of the Association for several years, as well as the net revenue to the Association from THE JOURNAL, from rents and from interest:

	ASSOCIATION INCOME.			Association expenses.	True profits.
	Journal.	Rents.	Interest.		
1899	$22,451.24	. . . . .	. . . . .	$ 5,843.39	$16,616.85
1900	21 984.79	. . . . .	. . . . .	7,182.57	14,8 2.22
1901	36 245.60	. . . . .	. . . . .	10,227.49	26 018.11
1902	46 698.05	. . . . .	. . . . .	5,935.49	40.140.56
1903	50,481.33	$1,400.34	$ 560.00	11,952.99	40 488.68
1904	57,0 2.22	1,195.31	1,295.82	16,0.8.32	43,465.03
1905	43,703 59	1,466.75	2,057.54	21,596.27	25,691.61

Thus, the Association has three sources of income. THE JOURNAL, rents and interest on bonds. The total of these, minus the Association expenses, gives the true profits of the Association.

There has been a gradual increase of the wages paid all the employés of THE JOURNAL. The union scale of wages has to be complied with to avoid trouble in having our work done, and as in every other line of business, skilled labor commands better prices, commensurate with the increased cost of living.

APPROPRIATIONS.

The appropriations for 1905 exceed those of 1904 by nearly $4,000.

The following appropriations were made:

$100 to the Committee on International Congress of Medicine.

$300 to the Committee on Scientific Research.

$250 honorarium allowed Dr. F. B. Wynn.

$600 was appropriated for the payment of secretaries of sections.

$500 was appropriated for Scientific Exhibit.

$1,000 was appropriated for Committee on Medical Legislation.

$300 was appropriated for Committee on Reciprocity.

As much of $4,000 as might be needed by the Council on Medical Education. Of this amount $639.43 had been used up to Dec. 31, 1905.

A few other appropriations made at the February meeting of the Board will be reported for 1906. The appropriation of $2,000 for the installation of a Chemical Laboratory is the chief one agreed on for 1906. In the opinion of your board much thorough work can be done here in aiding the Council on Pharmacy and Chemistry. The chemist to be employed here will act as secretary to the Council. Out of the appropriations a room is to be cut off and properly equipped with necessary laboratory supplies.

INVESTMENTS.

In view of the explicitness of the Treasurer's report, little need be said on this subject. We have, as he shows plainly, bonds with a par value of $39,000, bearing interest at the rate of 4 per cent., and a special deposit of $15,000 to be used in procuring as nearly as possible $15,000 of similar bonds when the market becomes suitable for the purchase. Up to the time of writing this report the market has been too high to enable the Association to realize 4 per cent. on the investment. But while this $15,000 is a special deposit, it is drawing interest at the rate of 3 per cent. per annum. We have now, as you see, a reserve fund of $54,000, just about one-third the amount needed to place THE JOURNAL on a rock-bottom foundation. No encroachment should be made on this fund; on the contrary, it should steadily be made to grow each year, till it has reached $150,000. Until then, there should be no listening to any suggestion of a reduction in membership fees or subscription rates.

BOOK-KEEPING, ETC.

The Audit Company reports (Exhibit A) that all the work was found in excellent condition, with "a continued improvement in the manner of handling the accounts and office work." All your property is kept insured and taxes paid. Your officers are all bonded in solvent bonding companies.

NATIONAL INCORPORATION.

Your board is informed by Dr. Charles A. L. Reed that further efforts to obtain a National Charter that would enable the Association to do business anywhere in the United States will be abandoned, as Congress could not grant such a charter. A charter secured through Congress would be limited in its powers by the laws, etc., governing the District of Columbia. We would recommend that no more money be expended along that line.

PLACE OF SESSION, EXHIBITS, ETC.

Your board has not been able to assume full responsibilities connected with the place of session, quarters for section meetings, railroad rates, etc., but if the amendments recommended for passage are carried, then we will feel the responsibility resting on our shoulders. This year that burden is borne by the local Committee on Arrangements.

FINALLY.

We hope that the work of your board, as set forth in this report, can be fully understood, and that whatever criticism may be indulged in may be not of an iconoclastic nature, but with a view to aiding us in our work. The work has been done. "Judge ye" not in a carping spirit, but with malice toward none. Of course, we have incurred the hostility of those firms and parties whose advertisements have been refused, but in each case an honest effort has been made to comply with what we have understood to be the expressed wish of the Association.

We would ask that the House of Delegates extend to Dr. George H. Simmons, Editor and General Manager, a most hearty vote of thanks for his year's work for the Association. Money paid for services rendered is not always a *quid pro quo*, thanks extended frequently being as much estimated.

We attach as Exhibit G the report of the Council on Pharmacy and Chemistry, submitted to the Board at its meeting in February, to which we invite your attention. We are glad to announce that through the courtesy of Surgeon-General Wyman and the Secretary of the Treasury, Dr. Reid Hunt, who is connected with the hygienic laboratory of the United States Public Health and Marine-Hospital Service, is now a member of the Council on Pharmacy and Chemistry. He takes the place of Professor Cushney, who, as will be remembered, was compelled to resign his active connection with the Council through his transfer to the Medical Department of the University of London, England. In addition, it is the intention to examine in the Hygienic Laboratory, from time to time, such proprietary and "patent" medicines as may be deemed advisable in the interest of the public health. We feel sure that you will join with your Board of Trustees in extending thanks to Surgeon-General Wyman for his assistance in this matter

WILLIAM H. WELCH, M. L. HARRIS, Secretary.

E. E. MONTGOMERY, Vice-Chairman

EXHIBIT G.

Report of the Council on Pharmacy and Chemistry.

The following report was presented to the Board of Trustees of the American Medical Association at its meeting held Feb. 2-3, 1906:

To the Board of Trustees of the American Medical Association.

Gentlemen:—We beg to make the following report:

A conference of the Council on Pharmacy and Chemistry was held at Cleveland, Sept. 11-12, 1905, to which certain manufacturing pharmaceutical and chemical houses were invited to send representatives, as the Council desired suggestions and criticisms regarding the general plan of the work. Several physicians were also invited. The rules were thoroughly considered and finally adopted in the revised form as follows:

(The term "article" shall mean any drug, chemical or similar preparation used in the treatment of disease.)

RULE 1.—No article will be admitted unless its active medicinal ingredients and the amounts of such ingredients in a given quantity of the article be furnished for publication. The general composition of the vehicle, its alcoholic percentage, if any, and the identity of other preservatives, if present, must be furnished.

RULE 2.—No chemical compound will be admitted unless sufficient information be furnished regarding tests for identity, purity and strength, the rational formula or the structural formula, if known.

RULE 3.—No article that is advertised to the public will be admitted; but this rule will not apply to disinfectants and food preparations, except when advertised in an objectionable manner.

RULE 4.—No article will be admitted whose label, package or circular accompanying the package contains the names of diseases, in the treatment of which the article is indicated. The therapeutic indications, properties and doses may be stated. (This rule does not apply to literature distributed solely to physicians, to advertising in medical journals, or to vaccines and antitoxins.)

RULE 5.—No article will be admitted or retained concerning which the manufacturer, or his agents, make false or misleading statements as to geographical source, raw material from which made, or method of collection or preparation.

RULE 6.—No article will be admitted or retained of which the manufacturer or his agents make unwarranted, exaggerated or misleading statements as to therapeutic value.

RULE 7.—Labels on articles containing "poisonous" or "potent" substances must show the amounts of each of such ingredients in a given quantity of the product. A list of such substances will be prepared.

RULE 8.—If the trade name of an article is not sufficiently descriptive of its chemical composition or pharmaceutical character, or is, for any other reason, objectionable, the Council reserves the right to include with the trade name a descriptive title in the book. Articles bearing objectionably suggestive names will be refused consideration.

RULE 9.—If the name of an article is registered, or the label copyrighted, the date of registration and a copy of the protected label should be furnished the Council. In case of registration in foreign countries, the name under which the article is registered should be supplied.

RULE 10.—If the article is patented—either process or product—the number and date of such patent or patents should be furnished.

The proposed book, "New and Non-Official Remedies," was also discussed, and it was tentatively agreed that it should be divided into two parts: Part I to consist of definite chemical compounds and simple pharmaceutical preparations, and Part II to comprise pharmaceutical mixtures. The plan of procedure referred to in the previous report was slightly elaborated. Since the conference the Council has considered the merits of various proprietary articles and has provisionally arranged and classified a large number of preparations which are considered worthy of recognition.

As indicated in the first report, the consideration of pharmaceutical mixtures—the vast majority of preparations belong to this class—proved a most difficult problem. Such a preparation is usually an ordinary mixture, made according to some physician's prescription, or after some well-known formula, modified in some way to disguise its identity, which has been placed on the market as a new preparation under a catchy or suggestive name, accompanied with extravagant therapeutic claims. Such preparations represent nothing new and involve no unusual skill in their manufacture. Their use is to be deplored, but if they are to be used a complete statement regarding their composition should be furnished to physicians. If this were done, and if all mystery regarding them were removed, their use would be very limited. It has been decided, however, that as many of these mixtures as conform to the rules will be placed in Part II of the proposed Annual, where, when similar, they will be grouped together and explicit reference be made to corresponding official preparations.

In this connection, however, it should be borne in mind that standard preparations, such as those in the Pharmacopeia and in the National Formulary—fully equal, if not superior, to the proprietary mixtures—are not only listed in the catalogues of the manufacturing pharmacists and chemists, but are also easily compounded by any experienced retail pharmacist.

While the Council is acting solely for the medical profession it has remembered that there is no antagonism between legitimate pharmacy and medicine, that there is a mutual dependence, and that, consequently, there should be a mutual cooperation between the Council and legitimate pharmacists and chemists. While most of the well-known firms have been cooperating with the Council; some seem to hesitate about doing so. The Council believes, however, that this hesitation comes from the fact that these firms have not fully appreciated the objects for which it is working, and which are believed to be as much in the interest of scientific pharmacy as in the interest of scientific medicine, and therefore, in the interest of all honest and legitimate manufacturers. The Council has endeavored to make it plain and convincing to manufacturers that in the present movement there is no intention to interfere with the proper exploitation of their products, and that it does not expect them to reveal the technical secrets involved in their processes of manufacture, but that it must insist that a truthful statement concerning the actual composition, or the medicinally active components, both as regards quantity and quality, must be given, together with tests for the identification and confirmation of such medicinal constituents.

Certainly as much to be depreeated, and more harmful in their effects than secrecy in composition, are the false and absurdly extravagant claims made by some of the otherwise reputable vendors of proprietary medicines. These claims equal and occasionally surpass the claims made by "patent-medicine" vendors in their advertisements in the newspapers. During the last few years this method of advertising has grown steadily worse, each advertiser apparently wishing to outdo every other in eulogizing his particular preparation. It has finally come to pass that a plain, truthful statement regarding the therapeutic value of an article is generally considered valueless, and even reputable firms have not hesitated to make statements in their advertising literature that have been far from the truth. Many manufacturers acknowledge this and excuse themselves by saying that others have done it and they had to. They acknowledge that loose methods regarding this feature of their business have been in vogue, largely due to unchecked competition by unscrupulous concerns. We presume there is no objection to a reasonable optimism on the part of the manufacturer; but obvious misrepresentations as to the therapeutic value are quite as dishonest as misstatements concerning the composition.

Another difficulty which the Council has experienced in its investigations of synthetics, mixtures and new remedies is found in the character of the names proposed therefor. It is a recognized principle that the name proposed for a remedy should not in any way mislead or deceive. If the name, therefore, is indicative of origin, the origin indicated must be the real one. If, on the other hand, it is indicative of quality or property, the preparation must have that quality or property. Names which, by their ending or otherwise, are indicative of definite classes of compounds, or which in any part of the name show derivation from any particular source or the possession of any particular quality, must be true to the indication. Many preparations would be excluded from classification by reason of false or misleading names.

Investigation has shown that, as a rule, the preparations placed on the market by the regular manufacturing pharmaceutical and chemical houses are as represented; at the same time we regret to state that in some instances otherwise reputable firms have been offering to the profession articles that are not in accord with the claims made for them. The Council does not think it wise to be more specific at this time, believing that these preparations will be withdrawn, or that a true statement will be made regarding their character and composition.

Investigation has also shown that certain remedies are

being manufactured under patents that do not conform to the specifications of the patents.

Attention is called to the fact that occasional statements respecting the nature of the substances occurring in the mixture or methods of preparation are made by manufacturers which seem to be contrary to the established principles of chemical reactions. As an illustration of this, it may be stated that the mere mixture of two substances, which may possibly react chemically, is not properly represented by supposing that complete chemical reaction has taken place unless that actually has occurred. This is especially true of certain very complex organic compounds, which, it appears, can not possibly be made by the preparation either of the pure acids or of the pure bases, but in which attempts are made to produce the combination by mixing the substances in the crude or unmanufactured state and assuming that the chemical reactions have taken place.

In these cases the statement of the manufacturer should convey the facts of the case and not the assumed reactions.

As was mentioned in the former report, an investigation of some of the so-called cod-liver oil preparations has led the Council to believe that some of these articles are fraudulent, since they contain no cod-liver oil, and that both the public and the medical profession are being greatly deceived in many articles that are placed on the market as tasteless or fat-free cod-liver oil.

These are the features of existing conditions that are retarding the work and delaying the approval for admission of some articles which otherwise might be accepted.

The Council recognizes that sufficient time should be allowed manufacturers to make the necessary changes in their labels, circulars and printed matter to conform to the rules. July 1, 1906, has been tentatively fixed as the date when compliance with the rules be required of all preparations. It is hoped that soon after that date it will be possible to issue the first edition of the proposed book, "New and Non-Official Remedies." Although the first number will not be complete, the annual revision will afford opportunity for the admission of such articles as may not at that time have been acted on.

It is hardly necessary to remind you that there is much detail work of a chemical nature connected with this work, and while some of the members of the Council have been devoting much time and labor in this direction it is believed that some of this detail work could be done much more satisfactorily if facilities for it were provided by you at the Association building. Therefore, the Council begs to suggest that, if it is possible to do so, a chemical laboratory be established by the Association with a competent chemist in charge. There is a great amount of work to be done, and it is work that must be continued if the medical profession in the future desires to protect itself from unscrupulous promoters.

The Council reiterates its former plea to those connected with hospitals for their co-operation in making clinical tests. There has been some co-operation of this nature, but not so much as the Council wishes it could have.

The prospects for a satisfactory solution of the various questions which confronted the Council at the beginning are more favorable as time goes on; it wishes to state, however, that the ultimate success of the work must necessarily depend largely on its endorsement by the members of the American Medical Association and by the physicians in general limiting their support to those manufacturers who are supplying them with honest preparations in a legitimate manner.

The evident appreciation of the efforts of the Council by the medical profession of the country is highly gratifying and encouraging.

Respectfully submitted,

C. Lewis Diehl, Samuel P. Sadtler,
C. S. N. Hallberg, J. O. Schlotterbeck,
Robert A. Hatcher, George H. Simmons,

F. G. Novy, H. W. Wiley,
W. A. Puckner, Julius Stieglitz,

Members of the Council on Pharmacy and Chemistry, American Medical Association.

On motion of Dr. F. D. Ferguson, the report was received; and on further motion of Dr. Frank Billings, it was referred to the Reference Committee on Reports of officers (page 1873).

Report of the Committee on Reciprocity.

REFERRED TO COMMITTEE (see page 1875).

Dr. W. L. Rodman, Philadelphia, read the report of the Committee on Reciprocity.

To the President and Members of the House of Delegates:

Gentlemen:—Your Committee on Reciprocity respectfully submits the following report: Owing to the geographical location of its members, one living in Kentucky, Colorado, Montana, New York and Pennsylvania respectively, but a single meeting of the full committee has been held during the year. There has, however, been considerable correspondence between the Chairman and other members, and a number of meetings between the members living in New York and Pennsylvania. Two of the members met by appointment at the recent meeting of the Medical Council in Chicago, and we considered the work being done by that body as closely allied in every way with the broad question of reciprocity (based on equity). We were much impressed with the meeting, and regret that the other members could not have been present. We are unanimously of opinion that reciprocity based on equity can only result in time through the excellent work now being carried on with a certainty of fruition by your Council on Medical Education. We wish to commend in the highest terms the valuable and unselfish work which has been done by the Chairman, Dr. Arthur D. Bevan, and his associates, and to state it as our belief that they have already accomplished all that could have been asked, and more than could have been reasonably expected in so short a time. Your committee believes that such a central or national body, and it only, can so carry on the work of medical education until what has been a reproach to our country shall greatly redound to its credit. Their functions are only advisory, and not mandatory, it is true, but their action has been thus far so conservative and reflects so fully the opinions and wishes of the profession at large, that already there is behind the Council on Medical Education a moral support and sentiment which have resulted in enacting their suggestions into laws by each of the sovereign states.

The standard requirements now recommended prerequisite to the practice of medicine consist of five cardinal points, as follows: "1. Preliminary requirements to be a high-school education or its equivalent, such as would admit the student to one of our recognized universities. 2. Preliminary requirements to be passed on by a state official, such as the superintendent of public instruction, and not by any one connected with the medical college. 3. A medical training in a medical college having four years of not less than 30 weeks each year, of 30 hours a week of actual work. 4. Graduation from an approved medical college required to entitle the candidate to an examination before a state examining board. 5. The passing of a satisfactory examination before a state examining board." More than this can not reasonably be asked at this time in the way of a standard. We would earnestly suggest, however, that the work of the Council would be made far more effective if an inspector, fully acquainted with medical teaching, were empowered to visit as many schools as practicable each year to see that published requirements are being met and lived up to. It is not difficult to do so on paper. Such an inspector should be given every possible support and assistance by the dean of every school visited, and his reports to the medical council should reflect accurately the didactic, laboratory and clinical work being done by the several colleges. In this way, and only in this way, will some of the schools be kept up to the mark. While it is manifestly impossible for all to be visited and carefully examined each year, the expectation that an examination may be made without warning will surely prove a stimulus where it is most needed.

We would also recommend that the Council on Medical Education urge on the several states and territories, through their examining boards, the recognition and acceptance of the commissions of all medical officers in the Army, Navy, and Public Health and Marine-Hospital Service without question or examination. The government services are, and have ever been, distinctly creditable to the country, maintaining a standard higher than that of any state, therefore such officers should be allowed to practice wherever they are stationed, or, on retirement from their respective services, to take up civil practice without further examination. The commissions of medical officers are pretty generally recognized and accepted now, but it is not to the credit of a few states that they withhold such courtesy from men of acknowledged talents and professional attainments. There are still good causes for complaint on the part of practitioners of merit and experience who, on account of ill health or other reasons, are compelled to change

their location and must submit to an examination in the state of their adoption. A case in point: A practitioner of the highest moral character and scientific attainments graduated at the University of Dublin 25 years ago. Ten years later he settled in Philadelphia, graduating from and subsequently teaching in one of its schools. After 15 years of hard and commendable work, which brought him a lucrative practice and fame more than national in character as a specialist, his health failed him and with his wife he sought relief in a far-distant state. Knowing of his high attainments and exalted character, I tried to get a license for him to do consultation work in his new home without examination. I happened to know well the chairman of the state board. I felt and explained that the services of this eminent specialist would be of service to the physicians where he was. The reply which I received, while perfectly courteous and sympathetic, was immediate and emphatic that this gentleman must not write a prescription or see a patient until he should have passed the state board. The said state has no reciprocal relations with any other state and exacts an examination of every practitioner coming within its borders. There are yet, and we think will be for some years, many such states. While keenly sympathetic with states having a high standard and the courage to maintain it, your committee feels that if such states find it safer and better for the interests of their respective commonwealths to recognize no state license, because of the low standard of some, then they should so amend their laws as to recognize a certificate of a general and central body such as the Council on Education. Dr. Frazier, dean of the University of Pennsylvania, one of the members of that body, knew well the standing of the physician referred to. The members of the committee are so located geographically that, frequently at least, one of them would know all about the applicant, and more often still could get perfectly satisfactory evidence of his fitness for licensure. The high standard of the Council makes it impossible that either a charge of incompetency or unfairness could be brought against any one. All are experienced teachers in the leading schools of this country, and their advice should be accepted by every state and territory. That they would be as careful and rigid in their examination as any state board no one can doubt. Then, if so, what are ahe advantages to the candidate for licensure?

1. Their sessions are held in Chicago, practically the geographical center of the country.

2. All its members are, and will always be, experienced teachers, and, therefore, competent examiners.

3. It is more satisfactory, economical, and less embarrassing to get a license before moving to a distant state.

4. Many would prefer a general license to practice, if it could be had, and would willingly pass a more rigid examination to get it. Moreover, a physician moving from one state to another seeking either health or fortune, is not assured of success in advance and may be compelled to move repeatedly. Should such be the case, as it frequently is, the physician is held up by the several state boards. All should be empowered to recognize a license granted by the Council on Medical Education, admittedly the highest authority on the subject, as they are in possession of all facts pertaining to the school whence the applicant graduated.

5. The work of the Council is already too laborious to permit of its examining all, or any, recent graduates. It might, however, be willing to examine those physicians caring to apply, who after at least ten years of honorable practice are compelled to change their location. Believing in a high standing for all states and at all times, we would not be understood as intimating that any state board should be less strict than it is in protecting the interests of the commonwealth it serves. A majority should be even stricter than they are. But we do maintain that the physician of ten or more years of practice and recognized moral standing, one who would be a credit to any community, should not be compelled to sit between men just out of college and take the same examination. The novitiate should rightly be examined rigidly in all the branches, and his examination is, and must be, largely didactic. The practitioner of experience is entitled to an examination chiefly clinical in character.

6. Chicago offers abundant clinical facilities and they could be utilized by the Council in the examinations.

The Confederation of Reciprocating, Examining and Licensing Boards has materially advanced the cause of reciprocity during the past year, as 13 states issued 488 certificates. The same states issued 720 certificates since 1902. Eight states in the confederation have made no report.

* No report received.

If all the states were to join the Confederation, which is unlikely, it would still be desirable to have a central board for the reasons already given. The good work now being done by the Council on Medical Education, the several state boards, the Confederation of Reciprocating Boards and medical colleges throughout the country, is an earnest of what can and should be done. Let us aid them in every way, for it is only by the co-operation of all these forces that reciprocity, just and abiding, can be reached. None other is desirable.

J. M. MATHEWS,
T. J. MURRAY,
WM. L. RODMAN, Chairman.

On motion of Dr. Percy, Illinois, it was referred to the Reference Committee on Medical Education (see page 1875).

The President called for the Report of the Committee on Organization.

Dr. J. N. McCormack, Chairman of the committee, asked for further time, which was granted (see page 1870).

The report of the Committee on Scientific Exhibit was called for, and as the Chairman, Dr. F. B. Wynn, Indiana, was absent, it was passed (see page 1871).

On motion, the House of Delegates then adjourned until 2 p. m., Tuesday.

Third Meeting—Tuesday, June 5

The House of Delegates convened at 2 p. m., and was called to order by President Mayo.

The minutes of the previous meeting were read and approved.

The Secretary read the report of the Committee on Walter Reed Monument as follows:

Report of Committee on Walter Reed Monument.

ACCEPTED AND COMMITTEE DISCHARGED.

The Committee on the Walter Reed Memorial Fund desire to submit, as is required, their report, and, as their work is practically finished, would ask to be discharged.

The amount subscribed to the fund up to May 1, 1906, as reported to the committee by General Calvin DeWitt, Secretary of the Walter Reed Memorial Association, is $20,943.64. The amount paid in is $19,730.64, leaving subscribed, but not yet paid, $1,213.

It was the desire of the committee and also of the Walter Reed Memorial Association that the sum of $25,000 should be raised. The committee regret very much indeed that American cities and towns which have been devastated by yellow fever have contributed much less than $1,000 all told, and nothing in the way of public, municipal or state subscriptions. They still further, and especially regret that the sum total from Cuba has been only $25. It seems to the committee that the country from which yellow fever was eradicated after having been continually present for 140 years, and which has had pointed out to it clearly the way in which future epidemics can be absolutely avoided, should certainly have made some substantial acknowledgement of the services of a surgeon who not only made a contribution of enormous value from the sanitary point of view, but who has established its future commercial prosperity.

The committee can not tell precisely the amount subscribed by the medical profession, but it is a very large proportion of

the nearly $20,000 collected to date. It gives us pleasure to call attention to the fact that while few business men have recognized the enormous money value of Dr. Reed's services, to say nothing of the saving of human lives, his own profession has given such substantial recognition of the worth of his services in preventing a disease which has committed such dreadful havoc in the past, but will never do so again.

Joseph D. Bryant, Victor C. Vaughan,
A. C. Cabot, Robert F. Weir,
T. S. Cullen, W. W. Keen, Chairman.
Committee.

On motion of Dr. V. C. Vaughan, Michigan, the report was adopted.

Dr. Philip Mills Jones, California, moved that the committee be discharged with the thanks of the House of Delegates for its work. Seconded and carried.

The report of the Committee on Scientific Research was called for, when the Secretary read a telegram from the Chairman of that committee, Dr. Alfred Stengel, stating, "Unavoidably detained; will present report of committee Wednesday."

Report of the Committee on Organization.

READ AND REFERRED TO COMMITTEE (see page 1873).

Dr. J. N. MacCormack, Kentucky, presented the report of the Committee on Organization, as follows:

Gentlemen:—Since my last report to the House of Delegates at Portland, I have made regular itineraries in the states of Minnesota, Oregon, California, Texas, Oklahoma, Tennessee, Illinois and Kentucky, and have held one or more meetings or attended the state meetings in North Dakota, Montana, Washington, Idaho, and Arkansas. As reports of the conditions found and the work done in most of these states have already been published in The Journal in a more extended form than would be possible or profitable here, I shall content myself with a brief account of two phases of my experience which appear to be of special interest and importance.

For two years or more laymen had been invited to occasional meetings, and my addresses have been more or less modified and elaborated to adapt them to such audiences. The possibility of receiving representatives from all classes of the laity, and finally of regular mixed and lay audiences into a general plan for a campaign of education of the public in regard to medical and health matters was such a gradual growth and evolution, that I am not sure that it can yet be said to be fully complete in my own mind even. I have given it as fair a test as was possible under existing conditions in the five states last visited, and the results were most gratifying wherever audiences were secured.

Singular as it may seem at first sight, I found that lay attendance at the meetings depended almost entirely on the extent of the medical organization in the community. As a rule, laymen of the thoughtful classes, who would especially appreciate and be responsive to the view of co-operative work suggested by me, have never attended such meetings in the past, did not know even that they could do so, or wanted to, and, in fact, will not do so unless personally invited and urged by their family physician or an authorized committee of the profession. In many localities I found that leaders in the profession, and even leaders in this Association, had little conception of the purpose of my visit, although they usually became most enthusiastic during the meetings, and after it was too late to secure the attendance of many of those whom it was most important to have present.

Once there, laymen of the intelligent classes took quite as active and intelligent interest in everything pertaining to the affairs of the profession as medical men did. I found it an easy task to make them understand that every interest of the profession, scientific, moral and material, concerned them quite as much as it did even the members of the profession. I discussed all of these interests in the plainest and most outspoken way, often almost to the point of tediousness in order to prevent misunderstanding, and men and women would almost invariably follow to the last word, with unbroken interest, and then take part in the public discussion which always followed in a way to indicate usually a most intelligent comprehension of the matter in hand. I am sure that the possibilities of this feature of the work have not even dawned on the mind of the profession in most communities.

The other phase of work on which especial emphasis should be laid is that relating to post-graduate work in the county societies. This is in such successful operation in a number of counties that it has passed the experimental stage. In a number of these the meetings are held weekly and in some two and even three times a week. In those securing the best results the course of study has been mapped out with care; regular teachers are selected from the younger element of local membership, and all available equipment and clinical material are utilized for scientific and practical demonstrations. Such a course is possible when as many as three real, live doctors can be conveniently grouped together in any county, or in any section of any county.

Next to the question of medical education, which affects the man already in practice only indirectly, how to make the county society what it should be, and what it can be in every jurisdiction, is the great problem now before the profession of this country.

As compared with it, all others sink into insignificance. Given these as a foundation in every county, the success of the state and national organizations is not only permanently assured, but with the mutual understanding and co-operation between the profession and the public, made possible through them, the difficulties in the way of securing and enforcing legislation and all similar matters will be gradually eliminated, and the profession will not only come into its own, but, what is still more important, benefits would come to the people of this country through a unified, vitalized, organized, co-ordinated profession, which would make it the most powerful civilizing and uplifting influence of modern life.

Another, and the concluding point, developed and emphasized in the course of my varied and extended experience in going over this country, and especially within the last year, has been the evidence at every turn of a powerful, alert and implacable foe to organization in the proprietary medicine interests, with its agencies and tentacles reaching into and utilizing every distracting and disaffected element in every section. Resourceful, untruthful and unscrupulous, with unlimited funds, and backed by a powerful element of both the professional and lay press, its literature, multiplied, distorted and misleading, has been showered on the profession like the leaves of Vallombrosa. Anxious only for results, it has carefully sought for every weak point in our line of defenses, varying its method and apparent object of attack as to time and locality with a skill and judgment worthy of a better cause. School interests are appealed to one week, journal prestige the next, and the personal prejudices and peculiarities so abundant in our profession, always with the one constant purpose in view of playing class against class and interest against interest, in order to serve its own unvarying and nefarious purposes. To this end advantage has been taken of our mistakes, unavoidable, in the evolution of such an undertaking; honest differences of opinion have been exaggerated or misinterpreted, with a cloud of dust always enveloping or concealing its own deformities, which would otherwise repel honest, but misguided members of our profession which the proprietary interests have been constantly able to use against us.

The defense against this and all similar and lesser evils is general, unusual and all pervading organization and unification, and especially of the kind which can only be fostered in county societies. To this, either as your representative or in my individual capacity, I have decided to dedicate the remainder of my life.

On motion, the report was referred to the Reference Committee on Reports of Officers.

Report of Reference Committee on Amendments to Constitution and By-Laws.

Dr. Alexander R. Craig, Pennsylvania, presented the report of the Reference Committee on Amendments to the Constitution and By-Laws as follows:

The committee would urge on the House of Delegates the advisability of extreme conservatism in changing the Constitution and By-Laws of the Association. The effort of the committee will be to recommend only such changes as in their judgment are demanded by the growth of the Association.

CHANGES IN ARRANGEMENTS FOR SESSIONS.

1. The committee recommend the adoption of the amendment to the Constitution, Article VIII, offered at the Portland session and awaiting your action at this session, viz.:

By adding the following: "The time and place of session may, however, be changed by the unanimous action of the Board of Trustees at any time prior to four months from the time selected for the session."

So that Article VIII shall read: "The Association shall hold an annual session at a time and place to be fixed by the House of Delegates. The time and place of session may, however, be changed by the unanimous action of the Board of Trustees at any time prior to four months from the time selected for the session."

ALTERNATES FOR DELEGATES.

Of the amendments suggested in the report of the General Secretary, and which this Reference Committee understands now to be before the House of Delegates for your action, the committee recommends the following change in Book 4, Chapter 12, Section 2, page 25:

The addition to this section of the word after "representative" the words "and an alternate," so that the last sentence of this section shall read: "Each Section shall also elect annually one representative and an alternate to the House of Delegates of the American Medical Association to serve one year."

PUBLIC SERVICE OFFICERS' MEMBERSHIP.

The committee further recommend that Book 1, Chapter I, Section I of the By-Laws, page 6, shall be so changed as to read:

Section 1. Membership—How Obtained.—A member in good standing of the constituent association of the state in which he resides may become a member of the American Medical Association by presenting to the General Secretary: (1) Satisfactory evidence of the above qualification; (2) written application for membership on the prescribed form; (3) the annual dues. Commissioned medical officers of the U. S. Army, U. S. Navy and U. S. Public Health and Marine-Hospital Service shall be members; they shall not be required to pay annual dues, nor shall they receive THE JOURNAL of the Association, unless on personal subscription.

In order to overcome the difficulty suggested by the U. S. Army, the U. S. Navy, and the U. S. Public Health and Marine-Hospital Service of making appointments to the House of Delegates for a term of years, your Reference Committee recommend the adoption of the following addition to the By-Laws, Book 2, Chapter 4, Section 2, page 9, the following sentence:

Except that delegates elected by the sections shall hold office for but one year, and appointments made from the U. S. Army, the U. S. Navy and the U. S. Public Health and Marine-Hospital Service shall be for one year.

Dr. Frank Billings, Illinois, moved that the report be accepted, and that the recommendations contained therein be considered, one by one. Carried.

Section I was read, after which Dr. Guthrie moved its adoption. Seconded. After some discussion by Drs. Coe and Moore, Dr. Coe moved to lay this section and the recommendation on the table. Seconded and lost.

Dr. J. N. Jackson, Missouri, thereon moved the adoption of the section as recommended by the committee, which was seconded and carried.

Section II of the report was read and adopted.

Section III was read, and after discussion by Drs. Grosvenor, Craig, Moore, Rodman, Vaughan, Cantrell, this section and the amendment were adopted.

Section IV was read and adopted, after which Dr. Frank Billings moved the adoption of the report as a whole, which was seconded and carried.

Report of Committee on Scientific Exhibit.

Dr. F. B. Wynn, Indiana, presented the report of the Committee on Scientific Exhibit:

The seventh scientific exhibit is submitted for your inspection. The first exhibits, in the very nature of things, were heterogeneous collections. The absence of pathologic grouping made inspection often tedious. The next step, therefore, in the evolution of the exhibit was the grouping of specimens or exhibits, to illuminate certain phases of pathology, hygiene, physiology, etc. The particular topics chosen have been varied from year to year, according to the subjects which were prominent before the medical and scientific world. The third step naturally sought was efficient demonstration of the exhibits presented. This third stage, begun three years ago at Atlantic City, has at this session attained a degree of perfection which it would be difficult to surpass. The program of demonstrations herewith submitted for your consideration would alone be worthy a meeting of this great organization. Its range and quality are not only a matter of pride to those concerned in its preparation, but show the pleasing fact of a growing tendency of scientific medical men everywhere, to marshal under the banner of the Association.

In view of the extraordinary character of exhibits and demonstrations, it has seemed to the committee that a volume published, containing copious illustrations and detailed descriptions of the demonstrations formally made, would afford the medical and scientific world very striking evidence of the quality and extent of the scientific work being done by members of the Association.

Brief reference may be made at this time to the beneficent influence of the Scientific Exhibit of the Association on smaller medical organizations. State associations quite generally, and even some county organizations, have adopted the exhibit idea. A powerful stimulus has been given to medical measures throughout the country. Those who have noted the exhibits from year to year must have observed the marked improvement in the artistic quality of the material presented. The national tuberculosis exhibit, recently seen in many of the larger cities of the United States, may likewise be looked on as an outgrowth of the work of this Association. The committee suggests that not alone in tuberculosis, but on various sanitary and hygienic questions, the exhibit idea, under judicious medical supervision, might be used with telling effect for instructing the laity. To this subject the Association should address itself.

In conclusion, the earnest thanks of the Association are due the large number of men who have contributed so abundantly to the success of the exhibit; and particularly to Drs. W. T. Councilman, Henry A. Christian and F. B. Mallory, for their energetic and masterful service in organizing and carrying the exhibit to a successful issue.

FRANK B. WYNN, Director.

On motion the report was adopted.

Loving Cup Given to Dr. Wynn.

Dr. T. J. Happel, Tennessee, presented a loving cup to Dr. Wynn on behalf of the Board of Trustees, and in so doing said:

Mr. President, Gentlemen of the House of Delegates, Dr. Wynn:—To me has been assigned by my confrères on the Board of Trustees a duty that should be, and would be, more pleasant to one who is a fluent speaker, or who could deal in other things than an array of facts or cold figures. I am but a plain, blunt man, a country physician, who knows not how to say things otherwise than in the most direct and the plainest possible way. What is said to-day will come from the heart.

I am directed to express to you the appreciation of the Board of Trustees, of this House of Delegates of the American Medical Association, in fact, of the medical profession of these United States, for the work you have done in bringing into the life of this Association, nurturing, and causing to develop beyond the expectation of the most sanguine, that which was first known as a pathologic exhibit, but which has now grown to such proportions as to have merited and received the title of "Scientific Exhibit." Prior to the beginning of this century such an annex to the sessions of this Association had never been dreamed of, or discussed.

The records show that this work of yours was begun in 1900, with sixteen exhibits, chiefly from the Indiana State Medical Society. The display was such as to attract the attention of many of those who attended the Association session at Atlantic City that year, and while there were only sixteen exhibitors, the importance of the work undertaken by you was at once recognized by the Association, and the Board of Trustees was requested to appropriate the necessary sum of money to enable you to not only keep up the good work, but to foster and develop it. The results of your labors were shown when in 1901, at St. Paul, there were twenty-nine exhibitors, which was the greatest number presenting specimens at any time, yet subsequent years have shown an increasing interest in the subject, there being not so many exhibitors, but more exhibits by those who sent specimens. While not much can be said for the beauty of the exhibit, it is rapidly becoming one of the most important features of the meeting of the American Medical Association. Your works remind me, Dr. Wynn, of a fine painting which I saw in the palm garden of the St. Charles Hotel, in New Orleans, when we went there in 1903. On the wall, finely framed, is, as already stated, an oil painting, done by one of the old masters, which, seen at a short distance, appears to be a ghastly, grinning, decomposing skull. You can imagine that you can almost see the destructive agents of death devouring its contents. As you withdraw yourself further and further from the painting, the appearance of it begins to change. The picture soon assumes the form and shape of a young lady, and at a certain distance, as one of the fairest of her sex, her eyes tinted with the blue of the violet, glowing with the light of the stars, and her cheeks painted with the pink of the peach blossom, indicative of the most perfect health. I say that your work reminds me of this picture—why? Because, close to these exhibits, we behold the destructive work of the different animalculæ, bacilli and germs producing death, but when out of sight of these studies, we realize that they are made for the purpose of discovering enough of the life cycle of each of these micro-organisms to combat them successfully in the human system, and to restore the blush to the cheek of the maiden, and the starlight to eyes that have been

dimmed by the work of some of the destroying agencies which your work has enabled us to identify and to guard against. I feel that I voice the sentiment of every one present here to-day when I express to you the wish that you may live long to carry on this work so auspiciously begun by you. We trust that this Scientific Exhibit, which is yet in its infancy, may continue to grow both in size and importance, till your fondest dream in regard to it may have been realized; that hope has reached full fruition.

Now, Dr. Wynn, as a token of our appreciation of the work you are doing for this Association in your special department, representing the Board of Trustees, and feeling that I express the good will of this House of Delegates for you, I present to you this loving cup, and drink to your long life and happiness in the pure water which it now holds. Keep it as an heirloom in your family, handing it down from son to son, telling them to keep it worthily, and when one of them asks whence it came let him be told that it was given you as a token of appreciation of the work which you have so unselfishly done for the advancement of the most truly scientific feature of the sessions of the American Medical Association.

Dr. Wynn thanked the Board of Trustees and the members for this beautiful tribute of their confidence, esteem, and appreciation of the work he and his colleagues had done and were doing.

Report of Committee on Recording Minutes.

READ, AMENDED AND APPROVED.

The report of the Committee on Recording Minutes was called for, and was read by the Secretary, as follows:

To the President and Members of the House of Delegates:—The committee appointed to consider the method according to which the minutes of this house are kept and published, and to make recommendations in reference thereto, begs leave to submit the following report:

1. The committee finds, by examination of the minutes for several years past, that at places they have been incomplete by reason of the omission of reports, resolutions, communications, etc., the documents in question being referred to, but not printed in full.

The committee recommends that such omissions be not made in the future.

2. The committee is of the opinion that the names of the members of the House of Delegates present at each session should be reported in the minutes. Inasmuch as this could not be done without a call of the roll, the committee recommends that calling the roll be made a part of the regular order of business at each sitting of the house.

3. The committee is also of the opinion that to prepare complete and full minutes of a session of the House of Delegates requires more time than is available between the sittings. The committee recommends, therefore, that, while the Secretary should read at the opening of each session a memorandum of what transpired at the previous sitting, such memorandum shall not be deemed the complete and final minutes of the session.

4. The committee recommends that as early after each annual session of the Association as can be done, the Secretary shall prepare full and complete minutes of the session and cause them to be published in pamphlet form for distribution to the members of the House of Delegates and to be inserted in THE JOURNAL for the information of the members of the Association, said minutes to be submitted for adoption at the next annual session, and, as a matter of course, to be subject to correction.

5. The committee recommends that the original notes of the proceedings of the House of Delegates, made by the official stenographer, be permanently filed, in order that should differences of opinion arise as to what was said or done, such notes can be referred to.

6. According to the information of the committee, adjourned meetings of this body have been held in the State of Illinois for the purpose of validating in that state business transacted in other states, and thus technically to comply with the requirements of the charter of the Association. Looking back over the official minutes for several years past, no minutes of such meetings have been found. The committee, therefore, recommends that the transactions of any such adjourned meetings as may be held in the future be published in THE JOURNAL and also appended to the minutes of the annual meeting recommended to be published in pamphlet form.

All of which is respectfully submitted.

DONALD CAMPBELL, W. S. FOSTER,
J. F. PERRY, F. PASCHAL,
W. H. SANDERS. July 13, 1905.

The Secretary, after reading the report, stated in reply that in two or three instances resolutions offered at previous meetings had been accidentally lost or misplaced by members of committees to whom such resolutions had been referred; hence only the gist of such resolutions could be printed in the minutes. Furthermore, the Association published the minutes of the House of Delegates in pamphlet form; that the shorthand notes of the official stenographer were on file and could be referred to at any time should differences of opinion arise; that the minutes of adjourned meetings of the Association for validating business transacted in other states had been recorded, but not published in the official minutes of the House of Delegates, as it was not thought necessary to do so.

Dr. Joseph W. Grosvenor, New York, moved that the report of the committee be considered section by section.

This motion was seconded and lost.

It was then moved that the report be adopted. Seconded.

Dr. W. H. Sanders, Alabama, reiterated the points contained in the report of the committee, and said as its Chairman he was glad to know the reasons for the incompleteness of the minutes in some particulars in the past. He was also glad to know that the shorthand notes of the official stenographer were placed on file; and that the minutes of adjourned meetings for validating business done in other states had been recorded. He said there was no intention on the part of any member of the committee to reflect on the work of anybody, but as the Association was undergoing a process of evolution it was essential to have the proceedings as complete as possible.

After discussion, which was participated in by Drs. Gray, Jackson, Chassaignac, Happel, Sanders, a delegate suggested that Section 1 of the report be stricken out as he thought it reflected on the official stenographer.

It was therefore moved, as an amendment, that this section be stricken out and that the report be adopted as presented.

The amendment was seconded, accepted, and the original motion as amended was carried.

Orators Nominated by Sections.

AMENDMENT REFERRED TO COMMITTEE (see page 1875).

Dr. E. Eliot Harris, New York, offered the following amendment to the By-Laws:

Chap. VII, Sec. 5, p. 13: "The Sections on Practice of Medicine, Surgery and Anatomy and Hygiene and Sanitary Science shall nominate one candidate from each section to be elected by the House of Delegates, to deliver orations under the auspices of the respective sections.

These nominations shall be submitted to the House of Delegates before the hour set for election.

This was referred to the Reference Committee on Constitution and By-Laws.

Report of Reference Committee on Reports of Officers.

Dr. Philip Mills Jones, California, presented the report of the Reference Committee on Reports of Officers:

Mr. President and Delegates:—Your committee has carefully considered the reports of officers submitted to it, and begs to report thereon, with recommendations, as follows:

President's Address (See page 1849).

INVITATION TO MASSACHUSETTS GUESTS.

We recommend the adoption of the following, suggested in paragraph 4 of the President's address:

Resolved, That all members of the Massachusetts Medical Society are hereby cordially invited to attend the various sessions of the American Medical Association now being held in this city of Boston, and to participate in the proceedings of the same.

THANKS TO SECRETARY.

Paragraph 8. Your committee feels that the President has placed this body under an obligation of gratitude to him for so eloquently stating the valuable services rendered our Association by its Secretary, and recommends the adoption of the following:

Resolved, That the American Medical Association extends to its Secretary, Dr. George H. Simmons, its sincere thanks for the able, conscientious and efficient manner in which he has conducted the affairs of his office and the ability which he has displayed in making THE JOURNAL of our Association the foremost medical publication in the world.

IMPORTANCE OF GOOD TRUSTEES.

We believe that this House of Delegates is again indebted to the President for directing our attention to the invaluable services rendered our profession and our Association by the Board of Trustees, and we heartily endorse his recommendation to use the greatest care in the selection of those whom we elect to this most important office, to the end that no person

be elected a Trustee whose affiliations are such as to be detrimental to the best interest and welfare of our Association. We recommend the passage of the following:

Resolved, That the Trustees of this Association be nominated orally and be elected by ballot of the House of Delegates in separate order. We further recommend that at least two nominations be made to fill each vacancy in the Board of Trustees.

Paragraphs 12 and 13 refer to the Constitution and By-laws and should be referred to the special and appropriate committee.

POLICY ON PUBLICATIONS.

Paragraphs 14 and 15. Your committee heartily endorses the opinion expressed by our President concerning the publications of the Association, and highly commends to the Trustees a continuance of the present policy relating to publications other than THE JOURNAL.

We also most heartily recommend for your endorsement the very moderate words of our President in condemnation of the unspeakable dishonesty and nastiness which are to be found in the nostrum and "patent-medicine" business.

ORGANIZATION WORK PRAISED.

We commend to your careful consideration the most remarkable work of our committee on organization and recommend the passage of the following:

Resolved, That the sincere thanks of the American Medical Association be extended to Dr J. N. MacCormack, and that we earnestly request him to continue his work of organizing the medical profession of the United States.

Report of the Secretary. (See page 1851.)

BIOGRAPHICAL CARD INDEX, ETC.

Most of paragraphs 2, 3 and 4 of this report deal with the Constitution and By-laws and properly go to that committee. In considering the balance of the report, dealing with membership, Councilors' bulletin and biographical card index, your committee is deeply impressed with the efficient and systematic manner in which the work of the Secretary for the betterment of the Association has been prosecuted. The fact must be recognized that when any great work is to be accomplished, the actual labor of direction and organization must be in a few hands; and we feel that the Association is to be congratulated on having in charge of this work two such able men as Drs. George H. Simmons and J. N. MacCormack. We earnestly recommend for your endorsement the various enterprises enumerated which have been originated by the Secretary.

Report of Trustees. (See page 1861.)

The report of the Trustees naturally divides itself into four sections: 1, The general conduct of the financial and business interests of the Association; 2, the business conduct and general policy of THE JOURNAL; 3, the work involved in undertaking to publish a directory of physicians; and 4, the work of the Council on Pharmacy and Chemistry, which is done under the supervision of the Trustees.

BUSINESS WELL HANDLED.

1. Your committee finds from careful examination of the report, that the business and general financial affairs of the Association have been conducted in an exceedingly able manner and recommends for your commendation the business acumen of the Trustees, and the manner in which they have handled and invested our funds and have worked toward the essential object of securing a safe and safely invested reserve fund. As the work of the Association increases from year to year and the magnitude of its responsibilities increases, the more evident becomes the desirability of having such a reserve fund to fall back on in case of any untoward emergency.

APPROVAL OF JOURNAL POLICY.

2. In regard to THE JOURNAL, your committee believes that every member of this House of Delegates fully appreciates the magnificent work that has been done in upbuilding THE JOURNAL and placing it in the foremost ranks of all medical publications. We believe that the Trustees and the Editor have done everything to carry out the wishes of the Association in regard to the business policy of THE JOURNAL, and we recommend the adoption of the following:

Resolved, That the American Medical Association heartily endorses and approves of the policy of accepting for publication all advertising matter coming within the provisions established by the Council on Pharmacy and Chemistry of this Association, believing that it is wise and desirable thus to present for the scrutiny of the physicians such articles as are honestly made and are ethically marketed.

WHEREAS, It has been noised abroad by the enemies of a united medical profession that this Association and the state medical associations are attempting or will attempt to destroy all medical journals not owned or controlled by them; and

WHEREAS, Much of the advance in medical science in the last fifty years has been due to the efforts and labors of medical journals owned and edited by physicians and others, and this Association and its work would have been greatly hindered and delayed had it not been for the moral support of these journals: now, therefore, be it

Resolved, That the American Medical Association heartily endorses, and requests its members to support, all such medical journals, no matter by whom owned, as are engaged in promoting the interests of scientific medicine and which refuse to accept financial aid or advertisements from venders of nostrums, or others inimical to the true interests of the profession.

VALUE OF DIRECTORY AND CARD INDEX.

3. Your committee agrees with the Trustees in the necessity for the medical profession keeping track of its own members. So far as the actual publication of a book or directory is concerned, your committee believes that the Association is quite right in undertaking to suppply an accurate volume of this sort at a reasonable price, and that it is better for the Association to do this work than to have any layman secure an equal or larger price from the members of our profession, for a less accurate publication of a similar sort.

But your committee believes that the mere publication of such a volume is a matter of secondary consideration. The real value of the work undertaken by the directory department, and the real value of the investment, is in the records secured and filed, on which records the data for the published volume are based. An illustration of the significance of this is to be found in California. The late lamentable disaster destroyed by fire all the records of the Board of Medical Examiners of the State Medical Society and of the County Clerk of the city of San Francisco. Fortunately, however, our Association, as part of the directory work, has secured and filed in Chicago full and accurate information concerning all licentiates of the State of California, so that we may replace these records for that stricken community. So valuable do we consider this portion of the work of conducting the directory department that we most strongly recommend the passage of the following:

Resolved, That the Trustees be requested to have constructed in the cellar of our building in Chicago, a brick vault in which all the records of this character pertaining to the graduation and licensing of physicians shall be kept.

COUNCIL ON PHARMACY AND CHEMISTRY (see page 1867).

4. Your committee has given this matter full and careful consideration and most heartily commends the endorsement of the work thus far accomplished by the Council. The magnitude of work placed in the hands of this Council can scarcely be realized by one who has not delved into the mire of corruption and fraud in search for the root of the nostrum evil. As the undertaking is large, so must firm and wise, though ever careful and sometimes conservative progress be made, and great patience must be exercised. We believe that the policy of the Trustees in the organization of the Council and in the prosecution of its work up to the present time, has been wise and safe, and we feel sure that your honorable body may, without hesitation, endorse the work of the Council and encourage its further activity along the lines which have been mapped out for it. The corrupting influences of fraud, deceit and dishonesty which have been ranged against the efforts of our Association, acting through the Trustees and this Council, are such as to demand the active support and co-operation of every honest man in support of the efforts of our Association to secure simple honesty and scientific betterment in materia medica preparations. We recommend the adoption of the following:

Resolved, That the American Medical Association extend its thanks and appreciation to the United States Public Health and Marine-Hospital Service for its co-operation in the work of the Council on Pharmacy and Chemistry of this Association, and to every member of that Council for the great work which they have done and are doing.

PHILIP MILLS JONES, Chairman.
DONALD CAMPBELL,
A. JACOBI,

Dr. Frank Billings, Illinois, moved that the report be considered section by section, which was seconded and carried.

Sections 1, 2, 3, 4, 5, 6, 7 and 8, with the accompanying resolutions, were adopted, after which Dr. E. Eliot Harris, New York, moved the adoption of the report as a whole, which was seconded.

After discussion by Drs. Grosvenor, Coe, MacCormack, Sanders, Ferguson, Vaughan, Simmons, Happel and Montgomery, the President put the motion of Dr. Harris, which was carried.

Dr. Harris thereon moved that the personal discussion be not entered on the records.

This motion was seconded by several, and carried.

Dr. C. E. Cantrell, Texas, moved that a committee of five

be appointed to take this matter up with the gentlemen who feel that they have cause for grievances and settle the matter. Seconded.

Dr. Harris said that this should come before the Committee on Miscellaneous Business; that that committee would be very glad to take the matter up and settle it in a way so that everybody would go away with good feeling.

Investigating Committee Proposed.

PROPOSAL LAID ON TABLE.

Dr. H. O. Walker, Michigan, presented a preamble and resolutions, with remarks, as follows:

Mr. Chairman:—Since the address of our worthy President of yesterday indicated the sentiment of uncertainty and distrust relating to the management of THE JOURNAL and sundry other matters, we naturally feel that these criticisms are both unjust and unfair, and yet every effort should be made to dissipate this feeling, at least from the minds of the members of this Association.

Therefore, Mr. Chairman, I beg leave to offer the following preamble and resolutions:

WHEREAS, The membership of the American Medical Association, numbering 19,285, is scattered throughout all the states and territories;

WHEREAS, The affairs of the Association are so intricate that it is difficult to make them clear to all; and

WHEREAS, Because of these facts there has arisen the sentiment which bids fair to become disagreeably large unless the causes on which it feeds be removed, viz., ignorance of the real truth; therefore, be it

Resolved, That a committee of five, namely G. Frank Lydston, Chicago; Frederick Holme Wiggins, New York; A. H. Cordier, Kansas City, Mo.; Duncan Eve, Nashville, Tenn., and D. W. Graham, Chicago, be appointed by the House of Delegates of the American Medical Association and instructed, first, to make an exhaustive study of the affairs of the Association, THE JOURNAL, etc.; second, to employ an auditing expert to go over all the books of the Association; to have power to summon officers and employées of the Association before it, to give needful testimony; and in such other ways as it may deem best to secure all facts necessary for such independent report as may be needful to accomplish its purpose.

Resolved, That a sum of money be appropriated sufficient to defray the actual expenses of this study.

Resolved, That this committee report to the House of Delegates at their next session in 1907.

On motion of Dr. J. N. Jackson, Missouri, the preamble and resolutions were laid on the table.

Dr. Philip Mills Jones, California, moved a reconsideration of the vote by which the preamble and resolutions were tabled. Seconded.

Dr. M. L. Harris, Illinois, raised the point of order that the House could not reconsider the vote by which the resolutions were tabled.

The President ruled the motion to reconsider out of order.

Committee on Insurance Proposed.

Dr. J. N. MacCormack, Kentucky, offered the following, which was referred to the Committee on Miscellaneous Business (see page 1875).

Resolved, That a standing committee on insurance is hereby created to consist of five members, two of whom shall be the President and Secretary, and the other three to be nominated by the President and confirmed by this House of Delegates. It shall be the duty of the committee to consider the relations and duties of the medical profession of this country to the insurance business, both companies and policy holders to confer, treat and act with authorized representatives of any of these interests, and it is authorized to speak and act for the profession in all matters relating to its duties and to give publicity to its plans and purposes at any time through THE JOURNAL, or otherwise, as may be deemed best.

Report of Committee on Credentials.

REFERRED TO COMMITTEE (see page 1875).

Dr. W. B. Dorsett, Missouri, reported on behalf of the Committee on Credentials:

The Committee on Credentials begs to report that in a number of cases delegates and alternates have appeared, bearing credentials faulty or improperly made out, placing the committee in a difficult and embarrassing position.

Your committee therefore begs to suggest that this House of Delegates request all State Secretaries to exercise all possible care in preparing and issuing credentials to all duly elected delegates and alternates.

We further suggest that this House of Delegates order that hereafter the Committee on Credentials be instructed to refuse to recognize any person or delegate or alternate not in possession of credentials properly made out and signed by the President and the Secretary of the state society from which the delegate comes.

The committee further suggests that the attention of the Presidents and Secretaries of all state societies be called to Book 2, Chapter 4, Section 1 of the By-Laws of the American Medical Association.

WALTER B. DORSETT, Chairman.
THOMAS MCDAVITT,
W. R. TOWNSEND,
H. BERT ELLIS.

This report was referred to the Reference Committee on Rules and Order.

California Library Committee Created.

Dr. Frank Billings, Illinois, presented the following preamble and resolutions, which were adopted:

WHEREAS, The recent disaster which occurred in California destroyed the general private medical libraries; and

WHEREAS, The need of medical books by the physicians of San Francisco and other afflicted cities of California is great; therefore, be it

Resolved, That Drs. Dana (chairman) of New York, Musser of Pennsylvania, Thayer of Maryland, R. C. Cabot of Massachusetts, Stockton of (Buffalo) New York, Forchheimer of Ohio, Sewall of Colorado, J. A. Capps of Illinois and Fischell of Missouri, be and are hereby made a committee to be known as the California Library Committee. Be it further

Resolved, That the committee be empowered to add to its numbers.

Resolved, further, That the committee be requested to select medical books and files of medical journals from libraries, medical publishers and private individuals and to forward the same to an appropriate committee of the County Medical Society of San Francisco.

Subscriptions of Members.

Dr. J. B. Donaldson, Pennsylvania, suggested an amendment, which was referred to the Reference Committee on Amendments to the Constitution and By-Laws, proposing to amend the By-Laws so that of the annual dues $4 shall be set aside for subscription to THE JOURNAL for each member (see page 1875).

Oppose Reduction of Insurance Fees.

Dr. D. Hubert Work, Colorado, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business (see page 1875):

Resolved, That the American Medical Association heartily endorses the action of many of its component county societies in their refusing to accept a reduction of the fees heretofore paid for life-insurance examinations by certain so-called old-line companies.

Urge Passage of Army Bill.

Dr. W. L. Rodman, Pennsylvania, offered the following preamble and resolution, which were adopted:

WHEREAS, The bill to increase the efficiency of the Army (Senate 1539), which has been for two years before Congress, has the support of the War Department, of the Secretary of War and of the President, who has sent to Congress a special message urging its passage, and has been approved by referendum by the American Medical Association: be it

Resolved, That the President of this Association be requested to appeal to the Speaker of the House of Representatives by telegram, asking his good offices in bringing this measure to a vote at the present session.

On motion, the House of Delegates adjourned until 5 p. m. Wednesday.

Fourth Meeting—Wednesday, June 6

The House of Delegates met at 5 p. m., and was called to order by the Second Vice-President, Dr. K. A. J. Mackenzie, Portland, Ore.

The minutes of the previous meeting were read and approved.

Report of Committee on Scientific Research.

READ AND REFERRED TO TRUSTEES.

The Secretary read the report of the Committee on Scientific Research:

Gentlemen:—Your committee would report that in accordance with the regulations of the Board of Trustees two grants have been made for the year 1906 to Dr. G. F. Ruediger, Chicago, for further work on "Streptococcus Infections," and to Dr. Richard M. Pearce, Albany, for work on "Ether Glycosuria and the Elimination of Uric Acid, Creatin, and Phosphorus."

Dr. H. T. Ricketts of the University of Chicago applied for a grant of $200 to aid him in an investigation of mountain fever in Montana. The committee was disposed to make this grant, but on investigation found that the Board of Trustees had limited the amount of individual grants to $100, and for that reason could not comply with Dr. Rickett's request, though the subject proposed was one of great interest, and his fitness for the investigation undoubted. In view of this, we would respectfully recommend that in future the committee be em-

powered to increase the amount of grants to $200 in desirable cases, the understanding being that, as a rule, the amount shall be kept at $100. A larger number of grants might easily have been made, as a number of applications were received. None of these, however, seemed to merit the favorable recommendation of the committee.

We have felt that though the entire appropriation is small, none of it should be utilized excepting in cases in which meritorious work should be encouraged. We have, therefore, felt no regret in the fact that the entire amount appropriated has not been utilized. The only difficulty experienced has been that in some few cases good work might have been aided had it been in our power to increase the grant to $200.

ALFRED STENGEL, Chairman.

The report was referred to the Board of Trustees.

Report of Reference Committee on Constitution.

AMENDMENT TO COVER SUBSCRIPTION BY MEMBERS.

Dr. Craig presented the report of the Reference Committee on Constitution and By-Laws. As a substitute for the amendment to the By-Laws to require that, of the annual dues, $4 shall be set aside for subscription to THE JOURNAL for each member, the committee recommends an addition to the By-Laws, Book 5, Chapter 15, page 29, so that this chapter shall read:

These By-Laws may be amended on a three-fourths vote of the House of Delegates: provided, that no amendments shall be acted on till the day following that on which it is introduced except that the Board of Trustees may, by unanimous vote make such changes, and such changes only, as may be required to adapt them to the rules and regulations of the United States postal authorities.

On motion of Dr. Philip Mills Jones, California, this section of the report was adopted.

The committee recommended that the House adopt a resolution to the following effect:

Resolved, That the Board of Trustees is hereby directed to set aside so much of the annual dues of each member as shall secure for the member a subscription to THE JOURNAL of the American Medical Association.

It was moved and seconded that this resolution be adopted.

After some discussion by Drs. Cantrell and Ferguson the resolution was adopted.

CHANGES IN METHOD OF ELECTION.

The committee recommends the following changes in the By-laws and advises that they be declared to become operative at the close of this annual session:

Book II—Chapter VII—Section 1, page 12—add so that the closing sentence of this section shall read: "The treasurer shall be nominated by the Board of Trustees, and the orators shall be nominated, respectively, by the Sections on Practice of Medicine, on Surgery and Anatomy and on Hygiene and Sanitary Science."

Book IV—Chapter XII—Section 3—page 25—change to read as follows: "The election of officers shall be the first order of business of the morning meeting of the third day of each annual session. To participate in the election of any section a member must have indicated on registering that he desires to affiliate with such section, and must have recorded his name and address on the section register book. The Sections on Practice of Medicine, on Surgery and Anatomy and on Hygiene and Sanitary Science shall each nominate of their section one to deliver at the ensuing annual session, respectively, the Oration on Practice of Medicine, the Oration on Surgery and the Oration on State Medicine."

On motion of Dr. W. T. Sarles, Wisconsin, this section was adopted.

TRUSTEES TO CONTROL LOCAL ARRANGEMENTS.

The following amendments to the By-Laws, introduce dat the last session by the Reference Committee on Amendments to the Constitution and By-Laws, were adopted:

Book III—Chapter X—Section 3—Strike out (a) "A Committee of Arrangements," *and re-letter the following names of standing committees.*

Book III—Chapter X—Striking out Section 4, recounting the duties of the Committee on Arrangements, add to Book III, Chapter IX: "Section 2. The Board of Trustees shall have full control of all arrangements for the annual sessions and shall provide meeting places for the Association, the House of Delegates and the various sections. It shall also have control of all exhibits. The Board of Trustees, in their discretion, may appoint a local committee of arrangements, which shall be at all times under the control of the Board of Trustees."

Chapter X—Section 7—page 29—Amend as follows: "If, after a place of session has been selected, it becomes apparent that satisfactory transportation rates can not be secured, or that the Association can not be properly entertained and cared for, the Committee on Transportation and Place of Session be and are hereby authorized to change said place of session, but said change shall not be made later than two months preceding the date fixed for the annual session."

On motion the report was adopted as a whole.

Report of Reference Committee on Business.

INSURANCE COMMITTEE APPROVED.

Dr. E. Eliot Harris, New York, presented the following report of the Reference Committee on Miscellaneous Business:

The Reference Committee on Miscellaneous Business respectfully approves the resolutions on the insurance question, asking the appointment of a special committee (page 1874).

As to the resolution offered by Dr. D. H. Work of Colorado, asking for an endorsement of the action of the several component county societies in the matter of the insurance question, the committee recommends that while it is in sympathy with the spirit of his resolution, yet in view of the fact that a committee on insurance is created by this report to deal with the subject in a broad and comprehensive way, it asks that the resolution be referred to the Committee on Insurance.

Respectfully submitted,

E. ELIOT HARRIS, Chairman.
A. D. PRICE,
W. D. HAGGARD.

On motion of Dr. J. R. Hollowbush, Illinois, the report of the committee was adopted.

Report of Reference Committee on Legislation.

ADOPTION OF LEGISLATION REPORT.

Dr. J. F. Percy read the following report of the Reference Committee on Legislation and Political Action:

We have reviewed the report of the Committee on Medical Legislation (see page 1853) and recommend its adoption. We further recommend that all questions of appropriations referred to in this report be referred to the Board of Trustees with the request that they be acted on promptly.

Respectfully submitted,

J. F. PERCY, Chairman,
WILLIAM E. ANDERSON,
J. R. KEAN.

On motion of Dr. W. T. Sarles, Wisconsin, the report was adopted.

Report of Reference Committee on Education.

COMMITTEE ON RECIPROCITY ABOLISHED.

Dr. Stuart McGuire, Virginia, chairman of the Reference Committee on Medical Education, presented the following report:

Your Reference Committee on Medical Education, to whom have been referred the reports of the Council on Medical Education (see page 1853) and of the Committee on Reciprocity (see page 1868), desires heartily to commend the work that has been done by both bodies.

The Council on Medical Education has made great progress in a most important undertaking. Much remains yet to be accomplished and the work must be continued. We understand from the chairman, Dr. Bevan, that the Council is already formulating a curriculum which, after being submitted to this body for approval, will be recommended to the various schools for adoption. In this connection we wish to recall the fact that the House of Delegates, at the Portland session, by a unanimous vote, advised the incorporation of a special course in medical economics in the curriculum of every school.

In connection with the report of the Committee on Reciprocity, we advise, with the approval of the chairman of the committee, Dr. Rodman, that the various recommendations contained in it be referred to the Council on Medical Education. Inasmuch as the work of the Council and of the committee covers the same ground, we can see no reason for the existence of both. Therefore, to simplify matters, we advise that the Committee on Reciprocity be abolished.

We think the thanks of the Association are due to Dr. Bevan, Dr. Rodman and the various members of the two committees for their faithful and effective work; also to the state boards and medical schools who have co-operated with them in their labors.

Dr. Philip Mills Jones, California, moved that the report with its recommendations be adopted. Seconded.

Dr. J. N. MacCormack, Kentucky, moved to amend that the Council on Medical Education be requested to take the matter up with the schools.

The amendment was seconded, accepted and the original motion as amended was carried.

Report of Committee on Rules.

PROPER CREDENTIALS TO BE REQUIRED.

Dr. J. Garland Sherrill, Kentucky, presented the following report of the Committee on Rules and Order:

Your Committee on Rules and Order begs to report on the Report of the Committee on Credentials (see page 1874) that Book II, Sections 1 to 4, page 9, fully covers the registration of delegates. We, therefore, recommend that the Secretary be asked to notify constituent associations that in the future these rules will be strictly enforced.

J. GARLAND SHERRILL, Chairman,
H. M. WORKMAN,
L. D. WILSON,

On motion, the report was adopted.

Ohio Resolution for Refund to State Journals.

LAID ON TABLE.

Dr. Charles L. Bonifield, Ohio, said that at a meeting of the Ohio State Medical Society, held last month at Canton, the delegates to the American Medical Association were instructed to present the following preambles and resolution:

WHEREAS, THE JOURNAL of the American Medical Association has accumulated a quarter of a million of dollars, thus proving that it does not need its entire income; and

WHEREAS, The state journals are of immeasurable value in maintaining organization; therefore, be it

Resolved, That the Secretary of the American Medical Association is hereby instructed to return to the treasurer of each state society that publishes a journal one dollar for each subscriber to THE JOURNAL of the American Medical Association from his state, and that each secretary of a county society in such a state is made an agent for receiving subscriptions for THE JOURNAL of the American Medical Association.

On motion of Dr. J. Garland Sherrill, Kentucky, these preambles and resolution were laid on the table.

Proposal to Remit Dues of California Sufferers.

APPROVED, BUT LATER RECONSIDERED (See page 1877).

Dr. J. N. MacCormack presented the following:

In view of the great financial loss experienced by the profession of San Francisco in the late earthquake and fire; be it

Resolved, That the dues of the members of this Association residing in San Francisco be remitted for the ensuing year.

It was moved that the resolution be adopted. Seconded.

The Secretary stated that there are other members of the Association who reside in small towns near San Francisco who were affected by the earthquake.

It was therefore moved as an amendment that the Secretary be instructed to investigate individual instances and that the Board of Trustees be requested to remit their dues.

The amendment was seconded and the motion as amended was carried (see page 1877).

Appropriation for Relief of California Sufferers.

VOTED AND LATER MODIFIED (see page 1877).

Dr. F. D. Gray, New Jersey, asked if any action had been taken by the House of Delegates with regard to any other form of relief for the San Francisco sufferers.

The Secretary said there had not.

After further remarks by Dr. Gray, pointing out the importance of voting a cash contribution to the sufferers, Dr. E. Eliot Harris, New York, moved that the House of Delegates appropriate $1,000 for that purpose, and that the matter be referred to the Board of Trustees. Seconded.

Dr. A. F. Jonas, Nebraska, moved to amend that the amount be made $5,000. Seconded.

The motion as amended was accepted, carried, and the matter referred to the Board of Trustees (see page 1877).

Florida Resolutions on Insurance Fees and Nostrums.

REFERRED TO COMMITTEE ON INSURANCE FOR FUTURE USE.

The Secretary read a letter from Dr. Joseph Y. Porter, Florida, presenting the following preambles and resolutions, which were endorsed by the Florida State Medical Association in annual session in Gainesville, Fla., April 19, 1906:

WHEREAS, There is a tendency on the part of old-line or legal reserve life-insurance companies to reduce the minimum fee paid for medical examination to three dollars; and

WHEREAS, It is the unanimous sentiment of the members of the Florida State Medical Association in session at Gainesville, April 19, 1906, that a minimum fee of three dollars is not a just compensation for the services rendered and responsibility assumed; therefore, be it

Resolved, By the Florida State Medical Association, that on and after July 1, 1906, no member of this Association shall make a medical examination for any insurance company, old-line, fraternal or assessment, now licensed to transact business in this state, or any insurance company which may hereafter be licensed to transact business in this state, for less than five dollars an examination, and that an additional fee of five dollars be charged where a microscopic examination is required; and be it further

Resolved, That a copy of this resolution be sent at once to the secretary of each component society for their action, and that said societies after acting on the matter shall forward at once the result of said action to the secretary of the state medical association, who in turn shall notify each secretary of the component medical societies of the final action taken.

On motion these resolutions were referred to the Committee on Insurance that is to be appointed.

Florida Resolutions on Council on Pharmacy.

ACCEPTED AND PLACED ON FILE.

The Secretary likewise read the following, which was adopted by the Florida Medical Association at its annual session, held April 19, 1906:

Resolved, That the Florida Medical Association expresses its hearty approval of the action of the American Medical Association in establishing a Council on Pharmacy and Chemistry to investigate non-official drugs and medicines.

It realizes that such an investigation is necessary to sift out the numerous and rapidly increasing number of worthless and harmful preparations that are being exploited among the physicians of this country. It has confidence in the Council and wishes to support the Trustees of the American Medical Association in carrying on the work already instituted by this body.

The Florida Medical Association also approves the action of THE JOURNAL of the American Medical Association in its campaign of educating the medical profession concerning the evils of nostrums and urges it to continue the good work.

On motion of Dr. E. Eliot Harris, New York, this communication was accepted and placed on file.

Dr. V. H. Stickney, North Dakota, presented a communication, which was referred to the Reference Committee on Miscellaneous Business.

On motion the House of Delegates adjourned to meet at 2 p. m. Thursday.

Fifth Meeting—Thursday, June 7

The House of Delegates met at 2 p. m. and was called to order by the President.

The minutes of the previous meeting were read.

Place of Session Arrangements Amended.

Dr. T. J. Happel, Tennessee, called the attention of the House of Delegates to the by-law adopted at a previous meeting, giving the Board of Trustees the power to change the place of session, and suggested that the words "three months" be changed to read "two months" (see pages 1870 and 1875).

Dr. Alexander R. Craig, Pennsylvania, moved a reconsideration of that part of the report of the Reference Committee on Constitution and By-Laws adopted at a previous meeting.

Carried.

He then moved to substitute the word "two" instead of "three," as suggested by Dr. Happel.

This motion was seconded and carried.

The minutes as amended were adopted.

The election of officers was then proceeded with.

Election of Officers.

Dr. E. Eliot Harris, New York, in nominating Dr. Bryant said:

I rise to present the name of a gentleman as a candidate for President who is the choice of the reunited medical profession of the State of New York and of its delegates sitting in this House.

I do not feel that it is necessary for me to describe his grand and noble traits of character and his high professional attainments to his friends here assembled. They are all well known to you. He needs no eulogy. I shall not ask for the time to deliver a panegyric. The encomiums which have been voiced by his many students and friends are not limited to the State of New York, but extend throughout the length and breadth of this land. They are matters of public record. I have simply the honor, as well as the privilege, to name your candidate for President of the American Medical Association—Dr. Joseph D. Bryant, of New York, or, rather, of the United States of America. [Applause.]

The nomination was seconded by the delegates from several states, after which Dr. T. J. Happel moved that the Secretary be instructed to cast the unanimous ballot of the House of Delegates for Dr. Bryant as President of the Association, which was seconded by several and unanimously carried.

The Secretary, in accordance with instructions, cast the ballot for Dr. Bryant, and he was declared duly elected.

The President appointed as tellers Drs. W. D. Haggard, Tennessee, and Edward B. Heckel, Pennsylvania.

The following officers were duly elected:

First Vice-President, Dr. Herbert L. Burrell, Boston.

Second Vice-President, Dr. Andrew C. Smith, Portland, Ore.

Third Vice-President, Dr. D. S. Fairchild, Des Moines, Iowa.

Fourth Vice-President, Dr. W. S. Foster, Pittsburg, Pa.

General Secretary, Dr. George H. Simmons, Chicago (re-elected).

Treasurer, Dr. Frank Billings, Chicago (re-elected).

Trustees: Dr. M. L. Harris, Chicago (re-elected); Dr. William H. Welch, Baltimore (re-elected); Dr. Miles F. Porter, Fort Wayne, Ind. (re-elected).

[The other members of the Board of Trustees, whose terms of office did not expire, are as follows: T. J. Happel, Chairman, Trenton, Tenn., 1907; W. W. Grant, Denver, 1907; Philip Marvel, Atlantic City, N. J., 1907; E. E. Montgomery, Vice-Chairman, Philadelphia, 1908; A. L. Wright, Carroll, Iowa, 1908; H. L. E. Johnson, Washington, D. C., 1908.]

Member of Judicial Council, Dr. D. C. Peyton, Jeffersonville, Ind. (re-elected).

[The other members of the Judicial Council are: P. Maxwell Foshay, New York, Chairman; George Ben Johnston, Richmond, Va.; W. B. Russ, San Antonio, Texas; W. S. Foster, Pittsburg, Pa.]

Chairman of the Committee on Transportation and Place of Session, John C. Munro, Boston.

[The other members of this committee, as appointed by the President, are named on page 1879.]

Atlantic City the Meeting Place, 1907.

Dr. E. Eliot Harris, New York, stated, on behalf of the Committee on Transportation and Place of Session, that the committee had carefully considered Jamestown, Asbury Park, Chicago and Atlantic City as places for the next session, and that the members of the committee voted unanimously in favor of Atlantic City.

Dr. J. Garland Sherrill, Kentucky, moved that the report be adopted. Seconded.

Time of Next Session Left to Trustees.

After considerable discussion relative to the time of meeting so as not to conflict with the meetings of state medical societies and the Congress of American Physicians and Surgeons, Dr. Frank Billings moved to amend that the Board of Trustees be requested to select a time for the session at Atlantic City either before or immediately after the Congress of American Physicians and Surgeons. Seconded.

Dr. T. J. Happel moved to amend, further, that the date of the next session be fixed not earlier than the middle of June. Seconded.

Dr. E. Eliot Harris, New York, moved as a substitute that the report be adopted and that the time of the session be left to the Board of Trustees.

The substitute was seconded, accepted and carried.

Orators Elected.

The following were elected orators:

Oration on Surgery—Dr. William H. Wathen, Louisville, Ky.

Oration on Medicine—Dr. James B. Herrick, Chicago.

Oration on State Medicine—Dr. Samuel G. Dixon, Philadelphia.

COMMITTEE ON INSURANCE.

John H. Musser, Pennsylvania, Chairman.

William H. Mayo, Minnesota. Joseph D. Bryant, New York.
Jos. N. MacCormack, Kentucky. Frank Billings, Illinois.

Relief for California Sufferers.

METHODS OF RELIEF MODIFIED.

Dr. J. N. MacCormack moved to reconsider the action taken by the House at a previous meeting (see page 1876) with reference to the donation to the sufferers in San Francisco, because, he said, a much more substantial method of relief had been suggested by Dr. Charles A. L. Reed, which met with the concurrence of the Board of Trustees and the delegates from California. Seconded and carried.

Dr. MacCormack then presented the following preambles and resolution, and moved that they be referred to the Board of Trustees:

WHEREAS, The medical profession of San Francisco have suffered irreparable loss, both in property and clientele; and

WHEREAS, It would conflict with the postal laws to remit the dues or subscriptions to THE JOURNAL of the members of this Association in California: therefore, be it

Resolved, That the American Medical Association extends its sympathies to our medical brethren in California and to their families, and pledges them the support of the profession of America in re-establishing themselves on a substantial basis for future usefulness; and, further, in order to give practical and substantial aid, that the Committee on Legislation, through the agencies already established by it, be and is hereby requested to undertake the creation of a fund, which, together with that already contributed through THE JOURNAL, shall amount to $50,000, which shall be used for the benefit of the reputable physicians of California by the committees of the California State Association and of the San Francisco County Medical Association established for that purpose.

After discussion it was moved to amend that the $5,000 appropriated yesterday stand, that the resolution as amended be adopted and that the members of the Committee on Medical Legislation raise as much money as they can. Seconded.

Dr. MacCormack accepted the amendment, and the resolution as amended was adopted.

Resolutions on Behalf of Contract Army Surgeons.

REFERRED TO COMMITTEE ON MISCELLANEOUS BUSINESS.

Dr. J. F. Percy, Illinois, presented the following preambles and resolutions, which were submitted by Dr. John P. Nagle, New York.

WHEREAS, The War Department has employed and now employs physicians by contract to perform the duties of medical officers, and these physicians are required to share the same risks and responsibilities as the commissioned medical officers, but are deprived of any rank while so employed; and

WHEREAS, General Orders of the War Department, Adjutant-General's Office, dated Feb. 13, 1900, gave a list of surgeons who served in the Spanish-American War who especially distinguished themselves by meritorious acts or conduct in service, and of this number two were acting assistant surgeons of the Army, two were commissioned medical officers and one was a civilian volunteer medical aid; and

WHEREAS, Dr. E. K. Johnston, an acting assistant surgeon of the Army, was commended by Major-General W. H. Lawton, commanding the First Division, U. S. Volunteers, at Manila, P. I., on Dec. 18, 1899, for exceptional daring during the battle of Zapote River, and was recommended for promotion as major or brigade surgeon; and

WHEREAS, Five thousand five hundred and thirty-two of the 12,000 members of the medical staff of the Army who served in the Civil War were acting assistant surgeons of the Army, many of whom distinguished themselves as physicians and surgeons and performed gallant and meritorious services, but are refused recognition for the services they have performed and are discriminated against by the War Department for no other reason than that they are or were acting assistant surgeons of the Army and, consequently, had and have no rank of office, although they were always under military orders, Army regulations and the articles of war: therefore, be it

Resolved, That this American Medical Association protests against the employment of physicians and surgeons in the Army by contract, without rank, to perform the duties of medical officers, and requests the President of the United States, who is commander-in-chief of the Army, and the Secretary of War to prevent such employment.

Resolved, That it is the sense of this Association that all physicians and surgeons who are and who have been employed by contract with the Army, and who have performed and are now performing the duties of medical officers, should be commissioned as acting assistant surgeons of the United States Army, with rank similar to the acting assistant surgeons of the United States Army.

On motion of Dr. W. D. Haggard, Tennessee, the resolutions were referred to the Reference Committee on Miscellaneous Business.

Resolutions on Ophthalmia Neonatorum Adopted.

Dr. H. V. Würdemann, Wisconsin, presented the following preambles and resolutions, which were unanimously passed by the Section on Ophthalmology and referred to the House of Delegates for action:

WHEREAS, Notwithstanding the long-continued efforts of the medical profession to make known generally the infectious character of ophthalmia neonatorum and its danger to sight, the ranks of the blind are still largely increased annually by those who have unnecessarily lost their vision as a result of this disease; and

WHEREAS, We possess in the silver salts an almost absolute specific for its prevention and treatment: therefore, be it

Resolved, That this Section recommends that a committee consisting of at least one ophthalmologist, one obstetrician and one sanitarian, with the invited co-operation of a subcommittee, consisting of the president and secretary of each state society, be appointed by the President of the Association to formulate and make effective the details of a plan that may give uniform legislation and definite instruction to the profession and laity concerning the prevention and treatment of this disease.

Resolved, That this Section recommends an ophthalmologist for such committee, to be appointed by the incoming chairman and the executive committee.

On motion the resolutions were adopted.

Wish The Journal Free to Medical Libraries.

REFERRED TO TRUSTEES.

Dr. A. Jacobi, New York, said he was delegated to present the following report:

The following preambles and resolutions were passed at the ninth annual meeting of the Association of Medical Librarians, held June 4, 1906, at The Fenway, Boston:

WHEREAS, The American Medical Association, in convention assembled at Denver, in 1898, passed a unanimous resolution placing the names of the medical libraries which are members of the Association of Medical Librarians on the free mailing list of THE JOURNAL of the American Medical Association; and

WHEREAS, The removal of these names from the free mailing list of THE JOURNAL at the end of the year 1903 has been a severe loss, especially to many of the smaller libraries; be it

Resolved, That the governing body of the American Medical Association be petitioned to restore to the free mailing list of THE JOURNAL of the American Medical Association the names of the libraries which are members of the Association of Medical Librarians; and be it further

Resolved, That Dr. A. Jacobi be a committee of one to present this matter before the governing body of the American Medical Association.

On motion of Dr. Alexander R. Craig, Pennsylvania, these resolutions were referred to the Board of Trustees with instructions that the request be granted.

Report of Davis Memorial Committee.

ACCEPTED AND COMMITTEE CONTINUED.

Dr. Henry O. Marcy, Boston, reported progress as chairman of the Nathan Smith Davis Memorial Committee.

Dr. T. J. Happel moved that the report be accepted, that Dr. Marcy be continued as chairman of the committee and that Dr. William E. Quine, Chicago, be made vice-chairman and requested to assist actively in this work. Seconded and carried.

Dr. E. D. Ferguson, New York, moved that the chairman of the committee, Dr. Marcy, and his coadjutors in the city of Chicago be authorized to appoint a secretary and treasurer of the committee and that Dr. Frank Billings be made treasurer.

This motion was seconded and carried.

Report of Committee on Cancer of the Uterus.

APPROVED AND FURTHER WORK AUTHORIZED.

Dr. F. F. Simpson, Pittsburg, presented the report of the Committee on Cancer of the Uterus:

In the consideration of cancer of the uterus your committee has been impressed by the urgent need of a general plan of public education on many medical subjects. While the Section of Obstetrics is naturally interested in promoting some effective means of reducing the frightful mortality in cancer of the uterus, each section of the American Medical Association is quite as intensely interested in similar work pertaining to matters of public health falling within its province. The needs of the hour seem to demand some ethical way of instructing the people in general regarding these several subjects. It is apparent that to be effective such instruction must be authoritative, systematic, painstaking, persistent, free from technical terms, free from suspicion of personal advancement, and it must reach the people through popular channels. For these reasons your committee has felt the necessity of widening the scope of its duties and herewith respectfully submits to the House of Delegates a plan for the organization of a General Board of Public Instruction:

SYNOPSIS OF A PLAN FOR THE ORGANIZATION OF A DEPARTMENT OF PUBLIC INSTRUCTION BY THE ASSOCIATION.

Objects.—To supply the community at large with established facts regarding matters of general moment and public health. To supply these facts ethically, in good taste and without the element of individual advancement. To harmonize and give the added value of combined effort to the several interests which are now working independently for the common good along medical lines. To direct this work under the auspices of the American Medical Association, thus giving unity of purpose among the workers and public expression to the aim and aspirations of the medical profession of America.

Organizations.—To further these aims a General Board of Instruction shall be composed of five representatives each from the Sections on Practice of Medicine, on Surgery and Anatomy and on Hygiene and Sanitary Science, and three representatives from each of the other sections of the American Medical Association. The members of the General Board of Instruction from each special section shall constitute the special board of instruction for the sections they represent.

Manner of Selection and Duration of Office.—The members of this board shall be appointed by the chairman of each section, the term of office being five years for the members of the Sections on Practice of Medicine, on Surgery and Anatomy and on Hygiene and Sanitary Science, and three years for each of the other sections of the American Medical Association. The tenure of office shall be so arranged that one new member shall be appointed annually from each section, thus preserving the individuality of the general constitution of the board and insuring a uniform continuity of purpose.

Selection of Subjects.—The discussion of many subjects should, of course, be restricted to the medical profession, but in order to direct uniform attention to them the board of instruction may consider that they merit special articles or circular letters, under separate cover, to the entire medical profession. Other subjects of value to the general public should be given publicity through the lay press or other popular channels of education. The section of the Board of Public Instruction, under whose jurisdiction the subject properly belongs, presents the subject to the general board, which shall finally decide on the propriety of its publication.

The Number of Articles to Appear.—This is to be determined by the appropriate special board. On consideration by the general board, however, the number may be curtailed, or their publication may be stopped at any time if it deem it wise.

Character of Articles.—This is to be determined by the special board having jurisdiction, but the final decision as to their publication or the channel through which they shall appear may be subject to the suggestion of and controlled by the general board. One essential feature of these articles is that there shall be the least possible reference, direct or implied, to any person or institution, in order that there may be no imputation, either direct or indirect, that the function of the board is employed for the promotion of individual advancement. Each article must be actually read by at least two-thirds of the appropriate special board and by three members of the general board. Each article shall receive the unanimous sanction of the special board and a majority of the general board before it may appear in public print.

Source of Articles.—So far as the public is concerned, each article shall be "approved by the American Medical Association," but shall not bear the name of the individual writer. The actual writers of the several articles must be selected carefully by the appropriate special boards, in order that the most authoritative information may be given to the public.

The avenues of distribution are to be determined by the General Board of Public Instruction. Articles for the general instruction of the public shall be published in conservative periodicals or magazines devoid of sensational basis, and which will honorably conform to the requirements of medical ethics. Another effective method of instruction shall be by lectures in public and private schools, in colleges and other institutions of learning. Public lectures on certain topics may well be conducted under the auspices of local county medical societies, before literary clubs, college settlements, etc.

If a plan of this general nature is inaugurated, your committee believes that the logical evolution may be a department of public instruction, which ultimately would have a very powerful function in the collection and dissemination of scientific, sociologic and statistical facts for the use of the medical profession and the instruction of the general public, thus rendering inestimable benefit to mankind. If the value of this work were established, as we believe is possible, it might logically lead to the establishment by our national government of an executive department encompassing all of these aims. Before our government can be induced to assume this responsibility it must be convinced of its need by actual demonstration. We believe such a scheme as this, if put into action, may bring about this much desired end.

In the absence of specific authority to act, your committee has refrained from the investigation of several facts. Among them may be mentioned the attitude of publishers to the ethical side of our problem; the cost of maintenance of a department; the manner of raising funds; the establishment of an endowment fund, etc.

We would, therefore, respectfully suggest that a committee be appointed to investigate these and other germane problems and that it make a definite report for adoption at the next session of this Association.

JOHN G. CLARK, Chairman.
THOMAS S. CULLEN. J. CLARENCE WEBSTER.
JOHN A. SAMPSON. F. F. SIMPSON.

Dr. Daniel H. Craig, Boston, moved that the report of the committee be adopted and that the President appoint at his con-

venience a committee of seven to investigate the matters suggested and to report for definite action at the next annual session. Carried.

Supplemental Report of the Board of Trustees.

Dr. T. J. Happel, chairman, presented the following supplemental report of the Board of Trustees:

To the House of Delegates of the American Medical Association:

Your Board of Trustees would submit the following supplemental report:

We have appropriated as follows:

ASSOCIATION EXPENSES.

Committee on Education, not to exceed	$ 4,000.00
Council on Pharmacy and Chemistry, not to exceed	3,500.00
Committee on Medical Legislation, not to exceed	1,000.00
Committee on Scientific Research	800.00
Secretaries of Sections	600.00
Scientific Exhibit	500.00
National Organizer's salary	5,000.00
Secretary Board of Trustees	100.00
Treasurer of the American Medical Association	200.00
Total Association expense account, not including traveling expenses of the organizer	$15,700.00

JOURNAL ACCOUNT.

New printing press	$20.000.00

SPECIAL APPROPRIATIONS.

San Francisco sufferers	$ 5,000.00
Total	$40,700.00

Taking the profits of last year in THE JOURNAL office as a basis of estimate, the House of Delegates will readily see that our reserve fund will be encroached on.

This appropriation of $5,000 to the San Francisco physicians is payable to the order of the Physicians' Relief Committee of that city, to be distributed by them. We would add that while this item will afford but a little help to each physician, still it must not be forgotten that there has been sent out through THE JOURNAL office already more than $10,000 on the collection which was authorized by your Board of Trustees.

In regard to the amount granted to the Committee on Medical Legislation, we desire to explain as follows: As suggested at Portland and ordered at this session, the business of this committee will be carried on in THE JOURNAL office under proper managerial administration, and in this way we hope to lessen the expenses of the same. T. J. HAPPEL, Chairman.
M. L. HARRIS, Secretary.

On motion of Dr. John B. Roberts the report was adopted.

Reports, Resolutions, Etc., to Be in Duplicate.

TYPEWRITIST FOR COMMITTEEMEN.

Dr. Happel presented the following preamble and resolution:

WHEREAS, Reports and resolutions presented to this body are referred to reference committees, to the Board of Trustees, etc.: therefore, be it

Resolved, That in future all reports, resolutions, amendments to the Constitution and By-Laws, etc., be furnished in duplicate, one copy to be furnished the Secretary for the official minutes and the other to committeemen; and that the Secretary be instructed to engage a typewritist for the use of committeemen in making their reports.

On motion the resolution was adopted.

Announcement of Committees.

The President announced the appointment of the following committees:

COMMITTEE ON SCIENTIFIC EXHIBIT.

F. B. Wynn, Indianapolis, Director.

COMMITTEE ON SCIENTIFIC RESEARCH.

Alfred Stengel, Philadelphia, Chairman.
L. F. Barker, Baltimore. L. Hektoen, Chicago.

COMMITTEE ON ORGANIZATION.

J. N. MacCormack, Bowling Green, Ky., Chairman.
Duncan Eve, Nashville. George H. Simmons, Chicago.

COMMITTEE ON MEDICAL LEGISLATION.

Charles A. L. Reed, Cincinnati, Ohio, Chairman (three years).
W. L. Rodman, Philadelphia. William H. Welch, Baltimore.
(One year.) (Two years.)

VOTE OF THANKS TO DR. REED.

Dr. MacCormack moved that the House of Delegates tender to Dr. Reed its thanks for the efficient manner in which he has conducted this work, and that the nomination of Dr. Reed for three years as chairman of the Committee on Medical Legislation be confirmed by a rising vote as an appreciation of his invaluable work. Carried unanimously.

COMMITTEE ON TRANSPORTATION AND PLACE OF SESSION.

John C. Munro, Boston, Chairman.
E. Eliot Harris, New York. W. A. Jayne, Denver.
Philip Mills Jones, San Francisco. Wm. H. Wathen, Louisville, Ky.

JUDICIAL COUNCIL.

P. Maxwell Foshay, Chicago, Chairman.
W. S. Foster, Pittsburg, Pa. D. C. Peyton, Jeffersonville, Ind.
Geo. Ben Johnson, Richmond, Va. W. B. Russ, San Antonio, Texas.

COUNCIL ON MEDICAL EDUCATION.

Arthur D. Bevan, Chicago, Chairman.
W. T. Councilman, Boston. J. A. Witherspoon, Nashville, Tenn.
Charles A. Frazier, Philadelphia. V. C. Vaughan, Ann Arbor Mich.

COMMITTEE ON AWARD OF SENN MEDAL.

A. F. Jonas, Omaha, Chairman.
Harry M. Sherman, San Francisco. J. F. Binnie, Kansas City, Mo.

COMMITTEE ON IMPROVEMENT OF THE TREATMENT OF UTERINE CANCER.

John G. Clark, Philadelphia, Chairman.
F. F. Simpson, Pittsburg. W. D. Haggard, Nashville, Tenn.
J. W. Bell, Minneapolis. Willard Bartlett, St. Louis.
Stuart McGuire, Richmond, Va. Henry Sewall, Denver.

COMMITTEE ON DAVIS MEMORIAL.

Henry O. Marcy, Boston, Chairman.
Wm. E. Quine, Chicago, Vice-Chairman.

Alabama, Eugene D. Bondurant, Mobile; Arkansas, C. C. Stephenson, Little Rock; Arizona, John W. Foss, Phoenix; California, R. F. Rooney, Auburn; Colorado, J. M. Blaine, Denver; Connecticut, N. E. Wordin, Bridgeport; Delaware, Alexander Lowber, Wilmington; District of Columbia, Joseph T. Johnston, Washington; Florida, J. D. Fernandez, Jacksonville; Georgia, Lewis H. Jones, Atlanta; Idaho, G. M. Waterhouse, Weiser; Illinois, E. C. Dudley, Chicago; Indiana, D. C. Peyton, Jeffersonville; Indian Territory, V. Berry, Wetumka; Iowa, William Jepson, Sioux City; Kansas, Charles E. Bowers, Wichita; Kentucky, John G. Cecil, Louisville; Louisiana, Charles Chassaignac, New Orleans; Maine, R. D. Bibber, Bath; Maryland, John Ruhrah, Baltimore; Massachusetts, Henry O. Marcy, Boston; Michigan, H. O Walker, Detroit; Minnesota, Alexander J. Stone, St. Paul; Missouri, N. B. Carson, St. Louis; Mississippi, E. H. Martin, Clarksdale; Montana, Donald Campbell, Butte; Nebraska, A. F. Jonas, Omaha; New Hampshire, Granville P. Conn, Concord; Nevada, J. E. Pickard, Virginia City; New Jersey, Edward J. Ill, Newark; New York, C. G. Stockton, Buffalo; North Carolina, E. G. Register, Charlotte; North Dakota, Paul Sorkness, Fargo; New Mexico P. G. Cornish, Albuquerque; Ohio, Frank Winders, Columbus; Oklahoma, J. A. Hatchett, El Reno; Oregon, H. W. Coe, Portland; Pennsylvania, James M. Anders, Philadelphia; Rhode Island, Stephen A. Welch, Providence; South Carolina, T. P. Whaley, Charleston; South Dakota, A. H. Bowman, Deadwood; Tennessee, Duncan Eve, Nashville; Texas, J. T. Wilson, Sherman; Utah, Union Worthington, Salt Lake City; Vermont, M. L. Chandler, Barre; Virginia, W. E. Anderson, Farmville; Washington, George W. Libby, Spokane; West Virginia, W. W. Golden, Elkins; Wisconsin, Arthur J. Burgess, Milwaukee; Wyoming, G. L. Strader, Cheyenne.

Foreign Visitors Honored.

The Section on Obstetrics and Diseases of Women submitted the nomination of Prof. A. von Rosthorn, of Heidelberg, for honorary membership, and on motion the nomination was confirmed.

On motion of Dr. Chassaignac, New Orleans, Professor Trendelenburg, Leipsic, Germany, was elected to honorary membership.

Message to Senator Hepburn.

Dr. Frank Billings called attention to the illness of Senator Hepburn, who drafted and introduced the pure-food bill, and moved that the President and Secretary be instructed to send a telegram expressing respect for him and extending the sympathy of the Association to him in his illness, with hopes for a speedy recovery. Carried.

Resolutions from Section on Hygiene.

A DEPARTMENT OF PUBLIC HEALTH DESIRED.

Dr. J. Walter Suiter, New York, presented the following preambles and resolutions which were unanimously adopted by the Section on Hygiene and Sanitary Science and referred to the House of Delegates:

WHEREAS, The rapidly increasing number and the scope of the sanitary problems constantly arising are of great importance to the growth and development of this country as well as its outlying dependencies; and

WHEREAS, Such problems require for their solution the most experienced and best trained sanitary talent, it follows that it is especially desirable that our Chief Executive have in his immediate presence a medical adviser, eminent and experienced in sanitary science, to counsel him at all times and thus lighten his responsibility in deciding on matters of far-reaching importance which so profoundly affect the lives and health of many millions of people for either good or ill: therefore, be it

Resolved, By the Section on Hygiene and Sanitary Science of the American Medical Association, that we ask the House of Delegates to take immediate and appropriate action which may bring before the Congress of the United States, as a means of materially advancing the prosperity and well-being of this nation, the impor-

tance and necessity of creating a Department of Public Health, with a regularly educated physician as secretary in the Cabinet of the President.

Resolved, further, That the secretary of this Section be authorized and directed to call the attention of all state boards and health commissioners of the larger American cities to the purport of these resolutions and to solicit their active co-operation to the end that suitable legislation may result in the furtherance of the object of the resolution.

On motion of Dr. Charles L. Bonifield, Ohio, the resolutions were referred to the Committee on Medical Legislation.

RESOLUTION ON THE HEALTHFULNESS OF CONTINENCE.

WHEREAS, There exists among the laity a general impression that sexual intercourse is necessary to the health of men; and

WHEREAS, It is claimed that this impression rests on the authority of the medical profession: now, therefore, be it

Resolved, That in the opinion of the Section on Hygiene and Sanitary Science of the American Medical Association, continence is not injurious to health, and that this Section reprobates the contrary doctrine as a menace to the physical and moral welfare of the individual and society.

PRINCE A. MORROW.

On motion this resolution was referred to the Committee on Improvement of the Treatment of Uterine Cancer.

RESOLUTION ON EDUCATION CONCERNING VENEREAL DISEASE.

Resolved, That it is the opinion of the Section on Hygiene and Sanitary Science of the American Medical Association that it should be the duty of state boards of health to disseminate literature to educate the people on the subject of the great black plague (venereal disease) as they do regarding tuberculosis and other infectious diseases.

LISTON H. MONTGOMERY.

On motion this resolution was referred to the same committee.

RESOLUTION ON MAKING VENEREAL DISEASE REPORTABLE.

Resolved, That in the opinion of the Section on Hygiene and Sanitary Science of the American Medical Association, gonorrhea, chancroid and syphilis should be included among diseases to be under the control of boards of health of the different states.

L. DUNCAN BULKLEY.

Referred to the same committee.

Dr. J. C. Hall, Mississippi, presented the following resolution, which was referred to the same committee as the previous resolutions:

Resolved, That the Mississippi State Medical Association believes that continence is compatible with health, and reprobates the contrary doctrine as a menace to the physical and moral welfare of the individual and of society.

Annual Meetings of State Societies.

Dr. Frank Billings said that at a former session of the House of Delegates the Committee on Organization presented a resolution, which was adopted, recommending that the constituent state medical societies hold their annual meetings, as near as possible, in the fall instead of in the spring. He reiterated that resolution and moved that the constituent societies be requested to hold their annual meetings in the fall. Carried.

Trustee May Not Be State Delegate.

AMENDMENT TO LIE OVER ONE YEAR.

Dr. Alexander R. Craig, Pennsylvania, offered, on behalf of the Reference Committee on Constitution and By-Laws, the following amendment:

Constitution—Article V—Section 1 (page 2, line 4 of the section) –after the words "constituent associations" insert "provided, however, that no constituent association may be represented in the House of Delegates by a member of the Board of Trustees of the American Medical Association." (To lie over until next year.)

Medical Journals and Nostrum Advertisements.

Dr. E. Eliot Harris, New York, offered the following resolution:

Resolved, That the committees on publication of the journals of medicine published by the state medical associations affiliated with this body be asked to assist the Board of Trustees in their effort to suppress the advertisement of medical nostrums and to co-operate in the work of securing pure-food and pure-drug laws in the United States.

On motion of Dr. C. E. Cantrell, Texas, the resolution was adopted.

Report of Committee on Reapportionment.

Dr. George W. Guthrie, Pennsylvania, presented the following report of the Committee on Reapportionment:

The Committee on Reapportionment begs leave to report that it has examined the certificates of membership of the constituent state associations and finds that a reapportionment of delegates on a basis of one delegate to every 500 members would constitute a House of Delegates of 147 members. Inasmuch as Section 3, Chapter 4, Book 2, of the By-Laws places a limit of 135 members to this House, we therefore recommend that the reapportionment for the years 1907, 1908 and 1909 be on the basis of one delegate to every 600 members, giving a membership from constituent state associations of 127, distributed as follows:

MEMBERSHIP FROM CONSTITUENT ASSOCIATIONS.

	No. Delegates 1903-06.	Cert. Memb. 1906.	No. Delegates on 500 basis.	No. Delegates on 600 basis.	Change.
Alabama	3	1,370	3	3	..
Arizona	1	104	1	1	..
Arkansas	2	766	2	2	..
California	4	1,783	4	3	—1
Colorado	2	716	2	2	..
Connecticut	2	780	2	2	..
Delaware	1	104	1	1	..
District of Columbia	1	484	1	1	..
Florida	1	281	1	1	..
Georgia	2	1,020	3	2	..
Hawaii	1	63	1	1	..
Idaho	1	75	1	1	..
Illinois	8	4,087	9	7	—1
Indian Ter.	1	....	..	..	1
Indiana	4	2,109	5	4	..
Iowa	4	1,719	4	3	—1
Kansas	2	1,202	3	3	+1
Kentucky	3	1,620	4	3	..
Louisiana	2	746	2	2	..
Maine	1	486	1	1	..
Maryland	2	929	2	2	..
Massachusetts	6	3,044	7	6	..
Michigan	4	1,966	4	4	..
Minnesota	2	1,105	3	2	..
Mississippi	2	930	2	2	..
Missouri	3	2,235	5	4	+1
Montana	1	175	1	1	..
Nebraska	2	714	2	2	..
New Hampshire	1	403	1	1	..
New Jersey	3	1,228	3	3	..
New Mexico	1	123	1	1	..
New York	10	6,578	13	11	+1
Nevada	1	53	1	1	..
North Carolina	2	1,242	3	3	+1
North Dakota	1	207	1	1	..
Ohio	5	3,482	7	6	+1
Oklahoma	1	676	2	2	+1
Oregon	1	332	1	1	..
Pennsylvania	8	4,574	10	8	..
Rhode Island	1	322	1	1	..
South Carolina	1	659	2	2	+1
South Dakota	1	245	1	1	..
Tennessee	3	1,055	3	2	1
Texas	5	2,650	6	5	..
Utah	1	130	1	1	..
Vermont	1	416	1	1	..
Virginia	3	1,413	3	3	..
Washington	1	507	2	1	..
West Virginia	2	597	2	1	1
Wisconsin	3	1,395	3	3	..
Wyoming	1	62	1	1	..
Philippine Islands	1	57	1	1	..
	126	58,859	147	127	Net gain 1.

This provides for the same representation as at present for 40 out of 52 state associations. In 6 cases the representation is diminished by one delegate, as follows: California, Tennessee, Illinois, Indian Territory, West Virginia, Iowa. In 7 states the representation is increased by one delegate each, as follows: Kansas, North Carolina, Missouri, Ohio, Oklahoma, New York, South Carolina.

This makes the membership of the House from state associations for the years of 1907, 1908 and 1909, 128. To this must be added the fifteen members from sections and army services, making a total membership of 142.

Respectfully submitted.

W. J. MAYO, GEORGE A. GUTHRIE.
G. H. SIMMONS, FRANK D. BAIN.
N. J. MILLER.

Dr. Alexander R. Craig moved the adoption of the report. Seconded.

Dr. Frank Billings moved to amend that the thanks of the House of Delegates be extended to the committee for its efficient work.

The amendment was seconded, accepted, and the original motion as amended was carried.

Oregon and Insurance Examination Fees.

Dr. Henry Waldo Coe, Portland, Ore., reported in relation to the insurance examination fee matter that the Oregon State Medical Society has recently passed a resolution directing its members not to accept the reduced fees for insurance examinations under penalty of expulsion from the society.

He said that this resolution was passed unanimously and with much enthusiasm.

On motion the resolution was referred to the Insurance Committee.

Extermination of Mosquitoes.

The Secretary read a telegram from the American Mosquito Extermination Society with reference to methods of destruction of mosquitoes, and on motion the communication was referred to the Reference Committee on Hygiene and Public Health.

Tropical Medicine Section Asked.

Dr. M. Herzog, Philippine Islands, moved that the President appoint a committee to consider the advisability of creating a section on tropical medicine and to report on it at the next annual session of the Association. Seconded and carried.

Vote of Thanks to Boston.

Dr. E. D. Martin, Louisiana, offered the following preambles and resolution:

WHEREAS, This is the largest session ever held in the history of the American Medical Association; and

WHEREAS, The profession of the city of Boston and its citizens have not only been untiring in their efforts, but have shown their ability to handle its membership and visitors in such a manner as to have given the most general satisfaction; and

WHEREAS, The entertainments have been so continuous and so grand as to excel all heretofore given; be it

Resolved, That the members of the Association and their guests desire hereby to express their thanks to the physicians of Boston, the governor, mayor, citizens, and especially to the ladies, for their untiring efforts in doing all that was possible to make our visit to this grand old city one never to be forgotten. We wish to include further in this resolution all institutions which have so kindly opened their doors to us and thereby added so much to our visit.

On motion of Dr. Billings the resolution was adopted unanimously.

The President called for the report of the Judicial Council, but as none of the members was present the report was passed.

Amendment to By-Laws.

Dr. J. N. MacCormack presented the following amendment:

Amend Section 5—Chapter X—Book III of the By-Laws, page 18, by striking out all of the first sentence after the words "five members" and inserting in lieu thereof the words "to be appointed by the President on the first day of each annual session from the delegates present, and to continue in office until their successors are appointed." (To lie over until next year.)

Dr. Frank Billings moved that the thanks of the House of Delegates be extended to the ex-President and to the present officers for the efficient way in which they have presided over the meetings. Seconded.

Dr. Billings put the motion and it was carried unanimously.

There being no further business to come before the House, on motion of Dr. E. Eliot Harris the House of Delegates then adjourned without date.

OFFICIAL MINUTES—GENERAL MEETINGS

First General Meeting— Tuesday, June 5

The meeting was called to order by the President, Dr. Lewis S. McMurtry of Louisville, Kentucky, at 10:30 a. m., in Mechanics' Hall.

Approximately six thousand people—physicians, their wives, daughters and guests—attended the meeting. Pink and white bunting formed a sky of color overhead, and American flags draped the platform.

Just before 11:30 the officers of the Association, members of the Local Committee on Arrangements, etc., marched into the hall and up the central aisle to the platform. Two policemen preceded the procession to clear the way, followed by a band. Then came Governor Guild, escorting the venerable chaplain of the United States Senate, Rev. Dr. Edward Everett Hale. At the sight of this distinguished couple the entire audience rose to their feet. Then handkerchiefs were waved and this was followed by loud applause. Mayor Fitzgerald was escorted by Dr. Arthur T. Cabot, president of the Massachusetts State Medical Society, and among others in the procession were the President, Dr. Lewis S. McMurtry, the President-elect, Dr. William J. Mayo, of Rochester, Minnesota; Dr. Herbert L. Burrell, Chairman of the Local Committee of Arrangements; Drs. George B. Shattuck, Frank B. Harrington, Reginald H. Fitz, Elliot B. Joslin, Chas. Harrington, J. Collins Warren, John C. Munro, Alonzo Garcelon, Chas. S. Minot, the Vice-Presidents and the Secretary of the Association, and several of the ex-Presidents.

President McMurtry called the vast throng to order and introduced Rev. Edward Everett Hale, who invoked Divine blessing.

At the conclusion of prayer, President McMurtry said:

"The American Medical Association is honored this morning by the presence here at these exercises of the governor of this great commonwealth. I regret to say, that the governor's official duties necessitate his leaving the platform immediately on the delivery of his address; otherwise it would be his pleasure to remain with us throughout the proceedings. Ladies and gentlemen, I have the great pleasure of presenting to you Governor Guild, of Massachusetts. (Applause.)

Address of Welcome by Governor Guild.

Mr. President, Ladies and Gentlemen:—Not even the official duties of the chief executive can ever bar Massachusetts from the duty of hospitality to friends gathered within her borders. (Applause.)

I come in the name of the commonwealth to bid you a most hearty welcome in this, the fairest month of all the year, to extend to you all the privileges that the commonwealth may extend to make your visit within our borders delightful and instructive.

The history of Massachusetts in medicine is too well known for me to rehearse it here. A more formal address of welcome will be delivered to you by my eloquent friend and associate in public office, Mayor Fitzgerald, of Boston. (Applause.) But while he will doubtless invite you to visit the local institutions, for which the city of Boston deserves just credit, I trust that your investigations will not be confined to the limits of this city. The commonwealth of Massachusetts has something to show you which we hope may prove of interest. I trust, for instance, that you will acquaint yourselves with the free distribution of antitoxin for the cure of diphtheria among the children of this commonwealth, carried on under the auspices of the commonwealth itself. (Applause.) I trust you will acquaint yourselves with that particular care for the unfortunate in which Massachusetts has been a leader, not only in the United States, we think, but of the entire world, the changing of poor, little, helpless, feeble-minded children into at least more useful members of society, and that has made the name of Dr. Fernald known throughout the civilized world. (Applause.) We trust you will visit the state institutions for the insane, and the schools where the blind and the deaf and dumb are taught to do their share in the duties of the world.

The colors which decorate this hall remind me that the service of medicine is not only of value in time of peace, but also in time of war. The physician in America is not even a physician merely; he has also been a citizen. The history of Massachusetts as a free commonwealth, like the history of the United States, began with the sacrifice of an American physician, a Massachusetts physician, at the battle of Bunker Hill. It was Dr. Warren, who phrased the immortal words, "How sweet and glorious a thing it is to die for one's country!" So we find a soldier who went into Cuba and led a victorious charge in which there was the necessary taking of life, who devoted himself to restoring law and order, and in stamping out disease, who devoted himself to the preservation of human life. I refer to Leonard Wood, the physician, of Massachusetts. (Applause.)

That brings me to just one other thought, and that is, proud as we are of Massachusetts, we acknowledge a broader brotherhood. Those of us who have served in time of war know when we touch elbows what it is when the surgeon waiting on you is from Columbia University, and the nurse has come from South Dakota, while you yourselves are from Massachusetts. We appreciate the fact that the boundaries of our states are becoming less and less as the years go on, and that proud as we may be in coming from Iowa, Kentucky, Minnesota, California, or from Massachusetts, we are proudest of all to find that the type of American is becoming one and the same all over the United States, and that we are brothers indeed, whether disaster comes as it has to San Francisco, or Galveston, or on the Eastern coast of the United States of America. (Applause.)

So, again, I bid you a hearty welcome. An American physician, from New York, has just published a most interesting volume on the "True Triumph of Japan." In this little book he speaks of the wonderful sanitary precautions taken in connection with the Japanese camps, and the care of the army. The history is wonderful. It reflects great credit on that grand empire of the Western ocean. But, perhaps, there is another war of which something might be said. Wars have been in many ways a curse to the world. Suffering and torment and trial are unavoidable. But, doubtless, there was a war in which our country was recently engaged, a war in which physicians especially were prominent, which stands unique according to the records of warfare among the nations. The number of lives saved by sanitation in one city in one year, the city of Havana, was more than the number of lives lost on both sides during the entire war, thanks to the skill and efficiency of the surgeons of the United States. (Applause.)

The President:—This Association is composed of representatives from every state and territory of the Union. We have present this morning a distinguished citizen of Massachusetts, whose name is familiar in every state and territory of this Union, and I am sure I will be presenting no stranger, even to this audience, gathered from every part of our great country, when I present to you President Eliot, of Harvard University. (Applause.)

Address of Welcome by President Eliot, of Harvard.

I welcome you to an exceptional community in which physicians and surgeons have for generations held equal rank with the members of all other learned and scientific professions. Massachusetts has long recognized in physicians and surgeons as a class powerful contributions to the public health and happiness, to the advancement of medical knowledge, to the industrial and economic interests of the community and its moral welfare. For generations this fortunate community has enjoyed the privilege of knowing intimately physicians who illustrated the highest qualities of human nature—men courageous and resolute under responsibility; imperturbable in the presence of danger, conservative, yet bold; in professional relations patient, cheerful and tender; diligent learners throughout life, and diligent teachers of sound doctrine concerning health and disease, virtue and vice. Experience of these noble qualities in the best physicians and surgeons during the past two hundred years has led Massachusetts to recognize completely the dignity and serviceableness of the profession of medicine and to treat it, therefore, with the highest official and social consideration. This is more than can be said with accuracy concerning the standing of the physician in many older and more conspicuous communities. (Applause.)

I welcome you as promoters of public health and efficiency to a community which, under the guidance of physicians has effectively protected its water supplies, regulated the production and sale of milk, food and drugs, controlled the smallpox, typhoid fever at the public expense, established humane treatment for the insane and defective, and supported admirable hospitals for the sick and injured, partly by the endowment method and partly at the public charge. All these beneficent

things it has done under the guidance and at the instigation of wise physicians, and accordingly this community pays to your profession the homage of its admiration and its gratitude. (Applause.)

I welcome you as members of a profession which relies for success and progress on careful observation, limited inference and exact recording—three scientific methods which are of universal application and utmost promise in human affairs. I welcome you as men who must have all their knowledge and skill available on the instant and at their fingers' ends. That is the best kind of knowledge and skill. I welcome you as men who do things rather than talk about doing them, or about what other people have done. I welcome you as men, who knowing human nature immediately, have good hope of serving and improving it. I welcome you as habitual bringers of comfort and help, both physical and moral, to men and women in personal peril or distress, and as prophets and missionaries who warn and defend the people against the most frightful perils of earlier times—against such pests as smallpox, cholera, yellow fever, tuberculosis and the bubonic plague, thus not only saving human life, but making the life of all mankind brighter and happier.

I welcome you to this historic town and commonwealth which have always stood for freedom of thought and speech, public order, universal education, reverence towards the past and hopefulness towards the future. May you enjoy to the full their beautiful June scenery, their associations with American history and literature, their many institutions of intelligent beneficence, and the cordial hospitality with which their citizens will try to convince you of their respect and good will toward the medical profession. (Applause.)

THE PRESIDENT:—We have another distinguished citizen of Massachusetts who is thoroughly at home in this audience. I present to you Dr. Arthur T. Cabot, president of the Massachusetts State Medical Society, who will deliver to you an address of welcome. (Applause.)

Address of Welcome by Dr. Cabot.

Mr. President, Ladies and Gentlemen:—I have the honor and the pleasure of representing the Massachusetts Medical Society and of bringing you a cordial greeting and hearty welcome from the profession of New England. We welcome also the distinguished guests that are drawn within our gates. I cannot call them strangers, for names like those of Widal and Trendelenburg are as familiar to American ears as those of our own masters in medicine. (Applause.) We feel honored that you have brought this great meeting to Massachusetts, and we will do what we can to help you to make it great in results as well as in numbers. We appreciate the effective work of this national association for the improvement of American medicine. There never was a time when the world had such faith in the possibilities of medicine as now. Medical research has made our knowledge exact and sure to a degree never before dreamed of. Knowledge brings power. It also brings responsibility. The practicing physician is to-day accountable and must see to it that our constantly increasing knowledge of disease is utilized to the utmost in the protection of the public health. It is only by the cordial co-operation of medical men throughout the whole country that the great tasks before us can be creditably achieved. We of Massachusetts gladly accept responsibility for our share in this united endeavor. The importance of coordinative action in obtaining the best results in public medicine is so evident that it may interest you if I should describe the effort now being made here in Massachusetts to concentrate the medical power of the state in the solution of one burning problem, that of how to control tuberculosis.

In order to cope satisfactorily with this disease, in order to insure that each patient is so cared for that he or she ceases to be a menace to family and friends, ceases to spread contagion, it is necessary to enlist the active interest of every physician in the state. Realizing this and aiming at an organization which shall reach into every town and village, shall be long-enduring, and shall not depend on the enthusiasm of a few for its future activity, the district societies have each and all appointed committees to study the problem as it is presented in their own localities and to formulate plans for efficient work. These committees, by their reports, keep the interest active in the district societies; they are of great assistance to the boards of health by securing for them the intelligent support of the profession, and the acquiescence of the community in restricting rules and orders. They are taking an active part in forming anti-tuberculosis societies among the laity; they are, in short, forwarding and guiding the movement against the great white plague, a movement which is becoming so wide-spread and so earnest that it has rightfully been named a crusade. Once or twice a year district committees meet together to report progress, to compare results and to discuss methods. In this way we hope to bring about a concerted and sustained plan of action and to constantly stimulate the interest and enthusiasm of practitioners throughout the commonwealth. Each physician must, as far as possible, see to it that no patient of his transmits the disease to any other person. When this responsibility is once widely felt, the fight against tuberculosis will be half won. Such a campaign, successfully carried forward, will do much to consolidate the profession and teach us to pull together, bring out our strength, and give us confidence in attempting the solution of other medical problems.

May not some similar plan be applied to the whole country under the auspices of this great association? And I hope and believe it may. This is but one corner in the field of work stretching before us, in which we can all labor, with constant opportunity, for mutual help. This meeting will make, I am sure, a decided step forward in medical efficiency and progress. We shall all carry away with us fresh inspiration and shall go back to our work better equipped and stimulated by this contact with others who have like ideals.

That your stay in Boston may be pleasant as well as profitable is our wish and endeavor. (Applause.)

THE PRESIDENT:—The Association is especially honored on this occasion by the delivery of the addresses to which we have listened—addresses expressive of the cordiality of the welcome which has been extended to us in this great city. But we have an additional address, and I have the pleasure as well as honor of presenting to you Mayor Fitzgerald, of the city of Boston. (Applause.)

Address of Welcome by Mayor Fitzgerald.

Gentlemen:—Once more, after an interval of forty-one years, your Association holds its convention in Boston, and I, as mayor, am privileged to throw open to you the gates of our official hospitality. It is, indeed, a rare privilege to greet the distinguished representatives of a profession which renders such universal service and has personal claims upon the good will of almost every man. Dealing with life itself and the mysteries of birth and death which envelop it, you develop in your calling the finest virtues of our nature. When we read of young physicians in Cuba and New Orleans giving up their lives in experiments designed to trace the source of infection in yellow fever, and when we remember that such instances of heroic sacrifice are the commonplace of medical history, we understand why the title of doctor should be everywhere one of dignity and affection.

You come from many states and foreign countries, single-minded in your devotion to one great central idea. I trust that, during your stay in Boston, you will observe that the government of this city is not uninfluenced by the same idea, but feels its due share of responsibility for the health of the people. We provide sanitary living conditions, a pure water supply, inspection of milk and vinegar, registration and quarantine of all contagious and infectious diseases, hygienic instruction in the public schools, and public parks, gymnasia, playgrounds and baths. Any inspection of our methods in the field of hygiene which should ignore the last named agencies would be sadly incomplete, for as you all know, prevention in this matter is a thousand times better than cure. (Applause.)

Yet prevention is not always possible, in spite of all our pains. There has always been practice enough for physicians and surgeons in Boston, and I believe we have had our share of the great names of your profession. One chair alone, the Parkman professorship of anatomy at Harvard, has had four such distinguished occupants as John Warren, J. Collins Warren, Oliver Wendell Holmes and Thomas Dwight, my associate in this reception and an honored member of the Board of Library Trustees. Indeed, the faculty of the Harvard Medical School has never been without names of national and international eminence; and the other monument on the Public Garden, erected in honor of Dr. W. T. G. Morton, of Boston, certainly commemorates one of the greatest discoveries ever made in the history of medicine. (Applause.)

Most of you, I presume, will visit our various medical colleges while you are here, and some of our well equipped hospitals, from the Massachusetts General Hospital, the oldest of all, to the City Hospital, of which Boston is no less proud than of its public library, its schools, its park system and its water works. The land and buildings of this institution represent an investment of over $3,000,000, and its various departments contain nearly a thousand beds. Its administration, which is in the hands of a board of trustees, who give their time and services without pay, is of the highest order; while the progressive spirit of its medical staff may be judged from the fact that the

Boston City Hospital was among the first to introduce pathological study in clinical work and to use antitoxins for diphtheria and the *x*-ray in diagnosis. (Applause.)

Other hospitals may be mentioned as deserving credit for success in special fields—such as the Carney Hospital, which for a long time was alone in receiving consumptive patients, and the Children's Hospital, which has done such noble work in correcting deformities and in preserving precious young lives. But there is one hospital still to arise and one monument not yet erected. The people of Boston have in tuberculosis a foe as insidious and implacable as the typhoid fever which scourges Philadelphia and Pittsburg. We have recently organized our defensive forces and laid the foundation of what I prophesy will be a great institution; and I here and now promise a monument, built by popular subscription, on any site he may select, to the member of your profession who shall forge the weapon by which we may effectively check the ravages of the great white plague. (Loud applause.)

Long addresses are not to your taste, gentlemen. Let me, then, briefly, but heartily, bid you welcome to Boston. I trust that your deliberations may be fruitful in good results for suffering humanity, and that you may succeed in your efforts to raise the standard of membership in your honorable profession. (Applause.)

THE PRESIDENT:—We will have the pleasure of having another address from another distinguished citizen of Boston, a member of our profession, and while we know that his name is familiar here in Boston, it is likewise familiar in medical circles throughout this entire country. I am sure that you will all be pleased to hear a word or two from our distinguished brother of this city, Dr. Herbert L. Burrell, Chairman of the Committee of Arrangements. (Applause.)

Address of Chairman of Committee of Arrangements.

Mr. President and Members of the American Medical Association:—The President has been good enough to speak of me individually; but what I am here for is to report as the Chairman of the Committee of Arrangements.

In behalf of the Committee of Arrangements, after I was appointed by the President, I was fortunate enough in securing the co-operation of gentlemen in medicine and the allied sciences to serve as associates on this committee. There have been associated with me more than seven hundred physicians, who have worked to arrange the necessary details for the conduct of the session, and to extend to you a cordial welcome. In fact, including the medical profession and the laity, there are actively engaged in the arrangements of this session between twelve hundred and fourteen hundred men and women in New England. Not the least are we indebted as a Committee of Arrangements to the wives of physicians, to representative women, and to the young ladies of Boston, who have generously contributed their services in arranging for your entertainment. The necessary funds for this session have been generously contributed by the medical profession. We have also received financial aid from public-spirited citizens. Harvard University and the Massachusetts Medical Society have cordially assisted in the preparation for the session. The commonwealth and the municipality, through their representatives, have already extended a welcome to you. We are deeply indebted to Tufts Medical College, to the Massachusetts Institute of Technology, and to many private societies and associations in this city who have generously placed their facilities at the disposal of the Committee of Arrangements. While the labor of preparation has been considerable, the burden has been lightened by the practically uniform co-operation of the medical profession and the public, who have striven to make the arrangements worthy of this great national association at its session in Boston. To me, personally, the arrangements have been a pleasure, owing to the helping hands that have been so generously extended. The Committee of Arrangements trusts, Mr. President, that the sole discharge of its duty will be to the advancement of knowledge in medicine. (Applause.)

THE PRESIDENT:—The ceremony attendant on the installation of the chief executive officer of this Association has always been an exceedingly simple one. On this occasion my duties in this respect are exceedingly simple and easy, because our President-elect is one whose name is so familiar in every part of this great country where scientific medicine is cultivated, that he is well and familiarly known. I have the exceptional pleasure in presenting to you your President-elect this morning, a gentleman of national and international reputation, a reputation won simply and alone by individual merit, without the aid of great institutional environment; a gentleman comparatively young for the position to which he has attained, and whose claim on the recognition of the medical profession of America represented in the American Medical Association is that of high scientific achievements, to which there is joined a superb and pure professional character. (Applause.) Ladies and gentlemen, it is my privilege and honor to present to you the President-elect of the American Medical Association, Dr. William J. Mayo, of Minnesota. (Loud applause.)

At the close of Dr. McMurtry's introductory speech, at the request of Dr. Burrell, three lusty cheers were given President Mayo.

President Mayo then delivered his address. This was published in THE JOURNAL, June 9.

Second General Meeting—Tuesday, June 5

The Association met at Jordan Hall at 7:30 p. m.

The Oration in Medicine was delivered by Dr. Frederick C. Shattuck, of Boston.

The Oration in Surgery was delivered by Dr. Joseph D. Bryant, of New York City.

These were published in THE JOURNAL, June 9.

On motion, votes of thanks were extended to these gentlemen for their scholarly and instructive addresses.

Third General Meeting—Wednesday, June 6

The Association met at 7:30 p. m.

Dr. W. H. Sanders, Montgomery, Alabama, delivered the Oration on State Medicine.

On motion, a vote of thanks was extended to Dr. Sanders for his admirable address.

Queries and Minor Notes

LIQUOR CRESOLIS COMPOSITUS.

GALLUP, N. M., May 24, 1906.

To the Editor:—I note that in the special article "The Pharmacopeia and the Physician," in THE JOURNAL, Feb. 24, page 582, under head of disinfectants, you mention liquor cresolis compositus, U. S., a mixture of equal parts of soap and cresol, and state that this preparation is an available substitute for the many expensive proprietary preparations, creolin, cresolyn, lysol, etc. Can you furnish any further information as to the formula, manipulations, etc., for producing this compound? What is the commercial cost of cresol? I have put the question to several pharmacists and none of them seem to be able to master the subject. One of the proprietaries mentioned in connection with liquor cresolis compositus creolin, it is claimed by the manufacturers, contains 50 per cent of cresylic acid. I have not been able to find cresol on any of the jobbing house drug lists, and if the compound can be made at less expense than the proprietaries cost, I would be glad to have the formula. It seems to me misleading, however, to claim that a compound which admittedly is 50 per cent. diluent should be equally effective in disinfecting power to pure acid carbolic, and why should it be less poisonous except for the dilution?

W. H. BEAR, M.D.

ANSWER.—The formula of the Pharmacopeia directs that: 80 gm. (5viss) potassium hydroxid be dissolved in 50 gm. (3ss) water contained in a porcelain dish, treated with 350 gm. (3iiiss) linseed oil and stirred until saponified. To this linseed oil soap the cresol is added and the mixture stirred until a clear solution is obtained. Then sufficient water to produce 1,000 gm. (3x) is added. This formula has been found satisfactory and produces a preparation which yields an almost clear solution when mixed with water, provided that the official cresol is used. This is offered by the Schoelkoff, Hartford & Co., Mallinckrodt Chemical Works and others at about 40 cents a pound. Chemically, the cresols may be considered as methyl derivatives of phenol, differing from the latter only by the introduction of a methyl group into the benzene nucleus, thus: C_6H_5OH is phenol, while $C_6H_4(CH_3)(OH)$ is methyl phenol or cresol. The introduction of this methyl group into phenol increases its antiseptic properties very materially, and, it is generally believed, at the same time decreases its toxicity. Fortunately, the presence of this methyl group decreases the solubility in water, thus while part of phenol will dissolve in 20 parts of water, part of cresol required 50 parts. Attempts to remedy this insolubility in water have led to the introduction of a host of cresol preparations. Of these the preparations of the type of the compound solution of cresol U. S., in which the cresol is rendered soluble by the presence of soap have been most satisfactory

7 Summer Diarrhea in Infancy. G. T. Myers, Norfolk, Va.
8 Cerebral Segmentation. W. Wood, New York.
9 *Modification of the Incision for Exposing the Mastoid Bone. L. J. Hammond, Philadelphia.

1. **Medicine and Law in Relation to Alcohol, Venereal Disease and Tuberculosis.** Knopf attributes the majority of crimes to drunkenness. It is the most frequent cause of social misery, domestic dramas, privation and want. Alcohol often leads to sexual overindulgence and illegitimate relations. Excessive alcoholic indulgence often precedes the contraction of syphilis and gonorrhea. Knopf believes in the enaction of laws so far as is possible, to prevent habitual drunkards from marrying. The laws which have already been made in relation to the suppression of alcoholism should be enforced. The "patent-medicine" curse should be suppressed. He also believes in the Gothenburger system, which consists in the manufacture and sale of alcohol by the government and giving the dispenser of alcohol a salary only; but he fears that this system is not practicable in our country. The common system of "treating" is at the root of much of this evil of alcoholism. Sanatoria for alcoholics are advisable. The author suggests a law making it prohibitive for persons suffering from gonorrhea or syphilis in any of the infectious stages to contract marriage. He also reviews the tuberculosis problem.

2. **Publicity in Venereal Prophylaxis.**—Lewis expresses clearly and emphatically his views regarding methods of instruction concerning venereal prophylaxis. The boy does not know the meaning of the approach of adolescence. He should be told the truth about the sexual instinct and the need of controlling it. His fears should be dispelled and he should be taught the dignity of virility. Principles of honor toward the young girl should be inculcated in him and the danger of venereal disease should be explained to him. Actual knowledge is of even greater importance to the girl. Her reputation for life is blasted by one mistake. The young people throughout this country should be taught hygiene and physiology. They should know about reproduction. False modesty and maudlin sentimentality should be cast aside. It is the duty of every practitioner of medicine to give instruction regarding the venereal plague in its different relationships. The curse of the past has been ignorance.

3. **Fatalities Among Athletes.** Coughlin presents the following conclusions: Athletes are prone to cardiac lesions, whether a physiologic hypertrophy, a hypertrophy with dilatation and endocarditis, a white spot on the heart, myocarditis, or the different valvular conditions. Pneumonia ranks high as a cause of death in athletes because of the cardiac embarrassment in connection with this disease. Athletes appear to be susceptible to infectious diseases, and when affected with these diseases succumb to them as readily as do others. Pulmonary tuberculosis is a cause of death in a large percentage of athletes. The average age at death of athletes is far below that of the average person in the ordinary walks of life. The game of football as played in America during the season of 1905 was the cause of an appalling number of serious injuries and fatalities, and it is very evident that something will have to be done to eliminate the dangerous features of the game, especially mass play. The idea in all athletics should be to improve and to make men, not to maim, cripple and bury them.

6. **Treatment of Typhoid.**—Landers contends that in typhoid the feces can be relatively disinfected. He prefers the sulphocarbolates as intestinal antiseptics. The sponge or full bath should be used. The diet should be one that can be digested and assimilated. Mild salines will keep the bowel cleared out. Landers has used this method for years and states positively that it will prove absolutely efficient.

9. **Incision for Mastoid Operation.**—Hammond describes this incision as being triangular instead of slightly semicircular as in the usual method. It begins about one-half inch back of the superior post-auricular attachment, extending through all the tissues obliquely backward, then downward along the hairy margin, to a point just below the middle of the posterior border. From this point the incision is again carried through all the soft tissues forward and downward to the posterior border of the diagnostic fossa. This incision avoids all post-auricular vessels and nerves. A roomy field is also furnished. The entire soft tissues overlying the mastoid which are always infected are lifted with their periosteum in one sheet. Drainage from the bony cavity will be perfect. The flap made conforms very closely to the outline of the mastoid bone.

15 Frontal Sinusitis as an Etiologic Factor in Acute Retrobulbar Neuritis. N. M. Black, Milwaukee, Wis.
16 Puerperal Eclampsia. W. H. Randle, Germantown, Philadelphia.
17 Diagnosis of Tabes in the Preataxic Stage. A. D. Young, Oklahoma City.

10. **Operation for the Liver and Gall Passages.**—McWilliams analyzes the results of 186 operations of the liver and gall passages. Of these, 111 were operations for biliary calculi with a mortality of 12 per cent., 99 were primary operations, with 11 deaths, and 12 secondary with 2 deaths. The causes of death were perforation of the duodenum with peritonitis, 1; cholemia and nephritis, 1; pylephlebitis, 1; peritonitis, 3; postoperative hemorrhage with jaundice, 3; postoperative shock, 1; uremia with suppurative recurrent colitis, 1; pneumonia, 1; unknown, 1. Jaundice was present in 69 per cent. of the cases; of patients with stones in the gall bladder alone, 43 per cent. had icterus, while of patients with calculi in the common duct 92 per cent. had jaundice. In only 4 of the patients was there a history of the passage of stones prior to the operation. Of the 99 primary operations 80 were on women and 19 on men, and the ages of the patients varied from 22 to 73 years. The mortality in cases in which the stone was in the common duct was 29.6, as contrasted with 6.5 per cent. mortality in the cases with calculi in the gall bladder and cystic duct.

This greater mortality in common duct operations is largely due to lack of drainage and has been improved in recent operations. In 69 of the patients surviving the operation the following results were obtained: 65 per cent. were cured of symptoms referable to the calculi; 10 per cent. were improved; 23 per cent. were not improved; 12 per cent. of the total 99 operated on required secondary operations. One per cent. had probable recurrence of calculi; 9 per cent. developed subsequent herniæ; 10 per cent. had calculi overlooked at the first operation. Postoperative lung complications occurred in 4 per cent; left saphenous phlebitis occurred in 1 case. The most common cause for secondary operation was persisting biliary fistulæ due in 2 cases to calculi overlooked in the cystic duct. In 2 cases calculi were overlooked in the gall bladder. In one case a calculus was overlooked in the common duct. In 2 cases the fistulæ were due to probable stricture of the biliary passages without the presence of calculi at the second operation. The lessons to be learned from these secondary operations are: 1. More thorough search for calculi at the primary operation, splitting the ducts wide open if necessary. 2. A primary cholecystectomy would have avoided the necessity for a secondary operation in all but 3 patients. 3. In only

one of these patients had a primary cholecystectomy been performed. This speaks very strongly for the removal of the gall bladder at the first operation, since it seems to give the greatest guarantee against future difficulties, hence greater certainty of cure.

11. **Regeneration of the Central Nervous System.**—In answer to the question, "Do central tracts of the nervous system regenerate"? Clark concludes as follows: Animal experiments fail to provide conclusive data that central tracts of the nervous system ever regenerate so that the former function is restored. In warm-blooded animals, and in the human species in particular, an abortive attempt on the part of the cord to regenerate is largely if not solely confined to fibers of undoubted peripheral type. Histologic analysis of cases of hemisection, compression paraplegia and myelitis, and the like destructive lesions of the cord, fails to show positive evidence that actual structural regeneration of axis cylinders ever occurs in the central nerve tracts of the human spinal cord. In case of complete division of the brain and spinal tracts there is simply degeneration, followed by sclerosis. A most acceptable reason for non-regeneration of such tracts is shown in that the compressed nerve fibers do not possess a neurilemma sheath, from which nerve regeneration mainly if not solely occurs. This lack in cord and brain tracts, in contrast to the regenerating peripheral nerves, is due possibly to a difference of embryologic origin for these two structures of the nervous system. The cases cited by Stewart and Hart for cord regeneration either do not fulfill the conditions of test, being merely hemisections, or, the evidences for regeneration are not definite or convincing. The two suture cases reported by Stewart and Hart and Fowler are good illustrations of this type. In case of complete transverse division of the cord there is no sufficient justification either from experimental or clinical data to warrant suture of the spinal cord in an attempt to cure the defect. experiments, therefore, show that injury to a single kidney, by calculus, direct trauma or obstruction to one ureter, is a powerful predisposing factor in the evolution of a surgical lesion of that organ.

23 **Unilateral Septic Infarcts of Kidney.**—Brewer records the history of 13 cases in which a unilateral septic infection of the kidney occurred under the form of a general septic disease in which the general symptoms overshadowed the local disease of the kidney. The lesion as shown by nephrectomy or by autopsy was in most cases unilateral and consisted of multiple septic infarcts. Eleven of the 13 patients were women; in 11 the right kidney was the one involved. A sudden rise of temperature to 104 F. was the mode of onset, chill occurring in 4 cases. Pain was felt in all but one case. Muscular rigidity was marked in 3 cases. Leucocytosis varied from 12,000 to 35,000. In 12 cases the urine contained albumin, in 5 albumin and pus, and in 5 more albumin, pus and blood. Two patients gave history of previous injury and one previous disease of the kidney, but probably evidence of previous lesion could have been obtained in more cases if it had been thoroughly sought for. In 6 cases in which nephrotomy was performed 5 patients died; in 7 cases nephrectomy was done and 6 patients recovered. Culture from some of the cases showed the presence of *Streptococcus pyogenes, Staphylococcus pyogenes aureus,* and the colon bacillus.

Brewer gives the results of experiments to determine why one kidney only is affected in these cases, although the pathogenic organism reaches the organ through the blood stream, and arrives at the following conclusions: None of the control animals which had received a moderate dose of pathogenic bacteria directly into the circulation without previous injury developed a surgical lesion of the kidney. Of 16 animals which in addition to inoculation received an injury to one kidney, 5 showed no lesion or only hyperemia and parenchymatous degeneration. Of the remaining 11 all developed distinct surgical lesions of the kidney, unilateral in the injured kidney in 8 cases. The renal lesions in these cases were practically identical with those observed in the clinical cases. The

25. **Death from Duodenal Obstruction.**—Maury has determined by experiment that if the stomach is excluded for seventy-two hours from communication with the lower gut the animal dies. The line at which an obstruction may occur without fatal effects, which he has called the lethal line, is situated 35 cm. from the pylorus. The cause of death is uncertain, but the author hopes to determine by subsequent investigation whether it is due to an intoxication resulting from a disturbance of the balance of secretion or to some interference with the cerebral circulation brought about by nervous impulses the result of the operation.

27. **Artificial Respiration.**—Green discusses the question as to the advantages and disadvantages of the method of positive and negative pressure in inducing artificial respiration, and what is the best method of applying positive pressure by intubation or tracheotomy. The objection that sudden introduction of air under pressure may lacerate diseased or collapsed alveoli is obviated by introducing a valve into the pressure apparatus which will secure the gradual increase of pressure. He has performed a large number of experiments on animals and sums up his results in the following statements: In dogs the positive pressure method of artificial respiration is efficient; severe operations may be performed with recovery; intubation is an easy and practical means by which to apply the positive pressure; the chief danger after the operation is completed lies in the accumulation, without proper drainage, of septic fluid within the chest.

The result of Sauerbruch's operation on the human being in thoracic conditions are by no means discouraging. It seems reasonable that with either method here discussed the field for thoracic surgery will develop in the direction of active intervention, rather than continue along the present lines of expectant treatment.

29. **Magnesium Sulphate Anesthesia.**—Blake summarizes the results obtained by Meltzer, Meyer, Haubold and himself in the induction of anesthesia by intraspinal injections of magnesium sulphate. It has been shown by animal experiment that the injection of magnesium sulphate intraspinally in the proportion of 0.06 gm. per kilo. body weight will produce a complete paralysis, both motor and sensory, extending upward to involve the whole muscular system and the sensorium. Larger doses produce death by paralysis of the respiration. Blake's report covers 14 cases. In some chloroform was used as an adjunct. No accurate estimate of the time required to produce general anesthesia can be given, but it varied from one to three hours. Analgesia appeared first, the local anesthesia

followed by general, which merged into coma lasting from two to ten hours or more. In some cases operations were done in the period of local anesthesia, unconsciousness not occurring. In 2 cases no anesthetic effect was noted; both patients were alcoholics. The reflexes were at first diminished, then abolished and then returned slowly. Retention of urine was present in all but 2 cases. The rate of respiration was slowed. This rate should be carefully observed, as it is an index of the danger line. Profuse diaphoresis was noted in a number of cases, and the bodily temperature was lowered in some cases. The heart's action was regular and moderate, and the blood pressure was not lowered. Vomiting occurred in cases in which the injection had marked effect. The action of the drug could be checked by removing cerebrospinal fluid and washing with normal salt solution. Magnesium sulphate has been tried in shock in strychnin poisoning, and for local anesthesia by external application, but its action has been disappointing. Blake reports 2 cases of tetanus treated with intraspinal injections of this drug, one patient recovering, the other not. He claims that it restrains the convulsions, relaxes the muscles of mastication, and produces a prolonged effect without injurious action except inhibition of the bladder entailing the need of catheterization.

31. **New Technic of Hernia Operation.**—Russell describes the improvement devised by J. A. Blake in 1900 by which the rectus muscle is made to cover the hernial opening. After the usual preliminary steps of the operation the internal oblique is retracted, the rectus is exposed and the cord being lifted from its bed, the muscle is sutured with two or three interrupted sutures of chromic gut, or, preferably, kangaroo tendon, to the reflected edge of Poupart's ligament. The cord is transplanted as in the Bassini operation, and the internal oblique is sutured to Poupart's ligament in front of the rectus. The external oblique is then sutured over the cord, folding it on itself, thus taking up the slack which had been produced in it by the hernial tumor. Excellent results have been obtained in 36 cases in which the author has used the method.

33. **Lembert Sutures.**—Eggers and Maury from a study of specimens from experimental gastroenterostomies conclude that one of three fates may occur to a Lembert suture: It may remain *in situ:* it may be partially intruded into the lumen of the gut; it may be entirely intruded and disappear in the intestinal contents. The cases which show intrusion are from animals which had a relative short postoperative life—less than a month. It is probable that the intrusion can be accounted for by the fact that the stitch was accidentally carried too deep and actually pierced the mucosa.

43 Recent Improvements in Perimetry. F. A. Davis, Denver.
44 Choked Disk and Brain Tumor. A. R. Baker, Cleveland.

39. **Morax-Axenfeld Conjunctivitis.**—Tooke says that the symptoms complained of are those of a burning sensation in the eyes, generally worse in the morning. There is usually a discharge and the lids are found tightly gummed together on waking. Both eyes are usually affected. The conjunctiva is slightly hyperemic and somewhat thickened near the ciliary margin, assuming a velvety appearance. The secretion expelled by contraction of the lid is seen on the lid margin as brownish-yellow crusts and the skin at the palpebral margin is erythematous and excoriated. The cornea is seldom affected, and ulcers, when they occur, are generally benign and shallow and do not spread. There are, however, severe cases accompanied by hypopyon and iritis. There is difference of opinion as to whether the diplobacillus is present in the nose. The disease may be spread through the air, and Axenfeld has devised a mouth veil to prevent bacteria being carried to the patient from the operator in the act of speaking. The same device has been adopted in the Boston Eye and Ear Infirmary. Sulphate of zinc in 0.5 per cent. to 1 per cent. solution acts as a specific, and when employed systematically will invariably cure the disease. Many observers, however, claim that this strength of solution is too strong and that equally good results are obtained by use of a 0.25 per cent. solution.

42. **Transillumination of the Eye.**—Würdemann has devised a modification of the De Zeng ophthalmoscope. The entire instrument is not much larger than a fountain pen and may be handled in the same manner. The small electric globe in the ophthalmoscope is replaced by another of the same size, on the end of which there is a lens. The cone-shaped screw cap of the instrument contains a glass rod about three-fourths of an inch in length, which comes in contact with the end of the lens. Nearly all the light is thus focused in the glass rod and is brought out through it to the tip of the instrument, and from there a beam of light is projected through the eye or the structures to be illuminated. The instrument is also efficient for illuminating the frontal and ethmoidal sinuses, the bridge of the nose and the maxillary sinuses.

49 Tinea Favus Papillaris. J. V. Shoemaker, Philadelphia.

47. **Early Diagnosis of Malignant Tumors.**—Landry gives the following characteristics suggestive of early malignancy of tumors of the breast, uterus and stomach: 1. Rapid growth. 2. Tendency of the tumor to invade surrounding tissues. 3. Pain, spontaneous, and of a lancinating and paroxysmal character, was long considered characteristic of malignancy, but is misleading. Pain is not characteristic of early cancer. 4. Too much importance should not be given to retraction of the nipple in cancer of the breast. Redness, edema, nodular development, ulceration, involvement of lymphatic glands and the development of the characteristic cachexia are late symptoms which should not be waited for before having recourse to radical treatment. Early examination in suspected cancer of the uterus and an early resort to exploratory operation in suspected cancer of the stomach are to be recommended.

50 *Report of 25 Cases of Pneumonia Treated with Pane's Antipneumonic Serum. G. Tartaro, Buffalo, N. Y.
51 *A Series of Tracheotomies. G. F. Cott, Buffalo, N. Y.

50. **Serum Treatment of Pneumonia.**—Tartaro treated 25 cases of pneumonia with Pane's antipneumonic serum with two deaths. He concludes that the serum does not produce any change in the physical signs, but mitigates the gravity of the disease, though, as a rule, it does not shorten the course except in children. The serum produces a drop of temperature of from 1 to 3 degrees. The earlier the injection the more marked, as a rule, is the decrease in temperature. Serum causes relief of the subjective symptoms in nearly every case. Its influence in causing disappearance of cyanosis is very marked. Cardiac and other complications in pneumonia due to pneumonic toxins are relieved by the serum. The principal objections to Pane's serum are: 1. It does not cut short the disease as antitoxin often does in diphtheria. This is explained by the fact that diphtheria is a toxemia and pneumonia a bacteriemia. 2. Pane's serum does not seem to have any power on the local manifestations of the disease. 3. The result of serum therapy is uncertain. This is probably due to the different pathogenic agents which produce pneumonia and the unicism of cultures employed in the production of serum and the different stages of the disease in which it is used. Tartaro believes that we can not dispense with serum therapy of pneumonia, however incomplete its activity.

51. **Series of Tracheotomies.**—In the course of 100 cases presenting indications for intubation in Cott's experience, tracheotomy became necessary in 26, so that he advises the surgeon to carry instruments and tubes for tracheotomy with his regular outfit for intubation. In the circumstances in

which it is usually performed the operation presents considerable difficulties, especially in children with fat necks, and when the light is bad and assistants lacking or inexperienced. The operator must depend mostly on his ingenuity in bringing the work to a successful issue.

60 *Rheumatoid Arthritis. E. L. Kannary, St. Paul.
61 Treatment of Rheumatism. L. C. Bacon, St. Paul.

55. **Surgical Treatment of Gastric Ulcer.**—Schwyzer recommends surgical treatment when internal treatment does not give satisfactory results. The main conditions are partly acute by perforation and hemorrhages partly subacute by gradual perforation into neighboring structures and small repeated hemorrhages and, finally, in the chronic form, long lasting moderate inflammatory and adhesive processes with pain and changes in the function of the organ, indigestion and retention of food. Gastroenterostomy is the usual operation for the relief of stenosis of the pylorus, but in cases in which the ulcer has cicatrized, pyloroplasty gives very good results. If malignancy is suspected pylorectomy is the operation of choice. In some cases, with indistinct symptoms of ulcer, very slight changes are found at operation, and yet the operation is successful in removing the symptoms which were probably due to the presence of adhesions. Gastroenterostomy with gastrostomy as performed in the Rutkowsky-Witzel operation is to be recommended for recurrent hemorrhage. This secures rest for the ulcer and is preferable to rectal feeding, which can not be continued for a long time. In profuse hemorrhage of sudden onset when recurring during the strict Leube treatment, the author would not delay operative interference, but would content himself with a jejunostomy if the ulcer could not be very easily excised. Schwyzer reports 20 cases, with recovery from the operation in all.

60. **Rheumatoid Arthritis.**—Kannary favors the infective theory of the etiology of rheumatoid arthritis and calls attention to the fact that it is very important to make a correct diagnosis of the acute forms from ordinary acute rheumatism. The temperature in rheumatoid arthritis is not so high as in acute rheumatism, the joints are swollen but not red. The swelling is fusiform and mostly in the periarticular structures. The pain is much less severe. There is no tendency to endocarditis. Salicylates have no influence and the disease progresses steadily to the chronic condition.

66 *Railway Brain Strain of, and Brain Strain Regulation of Railway Employés. C. H. Hughes, St. Louis.

66. **Railway Brain Strain.**—Hughes states that railway travel will not be freed from its present appalling peril till the exacting and exacted brain strain on its employés is lessened and the employés themselves take better care of their brains by the avoidance of all those influences when off duty that tend to vitiate the integrity of the mental powers, and by not seeking to do excessive overtime work. No railway is safe from the posibility, almost certainty, of accident when train dispatchers, engineers or switchmen serve continuously from forty-eight to seventy-two hours, or even for twenty-four hours, and it is the humane duty of the medical profession, with the present psychologic light on the ordinary brain's endurance capacity, to advise and to insist that such excessive brain strain in all departments of public service cease, especially when consequences are so serious as in the railway service.

76 Treatment of Paralytic Club Foot by Arthrodesis. W. R. Townsend, New York.
77 Observations on Broken Necks. R. H. Sayre, New York.

68. **Non-tubercular Joint Inflammation.**—Sayre urges the importance of rest and quiet in the early stages of arthritis deformans and tuberculous joint affections in giving freedom from pain, shortening the time of treatment, and lessening the amount of destruction in the joint. Instrumental protection is not to be employed to the exclusion of the many details of diet and hygiene so essential in the treatment of these cases, but simply added to them as a most helpful assistant.

73. **Passive Motion of Elbow.**—In several cases of excision of the elbow Davis succeeded in hastening restoration of motion by the use of the following apparatus: A leather sleeve was made, extending from the wrist to the elbow and laced up in front. To the under side was riveted a flat bar which extended six or eight inches (15 to 20 cm.) beyond the elbow and bent at a slightly obtuse angle. To this bar was fastened a weight of about one pound. It could be moved along the bar and fixed in any desired position by a screw. As the patient moves around the arm is continually jogging up and down in pendulum fashion. The weight on the lever should be so adjusted as to counterbalance the weight of the arm and hand. If the apparatus becomes irksome it can be left off for several hours and its use again resumed.

84 Case of Double Optic Neuritis Which Illustrated the Sometime Value of Agnosticism in Medicine. D. B. St. John Roosa, New York.

83. **Dermo Scale.** The scheme proposed by Allen is based on the metric system, the unit of the dermo scale being one-quarter of a millimeter. In order to designate a given lesion by the proper scale number it is necessary only to know its diameter in mm. or cm., multiplying the mm. by 4 and the cm. by 40; thus a lesion having a diameter of 5 mm. would number 20 of the scale, or the size of the French pea. Number 40 would correspond to 10 mm. diameters, or dividing it by 10 would give 1 cm. Number 100, corresponding to lesions the size of a shilling, quarter-dollar, sou, krone, etc., would be known at once to be of 2½ cm. diameter, while number 400, whose exact diameter is 100 mm. or 10 cm., corresponds to palm-sized lesions or tumors of adult fist-size. Allen says that if these few points be borne in mind and the scale numbers 1, 40 and 400 be remembered, it becomes an easy matter to think of all the sizes now designated by seeds and small objects as numbering from 1 to 40, and those designated by coins from 40 to 100, while beyond this the larger fruits, vegetables and anatomic parts of the body which have usually been brought into service would correspond to multiples of 100 indefinitely.

1. **Lung Complications After Anesthesia.** — Armstrong studied 2,500 cases of ether anesthesia, the anesthetic being administered in nearly all cases by means of the Clover inhaler. Among the 2,500 cases, 55, or 2.2 per cent., developed some lung complications; 32, or 1.28 per cent., came to autopsy. The youngest patient was 1 year of age and the oldest 78. There were 40 males and 15 females, that being about the proportion in which the sexes are represented in the operations. Out of 55 cases that developed lung complications, 35 occurred during the cold months of the year, from November to March inclusive. Not one instance of lung complication occurred in the last 500 cases. The lung complications all developed within forty-eight hours after the administration of the anesthetic. Of the 55 cases, 37 had some septic focus before the development of the lung complications. In 8 cases the presence of emphysema was noted before the administration of the anesthetic. In one case the patient suffered from chronic bronchial asthma, and in 9 cases chronic nephritis was present.

The 55 cases are again divided as follows: 1. Among the 14 cases of lobar pneumonia there were 10 of sepsis of some form. In 8 of these there was peritonitis, 3 being due to typhoid perforation; 3 patients had chronic nephritis, 1 aspirated vomitus, 1 suffered from fractured ribs, and 1 from diabetes. 2. There were 16 cases of bronchopneumonia, among them being 12 cases of sepsis of some form, including 6 cases of peritonitis, 1 of which was secondary to typhoid perforation; 3 had nephritis, 4 aspirated food or vomitus, 3 were trephining cases, and in 6 there was pre-existing emphysema. 3. Among the 19 cases of bronchitis there were 5 of trephining, in 7 there was peritonitis, in 3 nephritis; in 2 there was pre-existing emphysema, 1 with chronic bronchitis; in 1 there was typhoid perforation, and another patient had tracheotomy performed; this one aspirated blood. 4. Of the 3 cases of plastic pleurisy 2 were associated with tuberculous cervical adenitis, and 1 with cancer of the sternum; all these recovered. 5. There was 1 case of pleural effusion occurring in a patient suffering from suppurative mastitis with pleurisy on the same side. 6. There were 2 cases of empyema, 1 following excision of an epithelioma from the lower lip. There was no history of pneumonia preceding the empyema. One followed an operation for appendicitis with abscess and generalized peritonitis.

Armstrong reviews the causes for the occurrence of these complications which seem to show that the administration of ether *per se* was not a very active cause. In nearly all instances other more highly probable etiologic factors were pres-

ent, such as aspiration from the mouth and pharynx, and the operation performed, the abdominal operations predisposing markedly to the occurrence of these complications.

2. **Post-Anesthetic Acetonuria.**—Beesly summarizes his paper as follows: 1. Two separate conditions should be recognized—acute and chronic acetonuria. 2. Ether and chloroform invariably induce a temporary acute acetonuria which may be very detrimental even to an apparently healthy organism. 3. This acute anesthetic acetonuria is accompanied by symptoms of acid intoxication, sometimes ending in death, when the kidneys are unable to cope with the increased formation of acetone by a corresponding capability of excretion. 4. Although ether may produce a greater acetonuria, this is less harmful than that produced by chloroform, because ether is less injurious to the cells of the liver and kidneys, and thus does not hinder their power of elimination. 5. The more plentifully and rapidly excretion is carried on the less serious is the poisoning. 6. The effects of the poisoning are mitigated by the administration of alkalies, which may also be given with advantage before operation if poisoning be anticipated. 7. The usual risks of anesthesia are not increased by pre-exisent chronic acetonuria. 8. Anesthesia is dangerous with pre-existent acute acetonuria, especially if the anesthetic is chloroform. 9. A guarded prognosis must always be given when acute acetonuria is present with symptoms of poisoning. 10. Death following the administration of chloroform with symptoms of poisoning may be due to the idiosyncrasy of the patient.

4. **Pancreatic Reaction in the Urine.**—The details of Cammidge's improved method of examining the urine in suspected cases of pancreatic diseases are as follows: A specimen of the twenty-four hours' urine, or of the mixed morning and evening secretions, is filtered several times through the same filter paper and examined for albumin, sugar, bile, urobilin and indican. A quantitative estimation of the chlorids, phosphates and urea is also made, and the centrifugalized deposit from the urine examined microscopically for calcium oxalate crystals. If the urine is found to be free from sugar and albumin, and of an acid reaction, 1 c.c. of strong hydrochloric acid (specific gravity 1.16) is mixed with 20 c.c. of the clear filtrate, and the mixture gently boiled on the sandbath in a small flask, having a long-stemmed funnel in the neck to act as a condenser. After ten minutes' boiling the flask is well cooled in a stream of water, and the contents made up to 20 c.c. with cold distilled water. The excess of acid present is neutralized by slowly adding 4 grams of lead carbonate. After standing for a few minutes the flask is again cooled in running water and the contents filtered through a well-moistened, close-grained filter-paper until a perfectly clear filtrate is secured. The filtrate is then well shaken with 4 grams of powdered tribasic lead acetate and the resulting precipitate removed by filtration, an absolutely clear filtrate being obtained by repeating the filtration several times if necessary. The large amount of lead in solution is removed either by treatment with a stream of sulphuretted hydrogen or by precipitating the lead as a sulphate. For this purpose the clear filtrate is well shaken with 2 grams of finely-powdered sodium sulphate, the mixture heated to the boiling point, then cooled to as low a temperature as possible in a stream of cold water, and the white precipitate removed by careful filtration; 10 c.c. of the perfectly clear transparent filtrate is made up to 18 c.c. with distilled water and added to 0.8 gram of phenylhydrazin hydrochlorate, 2 grams of powdered sodium acetate and 1 c.c. of 50 per cent. acetic acid contained in a small flask fitted with a funnel condenser. The mixture is boiled on a sandbath for ten minutes, and then filtered hot through a filter paper moistened with hot water into a test-tube provided with a 15 c.c. mark. Should the filtrate fail to reach the mark, it is made up to 15 c.c. with hot distilled water. In well-marked cases of pancreatic inflammation a light yellow, flocculent precipitate should form in a few hours, but it may be necessary to leave the preparation to stand over night before a deposit occurs. Under the microscope the precipitate is seen to consist of long, light yellow, flexible, hair-like crystals, arranged in sheaves which, when irrigated with 33 per cent. sulphuric acid, melt away and disappear in from ten to fifteen seconds after the acid first touches them.

The urine employed for the experiment should be fresh, and not have undergone fermentative changes. If alkaline in reaction it should be made acid with hydrochloric acid before the test is commenced; any glucose that may be present should be removed by fermentation after the urine has been boiled with the acid, and the excess neutralized.

5. **Extroversion of Bladder.**—Bond reports a case of extraperitoneal rectal implantation of the ureters for extroversion of the urinary bladder in a young man 17 years of age. Three years after the operation the patient had practically no difficulty with the urine, which is voided from the bowel four or five times in the twenty-four hours.

15 Extensive Rupture of the Liver Without External Injury. F. S. Lloyd.

9. **Cheyne-Stokes Phenomenon in Cerebral Compression.**—The features of the occurrence of periodic phenomena in cases of cerebral compression on which Trotter lays special stress are as follows: 1. The Cheyne-Stokes phenomenon is in such cases no mere terminal symptom and, therefore, of necessarily slight interest, but one of the most characteristic forms of the vasomotor reaction and one which may be manifest nearly from the onset of compression. 2. Various modified forms of the phenomenon occur and may cause confusion, especially when the respiratory periodicity is absent. 3. Periodic movements are no less frequent and characteristic than when the phenomenon occurs in disease and that they may be of diagnostic importance in rendering manifest a paralysis and in being movements which are to be distinguished from those due to focal irritation.

10. **Action of Electrical Discharges on Bacteria.**—Foulerton and Kellas conducted an elaborate series of experiments with the view of determining the action on bacteria of electrical discharges of high potential and rapid frequency. In all the experiments in which a decided germicidal effect was observed it appeared that this was due entirely to the action of substances formed as the result of electrical action on the atmosphere in which the discharge occurred; and it appeared that under the time conditions of the experiments the electrical force employed was not capable of exercising any injurious action on the bacteria tested. And it is probable that when in medical practice cases of lupus and certain other cases in which there is an exposed ulcerated surface are treated by "high-frequency" discharges, the results produced are due entirely to the action on bacteria of nitrous and nitric acids formed in the neighboring air. From a therapeutic point of view the use of high-frequency discharges in such cases must be looked on mainly as an efficient method for bringing germicidal substances in a nascent and very active condition into contact with the bacteria present in the lesion exposed to the action of the discharge.

11. **Hemorrhagic Bronchitis.**—Castellani reports two cases of hemorrhagic bronchitis, the disease having begun gradually and without any apparent cause. The sputum was examined carefully repeatedly for three weeks, but no tubercle bacilli could be found. Several guinea-pigs were also inoculated with negative results. The expectoration, especially when much blood was present, was teeming with spirochetes. The saliva and superficial scrapings from the gum were also examined; some spirochetes were present, but always in small numbers. The spirochetes were always very numerous and stained well by

the Leishman method, generally taking up a bluish tint; they could be stained also with the ordinary anilin dyes, though not so well. They were generally mixed with some bacteria, but sometimes when the sputum was collected in sterile Petri dishes and preparations made at once they were practically the only germs present. Vincent's fusiform bacilli were never observed. These spirochetes were not all alike. They are divided morphologically into several groups: 1. Very thick individually, from 15 to 30 microns in length, with irregular waves which varied in number but were never very numerous. The parasites, with the Leishman method, stained deep blue; they were ponited at both ends. 2. Spirochetes resembling the *Spirochæta refringens* (Schaudinn) with a few graceful waves and pointed extremities. 3. Thin, delicate spirochetes with numerous small, rather uniform waves and tapering ends. Sometimes one of the extremities was blunt while the other was pointed. 4. Very delicate parasites, though thicker than the *Spirochæta pallida*, with very few waves, generally irregular in shape.

21. **Hernia and Insurance Against Industrial Accidents.**—Berger has been making a study of the etiology and origin of hernia, especially with regard to the influence of overstrain or accidents while at work. He outlines the conduct for the examining physician in case of an industrial accident, his conclusions harmonizing with the views adopted at the international congress for workingmen's insurance held in Belgium last year, and also with recently published manuals on industrial accidents. In the great majority of cases the hernia is not a sudden accident; it is an infirmity made imminent by some congenital malformation.

22. **Internal Hernia Through the Foramen of Winslow.**—This article is based on personal clinical experience and 18 cases from the literature. When the patient is examined soon after the occurrence of the hernia, a round, circumscribed tumor is noticed in the epigastrium or at the umbilicus, but it soon blends into the increasing general distension of the entire abdomen. This early tumefaction is important for the diagnosis. It may be directly in the center or more toward the right, and its center may coincide with the umbilicus or lie considerably above it, but always below the costal arch. In none of the cases on record was the trouble correctly diagnosed. In some it was overlooked even at the laparotomy. The small intestine is generally involved. The stomach is forced forward and the afferent loops of intestine are distended and held immovable under the liver, high up to the right. No hernial sac is visible except in the rare cases in which the intestine has slipped between the two sheets of the great omentum. When the finger is able to trace the course of the incarcerated intestine, the pulsations of the large hepatic artery can be perceived. In the 11 cases in which an operation was undertaken it proved to be too late to save the patient in all but four instances. An incision into the intestine should be made to evacuate it, after which reduction of the hernia is easy. There is a sheet of loose cellular tissue, between the vena cava and the duodenum, through which it is easy to expose the lower part of the foramen of Winslow after incising the anterior sheet of the lesser omentum over the upper duodenum, parallel to its longitudinal axis.

26. **Epileptiform Seizures of Pleural Origin.**—Roch reviews 54 cases of convulsions suggesting epilepsy in which the inciting cause was some affection involving the pleura. The pleurisy in some cases favored the development of convulsions primarily due to other causes, but in others the pleurisy was evidently the sole inciting cause. This action is manifestly a reflex phenomenon. It was observed unmistakably in 4 well-defined cases. This assumption is also sustained by the cases on record of severe nervous disturbances in pleuritics, independent of operative trauma, such as coughing, hemiplegia or sudden death.

27. **Radicular Sciatica.**—This article discusses the diagnostic and prognostic importance of the topography of the disturbances in the objective sensibility in the course of sciatica, neuralgic, neuritic or radicular. In the 6 cases of the latter variety reported in detail with diagrams, 3 of the patients were syphilitics, 2 alcoholics and 1 tuberculous. In sciatic neuralgia and neuritis the trunk of the nerve is altered or compressed at some point, and the sensory disturbances are of the segmentary type. In addition there is a type of sciatica due to alteration of one or more of the roots which constitute the sciatic nerve.

29. **"Epigastric Point" in Emphysema of the Lungs.**—De Brun calls attention to the painful point observed in heart affections or with disturbances in the pulmonary circulation. The right ventricle can not become dilated without causing pain, whether the dilatation is due to emphysema of the lung or to a mitral lesion. This tenderness, De Brun states, is thus a valuable, hitherto unappreciated, symptom of something wrong in the right ventricle from disturbances in the pulmonary circulation. Fifty-four case histories are summarized to sustain this view. The first refers to a woman of 67 who had suffered for ten years from a singular and severe gastralgia. All kinds of treatment had been instituted without relief. There was no dyspnea, but there were evidences of pronounced emphysema of the lungs, and the gastralgia was aggravated by everything that would aggravate a cardiac lesion. Under the influence of potassum iodid relief was obtained within twenty-four hours, with a permanent cure of the gastralgia. Sixteen years's experience has confirmed this connection between the pain in the stomach and some disturbance in the pulmonary circulation, and the prompt relief under potassium iodid or heart tonics. The pain is usually in the upper part of the epigastric region. The sensation is sometimes that of oppression, tension and a dull pain, sometimes extremely intense pain, radiating to the lower part of the back. The pain is permanent and is usually aggravated by reclining, and it is always increased by pressure. It is also always accompanied by hypertrophy of the right heart and pulsation visible in the epigastrium. It may accompany or just precede asystolia.

31. **Influence of Sugar on Working Capacity.**—The results of Féré's extensive experiences may be summarized in the

statement that sugar has a stimulating action, but, like all stimulants, its use is followed by a period of depression. Sweets for dessert stimulate digestion and disguise the fatigue of digestion, but it is a question whether there is not a deficit left after this transient stimulation.

32. **Causes of Mental Pathology.**—De Montyel recognizes six conditions alone as able to cause a mental affection, and then only in the predisposed. They form three groups: 1, the infectious group, with typhoid fever and chronic malaria; 2, the toxic group, with chronic alcoholic and lead poisoning, and 3, the physical group, with traumatism of the skull and sunstroke.

34. **Cancer on Genitals of Dogs.**—Sticker reviews the literature on the subject of malignant tumors on the external genitals of dogs, and shows that the tumors observed by various writers were all practically of the same type, round-celled sarcomas. While ordinary infectious processes start in the mucosa, as a rule, the sarcoma always develops from the submucosa and is solitary. Several instances are known of transmission of the sarcoma by coitus, but this may have been due to contact transplantation of tissue in some excoriation, and can not be used as an argument in favor of the contagious nature of the affection. Spontaneous transplantation under these circumstances is favored by the superficial location of the sarcoma and its tendency to break through to the surface. Sticker observed several instances of the healing of a transplanted sarcoma, while in the controls the sarcoma progressed to a fatal termination. He affirms that this is the first time that it has been demonstrated experimentally that cancer can heal spontaneously. Animals who thus spontaneously recovered from their malignant growth were not susceptible afterward to further transplantation, but acquired active immunity to cancer. The malignant growth can be transmitted to another animal only by transplantation of the intact cells of the growth, while an infectious process can be transmitted by inoculation with the virus, free from cells. Infectious processes induce metastasis only by way of contact infection, but a sarcoma may develop metastasis in any of the internal organs.

35. **Superficial Cancer.**—In Coenen's first case, the patient, a woman of 79, presented a carcinoma on the right cheek near the nostril, and a second, entirely separate, carcinoma on the left cheek just below the eye. In 6 other cases observed in the clinic, and in several others reported in the literature, multiple carcinomas were observed on the face and neck. Seborrheic eczema of the face seems to favor the development of multiple cancers, as also working in paraffin and in tar. In the second case illustrated an adenocarcinoma had developed on the chest of a man of 69, at about the third rib. The few similar cases of cancer on the trunk are reviewed and the pathogenesis discussed.

36. **Elephantiasis of the Scalp.**—Under the influence of repeated trauma a small tumor developed on the side of the brow and head which gradually assumed the characteristics of acquired elephantiasis.

39. **Experimental Pancreas Affections.**—Guleke has been studying on a large number of dogs the affections of the pancreas induced by injection of oil, bile or blood, in the outlet of the pancreas, or by ligature of its blood vessels. The resulting disturbances closely resembled those of acute pancreatic affections in man. The essential feature in all seemed to be necrosis of the pancreas. The intensity and the extent of this necrosis were the decisive factors for the course of the affection. The hemorrhages, especially the so-called apoplexies, were more or less subordinate features, although of the greatest importance in the etiology. His experiments further demonstrated that in acute necrosis of the pancreas death is due essentially to intoxication with trypsin. In the chronic cases the disturbances are more in the nature of those observed after extirpation of the pancreas, but in the acute cases everything points to trypsin intoxication. This assumption is confirmed by the fact that it proved possible to immunize dogs against trypsin intoxication and against transplantation of pancreas tissue, otherwise fatal.

41. **Cosmetic Operations on Ears.**—Payr has had gratifying results in operations undertaken to reduce the size of overprominent ears. The special features of his technic are the excision of a vertical, sickle-shaped piece of cartilage from the back of the ear, the outer edge parallel to the rim of the ear. The next step is the partial detaching of a broad horizontal strip at right angles to the first, its base being left attached. This strip is turned back and drawn under a bridge flap cut in the periosteum of the mastoid process. By traction on this flap the ear is drawn back more nearly parallel to the head. The cross-shaped defects left in the ear are sutured and the skin over them, thus materially reducing the size of the ear and bringing it back parallel to the head. The pieces of cartilage are easily mobilized and the excess of skin left in front by the reduction in size was soon taken up by the growth of the child in his cases. Fifteen illustrations accompany the article.

43. **Total Luxation of the Spine.**—Steinmann has found records in the literature of 19 cases of total luxation of the spine between the second and seventh cervical vertebræ without irreparable injury to the spinal cord. He gives a summary of each and then describes a case personally observed. There were no signs of paralysis of the limbs, rectum or bladder in his patient, and no disturbances in swallowing or breathing, and yet radiography and the position of the head, etc., indicated total forward luxation of the fifth cervical vertebra with fracture of the sternum. In all the cases the accident had been a fall or blow on the head or back of the neck. In 4 of the cases the paralysis vanished at once when the luxation was reduced. In only one of the 20 cases did partial paralysis persist. In 12 the attempt at reduction proved successful; in one case the luxation was reduced under mere orthopedic measures, and in 7 no attempt at reduction was made. Six of this latter group remained permanently free from paralysis, although much hampered by the abnormal position of the head and restriction to movement, the condition growing constantly

worse instead of better. Steinmann concludes from his analysis of all this material that in all recent cases the dislocation should be reduced whether there are signs that the spinal cord is injured or not. But as it is often impossible to distinguish whether the luxation is accompanied by fracture or not, the technic should be such as to do no harm in case of fracture. The spine should be stretched with lengthwise extension and then a very slight push backward or bending of the upper part of the spine will generally bring the parts into place or they spring into the proper place spontaneously. In no event must the pathologic position of the dislocated vertebra be aggravated, as this is liable to compress the spinal cord still more. Anesthetics are contraindicated when there are disturbances in respiration owing to injury of the roots of the phrenic nerve by a high luxation. On the other hand, anesthesia facilitates palpation and aids in relaxing the muscles for the extension. When the luxation is more than a few days old, the possibility of fibrous adhesions should make the surgeon hesitate about interfering. If, however, the spinal cord is known to be intact, simple extension could scarcely do harm, although no attempt at reduction of an old luxation of the kind is on record. It might be possible to remove the spinous process and part of the dislocated vertebra—a procedure which Steinmann is ready to undertake in his case if conditions become aggravated by callus formation and subsequent compression of the cord. Lengthwise extension can be done with confidence, as the ligaments in these parts stand great traction without laceration; even in children, tearing of the ligaments is the rarest exception. The danger of transportation and of delay impose it as a duty on the attending physician to reduce the dislocation at once, even when there are signs of injury of the cord. The article is illustrated.

44. **Tuberculosis of Thorax Wall.**—König's article is based on 110 cases. No age or sex seemed to predominate. He gives summaries of all the cases and insists on the necessity for removal of the focus into sound tissue, as in treating a malignant growth. Four of the patients succumbed during or soon after operation, but 73 were dismissed cured and known to be in good health for some time afterward. In 33 cases the patients left before the wound had entirely healed. The cases in which the lesion was under the breast sometimes required several operations before a complete cure was finally attained. The breast had to be turned back or amputated. He always dusted the defect with iodoform before closing the wound, with or without drainage or gauze packing. The wire saw was sometimes found useful. Resection of the cartilage generally proceeded more easily when the incision was made with the knife down on an elevator introduced beneath.

45. **Remote Results After Complicated Fractures of the Skull.**—Brewitt studies here the remote results in 72 cases of complicated fracture of the skull in individuals between 2 and 65 years of age. All but 7 were males. Ten of the patients succumbed to their injury, and 2 still had slight symptoms when dismissed, but 60 were freed from all disturbances. Of the latter group 41 have been examined again recently. Of the 38 patients treated by reimplantation 24 are in good health, 2 have slight and 2 such severe disturbances that they are unable to work. None has developed epilepsy. In the 4 patients treated by a secondary plastic operation, 3 are in good health, but 1 has considerable trouble. An open defect in the skull was left in 30 cases, and only 9 of these patients are in good health to-day; 2 have slight and 1 severe disturbances; 1 has epilepsy and 8 have succumbed to the consequences of their injury, while 9—all free from disturbances when dismissed—have been lost from sight. The reimplantation technic here, as in the experience of others, has maintained its supremacy. The aim should be to close a recently acquired defect in the skull as soon as possible, for the remote results in patients thus treated are much better than in those whose defect in the skull healed without attempt at closure. There is grave danger of injury to the exposed tissues from the ordinary trifling accidents of daily life, and the brain in such cases is less resistant to injury than under other conditions. The finest results were attained when the defect was closed with the fragments recently torn out.

49. **Intravesical Operating.**—Klose has modified the Nitze method of removing tumors in the bladder with the electrocautery. His snare is light and larger than the size of the tumor. Being made of steel, it stands traction well. He turns on the current for two or three seconds and then turns it off, repeating this alternately until the tumor has been entirely detached and drops off. The advantage of this rather tedious technic is the avoidance of all hemorrhage. He gives illustrations of his modified instrument and of a large tumor removed with it without the loss of a drop of blood.

50. **Enterocele.**—Antonelli describes his technic, which he styles the "perfecting of the familiar Murphy method." He reports its sucessful application in a case of circumscribed peritonitis with adhesions, the loops of the intestine involved being at the same time confined in an inguino-scrotal hernial sac.

51. **Test for Chlorin in Urine.**—Ekehorn uses a graduated glass tube about 15 mm. in diameter and 22 cm. long. The first line is engraved at the point corresponding to 2 c.c. of urine, and is marked U. Another line above is marked 1 and corresponds to 1 c.c. of the indicator. The third line is marked zero, and corresponds also to 1 c.c. The tube is graduated above this with lines marking the cubic centimeters up to 55 c.c. Two c.c. of the urine are placed in the tube and 1 c.c. of the indicator, up to the line I. The second reagent is then added until the tint changes. The test is a modification of Volhard's titration test.

54. **Myelomatosis, Leukemia and Hodgkin's Disease.**—Hoffmann defines myelomatosis as the multiple development of malignant tumors in the bone marrow, originating in hyperplasia of one of the cellular elements of the mother soil (lymphocyte, myelocyte, plasma cell). The tumor does not show the characteristics of the mother soil. Leukemia he defines as an affection of the blood, the prominent features of which are the increase in the lymphadenoid tissue as well as in certain groups of the white corpuscles. The hyperplasia in the lymph glands and bone marrow maintains the type of the fundamental tissue, and hence the increased output of the round cells in question. The morbific agent is similar to or the same as Flexner's lymph, spleen or myelo-toxin. As the first two or the third predominate there is a lymphocyte or a myelocyte leukemia. The hyperplasia of the lymphadenoid and the myeloid tissue is the expression, he states, of efforts at compensation or formation of antitoxin. Pinkus' pseudoleukemia with relative lymphocytosis and the histologic picture of leukemia must be regarded as a form of lymphocyte leukemia in which the overproduction just covers the loss of lymphocytes. Hodgkin's disease, on the other hand, consists in inflammatory hyperplastic processes in the lymphadenoid tissue, destroying its structure. No specific changes in the blood picture follow. The increase of the round cells, with the partial alteration of their types, eosinophiles, plasma cells, etc., and the profuse formation of connective tissue, may lead to the formation of large tumors.

55. **Prevention of Death from Otherwise Fatal Experimental Burns.**—Helsted announces that preventive artificial anemia of the region of a burn was able to prevent the death of the animal in his numerous experiments, within certain limitations of temperature. His examination of the blood in 30 cases of severe burns showed that determination of the proportion of hemoglobin is an important aid for the prognosis. In all the extensive fatal burns pronounced hemoglobinemia was observed, and it was present in slighter extent in all the cases of extensive burns showing impairment of the general health. In case of extensive burns without much effect on the general health, no hemoglobinemia was apparent. In his experimental work he found that an isolated lesion of the blood caused the same hemoglobinemia, hemoglobinuria and ventricular hemorrhage as in case of extensive cutaneous burns. For this isolated lesion of the blood he withdrew 10 c.c. of blood from the carotid artery of a rabbit and heated it in the water-bath to 60 C., then cooled it to body temperature and reinjected it into the artery. The effect on the rabbit was apparently the same as that of a severe fatal superficial

burn. When an Esmarch tourniquet was applied to the legs of a rabbit and the femoral arteries and veins were ligated, and the legs were then held in water at 60 C. for three minutes, the animals survived, with little disturbance, while all the controls, without the artificial anemia, succumbed in a day or so. The metabolism declines when part of the blood has been heated to the coagulating point of the fibrinogen. Numerous other experiments are related and an extensive bibliography on the subject of death from burns is appended.

56. **Hypernephroid Carcinoma and Sarcoma.**—Neuhäuser has been studying the collection of kidney tumors in the Jewish hospital at Berlin, 103 in all. No less than 69 belong to the group of hypernephromas. In 2 he found unmistakable evidence that true carcinoma had developed out of a hypernephroma. Displaced suprarenal germinal matter had lodged in the kidney in early embryonic existence, a hypernephroma had developed from this, and the carcinoma from the parenchyma of the hypernephroma. Neuhäuser is far from maintaining that embryonal displacement of germinal matter is the only cause of these cancers, but in these cases it was evidently the first embryologic cause, without which these carcinomas would never have developed. The same applies also to some cases of sarcoma developing in a hypernephroma which are in the collection. The sarcoma had developed from the stroma. Clinical details of the 9 cases with hypernephroid malignant growths are given in conclusion. There are three colored plates of the histologic findings.

57. **Operative Treatment of Contusion of Abdomen.**—Voswinekel gives the particulars of 17 cases of subcutaneous injury of the digestive tract in which an operation was done. He declares that the lesson learned from this experience is that operative treatment is imperative at the earliest possible moment when there is a probability that the stomach or intestines have been injured by a contusion. If the shock is too pronounced for immediate operation, every effort must be made to bring the patient out of the shock, with restoratives and saline infusion. Every moment lost adds to the danger of the development or progress of the almost inevitable peritonitis. Besides the signs of shock, the most important indication of a subcutaneous injury of stomach or intestines is the intense painfulness on pressure, generally at the injured point, and the rigid tension of the rectus muscles with the abdominal walls flat or drawn in. In case of small circumscribed injuries, it may be sufficient to suture the wound in the intestine and to reinforce it with serosa drawn up over it, but in case of extensive injury it is better to resect the injured portion. Even if the patient is not seen until after the peritonitis is established, an operation is always justified, although the prospects of saving life are then small. Careful rinsing out of the entire abdominal cavity with large amounts of sterile salt solution should never be omitted, he adds, as this is the only means of cleansing the peritoneal cavity of infectious material. Even if this is not entirely accomplished, yet in the larger proportion of cases the peritoneal cavity can thus be flushed out and the peritoneum left in condition to take care of the rest.

65. **Blood and Hemorrhages in Affections of Digestive Tract.**—Ewald has not been able to detect any characteristic formulas for the blood in diseases of the digestive tract. He states that the discovery of "occult" or invisible hemorrhage, in the stomach contents or in the feces, is a valuable aid in the differentiation of ulcer of the stomach and cancer, and cites a number of instructive examples from his own experience. He has not had very favorable results from the use of gelatin, adrenalin, etc., in treatment of gastric hemorrhage, but reports that he was able to arrest recurring profuse hemorrhage by rinsing out the stomach with ice water. Eight patients thus treated were much debilitated from the hemorrhages and all other measures had failed. As a last resort before calling on the surgeon, a small amount of morphin was injected, the throat was cocainized to prevent retching or vomiting from reflex irritation, and ice water was then poured in through the stomach tube. The tube was introduced only just past the cardia so as not to irritate the walls of the stomach. As more ice water was poured in the tube was pushed in a little farther, until the water flowed out clear from blood. It was astonishing how much blood-stained water was obtained in this way, with numerous clumps of blood, but the hemorrhage was definitely arrested. As blood in these cases passes into the intestines and decomposes there, he flushed out the intestines to prevent irritation from this source. In case of collapse he injects camphorated ether, 1 to 6, with enemas of wine with egg or peptone, and hot compresses to the hands and feet. In case of threatening hemorrhage with small pulse, anemic heart sounds and anemia of the brain, saline infusion is indicated. By introducing the saline solution through two needles at the same time, and massaging away the fluid as it enters, it is possible to inject as much as a liter of water in a very short time. He prefers the subclavicular region for the injection. The blood regenerates quite soon in favorable cases. The results to date of operative treatment of gastric hemorrhage are not very promising. Better prospects are opened by the recent announcement that gastroenterostomy is able to arrest hemorrhage and to prevent its recurrence, even when the actual source of the bleeding is not discovered. This result may be due to postoperative contraction of the dilated stomach. Hemorrhages from the lower rectum, especially hemorrhoidal, are very easily controlled. Cold sitz baths or introduction of pieces of ice or injection of ice water generally arrest them, and the tendency can be combated by astringent injections or applications. External nodules can be treated with an ointment of chrysarobin 0.8 gm.; iodoform, 0.3 gm.; extract of belladonna, 0.6 gm; and vaselin, 15 gm., rubbed in several times a day, the internal nodules with suppositories of the same. Each suppository consists of: Chrysarobin, 0.08 gm.; iodoform, 0.02 gm.; extract of belladonna, 0.01 gm., and cocoa butter to 2 gm. Two such suppositories are used daily. This not only arrests the tendency to hemorrhages, but shrivels and reduces the sensitiveness of the nodules. A frequent source of anemic conditions is afforded by continuous bleeding from unsuspected hemorrhoids high in the rectum. The stools do not show the presence of blood except by microscopic and chemical tests. Ewald has had good results in obstinate hemorrhoidal hemorrhages from the internal use of a mixture of coagulating, astringent and laxative drugs, calcium oxid, bismuth gallate, senna, etc.

69. **Treatment of Empyema of the Pleura.**—Braun states in the course of this clinical lecture that he does not believe that puncture and aspiration are sufficient to cure empyema in the pleura, as a rule. An incision with resection of a piece of rib from 4 to 6 cm. long will provide much better conditions for evacuation of the pus and final healing. Ether is contraindicated by the usually coexisting bronchitis. In case of much dyspnea or debility, or if the pulse is weak and bad, general anesthesia must be avoided as it is liable to prove fatal at the time or soon after. Infiltration anesthesia will be found useful in these cases, as also for other adult patients who are not too timorous. None of the valve cannulas to prevent pneumothorax has proved effectual. To promote the expansion of the lung during the healing of the empyema chest gymnastics are needed. Braun urges his patients to blow a trumpet or to blow up an air cushion, or something of the kind, to insure deep expirations. Sometimes healing is delayed by suppuration in narrow passages leading upward, and they should be curetted or have 10 per cent. iodoform glycerin injected. In tuberculous empyema the indications are the same as under other circumstances if the patient is in good condition otherwise. Even in advanced pulmonary tuberculosis repeated tapping will bring great relief. Evacuation of the pus through the back, in the seventh or eighth interspace, with injection of 15 or 20 c.c. of 10 per cent. iodoform glycerin is liable to keep the patient in good condition for a long time. The injection can be repeated when the iodin has disappeared from the urine, which is generally in from two to five weeks. In case of bilateral empyema it is wise to wait until the patient has recovered from the operation on one side and the lung has expanded once more, before attempting intervention on the other side. He has thus treated and cured 2 patients. In case of an old empyema in a child, he advises injection of salt solution or of iodoform or carbolic acid, glycerin or hydrogen dioxid, which may cure without the necessity for more extensive operative measures. When the apex of the pleural cavity is involved, the operation may have to be in several stages with long intervals. The resection of the thorax, however, gradually restored the patient to almost normal health and strength if the empyema was not tuberculous. Such an extensive operation as resection of the thorax should not be attempted in case of a tuberculous process unless the patient is in good general condition.

70. **Practice and Theory of the Overpressure Technic for Operations in the Thorax.**—Brauer describes the mode of action of the underpressure and overpressure methods of maintaining the respiratory functions of the lungs unimpaired when the thorax is opened. The effect on the blood vessels is the same, he shows, whether the lungs are kept expanded by compressed air or by being opened up in rarefied air. The criticisms of one technic apply equally to the other, but the general results, on the whole, he thinks, are more favorable with his overpressure technic than with the Sauerbruch underpressure pneumatic cabinet.

71. **Treatment of Hypertrophied Prostate.**—Kümmel has had extensive experience with various methods of treating enlarged prostate. He has abandoned the operations of castration, resection of the vas and ligation of the afferent vessels, and now operates directly on the prostate by the high cut or perineal route. If these operations are refused or the general condition does not permit, he applies the Bottini technic. He remarks that spinal anesthesia is particularly suited for prostatectomy, and has materially reduced the dangers of the radical operation for hypertrophied or cancerous prostate. Hypertrophy of the prostate is generally progressive, and it soon proves impossible to introduce the small catheter which at first passes readily. For this reason, and also to aid in keeping the pasage open, he commences with quite a stout catheter, leaving it in place for several days in case of retention from enlargement of the prostate. If spontaneous urination does not follow its removal he introduces it again for another trial. If this also fails he advises operative interference. He remarks that the "catheter life" is never a long one, as the patients soon succumb to pyelonephritic and septic processes, as a rule.

72. **Radical Treatment of Carcinoma of Colon.**—Neumann has been much gratified with the results in 6 cases of carcinoma of the colon which he treated by first clearing out the bowel and later resecting the malignant process. He made an opening into the cecum in most cases, evacuated it, and prepared the bowel for the resection by injections and purgatives, the site and movability of the cancer being thus absolutely determined before attempting the secondary resection. The particulars of all his cases are given and also of 2 others treated by a different technic, with the death of one patient. He gives an illustration of the two skin flaps with which he closed the artificial anus when it was no longer needed. In one case the opening into the cecum was made Nov. 1, 1904; the left flexure in the colon was resected November 21, and in January, 1905, the fistula into the cecum was closed by a third laparotomy, and the patient left the hospital in apparently perfect health. In September she returned with a very large metastasis in each ovary and disseminated nodules on the serosa of the intestine. The ovarian tumors were removed by a fourth laparotomy, in October, 1905, and the patient has since been subjectively well. He followed Mickulicz's technic in 3 cases of cancer of the sigmoid flexure, with the complete cure of the patients to date. The results of thus operating in several stages far surpass those obtained by other less tedious technics, even although it may prove impossible in some cases to insure the final healing of the fistula into the intestine.

74. **First Transportation of the Wounded.**—Colmers was at Charbin and soon learned that any attempt to remove the wounded soldiers severely injured in the abdomen was almost certain death. On the other hand, they almost invariably recovered when left undisturbed except for the necessary operative measures. He consequently advises that the wounded of this class should be left on the battle-field after being made as comfortable as possible, the spot where they lie marked with a pennant, or a light tent set up over them. After all the other wounded have been carried off the field these wounded may be collected into one or more central points, and in case the army is retreating, be entrusted to the care of the enemy or left in charge of a physician and nurses. Many of the severely wounded in the late campaign would have recovered if they could have been spared the fatal transportation. He adds that the surgeon's time at first is better employed in tending a large number of slightly and moderately wounded men than in spending the same time in caring for one or two of the very seriously wounded.

76. **To Insure Asepsis in Operations.**—Döderlein has been investigating the bacteriologic findings under the latest improved aseptic technic. He has a number of sterile cotton pledgets ready in test-tubes, and during the course of the operation these pledgets are taken up with forceps and used as a swab to wipe off some part of the wound, instruments or operator's hands. The pledgets are placed at once in liquefied agar, which is then poured out on Petri dishes with the pledgets. In 5,000 such tests he found that even when gloves, masks and other modern devices to insure asepsis had been used, yet the bacteriologic findings were always positive. He advises others to make these tests now and then to verify the asepsis of their technic. The folds in rubber sheeting, rubber rings on vials, etc., are liable to harbor germs in large numbers even after supposed complete disinfection. After eliminating all these sources of germs he discovered that the patient's own skin was the perennial source of germs notwithstanding most careful preliminary disinfection. Asepsis on the part of the operator and instruments always encountered this nest of bacteria on the patient's skin. To prevent trouble from this source he now paints the skin with an impermeable coating of rubber. He found that collodion, celluloid dissolved in acetone, and similar varnishes cracked away from the skin as they dried, and left the edges of the wound exposed. This disadvantage he obviated by using a special mixture of rubber

with formalin, benzine and ether. The skin is cleansed, shaved and painted with tincture of iodin. It dries in a couple of minutes, when the rubber mixture is applied and dusted with talcum powder, which is brushed off again. The skin is then found covered with a very thin, clinging, impermeable membrane. Tests after an operation in which the field is thus protected show that there are no more germs than when the operation was begun. The organism is thus spared the struggle with germs introduced from the skin, while careful technic excludes germs from the exterior.

78. **Perforation of Bladder During Curetting.**—Stern describes a case of perforation of the bladder wall with a catheter curette. The patient was a thin woman of 57; the operation had been undertaken for the removal of a papilloma in the inflamed bladder. The distance had been carefully measured and the curette was introduced very cautiously, under chloroform, but almost at once the tip could be felt close under the abdominal wall. He advises against attempting to curette the bladder without opening the organ above. High incision allows oversight of the field and has direct curative action. It also prevents the bladder from contracting and thus favoring perforation.

79. **Successful Simple Surgical Treatment of Sciatica.**—Pers reports 2 very severe, old and obstinate cases of typical sciatica completely cured by surgical intervention. He exposed the sciatic nerve and found that it appeared red and dull, instead of presenting its usual shiny, ivory aspect. This appearance was due to the presence of a fine network of connective tissue fibers completely encircling the nerve and pinning it down. This network extended down to the junction of the middle and lower thirds. He cautiously removed this network, thus releasing the nerve and restoring its normal aspect. The diagnosis was perineuritis resulting from an extinct or existing neuritis. In both cases the patients were completely freed at once from all their neuralgic troubles.

82. **Diagnosis and Treatment of Inherited Predisposition to Phthisis.**—Spengler styles the inherited syphilitic taint the one important inherited predisposition to consumption. The syphilitic taint may be so slight as not to be recognizable by ordinary diagnostic aids. It may date from the third or fourth preceding generation, he states, but it can be detected by the tendency to interposed harsh breathing (Rauschen). The inspiration begins with vesicular breathing, but this ceases abruptly and is followed by harsh breathing as the inspiration continues, followed by normal or vesico-bronchial expiration. This interposing of the harsh breathing is extremely characteristic. The anatomic basis of the sound is proliferation of the connective tissue or hypertrophy of a cirrhotic lung, similar to the hypertrophic cirrhosis of the syphilitic liver. Another sign of this latent inherited syphilis is the tendency to scaling after injection of his Perlsucht tuberculin. He has noticed further that all persons with a tendency to rachitis exhibit the same harsh breathing and scaling, and this has convinced him that rachitis is the result of syphilis in some preceding generation. Other signs of this special predisposition are a tendency to snoring breathing; the lack of proportion between the extent of the physical signs of tuberculosis and the slight general manifestations; the early and predominant tuberculous involvement of the larynx, especially in case of existing diabetes in comparatively young subjects; the obstinate anemia unexplained by the pulmonary affection, and the intense hyperleucocytosis in the sputa with disintegration of the nuclei. He presents evidence to prove that it is easy to control this predisposition and, by holding it under control, to remove the factors that favor progression of the tuberculous infection. He accomplishes this by means of the percutaneous administration of iodin, rubbing it into the skin in the form of a salve. Iodin internally is ineffectual. The characteristic symptoms rapidly subside under this treatment, supplemented perhaps by inunctions with corrosive sublimate. As these symptoms subside the conditions predisposing to tuberculosis are banished. He has been able to cure 100 per cent. of his patients with tuberculosis in the early stages by combining this iodin with his bovine tuberculosis tuberculin treatment. The leucocytes of these *Erbdispositerter*, as he calls them, are less bactericidal than normal leucocytes, and it is exceptionally hard to confer agglutinating properties on their serum. After adequate iodin treatment, however, these differences from the normal are no longer seen.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE PRACTICAL MEDICINE SERIES, Comprising ten volumes on the Year's Progress in Medicine and Surgery. Under the General Editorial Charge of G. P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Vol. III. The Eye, Ear, Nose and Throat. Edited by C. A. Wood, C.M., M.D., D.C.L., A. H. Andrews, M.D., and T. P. Head, M.D. Series 1906. Cloth. Pp. 368. Price, $1.50. Chicago: The Year-Book Publishers.

INTRODUCTION TO MATERIA MEDICA AND PHARMACOLOGY, Including the Elements of Medical Pharmacy, Prescription Writing, Medical Latin, Toxicology, and Methods of Local Treatment. By O. T. Osborne, M.A., M.D., Professor of Materia Medica, Therapeutics and Clinical Medicine in the Yale University. Cloth. Pp. 167. Price, $1.00 net. Philadelphia: Lea Brothers & Co., 1906.

HEALTH'S MANUAL OF MINOR SURGERY AND BANDAGING for the Use of House Surgeons, Dressers and Junior Practitioners. Thirteenth Edition. Revised by B. Pollard, F.R.C.S., Surgeon to University College Hospital, and Teacher of Operative Surgery in University College, London. Cloth. Pp. 409. Price, $1.50 net. Philadelphia: P. Blakiston's Son & Co., 1906.

COLLECTED STUDIES ON IMMUNITY. By Prof. P. Ehrlich, Privy Councilor and Director of the Royal Institute for Experimental Therapy, Frankfürt, Germany, and by his Collaborators. A Chapter written expressly for this Edition by Professor Ehrlich. Translated by C. Bolduan, First Edition. Cloth. Pp. 586. Price, $6.00. New York: John Wiley & Sons, 1906.

DISEASES OF THE NOSE AND ITS ACCESSORY SINUSES. By H. L. Lack, M.D., F.R.C.S., surgeon to the Throat Department of the London Hospital and Lecturer on Diseases of the Throat to Its Medical College, etc. With 124 Illustrations. Cloth. Pp. 399. Price, $8.50 net. New York: Longmans, Green & Co., 1906.

CONSUMPTION, Its Relation to Man and His Civilization. Its Prevention and Cure. By J. B. Huber, A.M., M.D., Fellow of the New York Academy of Medicine; Member of the National Association for the Study and Prevention of Tuberculosis. Cloth. Pp. 536. Price, $3.00 net. Philadelphia: J. B. Lippincott Co., 1906.

DIE HAMORRHOIDEN, ihre Ursachen, Symptome und Behandlung. Gemeinverständliche Darstellung. By Dr. F. Kuhn dirigierendem Arzt am Elisabeth-Krankenhaus in Kassel. Mit 20 abbildungen in Text. Paper. Pp. 65. Price, 2 marks. Munich: Verlag der Aerztlichen Rundschau, 1906.

TRANSACTIONS OF THE AMERICAN PEDIATRIC SOCIETY, Seventeenth Session, Held at Hotel Saganmore, Lake George, N. Y., June 19-21, 1905. Edited by L. E. La Fetra, M.D., Vol. XVII. Reprinted from Archives of Pediatrics, 1905-1906. Cloth. Pp. 228. New York: E. B. Treat & Co., 1906.

MODERN SURGICAL TECHNIC IN ITS RELATIONS AND WOUND-TREATMENT. By C. Y. Pearson, M.D., M.Ch., F.R.C.S., Professor of Surgery, Queen's College, Cork. Illustrated, with Two Colored and Other Plates. Cloth. Pp. 392. Price, $3.50 net. New York: William Wood & Co.

NOTES ON SURGERY FOR NURSES. By J. Bell, M.D., F.R.C.S., Edin., Consulting Surgeon to the Royal Infirmary, and to the Royal Edinburgh Hospital for Sick Children. Sixth Edition, thoroughly revised. Cloth. Pp. 187. Price, $1.50 net. New York: William Wood & Co.

SANITARY LEGISLATION IN THE UNITED STATES Enacted During the Year 1905. Special Bulletin of the State Board of Health. Compiled for the State Board of Health by C. V. Chapin, M.D. Cloth. Pp. 318. Providence, R. I.; E. L. Freeman & Sons, 1906.

DIE ZUCKERKRANKHEIT (Diabetes). Ihre Ursachen und Bekämpfung gemeinverständliche dargestellt. Be Dr. O. Burwinkel Kurarzt in Bad Nauheim (Winter San Remo). Paper. Pp. 31. Price, 1.20 mark. Munich: Verlag der Aerztlichen Rundschau, 1906.

STUDY OF THE CAUSE OF SUDDEN DEATH FOLLOWING THE INJECTION OF HORSE SERUM. By M. J. Rosenau and J. F. Anderson. Hygienic Laboratory—Bulletin No. 29. April, 1906. Paper. Pp. 95. Washington: Government Printing Office, 1906.

DER ALKOHOL UND DER ALKOHOLISMUS. Ein Wegweiser zum Verständnis moderner Kulturarbeit. von Dr. med. Kurt Bleibtreu, Waldsanatorium Tannenhof-Friedrichroda. Paper. Pp. 84. Price, 1.40 mark. Munich: Verlag der Aerztlichen Rundschau, 1906.

Address

WORK OF THE SECTION ON OPHTHALMOLOGY.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON OPHTHALMOLOGY AT THE FIFTY-SEVENTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, BOSTON, JUNE 5-8, 1906.

LEWIS H. TAYLOR, M.D.
WILKESBARRE, PA.

To present to you a résumé of the progress of ophthalmology during the past year, if such résumé should contemplate even a brief review of the numerous articles written, would occupy far more time than should properly be allotted to an introductory address. The omission of this formal duty by some of my predecessors has, I am sure, had the approval of the Section. An excellent review of this character by Dr. John Green, Jr., may be found in the *Interstate Medical Journal* for January, 1906, and a still more comprehensive analysis of the work of the year may be found in the excellent "Ophthalmic Year Book," edited by two of our most active workers, Drs. Jackson and de Schweinitz.

A pleasing feature of our last meeting was the presence with us of Professor Hirschberg, of Berlin, who gave an interesting address and who participated in the discussions of the scientific work of the Section. The custom inaugurated a few years ago by Dr. Allport, and since followed by others of my predecessors, of inviting a distinguished foreigner to attend the meeting of our Section and to deliver an address on some special topic is one well worthy to be followed by subsequent officers of the Section.

I regret exceedingly that I do not have the pleasure of introducing to you to-day one whom many of us know and whom we all honor for his scholarly work in ophthalmology. An invitation was extended some months ago to Prof. Carl Hess, of Würzburg, to be present as the guest of the Section and a formal acceptance was received from him. He was looking forward with pleasure to his visit to America, and had even written the address which he expected to deliver before us, when later, much to his regret and ours, he was forced by circumstances which he could not control to cancel his engagement and to postpone his visit indefinitely. It is to be hoped that we may be favored by his presence at some future time. Owing to the late date at which we received his declination it was not possible to secure another in his stead.

It is with sincere regret that I announce the death of one of our prominent workers, Swan M. Burnett, of Washington, D. C., which occurred suddenly on January 18 of the present year.

As late as December 29, in a letter to me, he accepted an appointment for committee work and wrote: "I hope to pull along far enough on the road to 'Wellville' to be able to go to Boston in June and to prepare a paper for you." He was interested in this Section from its inception and was its secretary in 1880-81. His work in our specialty is so well known to you all that it seems scarcely necessary to mention it here. Scholarly, earnest, devoted to his work, he was always ready by voice or pen to advance the science that he loved so well. In his death, ophthalmology has suffered a great loss.

The lack of time for a full discussion of the many interesting papers read before the Section has been a serious detriment in the past, and in order that this detriment may be removed we come before you this year with a new plan, that of having the papers published in advance of the meeting and in the hands of the members of the Section, so that each member may be fully ready for discussion, if he so desire, and that adequate time may be given for full consideration of special papers that may come before us. This plan has been considered for some years by others, and an effort was made by our present secretary to introduce it two years ago, but it failed owing to lack of co-operation in the office of THE JOURNAL. Its successful introduction this year is due to the untiring efforts of our energetic secretary and to the hearty co-operation of the editor of THE JOURNAL as well as of all those whose names appear on the program. It is possible that some of you may not cordially accept this plan. There is always room for honest difference of opinion, but we believe that it is worthy of trial and, with such modifications as your judgment will suggest, is worthy of adoption for subsequent meetings.

The importance of the suggestion made in their inaugural addresses by at least two presidents of the American Medical Association that the secretaries of sections should be, in a measure, permanent is well shown by the good work of our Section during the past three years. The policy of re-electing the secretary for a term of years is certainly a good one for the Section, though rather trying to the member who accepts the arduous duties of the office. Such a one should, at least, be relieved of all expense in connection with his work as secretary. The growing interest in the Section, the valuable volume of Transactions issued to members, together with the increased cost of mailing the copy of papers printed in advance of the meeting, would be grounds for suggesting an increase of assessment to at least $2.00 a member in order that the expenses may be equitably borne by the whole Section. Especially will this be advisable if the plan adopted for this year should be continued.

There are many reasons why this Section should be the true representative Ophthalmological Society of the United States. As the American Medical Association with its new constitution aims to represent the medical profession of the whole country, so this, one of the oldest sections of the general association, should represent the organized ophthalmologic profession of the whole country. It is the only ophthalmological society from

which no reputable oculist can be debarred by the vote of personal prejudice, or his entrance thereto be delayed by the slow-working process of membership committees. If his standing in his community is such as to admit him to membership in his local society, he is thereby entitled to membership in the American Medical Association and, if he so elects, to membership in this Section. Representing thus the entire profession of the country, we have in our ranks the very best workers that are to be found in our specialty; because we may have all of those who are entitled to membership in the most exclusive association of oculists, as well as all reputable younger workers whose reputations as scientific investigators are still to be established.

For the very reason that we represent in this peculiar manner the entire profession, the utterances of this Section, when unanimous, or nearly so, should have greater weight than the expression of any other ophthalmological society in the country, and the time has surely arrived when this Section, as such, should give definite expression of opinion and stamp with its approval certain features of our art on which the majority of us can agree. By no means would we imply that the last word has been said on any procedure or theory in ophthalmology, nor should there be any limit whatever to individual investigation or progress. More than twenty years ago a friend of mine who has since become eminent in his own specialty said to me: "Ophthalmology is finished. You will find nothing new in it." If he could carefully survey the field at present, he might readily conclude that it is not finished yet.

It is possible that there may be some more words to be said on the ocular muscles, their function, their defects, and their treatment before we shall arrive at definite conclusions to which we may all subscribe. One of the masters in this particular field who has spent much time in investigation and has written largely in expression of his views recently said at the close of a most interesting address: "I feel as if I were only on the threshold of this study."

Even cataract operation may be changed. The excellent results as shown in the recent interesting paper of Major Smith, of India, may lead us to think that a going back to old methods may really be a going forward in progress. The subject of bacteriology, which we hope to discuss quite thoroughly at this meeting in the symposium presented in our program, will not be ended this year, nor the management of ocular tumors, nor the use of electricity, nor others of the interesting questions that will be brought to your attention in our present program. There will still remain fields for investigation by the young ophthalmologist and plenty of opportunity for him to help settle the questions that have perplexed the elders. Refraction, as we all know, occupies a large part of the time of every ophthalmologist, and yet very little is said about it at our various meetings. Possibly many feel that so much has been said in the past that this is one of the points on which we are all agreed. I fear, however, that there is considerable divergence of opinion, and I wonder that so little attention is paid in our meetings to the various phases of this important subject.

There are some matters, however, about which we should be ready to give definite expression. For instance, the amount of instruction in ophthalmology that should be given in our medical colleges. This expression should be either by the appointment of a committee to formulate a course of instruction or by stamping with our approval the work already done by leaders in this line. The ignorance which treats a glaucoma by instillation of atropia or regards this or iritis as merely a form of neuralgia should not be tolerated in coming medical graduates. Only two years ago a resident physician, standing by me at the performance of a cataract operation, asked what the black stuff was that I removed from the eye when the iridectomy was made. He had spent four years in an excellent medical school, and yet he had never seen a cataract operation and did not know the difference between the cornea and iris, and he was a good resident, too, and better qualified to enter on practice than many others.

The subject of ventilation of school buildings, in its bearing on health and eyesight, as so ably presented by my immediate predecessor, as well as the general hygiene of school life in its bearing on eyesight, might well receive our consideration and definite approval.

Especially should we stamp with our disapproval certain pernicious forms of kindergarten work which demand excessive use of the eyes at close work at an age when eyes should not be subjected to such strain.

Above all, may we not hope at an early date for a still more definite expression from the Section on the subject of preventive blindness? Much excellent work has been done in this direction, and I think in the general principles involved we are fairly unanimous. I trust you will be ready to vote favorably on the resolutions that will be presented later, prepared by Dr. Park Lewis, of Buffalo, asking for the appointment of a committee by the Association to work out the details of a plan that may give us definite and uniform legislation throughout the country, and definite instruction to the general profession and laity, and thus supplement the excellent work already done by Massachusetts and a number of other states of our Union. These are a few of the questions that would seem to me to be worthy of your notice.

I welcome you most heartily to this twenty-seventh annual session of the Section on Ophthalmology. We come before you with a full program of interesting and varied papers, and I cordially invite you all to participate in a full discussion of the same.

Before entering on our stated program, I want to express my sincere appreciation of the honor you have conferred on me in electing me chairman of this flourishing Section and to thank you most heartily for the same.

A MORE UNIFORM STANDARD FOR THE ILLUMINATION OF VISUAL TEST-TYPES.*

CHARLES H. WILLIAMS, M.D.
BOSTON.

At our last session in Portland, Oregon, the illumination of some test-types which I showed was criticised, and justly so, on account of being too intense. If the light reflected from the test-type card is too bright the retina soon becomes fatigued, there is more irradiation, and the results obtained are less reliable than where a weaker illumination is used; on the other hand, if the light is too weak, we do not get a proper measure of the acuteness of vision under the conditions of ordinary use. We need some standard which will come between

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

these two extremes, which will be constant, so that the acuteness of vision of any individual to-day can be properly compared with his record of any previous time, and which will allow the reported records of one examiner to be compared with those of another.

It is easy to measure with great accuracy small differences in heat, or in the amount of an electric current, but with light these measurements can not be made with anything like the same accuracy, and for the purpose of measuring the amount of light reflected from a card of test-types, and of noting the point where the light reflected from the card becomes so much reduced in comparison to that reflected from the surface of the letters that the letters can no longer be read, it has been necessary to devise two special forms of photometer, which will be explained later.

STANDARD ILLUMINATION.

For practical purposes it will be best to state first the conclusions which have been reached after many trials and then to describe some of the tests. The most satisfactory results have been obtained by hanging the card of test-types in a cabinet painted a dull black, the opening being three feet wide by four feet high. On each side of this rectangular opening, right and left, is arranged a vertical column of small incandescent lamps of 5 candle power each, eight on each side, made to burn four in series on a current of 110 volts. These lamps are arranged at equal intervals, the highest and lowest being as near the top and bottom of the cabinet as possible, and are so placed that the lamps of one side come opposite the intervals between the lamps of the opposite side, thus making a more even distribution of the light. This vertical column of eight lamps on each side is protected by a blackened tin screen so that no light will pass direct from them to the observer, but so that the full amount of light will be thrown on the test card. The lights are one foot in front of the plane of the test-types, and about fourteen inches from the nearest edge of the card, and "frosted" bulbs are used.

With the lights arranged in this way, an even and constant illumination will be obtained over the whole surface of the card, the light will not be too intense, especially if the test-types are printed on paper of a light brownish tint, or, which is the same thing, if the paper has become darkened with age.

The above arrangement supposes that the office is supplied with an electric current, which is almost a necessity at the present day, but in many cases this is not available, and we need some measure of the amount of light reflected from a series of test-types at the ordinary distance of five meters, and some means of comparing this light with the amount reflected from such a standard as above described.

THE SIMPLEX PHOTOMETER.

A "simplex" photometer, which I devised last summer for measuring the relative brightness of signal lights at a distance of half a mile or more, seems to answer also for the comparison of the light reflected from different test cards, or from the same card under varying illumination.

This photometer consists of two developed glass negatives cut in strips about six inches long by three-quarters of an inch wide, placed face to face and mounted in a metal case. The film on each negative increases in density in a geometrical ratio from the clear end toward the dense end. These negatives are made at the Observatory of Harvard College with the same apparatus which is used for making photometric films for astronomical work and they give a very even and regular gradation.

To measure the brightness of a light, the photometer is held in front of the eye so that the light to be measured is seen through the clear end of the photometer film, the glass is then slowly moved so as to bring the denser portions of the film in line with the light until a point is found where the light is just extinguished by the absorption of the film. The amount of light cut off by the film at this point measures the intensity of the light tested, and can be read off on a scale attached to the glass photometric negative. It has been found most convenient to mount the negative in a metal case

Figure 1 shows the instrument closed, as it is carried in the pocket.

Figure 2 shows the instrument open ready for use. The cap is removed, the wire at the end of the cap is slipped over the end of the instrument to make a shield for the observer's eye.

shaped like a razor case, a sighting hole is punched in both sides of the case through which the light to be tested is observed, and directly below this is another hole in one side of the case through which the scale of the instrument can be read (Fig. 2).

Figure 3 shows the position in which the photometer is held when in use, resting firmly on the nose with the hole in the case before the eye.

The accurate marking of the scale on these instruments was rather difficult. The developed negatives

Figure 3 shows the position in which the photometer is held when in use, resting firmly on the nose, with the hole in the case before the eye.

giving a gradually increasing density of film were made with the greatest care, so far as selection of plates, time of exposure, developer, etc., were concerned; yet with the greatest attention to details the films could not all come out alike, and, although there was very little trou-

ble as to the gradually increasing density of the film, yet some films would be denser throughout than others, and a certain point, say at 10 cm. from the clear end of the film, would not, in all cases, cut off the same amount of light. In order to have a uniform scale for all the instruments, it was found necessary to have a series of standard shade glasses prepared. Each photometer was then compared with this set of glasses, and the scale of each instrument was marked from the result of this comparison. These standard shade glasses were made under the direction of Mr. E. S. King, of the Observatory staff, who has been very helpful

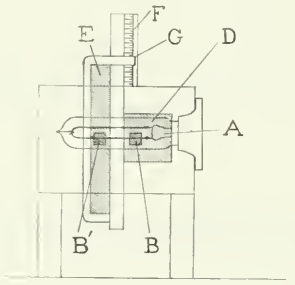

Fig. 4.—Front plan.

throughout these investigations, and a series of standard shade glasses was finally obtained which did not vary more than 1/10 of a stellar magnitude from the calculated amount in the quantity of light they cut off. This series of glasses consisted of six pieces which cut off an amount of light equal to 1, 2, 3, 4, 5 and 10 stellar magnitudes, respectively, and by comparing each photometer with this series of glasses, used either singly or in combination, a series of points was established where the instrument cut off an amount of light equal to 1, 2, 3, etc., stellar magnitudes up to 15, and the scales were established uniformly in this way.

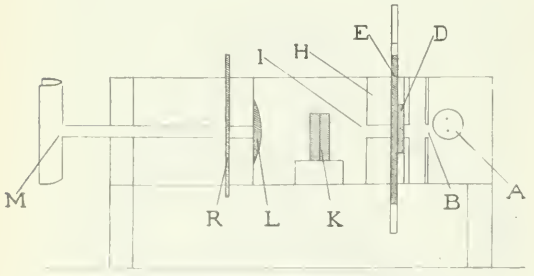

Fig. 5.—Side plan.

The amount of light to be measured, especially in the tests of distant signal lights, was in many cases so much less than a candle power that a scale based on the unit of a stellar magnitude was adopted as being the best. A scale of stellar magnitudes may be stated as a scale of brightness proceeding in geometrical ratio, each magnitude being about 2.5 times as bright as the magnitude next fainter, a difference of five magnitudes being equal to a difference of brightness of the lights in the ratio of 1 to 100. The pole star has a brightness of about 2.12 magnitudes. The ratio of 1 to 2.5 as representing one stellar magnitude has been determined by astronomers by taking the lists of stars which the older astronomers had constructed as giving an estimate of their brightness, as of the first, second, etc., magnitude, and on careful remeasurement finding that a difference of one magnitude between one star and another corresponded on the average to the ratio of 1 to 2.5.

In order to make an accurate comparison of the photometric films with the standard shade glasses, I made a new photometer. The problem was to have an intense light, equal to about 17 stellar magnitudes, placed before each of two openings so that each would receive an equal amount of light; behind one of these openings was the standard shade glass, behind the other opening was the photometer film to be measured, and, the light having passed through them, was to be so directed that when seen in the field of the eyepiece part of the field would be lighted by the rays which came through the film, and the other part by the rays which came through the standard shade glass, these two areas just touching along one edge so that their brightness could be compared. By moving the film, a point is quickly found where the light of the two areas is equal, and this shows the point where the film absorbs the same amount of light as the standard glass with which it is being compared.

The comparison photometer is arranged thus: In a box (Figs. 4 and 5) about 16 inches long, 4.5 high and 6.5 wide, at one end is a candelabra incandescent lamp

Figure 6.

ARRANGEMENT OF COMPARISON PHOTOMETER.

with a long straight film, A, which gives an intense and equal light for each of the openings B and B′ in a metal screen, the standard glass D being placed behind B and the photometer film E behind the opening B′. The photometer film E was held in a movable frame so that it could be easily moved up and down vertically to bring any part of the film behind the opening, and a scale F was fixed to the stationary part of the frame so that a pointer G on the movable part would give a reading showing the distance of the point on the film behind the opening B′ from the clear upper end of the film. A partition H in the box cut off any stray light and had an opening I in line with the openings B and B′ in the screen. A prism of twenty degrees K was placed with its apex vertical and 4.25 inches from the openings B and B′ in a line midway between them, and the prism was arranged to move horizontally on the bottom of the box so as to be capable of such adjustment as would bring the edge of the lighted area from one of the openings B in juxtaposition to the other B′ when seen in the eyepiece M. At 2.5 inches from the prism was a convex cylindrical lens L of ten diopters with the axis horizontal, and in the end of the box a tube with a small hole, 1/10 inch in diameter as an eyepiece at the end M, through which the light from the two openings could be seen and compared. The result of this arrangement was to give at the eyepiece M the picture shown

in Figure 6. Two light areas O and P are seen, the light of O coming through the opening B′ and the movable photometric film E, the light of P coming from the opening B through the standard shade glass D. If the film is lowered the field O will appear lighter than P, and if the film is raised the field O will become darker than P, and a point can quickly be found where, by moving the film, these two lighted areas appear to be of the same brightness, and at this point the scale F is read, giving the distance from the end of the film to the point where the density of the film behind the opening B is just equal to that of the standard shade glass, placed behind the opening B.

In order to act as a regulator and keep the intensity of the light about the same, and at a point where the retina is more sensitive, no matter whether the film E is being compared with lighter shades, of 1 or 2 magnitudes, or with a denser shade of 12 or 13 magnitudes, a second film R covering the whole field as seen in the eyepiece M, is placed behind the cylindrical lens L, and is arranged to move vertically. When the lighter shades are being tested the film R is raised so as to cut off more light, and when the darker shades are tested the film R is lowered so as to cut off less light.

Five readings were taken with the film and shade glass in the first position, then the frame holding the standard glass and film was reversed and another set of five readings was taken in the reversed position. In this way any inequalities in the instrument, such as the light absorbed by the prism, any inequalities in the light from the two openings, etc., were neutralized. The mean of these ten readings was taken to fix the desired points on the paper scale pasted on the glass of the photometric film.

The result of careful measurement of 62 of these photometers has shown that these points when laid off on co-ordinate paper form a practically straight line and, instead of measuring a point on the film for each stellar magnitude from 1 to 15, it is sufficient to measure the position of three points, say 2, 7 and 12 magnitudes, a straight line is then drawn through these three points when laid off, using the stellar magnitudes for ordinates, and the distance from the end of the photometer to the point where the lights are equal for the abscissas, and this will give a line from which the intervening points of the scale can be found with great accuracy.

TESTS AND RESULTS.

With a "simplex" photometer constructed as above, if we look at the letters on the test-types which represent a vision of 5/50 or 6/60, through the opening in the photometer case, and gradually withdraw the film, we shall find at from 9 to 10 on the scale the form of these largest letters on the test-types has become indistinguishable; in other words, by reducing the light reflected from the test-type card by an amount equal to about ten stellar magnitudes we just cause the largest letters to disappear when the test-types are illuminated by the standard light mentioned at the beginning of this paper. If we find that the largest letters are extinguished before we reach the ten-magnitude point on the photometer, it shows that the illumination of the test-types is more feeble than the standard, but if the photometer scale gives more than ten magnitudes it shows that the illumination is too bright, and by how much.

With the above standard of illumination if we test the point where the line of letters representing average normal vision of 5/5 or 6/6 disappears, we shall find that this corresponds to about 4 or 5 magnitudes on the photometer scale. This would seem to indicate that if we require a certain intensity of light, viz., the standard amount reduced by ten magnitudes, to read the largest letters, V. = 1/10 or 5/50, we require one hundred times as much, or the standard reduced by only five magnitudes, to read the smallest letters, V. = 1 or 5/5. This proportion also seems to hold good for other amounts of acuteness of vision. The distance being, as before, at five meters, and the illumination of standard brightness, the photometer readings for one observer showed normal vision, V. = 1 at 4 magnitudes, V. = 0.5 at 6.5 magnitudes, V. = 0.25 at 7.75 magnitudes. Another observer gave 5, 7 and 8 magnitudes, respectively.

If we reduce the amount of illumination by introducing a given amount of resistance into the circuit of our lamps, say 10 and 20 ohms, we find that for the largest letters, V. = 0.1, or 5/50, we get the results as given in Table 1.

TABLE 1.

	Full Current.	10 ohms.	20 ohms.	
Observer A...	10.0 mag.	8.8 mag.	8.0 mag.	Right eye.
	10.0 mag.	9.0 mag.	8.0 mag.	Left eye.
Observer B...	9.5 mag.	8.25 mag.	7.25 mag.	Right eye.
	9.75 mag.	8.5 mag.	7.5 mag.	Left eye.
Observer C.....	10.0 mag.	9.0 mag.	8.0 mag.	Both eyes.

This seems to show that as the strength of the current in these lamps is reduced there is a falling off in the amount of light reflected from the test-type card equal to about one magnitude for each 10 ohms. That is to say, for these resistances the reflected light is reduced two and one-half times for each step, and, as the ratio of the intensity of the light increases in geometrical ratio, we find that with the full current the light reflected from our test-type card is two and one-half times as bright as when a resistance of 10 ohms is placed in the circuit and is six and three-tenths times as bright as when a resistance of 20 ohms is placed in the circuit.

The differences in magnitudes and the brightness of the lights are shown in Table 2.

TABLE 2.

Difference in magnitude.....	0.	0.5	1.0	1.5	2.0	2.5	3.0	3.5	4.0	4.5	5.0
Ratio of brightness.....	1.	1.6	2.5	4.0	6.3	10.0	16.0	25.0	40.0	63.0	100.0

According to this table, if we examine two lights with the photometer and find that one light is just cut off at 3 on the scale, and the other at 5, it shows that there is a difference between these lights of two magnitudes in their intrinsic brightness, and that one light is 6.3 times as bright as the other. If we find that one light cuts off at 5 and the other at 9 on the scale, there is a difference of four magnitudes, and one light is 40 times as bright as the other.

DISCUSSION.

DR. O. F. WADSWORTH, Boston, said that he had tested Dr. Williams' arrangement in comparison with other methods. It seemed to him that this illumination is practically as good as a good North light, but there is, particularly if a white background is used, a little too much intensity. Even the yellow tint that he has given these cards might be improved on. There is no question that on very dark days one can not satisfactorily use daylight, no matter how good it may be under ordinary circumstances, and then artificial light must be employed. Within certain limits, Dr. Wadsworth thinks, there is no practical difference in the amount of vision, but there is no question that a standard illumination which every one is to use must be secured by artificial light. Dr. Wadsworth

thought the photometer very simple, very easily used, very accurate and very practical. With a standard determination of light we must have also a standard test type. These types of Dr. Williams are uniform. All the letters are to be made out with about the same ease. There is the disadvantage that there are comparatively few letters that can be used and the patient can readily become familiar with the letters. We gain an advantage in one way and lose it in another.

Dr. Nelson M. Black, Milwaukee, Wis., said that one of the main objects of the Section on Ophthalmology of the American Medical Association should be to standardize the various methods and apparatus used in testing the eyes. This has been done along some lines. We understand when a case is reported as having V. equals 6/vi or 20/20 that it represents the visual acuity measured by the Snellen standard test types at a standard distance. Dr. Black said that he had devised, and for the past five years had used, a luminous test-type cabinet (*Ophth. Record*, April, 1904), in which the letters are engraved on porcelain and transillumined with three incandescent lamps of eight candlepower each. This gives perfect and constant illumination and is less tiring to the retina than reflected light. Dr. Black remarked that Dr. Williams opened his paper with the statement that the illumination of his charts was justly criticised at Portland last year as being too intense. He asked, why shouldn't Dr. Williams be in error again? He thought that the first need is to adopt a definite standard of illumination for charts expressed in units of candlepower or some such definite standard. Then by the use of Dr. Williams' neat little phorometer one can see that the adopted standard is maintained.

Dr. Myles Standish, Boston, thought that Dr. Williams' method is radically wrong. To put a light card in a black box and have a patient look at it for the length of time necessary for an examination is wrong physiologically. To look at this card very long will tire sensitive eyes. In order to use the eyes physiologically the light must be arranged physiologically, with an even illumination. If one goes into a dark chamber and bores a hole through the shutter into the broad light and looks at it, no matter how strong the eyes are, one will have to relieve them by turning the head. The amount of fatigue that comes from looking at letters on a light background when the eyes are adjusted to a dark area is great. If the walls were constructed of some material that would not make a brilliant contrast the ability of a patient to read 20/20 after looking at it for some time would be improved. I have tried some experiments in this direction and am sure this is a just criticism. The excellent photometer I hope every one will try. It is a most beautiful little instrument.

Dr. H. V. Würdemann, Milwaukee, agreed that there is a necessity for a uniform illumination for test types. Many ophthalmologists use charts many years of age, dark-brown in color and the black of the letters hardly distinguishable in the rows of small type. Such charts can not get the full visual acuity of the eye. A chart such as Dr. Williams has presented may bring out a good visual acuity, but after looking at it for a few minutes secondary images of the chart appear on looking up at the ceiling, showing retinal fatigue, due to too great a contrast between the background and the chart. This also occurred in using the Nelson M. Black charts, which are a modification of the Moorfield charts. Therefore the background of Dr. Würdemann's room, which was painted black, had to be changed to a dark gray. With a modification of a gray background he thought the charts quite as good as the Nelson M. Black charts and much better than others.

Dr. Lucien Howe, Buffalo, suggested that there was confusion of two things: one, the illumination, and, quite a different thing, the letters. Dr. Howe called attention to the fact that twenty years ago he discussed this subject, referring to the Crooks radiometer as a very good optometer, the little thing seen revolving in the opticians' windows. It is a very excellent optometer and as a rough method will still find its use, though it is not to be compared with the very excellent method of Dr. Williams. Dr. Howe thought that this has a better scientific basis and he expects to use it a great deal. As to the letters, Dr. Howe said that Dr. Williams has been working on this subject for a number of years. Very few have given such attention to the subject as he has, and so Dr. Howe felt inclined to accept his views in the matter.

Dr. Charles H. Williams, Boston, explained that this amount of light on the card is equal to a good fair summer day's light, diffused daylight, and is equal to ten magnitudes of a photometer. That is the standard. In regard to Dr. Würdemann's criticism as to the secondary images, Dr. Williams said that one can not get any letters that are visible that will not do that after the eyes are fixed constantly on one of the letters. Dr. Williams said that as to the criticism made by Dr. Standish of the background, that would be very easily remedied by simply painting the background another color, and he sees no objection to doing that.

A NEW SUPPLEMENTARY TEST FOR COLOR VISION.*

NELSON MILES BLACK, M.D.
MILWAUKEE, WIS.

The dissatisfaction expressed by those who are required to undergo examinations for color vision is general and in railway service it even extends to the officials. This has created a demand for some test supplementary to the Holmgren wool test which is universally used.

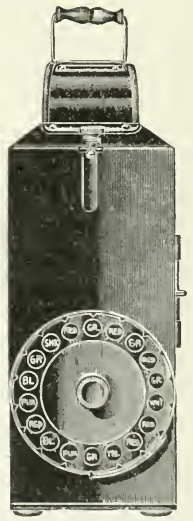

Fig. 1.—Dr. Charles H. Williams' lantern for testing color vision.

The fact that, in practice, railway men and pilots are dependent at night on light transmitted through colored glass has caused an endeavor to devise a test which shall, as nearly as possible, approximate the actual conditions; hence the lanterns. Many are in general use on a number of our largest railway systems. Dr. Charles H. Williams' lantern is probably the best in this country (Fig. 1).

It is conceded that the worsted test of Holmgren will not detect all kinds of color defects, but it must be also granted that no other known test will, and that the Holmgren test is equal, if not superior, to any yet de-

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

• The semaphore lamps used in railway service being the source of illumination.

vised.[1] "An exact test can only be made by the spectroscope by determining the limits of the spectrum and the places of the neutral lines." This, however, is not practical for use in examining railway employés.

The value of the Holmgren test lies in its requirement of a comparison of colors. This is exactly what must be done in practical work; an engineman must draw comparisons between lights of different colors at greater or less distances, with their intensity reduced by atmos-

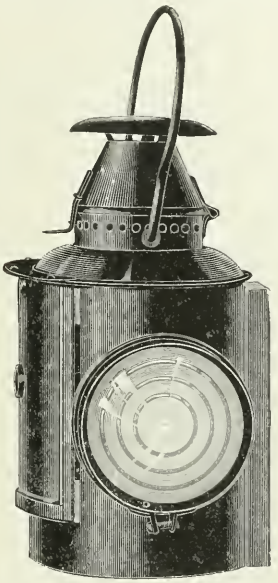

Fig. 2.—Adams, Westlake & Co.'s non-sweating ventilation semaphore lamp.

pheric conditions, by the interference of smoke or steam or by poorly trimmed lamps and dirty lenses and roundels; consequently to meet the demands a supplementary test must conform to several principles which Prof. E. W. Scripture[2] (director of the psychological laboratory of Yale) outlined in his address on "Color Blindness and Its Tests" before the New York Railroad Club:

1. The test must "fit exactly the conditions found in practice."
2. "The person tested should be required to name the objects, for that is what he does inaudibly when he is at work."
3. "The objects for testing should resemble the objects in actual use."
4. "A comparison of colors must be required."

Two more principles should be added and emphasized:

5. The test must give the impression of a signal seen at a distance.
6. The test must be such as may be conducted indoors.

The various lanterns in use fulfill the above requirements to a greater or less degree, but fail in many particulars. "To fit exactly the conditions found in practice," which really includes the fifth principle, "a signal light must be recognized by the engineman at sufficient distance in which to control his train." Mr. R. Quayle, superintendent of motive power of the Chicago & Northwestern Railway, kindly furnishes the following data, which are the result of some recent experiments in controling fast trains: "With the ordinary brake, 70 pounds train-line pressure, a six-car train running 70 miles an hour can be stopped inside of 2,000 feet, approximately 1,900 feet, and when the high-speed brake, 110 pounds pressure, is used on the same train running at the same speed the train can be stopped in 1,450 feet.[3] It will be seen that a signal must be read at not much less than one-half mile (2,640 feet), as a few seconds are necessary for the engineman to shut off his steam and apply his air, and in each one of these seconds a train traveling 70 miles an hour is covering 88 feet."

The suggestion of distance is attempted in the various lanterns by reducing the size of the opening transmitting the light, but this does not by any means meet "the conditions found in practice," as the intensity of the illumination through the small opening is the same as through the large, the source being identical; the only difference is the area of illumination. When the opening is small there are a great many radiating lines of light which give the appearance of a larger opening than really exists.

On account of the distance remaining the same with the worsted and lantern tests, there is a certain class of color defectives and *a class most to be feared* that the Holmgren test and any lantern test so far devised will not detect. These are known as chromic myopes.[2] [4] Up to a certain distance their color vision is normal; beyond they can only determine that one color is darker or lighter than another. Such cases the Holmgren worsted test will not detect, nor will the lantern, even with the small opening to simulate distance, unless they are re-

Fig. 3.—Combination disc and semaphore block.

moved beyond the far point for such individual's color sense. Dr. Charles A. Oliver[4] has called especial attention to this fault in the tests now in vogue. The effect

on a signal light from atmospheric conditions, smoke, and steam is simulated by using smoke glass of various shades for lessening the intensity, ground glass to represent fog or mist and ribbed glass to simulate rain. These produce the desired effects very well.

"The person tested should be required to name the objects"; it is unnecessary in the test for him to name the color. If the indication is recognized, that is sufficient; for instance, "stop" for red, "clear" for white or green as the case may be and "caution" for green or yellow depending on meaning of colors used. The

Fig. 4.—Diagram of first formula.

Fig. 5.—Diagram of second formula.

ignorance of color nomenclature is well known and has many times been mistaken by an inexperienced examiner for color defect.[5]

"The objects for testing should resemble the objects in actual use." The lanterns do, to a certain extent, but many of those examined are suspicious and imagine there is some trick about the lanterns.

"A comparison of colors must be required." Professor Scripture[2] calls especial attention to this important factor in the paper above referred to and suggests: "Three colors at a time is a number agreeable to the subject. It is a fact well established by experimental psychology that under ordinary circumstances the mind can not attend to more than five objects at a time; the number three is well within the limit."

Professor Scripture's[2] "color sense tester" carries out this idea of comparison. None of the lanterns I am familiar with do. One or, at the most, two lights are exhibited simultaneously. This does not carry out the fourth principle, but is a fault easily remedied. The color sense tester is not constructed to suggest the impression of distance.

In the test about to be described the optical laws are brought into operation which reduce the apparent size of an object when looking through the wrong end of an opera or field glass. The idea of utilizing this as a supplement to the worsted test was suggested while making comparative range tests of various makes of roundels.[6] This was done with the so-called "reducing lens test" used by Dr. William Churchill[7] of the Corning Glass Works, and it is through his courtesy I am enabled to adapt it for a color test.

The apparatus consists of a brass tube with a dead black lining, about 150 cm. long and 4 cm. in diameter, mounting a combination of biconcave lenses. One end is fitted with a hood similar to that used on the ordinary stereoscope, tapered to size of tube. The tube should be mounted in a screen to prevent the person being examined from seeing the source of illumination. The illumination consists of three Adams, Westlake & Co.'s non-sweating ventilation, standard semaphore lamps (Fig. 2). These are placed 400 cm. from the lens farthest from the eye-piece in the tube and form a right angle triangle, whose base is 225.8 cm. and one side 198.12 cm. from center to center of lenses in the lamps. This conforms to the arrangement of signals on one post in practice according to Mr. L. R. Clausen, signal engineer C., M. & St. Paul R. R., and Mr. J. A. Peabody, signal engineer C. & N. W. R. R. (Fig. 3).

The lenses used in the lamps are the latest pattern corrugated semaphore lens manufactured by the Corning Glass Company. This lens collects the divergent rays into a nearly parallel beam; it is 5⅜ inches in diameter and has a 3½-inch focus. The fronts of the lamps are fitted with cells very much like those in a trial frame into which the colored glass or roundels used in service may be placed. The colors used in railway service are red, green, white and yellow, but in the test these are used in darker and lighter shades to determine if the candidate can discriminate between different shades of a color.

An attempt to produce the effect of fog, mist, smoke, steam, rain and lowered intensity, due to different atmospheric conditions, is made by interposing ground glass, yellow glass and different shades of smoke glass which produce the desired effect.

The apparent reduction secured may be deduced from the following formula:[8]

$$d' = d + \frac{e\,(p)}{f}$$

d = the real distance from the light
d' = the imaginary distance from the light to the eye.
e = distance from the lens to the eye.
p = distance from the lens to the light.
f = focal distance of the lens.
The maximum reducing effect would be obtained if e = p.

As every lens reduces the intensity of a beam of light

10 per cent. by reflection, and every reflection in a mirror reduces the intensity 15 per cent., allowance must be made for the loss by the following formula:

$$d^1 = 105.4 \text{ per cent. } d + \frac{e\,(p)}{f}$$

When a second lens (Fig. 5) is used, it is necessary to calculate the distance (p_1^1) from the lens to the apparent position of the object or light behind it; this is obtained from the formula:

$$p_1^1 = \frac{p^1(f)}{p^1 - f}$$

Then p^{11} of the second lens becomes p^1 of first lens + e^1 of first lens and d^{11} becomes ($p_1^1 + e^1$) + e^{11} as indicated in the calculation following:

To ascertain the effect produced by two lenses get the apparent distance given by one, then multiply by factor $\frac{d^{11}}{d^{11}}$ for second lenses as indicated in the calculation.

The following example will illustrate using two — 20 D. lenses, with object 400 cm. from first lens, the lenses 75 cm. from each other and the eye 75 cm. from the second lens. The formula becomes (Fig. 5):

Lens 1. $d_2^1 = p^1 + e^1 + \frac{e^1 p^{11}}{f}$

$d_2^1 = (400 + 75 + \frac{75(400)}{5}) 105.4\%$

$d_2^1 = 475 + 15 \times (400)$

$(6475)\ 105.4\% = 6824.65$ cm.

Lens 2. $p^{11} = p_1^1 + e^1$ $\qquad p_1^1 = \frac{p^1(f)}{p^1 - f}$

$p_1^1 = \frac{400(5)}{400+5} = 4.94$ cm

$d_1^1 = p_1^1 + e^1 + e^{11} + \frac{e^{11}(p^{11})}{f}$

$d_2^1 = 4.94 + 75 + 75 + \frac{75\ (79.94)}{5}$

$d_2^1 = 154.94 + 15(79.94)$

$d_2^1 = (1354c \text{ or } 8.74d^*) 105.4\%$

$d_2^1 = 9.21d^1$

But Lens 1 gives apparent distance of 6,824.65 cm.; therefore, combined effect of the lenses is:

6.824.65 cm. +9.21 cm. = 62,855 cm.
62,855 cm. = 628.55 m. or 2,055 feet.

The test is conducted as follows and may precede or follow the Holmgren wool test, as is desired. If it precedes, it will often indicate what to look out for in the wool test. The person to be examined is shown the semaphore lamps arranged in the triangle with the roundels in place; a clear, red and green or any combination that is used on his road, and is informed he is to state what the signals indicate; he is then seated behind the screen and the lenses placed in the telescope tube to give the lights the appearance of being about one half-mile distance. Several combinations are made which are recorded: Signal No. 1, "danger." "stop" or red; No. 2, "caution," "clear" or green or white; No. 3, "danger" or red, as the case may be. If the candidate wishes to give the name of the color or its indication, it makes no difference. The intensity of the lights may now be varied with smoke, ground or ribbed glass, or one or more of the lights may be blocked out by placing a blank in the cell. If there is some difficulty in interpreting the signals with the apparent reduction equal to one-half mile, arrange the lens to give the apparent reduction of less than one-half of a mile and try same. Other candidates may watch the proceedings, but are not allowed to communicate with the person being examined.

The main reason assigned by Dr. Charles H. Williams[9] for a supplementary lantern test is that "some cases are able to pass the wool test correctly and without hesitation, who when examined with the lights from a distant signal may be unable to distinguish the red or green with any reasonable degree of certainty, and, in fact, often confuse these colors. This occurs most frequently in cases of acquired defect in color vision caused by excessive use of tobacco or alcohol or by a combination of the two. In such cases there is often a small defect in the central part of the retina so small that the retinal image of the skein of worsted is large enough to be formed partly within the affected area, and partly beyond it, and if any part of it falls on healthy retina its color can be at once recognized. If the object is small, like a distant signal light, the retinal image is formed wholly within the affected area, and the color is not recognized. At night there is often no other means of distinguishing between safety and danger, except by the quick and accurate recognition of the color of a railway signal or the side light of a ship, and it is of a special importance that the test for color perception should include a test resembling as nearly as possible the conditions of service and of such a kind as to show conclusively, after the test has been made, whether the person can be relied on to recognize quickly and accurately the color of a distant signal light."

Such cases are rare and it would be natural to suppose that with a relative or absolute scotoma sufficiently large to cause confusion in the recognition of a distant signal, or blot it out entirely, the form vision would be so diminished as to throw out the candidate at once. The reducing lens test will meet the demand in such a case even better than the lanterns will, because of the radiating rays from the small opening. If three lights are displayed and only two seen, or the color not recognized of the third, or the two lights displayed and only one seen, it would lead one to suspect a condition as above described, and further tests should be made to ascertain the condition.

To summarize: The test fits exactly the conditions found in practice. The objects used in testing are the same used in actual practice, the person tested is required to designate what he sees either by name or to indicate its meaning, which he does in practice. The fault of all lantern tests is overcome by simulating distance, by a relative reduction in the size of the image. The factor which gives the success to the Holmgren worsted test, that of comparison, is followed, the impression of distance is maintained, and the test may be used as an office test. The only thing we can do is to produce a gale of wind or a rainstorm or the roar and noise of the engine for the benefit of the candidate while being examined.

128 Wisconsin Street.

DISCUSSION.

DR. CHARLES H. WILLIAMS, Boston, thought that a practical difficulty is that the men can give the names to the impressions which they receive from the two lights, although they may be extremely defective in color perception. They learn to give the name of green or red to a certain stimuli which they receive, where the choice is simply between the colors they have been in the habit of using, but on testing them with different shades of red or green the defect is discovered. It comes out clearly with the worsteds and with the testing lantern Dr. Williams devised some years ago. Dr. Gardner, of

9. Williams, Charles H.: "The Need of a Supplementary Lantern Test for the Proper Examination of Color Perception." Boston Medical and Surgical Journal, July 30, 1903.

Chicago, had a bright man who was decidedly defective in his color sense and Dr. Gardner told him that it was incurable. The man said he would cure himself and in a year's time came back and Dr. Gardner could not catch him. At the end of the test, however, the man happened to pick up a piece of glass from the table, saying, "Why, doctor, where did you get that beautiful green glass?" The glass was a ruby red, but a different shade of red from that with which he had been training.

Dr. O. P. Frank, Chicago, said that the formula given by Dr. Black does not take into account that the light varies according to the square of the distance. The focal length of the lens, the thickness of the glass and the source and kind of light must also be taken into account. Dr. Frank asked the source of the value of 105.4 per cent. He quoted Dr. Black as saying that the intensity of light loses 10 per cent. by reflection. Dr. Frank thought absorption was meant. The angle of incidence, too, must be taken into account, for the absorption varies according to the angle of incidence.

Dr. W. R. Parker, Detroit, reported that he had had patients who passed perfect examinations with the worsted who afterward failed with the lantern. One man had a miniature set of skeins with which he had spent hours practicing. He had so trained himself that he could tell all of the colors, and it was only by the comparative tests, two shades of the same color, that his color blindness could be detected.

Dr. Nelson M. Black, Milwaukee, said that a change of shades can be had by slipping into the lantern any of the various shades of glass used in railroad work. This instrument is only in the experimental stage and the working out of the formula may be far from being perfect. It has been proven photometrically that 10 to 15 per cent. is lost by reflection and an additional amount by absorption. This can be seen when riding in a car at night and seeing the reflection of the whole interior of the car.

AN ANALYSIS OF FORTY CASES OF MENINGITIS IN INFANCY.*

JOHN LOVETT MORSE, A.M., M.D.

Assistant Professor of Pediatrics, Harvard Medical School; Assistant Physician at the Children's Hospital and at the Infants' Hospital; Visiting Physician at the Floating Hospital.

BOSTON.

These cases, equally divided between the tubercular and cerebrospinal forms, were all patients in the wards of the Infants' Hospital. The diagnosis was made in every case by autopsy or lumbar puncture. A marked predominance of mononuclear cells in the spinal fluid was considered diagnostic of the tubercular form, and of polynuclear cells of the cerebrospinal form. In all but three of the cerebrospinal cases the meningococcus was also found. This study was undertaken to determine, if possible, something as to the symptomatology of meningitis in infancy and as to the differential diagnosis between tubercular and cerebrospinal meningitis at this age.

GENERAL SUMMARY OF CASES.

Onset.—The onset was sudden in four of the tubercular cases, the first symptom being convulsions in three and coma in one. In the other tubercular cases the onset was slow. The onset was also sudden in four of the cerebrospinal cases, the first symptom being convulsions in three and high fever and vomiting in one. The onset was slow in seven of the cerebrospinal cases, definite symptoms pointing to the brain not developing until after from four days to two weeks. There was some vomiting in four, but no more than would be expected in any slight disturbance at this age. All had more or less fever, while in two the symptoms were those of a "cold." In the other cerebrospinal cases there were mild meningeal symptoms from the first. They were, however, not at all severe or rapid in their movement.

Duration.—The duration in the eighteen tubercular cases with complete records varied between one and forty-four days, being respectively, 1 day, 6 days, 7 days, 8 days, 9 days, 9 days, 11 days, 12 days, 13 days, 13 days, 14 days, 14 days, 15 days, 17 days, 19 days, 31 days, 31 days and 44 days. The duration in the 18 cerebrospinal cases with complete records was 7 days, 10 days, 14 days, 15 days, 18 days, 3 weeks, 4 weeks, 40 days, 7 weeks, 7 weeks, 7 weeks, 10 weeks and 6 months in the cases which died, and 4 weeks, 4 weeks, 5 weeks, 9 weeks and 3 months in those which recovered.

One of the patients who recovered developed internal hydrocephalus later and probably died. Two, at least, of the others were left paralyzed and blind.

Temperature.—The temperature was normal, or nearly so, in five tubercular cases which were under observation from 4 to 6 days at or near the end of the disease. It was also normal in four of the cerebrospinal cases during periods varying from 4 to 16 days in the midst of the disease, after which they passed from observation. It was always under 101° F. in three of each class, and went over 101° F. in 10 of the tubercular and 13 of the cerebrospinal cases. The temperature was markedly irregular in 6 of the tubercular and 14 of the cerebrospinal cases. A terminal rise was frequent in both series.

Pulse.—A slow pulse was unusual in both classes. It was under 100 in but 4 of the tubercular and 2 of the cerebrospinal cases. The lowest points reached were 70 in one case, 80 in two cases and 90 in three cases. A slow pulse was never constant, was never present at two consecutive observations and never lasted, even intermittently, more than a few days. The rate was usually rapid and was over 140 some or most of the time in 13 of the tubercular and in all of the cerebrospinal cases, in several instances being as high as 200. The pulse rate was almost always irregular in both classes and there was always a terminal rise.

Respiration.—A low respiratory rate was also very unusual. It was under 20 in only three of each class, and when low, never persisted any length of time. It went over 50 in 14 of each class. The rate of the respiration was almost always irregular and there was usually a terminal rise. Cheyne-Stokes respiration was noted in 7 of the tubercular cases and in none of the cerebrospinal. It probably occurred much more frequently than appears from these figures, however, as it was undoubtedly not recorded in many instances.

Nutrition.—The nutrition of the babies with cerebrospinal meningitis was on the whole much better at entrance than that of the tubercular cases. Emaciation was usually very rapid in both classes, although in rare instances the nutrition was wonderfully maintained in the cerebrospinal form.

Mental Condition.—In most of the cases of both types the patients were stupid or unconscious throughout the greater part of the disease. One of the tubercular patients, however, was conscious up to the last two days, and another up to the last three days of life. Stupor did not come on in two of the fatal cerebrospinal cases until after twelve days and four weeks, respectively, and three patients who recovered were conscious throughout the whole course of the disease.

Vomiting.—All the patients with cerebrospinal men-

* Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

ingitis vomited at some time. In five the vomiting occurred early and in seven late in the disease, while in the others it was present throughout. There was no vomiting in seven of the tubercular cases; in four it occurred only in the beginning and in four only late; in the others throughout the disease. Vomiting was explosive in only three of the cerebrospinal cases and in none of the tubercular.

Constipation.—Constipation was present in seven of the tubercular and six of the cerebrospinal cases, but was absent in the others. It was not marked in any case.

Restlessness.—Restlessness was noted in three of the tubercular and in none of the cerebrospinal cases.

Pain.—Pain was evident in five cases of each class.

Twitching.—This symptom occurred in six of the tubercular and in one of the cerebrospinal cases.

Convulsions.—Eight of the tubercular and nine of the cerebrospinal patients had convulsions. Nine of each class had none, while three of the tubercular and two of the cerebrospinal had none, unless they occurred after the patients passed from observation.

Neck Symptoms.—The neck symptoms, retraction, rigidity and tenderness, were much more marked in the cerebrospinal cases than in the tubercular, two or more of them being present in every case but one. They were all present in all but three cases, while in these there was either retraction or rigidity, or rigidity and tenderness. Retraction was noted in but six of the tubercular cases, rigidity in nine and tenderness in three, there being no neck symptoms whatever in eight. When they were present, moreover, they usually appeared late in the disease and were very inconstant. In the cerebrospinal cases, however, the neck symptoms usually appeared early and persisted throughout the disease, although they varied a great deal from time to time, not only in degree but in their combinations.

Paralysis.—There was no paralysis in any case in which there was no spasm. When there was spasm it was very difficult to determine whether there was or was not paralysis also, although in four of the cerebrospinal cases it was almost certainly present.

Spasm.—There was definite spasm of the extremities in thirteen of the tubercular and in fifteen of the cerebrospinal cases. It was absent in three of each class during the whole course of the disease, and in four of the tubercular and one of the cerebrospinal as long as they were under observation. Both upper and lower extremities were generally affected, but when only one was involved it was usually the legs.

Kernig's Sign.—Kernig's sign was present in three of the tubercular cases and in nine of the cerebrospinal. In three of the latter it was very marked. It was absent in eight of the tubercular and in six of the cerebrospinal cases throughout the whole course of the disease, and in four of the tubercular as long as the patients were under observation. In the cases in which it occurred it was usually inconstant and often present on but one side, the side also varying from day to day.

Knee Jerks.—The knee jerks varied from day to day in both series, being normal at one time and increased or diminished at another. They were almost always alike on both sides. They were increased at some time in eleven of the tubercular and in ten of the cerebrospinal cases; diminished in three of the tubercular and in five of the cerebrospinal and were absent in two of the cerebrospinal.

Ankle Clonus.—This was noted in but one case, which was of the tubercular type.

Strabismus.—Strabismus was noted in eight of the tubercular and in nine of the cerebrospinal cases. It is possible, however, that it may have been present in other cases and not noted.

Pupils.—Inequality of the pupils was noticed in but one case of each class. Failure of the pupils to react to light was noted in five of the tubercular and in six of the cerebrospinal cases. In most of these, however, the pupils at other times reacted to light. In the rest the reaction was always present.

The fundi were not examined in any of the tubercular cases, but were normal in five of the cerebrospinal cases, in several of which apparently the patients could not see. In one other, changes were found in the optic nerve.

Fontanelle.—The fontanelle was closed in three of the tubercular and in two of the cerebrospinal cases. It was level throughout the whole course of the disease in four of the tubercular and in two of the cerebrospinal cases, while in one of the tubercular it was level as long as the case was under observation. It was always elevated in seven of the tubercular and in eight of the cerebrospinal cases, and always depressed in one of each class. In the rest the condition of the fontanelle varied from time to time.

Abdomen.—The condition of the abdomen varied from time to time in most cases. It was always sunken in eight and always distended in two of each class. Spasm of the abdominal muscles was noted in but one case of each class. In the others the walls were always lax.

Spleen.—The spleen was palpable in three of the tubercular cases and in one of the cerebrospinal.

Leucocytosis.—The blood was examined in only four cases, two of each class. Both of the cerebrospinal cases showed a marked leucocytosis. One of the tubercular showed 9,000 leucocytes and the other 23,200.

Urine.—The urine was normal in the nine cases of the cerebrospinal form in which it was examined. It was normal in nine of the tubercular cases, while in three of the others there were evidences of slight irritation of the kidneys.

Eruptions.—There were no eruptions in any of the tubercular cases and in only one of the cerebrospinal. In this case there was a general herpetic eruption.

Lumbar Puncture.—One or more lumbar punctures were done in eighteen of the tubercular and in nineteen of the cerebrospinal cases. The pressure varied from time to time in the same case. It was designated as low in three of the tubercular and in seven of the cerebrospinal, normal in five of the tubercular and in two of the cerebrospinal, high in nine of the tubercular and in seven of the cerebrospinal, while it was not noted in three of each class. The character of the fluid varied from time to time in both classes. It was noted as slightly turbid in thirteen of the tubercular and eleven of the cerebrospinal, very turbid in two of each class and purulent in four of the cerebrospinal cases. The fluid was clear in three of the tubercular and in one of the cerebrospinal cases.

SYMPTOMATOLOGY OF MENINGITIS IN INFANCY.

It is evident from the figures just given that the picture of meningitis in infancy may differ materially from that which is given in most text-books as characteristic of the disease. Certain points of difference brought out by the analysis of these cases are especially

worthy of note. These are: the usual rapidity of the pulse and respiration; the infrequency and inconstancy of a slow pulse and respiration; the frequency of vomiting, both as an early and late symptom and the infrequency of explosive vomiting; the infrequency of constipation; the infrequency of manifestation of pain; the relative infrequency of convulsions and of Kernig's sign; the variability of the knee jerk; the absence of ankle clonus; the absence of bulging or even the presence of depression of the fontanelle throughout the whole or a part of the course of the disease in certain cases; the almost constant absence of retraction and spasm of the abdominal muscles; and the frequent diminution or absence of increase in the spinal pressure as shown during lumbar puncture. (It is probable, however, that the pressure shown by lumbar puncture often does not correctly represent the cerebral pressure.)

COMPARATIVE SYMPTOMATOLOGY OF TUBERCULAR AND CEREBROSPINAL MENINGITIS.

These figures also show certain points with regard to the comparative symptomatology of the two types of the disease which differ from the usual conception. It is noteworthy that the onset was sudden with convulsions or stupor in four of the tubercular cases, and that it was slow with no symptoms pointing directly to the nervous system until after several days or two weeks in seven of the cerebrospinal cases, while in only four of this type was there the sudden onset usually considered typical. The short duration of the disease in many of the tubercular case is very striking, being but a week or less in three and two weeks or less in twelve of the eighteen cases with complete data. The long duration in many of the cerebrospinal cases is also noteworthy, many lasting weeks or months.

The marked similarity in the degree of the symptoms in the two types is most striking. The behavior of the temperature, pulse and respiration was practically the same in both classes, as were also the mental condition, the vomiting and condition of the bowels. Convulsions and pain were about equally common. There was no essential difference in the behavior of the eye muscles. Spasm of the abdominal muscles was absent in both classes. Restlessness and twitching were rather more marked in the tubercular cases. These symptoms, however, are comparatively unimportant. The neck symptoms were much more marked and more constant in the cerebrospinal cases, while paralysis, spasm of the extremities and Kernig's sign were also, on the whole, more marked and more constant. The tendency to increased cerebral pressure, as shown by the level of the fontanelle, was also greater in the cerebrospinal form. The general condition of the babies was also rather better in this type. The spleen was enlarged rather more frequently in the tuberculous cases, but, as splenic enlargement is so common in infancy and arises from so many causes, it is probably of no importance in the diagnosis between these two conditions. The spinal pressure, as shown by lumbar puncture, was so variable and inconstant that no conclusions can be drawn from it. The character of the fluid, however, showed in a general way certain differences, the degree of turbidity being, on the whole, decidedly greater in the cerebrospinal cases.

The value of the presence of a reasonable cause for tubercular meningitis in differential diagnosis is shown by the frequency with which such a cause was present in these cases. There was a history of direct exposure to an adult with tuberculosis, usually a parent, in six. In another it followed a tuberculous knee and in two others tuberculosis of the lungs. In one it was subsequent to a bronchopneumonia and in another to whooping cough. In five cases, however, there was not only no known exposure to tuberculosis and no previous illness, but the babies were entirely breast-fed.

The examinations of the blood were too few to be of value in differential diagnosis. They showed the usual leucocytosis in the cerebrospinal form. The high count of 23,000 in a tubercular case, however, shows that the presence of a high leucocytosis does not justify the diagnosis of cerebrospinal meningitis.

Repeated lumbar punctures were done in a number of cases of both forms for the relief of pressure, the fluid being withdrawn until the fontanelle was level or slightly depressed. Improvement in the symptoms and in the patient's comfort was noticeable after each withdrawal of fluid, the symptoms returning again with the increase of the fluid. In no case, however, was any effect on the course of the disease noted.

CONCLUSIONS.

The picture of meningitis in infancy is materially different from that of meningitis in childhood and from that given in most text-books. The tubercular form has a more sudden onset and a shorter course than in later life. The symptomatology of the tubercular and cerebrospinal forms is essentially the same at this age, although the symptoms of spinal and, to a less extent, of cerebral irritation are, on the whole, more marked in the cerebrospinal. These differences, however, are insufficient to justify a differential diagnosis. The history or presence of a reasonable cause for the tuberculous form points strongly to this disease, but such evidence is frequently entirely wanting. A positive diagnosis between the two forms is impossible on the symptomatology and can only be made by an examination of the cerebrospinal fluid obtained in lumbar puncture. Lumbar puncture has no curative value in cerebrospinal meningitis, but is very useful for the relief of symptoms in both forms.

DISCUSSION.

DR. F. S. CHURCHILL, Chicago, said that Dr. Morse's experience coincides exactly with his and emphasized his remarks about the value of blood cultures. All physicians know how difficult it is to make a diagnosis of meningitis and how the blood cultures will often clear up the situation. The examination of the sediment of the spinal fluid is very important. Almost invariably it will show the character of the cells—the excess of lymphocytes, especially in tuberculosis. He asked Dr. Morse whether any differential blood count was made and if so if there was any difference in the lymphocyte count. Dr. Churchill stated that he saw an interesting case a year or two ago in which lumbar puncture was done; not, however, for diagnosis, but as a matter of scientific interest. The first puncture showed this excess of lymphocytes, but no tubercle bacilli. The diagnosis was confirmed at autopsy by finding the characteristic lesions. He also asked how many times a day examination was made for Kernig's sign. His observations show that sometimes one will find it and at other times it will not be possible to get it. At the autopsy of the case referred to one of the best pathologists in Chicago found no evidence of tuberculosis, except in the meninges.

DR. W. P. NORTHRUP, New York City, said that he thinks that there is no standard of psychical symptoms in meningitis. In the last epidemic of meningitis in New York it fell to his lot to classify and group the symptoms observed by the medical inspectors, and he came very close to the same hard rock that Dr. Morse struck. It seemed to him that the cases did not present the symptoms which would be expected. Dr. Northrup asked if there is a slow pulse in the onset of the disease. He indorsed what Dr. Morse and Dr. Churchill said

in regard to the lumbar puncture. Lumbar puncture ought to settle the diagnosis as to tuberculous meningitis. He mentioned one case in which practically no fluid could be obtained in the lower portion of the spine; on making the puncture from the upper portion as much as two ounces was withdrawn and this was repeated to take off the pressure. He said that Dr. Morse's paper is interesting in showing the variations from the standard set by the text-books. This has been observed in commission work. It seemed impossible in putting on a number of new inspectors to direct them to judge a case by a certain standard.

The lumbar puncture is also good for another purpose; for instance, in the case referred to an abscess developed in the vault of the pharynx. It seems to Dr. Northrup a good routine plan to do lumbar puncture to give some knowledge of the prognosis.

He said that during the epidemic in New York he had one patient who was sick for 155 days. She was a girl in splendid physical condition, a basket-ball player, and weighed about 120 pounds. In the last days of her illness she scarcely weighed forty pounds. This emaciation seems to Dr. Northrup to be one of the marked features.

DR. C. G. KERLEY, New York City, stated that Dr. Morse's observations coincide with his own. He agrees with Dr. Morse in regard to the value of lumbar puncture in the differential diagnosis of tubercular and spinal meningitis. Routine lumbar puncture is also valuable in another respect; for instance, it is very embarrassing for a man to make a diagnosis of tubercular meningitis, cerebral or spinal meningitis, and have the child get well after the administration of a dose of castor oil. It is bad for the practitioner and worse for the consultant. In recent examinations for the tubercle bacillus twelve cases have shown this bacillus in the meshwork of fibrin which sometimes forms in the spinal fluid.

DR. ARTHUR W. FAIRBANKS, Boston, mentioned two cases, one on account of the peculiar character of the onset, the other because of the peculiar postmortem condition. Both were cases of tuberculous meningitis in children 6 years of age. The first patient was a girl, brought to him because of uncontrollable disobedience, formerly having been a docile child. The condition began with having a temperature of about 101. The mind was perfectly clear, there being nothing but the lack of the former docility. On attempting to examine her the nearest approach was resisted with the greatest ill temper and attempts to scratch and bite. In striking contrast to this was the change which occurred eight days before death, when all resistance ceased and she allowed him to examine her with perfect freedom. Sensation was diminished. Her expression was that of having just wakened from a dream, and this same expression Dr. Fairbanks has seen in two or three other cases. She had internal strabismus in the right eye and had previously had it in the left. The pulse was at first irregular, but became normal. There was sinking away of the abdomen. There was no motor paralysis, except that of the abdominal muscles. On spinal puncture the clot in clear fluid did not reveal tubercle bacilli. She had some weakness in one extremity. The other case had been received in the ear ward of the hospital for otitis. There was improvement and transference was made to the medical ward. Tremor was noticed in each extremity. The discharge from the ear ceased completely. There was no twitching or other motor disturbance. This condition was promptly followed by ataxia and the child became unable to walk. The first thought was of an abscess in the cerebellum from the trouble in the ear, but the trouble had cleared up. During the last twenty-four hours the psychical condition changed. Dullness came over the child and it could not be prevented from falling asleep. The pulse suddenly dropped from 150 to 75, while the temperature steadily rose. Puncture of the spinal canal was made and the fluid showed a fine clot in the clear fluid. This illustrates Dr. Morse's point relative to the relief of symptoms. The child immediately brightened up, though it died soon after. The entire surface of the cerebellum was covered with tubercles and section of the vermiform showed complete caseation. The chief symptoms were ataxia and tremor, dullness of intellect, rise of temperature and lowered pulse.

DR. EDWIN E. GRAHAM, Philadelphia, said that in the differential diagnosis of tubercular and spinal meningitis he thinks almost all physicians are agreed on the value of lumbar puncture. Of course, the non-tubercular form may become the tubercular form. Recently he saw that occur in the wards of the Philadelphia Hospital. The child had been in the hospital for a non-tubercular meningitis for several months, and had been under observation in another institution for about four months. A few weeks before death, fluid removed by lumbar puncture showed the condition to have become tubercular and this was proved at autopsy. There must be a borderline where these two conditions meet, where the non-tubercular variety may become tubercular.

DR. WILLIAM J. BUTLER, Chicago, said that Dr. Morse's careful clinical study has presented the differences between a meningitis of infancy and that of later childhood so clearly that it hardly needs discussion. In the diagnosis of meningitis in infancy, however, the rigid neck, retracted neck, Kernig's sign and Babinski's sign all seem to have a minor place, whereas they are almost essential in the diagnosis of meningitis in adult life. Concerning the differentiation of tubercular and cerebrospinal meningitis, the diagnosis seems practically impossible, unless the meningococcus is found in the spinal fluid. In so far as the blood findings are concerned, Dr. Butler's experience is that they are practically valueless so far as leucocytosis is concerned, although he is in favor of the lumbar puncture because in the tubercular form one will find as high as 30,000 leucocytes present.

DR. J. L. MORSE said that no differential count of white corpuscles was made in the blood. Kernig's sign was only examined for daily; it may have been present at other times of the day when not tested. He feels that it is of comparatively little consequence. Concerning the leucocyte count and a differential diagnosis, of course, a high leucocyte count does not rule out tubercular meningitis, but he thinks that a leucocyte count almost rules it out. In regard to meningitis and the lumbar puncture, he said that at the clinic at the Infants' Hospital lumbar puncture will be done and the various fluids of spinal meningitis will be shown.

THERAPEUTIC VALUE OF CHRYSOPHANIC ACID IN DERMATOLOGY.*

CHARLES JAMES FOX, M.D.

HARTFORD, CONN.

I desire to present in this paper some clinical observations and suggestions as to the value of chrysophanic acid as an effectual therapeutic remedy locally in certain superficial parasitic skin diseases.

Chrysophanic acid is obtained from "Goa powder" which is found in the heart wood or cavities formed by decay in the wood of *"Andira Araroba,"* a tree found in Brazil. It is also found in Rhein, U. S. P., and is produced by the oxidation of Chrysarobinum, U. S. P., a constituent of Goa powder. Lieberman proved that in the latter the acid was very largely present and easily transformed by oxidation. It is a pale orange yellow microcrystallin powder, odorless and tasteless and which, on exposure, to air, turns a brownish yellow color. The remedy has long been used in Brazil, and has spread through Portuguese commerce to India and the East, while its general European and American employment is comparatively recent in certain varieties of skin disease.

It was first noticed in 1876, in London, England, in Fox's "Skin Diseases of India," and then since then it has at times been favorably endorsed as a dermatological remedy.

* Read in the Section on Cutaneous Medicine and Surgery of the American Medical Association at the Fifty-seventh Annual Session, June, 1906.

In some 65 cases of psoriasis it exerts a specific power and is therapeutically of great value. The following case reports illustrate its potency:

CASE 1.—Mr. A., aged 28, an active business man, a native of Connecticut, consulted me Jan. 28, 1906.

Family History.—Negative, except that two cousins had had erysipelas.

Personal History.—He had had no illness since childhood, except some infantile disease, but four years ago he noticed a series of patches over the extensor surface of both limbs, the tips of both elbows and both knees, and a few weeks later patches were found on the scalp and trunk. These were dry, red, primarily rounded in character, and covered with imbricated silvery adherent scales, much more copious on the scalp and forehead, but to a lesser extent on the extremities. He gave a history of treatment internally, but with little results, from arsenic, mercury and other special remedies.

Physical Examination.—Height, 5 feet, 10¾ inches; weight, 119 lbs.; temperature was 98.5; pulse, 74; respiration, 17. Lungs, liver, heart, spleen and kidneys were normal.

Treatment.—Believing that local remedies would be more effectual by removing and preventing the renewal of the scales, on January 28, I placed him on internally Pil. phosphori 1/30 grain, three times a day, and locally Unguentum chrysarobini, U. S. P., applied twice a day (10 per cent.) continued with semi-weekly observations until March 1, when pain in the epigastrium with copious diarrhea became constant, showing the maximum effect of the phosphorus, and this was discontinued. Then an ointment containing 20 grains of chrysarobin to the ounce of benzoated lard, was ordered.

Course of the Disease.—On March 8 there was some improvement. Treatment was continued. March 15: There was marked improvement, only traces of the eruption were found on the abdomen and lower extremities. Treatment was continued. March 22: He had now steadily used the ointment since March 1. There were no traces of the eruption found in any portion of the body except faint stains on the right knee. March 29: There were no traces whatever of the eruption and he had no further trouble. The dark, yellow stains had disappeared, following the application locally of weak solutions of chlorinated lime, morning and night.

My conclusions were that after a certain time the antagonism of phosphorus of psoriasis finds its equilibrium, and that the antagonism in question, although real, nevertheless had a limit which falls short of a complete cure, but that the specific value of the acid in psoriasis seems to be now unquestioned. The following will illustrate its value in 114 cases of *eczema:*

CASE 2.—Mr. B., aged 18, a native of France, consulted me Nov. 28, 1905.

Family History.—Negative, except that two sisters had the same eczema.

Personal History.—The patient has always been well since childhood, but has suffered from eczema for the past nine years with no benefit from any plan of treatment.

Physicial Examination.—Lungs, liver, heart, spleen and kidneys were normal; height 5 ft. 8¾ inches; weight, 117 lbs.; pulse was 69; temperature, 98.5; respiration, 17. Eruptions were present on the scalp, face, trunk and lower limbs.

Treatment.—The patient was placed on proper diet and the bowels were kept freely open with tonics, which constituted the only internal remedy. Unguentum chrysarobini, xx grains to the ounce of benzoated lard, was ordered applied locally twice a day.

Course of Disease.—On December 1 there was some improvement, but I ordered the ointment applied morning, noon and night. December 15: The eruption had almost disappeared; treatment was continued. December 20: The patient presented himself with all eruption absent.

It is remarkable that what seems to be no more than a common irritant should possess so peculiar specific a value. Some who are opposed to its use say that it produces an eczema, and indeed it does, but in this very fact resides its virtue. I have used it in children with excellent results.

In Herpes circinatus it is also of value. The remedy was effectual in some 35 cases.

CASE 3.—Mr. C., aged 28, came to my office Nov. 30, 1905.

Family History.—Negative.

Personal History.—He had had no illness except pneumonia, eight years ago, from which he fully recovered.

Physical Examination.—Lungs, liver, heart, spleen and kidneys were normal. He is well-nourished; height, 5 ft., 11 inches; weight, 119 lbs.; temperature was 98.5; pulse, 71; respiration, 18. The eruption was extensive. There was a cluster of vesicles near the spine of the neck extending over the scapula, then to the shoulder and axilla, whence the main line ran along the outer side of the arm until it reached the elbow when it turned inward, followed the inner side of the forearm and went across the palm of the hand, terminating by several patches on the palmar and inner side of the ring finger.

Treatment.—The chrysarobin ointment was applied (20 grains to the ounce) morning, noon and night, with the necessary tonics and laxatives in the form of aperient waters.

Course of the Disease.—On December 5 the eruption had almost disappeared. Treatment was continued. December 15: The patient had no eruption and was apparently cured. December 22: The patient called and reported no return of the affection.

In sycosis I regard chrysophanic acid highly, as seen in the report of the following (one of eleven cases):

CASE 4.—Mr. D., aged 23, a native of Massachusetts, consulted me Nov. 20, 1905.

Family History.—This was excellent, except that one cousin on his mother's side had erysipelas.

Personal History.—He had pneumonia when 10 years old with full recovery; he had no other illness until the present, which was contracted some three months ago while away on a southern trip. Prompt treatment ever since had failed to give any except temporary relief.

Examination.—Papules and pustules were present involving the beard, whiskers and moustache, also to some extent the vertex, accompanied by inflammation and suppuration especially. When the hairs were extracted they seemed to be covered with a whitish powder. The patient was very nervous and had suffered from insomnia for nearly two weeks. Lungs, liver, heart, spleen and kidneys were found normal. Pulse was 68; temperature, 98.5; respiration, 17. There was general emaciation; he was about 22 lbs. lighter than when first taken ill.

Treatment.—Epilation was ordered and 20 grains of chrysarobin to the ounce of benzoated lard twice a day with needed tonics.

Course of Disease.—On November 30 there was some improvement along the sides of the face. I ordered the ointment applied morning, noon and night, and continued epilation regularly. December 3: There was marked improvement. December 7: The patient had fully recovered. December 15: There was no return of the disease and all the affected parts had become normal.

After epilation, the application of the acid seemed to enter the pustules and to strike at the root of the disease, the contents of the pustules being converted into a white substance, doubtless effectually destroying the offending parasite. This opens a new field for favorable observation.

DERMATITIS VENENATA.

Externally the application is liable to produce a peculiar deep, almost copper-red erythema, but after a few days the skin returns to its normal appearance. This shows the detergent properties of the acid, and all stains are soon removed by using a weak chlorinated lime solution. When the application of the drug is discontinued the bright red hue gradually changes to an Indian red; then in a few days desquamation occurs, and very soon the normal white skin is the result. The

best way to apply the ointment is to rub it thoroughly into the scaly patches with a swab or tooth-brush. As it stains the nails badly, I prefer, sometimes in order to confine the ointment to the diseased tract, to rub it into a soft paste with water and to rub it over the patches, especially in psoriasis from which the scales have been removed. When this is dried, a layer of thin collodion should be applied over each patch and allowed to harden as a protective coating. Subsequently the patches are removed and the white skin appears. My favorite formula is: ℞ Chrysarobini, 10 parts; acidi salicylici, 10 parts; etheris, 15 parts; collodii flexilis add 100 parts.

Paint over the patches every day until they disappear and smooth skin appears. This preparation should be used with great caution, however, and when the skin is irritable and the congested patches are increasing in numbers it is then contraindicated, like arsenic internally. When the eruption is disappearing, or when chronic-thickened patches remain unchanged for a long time, an ointment of varying strength will effectually and speedily remove the scales and lessen the infiltration. I am not in favor of using the remedy on the scalp or face ordinarily, because it discolors the hair and conjunctivitis may follow.

706 Connecticut Mutual Building.

DISCUSSION.

DR. HENRY G. PIFFARD, New York City, gave a brief review of the early history of chrysarobin, which is made from the goa powder, and comes from Bahia, a Brazilian port. The speaker said that there is a vast difference in the various preparations of the drug that are on the market; some are slightly inert, some have very little effect, and some are very active.

DR. WILLIAM S. GOTTHEIL, New York City, said that in using chrysarobin he did not expect to get the proper effect from the drug unless the preparation was sufficiently strong to produce a decided reaction of the skin. He frequently used a 30, 40, or 50 per cent. ointment, which in that strength made a semi-solid mass, his object being to produce an inflammatory reaction in the skin. Most of the poor results from the use of the drug could be attributed to the weak or inert preparations that were applied.

DR. JAMES C. WHITE, Boston, said that he did not agree with Dr. Gottheil that it was necessary to produce a dermatitis in order to get the beneficial effects of chrysarobin. Personally, he preferred to use it strong enough to get its curative effects only, without producing a dermatitis. The latter was largely a matter of individual idiosyncrasy; in some persons a dermatitis would develop from its use, while in others such a result would never follow. The same is true of certain other drugs.

DR. R. A. MCDONNELL, New Haven, Conn., in referring to the objection to the use of chrysarobin on the scalp for fear of causing a conjunctivitis, said that he had applied it in many cases of fungous disease of the scalp with very satisfactory results, and without producing a conjunctivitis. He regards it as one of the most reliable remedies, particularly in parasitic diseases of the scalp.

DR. EDMUND L. COCKS, New York City, said that about a year ago he treated ten cases of parasitic disease of the scalp with chrysarobin with undoubted success, and without any resulting conjunctivitis or dermatitis. The scalp was first shaved, and then a solution of chrysarobin, one dram to two ounces of collodion, was painted on every second or third day, and reapplied as often as the application cracked.

DR. HENRY C. BAUM, Syracuse, N. Y., said that he thought the chrysarobin should only be used on the scalp in exceptional cases. Kaposi himself had warned his pupils regarding the possible dangers of applying the drug in that locality. Dr. Baum said that he had seen a number of cases of violent dermatitis follow the use of chrysarobin on the scalp. He recalled one instance where a physician had applied a small amount of chrysarobin to a ringworm of the nose in a young woman. It produced a violent dermatitis which extended to the eyes, and culminated in complete blindness. In every instance in which the drug was applied to the face or scalp, the case should be watched with the greatest care, and only a small area treated at a time until the individual idiosyncrasy of the patient could be determined.

DR. L. WEISS, New York, said that in using chrysarobin on the face or scalp, the possible resulting dermatitis could be prevented from spreading by the application of zinc gelatin, which acts as a compress.

GENERALIZED MULTIPLE PIGMENTED SARCOMA ORIGINATING IN THE SKIN.*

WILLIAM FRICK, A.M., M.D.
AND
FRANK J. HALL, M.D.
KANSAS CITY, MO.

The subject of this paper is generally recognized as presenting a distinct clinical picture, differing from all other sarcomata. The metastases may invade all the soft tissues. The distribution of the metastases appears to be by way of the blood stream and the lymphatics. There is always pigmentation, sometimes much, at other times little. In the same case we may find one nodule black and another white. The pigment is unevenly distributed. Some of the metastatic tumors appear entirely without pigment, while others in the same case are deeply pigmented. This pigment is the dark-brown, granular material known as melanin and is the same material that we find in normal skin and in pigmented moles. The disease is one of the most fatal of malignant tumors, and after metastases take place the case is practically hopeless.

The cases of multiple pigmented growths which are recorded as recovering either spontaneously or by arsenical treatment are evidently not of this variety, but probably can be placed in another class, described by Boeck[1] as "multiple benign sarcoid of the skin." Boeck has still further studied this disease in more recent cases and concludes that it is allied to tuberculosis, and therefore suggests the name *benignes miliar lupoid*[2] as a suitable one.

The beginning of this very malignant disease is most frequently in a pigmented mole, but not always so, as one would be led to believe by Unna's statement.[3] Crocker[4] reports a case which began as a blister, apparently due to friction on the outer side of the right foot. In the course of five months it became a fungating mass, slightly pigmented. The primary tumor was excised and followed promptly by metastatic tumors distributed through the body generally, which proved fatal in four months from the removal of the first tumor. In his report of a series of cases, J. C. Johnson[5] says of Case 7: "A most careful search failed to reveal any nevus or other melanotic growth of the skin or mucous membrane. There was no scar resulting from the removal of such tumor." In the body of his paper he intimates that the origin of this case may have been in the cortical por-

tion of the adrenal, and cites another case in which the origin was claimed to have been from the same structure. In one of the cases reported in this paper the first tumor observed was on the glans, at the edge of the meatus. In a few months this became a fungating mass, involving the entire glans penis, on account of which the penis was amputated.

Melanotic whitlow is also mentioned by Crocker and by Johnson. It was first described by Hutchinson and begins at the nail fold without the appearance of a nevus.

We must also recognize the fact that pigmented sarcomata originate in the eye, and if not early removed give rise to the same generalized metastatic tumors. There seems to be no attempt on the part of oculists to call these by any other name than sarcomata. Johnson, in his work on "Melanoma,"[6] gives statistics gathered by Eves, which indicate that of 261 cases of generalized melanotic tumors 84, or about 32 per cent., originated in the eye, while 177, or about 68 per cent., originated in the skin.

Before 1893 the disease was recognized as "multiple pigmented sarcoma." In that year Unna published his work on the origin of pigmented moles[7] or soft nevi. In this work he tries to show that these are derived from epithelium, and hence that tumors originating in them are carcinomata. To these he gives the name "nevocarcinoma," a name which he considers expressive of the character and also of the origin of the disease. The work and the opinions this great investigator gives to the world always demand consideration. His opinion on this subject gave a new impetus to the original work and caused a difference of opinion among investigators. Some agree with Unna, while others do not. In this country Gilchrist,[7] Schalek[8] and Ravogli[9] are advocates of Unna's theory. The recent work of J. C. Johnson on "Melanoma" is intended to prove that the tumor cells of pigmented moles are derived from the endothelium of superficial lymphatics.

This investigator has gone thoroughly into the histology of "soft nævi" and also of malignant melanotic tumors and his opinion is certainly entitled to careful consideration. In this work, however, he also records other melanotic growths which he unhesitatingly pronounces carcinomatous. There are also other cases of undoubted melanotic carcinomata on record. Prof. Eduard Lang[10], February 17, 1905, reported to a Vienna medical organization, (*K. K. Gesellschaft der Aerzte in Wien*) a case of very extensive growths in a man 52 years old. The duration of the disease was 23 years and very many pigmented lesions were present, which proved on histological examination, to be carcinomatous.

In 1904, Dr. W. W. Keen read before the surgical section of this Association a paper entitled: "The Danger of Allowing Warts and Moles to Remain Lest They Become Malignant."[11] This paper is of great clinical interest. It gives the clinical histories of 25 cases of malignant tumors originating in these apparently innocent growths. Some of these were sarcomata while others were carcinomata. From case histories the carcinomatous melanotic tumors appear much less rapid in their fatal effect.

Prognosis in these cases is of the very worst. Treatment seems to accomplish nothing. Arsenic and other tonics are of no avail. Coley's toxins do no good, and even the wonderful *x*-ray seems of no value whatever. The only thing that offers any encouragement is complete excision of the primary tumor. Even this fails many times, either because the operation is not radical enough, or because the tumor cells have already been carried some distance from the original site of the disease. In the first case of this series, the original growth was apparently completely excised and yet it was only a few months before metastatic tumors made their appearance. In a number of Dr. Keen's cases the original tumor was completely excised, but the operation was followed in a short time with generalized distribution and death. Yet if these tumors are excised, with a wide margin, quite early in their development, a few days after growth can be observed, we believe a fatal termination can often be avoided. The patient in the first of the following reported cases was observed rather closely by me during the last three months of his life. The development and multiplication of tumors were rapid.

Case I.—Male, aged 65. He has been married 42 years and has raised a family of four children, all of whom are living and well. His wife is also living and moderately healthy.

Family History.—His father died with pulmonary hemorrhage (tuberculosis) at 55. His mother died at 35 with some acute puerperal disease shortly after the birth of a child. One sister is living and healthy at the age of 68. One brother died in infancy; one with acute paralysis when 63 years old; one was a "hard drinker" and died at 66 directly following a spree, from some cause not known; and the last brother died at 65 with "nervous prostration." This last brother had a hard lump on one hand in the last years of his life.

Personal History.—The patient states that eczema was a family inheritance, and that most members of the family suffered more or less with this disease in youth. The patient had "scald head" from babyhood until about 20 years old. Aside from this he was a healthy man all his life until about July, 1903. His occupation was farming until 1897, first in Minnesota, then in Nebraska and Oklahoma. He served one year in the Army, under Thomas in the Civil War. In 1897 he moved to Salt Lake City and engaged in mission work—keeping rooms and providing food for the poverty-stricken class of people there.

For many years (he does not know how long) he had a mole of a brown color on his back between the shoulders. He first noticed this begin to grow in July, 1903. About a month previous to this he had a pleurisy on the right side. The mole seemed to become inflamed and painful and continued to grow. He sought medical advice and was advised to have the tumor excised, which he did perhaps two months after first observing the increase in size. A few months later he observed a growth in the right axilla and another on the right side of the neck. These were entirely subcutaneous.

Examination.—I first examined this patient in July, 1904. He came to see me because his general health seemed to be below par, and because instead of one tumor on his back a group of six or eight had made their appearance. The one in the axilla was becoming uncomfortable on account of its size. It was at that time about the size of a hen's egg and quite hard. Those grouped on the back varied in size from a pea to an ordinary marble; some were almost entirely subcutaneous while others quite decidedly involved the skin. Some were bluish in color while others seemed simply red, no pigment apparent through the skin. One of the most prominent of the skin tumors was excised for histologic examination. It was quite firm to the touch, and alveolar in structure, with a moderate amount of pigmentation.

Subsequent History.—After this he went to the sanitarium at Battle Creek, Mich., where another nodule was excised, and he was advised to return home since chances for successful treatment were practically nil. Arsenical treatment was given

a trial without benefit, also tonics such as quinin, iron and strychnin. No improvement followed, but more nodules continued to appear, and they were seen to appear farther from the site of the original tumor. As a last resort hypodermic injections of Coley's toxins were administered. Six injections were given from August 7 to September 2 without any improvement whatever, but instead, new nodules continued to appear almost daily. Since the injections rendered him quite uncomfortable for two or three days, a rise of temperature following each one, we listened to his objections and desisted from its farther use. By this time the nodules were scattered all over the body, back, abdomen, legs, arms and even the backs of the hands. Patient said he felt as though there were some growing in his stomach. As the disease advanced it seemed to progress more rapidly. About the first of October the man was no longer able to retain food, vomiting was frequent, and food taken in the stomach seemed to distress him, so he quit taking any for a week or more. Still the nausea and vomiting were present. A little later his right leg became cold and numb —due to pressure of a large tumor as ascertained at autopsy. October 26, at 10 p. m., he died, and at 9 a. m. October 27, an autopsy was held.

Autopsy Report.—Man, 6 feet 2 inches in length, emaciated. Tumors distributed over the surface of the body generally. Small on abdominal surface and purple blue. Over back, larger and black in color, elevated mushroom-like. Subcutaneous fat practically nil. Abdominal cavity contains small quantity of gas. Pericardium full of fluid. Whitish-red tumor nodules on the surface of pleura and liver, in mesentery and in the epiploica of colon. They vary in color from pinkish white to dark liver color. Small amount of serous fluid in abdominal cavity. Dilated gall bladder filled with bile and reaching to crest of ileum. Thoracic duct full of nodules. Large white nodule situated at the bifurcation of the iliac artery. The stomach presents a large dilatation at the cardiac end and appears diminished in size at the pyloric end. Stomach is slightly adherent at spleen. Large masses of tumors cover a diphragmatic hernia at the cardiac end of the stomach. Half pint of bile-stained fluid in stomach. No nodules in the stomach. Pancreas contains tumor nodules throughout its length. Large tumor masses at head of pancreas occlude common duct, causing dilatation of gall bladder. Left adrenal gland much enlarged and full of tumor nodules. Left kidney normal in size and contains a few subcapsular tumors and many in the perinephritic tissue. Large quantities of clear fluid in left pleural cavity. Left lung small and flabby. Peribronchial portion contains tumor masses. The upper portion of lower lobe is emphysematous. Section into this region reveals a quantity of greenish-yellow pus. Right lung normal in upper portion, but presents consolidation in lower half and over the surface is scattered a small number of white nodules. The consolidated portion when cut discharges quantities of bloody fluid. No deep-seated nodules discovered. Pericardium full of nodules greatly thickened and distended by straw-colored fluid. The heart presents innumerable tumor elevations over its entire surface, destroying the landmarks of the organ. Nodules are all firm and vary in color from white to a deeply pigmented—almost black. Liver is normal in size, of a dark brownish color, mottled with lighter areas and presents on its surface several nodules.

The most striking thing in this case is the great tumor development on and through the heart, and next to this the number developed in the thoracic duct.

We are indebted to Dr. Geo. M. Gray of Kansas City, Kans., for the history of this case.

CASE 2.—Male, aged 33, was admitted to St. Margaret's Hospital, Nov. 17, 1904. Nationality Irish, single, occupation, stone-cutter. Residence, Kansas City, Mo.

Previous History.—He had what was supposed to be a chancre 18 months ago, and after treatment for a period of six months the penis was amputated. (The surgeon who amputated the penis writes that the growth was cauliflower-like and involved the entire glans. He saw the case first Dec. 11, 1903, and performed amputation Dec. 22, 1903. He supposed it a case of syphilis and gave antisyphilitic treatment. The enlarged glands in the groin diminished in size after the amputation. The patient disappeared from his observation about three weeks after operation.) At the time the penis was amputated the inguinal glands were enlarged and one in either groin above Poupart's ligament was as large as the end of the index finger. These continued to grow after the penis had healed, and one on the right side broke down, discharging a very offensive fluid, and on account of this condition he applied to St. Margaret's Hospital.

Family History.—His father is dead; his mother is living and in good health. One brother and three sisters are living and in good health.

Present Illness.—The trouble began 18 months ago with a sore on the penis near the meatus, which persisted in spite of all treatment for six months, when the penis was amputated. This sore made its appearance about three weeks after venereal exposure and was supposed to be venereal. Before the penis was amputated the glands in both groins began to enlarge, but following the amputation he thinks they diminished somewhat except the larger ones. During the past 11 months they have been steadily enlarging until two weeks ago, when the mass on the right side broke down, discharging a bloody fluid of very bad odor.

Examination.—This revealed a large mass on each side of median line well above Poupart's ligament. One on right side was ulcerated. These masses were excised Nov. 21, 1904. At the time of operation I could make out nodular masses extending down into the pelvis on either side supposed to be glands.

Postoperative History.—He left the hospital Jan. 26, 1905. Before he left it was observed that something was not right mentally; and he left the hospital without permission or advice from the doctor. After this date we lost track of him for 18 days, but we can readily understand that during these days there was continued development of tumors with more evidences of brain disturbance. On February 13 the ambulance of the Kansas City General Hospital was sent to move him from a rooming house to the hospital. It seems the driver or those in charge of the ambulance did not fully appreciate the man's condition and he was permitted to fall down a flight of stairs. He was picked up in an unconscious condition and taken to the hospital, where he died the next day without regaining consciousness. The autopsy was made about 24 hours after death. The development of the sarcomatous tumors in the brain was considered sufficient to account for the mental disturbances noticed in the last few weeks of his life and for the unconscious condition 24 hours before death.

Autopsy Report.—Male, aged 33, length 5 feet 7 inches, weight 140 pounds.

External Appearance: The whole anterior surface of the body is covered with dark, smooth nodules varying in size from a wheat grain to a walnut and having a pale blue color through the skin. The glans penis has been amputated and there are operative scars in both inguinal spaces.

Brain: On removing skull the brain is found to contain several deeply pigmented nodules about an inch in diameter that adhere to the dura.

Abdomen: On opening the abdomen the intestines are found to be collapsed and the great omentum crumpled up under the stomach. Abdominal cavity free from fluid. Mesentery of small intestine full of blood. Duodenum bound down by adhesions.

Stomach lies well to the left of body and contains fluid; surface is smooth. From cut surface tarry blood exudes.

Liver is somewhat large, right lobe dark prune color. Right adrenal taken away with liver. Liver contains no nodules, but cut surface is a dark mahogany brown and blood exudes from it. Gall bladder is normal—free from stones.

Spleen normal in size, olive-shaped, anterior portion contains chestnut-sized nodule which is soft in consistency and contains cystic center.

Pancreas normal in size and position. Splenic end enveloped in adhesions containing tumor nodules.

Sigmoid flexure shows large lymphatics.

Left kidney possesses no perinephritic fat and lies in normal position. Adrenal attached to kidney. Kidney surrounded by a

mass of tumors which lie external to the gland. Section of organ shows reddish-brown surface, uniform in color except at tips of pyramids, which are whitish. No nodules in kidney. Right kidney surrounded with a quantity of clotted blood. Organ similar to left except that there is a large nodule within the pelvis. Retroperitoneum full of nodules along the line of great vessels especially. Some tumor masses in the anterior peritoneum.

Thoracic Cavity: Lungs collapsed, left free and right adherent in upper portion where the apex is tightly fixed and contains many calcareous deposits. Lungs present hypostatic condition in posterior part. Anterior portions crepitate throughout. Nodules of various sizes all through the lungs. Pericardium covered with nodules up to the size of a pea. Pericardium contains small quantity of fluid. Two dark corn-grain sized nodules situated at base of heart near pulmonary artery. Small quantity of thin blood in right heart. Left heart contains tarry blood. Valves of the heart normal and muscles also normal.

Within the urethra near where the glans was amputated is a small, black, pea-sized tumor. It is situated in the mucosa

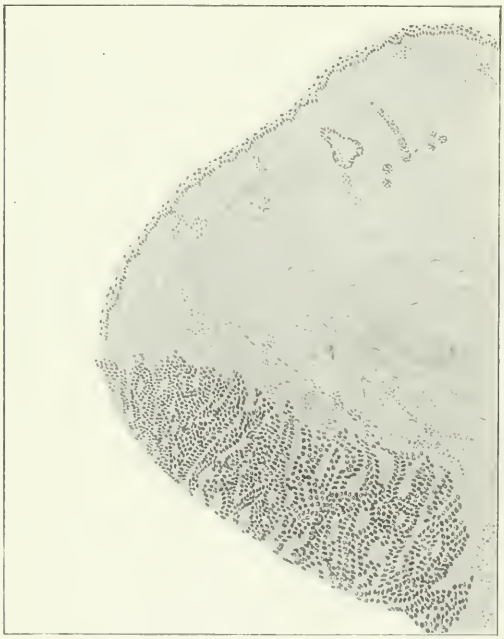

Fig. 1.—Low power drawing from a small, cutaneous nodule from Case 1.

and tends to obstruct the lumen of the urethra. The tunica vaginalis of the right testicle contains fluid. A few pea-sized tumors are found beneath the tunica. Within the testicle substance one small nodule. Left testicle contains no palpable tumor.

The point of greatest interest in this autopsy was the discovery of the tumor in the urethra. It was very dark, in fact the blackest one found and involved only the mucous membrane. We were led to speculate on the possibility of this being the real primary tumor in this case. I have not been able to find, in the literature, another case of the original tumor developing on or in the penis. Cases of sarcoma of the penis have been reported, but not of this variety, so far as I have been able to ascertain.

CASE 3.—This case was in the practice of Dr. George W. Davis. Dr. Reyling made the histologic examinations and sent specimens to various other pathologists. It has been reported as Case 3 in Dr. Johnson's[12] series of cases. The photographs are of this case and show the distribution of the tumors over trunk, arms and face. Tumors were also on the other parts of the body. The photographs were taken and kindly furnished me by Dr. J. W. Perkins, who saw the case in consultation. The history of this case was difficult to obtain, but the origin was supposed to be in a pigmented mole. The tumors were extraordinarily numerous and very dark. Dr. Johnson says, in his report, that the very dark color was due partially to minute hemorrhages into the tissue.

We wish to place case 4 on record as it is one of the infrequently observed cases of melanoma occurring in the black race.

Patient.—This was a colored woman who came to the Kansas City General Hospital about two years ago because of a decline in health and the general development of tumors all over her body. She was about 30 years of age and of good muscular development. No family history was obtained by me.

Examination.—Her skin was a dark brown, but the tumors were much darker than the other skin. They varied in size from a pinhead to a good-sized marble, and some of them stood out very prominently, in shape resembling very much an or-

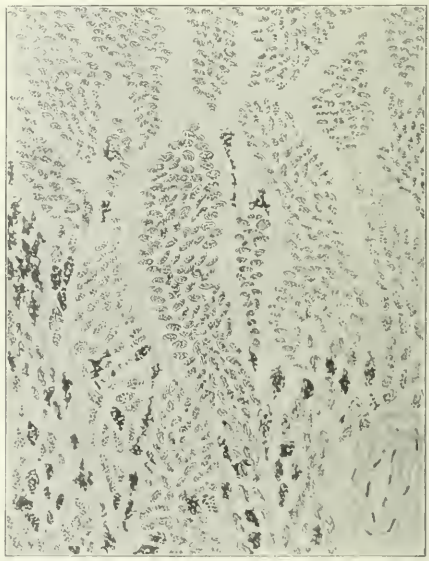

Fig. 2.—High power drawing from the same, showing alveolar structure, distribution of pigment and type of cell.

dinary, smooth doorknob. Many of these tumors left no doubt of the involvement of the skin in the growth, while others seemed to be subcutaneous. The origin was said to be in a mole. In the week that this patient was at the hospital many new tumors were observed springing up. The case was certainly one of this character.

Dr. T. C. Gilchrist[13] reports a case in a negro man, with microscopic report of tumors, and remarks that he could find but two other cases recorded in colored people. We intended securing a nodule for histologic examination and also a photograph of the patient, but she escaped from the hospital before either could be done, and was not heard from afterwards.

DISCUSSION.

DR. DAVID LIEBERTHAL, Chicago, said that he thought the title of the paper presented by Dr. Hall was misleading. Instead of multiple pigmented sarcoma, it should have been melanosarcoma. The name multiple pigmented sarcoma should be limited to the type first described by Kaposi in 1879, of which there are over a hundred cases recorded. This type differs from melanosarcoma in its clinical aspects and course. It usually first develops on the dorsal surface of the hands and feet, and gradually spreads upward, at last invading the internal organs, such as the liver and intestines, especially the large intestine, terminating fatally in six, seven or even twenty years. It never develops from warts, but has its origin in apparently normal skin. In its histologic appearance it differs markedly from melanosarcoma in the arrangement of the cellular elements. The pigment in melanosarcoma is mostly melanin, while in the multiple pigmented form hemosiderin is prevalent. Both of these forms of sarcoma, Dr. Lieberthal said, are ultimately fatal. With melanosarcoma the course is usually a brief one. As regarded treatment, nothing seemed to have any influence but the *x*-ray, which, according to latest reports, benefits materially the lesions of the multiple pigmented type.

DR. A. RAVOGLI, Cincinnati, said that he agreed entirely with Dr. Lieberthal regarding the distinction between multiple pigmented sarcoma and melanosarcoma. He recalled a case of the latter affection which proved fatal in the course of four or five months. It first appeared as a small, warty growth on the foot, and was followed in a short time by an enormous enlargement of the glands in the groin, and the case rapidly progressed to a fatal issue. Dr. Ravogli also mentioned a case of multiple pigmented sarcoma of the Kaposi type, consisting of smooth, brownish spots on the leg, and which ran a course extending over a period of five years. These cases, he said, must also be differentiated from melanosarcoma, of which affection he saw an instance in a woman who presented herself with an apparently simple lesion which was regarded as a nevus. Starting from this lesion, the disease rapidly spread over the chest, the breasts also becoming involved, and the patient died in the course of four or five years, in spite of the use of the *x*-ray. Large doses of arsenic were also given without avail. It is important to differentiate between these three affections, he said, especially on account of the different prognosis that is attached to each.

DR. ALEXANDER J. ANDERSON, Newport, R. I., reported a case that came under his observation about 18 months ago. The patient was a woman who had had some glands removed from the left groin about five years before, which were supposed to be carcinomatous. When Dr. Anderson first saw her, about 18 months ago, she had a pigmented lesion about the vulva, which was removed by a surgeon. It had the appearance of a melanotic growth, but the pathologist pronounced it a lymphoma. A year later, when Dr. Anderson again saw the woman, the pigmentation at the site of the previous lesion was well marked and she had a new growth, about the size of a duck's egg, in the right groin, which proved to be a melanosarcoma. The patient recovered from that operation, but before she could receive further treatment, metastatic growths developed in the breast and elsewhere, which proved fatal in the course of a few months.

DR. B. W. STEARNS, Binghamton, N. Y., stated that he had given the subject considerable attention for the past six years, and he is inclined to believe that too much emphasis is laid on the classification of malignant growth and too little on the treatment. He also referred to the fact that the course and development of these growths seems to be influenced by the constitution of the patient. Their locality and other factors should be borne in mind in diagnosis. Thus far the only treatment accepted by the profession generally is the early removal either by the knife or by caustic pastes. If all the physicians of a city or certain locality would place all cases of malignant growths under the care of one physician who is interested in the subject, perhaps in the future some more successful line of treatment might be developed. He referred to a case of epithelioma of the temple which was excised. At the same time there was some enlargement of a section of the parotid gland, which was not interfered with, the reason given by the surgeon being that it would have destroyed the duct. After three years the growth returned at the site of the original lesion and gradually extended over the face. A fatal issue is expected, and all that can be done for the patient now is to keep her comfortable by the application of a dressing which relieves the pain and removes the offensive odor. The dressing in this case is:

R.	Thiosinamin	gr. xx	1 | 3
	Atropini	gr. i	06
	Adrenalin, chl. solut.		
	Ergotini		
	Fld. ext. thuja, āā	ʒss	2
	Cocainæ hydrochlor	gr. x	6
	Alcoholis dil. q. s.	ʒi	30

This was applied with absorbent cotton and gauze daily.

DR. HALL said that he is not in a position to discuss the subject in a clinical way, as his work is limited to pathology. He agreed essentially with the statements made by Dr. Lieberthal.

THE TREATMENT OF LATERAL CURVATURE OF THE SPINE.*

ROBERT W. LOVETT, M.D.
BOSTON.

The treatment of lateral curvature of the spine presents the most difficult problem in the orthopedic surgery of to-day. This is, in part, because of the intrinsic difficulty of the problem and, in part, because the treatment of this condition has been, in a measure, relegated to the domain of gymnastics and, to a certain extent, set apart from other surgical deformities and considered as an affection outside of the ordinary surgical principles.

The treatment has consisted, in a large measure, of inadequate and irrational gymnastics sanctioned by tradition and often carried out by persons with a very imperfect knowledge of the subject.

The following statistics[1] collected among school children show lateral curvature of the spine in a surprisingly large percentage of all cases:

	Number of Children.	Per cent. of Scoliosis.
Guillaume (Neuchatel) ..	731 (boys and girls)	29
Krug (Dresden)	1,418 (boys and girls)	25
Hagmann (Moscow)	1,664 (girls)	29
Kallbach (Petersburg) ..	2,333 (girls)	26
Scholder (Lausanne) ...	2,314 (boys and girls)	24.67

There is no reason to suppose that American children are any less affected than the children in Germany, Russia and Switzerland.

Any pathologic condition which affects 25 per cent. of the children of a community is worthy of serious consideration. The deformity should be considered as a definite surgical problem to be met by adequate surgical means.

In taking up the treatment of this condition it is of great importance to recognize two distinct types which have not been sufficiently separated. These are (1) the postural or functional and (2) the structural or organic type.

THE POSTURAL OR FUNCTIONAL TYPE.

This type of lateral curvature of the spine has been described as "lateral curvature without rotation," faulty attitude, functional malposition and by similar names,

* Read before the Surgical Section of the Medico-Chirurgical Faculty of Maryland at Baltimore, Dec. 15, 1905.

1. The data on which much of this paper is based are contained in these articles: R. W. Lovett: Boston Med. and Surg. Journal, June 14, 1900; Oct. 31, 1901; March 17, 1904; Sept. 28, 1905. Also Am. Jour. of Anatomy, vol. ii, No. 4, p. 457. Schulthess, Schanz and Lovett: Verhandl. d. Deutsch. Gesellch f. Orth. Chir., vol. iv.

all of which are fairly descriptive. It is characterized by a single curve of the spine of slight degree, the deviation of the most divergent of the vertebræ being rarely more than an inch from the median sagittal plane of the body. This median plane of the body is best recognized by holding a string with a weight on its lower end behind the patient which serves as a plumb line falling below in the cleft of the buttocks. The spinous processes of each of the vertebræ should be marked on the skin by ink or a flesh pencil. In the normal spine each one of the marks should lie under the plumb line, and total scoliosis is recognized by a gradual sweep of the vertebral column, most often to the left, 90 per cent. of all cases of total scoliosis being to the left and 10 per cent. to the right.

Taking this, the most common type of postural curvature, the left total curve, the diagnostic points are four.

1. The spine is involved in a gradual sweep, with the convexity to the left, returning nearly or quite to the median line at the top.

2. The left shoulder is high and the right shoulder is low.

3. In looking down on the child from above, the shoulder girdle is seen to be twisted in its relation to the pelvis and no longer lies in the same plane, the right side of the shoulder girdle being carried back and the left side forward. This is clearly seen by standing above the child and sighting the back of the upper thorax against the buttocks, when it will be seen that the right side of the shoulder girdle is further back than the left. This is an expression of the rule that a spine can not be bent laterally without at the same time twisting.

The attitude is, therefore, a physiologic malposition within the normal movements of the spine and implies no organic change in the vertebræ, ligaments or muscles. Such changes exist, of course, in cases of long standing, but so long as the type described persists there is no evidence of anything further than an exaggerated physiologic position.

4. If the child with a left total scoliosis bends forward until the trunk is horizontal, the right side of the back is generally to be found higher than the left when one glances along the level of the spine from behind or in front. The elevation is very slight and has been the cause of much discussion, having been very imperfectly understood and being described under the names of concave-sided torsion, retro-torsion, etc. It is evidently merely the persistence of the backward twist on the right side described under the previous heading, which is carried over into the position of forward bending. It is to be reproduced with the model or child who stands with the right foot on a book and is within the physiologic limits of the normal movements of the spine. Postural scoliosis is, therefore, best described by the name "faulty attitude," and its treatment is greatly cleared up by this conception. Such postural curves may persist unchanged as total curves, they may be cured, or they may be changed into compound structural curves.

Transitional cases from the postural curves to structural curves are, therefore, to be expected, and it is well to be on one's guard against apparent cases of postural scoliosis in which one or more of the signs described are wanting, as many of these on investigation will be found to be cases changing from postural to structural types.

STRUCTURAL OR ORGANIC LATERAL CURVATURE.

In this form of lateral curvature there is to be found an organic change in the vertebral column and its attached structures. Structural curves may be either single, involving the whole or a large part of the spine, in a curve convex in one direction, or they may be compound (combined), consisting of two curves in different parts of the spine with their convexities in opposite directions. Even three curves may be seen, one being the principal curve with two curves in the opposite direction, one above and one below. One curve is evidently the primary one and the others are spoken of as secondary or compensatory, although it is not always possible in severe cases to identify the original curve.

The characteristic feature of structural scoliosis is the presence of a backward prominence of the chest or loin on the convex side of the lateral curve, that is the side toward which the spine yields. In the postural scoliosis described above it has been seen that the backward prominence is on the concave side of the lateral curve, that is to say, in a left curve it is on the right side. In structural scoliosis this prominence, on the other hand, is always on the left side in left curves and on the right side in right curves. In extreme cases it forms a very great deformity and can be clearly seen when the patient stands erect. In mild cases the patient must bend forward with the trunk in the horizontal position to enable this so-called rotation to be clearly evident when it is noted in a difference of level of the two sides of the thorax or of the two sides of the lumbar region. This convex-sided rotation is not within the normal mechanism of the spine and is to be regarded as a superadded pathologic phenomenon due to the yielding of the structures forming the vertebral column. In many cases we can assign no better cause for it than to assume an abnormal plasticity of bone in the individual case which has led the vertebræ, under the influence of unequally distributed weight, to yield to one side and in yielding to twist.

In case of every structural lateral curvature, therefore, we have two elements to consider: (1) the lateral curve and (2) the twisting of the vertebræ toward the convexity of the lateral curve (the rotation). The curved region in structural lateral curvature becomes stiff and loses much of its mobility, while distortion of the body outline, prominence of one hip, elevation of one shoulder and a lack of symmetry in various directions are the expression of the condition. The vertebræ are changed in shape, the ligaments and muscles on the convex side shortened, and a very decided resistance to the restoration of symmetry exists in the column and its attached structures. It is evident, therefore, that the same treatment is not required for the postural and structural cases, and the two varieties of treatment will be discussed separately.

TREATMENT OF POSTURAL SCOLIOSIS.

Defining postural scoliosis as faulty attitude, it is evident that the treatment consists in the substitution of a correct attitude for the faulty one. The prognosis is good for a complete recovery and efficient treatment is satisfactory. The correct attitude is to be obtained by restoring flexibility to the column if it is limited on one side, by exercises consisting of bending to one side, hanging, circumduction of the trunk and similar simple exercises. Having a column flexible in all directions to work on, the patient is then given what amounts to the "setting up drill" of the recruit in the American

army. In other words, he is taught to stand correctly by a series of exercises maintaining the erect position. The treatment lies within the range of any good teacher of gymnastics who will carry out the instructions of the surgeon.

The causes of failure are to be found in the fact that such children are generally in poor muscular condition and are often overworked at school or under unfavorable conditions at home. Having placed the patient under the most favorable conditions obtainable and having corrected errors of vision if they exist, having built up a short leg if it is present, having removed the entire weight of the clothing from the tips of the shoulders (where it ordinarily is carried by the child's waist), the patient should work on the exercises described for from half an hour to two hours a day for a period of some weeks. The exercises should not be pushed beyond the limit of fatigue, and after the active period has ceased the child should do home gymnastics and be kept under supervision for at least a year. The length of treatment, the period of the exercises and the extent to which they can be pushed will depend on the vigor of the child, as half-way measures are not likely to be successful and exercises done at home under the supervision of careless parents are less efficient than those given by persons trained in the art of gymnastics.

THE TREATMENT OF STRUCTURAL LATERAL CURVATURE.

The treatment of structural lateral curvature presents a much more serious and much less encouraging problem than the treatment of postural cases, for reasons which must be self-evident. It must be repeated that there are two elements to be attacked, the lateral curve and the rotation. The spine is stiff in the curved portions, the vertebræ are, to a certain extent, distorted, gravity is at work many hours of the day to continue the deformity, and measures must be vigorous, adequate and surgically sound to produce a permanently satisfactory result. Under good conditions and adequate treatment structural lateral curvature in young children of a moderate grade should be cured, in older children it should be permanently improved, and in adolescents and adults very great improvement in symmetry of a permanent character is to be obtained under efficient treatment.

The causes of failure lie in the unwillingness of the parents or the patient to submit to sufficiently long-continued and effective treatment to remedy a condition which, on the slightest consideration, can be seen to be one which is necessarily difficult and resistant.

The gymnastic treatment has fallen into great disrepute by its careless and indiscriminate use in cases of this class, and the treatment by braces or jackets alone, on the face of it, is unsurgical and inadequate. Merely to hold a stiff column in a position of deformity by a brace or jacket, as is so often done, is no treatment at all and is a detriment rather than a help, because it leads to atrophy of the muscles which are always trying to maintain as erect a position as possible.

The surgical treatment of structural lateral curvature, therefore, must consist of two divisions: First, to loosen up the stiffened parts of the spine to make an improved position possible, and, second, to hold the improved position when it has been rendered possible. These two elements are not sufficiently separated as a rule in treatment; they frequently go hand in hand and treatment must often be simultaneous for both, but it adds very much in a clear formulation of treatment to keep the two things perfectly separate. They will, therefore, be discussed separately.

A. TREATMENT TO LOOSEN UP THE SPINE AND MAKE AN IMPROVED POSITION POSSIBLE.

1. Gymnastics.—The object of free standing gymnastics is, by side bendings of the spine to increase the flexibility of the stiffened portions and to cultivate the muscles which aid in maintaining the erect position. The method is open to the objection that the force exerted is not sufficiently localized, but is distributed over the spine. It is essential that the pelvis should be fixed during such exercises as otherwise the pelvis is displaced and the movement becomes a general and not a local one. So far as lessening the curves in cases of even moderate severity goes, the treatment can not be regarded as wholly efficient and, although perhaps the commonest type of treatment in general use, it is not, as a rule, accompanied by satisfactory results in any but the slighter cases.

Such exercises should be simple and corrective in the strict sense; that is to say, an exercise which is of use should be seen to straighten the spine visibly. Complicated exercises are dangerous and unsurgical. This part of the work lies within the capabilities of any competent, properly educated teacher of gymnastics who will observe the case carefully and will be satisfied to give only exercises which can be seen to secure an improved position. Such work to obtain results must be given by a competent gymnast for a period of from one to three hours a day, according to the vigor of the patient, and must be continued under personal supervision for a period of some weeks to obtain satisfactory results. After this exercises at home can be substituted for part of the personal work.

2. Gymnastics Given in Apparatus. — By means of apparatus constructed on the pendulum principle, gymnastic exercises can be very much more correctly localized and the work of loosening the spine and of strengthening the desired muscles can go hand in hand. This method, which is in general use in Germany, has never found a foothold in this country on account of the complicated and expensive apparatus. It is suited to all cases, except the severest, and used for a proper period of time is capable of producing most excellent results.

3. Passive Stretching of the Spine.—Passive stretching of the spine with a view to restoring mobility and making an improved position possible in the curved portion is generally secured by hanging by the arms and by traction on the head by means of a Sayre sling. A pull in the length of the vertebral column is not, however, an economical use of force. The hardest way to straighten a bent stick is to pull the two ends apart, and the easiest way is to press the point of the curve against the knee, while the two ends of the stick are held with the hands. The advantage of traction made on the head in this way lies in the fact that the corrective force is distributed through the whole column.

Apparatus for the purpose has been devised and is known as the Weigel-Hoffa frame in which the patient is suspended by the head, while pads are run in from the sides of the frame, making lateral pressure in various directions. Here, again, the use of force is not economical, as traction in the length of the spine tends to stiffen it against side pressure. In other words, more displacement is possible in a slack than in a stretched spine. Some experiments were made on the cadaver,

with a normal spine, where a side pull with twenty-five pounds was made, the pelvis and shoulders being fixed. A traction force of seventy-five pounds was put on the head and a side pull of twenty-five pounds made. Under these conditions it was possible to secure only half as much side displacement of the spine as when traction was not used. A confirmatory experiment was made with a healthy boy of 15, using seventy-five pounds of head traction and fifteen pounds of side pull, and the result was the same.

Traction on the head is, therefore, not an economical application of corrective force, and when traction is used, lateral corrective force displaces the spine less than when traction is not used.

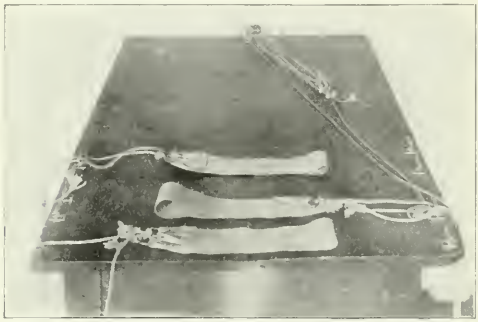

Fig. 1.—Stretching board with loops, ready for application.

Stretching of the lateral curve of the spine is, therefore, to be obtained most economically by pressure on the slack spine, which is most easily secured by having the patient lie prone, and the corrective force should be divided into two elements, the force to correct the rotation and the force to correct the side deviation. A simple apparatus for this is as follows (Fig. 1):

Fig. 2.—Stretching board with loops applied to patient.

The patient lies face downward, with the knees flexed, on a board three feet wide by four feet long. Assuming the case to be of a right dorsal curve, a broad canvas strap is passed around the left upper thorax, over and under the patient, and fastened to a cleat on the right side of the board. This furnishes a point of pressure to the left against the upper thorax at the level of the axilla. A broad canvas strap is then passed around the pelvis of the patient above and below and is fastened to a cleat at the right side of the board. This furnishes a point of pressure to the left at the level of the pelvis. A broad canvas strap is then passed around the thorax at the level of the greatest point of curve; it passes above and below the thorax and its upper end is fastened to a cleat at the left side of the board (Fig. 2). Its lower end is fastened by means of a string into a compound pulley attached to a cleat at the left side of the board. By means of this pulley any reasonable degree of force may be exerted against the right side of the thorax, pulling it to the left and

Fig. 3.—Machine for intermittent correction applied to patient.

at the same time that it pulls it tends to reduce the rotation from the fact that its upper end is fastened and its lower end moving toward the pulley.

A better and much more efficient appliance has been made by Dr. Z. B. Adams of Boston.

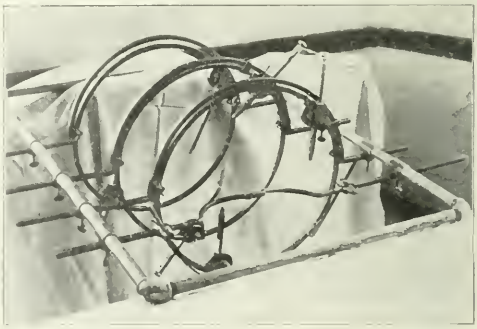

Fig. 4.—Apparatus for forcible correction by plaster jackets.

In this a patient lies prone, with the knees flexed, on a table which is split transversely into five parts. The lower one, on which the pelvis rests, is furnished with two sliding wooden horns which hold the pelvis firm. The next three pieces are provided with a pad sliding in from the side and a pad coming down from the top. These three movable pieces slide from side to side and also rotate on a gas pipe running the length of the table longitudinally. The patient is placed in the apparatus, the pads are adjusted to the side and back of the loin or thorax, or both, and by side pressure and a twisting of each arm, both rotation and lateral deviation are corrected separately at each level. In this way it is possible to correct both lateral deviation and

rotation at one, two, or three levels for the purposes of stretching the spine by directly applied pressure. The top part of the table farthest away from the pelvis of the patient is fixed, and on it rest the arms and head.

The patients are stretched daily in this apparatus and left in the corrected position for as long a time as can be borne comfortably, generally from fifteen minutes to half an hour.

4. Stretching by Means of Plaster-of-Paris Jackets (Forcible Correction).—In severe cases of structural lateral curvature no means of treatment is so efficient as continuous stretching by means of plaster jackets applied under force. This method is spoken of as "forcible correction." Such jackets are applied in the hope of stretching the contracted structure and of inducing an improvement in the curve. By virtue of their being at work day and night they accomplish much better results than are to be obtained in any other way.

Corrective jackets should be applied to the patients prone, and preferably with the legs flexed, as this diminishes the physiologic curves of the spine and further simplifies the problem. With a patient thus lying prone,

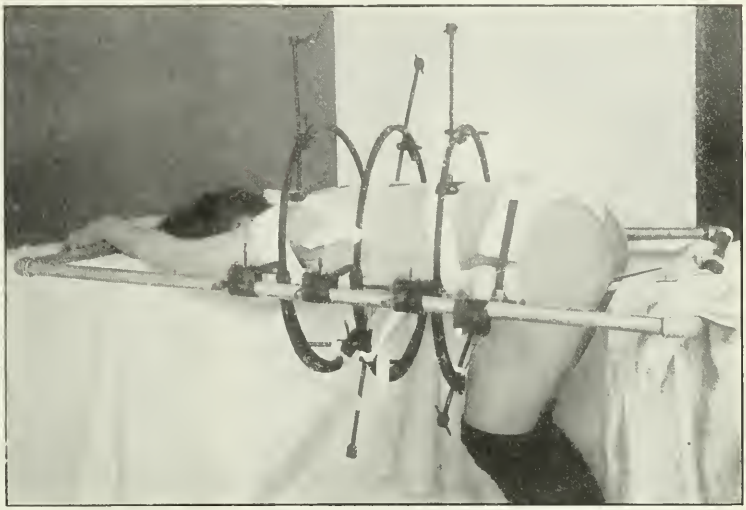

Fig. 5.—Apparatus for forcible correction by plaster jackets applied.

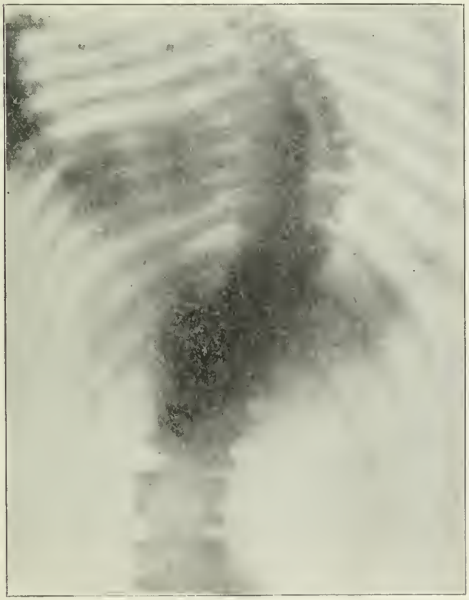

Fig. 6.—Radiogram of patient 17 years old lying on the back before application of jacket.

Fig. 7.—Radiogram of same patient taken after application of plaster jacket through windows cut in front and back of jacket.

They have been applied, as a rule, to the patients suspended by the head, but the reasons already stated as to the mechanics of this position apply here also.

the spine is in the most favorable condition for side correction both as regards side deviation and rotation, and by an intelligent application of force to correct

both of these elements at different levels, in the case of compound curves, great improvement is to be obtained. In this improved position the jacket is applied.

A correct application of this method is to be found by having the patient lie prone in a gas-pipe frame on two straps of webbing running from end to end, cross straps supporting the pelvis and shoulders. By means of webbing straps attached to the side of the frame, in a right dorsal curve, one going around the left side of the pelvis and another around the left upper thorax, while a third pulls on the right side of the thorax against these as points of resistance, great improvement in the position may be obtained, which is secured by the application of a plaster jacket.

A thoroughly efficient apparatus has been devised by Dr. Z. B. Adams as follows:

The apparatus consists of a heavy gas-pipe frame three by four feet. The patient lies face downward on two webbing strips running from end to end of the frame with the legs flexed. Near the bottom of the frame is an adjustable cross-bar bent to fit into the flexure between the thigh and the pelvis on which the patient rests the lower part of the body. Sliding on this bar are two arms, which slide in and clamp down on the buttocks, holding the pelvis steady on the cross-bar. This bar is movable from side to side in order to induce or correct curvature in the lumbar region when necessary. There are three vertical transverse rings two feet in diameter fastened to pieces on the sides of the frame so that they can be moved to any desired point along the frame. These rings are also movable from side to side and by an independent movement they can also be rotated through a half circle. Any one of these movements can be checked at any point by turning a screw. The shoulders are held by a pair of axillary straps fastened together by a strap across the chest in front. These straps are suspended from the ring nearest to the top of the frame and can be made to hold the shoulders in any desired degree of twist by a rotation of the ring (Fig. 3).

Each ring is provided with two long rods at the two poles of the ring. These rods are adjustable on the ring and can be set at any desired angle to it. They can be pushed up or down and are controlled by a ratchet. By rotating the ring and adjusting the angle of the rods they can be made to press down or up on any part of the back or chest.

For the application of the jacket the patient lies on the face on the two webbing strips, the lower part of the trunk resting on the cross rod and the bars clamping the buttocks; the feet rest on the floor and the arms are extended above the head. The rings are then adjusted at the two levels where it is desired to make correction (Fig. 4). For side correction a bandage is fastened to one side of the ring, carried around the patient's side over a heavy pad of felt, and back to the ring. The same is done to the other ring at the other level where side correction is desired, while the top ring controls the shoulders. The rings are then pulled to one side, the bandages around the patient tighten, and any endurable degree of side correction obtained.

When the side correction is made the ring is rotated till the rods are opposite the points where it is desired to correct rotation. They are then pushed down on to the patient, their points being protected by sheet-iron pads two by three inches, which are covered with heavy felt. These pads are incorporated in the jacket (Fig. 5).

A plaster jacket is applied to the patient held in this way. It is easy to see that the method is perfectly definite and that the amount of force at the operator's disposal is very great.

That a practical gain in the curved part of the spine may be secured by this method is demonstrated by the two *x*-rays shown in the illustrations (Fig. 6). The patient was a girl of 17, with a severe right dorsal curve, who was extremely rigid and had never been treated. The first *x*-ray was taken with the patient lying on the back. A corrective jacket was applied in the Adams apparatus, the front and back of the jacket were cut away to permit another *x*-ray, and the improvement in position is evident (Fig. 7).

It seems reasonable to hope that the maintenance of such an improved position may be expected in time to produce a change in the shape of the vertebræ, and such jackets are worn for a period of from one to three weeks. They are then removed and others applied so long as it seems possible to obtain any further correction (Figs. 8 and 10). This short period is adopted in order to prevent as much as possible the atrophy of the muscles incident to the fixation of the trunk.

The treatment after removal of these jackets will be considered in the next section.

B. TREATMENT TO RETAIN THE IMPROVED POSITION.

Although it may be possible to secure a very great improvement in position by means of the measures described, it has been demonstrated clinically that such results are not permanent, and that to become permanent such improved position must be maintained for a long time, and that the ultimate cure must rest in the development of the muscles which maintain the improved position. The intelligent use of gymnastics in this connection is, therefore, of great importance. This consideration of gymnastics is entirely independent of those mentioned before, where they were spoken of merely as measures to secure flexibility. In this connection they are spoken of as measures to maintain the improved position.

It is impossible to go into the individual exercises, but for practical consideration they may be divided into four types:

1. Self-Correction Gymnastics.—With the hands on the head or the hips, the patient lifts herself into a corrected position, which she maintains as long as possible, while the arms are taken away from the supporting point. A second type of this exercise is to be found in the so-called "Hoffa self-correction," in which the patient with a right dorsal curve places the right hand on the thorax and the left hand on the left hip, and by a side pressure presses the right side of the thorax to the left.

2. Gymnastics for the Contraction of the Muscles on the Convex Side of the Lateral Curve.—A distinctive group of exercises intended to maintain the correct position consists in the repeated contraction of the muscles on the convex side of the lateral curve. Such exercises consist of side bendings against resistance and active exercises which are as heavy as they can be made. In a left lumbar curve, for instance, the patient hangs by the hands from a bar and lifts both legs sideways to the left, contracting the left lumbar muscles and straightening the curve.

3. Backward Bending Gymnastics.—Backward bendings have been found to have a beneficial effect in maintaining the corrected position. Simple symmetrical backward bendings can be carried out by having the patient lie on the floor, with the feet held, and raising the head and chest with the arms behind the head or on the hips.

4. Symmetrical Heavy Gymnastics.—The raising of heavy bars and weights calling for simultaneous muscular contraction of the two sides is distinctly beneficial in maintaining an improved position of the spine, and, of all the exercises mentioned, is perhaps the safest in inexperienced hands. Dumb bells of from five to ten or twenty to thirty pounds and bars weighing from ten

to thirty pounds. Examples of the exercises are as follows: A heavy bell is taken from the floor and raised above the head alternately by each arm, a heavy bar is raised above the head with both arms, and the patient should reach up and look up at the end of each movement, raising the bar to the highest possible point. The patient lies on the back on the floor and raises a bar from the level of the chest to the full extent of the extended arms. In such exercises the patient should be pushed to the limit of fatigue.

Although the exercises have been divided sharply into four groups, it must be evident that combinations of these groups are likely to be of value, and here again only exercises which can be seen to be corrective should be given. Such work to accomplish results must be carried on from two to four hours a day for a period of at least six months following forcible correction.

The present discredit of gymnastic retentive treatment is due to its use in too small dosage and to a failure to appreciate that a problem so grave as the maintenance of an upright position in a spine, which tends to curve, is to be obtained only by a high degree of muscular development and that this can not be obtained in exercise periods of half an hour, given three times a week, but that treatment must be vigorous and long continued.

Fig. 8.—Patient of whom the radiograms were taken before treatment.

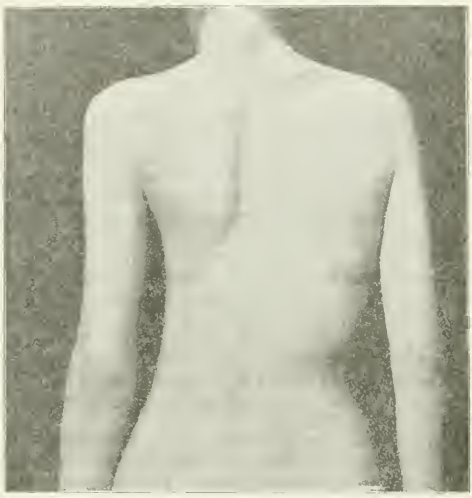

Fig. 10.—Same patient after one corrective jacket.

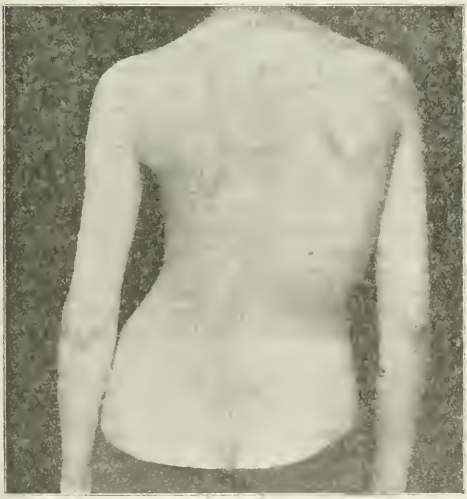

Fig. 9.—Patient 17 years old, never previously treated, before treatment.

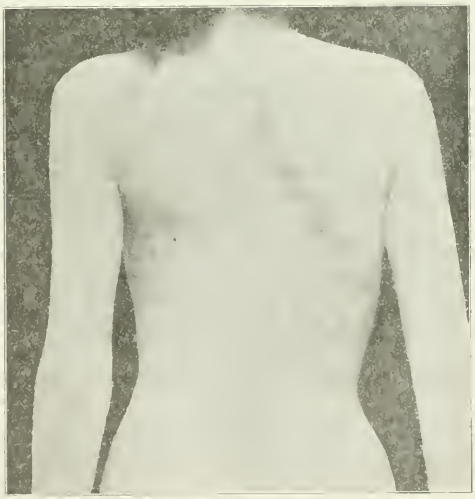

Fig. 11.—Same patient after two jackets. Whole interval three weeks.

5. *Retention by Apparatus.*—After forcible correction either by intermittent means as described or after the removal of jackets furnishing continuous correction, it is desirable that some form of retentive apparatus should be worn for some months (at least, to maintain the corrected position obtained) until the muscles are strong enough to enable the apparatus to be dispensed with.

Braces, as corrective apparatus, have no place in the treatment of severe lateral curvature and should be regarded only as means to retain the gain secured by other measures.

The most easily made and available corset is to be manufactured by removing from the patient the last corrective jacket, filling it with plaster-of-Paris and water, thus securing a torso of the patient. This torso is then further corrected by cutting away the plaster on the convex side and by building up on the concave side so as to secure a symmetrical or overcorrected model, on which a jacket may be applied. It is then shellacked and covered with a layer of stockinet or an undershirt, and a plaster jacket, having been applied on the torso, is cut off, furnished with lacings and supplied to the patient. All plaster jackets applied for forcible correction and retention must embrace the shoulders and even the head should be included, but the disfigurement is so great that most patients are unwilling to submit to it in America.

On the torso obtained as described may be constructed jackets of celluloid, leather or other material, or corsets made of cloth reinforced by steel. Into the construction of these more complicated forms of apparatus and braces there is no space to enter here. Any brace which maintains the corrected position fulfills the requirement. After a forcible correction it is generally necessary that a jacket should be worn from one to two years and gradually discontinued as the corrected position can be maintained for a longer and longer time.

The gravity of the condition to be met in structural lateral curvature must be recognized and a full appreciation of the very difficult problem that treatment presents is necessary. The failures to secure the results which are possible are to be attributed to our not applying sufficiently vigorous and sound surgical means and to not continuing our treatment for a sufficient period of time. When 30 grains of quinin are needed it is of little use to administer 1 grain, and the reluctance of patients to undergo adequate and long-continued treatment for the result of a deformity which does not threaten life is, and always will be, an obstacle to the generally successful treatment of this deformity.

BACTERIOLOGY OF THE BLOOD IN TYPHOID FEVER.*

JOSE L. HIRSH, A.B., M.D.
Professor of Pathology, University of Maryland.
ASSISTED BY E. B. QUILLEN, M.D., AND W. V. S. LEVY, M.D.
Resident Pathologists, University Hospital.
BALTIMORE.

The views regarding the nature of typhoid fever have undergone considerable changes in recent years. While this was formerly considered as an intestinal disease, or as a disease with especial localization in the intestinal tract, the modern conception regards it as a true septicemia. Instead of local lesions in the intestines with subsequent blood infection, the organisms of the disease are first conveyed to the general circulation and the intestinal lesions, when present, are to be regarded as the secondary changes.

His,[1] in his studies of typhoid stools, has demonstrated the fact that in most cases the bacilli appear late in the stools, and are often absent in those cases recognized as the disease without intestinal lesions. Furthermore, the organisms may often be obtained from the blood several days earlier than from the stools. That the infection occurs most often through the gastrointestinal tract is highly probable, and that micro-organisms may penetrate the normal mucosa without leaving any trace of their presence has been amply demonstrated to be the case with the tubercle bacillus and doubtless the same method of general blood invasion occurs in typhoid fever. At the time that we are able to recognize the disease clinically there are usually well-marked lesions in the intestinal and mesenteric lymphatics.

Typhoid bacilli are usually found widely distributed throughout the tissues after death and usually in clumps, a condition probably due to the agglutinating powers of the blood on the bacilli. The work of Mallory[2] seems to show that the lesions of typhoid fever bear no intimate relation to the typhoid bacilli. He concludes that the typhoid bacillus produces a mild, diffusible toxin, partly within the intestinal tract and partly within the blood and organs of the body. This toxin produces a proliferation of the endothelial cells, which are phagocytic. The swelling of the spleen and lymphoid tissue is due almost entirely to the formation of these cells. The necrosis of Peyer's patches is due to the occlusion of the veins and capillaries by thrombi, which owe their origin to degeneration of phagocytic cells beneath the lining endothelium of the vessels.

The occurrence of the typhoid organisms in the fetus was first noted by Ernst.[3] Similar conditions have been described by Eberth,[4] Freund and Levy, Richardson, Lynch[5] and others. A case recently coming under my notice was of interest on account of the pathologic, rather than the bacteriologic findings. A woman aborted in the third week of typhoid fever during the fifth month of pregnancy. Her blood showed a positive Widal reaction in a dilution of 1 to 100, though no bacteriologic examination of her blood was made. Postmortem examination of the fetus showed an enlarged spleen, and the mesenteric glands and Peyer's patches were congested and swollen. Bacteriologic examination of the blood and spleen gave negative results, although the blood gave a positive Widal reaction in dilution of 1 to 50.

In one of the cases reported by Cole,[27] the blood of the mother, examined on three different occasions, gave negative cultures for typhoid bacilli, and after abortion Lynch[5] succeeded in isolating the bacilli from the fetus. Lynch collected 16 undoubted cases in which the typhoid bacilli were isolated from the organs of the fetus. In none of these cases were intestinal lesions found. Probably the cause of the infection of the fetus in these cases is the associated hemorrhagic infarcts of the placenta, which Lynch found in his case.

The occurrence of the *Bacillus typhosus* in the urine of typhoid patients has been demonstrated by various

* From the Pathologic Laboratory of the University of Maryland. Conducted under the Charles Frick Fund.

observers in a large number of cases. In 1881 Bouchard claims to have isolated the organism from the urine in 50 per cent. of cases. In 1890 Neuman[6] isolated the bacillus in 11 out of 48 cases. Horton Smith[7] found them in 3 out of 7 cases which he investigated, and Richardson[8] in 23 out of 104 cases. Gwynn[9] has found as many as 50,000,000 typhoid bacilli in 1 c.c. of urine. In this connection, it is interesting to note that the organism may persist in the urine for a long time after the attack of typhoid fever; Young's[10] case showed the persistence of the organism in the urine for 7 years after the attack of typhoid fever and in Houston's[11] case it remained for 2 years.

The occurrence of the bacilli in the urine in from 25 to 30 per cent. only of the cases and the fact that it has seldom been found before the end of the second week, offers but little aid to the clinical diagnosis of the disease; but its frequent presence and its persistence in the urine is of great practical import in showing the danger of infection from this source. Bacilli of typhoid fever have been isolated from the stools in many cases, and while the method of His[12] and the more recent one of v. Drigalski and Conradi[13] are less complicated than previous methods, yet neither are practical on account of the difficulty of isolating the bacilli in pure cultures.

Isolation of the organism from the spleen *intra vitam* has not proved feasible, even though several investigators have succeeded in so doing. The dangers from hemorrhage from the enlarged and softened spleen is not a negligible quantity. The bacteriologic examination of the rose spots has been more successful, although, as with the urine, the bacilli are obtained at a time when it is practically useless for a clinical diagnosis, as the symptom complex is fairly well established at the time the rose spots appear.

Neuhaus[14] isolated the organism from the rose spots in 9 out of 15 cases. Neufeld[15] cultivated the bacilli from the spots in 13 out of 14 cases. He made incisions into the spots and transferred the blood with the tissue scrapings into bouillon. Curshman[16] made an examination in 20 cases, with positive results in 14 cases. Richardson[17] cultivated the organism in 5 out of 6 cases from the spots. Neufeld assumed that the bacilli found lodgment in the skin outside of the blood and were so protected from the bactericidal action of the blood; accordingly Richardson[17] modified Neufeld's technic by freezing the spots with ethylchlorid and so driving all the blood out of the skin. The skin having been frozen, a small cross incision was made over the spot, the substance of which was immediately curetted out and transferred to a tube of bouillon. In both Neufeld's[15] and Richardson's[17] studies it was possible to obtain the typhoid bacilli several days before the Widal reaction was positive. Neufeld's series 7 out of 8 cases, the diagnosis made from the rose spots was 6 days ahead of that made by the Widal reaction. In all of Richardson's cases the blood cultures were ahead of the Widal.

E. Frankel,[18] by excising the spots, has been able to demonstrate the bacilli in sections, and finds them chiefly outside the blood capillaries in the small interstices of connective tissue.

Although the earliest attempts to isolate the organism from the circulating blood were negative, as early as 1884, Gaffky[19] called attention to the probability of the invasion of the blood by the typhoid bacillus, and in the following years Frankel and Simmonds[20] were successful in isolating the organism in 1 out of 6 cases. The earlier results were very much at variance, some observers claiming to be able to isolate the organism in a large number of cases, while others constantly had negative results. The work of Stern,[21] in calling attention to the germicidal action of the blood, had considerable influence on later investigations, and, although, Thiemach[22] was able to isolate the organism in but 1 out of 7 typhoid patients, he recognized the fact that the cause of his failure was in not making sufficient dilutions of the blood. Kuhnau[23] was able to obtain the organism in 11 out of 41 cases. He used a large quantity of blood, about 10 cc. and diluted it in large quantities of agar, and made plates. Schottmüller[24] in an examination of 220 cases, from 1899 to 1902, found the typhoid bacillus in the circulating blood in 182 cases, 827 per cent. He prefers agar to bouillon, as the colonies are fixed and thereby readily isolated. He collects about 20 cc. of blood from the arm, and adds from 2 to 3 c.c. of blood to 6 c.c. of agar and then pours the plates; he has found from 5 to 2,000 colonies, per 100 c.c. blood.

Auerbach and Unger[25] report a study of 10 cases of typhoid fever, in which 7 gave positive results. The rather large percentage of positive findings is remarkable, considering the fact that they used very small quantities of blood, obtaining a few drops from the finger tips and the lobe of the ear. The majority of workers who have followed this plan have failed to isolate the organisms, as we did ourselves in the first few cases we studied and which we have not included in our statistics. Castellini[26] used large quantities of bouillon, which he inoculated with from 10 to 40 drops of blood, which was obtained from the median vein of the arm; each flask contained about 300 c.c. of bouillon, so that the blood was used in large quantities and sufficiently diluted to lessen the germicidal action. He isolated the *Bacillus typhosus* in 11 out of 14 cases.

In this country, the earliest reports are by Cole,[27] who was able to obtain the organism in 11 out of 15 cases examined. He also made use of large quantities of blood with large dilutions in bouillon. Hewlett[28] found the organism in 20 out of 24 cases, 83 per cent. Kerr and Harris[29] reported 56 cases, 31 of which were positive and 26 negative. Courmant and Lesieur[30] found the bacillus constantly present in all cases examined by them. Warfield[31] found the specific organisms in 33 out of 43 cases examined. Coleman and Buxton[32]

in a study of 60 cases, have obtained the organism in 34. Trappe[33] in 38 cases had positive results in 25. He attributes his rather low percentage of positive findings to the fact that many of his cases were examined late in the course of the disease, at a time when the organisms had probably disappeared from the blood. Duffy[34] reports his examination of 88 cases with especial reference to the relationship of the temperature to the presence of the organism. In 56 cases in which the temperature was above 102 F. the bacilli were present in the blood in every case, and in 23 cases in which the temperature was 100 or 101 F. the bacilli were cultivated from the blood in 10 cases, or 43 per cent.

Our investigations consist of a study of the blood in 100 cases of typhoid fever. All the cases were from the wards of the University of Maryland Hospital, and as is the case with such patients, it is often impossible to obtain a very exact history as to the beginning of the attack; still in the large majority of cases we think the day of the disease as given is fairly accurate. All of the cases were clinically typhoid fever, although as will be stated, some ran a very mild course.

The technic employed was practically that given by Cole. The skin over the anterior surface of the arm at the bend of the elbow was thoroughly cleansed with soap and hot water, then washed with alcohol and ether, and kept wrapped in a hot towel soaked in bichlorid solution for several hours. A bandage is fixed about the arm just below the shoulder, so as to make the veins stand out prominently. The operation consists in drawing 10 c.c. of blood from one of the superficial veins of the arm. An ordinary hypodermic needle with a syringe holding 10 c.c. is used; needless to say, all aseptic precautions must be used. The 10 c.c. of blood obtained is then divided into four flasks, each flask containing 300 c.c. bouillon. The flasks are then placed in the thermostat and allowed to incubate from 24 to 36 hours.

* Suggestive.

In our work the identity of the typhoid bacillus was, in many cases, made by cultures and agglutination, but in every case the crucial test was the positive agglutination of the bacilli in a dilution of 1 to 50 within one hour with known human typhoid serum.

A study of our 100 cases shows that the typhoid bacilli were found present in the circulating blood in 78 cases and absent in 22 cases, and as to the time of the disease, were distributed as follows:

First week—16 cases, 12 positive, 75 per cent
Second week—50 cases, 43 positive, 86 per cent

Third week—24 cases, 19 positive, 79.3 per cent.
Fourth week—7 cases, 1 positive, 14.3 per cent.
Relapses, 4 cases, 4 positive, 100 per cent.

As to the stage of the disease in which the bacilli are most apt to be found there seems to be general accord. Our largest number of positive findings were in the second week of the disease, a time when the bacilli are probably present in largest numbers. Our positive results in the first and third week are practically the same. After the third week the positive findings are greatly reduced and in the majority of cases we believe they are absent after the twenty-first day. In an analysis of 604 cases collected from the literature by Coleman and Buxton they find 93 per cent. of positive cases in the first week, 76 per cent. in the second week, 56.5 per cent. in the third week and 32 per cent. in the fourth week.

Our earliest date of positive findings in the original attack was on the fourth day; there were two cases on the fifth day. The latest day on which bacilli were present, exclusive of relapse, was the twenty-eighth. Schottmüller's earliest finding was on the second day and the latest on the forty-second day. Courmant found the organisms present usually as early as the fifth day and present until the end of the third week. Cole's earliest positive result was on the sixth day and the latest on the twenty-seventh day; Hewlett found the bacilli in one case on the third day.

The number of relapses in our series is small, though important in showing the relationship to the original attack. A relapse is undoubtedly a reinfection of the blood with the bacilli. All the relapses gave positive results, one on the second day, one on the third day and two on the fifth day. One of the cases (Case 38) gave negative results in the original attack on the twenty-seventh day, and on the thirty-fifth day of the disease (and the second day of relapse) showed the presence of typhoid organisms. Just why this reinvasion of the blood should occur we are unable to say.

We may conclude, therefore, that the organism is present in a large majority, if not all cases of typhoid fever in the blood, early in the attack and that it disappears by the end of the third week, or soon thereafter, and that a relapse is a second infection, associated with the reinvasion of the blood by the organism. We have not been able to confirm the statement of Kuhnau, that the organisms are found only in the stage of hyperpyrexia, or that of Duffy, who found them present in every case where the temperature was above 102 F. While it is true that the majority of our positive cases occurred in the second and third week, when the temperature was high, we encountered several cases of hyperpyrexia, temperature 104 F., which were negative after several examinations. On the other hand, several mild cases, in which the temperature at no time was above 102 F., gave positive results. While Widal was able to find the organisms present in severe cases only, the majority of authorities have been able to find no relationship between the severity of the attack and the presence of the bacilli.

Case 69 of our series, although of great severity from the onset, death following perforation, failed to show the organisms at any time, although cultures were made on the seventh and fourteenth days. Cases 53 and 89 were likewise negative, the latter case being associated with great tympanites and repeated intestinal hemorrhages. Cases 13, 36 and 80 were also classified as severe infections and gave positive results. Cases 10, 18, 44 and 60 were very mild and showed organisms early in the fever, while cases 34 and 53, of moderate severity, failed to show any organisms.

In 23 of our cases the Widal reaction was negative or merely suggestive at the time the bacilli were obtained. Rose spots were present in 56 cases, and absent in 22 cases at the time of positive findings. The value of a bacteriologic examination as a means of diagnosis in certain obscure cases of typhoid fever can not be questioned. If the bacteriologic examination is positive, the diagnosis is assured. While the Widal reaction is more easily carried out, it is often misleading, as it is occasionally absent or does not appear until late in the attack of typhoid, and is occasionally found in those very diseases which clinically resemble typhoid fever. We have recently encountered 3 cases of acute miliary tuberculosis all of which closely simulated typhoid fever, one of which gave a positive Widal reaction, another a suggestive reaction; negative findings in the bacteriologic examination of the blood was a valuable point in the differential diagnosis.

CONCLUSIONS.

From these studies we conclude:

1. That the *Bacillus typhosus* is present in the circulating blood in every case of typhoid fever at some time during its course.
2. The bacilli invade the blood very early in the disease.
3. The bacilli usually disappear from the blood by the end of the third week.
4. Relapse is associated with the reinvasion of the blood by the organism.
5. The bacteriologic examination of the blood is a valuable adjunct in the diagnosis of obscure cases of typhoid fever.

ATROPIN AND STRYCHNIN COMBINED, A SPECIFIC FOR SEASICKNESS.*

BRIG.-GEN. ALFRED C. GIRARD, U. S. A. RETIRED.
Late Assistant Surgeon General, U. S. A.
SAN FRANCISCO.

It is not the intention of this report to discuss the pathology or symptoms of seasickness, but, since the subject has been taken up by this Congress, to bring again before the profession a remedy which I advocated as long ago as 1888 and again in my "Letters from Europe," published in 1893 in THE JOURNAL of the American Medical Association, to-wit, the combination of atropia and strychnia.

Since then I have privately advised many physicians of my observations and while on duty as Medical Superintendent of the Army Transport Service in San Francisco induced many of the surgeons of the transports to give the remedy a trial. I used the treatment on myself experimentally and gave it to many persons on various ocean trips.

At first I used atropin and strychnin in conjunction with caffein, but after many trials abandoned the latter, because, given hypodermically (which is the safest and most expeditious method), it occasionally gave rise to local inflammation.

For many years I had believed that I was the original discoverer of this treatment, but it seems that other physicians have used it at times independent of my investigations, and I, therefore, do not pretend to absolute originality, but I believe this report represents the views of many observers working under my instructions under various circumstances and more than any individual views will establish the value of the treatment.

* Report presented to the International Medical Congress at Lisbon, April 17, 1906.

My observations show that in almost every instance a hypodermic injection of 1/120 of a grain of atropin sulphate (0.0005 mg.) with 1/60 of a grain of strychnin sulphate (0.001 mg.) is readily borne by adults and, as a rule, causes no disagreeable sensation. This may be taken at the commencement of a voyage, or when the sea commences to be rough, or at the advent of a storm when the motion of the water causes nausea; this dose is at times not sufficient with persons refractory to the action of belladonna, and I have repeated it twice at hourly intervals before incipient dryness of the throat, or disturbance of vision warned me that atropinism had been reached, when in every instance of my observation the symptoms of seasickness disappeared. Other observers found this dose in rare instances too great.

The advantage of hypodermic medication is the rapidity with which the effect is produced, and the certainty that no accumulating action need be feared, as is the case when the remedy is taken *per orem*—perhaps too late to prevent nausea—and possibly remaining in the stomach undissolved, without apparent effect, when it might be followed by a second dose, both operating together and acting in too severe a manner. This happened in an instance when I entrusted the remedy to a lady going from Manila to Hongkong. She encountered a sudden severe storm and treated a number of her lady friends aboard with the uncertainty of medication by the mouth and overdosed them so as to result in severe symptoms of atropinism.

As a rule, one dose is sufficient for a whole voyage, apparently overcoming the disturbance until the voyagers acquire their "sea-legs," but in a long trip with severe weather occasional doses are required to keep up the effect.

The rationale of the treatment may be found in the stimulating effect of the atropin on the circulation in the brain, while the strychnin causes a similar action through the spinal cord in the respiration.

I have a few instances of my own observation and extracts of reports made by medical officers and patients. The general consensus of opinion is that the remedy is a specific. I am satisfied from my own observations that when it failed there must have been some complications which I was always able to meet in my experiments.

On one of my ocean trips, one of the passengers was a surgeon of the army who had occupied a similar position in the navy, but had been compelled to resign because in any kind of weather on board ship he continually suffered from seasickness. I gave him one dose of the remedy when we left the harbor, and for safety's sake repeated it on two subsequent days, and this officer remained free from seasickness.

Another officer suffered from severe headache and attributed it to "biliousness" without being benefited by any treatment. I suggested seasickness as the cause, and by one dose of the remedy the illness was cured.

Letter of M. A. Delaney, first lieutenant and assistant surgeon, U. S. A.:

Office of the Surgeon,
U. S. Army Transport Sheridan,
San Francisco, Cal., Dec. 28, 1904.

Col. A. C. Girard,
Asst. Surgeon-General U. S. A.
San Francisco, Cal.

Sir:—I have the honor to report in regard to the value of the prescription for seasickness which you gave me for trial whilst stationed in Manila, P. I., as follows:

While transport surgeon on the *Sheridan* on the trip from Manila, P. I. to San Francisco, California, Nov. 15, 1904, to Dec. 15, 1904, I had a very good opportunity to test its value as nearly one-half of the passengers on board were seasick and in nearly every case it gave prompt relief. In some of the cases it was given by mouth and while slower in action, yet it was effectual. In three very severe cases, among them myself, it gave first-class results and in a very short time I was able to resume my duties without any further inconvenience. It was also used in the cases of five hospital corps privates (in these cases hypodermically) and in a very short time they were able to resume their work and take food.

As I personally used this remedy, I can unhesitatingly say that it was a great benefit to me.

Extract from Report of Transport Surgeon H. C. Moses:

Report of *mal de mer* treatment with the Girard mixture: Number of cases treated, 38; number relieved after first treatment, 20; number of recurring cases in which decided relief or temporary relief was noticed, 16. The average number of treatments received by these 16 cases was 4. Number of cases in which no relief was noticed, 3. These cases received but one treatment and it is reasonable to suppose did not get the full physiologic action of the remedy.

Extract from letter of First Lieutenant and Assistant Surgeon W. T. Davis, transport surgeon:

Manila Bay, Pacific Islands,
Sept. 29, 1906.

Col. A. C. Girard,
Asst. Surgeon-General, U. S. A.,
Manila, P. I.

Sir:—I have the honor to report, as requested, on the results of the treatment of *mal de mer* by means of hypodermic injections of the sulphates of atropin and strychnin.

Number of cases treated, 20; number cured by one injection, 12; number cured by two injections, 5; number not affected, 3.

I find this treatment to be a specific in a large majority of the cases.

Extract from letter of Col. B. F. Pope, assistant surgeon-general, U. S. A.:

I specially write to inform you of the successful use of your prescription for seasickness, both on Mrs. Pope and myself and Col. D.

We were greatly prostrated by seasickness during the first twelve hours. A single injection put Mrs. Pope on her feet, and more important than all, entirely relieved her of sea terror so that she said the boat might turn over for all she cared. With her I repeated the dose once in twenty-four hours until we got into smoother water, when no more was necessary.

Col. D. (who usually took to his bed as soon as the steamer left the wharf and did not rise until the end of the journey) required but one injection. I took two. Others took one or two and always good results.

Extract from letter of Capt. Dwight B. Taylor, assistant surgeon U. S. Vols., transport surgeon:

There is no doubt in my mind of the complete efficacy of this prescription, and the patients were all greatly pleased at its prompt and lasting action. The Americans who had it had not yet vomited and did not; they were all about ready to when they received the treatment. Some of the Japanese (crew) had vomited, but they were all right and at work after taking the medicine. By seeing the effect of the treatment in patients who had vomited and those who had not, I am the more convinced of its value.

Extract from letter of Capt. Samuel D. Crawford, 28th U. S. Vols., on board the U. S. A. T. *Kilpatrick:*

On Board the U. S. A. T. Kilpatrick.

Col. A. C. Girard,
Chief Surgeon, General Hospital,
Presidio, San Francisco.

Sir:—I have the honor and pleasure to tell you how much I am indebted to you for the relief which your anti-seasick remedy gave me a few days ago. Dr. Kelly, the ship's surgeon, had announced in a posted notice that he would give the passengers the benefit of the remedy, and in every instance in

which he applied it, either before to prevent or afterward to give relief, he was successful. I think it is a wonderful discovery, and I am sure that if the sea-traveling public could have the privilege of having the remedy at hand, it would make countless thousands happy, and will be an assurance to those who do not travel at sea because of seasickness, that would enable them to enjoy life on the ocean wave without the old time periods of travail and despondency. I sincerely hope that the environments of the service will not prevent you from placing this remedy on the market, and I am sure that a grateful public will rise to bless you every time they have occasion to travel on the high seas.

Extract of letter of Dr. T. G. Holmes, transport surgeon, U. S. A. T. *Grant:*

After the second day I used it for six passengers, with prompt relief in every case; two only had any subsequent nausea, which yielded to a repeated hypo. Among the soldiers I used it for ten, with equally prompt and satisfactory effect and no subsequent nausea.

Extract from letter of Captain (now Lieutenant-Colonel) E. T. Fremont:

I write just a line to thank you greatly for the benefit to me of your remedy for seasickness. I only took two doses (and for me the atropin as put up was halved, as the whole tablet made me sleep too much and made my throat tremendously dry) and thereafter I steadily improved. No matter how rough, I was not again affected.

Extract from letter of Mrs. M. S. R.:

I can thank you most sincerely and gratefully for the remedy for seasickness. We had a most trying and stormy passage, and by the daily use of the small pills I managed to stay on deck every day. I am such a miserable sailor that I feel sure nothing would absolutely cure me, but as I am usually in bed, deathly ill, from San Francisco here, and not able to keep any food down, I am sure you can see how much good you did me when I was only actively ill twice and able to stay on deck all the time.

Extract from letter of Capt. I. T. Jenks, 24th Infantry:

Your prescription worked marvels with me. We had a rough trip and I did not miss a meal.

I have many more letters of the same import, but these ought to suffice.

I notice in the daily press in a telegram from Lisbon, February 10, the following:

"The Anti-seasickness League will hold a meeting here in April, when one hundred physicians will charter a steamship and go out to sea to try personally the medicines which have been advanced as preventives of seasickness. Six hundred invitations have been sent to members of the medical profession, and out of the acceptances one hundred will be chosen to go on the voyage."

This appears to be an excellent opportunity of bringing my investigations to the notice of the profession, and I hope that this paper will be read in full and be given due consideration.

I conclude with an observation made again lately that the success or failure of the remedy greatly depends on the patient himself. This happened in the case of an officer to whom I gave a number of doses of tablets containing the atropin and strychnin. He was undergoing a voyage on a small coastline steamer. The weather was very rough and the vessel rolled and pitched greatly. He took the medicine before leaving and was not affected by the sea. On his return, vessel and weather being similar, but the stomach full, he was not benefited, as probably the remedy did not have time to be absorbed, and he suffered greatly for several days.

JOINT MANIFESTATIONS IN HEMOPHILIA.*

EDWIN W. RYERSON, M.D.

Orthopedic Surgeon to Cook County and St. Elizabeth's Hospitals; Assistant Professor of Orthopedic Surgery, Chicago Policlinic Associate in Surgery, Rush Medical College.

CHICAGO.

Fifty years ago clinicians clearly recognized the frequency of joint lesions in hemophiliacs, but were unable to agree on the pathology of these lesions. Elsässer considered the condition to be merely coincident arthritis due to gout, and Lange, in 1851, supported this view. As late as 1870 we find Grandidier insisting on a rheumatic or gouty diathesis as the sole factor, although Volkmann, in 1868, had clearly shown that hemorrhages into the joints occurred frequently and with little traumatic cause in bleeders. Wickham Legg, about 1870, wrote an able monograph with some mention of the arthritis, and ten years later concluded correctly as to the etiology.

Reinert and Lossen made strong pleas for the hemorrhagic nature of the joint lesions, but as late as 1892 we find no less an authority than William Osler apparently unwilling to hazard a theory, although Poncet, Charcot and Redfern had given good descriptions of the changes in the synovial surfaces. It was not until the able and convincing paper of König was published, in 1892, that the profession at large became awakened to the true cause of the arthritis.

It is interesting to read that the greatest authority in the world on tuberculosis of joints should have operated on two hemophilic knees in one year under the impression that they were tuberculous. In 1896 an Omaha surgeon reported another case, and I have heard of two others which I have been unable to find. All these operations resulted fatally from slow oozing some days after the operations, in spite of every form of treatment then recognized as advisable. All these cases so strongly resembled tuberculosis that a consideration of the differential diagnosis assumes great importance to the operating surgeon.

Although any joint may be affected, the vast majority of the hemorrhages occur in the knee, and, of course, the male sex is far more liable to suffer than the female. I believe that a careful and painstaking examination will reveal the true condition in practically every case if the possibility of hemophilia be borne in mind. The diagnosis in the early or acute stage presents several difficulties. It is probable that many cases go unrecognized, and, in fact, in a case of effusion into the knee joint following a moderately severe trauma, with no rise in temperature and no great pain, it may be impossible to make the correct diagnosis without aspiration of some of the fluid. There seems to be a well-recognized disinclination on the part of many hemophiliacs to admit the fact that they are bleeders, and several observers state that the diathesis is even strenuously denied by the patients.

PATHOLOGY.

I shall not attempt to review the literature of hemophilia in general nor to theorize as to its essential cause. It is now clearly recognized that the joint manifestations are due to an intracapsular hemorrhage. Rheumatism and gout play no part whatever, although there is perhaps no reason why they may not coexist. The hemorrhage may occur without any appreciable trauma, though more often a slight fall or blow is the exciting

* Read before Chicago Pediatric Society.

cause. The authors all agree that at least one such attack, even if severe, may be recovered from with perfect restoration of joint function, but that, if repeated, some disturbance of mobility may remain permanently. The pathologic findings may be conveniently divided into different stages. König's classification is satisfactory if slightly modified.

First Stage.—The first stage is simply the presence of free fluid blood in the joint. It is rapidly absorbed under proper treatment, and leaves no traces except a moderate brownish or yellowish discoloration of the capsule and synovial surfaces, due to the retention of blood pigment. The articular cartilage on the ends of the bones does not lose its gloss or whiteness, and joint function becomes normal. Many patients after an attack of this kind have no recurrences in any individual joint, though several articulations may suffer in succession. These cases, therefore, present little of interest to the orthopedic surgeon and are usually treated successfully by the general practitioner as acute articular rheumatism.

Second Stage.—With repeated hemorrhages in a single joint, distinct pathologic changes take place which are very remarkable. The capsule becomes thickened and succulent and much darkened. A fibrinous deposit appears all over the capsule and the synovial folds. Delicate, brownish, pigmented tufts form on these areas, and later filiform, slender threads grow from them and float swayingly about in the blood serum, like seaweed. The articular cartilage itself is invaded by brownish patches and tufts, and begins to degenerate, and curious characteristic defects are left, shallow, irregular, like the outlines on a map. The rest of the cartilage becomes brownish and loses its gloss.

Third Stage.—Later comes the third stage, with adhesion of these little tufts to the opposite articular cartilage, causing a more or less complete ankylosis. The fluid in the joint is absorbed, and only the thickening of the synovial surfaces, and the ankylosis remains, with usually a marked flexion of the joint. There is never any tendency to abscess or to sinus formation.

CLINICAL MANIFESTATIONS.

The clinical picture in the first stage may be confusing. Some cases closely resemble rheumatism with pain, swelling and joint effusion. This type usually follows trauma and when less severe may be diagnosed as simple synovitis; while other cases come on spontaneously with a painless and fluctuating swelling of the joint and little or no interference with function. Either variety progresses rapidly to perfect cure unless followed by exacerbations due to repeated hemorrhages. In the second stage we see what is often a perfect picture of a tuberculous joint in a subacute condition, thickened capsule, effusion, limitation of motion, beginning flexion-deformity and spasm of hamstring muscles. This was the condition of the joints operated on by König. Atrophy of the limb is pronounced and the differential diagnosis is most difficult. In the third stage there may be a complete bony ankylosis, as in a case reported by Summers, with atrophy and marked flexion, or perhaps a great limitation of motion, with the patella fastened to the femur by small areas of bony adhesions arising in places where the cartilage has been destroyed.

It is stated that a rise of temperature may occur during acute attacks of hemarthrosis, to as high as 102 F., but it is rare, and rapidly subsides, becoming normal in a few days.

DIAGNOSIS.

First Stage.—The conditions most closely resembling the first stage of hemarthrosis are acute synovitis and intermittent hydrops. In acute synovitis there is always a history of a fairly severe injury, the pain and discomfort are generally greater, and a local point of distinct tenderness can be made out at the site of the injury. The pain on motion and the functional disability are greater than in hemarthrosis and the effusion disappears more slowly. A careful aspiration of the fluid, under rigid asepsis, and using a needle of a very small caliber, would probably be harmless in any case and would afford valuable information. It is practically painless, if skilfully done, and I recommend it as a routine procedure in doubtful cases.

Intermittent hydrops, or hydrarthrosis, is a very rare disease, only about 70 cases being reported in the literature. It is characterized by a sudden painless, or nearly painless, effusion into the joint, a rapid disappearance of this effusion, and a complete recovery, followed by a series of precisely similar attacks at remarkably regular intervals, this periodicity, the mildness of the attack, and the absence of any traumatism being the chief characteristics. In a few cases, the pain has been a more prominent feature. Nothing is known of the etiology, and aspirations have shown usually a clear sterile fluid.

The various forms of infectious arthritis, such as gonorrheal, typhoid, pneumococcus, scarlatinal, and so forth, as well as the ordinary pus-germ infections, are much more painful and persistent than hemarthrosis, are attended with greater constitutional disturbance, and have the antecedent disease as a suggestive factor in the diagnosis. Acute articular rheumatism is rarely confined to a single joint, and has the same general diagnostic differences as the other infectious arthritides.

A true hemarthrosis is unquestionably the cause of the joint symptoms occurring in the so-called hemorrhagic diseases, such as Henoch's purpura, purpura rheumatica (Schoenlein's disease), purpura hemorrhagica, and scurvy. In these diseases the petechial hemorrhages into the skin and mucous membranes will at once suggest the probability of a similar involvement of the synovial tissues.

Second Stage.—In the second stage, the thickened capsule, the limited motion, and the beginning flexion suggest tuberculosis, but careful examination will show that the spastic contraction of the hamstrings is not a true reflex spasticity, but can be voluntarily relaxed. Also, there is no free fluid in hemophilic joints after the hemorrhage has been absorbed, and no individual points of tenderness can be found. Nearly all, if not all, tuberculous joints show a permanent increase in both local and bodily temperature, the latter usually reaching 99 or 99.5 degrees in the afternoon. The general onward march of the lameness and swelling, without any very sudden exacerbations or remissions, together with perhaps a cold abscess or night cries, would point to tuberculosis. Some of the so-called chronic rheumatoid diseases, especially arthritis deformans, bear a certain resemblance to hemarthrosis, but the characteristic grating, the slow onset, the involvement of several joints and the presence of irregular bony or cartilaginous hypertrophies at the edges of the joints would exclude hemarthrosis.

Third Stage.—In the third stage the clinical picture may be exactly that of an old tuberculous joint with complete ankylosis and without evidence of suppuration. It may be absolutely impossible to make a diag-

nosis without the aid of a complete and intelligible history of the case. The flexion of the hemophilic knee is usually not so exaggerated as that of an untreated tuberculous knee, and there is less backward displacement of the head of the tibia. Before considering operation in any old ankylosed joint where the history and examination do not positively rule out hemophilia, a test of the coagulability of the blood should be made.

TREATMENT.

The treatment in the primary stage should be such as will promote the absorption of the effused blood. I recommend aspiration with a fine needle, believing that it is of great importance to prevent, so far as possible, the deposit of fibrin on the joint surfaces, and that it is hardly possible for a fatal hemorrhage to occur through the wound of a small needle. After the blood has been removed, a few cubic centimeters of adrenalin solution should be injected, and a pressure bandage applied for five or six hours. The absorption of the blood, in case aspiration be deemed inadvisable, can be hastened by free use of the affected joint. It should not be put up in a plaster cast or in any other kind of fixation, after the first day, because any aseptic fluid in any joint will be absorbed more quickly under motion and massage than under fixation. This has been well demonstrated by Hosmer, Henrotin, and others in their treatment of acute synovitis. Constitutional treatment by such drugs as gelatin, adrenal extracts and calcium chlorid offers some security against future attacks, and should be tried faithfully. It does not show any great uniformity in results.

In the later stages, when there is a tendency to flexion, it is wise to apply traction until the joint is straightened, and then to use a splint or cast until the tendency has disappeared. Ankylosis in flexion might be corrected by the Goldthwait genuclast, by forcible manual redressment, or even by osteoclasis, followed by immobilization until ankylosis in good position has occurred. Any cutting operation should be shunned like the plague.

THE PHARMACOPEIA AND THE PHYSICIAN.

SUBSTANCES USED AS VEHICLES.

CHAPTER XXVI.

The great majority of physicians pay all too little attention to the art of rendering their prescriptions pleasing alike to the eye and to the palate. Even in medical schools, if the matter is considered at all, it is usually deemed sufficient to instruct the student to give the mixture a sweet taste, by the addition of syrup, or a distinctive aroma by the addition of one or the other of the official medicated waters, with little regard for individual taste or the nature of the mixture. In the matter of appearance it is commonly considered quite sufficient to avoid the inky mixtures produced by the addition of iron compounds to preparations containing tannin, or tannin-like substances.

From the point of view of the patient it is safe to say that the appearance of a mixture is often of even greater importance than the taste, not alone in so far as it concerns the individual preference of the patient, but even to the extent of affecting the absorption and the subsequent assimilation of the medicine, since we know that the digestive secretions are stimulated by tempting looking substances and are inhibited by those which appear disgusting. In the case of women and children the subjects of flavoring and coloring are of much more importance than with men.

While the average physician will, no doubt, rightly consider that this subject does not deserve very extensive study on his part, he must admit that the observance of a few easily acquired rules may be well worth remembering.

Unlike the question of ready-made formulas for a great variety of conditions demanding individual consideration, there is no reason why flavoring and coloring should not be reduced to the very simplest forms and used as a routine whenever the mixture admits of it.

Despite the pernicious activity of manufacturers of ready-made pills and tablets in flooding the market with all possible substitutes for tinctures, fluid extracts and solutions, it has been amply demonstrated that these solid forms of medicine can not compare in efficiency or in usefulness with the equivalent preparations given in liquid form. We will, therefore, confine ourselves entirely to the discussion of these liquid forms of medicine and to enumerate and point out the uses of the several preparations that are available as solvents, or as vehicles, for the administration of otherwise solid substances.

On a subject that is so far-reaching and varied as this must be, it will, of course, be evident that the several matters can not be taken up in detail, but must of necessity be more in the nature of suggestions for observation and study. With the wealth of material that is available, by the use of the official aromatics and diluents, it should be a comparatively easy matter for a physician to become thoroughly familiar with the properties and possible uses of at least several of these preparations and by judicious combination to produce not alone a variety of mixtures, but, also, to impart to them an individuality in which he may well take pride.

Many of the comparatively tasteless substances merely require the addition of some mildly aromatic solvent or diluent, such as the aromatic medicated waters. Substances that are more acrid, bitter or saline in taste may be masked by the addition of a small amount of syrup to the aromatic, or by the addition of a preparation containing glycyrrhizin, like the now official elixir adjuvans. Nauseous bitters are best masked with strong aromatics and syrup. The simple but persistent bitters, such as quinin and strychnin, are agreeably modified by such an aromatic as tincture of sweet orange peel, wine and sufficient syrup to suggest sweetness. As an example of such a preparation we may mention the bitter wine of iron, which will be appreciated if one will but taste this really elegant preparation.

Medicated Waters.

The most simple and, therefore, the most readily available of the official diluents or vehicles are the aromatic, medicated waters. They are particularly well adapted for dissolving such comparatively mild tasting substances as potassium citrate, sodium benzoate, sodium salicylate, morphin sulphate and antipyrin.

One of the most pleasant of these preparations is:

Aqua Amygdalæ Amaræ.—U. S.—Bitter almond water. This contains about 0.1 per cent. of oil of bitter almond, and appears to be particularly adapted for use with sedative expectorants such as codein sulphate.

Average dose: 4 c.c. (1 fluidram).

The following are particularly well adapted for use with children:

Aqua Anisi.—U. S.—Anise water, and

Aqua Fœniculi.—U. S.—Fennel water. They contain about 0.2 per cent. of the respective volatile oils and have long been popular as correctives or diluents for medicines such as fever mixtures and mild anti-diarrhea mixtures, designed primarily for children.

Average dose of either of the above: 16 c.c. (4 fluidrams).

Another aromatic water that has met with considerable use is:

Aqua Cinnamomi.—U. S.—Cinnamon water also represents approximately 0.2 per cent. of the volatile oil and, as a flavor, is sometimes preferred.

Average dose: 16 c.c. (4 fluidrams).

By far the most popular of the aromatic waters are:

Aquæ Menthæ Piperitæ.—U. S.—Peppermint water, and

Aquæ Menthæ Viridis.—U. S.—Spearmint water. These, like the preceding, are simple solutions of volatile oils in water

and represent approximately 0.2 per cent. of their respective volatile oils.

Average dose of either: 16 c.c. (4 fluidrams).

Peppermint water, or spearmint water, is particularly well adapted for use with the mild alkalies such as potassium bicarbonate or sodium bicarbonate, or mixtures of these with other soluble salts.

The efficiency of solutions of the alkaline bicarbonates may usually be enhanced by the addition of a simple bitter, such as tincture of nux vomica or tincture of calumba.

Simple solutions, even such as contain a small addition of a bitter substance, should be directed to be filtered, as this adds materially to the appearance of the mixture and thus enhances its palatability and efficiency.

When a vehicle having more pronounced characteristics is desired the official aromatic elixir will probably serve to meet more possible indications than any one other preparation. It may also be varied by the addition of the fluid extract of glycyrrhiza, as in the official elixir adjuvans, or by the addition of one of the official spirits, syrups, aromatic tinctures or simple wines.

Aromatic elixir is particularly useful in connection with the scale salts of iron, the bitter alkaloids, and also with the soluble bromids and iodids.

The following are among the preparations that will be found to be of use in connection with the possible modifications of the simple elixir:

Elixir Aromaticum.—U. S.—Aromatic elixir is practically a solution of a mixture of the oils of orange peel, lemon, coriander and anise in 25 per cent. alcohol, containing about 38 per cent. of syrup. The resulting preparation is not alone strongly aromatic, but is also sufficiently dense to hold finely divided substances well in suspension, while the alcohol content is not sufficient to be objectionable in the ordinary doses.

Elixir Adjuvans.—U. S.—Adjuvant elixir. This is a simple mixture of 12 parts of fluidextract of glycyrrhiza with 88 parts of aromatic elixir, and is particularly well adapted for masking acrid, bitter or saline materials. The contained glycyrrhizin not being soluble in acid solutions, the preparation is obviously not suited for use with diluted acids or acid salts.

The official spirits that may be used as additions to aromatic elixirs or as correctives to other alcoholic or hydroalcoholic solutions are:

Spiritus Anisi.—U. S.—Spirit of anise contains 10 per cent. of oil of anise in alcohol.

Average dose: 4 c.c. (1 fluidram).

Spiritus Amygdalæ Amaræ.—U. S.—Spirit of bitter almond contains 10 per cent. of oil of bitter almond in alcohol, and is the most potent of the official spirits. It is markedly aromatic and a very small quantity usually suffices to impart a distinctive almond odor and taste.

Average dose: 0.5 c.c. (8 minims).

Spiritus Cinnamomi.—U. S.—Spirit of cinnamon contains 10 per cent. of oil of cinnamon.

Average dose: 2 c.c. (30 minims).

Spiritus Gaultheriæ.—U. S.—Spirit of gaultheria is a useful preparation for cases in which the patient appears to have a predilection for teaberry or wintergreen. This preparation imparts a distinctive odor and taste and should be used with caution, as it appears to be objectionable to many people. It represents 10 per cent. of oil of gaultheria.

Average dose: 2 c.c. (30 minims).

Spiritus Menthæ Piperitæ.—U. S.—Spirit of peppermint and

Spiritus Menthæ Viridis.—U. S.—Spirit of spearmint, in addition to containing 10 per cent. of the respective volatile oils also represent the alcohol-soluble portion of 1 per cent. of the respective dry crude drugs, which impart to them a distinctive yellowish-green color.

Average dose of either: 2 c.c. (30 minims).

The aromatic tinctures that are particularly useful for adding distinctive characteristics to liquid mixtures are:

Tinctura Aurantii Dulcis.—U. S.—Tincture of sweet orange peel. This preparation is directed to be made from the fresh peel and represents approximately 50 per cent. of the crude drug. It is a delicate but efficient aromatic and is useful in connection with any of the hydro-alcoholic mixtures.

Average dose: 4 c.c. (1 fluidram).

Tinctura Cardamomi.—U. S.—Tincture of cardamom represents 20 per cent. of cardamom in diluted alcohol.

Average dose: 4 c.c. (1 fluidram).

Tinctura Cardamomi Composita.—U. S.—Compound tincture of cardamom represents 2.5 parts each of cardamom and Saigon cinnamon, 1 part of caraway, 0.5 parts of cochineal and 5 parts of glycerin in sufficient diluted alcohol to make 100 parts.

Average dose: 4 c.c. (1 fluidram).

Tinctura Lavandulæ Composita.—U. S.—Compound tincture of lavender consists of a mixture of 0.8 parts of oil of lavender flowers and 0.2 parts of oil of rosemary in 75 per cent. alcohol, which is used to exhaust 2 parts of Saigon cinnamon, 0.5 part of cloves, 1 part of nutmeg and 1 part of red saunders, enough of the menstruum being added to make 100 parts.

(The possible uses of this preparation are probably best illustrated by the official solution of potassium arsenite, which is flavored and at the same time colored by the use of 3 per cent. of this tincture.)

Average dose: 2 c.c. (30 minims).

Tinctura Vanillæ.—U. S.—Tincture of vanilla represents 10 per cent. of vanilla in 65 per cent. alcohol and is sweetened by the addition of 20 per cent., by weight, of sugar.

The official simple wines are:

Vinum Album.—U. S.—White wine. This is an alcoholic liquid, made by fermenting the juice of fresh grapes, the fruit of *Vitis vinifera*, and usually contains about 10 per cent. of alcohol.

White wine constitutes an excellent vehicle for a number of acrid or bitter substances, and is particularly useful as an addition to the official aromatic elixir. If from 10 to 25 per cent. of white wine be added to aromatic elixir it will impart to the latter a distinctive and generally agreeable odor and taste.

Vinum Rubrum.—U. S.—Red wine is an alcoholic liquid that is made by fermenting the juice of fresh red-colored grapes, the fruit of *Vitis vinifera*, in presence of their skins, and subjected to the usual cellar treatment for fining and aging.

The official syrups that are generally well known or widely used as diluents, correctives or vehicles are:

Syrupus Acidi Citrici.—U. S.—Syrup of citric acid. This is a slightly acid syrup, flavored with tincture of fresh lemon peel, and is useful in connection with the aqueous solutions of the alkaline salts of organic acids, such as potassium citrate.

Syrupus Aurantii.—U. S.—Syrup of orange also contains a trace of citric acid and has a pleasant acidulous taste. It is frequently used in place of the syrup of citric acid and is preferred by many.

Syrupus Pruni Virginianæ.—U. S.—Syrup of wild cherry, while it represents the aqueous extractive of 15 parts of wild cherry, is most largely used as a pleasant vehicle or as an addition to other diluents, particularly in connection with expectorants.

Average dose: 4 c.c. (1 fluidram).

Syrupus Tolutanus.—U. S.—Syrup of tolu represents the water-soluble portion of 5 per cent. of tincture of tolu, and, like the preceding, is frequently used as a corrective to mixtures that are designed for use as expectorants.

Average dose: 16 c.c. (4 fluidrams).

Syrupus Sarsaparillæ Compositus.—U. S.—Compound syrup of sarsaparilla contains fluidextract of sarsaparilla, fluidextract of glycyrrhiza and fluidextract of senna, and is flavored with a mixture of the volatile oils of sassafrass, anise and gaultheria.

This preparation constitutes an interesting reminder of the widespread use of sarsaparilla as a universal panacea almost a century ago, but is now seldom used for any other purpose

than a vehicle. It is particularly useful for such acrid drugs as the soluble mercurial salts and the iodids and bromids.

Average dose: 16 c.c. (4 fluidrams).

For use with immiscible liquids, for making emulsions and for suspending insoluble powders in aqueous solutions it is an almost universal practice to use the official mucilages or gums.

MUCILAGO ACACIÆ.—U. S.—Mucilage of acacia, containing 34 per cent. by weight of acacia, 33 per cent. of limewater and 33 per cent. of distilled water, is probably the best known of these several preparations. It has a very wide field of usefulness, but as acacia is precipitated by alcohol it is not useful in connection with strongly alcoholic liquids. The presence of limewater may prove to be a disturbing factor in connection with solutions of the alkaloids, and here it may be readily substituted by the syrup.

SYRUPUS ACACIÆ.—U. S.—This represents 10 parts of acacia in a moderately heavy syrup.

MUCILAGO TRAGACANTHÆ.—U. S.—Mucilage of tragacanth contains 6 parts of tragacanth, 18 parts of glycerin and sufficient water to make 100 parts. This preparation is particularly useful in connection with alcoholic liquids and is very widely used for suspending the content of resinous tinctures in aqueous mixtures.

Another preparation that is used quite extensively to mask acrid, bitter or otherwise disagreeable drugs is the recently readmitted

EXTRACTUM MALTI.—U. S.—Extract of malt occurs as a semi-solid extract, having the consistency of thick honey, and is itself considered to be nutritive, tonic and laxative. It has been used quite extensively, particularly in connection with several well-known proprietary preparations, as a vehicle for cod-liver oil, cascara sagrada and the bitter alkaloids like quinin and strychnin.

Average dose: 16 c.c. (4 fluidrams).

Suggestive Coloring.

The subject of coloring is a much simpler one than is that of flavoring, but is of almost equal importance, if we are to judge by the practices that have been followed by manufacturers of elegant proprietaries for upward of a quarter of a century.

Coloring agents are primarily divided into such as are useful with alkaline and neutral substances and such as are useful with dilute solutions of the official acids and acid salts.

For those of the first class, preparations containing carmin or cochineal, for red, and glycyrrhizin for brown are readily available. For the solutions of acids and acid salts, however, neither of these substances would answer, as they are both precipitated by acids, and we have recourse, therefore, to cudbear for the red and caramel for the brown.

Taking the official aromatic elixir as a type, this may be colored a bright red by the addition of from 10 to 20 per cent. of the compound tincture of cardamom, which contains cochineal, or it may be given an equally bright red color by the addition of 1 per cent. of the tinctura persionis (cudbear) of the National Formulary. Cudbear is the source of the bright red color that is so common in proprietary preparations, and as cudbear itself has no known medicinal properties, apart from the pleasing suggestiveness of the resulting preparation, we must naturally conclude that the manufacturers of proprietary preparations have succeeded in impressing not alone the patient, but, in many cases at least, the physician also, by the judicious use of pretty colors.

The use of caramel or burnt sugar is too well known to need further comment, apart from the fact that the National Formulary contains a formula for a compound tincture of cudbear which contains 10 per cent. of caramel and will be found useful when a brownish-red preparation is desired.

A very pleasing golden-yellow mixture that appears to be fairly stable with either acid or alkaline solutions may be obtained by adding 1 per cent. or even less of the now official tincture of hydrastis. This preparation, though made with 65 per cent. alcohol, mixes readily with the official elixir, but precipitates slightly when added to aqueous solutions, and they should, therefore, be directed to be filtered before being dispensed.

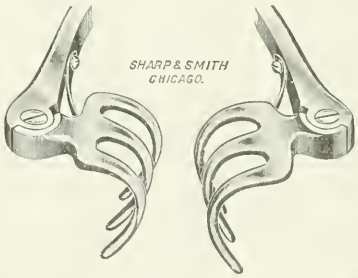
New Instrument

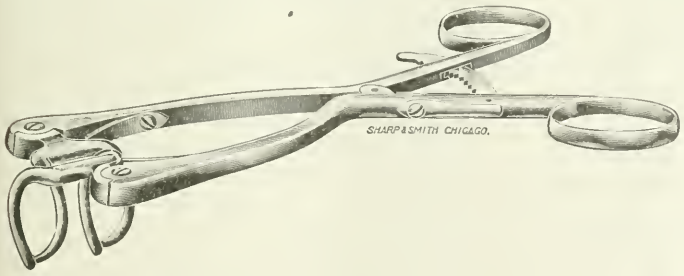
A NEW SELF-RETAINING WOUND RETRACTOR.

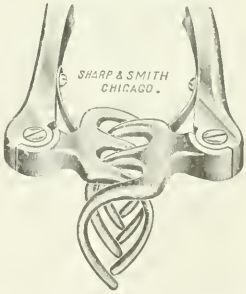
CHARLES ADAMS, M.D.
CHICAGO.

For the past ten or twelve years I have made use of a self-retaining retractor which I believe to be of sufficient value to merit publication of its description.

By the backward crossing of the teeth of the instrument when closed the retractor can be introduced with facility in a small wound. The operator can adjust the instrument to the required degree of traction and can depend on it to retain its place.







With these advantages, the retractor may take the place of one assistant and thus diminish the chances of infection, which are always increased in proportion to the number of hands coming into contact with the wound.

The retractor has been made in two sizes, the longer for abdominal work, the smaller for herniotomies, adenectomies, etc.

SATURDAY, JUNE 23, 1906.

FOURTH OF JULY TETANUS.

In another week we shall experience our annual tetanus inoculation experiment, its size depending on the extent to which public authorities permit the violation of the laws that, in nearly every community, prohibit the use of firearms. The results of the inoculations depend on two factors, the patient and his family, and the family physician. For every blank cartridge, giant cracker or cannon wound, public authorities or public sentiment are responsible. For every one of these wounds that causes tetanus, neglect on the part of patient or of his physician is responsible. We state these facts thus plainly because thorough study of the Fourth of July casualities for several years has taught us that they are facts. In 1903, the total result of the celebration was 466 dead, 415 cases of tetanus and 3,983 injured; in 1904, it was 183 dead, 105 cases of tetanus and 3,986 injured; in 1905, it was 182 dead, 101 cases of tetanus and 5,994 injured. The great and gratifying decrease in the number of deaths, and especially of tetanus, since 1903, we must ascribe to two chief causes; first, the reduction in the use of blank cartridges as a means of celebration; and second, the improved care received by patients with blank cartridge wounds. As to the decrease in these wounds, the number in 1903 was 1,672; in 1904, 1,005; in 1905, 809. This decrease occurred as the result of enforcement in many cities of laws controlling the sale and use of pistols for celebration purposes, and because of the agitation in the daily papers and medical journals against this source of tetanus. That this explanation is correct is shown by the great increase in injuries from other causes against which there was no special agitation.

The improved care of blank-cartridge wounds is well shown by the reduction in cases of tetanus, which decreased in number by 75 per cent., while the number of blank-cartridge wounds decreased but about 30 per cent. in one year and 50 per cent. in the other. This was due partly to the more general understanding by the laity that blank-cartridge wounds are extremely dangerous because of the frequency of lockjaw following them, hence a larger proportion of boys with such wounds received prompt medical attention than was formerly the case. Partly it was due to a corresponding appreciation on the part of practicing physicians of the dangers of these wounds and the necessity for vigorous surgical treatment. As a result, more such wounds were treated by thorough opening, cleansing and free drainage, which reduced the subsequent occurrence of tetanus to a comparatively small percentage of the former incidence. More progressive physicians insisted on a prophylactic injection of tetanus antitoxin, and were able to rest assured that tetanus would not develop in any of their patients. We have no reason to expect that conditions this year will be much different from those of last July. In a number of cities public opposition to dangerous methods of celebration has increased, and in these an improvement may be expected such as was observed in other cities where the same attitude was adopted in the two preceding years. It is to be hoped that in communities in which a good start has been made no retrogression will occur. But at the best there will be several hundred cases of blank-cartridge wounds brought to physicians for treatment, and our greatest responsibility lies with these. We still, occasionally, sadly note in accounts of fatal tetanus cases that the patient saw a "doctor" who dressed the wound, and said that it was not serious: fortunately this statement is seen far less frequently than it was, but that it ever appears is a reproach to our profession.

We can add nothing to what we have previously said concerning the prophylaxis of Fourth of July tetanus, the sum and substance of which is that every penetrating or lacerated wound received from Fourth of July explosions must be treated as if it were known to contain tetanus bacilli in its deepest recesses. Only thorough opening and exploration of the entire tract under anesthesia, followed by thorough use of antiseptics, and free open drainage, can be looked on as an adequate cleansing. This should be followed at the earliest opportunity by the injection of from 5 to 10 c.c. of tetanus antitoxin (depending on the age and size of the patient). That the antitoxin is an essential feature of the prophylaxis has been repeatedly demonstrated by the occurrence of tetanus in patients whose wounds have been treated carefully, according to surgical principles.[1] That antitoxin is effective as a prophylactic has been equally well demonstrated, both in veterinary and hospital practice, and in our annual Fourth of July epidemics of the past several years. Consequently we feel safe in saying that if every Fourth of July injury were treated in the thorough manner outlined above on the day that it is received, there would be no tetanus epidemic.

Curative treatment of tetanus still offers us but a slight degree of encouragement. There can be no doubt that a distinct progress has been made, for the number of recoveries reported during the past two years has decidedly increased. To judge from the reports received, the greatest measure of success has been obtained by those who have practiced the combined intraspinal and intraneural injection of antitoxin, as described by Rog-

1. Noer: The Journal, Feb. 10, 1906, p. 432, and the accompanying editorial, p. 436.

ers;[2] at the same time withdrawing much of the toxic cerebrospinal fluid and giving abundant subcutaneous injections of antitoxin. Controlling the spasm by intraspinal beta-eucain injections, as advocated by Murphy, together with the usual administration of sedatives and chloroform as indicated, seem to be valuable auxiliaries. The use of magnesium sulphate injections as proposed by Meltzer[3] must still be regarded as in the experimental stage. Matthew's[4] method of injection of a solution containing calcium and other salts seems to depend similarly on the depressant effect of the alkaline-earth ions (calcium, magnesium) on the central nervous system. In spite of all these methods, however, recovery from tetanus remains an exceptional termination, and we must rely for our chief results on prophylaxis, both legal and surgical.

INSANE ASYLUM SCANDALS.

Although it might seem to be a part of the general tendency to the exposure of abuses, real and alleged, at the present time, there is nothing specially unusual in the fact that three or four separate insane asylum investigations, based on serious charges, have been under way during the past two or three weeks. Institutions of no other sort are looked on with more jealous scrutiny by the public than insane hospitals and there are none against which charges are more readily believed. When a real scandal occurs it is immediately made the most of by the newspaper, and the public is seldom in the proper state of mind to estimate the facts at their real worth and signification.

There is, unfortunately, too much ground for the lack of confidence that exists. Owing to the fact that in many parts of this country public asylums are considered more or less as political institutions and the positions in them as party spoils to be used by partisan politicians as part of their patronage, many abuses have crept in, and when scandals do occur they are well utilized for political purposes. The superintendents and higher officials, if not the whole working personnel of the institutions, are likely to be selected largely according to their political preferences and influence, and, though often respectable men and sometimes able in a professional way are not qualified as experts for their special responsibilities. Hence, the low standing of American psychiatry. Many unworthy and unfit persons are included in employés selected on political grounds, and the necessary discipline of the institution is corrupted by political "pull." There is little or no incentive to the acquisition of special qualifications on the part of the medical or attendant force; hence, neglect, if not abuse, is pretty nearly sure to follow. The trustees or directors are business men or politicians with no adequate ideas or ideals of the true functions of the institution. The superintendent is generally a respectable physician, but too often is selected for his political rather than his general qualifications, and the medical staff, if not chosen by him, are chosen on the same general principles. If the superintendent is allowed to select his assistants, some attention to their qualifications may be given, but their political standing must usually be all right. They are in any case apt to be little regarded by the trustees unless they have strong political backing, and their position and social standing in the institution, so to speak, largely depends on the personal equation of the superintendent.

That there have not been more asylum scandals under such a condition of affairs is surprising. The possibilities of such a system are self-evident, and the reason they are not realized in every case is because there is more good in human nature and more sense of responsibility in political appointees than the system itself demands. There are many institutions in this country that are conducted in a fairly respectable way even under such a system, and where political changes are not frequent actual progress and reforms may be brought about. The conditions, however, are better than they were, the tendency to reform is certainly spreading and, taking the country as a whole, there are reasons for encouragement. There is even an encouraging prospect that the politically-managed insane asylum will soon be the exception and not the rule throughout the land.

While we attribute the major part of the evils and the consequent lack of confidence on the part of the public to the past and present political management of these institutions, it does not follow that asylum scandals would entirely disappear were there no partisan political management whatever. Accidents, misuse of patients and other evil happenings are always liable to occur even when the *morale* of the institution is kept at its highest point, and this depends not only on the personality of the superintendent, his professional ability and his selection of his subordinates, but also on the element of chance to a certain extent. Even ideal institutions, and there are such, may not escape. "Accidents will happen in the best regulated families" and in the best regulated institutions as well, though their occurrence may be reduced to a minimum. No one can foresee all the possibilities, and, though a retrospect may show a fault, it is not always necessarily a very blamable one.

In Great Britain at the present time the institutions, public and private, for the care of the insane are probably as well regulated and guarded against such misfortunes as anywhere in the world, and yet it is in one of these that a scandal that was worse in its way than anything that has ever been reported from an American

4. "The Prophylaxis and Treatment of Fourth of July Tetanus," THE JOURNAL, June 18, 1904, p. 1621. Special article giving details of surgical methods and use of antitoxin. Included is the formula given by Matthews for calcium-containing salt solution (published in THE JOURNAL of August 29, 1903, p. 565.

asylum has occurred within a very few years. Under the conditions existing over there it excited little public comment, as public hospitals for the insane have, as a rule, the public confidence, and the mishaps that occur are so rare that they are not considered necessarily avoidable when they do happen. The commissioners in lunacy investigate, and their decision is accepted as trustworthy and final. In this country such an occurrence would have been exploited *ad nauseam* by the yellow newspapers, and in states where the traditions of political control still continue would probably receive a whitewashing report that might not whitewash and possibly be utilized as the basis of partisan recriminations. If due to a general laxity of discipline the blame might be shoved off on some subordinate, since the party can not afford to suffer through recognition of the responsibility of the higher authorities. Each such untoward happening should be an insurance against its repetition and every investigation a step toward reform of existing evils, and we believe that this will after all be the ultimate result.

It must be remembered, moreover, that in many cases unfounded charges are liable to be made. There is a considerable class of the insane that are very properly detained in institutions very much against their will, and we can not expect them always to take a favorable view of what they see and experience. Many, when fitted to be discharged from custody, still retain an irrational state of mind as regards their detention and are liable to imperfect and prejudiced recollections of their treatment. The position of an asylum superintendent is not always a pleasant one on this account, no matter how well meaning and conscientious he may be, and more than one has himself become insane as a result of his experience.

What is needed in this country, first of all, is absolute abolition of any idea that a charitable institution of this kind has any connection with politics, next a proper supervision of these institutions by some higher authorities like the British commissioners in lunacy, men selected solely on account of their experience as alienists, their known integrity, and possibly also in one of the members a high legal standing. Then there should be a system of promotion by merit and of special education of the medical staff in psychiatry. The state should educate its alienists from interne up to superintendent, as is done in New York State, and a subordinate position should not be considered as a mere temporary episode in the career of a young practitioner. The social standing of the assistant physicians should be higher. They should be encouraged to do good work and should get due credit for it and due reward, and responsibility should be accompanied by corresponding authority. At present too often the superintendent is all in all to the trustees and the rest of the medical staff a matter of very slight consideration. Lastly, there should be no undue secrecy about the internal workings of the institution and certainly no suppression of facts from those who are entitled to know; the business administration should always be subordinate and the medical and humane functions of the institution be first considered. It is needless to say that the utmost care should be exercised in the selection and retention of attendants and other subordinates and that the humane ideas of treatment of the insane should everywhere be inculcated and prevail. These are self-evident necessities of a successful administration.

THE RELATION OF WINDS TO SICKNESS.

Every one is familiar with the statements regarding the astonishingly low mortality in Chicago, and we are not venturing to criticise their accuracy. We are ready to admit that it is becoming increasingly difficult for people at any age to die in that fortunate city, and that stockyard odors, dirty streets, inadequate sanitary inspection and even impure foods are powerless in the face of the life-giving forces of the climate of Chicago. It is only when an attempt is made to explain the causes of this victory over the common enemy of mankind that we are apt to raise a slight protest. For instance, we are informed by the Bulletin of the Health Department that the soubriquet, "Windy City," is one that Chicago should be proud to bear, for "it is to the great wind movement of the city that it largely owes its pre-eminent healthfulness." The bulletin goes on to quote Prof. E. G. Dexter, of the University of Illinois, who, in a recent work, made the statement that such "phenomena" as "absence from school, absence from public duty, clerical errors, sickness and death" are more frequent in periods of aerial stagnation than in those of high winds.

Without going into the question of how Professor Dexter's statistics were gathered, and the other factors which influence mortality aside from atmospheric conditions, we wish simply to give the reverse side of the high-wind question as presented by Hueppe of Vienna.[1] To Hueppe the term, "Windy City," so long applied to Vienna, is synonymous with "Consumptive City." High dry winds, with their inevitable accompaniment of dust, he thinks, are responsible, in large degree, for the enormous mortality from tuberculosis in Vienna as compared with other large cities, such as Berlin and London. Berlin's mortality in ten years was 23.1 per 10,000 of population. London's, for the same period, was only 17.7, while Vienna's reached the astounding height of 46.4. Hueppe goes on to say that we realize the harmful effects of dust in closed spaces, in cotton and wool factories, cutleries, stone-cutting establishments, etc. Why, then, should we not recognize the dangers of dust-laden air in the streets, especially when we consider the nature of the dust. It is by the irritating effect on the lungs that dusty air increases pul-

1. Wien. klin. Wochft., 1904 p. 1001.

monary tuberculosis by preparing the lungs for tuberculous infection rather than by actually conveying the infection, for such dust off the streets is probably seldom rich in tubercle bacilli. Another danger is that of secondary infection. A case of uncomplicated tuberculosis may, by the inhalation of street dust, be changed into one of mixed infection. Thus may be explained the low rate of mortality from tuberculosis in damp, muddy, foggy cities, such as Berlin and London, as compared with dry and windy ones.

The mortality rate from tuberculosis in Chicago for ten years, from 1890 to 1899, inclusive, the period covered by Hueppe's statistics, is 17.1, a rate only very slightly below that of London. Yet in London conditions contributory to tuberculosis are exceptionally bad; 30 per cent. of the people live in poverty, alcoholism abounds, while overcrowding and underfeeding and physical degeneracy due to generations of poverty are seen to an extent unknown in any American city. Why, then, should Chicago, with her comparative prosperity, her lack of serious overcrowding and of old infected tenements, have a death rate from tuberculosis almost equal to London's? May not the reason be sought in the dust-laden atmosphere, caused by unclean streets and high winds? For though the general mortality of Chicago is low, yet the death rate from tuberculosis is proportionately high, being always since 1892 more than one-tenth of the whole.

DUST REMOVAL, NOT DISPERSAL.

We are in the midst of the dust season, and the problem of the removal of the fine particles that gather over everything, and especially on wearing apparel, is once more acute. Since the invention of the vacuum process by which dust is sucked up into a receiver to be carted away instead of being merely swept or brushed up into the air and then allowed to settle down again, these old-fashioned methods have come to seem especially obnoxious. In houses, especially where there are children, it would seem to be advisable that clothes, if dusted within the house at all, should be brushed in some special part of it quite segregated from the ordinary living rooms, and that no brushing should be done at night before the retirement of the family. Undoubtedly many of the so-called summer complaints are really not diseases of hot weather so much as of dusty weather. The dust is blown hither and thither and settles on the food and on the hands and thus readily finds its way into the digestive tract. For most people, such opportunities for infection mean nothing, since their resistive powers are quite sufficient to protect them, but for children and those in delicate health the presence of such infectious material in the intestinal tract may make all the difference between good physical condition and even severe illness. It is especially while traveling that the dangers of dust become more serious. It seems a pity that with the amount of energy that might readily be employed on a railroad train, for instance, for running some simple vacuum contrivance for the proper removal of dust, there should as yet be nothing of the kind hinted at even on the best trains. The morning brushing in the Pullman car is undoubtedly a source of considerable danger for persons with delicate throats or with weak lungs or with sensitive gastrointestinal tracts. It is here evidently that the next great hygienic improvement on cars and in dwelling houses must come. The old-fashioned methods are entirely too prone to produce serious results, and physicians should be leaders in the movement to relegate them to the lumber heap of disused things of the past.

AN AGED ATHLETE.

An old-time champion pedestrian, whose record 30 or 40 years ago aroused the country, has recently at the age of nearly 70 performed the feat of walking from Philadelphia to New York, a distance of 96 miles, in a little over 23 hours and finished the task in excellent physical condition. This is a good example of the fact that the physical organization of man need not necessarily go to pieces before the allotted three score years and ten, when, according to some, the system is worn out and useless. Of course, this man Weston is an exceptional case, but he shows what the possibilities are, and probably a great many other individuals of as great age could do likewise.

"THOU SHALT NOT KILL."

That misguided doctor in the Iowa legislature who created a newspaper furore last winter by his bill asking for compulsory killing off of incurables, threatens to introduce the same measure again, according to the newspaper press reports. It was considered a joke then, but evidently it was not so intended. The idea seems to suit a certain class in whom the moral principles are somewhat perverted or confused and the intellect more or less defective, judging from arguments brought forward in favor of the proposition. Fortunately, these individuals are few. The alleged plea that incurables are practically put out of existence in large hospitals is simply a libel on the profession and should be resented by us all as such. The state of Iowa will seriously endanger its reputation for good morals and good sense, if its legislature gives this proposition any semblance of a respectful consideration. The sixth commandment is still in force.

A NOTED X-RAY VICTIM.

The recent death of a prominent Rochester (N. Y.) physician from cancer, attributed to excessive exposure to the *x*-ray, adds to the long list of the martyrs to medical science and is a striking evidence of the dangerous possibilities of this very powerful agent. There have been many cases of inconvenient symptoms among *x*-ray workers, but we believe there are few serious cases that have originated of late years. Dr. Weigel was a pioneer in this line of investigation, and it is likely that he neglected due precautions before their necessity had been demonstrated by general experience. The fact that his case was diagnosed as cancer by one of the most eminent pathologists and that its clinical history was such as to warrant the diagnosis is suggestive. It does not favor the parasitic theory of that disease nor does it

necessarily disprove it. It shows very clearly, however, that the action on cell growth of the *x*-rays, which are so often beneficial in malignant disease, is not in all cases a very controllable one, and it emphasizes the necessity of special caution in their use.

FEE BILLS AND ANTI-TRUST LAWS.

The attorney general of Kansas has given out an opinion, according to newspapers, that the mere organization of physicians and the giving out of a scale of fees is a violation of the antitrust laws of the state. Of course, this is merely one official's opinion, but it can be acted on as the law until the courts decide otherwise. We do not know the full facts of the case as regard the points submitted to the attorney general by the county attorney who raised the question, but his decision seems to be a broad one, covering all society fee bills. Ordinarily these are understood by the profession as simply the expression of what is a reasonable charge for the services rendered and as not limiting the physician's or surgeon's privilege to charge more or less according to the special circumstances of the case. How such could be a violation of any reasonable laws is not very obvious. There have been medical fee bills as long as there have been medical societies, and they have been recognized and admitted as evidence in courts of law thousands of times.

Medical News

ARKANSAS.

State Medical Society Meeting.—In the report of this society, published in THE JOURNAL, May 26, it was stated that Dr. Morgan Smith recommended the administration of menthol in the treatment of uncinariasis. We are informed that Dr. Smith did not recommend the administration of this drug in the treatment of uncinariasis, in fact, did not touch on the treatment of the disease, as the subject was arranged in the form of a symposium as follows: "Prevalence of Uncinariasis in Arkansas, Etiology, Symptomatology and Pathology," Morgan Smith, Little Rock; "Diagnosis, Prognosis, Prophylaxis and Treatment," W. S. Stewart, White Oak. The mistake of the correspondent who sent us the report of the meeting probably arose from confusion of menthol with thymol which was recommended by Dr. Stewart.

CALIFORNIA.

Personal.—Dr. and Mrs. W. Jarvis Barlow, Los Angeles, are taking a trip to Alaska.——Dr. Trusten P. Peery, Yuba City, has been appointed physician of Sutter County.——Dr. John E. Hubble, Lordsburg, has gone to Chicago for two months.

A Correction.—Dr. Oswald M. Justice, Los Angeles, whose death by suicide was reported in a portion of the issue of THE JOURNAL of January 20, writes under date of May 29 as follows:

> I am alive and well and have never been convicted of any crime nor sentenced to any imprisonment. I am now, and for several years have been, practicing my profession in Los Angeles. I was greatly surprised and shocked to read the article in question. It is untrue and libellous. It is needless to say it has inflicted on me and my many friends great mortification and distress, and has done me irreparable injury, as well as injure my reputation and my business.

We regret that this error occurred. The fact is, however, that after only a few copies of THE JOURNAL containing the notice had been printed, it was realized that the source of the information was not sufficiently authentic without further verification and the item was at once removed.

Commencement.—The annual graduating exercises of the College of Physicians and Surgeons, Los Angeles, were held June 6. A class of three was graduated. Dr. Charles W. Bryson presented the diplomas, and Dr. James P. Booth delivered an address on "The Vicissitudes of the Young Practitioner."

At the annual commencement exercises of the College of Physicians and Surgeons of San Francisco, May 17, a class of 29 was graduated. Dr. David A. Hodghead, dean and secretary of the college, announced the names of the graduates, and Dr. Winslow Anderson, president of the college, conferred the degrees.

ILLINOIS.

Personal.—Dr. Bruce D. Parrish, Mattoon, has been appointed physician to the Odd Fellows' Home.——Dr. W. M. Avery, Compton, has been appointed physician for the Paw Paw district of Lee County.

Podstata Goes to Elgin.—Dr. Vaclav H. Podstata, superintendent of the Cook County Institutions, Dunning, has resigned to accept the superintendency of the Illinois Northern Hospital for the Insane, Elgin, made vacant by the resignation of Dr. Frank S. Whitman. He assumes his new duties on July 1.

Investigation at Kankakee.—The grand jury, which for two weeks has been investigating the charges of cruelty and gross mismanagement of officials of the Illinois Eastern Hospital for the Insane, Hospital, adjourned June 15, after submitting a report which sets forth that all except one of the alleged cases of mistreatment were found to be baseless. An indictment was found against an attendant who had assaulted a deaf and dumb patient.

Chicago.

Commencement.—At the commencement exercises of Rush Medical College, June 13, 52 students received the degree of doctor of mdicine, and Dr. Roswell Park, Buffalo, N. Y., delivered the annual address.

Annex to St. Luke's.—The plans for the George Smith memorial addition to St. Luke's Hospital have been completed. The building will be six stories in height, with a frontage of 135 feet on Michigan Avenue. It will have 112 private rooms, a number of which are to be arranged in suites, with private baths. The building is designed to afford accommodation for the superior grade of private patients.

Health Report.—The mortality for the week ended June 16 is, with one exception, the lowest on record for June. During the week 436 deaths were reported, or 87 less than for the previous week. This is equivalent to an annual death rate of 11.09 per 1,000. Consumption heads the death list for the first time in several months with 60 deaths; pneumonia caused 50 deaths; violence (including suicide), 38; acute intestinal diseases, 33; nephritis, 28, and nervous diseases, 22. Two deaths were reported from insolation.

Personal.—Drs. Ludvig Hektoen, W. A. Evans and Maximilian Herzog have been appointed to represent the trio of civil investigators of the Union Stock Yards. The object of this committee is to investigate sanitary conditions at the stock yards.——Drs. Harold N. Moyer and Frank Allport were given the degree of LL.D. at the annual commencement of Notre Dame (Ind.) University, June 14.——Dr. Daniel A. K. Steele, president of the College of Physicians and Surgeons, was given the degree of LL.D. at the commencement exercises of the University of Illinois, Champaign, June 13.

INDIANA.

Laboratory Closed.—The Laboratory of Pathology and Bacteriology of Indiana University closed for the summer vacation, June 10. Since its opening in the spring, the laboratory has received for examination more than 20 pathologic specimens a week from the physicians of the state. It is hoped that in the summer of 1907 and thereafter arrangements will be made so that the closing of the laboratory in summer will be unnecessary.

Academy of Medicine Meeting.—At the semi-annual meeting of the Fort Wayne Academy of Medicine, May 31, Dr. George W. McCaskey read a paper on the "Relation of Diseases of the Gastrointestinal System to Conditions of Hypertension," which he read before the International Medical Congress at Lisbon. The following officers were elected and installed: President, Dr. William Ranke; vice-president, Dr. Adam L. Schneider; secretary, Dr. Alfred Kane, and treasurer, Dr. Allen Hamilton.

Win from State Board.—Dr. Mary A. Whery, Fort Wayne, whose license to practice medicine was revoked for alleged participation in an illegal operation, and who appealed to the circuit court, had a decision rendered in her favor, June 2.——The State Board of Medical Registration and Examination has filed in the circuit court a motion to modify the judgment in the proceedings instituted by it against Dr. Nelson B. Ross, Muncie, whose license was revoked a few weeks ago. The judgment shows a finding against the board, which desires the record to show a dismissal of the case.

Personal.—Dr. Albert E. Bulson, Jr., Fort Wayne, secretary of the Section on Ophthalmology of the American Medical Association, has sailed for Europe, and expects to visit Berlin, Zurich, Würzburg, Paris and London.——Dr. W. H. Mainwaring, professor of pathology, Indiana University, will give a course of 24 lectures on pathologie physiology before the students of Rush Medical College, Chicago, during the summer quarter, and will assist in the regular class work in general pathology in the University of Chicago.——Dr. James H. Walker, Henryville, who was operated on for appendicitis in Louisville, June 9, is reported to be improving.——Dr. Samuel N. Hamilton, Connersville, has been elected medical director of the Grand Army of the Republic for Indiana.—Dr. Clifford H. Mayfield, Indianapolis, has been installed assistant surgeon of the Indiana State Soldiers' Home, Lafayette, vice Dr. Logan Stanley, resigned.——Dr. D. F. Davis, New Albany, has gone to Europe.——Dr. Clarence Province, Franklin, has been elected a member of the city school board.——Drs. Chester C. Funk and Francis A. Mitchell have been appointed members of the New Albany board of health, and Dr. Funk has been made secretary of the board.——Drs. James M. Dinnen and L. Park Drayer, Fort Wayne, Dr. N. Howard Thompson, Wabash, Dr. Laughlin O. Malsbury, Peru, and Dr. John P. Hetherington, Logansport, have been appointed surgeons for the Fort Wayne & Wabash Valley Traction Company.

KENTUCKY.

Personal. Dr. and Mrs. J. N. MacCormack, Bowling Green, sailed for Europe on the *Majestic*, June 13. They will spend three months abroad.——Dr. Hugh M. McCullough, Louisville, has been appointed sanitary health inspector, vice Dr. Llewellyn P. Spears.——Dr. Hubbard K. Adamson, Maysville, was taken suddenly ill while attending the meeting of the Kentucky State Railway Surgeons at Richmond, May 30.

MARYLAND.

Personal.—Dr. Harry S. Jarrett has resigned as resident physician of the Endowood Sanatorium for Consumptives in Towson, and will be succeeded by Dr. A. M. Forster of New Haven, Conn.——Dr. Thomas S. Cullen has resigned from the staff of the Cambridge Hospital and has been succeeded by Dr. Guy L. Hunner.——Dr. Charles A. Wells, ex-mayor of Hyattsville, was presented by his friends with a silver punch bowl, May 30.——Dr. William S. McPherson, Catoctin Furnace, has been appointed justice of the peace for Frederick County.

Baltimore.

Commencement.—At the annual commencement exercises of Johns Hopkins University a class of 84 was graduated. Seven members of the class were women.

Monument to Bosley.—A granite monument is being erected in the Prospect Hill cemetery at a cost of $1,500 to the memory of the late Dr. Grafton M. Bosley.

Meat Inspection a Farce.—Dr. John S. Fulton of the State Board of Health charges that the meat inspection in Baltimore is a farce. He states that he knows of sick and disabled animals having been killed and sold for food.

Alumni Meeting.—The twelfth annual banquet of the Maryland University Alumni Association, Washington Branch, was held June 8. The following officers were elected: Dr. Otho M. Muncaster, president; Drs. William L. Robins and William N. Souter, vice-presidents; Dr. W. M. Simpkins, secretary and treasurer, and Dr. Wilson P. Malone, corresponding secretary.

Personal.—Dr. Charles H. Bunting of Johns Hopkins has been elected professor of pathology at the University of Virginia, and Dr. Reed Hunt, formerly of Johns Hopkins, but now of the United States Public Health and Marine-Hospital Service, has been made professor of physiology in the same institution.——Dr. Benjamin T. Winchester has returned from Europe.——Dr. G. Milton Linthicum was given the degree of M.A. by St. John's College, Annapolis.——Dr. F. S. Carey has been appointed resident physician at Elkins, W. Va.

MASSACHUSETTS.

Banquet to Old Physician.—On May 31 the physicians of Lowell celebrated the fiftieth anniversary of the entrance of Dr. William Bass into the practice of medicine by a banquet in his honor, over which Dr. George H. Pillsbury presided as toastmaster. An antique wall clock was also presented to Dr. Bass, the presentation address being made by Dr. John C. Irish.

State Society Election.—At the one hundred and twenty-fifth annual meeting of the Massachusetts Medical Society the following officers were elected: President, Dr. George W. Gay, Boston; vice-president, Dr. Leonard Wheeler, Worcester; treasurer, Dr. Edward M. Buckingham, Boston; recording secretary, Dr. Francis W. Goss, Roxbury; librarian, Dr. Edwin H. Brigham, Boston, and chairman of the committee of arrangements, Dr. George S. C. Badger, Boston.

McLeod Expelled.—At the annual meeting of the Massachusetts Medical Society, on June 13, in accordance with the by-laws, the secretary, Dr. Francis W. Goss, Roxbury, moved that the sentence imposed by the board of trials in the charges against Percy D. McLeod, Boston, be imposed, and that Dr. McLeod be expelled from the Massachusetts Medical Society. The motion was unanimously carried, and Dr. McLeod was disbarred from membership on the ground of "conduct unbecoming a physician and member of the society."

MISSISSIPPI.

Mississippi to Have Medical College.—Work has begun on the building for the Mississippi Medical College, Meridian, to be opened next fall. The institution has been incorporated with a capital of $25,000, by Drs. N. L. Clarke, M. J. Lowry, J. E. Neal and others. The following are announced as the medical members of the board of trustees: Drs. W. W. Hamilton, J. R. Tackett and Thomas A. Barber, Meridian; G. H. McNeil, Newton, and Robert S. Curry, Columbus.

Mississippi Medical and Surgical Association.—This association, an organization of the colored physicians of the state, held its sixth annual meeting at Natchez, April 25 and 26. The following officers were elected: Dr. Albert W. Dumas, Natchez, president; Drs. Edward P. Brown, Greenville, and Dr. A. J. Lopez, vice-presidents; Dr. L. P. Burbridge, secretary, and Dr. Nichols, Okolona, treasurer. At the close of the meeting a banquet was given, over which Prof. G. W. Brumfield presided as toastmaster.

State Association Meeting.—The annual meeting of the Mississippi State Medical Association was held in Jackson, April 17, 18, 19 and 20, under the presidency of Dr. Edward H. Martin, Clarksdale. The association was welcomed to Jackson by Bishop Charles B. Galloway of the Methodist church, father of the health officer of Jackson, and Dr. T. P. Lockwood, Crystal Springs, responded. In his annual address the president reported the work done by the association during the past year, showing its growth and advancement. Tuberculosis was the subject of a symposium in which Dr. W. A. Evans of Chicago read a paper on the prevention of the disease, Dr. H. Wernicke Gentles, Chicago, a paper on the early diagnosis of the disease, and Dr. H. L. Sutherland, Rosedale, one on tuberculosis among the negroes. A feature of one session was the paper by Dr. Joseph H. White, United States Public Health and Marine-Hospital Service, on the permanent eradication of yellow fever and malaria, which was read by Dr. Peter W. Rowland, Oxford. The following officers were elected: President, Dr. Walter W. Crawford, Hattiesburg; vice-presidents, Drs. John W. Young, Grenada, John R. Tackett, Meridian, and Elbert A. Cheek, Arcola; secretary, Dr. Lee T. Fox, Benela (re-elected); treasurer, Dr. John F. Hunter, Jackson (re-elected); delegate to the American Medical Association, Dr. John Darrington, Yazoo City, and alternate, Dr. Hugh H. Haralson, Vicksburg. The association will meet in Gulfport in April, 1907.

NEW JERSEY.

Diphtheria Closes School.—Owing to the prevalence of diphtheria among the pupils of Cherry Street school, Elizabeth, the school has been closed by order of the board of health.

Physician Wins Suit.—In a suit for $20,000 damages brought by George Lees, North Plainfield, against Dr. Albert Wickman, Newark, for alleged improper treatment in applying a plaster cast for spinal curvature, the jury, on May 25, returned a verdict of no cause of action.

New Staff for Hospital.—The following have been appointed members of the staff of St. Joseph's Hospital, Paterson: Drs. Edward F. Denner, William Kerr and Charles J. Kane, surgical department; Drs. Charles M. Campbell, James O'Donnell and Charles H. Scribner, medical department, and Dr. James W. Atkinson, ophthalmologic department.

Personal.—Dr. Samuel D. Mayhew, Bridgeton, was operated on for appendicitis, May 8.——Dr. W. Blair Stewart has been elected first vice-president of the Atlantic City board of trade.——Dr. Benjamin Gutmann has been appointed health officer of New Brunswick, vice Dr. Staats V. D. Clark.——Dr. Frederic J. Hughes has been appointed school physician of North Plainfield vice Dr. J. Hervey Buchanan.

Free Antitoxin Bill Vetoed.—The governor on June 8 vetoed the bill providing for the free distribution of antitoxin by the state to individuals unable to pay for the remedy. His reasons

are that it is the function of the municipality and not of the state to supply necessities to the poor, and, further, that physicians should not be compelled to risk the loss of practice by designating what patients are or are not indigent.

Aid for Physicians' Families.—The twenty-fourth annual report of the Society for the Relief of Widows and Orphans of Medical Men of New Jersey shows that during 1905 four deaths occurred, and claims amounting to $724.25 were paid to the widows. The permanent fund has been increased by nearly $1,000 and now amounts to $6,573.12. The receipts for the year were $1,659.72, and the disbursements $1,264.50.

Hospital Seeks Relief.—The trustees of the Cooper Hospital, Camden, have appeared before the city council business committee in an effort to have the property owned by the institution exempted from taxation. It was shown that the income of the hospital was about $15,000 and that the taxes amount to about $5,000 a year. During 1905, 1,026 emergency cases were treated, 18,500 persons were cared for in the dispensary, and practically all the southern part of New Jersey is dependent on the institution.

NEW YORK.

Resolutions Regarding Dr. Weigel's Death.—At a special meeting of the Rochester Academy of Medicine, June 1, resolutions were unanimously adopted setting forth the loss sustained by the Academy in the untimely death of Dr. Louis A. Weigel, its president and one of its charter members.

Centennial of County Society.—The Medical Society of the County of Ulster will celebrate its one hundredth anniversary June 26 at the court house, Kingston, N. Y. Dr. Albert Vander Veer, Albany, will speak on "The Advancement of Medicine and Surgery During the Past Century"; Hon. John J. Linson, Kingston, on "Expert Medical Testimony." Hon. G. D. B. Hasbrouck, Kingston, will discuss "The Physician in Politics", and Drs. E. H. Loughran and A. H. Mambert, Kingston, will give the history of the society.

NORTH CAROLINA.

Communicable Diseases.—During April measles was reported in 41 counties, whooping cough in 34, smallpox in 29, typhoid fever in 24, diphtheria in 13, influenza in 8, scarlet fever in 6, cerebrospinal meningitis in 4, mumps in 3, and chickenpox in one county.

Released on Bond.—Dr. Joseph B. Matthews, recently convicted for killing his wife with strychnin at Greensboro, and sentenced to imprisonment for 20 years, has been released under bond of $5,000, and has been taken to a sanitarium near Baltimore, to be treated for the morphin habit.

PENNSYLVANIA.

Cornerstone Laid.—The cornerstone of the Passavant Memorial Home for the Care of Epileptics at Rochester was laid June 7.

New Hospital.—The new Columbia Hospital, Wilkinsburg, erected by the United Presbyterian Women's Association at a cost of more than $200,000, was formally opened June 1.

New Health Board.—The health board of Freeport has organized with Dr. Robert L. McCurdy as president, Dr. Charles A. Rogers, vice-president, and Dr. L. Walker Schmatterly, secretary and treasurer.

Illness and Accidents.—Dr. James P. Gilligan, Wilkesbarre, underwent an operation for appendicitis at Mercy Hospital, May 30.——Dr. James M. Gelwix, Upper Strasburg, is critically ill at his home.

Military Appointments.—Dr. P. Francis Gunter, Scranton, has been appointed assistant surgeon of the Thirteenth Infantry, N. G. Pa.——Dr. Wiliam E. Keller, Scranton, has been reappointed surgeon of the Thirteenth Infantry, N. G. Pa.——Dr. S. E. Ralston has been appointed surgeon of the Eighteenth Infantry, N. G. Pa., with the rank of major, vice Major C. C. Wiley, Pittsburg, appointed brigade surgeon and assigned to the staff of General John A. Wiley.

Personal.—Dr. G. R. S. Carson has been appointed surgeon in the eye, ear, nose and throat department of the Pottsville Hospital, vice Dr. George H. Halberstadt.—— Dr. Samuel R. Crothers, mayor of Chester, has been appointed local surgeon for the Philadelphia, Wilmington & Baltimore Railroad, succeeding the late Dr. F. Farwell Long.——Dr. Joseph D. Findley, Altoona, has been appointed representative of the State Department of Health for Blair County.—— Dr. and Mrs. S. Harper Smith, McKeesport, celebrated the twenty-fifth anniversary of their wedding, June 3.

Philadelphia.

Hospital Wing Dedicated.—The new five-story addition to St. Agnes' Hospital was dedicated May 29 by Bishop Prendergast, with impressive ceremony. The new wing contains accommodations for 180 private patients and cost $350.000.

Medical Inspectors Injured.—Drs. Elmer G. Whinna and Charles A. Groff, assistant city medical inspectors, are confined to their homes by injuries received while attempting to alight from street cars.

University Commencement.—The one hundred and fiftieth annual commencement exercises of the University of Pennsylvania were held in the Academy of Music, June 13. More than 500 students received diplomas and the annual address to the graduating class was delivered by Prof. John B. McMasters. The medical degree was conferred on a class of 102.

Personal.—Dr. William W. Keen has been elected a trustee of Vassar College to fill the vacancy caused by the death of Dr. Edward Lathrop.——Dr. Louis Starr sailed for Europe on the *Celtic*, June 15.——Dr. John M. Swan sailed for Europe, June 16.——Dr. Susan Rogers Corson, Lansdowne, sailed for Europe on the *Friesland*, June 9.——Dr. Boardman Reed has moved to Alhambra, a suburb of Los Angeles, Cal.

Jefferson Alumni Meeting.—The Alumni Association of Jefferson Medical College held its annual meeting June 1, at which the following officers were elected: President, Dr. W. M. Late Coplin; recording secretary, Dr. Charles S. Barnes; corresponding secretary, Dr. Aller G. Ellis; Dr. Randle C. Rosenberger, treasurer, and vice-presidents representing every state of the union, Hawaii, the Philippine Islands, the Army and the Navy.

Health Report.—The total number of deaths reported for the week aggregated 414, a decrease of 82 from the number reported last week, and a decrease of 7 from the number reported in the corresponding week of last year. The principal causes of death were: Typhoid fever, 16; measles, 6; pertussis, 9; diphtheria, 4; consumption, 55; cancer, 25; apoplexy, 23; heart disease, 39; acute respiratory disease, 26; enteritis, 34; Bright's disease, 31; suicide, 4; accidents, 15, and marasmus, 5. There were 234 cases of contagious disease reported, with 21 deaths, as compared with 282 cases and 32 deaths reported in the previous week.

Woman's College Notes.—Dr. Clara Marshall has resigned the chair of therapeutics in the Woman's Medical College of Pennsylvania, to take effect June 1, 1906. Although the dean has always been a member of the faculty, the trustees, on recommendation of the faculty, have appointed Dr. Marshall as dean. The title of the chair of materia medica and therapeutics has been changed to that of materia medica, therapeutics and clinical medicine, and Dr. Arthur A. Stevens has been appointed professor.——Of 93 men and women who took the competitive examination for admission to the Philadelphia Hospital and who were placed on the eligible list, the highest average obtained was 82.2, and a graduate of the Woman's College obtained the fourth place, with the mark of 81.6.—— Dr. Mary J. Martin secured third place in the examination by the State Board of Examiners of North Carolina in a class of 132. The highest average obtained was 94 2/7, and Dr. Martin's average was 93 6/7.

VIRGINIA.

Personal.—Dr. R. C. Brunk, first assistant physician of the Central State Hospital, Petersburg, has resigned, and has been succeeded by Dr. Robert S. Talbot.

Commencement.—The eighty-second annual commencement exercises of the University of Virginia, Medical Department, Charlottesville, were held June 10, when a class of 21 was graduated.

Personal.—Dr. Edward W. Finn, Dedham, has been appointed town physician for 1906 and 1907 by the overseer of the poor.——Dr. Arthur B. Lamb of Harvard University has been appointed director of the Havemeyer Laboratory of Chemistry, New York University, vice Dr. Maurice Loeb, resigned.

GENERAL.

American Association of Pathologists and Bacteriologists.—The sixth annual meeting of this association was held at the Johns Hopkins University, May 19. The following officers were elected for the ensuing year: President, Dr. Welch; vice-president, Dr. A. S. Warthin; treasurer, Dr. H. U. Williams; secretary, Dr. H. C. Ernst.

CANADA.

Hospital for Infectious Diseases.—Plans have been issued for a $6,000 hospital for infectious diseases at Peterboro, Ont.

British Columbia Medical Association.—The annual meeting of the British Columbia Medical Association will be held in Vancouver, August 1 and 2.

Nova Scotia Reciprocity with Great Britain.—The province of Nova Scotia is the first to seek medical reciprocity with the United Kingdom under amendment to the medical act of 1905.

Birth Rate in Montreal.—There is no race suicide in Montreal. During the week ended June 2, 196 births were registered in that city, the average being about 130. One hundred and two were males and 94 females.

Hospital Sunday.—Sunday, May 20, was hospital Sunday in all churches in Victoria, B. C. The money collected will be devoted to the erection of a maternity ward in connection with the Royal Jubilee Hospital of that city.

Queen's University, Kingston, Ontario.—The Ontario government at its recent session made a grant of $50,000 to the medical department of Queen's University, Kingston, Ont. The money will be used for a new laboratory building to house the departments of physiology, pathology, bacteriology and public health.

University News.—Convocation was held at Toronto University on the afternoon of June 8.——There were 99 candidates in final medicine this year at McGill University, of whom all but 7 were successful in their examinations. Mr. R. S. Mc-Arthur of Summerside, P. E. I., was the winner of the Holmes gold medal for the highest aggregate in all subjects.

Personal.—Dr. D. J. Gibb Wishart, Toronto, has returned home from attending the meeting of the American Medical Association at Boston.——Dr. Bruce L. Riordan, Grand Trunk surgeon at Toronto, has returned from a trip to Ireland.——Dr. C. J. Fagan, secretary of the Board of Health of British Columbia, has taken action against a Victoria newspaper to restrain it from using his name in connection with the advertisement of a certain "patent medicine" which he had analyzed and which he stated contained no poison.

The Ontario Medical College for Women Closed.—The Ontario Medical College for Women has gone out of existence. In future women desiring to study medicine in Canada will be provided with instruction by the medical department of the University of Toronto. The question of the co-education of medical students in the provincial university will be taken up by the university faculty shortly and full arrangements perfected for the reception of women. It is likely that special dissecting rooms will be provided. The Ontario Medical College for Women had been in existence for 22 years. During those years it has turned out 121 graduates. The first term commenced in the fall of 1883 with one student in attendance. The free dispensary for women, established in 1899 in connection with the college, will be continued. Dr. R. Barrington Nevitt has been dean for a number of years.

FOREIGN.

Physicians in French Chamber of Deputies.—Since the recent elections the French Chamber of Deputies numbers 46 physicians among its members and 9 pharmacists.

Cerebrospinal Meningitis in Germany.—It is announced by the *Allg. med. Cent.-Ztg.* that there have been 864 cases of epidemic cerebrospinal meningitis in Prussia since January 1, with 392 deaths. The majority have occurred in the Oppeln district, 585 cases, with 283 deaths.

Testimonial to Brouardel on His Retirement.—As mentioned recently, the professor of legal medicine at Paris, Paul Brouardel, is to retire to private life this spring. A subscription has been opened to present him with a souvenir tablet on the occasion of his retirement. Subscriptions of any amount will be received. They should be sent soon to Dr. Logez-Duc, secretary of the fund, rue de Mauberge 81, Paris X.

Cerebrospinal Meningitis in Glasgow.—Several cases of cerebrospinal meningitis have occurred in Glasgow, Scotland, during the past few weeks, and the health committee is considering the advisability of including it in the list of notifiable diseases. With this object in view, the committee has circularized the medical profession of the city to obtain details of the number of cases which have occurred during the last twelve months.

Treatment of Whooping Cough with Chloroform.—It is announced from Paris that Dr. H. de Rothschild has witnessed the abatement of the spasmodic cough in a child with whooping cough on whom he was operating for dislocation of the hip joint. Before the operation the child had averaged 39 attacks of coughing in the 24 hours, but has not had a single attack since. He has since treated 9 other children with unusual severe whooping cough by having them inhale a mixture of chloroform and oxygen for five minutes. In 2 the attacks have not recurred; in the others they dropped from 29 to 12, not returning after the fourth day. In the others the cure was not complete for several days.

Hydrophobia in Germany.—The official figures for Prussia in 1904 have recently been published. It seems that 365 persons

were bitten during the year by rabid or supposed rabid animals, including 5 cats, 6 cattle, 1 horse, 2 pigs and 211 dogs. All but 35 of the individuals applied for treatment at the Berlin Institute for Infectious Diseases. Eight of the total number developed hydrophobia and died; 2 of these had not received any treatment, 1 had been treated by local disinfection alone, and 5 had taken the regular Pasteur course of treatment. In one of the latter group death occurred 218 days after the injury.

German Society for Prevention of Venereal Disease.—The Berlin branch of the German Preventive Society held a public meeting recently in the city hall building. Oppenheim delivered an address on "Sexual Diseases and Nervous Affections", and Rosenthal on the "Action of Alcohol in Relation to Sexual Diseases." Heller concluded the proceedings with an earnest appeal for the foundation of a home for syphilitic infants, similar to the one founded by Welander at Stockholm, which has done such good service in segregating the victims of inherited syphilis and mitigating or entirely curing their disease while safeguarding the public.

Proposed Free International Sanitarium at Carlsbad for Physicians.—The local medical society has presented a petition to the Carlsbad authorities asking that an international sanitarium be founded at Carlsbad for needy physicians. The petition states that the spa owes its renown to the appreciation by medical men generally of its courses of mineral waters and their systematic application. If a sanitarium with 20 rooms could be erected, 140 physicians could be given a four weeks' course of the waters during the season, April 1 to October 1. The petition adds that such an establishment would combine the humane with the practical and useful, and would win still more friends for the spa. Last year nearly 60,000 persons took the regular course of treatment, with 150,000 transient guests.

To Reduce Possibility of Infection in Abdominal Operations.—Theilhaber writes to the *Muench. med. Wochft.* to relate the great improvement in his results since he has adopted the plan of a second disinfection before attempting to ligate a pedicle in his operations. He presents evidence to prove that operations requiring ligature of a pedicle have a higher percentage of infection than other operations, even much more protracted ones, in which there is no pedicle to be ligated. When he reaches the stage of ligating the pedicle he closes the abdominal wound with forceps and disinfects his hands anew, then opens a hitherto untouched vessel containing a fresh set of instruments for the ligature. He either dispenses with assistance at this stage or requires his assistants to disinfect their hands anew.

International Congress for "Occupation Affections."—The completion of the Simplon tunnel is being celebrated by Italy with various international congresses. An international exhibition of hygiene is now in progress at Milan, and the first international congress for occupation affections opened last week at the same place. Celli led the discussion on the professional affections of workers in tobacco, and Bruns and Perroncito discussed miners' anemia. The medical senator, De Cristoforis, presided over the congress. In an editorial in the *Gazzetta degli Ospedali*, Maragliano hails it as "another step toward the realization of the political medicine which is coming to be the spirit of modern medicine." He declares that medicine can not hold aloof from politics much longer. He uses the term politics not in the sense of aspiring for power, but as "the exalted and noble effort to devote one's energies to promoting the welfare of the nation and safeguarding the vital interests of the citizens. Political medicine should be the principal factor in protecting wage-earners against insidious or manifest infirmities dependent on the exercise of their trade." He rejoices that Italy has taken the lead in summoning this international conference on the subject.

Precipitation Test of Strength of Roentgen Rays.—G. Schwartz of Vienna demonstrated at a recent meeting of the local medical society a method of measuring the strength of the Roentgen rays which is based on the precipitation of calomel, as a chemical reaction to the rays, in a mixture of ammonium oxalate and corrosive sublimate. This mixture is a clear fluid which, sheltered from the light, keeps indefinitely. Exposure to daylight or to the Roentgen rays causes precipitation of calomel. The amount precipitated is determined by centrifuging in a graduated capillary tube. Three mm. of the precipitate in the capillary tube corresponds to about the strength of a Holzknecht unit. The *Wiener klin. Wochft.* for May 31 contains his detailed description and comparison of this technic with the usual methods of testing the strength of the rays, especially with the Freund-Hardy Wilcox iodoform chloroform colorimetric test. The latter has the disadvantage of being a subjective test, depending on the observer's estimation of color. The change in the tint, after exposure to the rays, continues progressively after the rays have been withdrawn. Schwartz states that his technic allows the measurement of one-ninth or even one-twenty-seventh of the minimal effectual therapeutic dose of the rays.

LONDON LETTER.

Pasteurized Milk and Infant Feeding.

The fact that several of the large London dairy companies are supplying pasteurized milk without any indication that the milk has been so treated has been discovered in the following manner: At a children's hospital the medical staff decided to use pure, fresh milk unaltered by heat or preservatives or otherwise. Special precautions were taken to insure the purity of the milk, which was to be supplied in sealed and sterilized bottles and kept on ice. A large dairy company undertook to do this and was supposed to have done so for 18 months. Then it was discovered that for 12 months the milk had been pasteurized. The company, when taxed with breach of contract, expressed regret, but said they had acted on high medical authority and that pasteurized milk was safer for infants than milk not so treated. At another children's hospital there were under care three cases of scurvy for which fresh cow's milk, raw meat juice, scraped potato and lemon juice were given. In none of the cases did the usual speedy resolution of the subperiosteal hematoma occur. That three consecutive cases of scurvy should take this extraordinary course led to an inquiry. It was discovered that the dairy company to the hospital had been supplying pasteurized instead of fresh milk without informing the hospital authorities. On the substitution of fresh for pasteurized milk the children began to improve.

Jubilee of the Society of Medical Officers of Health.

The jubilee meeting of the Society of Medical Officers of Health was held recently. The president, Sir Shirley Murphy, delivered his presidential address on "The Medical Officer of Health, 1856-1906." He contrasted some of the problems that confronted the medical officer of health at the time of the foundation of the society in 1856 with those which faced him in the present day. In that period the death rate in England and Wales had fallen 18 per cent.—the male death rate 16 and the female 20 per cent. The death rate from preventable diseases had fallen 42 per cent. Medical officers of health must always be prepared to widen the horizon of their work. Already they possess a knowledge of disease prevention which goes far beyond that available for the early members of the society and that knowledge must rapidly grow.

Correspondence

Newspaper Tactics and the "Patent-Medicine" Question.

ST. LOUIS, June 11, 1906.

To the Editor:—In the St. Louis *Republic* for June 6 appeared the following paragraph: "At the meeting of the American Medical Editors' Association, what was termed 'the unwise agitation against medical advertising and proprietary medicines,' was strongly denounced. Dr. Kenneth W. Millican, of the *Medical Review*, St. Louis, said: 'What should be insisted on in the advertising world is that the advertising should be honest. I can not join in this outcry which has been raised against patent-medicine advertising. The spirit of commercialism is rampant, and it must be regarded by the journals. When those ends are sought honestly they are proper enough. The aim of professional men is rendering service, and any reasonable means to that end is proper. There is no sound reason why physicians should oppose advertising.'"

Now, as one sentence in this passage attributes to me a statement the exact opposite of the position I have always taken, I addressed to the St. Louis *Republic*, on June 6, the following letter:

JUNE 6, 1906.

To the Editor, St. Louis "Republic," City:

Sir: In your issue for June 6, in a dispatch dated Boston, Mass., June 5, you publish a statement concerning my paper read at the American Medical Editors' Association, at Boston, which in one particular entirely reverses the position that I took. Your correspondent makes me say: "I can not join in this outcry which has been raised against patent-medicine advertising." This statement is

such a garbled report of what I actually did say that I must request you to give me an opportunity of correcting it. It is obvious that the passage which your correspondent has, I am afraid deliberately, misrepresented is the following: Speaking of the question of the advertising of proprietary remedies—so-called "ethical" remedies because they profess to be advertised to the profession alone—I stated, "but we (i. e., medical editors) can not consistently join in the outcry that has been properly raised—and it is immaterial whether that outcry is due to a single-minded devotion to the public good or is simply the crafty use of a worthy object for purely selfish purposes—against patent medicines and nostrums that prey on the public to its detriment, so long as we do not hold fast to the first principles in regard to those preparations that appeal to us for our sanction." In other words, so far from saying that I can not join in the outcry against patent nostrums, I take the position that we all ought to join in that outcry, but that to do that effectively medical editors should agree on a principle whereby the rectitude of a proprietary medicine may be judged before its advertisement is accepted for a reputable medical journal; and I proceed to instance the principle which has been in force since the beginning of this year by the *St. Louis Medical Review*, in the following words: "We, therefore, shall not accept in future, and we have advised all our present advertisers that we shall not renew for 1906 the advertisement of any remedy that does not give its essential constituents so far that the physician using it may know, or can ascertain by reference to a Dispensatory or a standard text-book of therapeutics, its physiologic action and therapeutic character; and, if it contains drugs of pronounced potent physiologic effects or toxic character, the amount thereof that he is giving."

The whole gist of my argument, therefore, instead of being a statement that "I could not uphold the outcry against the nostrums," was an urging on medical editors to purge their own advertising columns so that all might take part in this outcry with greater consistency and cleaner hands. But I further urged moderation, common sense, a just regard for the legitimate interests of all parties, the public and the manufacturer as well as the physician, and a freedom from hysteria or blind slashing out at random.

Yours very truly, (Signed.) KENNETH W. MILLICAN.

On June 8 I received the following reply:

June 7, 1906.

Dear Doctor Millican:—Your letter of the 6th in relation to a dispatch from our correspondent at Boston has been received and will have due attention. I feel sure, however, that he had no motive or intent in placing a misconstruction on your paper.

Yours very truly,

(Signed) ——News Editor.

Dr. Kenneth W. Millican, City.

On receipt, in deference to the disclaimer as to motive, I authorized by telephone the omission of the words "I am afraid deliberately" in reference to the correspondent's misrepresentation. Considering the injurious nature of the misrepresentation, I had a right to expect a prompt and immediate publication for my repudiation of the statement ascribed to me. It is now five days since the statement was made, but I have seen no retraction so far. When it does appear, if it appears at all, it will be too late to correct the false impression created by the original paragraph. There may be many points in which the *Review* may take issue with the American Medical Association or its JOURNAL, but at least we fight fair and do not state one thing in our columns and try to curry favor by stating its opposite under circumstances in which that opposite might possibly be more popular.

KENNETH W. MILLICAN,
Editor *St. Louis Medical Review.*

The Advertising of the Battle Creek Sanitarium Company.

OFFICE OF
THE BATTLE CREEK SANITARIUM.

BATTLE CREEK, MICH., June 15, 1906.

To the Editor:—My attention was called a few days ago to an article which appeared in your columns from the pen of Dr. Pusey, criticising the Battle Creek Sanitarium because of certain advertisements which are published in newspapers over the name of the Battle Creek Sanitarium Co., Ltd. I desire to call your attention to the fact that the Battle Creek Sanitarium Co., Ltd., and the Battle Creek Sanitarium are two entirely independent institutions. The Battle Creek Sanitarium is incorporated under the charitable statutes of Michigan as the Michigan Sanitarium and Benevolent Association. The Battle Creek Sanitarium Co., Ltd., is a commercial manufacturing firm doing business in Battle Creek, which some years ago acquired by purchase the food business formerly conducted by the Battle Creek Sanitarium.

Enclosed you will find a copy of a letter written by me to the said Battle Creek Sanitarium Co., Ltd., and also a copy of their reply. I will be greatly obliged if you will publish these letters, together with this letter, in your columns, feeling that this explanation is due to the readers of THE JOURNAL who have read Dr. Pusey's criticism. J. H. KELLOGG.

BATTLE CREEK, MICH., June 12, 1906.

BATTLE CREEK SANITARIUM CO., Ltd.,
Battle Creek, Mich.

Gentlemen:—Several physicians have called my attention to an article which recently appeared in THE JOURNAL of the American Medical Association severely criticising the advertising matter which is being sent out by your company and implicating the Battle Creek Sanitarium in the matter.

It is my duty, as superintendent of the Battle Creek Sanitarium, to call your attention to the fact that when the trade rights to the food business formerly carried on by the Battle Creek Sanitarium were conveyed to you by a sale on Dec. 25, 1902, it was with the distinct understanding that the manufacture and sale of these foods should be conducted in a thoroughly ethical manner, and that the advertising matter should be of such a character that no intelligent or scrupulous physician would have any reason for complaint. It was distinctly understood that the copy prepared for advertising matter should be submitted to me, or to some other medical man who might be designated by the board of directors of the Battle Creek Sanitarium, to be criticised before being sent out, so that the reputation of the Battle Creek Sanitarium as an ethical institution should be thoroughly protected. The Battle Creek Sanitarium management would not have disposed of its trade-marks and other business interests connected with the manufacture of foods under any other conditions.

I was shocked and ashamed when my attention was called to the article from Dr. Pusey, and especially when I afterward learned that this advertisement, or one similar to it, had been published in periodicals of such character that no reputable institution could afford to be represented in their columns. I consider Dr. Pusey's censure entirely just in every particular, with the one exception that it does not apply to the Battle Creek Sanitarium, but rests wholly on the management of the Battle Creek Sanitarium Company, Ltd. It is manifest that you have neglected to comply with the special agreement which was entered into for the protection of the Battle Creek Sanitarium, and which was necessary because of the similiarity of your name to that of the sanitarium. If you had submitted the copy for the advertisement complained of for inspection, it certainly would have been condemned. Since my attention has been called to the matter, I have learned that other announcements, through circulars and otherwise, which you have been sending out, contain many objectionable phrases and statements, which are not in harmony with the spirit of the understanding above referred to.

I am now writing you at the request of the board of directors of the Battle Creek Sanitarium to ask that you will suppress all publications of the sort complained of, and that you will hereafter, in accordance with your agreement, submit all advertising copy for inspection, and that you will so modify the name of your company that the public will not be in danger of confusing your business with that of the Battle Creek Sanitarium. The action requested of you is necessary for the protection of the good name of the Battle Creek Sanitarium, which has always conducted its business in a strictly ethical way, and has given no countenance to, or had any sympathy with, unethical and unprofessional methods of appealing to the public.

We request that you will take prompt and thorough-going action in relation to this matter. Respectfully,

J. H. KELLOGG.

BATTLE CREEK, MICH., June 14, 1906.

J. H. KELLOGG, M.D., Battle Creek, Mich.

Dear Sir:—Your favor of June 8 received. We regret to be obliged to acknowledge our remissness in the matter to which you call our attention. Our only apology is the fact that business duties have crowded us to such an extent that we have trusted the preparation and placing of our advertising matter to our advertising agents more than we should have done, and so we were not aware that the general instructions which we had given and which we believed to be in harmony with the agreement entered into with the sanitarium, were not being strictly carried out. We frankly admit our oversight in this matter and will immediately comply with each of the requests made by you and will see that hereafter there is no reasonable ground for complaint.

Assuring you that we have no sympathy with the unprincipled methods of advertising commonly employed by nostrum vendors and certain manufacturers of proprietary food products, and that we desire to conform in the strictest manner with both the letter and the spirit of the agreement to which you refer, in the interests of our own business as well as yours, we remain,

Very truly yours,

BATTLE CREEK SANITARIUM FOOD CO.
M. W. WENTWORTH, President.

P. S. Kindly note that our firm name has been changed so that there can be no possible confusion of our business with yours in the public mind.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending June 16, 1906:

Kulp, John S., surgeon, promoted to rank of major, to date from May 26, 1906.

Sweazey, V. E., asst.-surgeon, left Army General Hospital, Washington Barracks, D. C., on leave of absence, to include July 1, 1906.

Hallock, H. M., surgeon, sick leave of absence extended two months.

Page, Henry, asst.-surgeon, assignment to duty at the U. S. Military Prison, Fort Leavenworth, Kans., revoked, and ordered to Fort Clark, Texas, for duty.

Fuller, Leigh A., asst.-surgeon, relieved from duty at Fort Clark, Texas, and ordered to the U. S. Military Prison, Fort Leavenworth, Kans., for duty.

Gray, Wm. W., deputy surgeon-general, left chief surgeon's office, Headquarters Department of the Gulf, Atlanta, Ga., on sick leave of absence.

Kirkpatrick, Thos. J., asst.-surgeon, left Fort Moultrie, S. C., en route to Fort McPherson, Ga., for temporary duty.

Robbins, C. P., asst.-surgeon, left Madison Barracks, N. Y., on ten days' leave of absence.

Boyer, Perry L., asst.-surgeon, left from temporary duty at Oakland, Cal., with 2d Squadron, 1st Cavalry, en route to rejoin station at Fort Sam Houston, Texas.

Ekwurzel, Geo. M., asst.-surgeon, relieved from temporary duty at Army General Hospital, Washington Barracks, D. C., and ordered to Fort Hamilton, N. Y., for temporary duty.

Appel, D. M., deputy surgeon-general, detailed member of Army retiring board, San Francisco, vice Lieut.-Col. Louis Brechemin, deputy surgeon-general, relieved. Detailed member of examining board, San Francisco, vice Lieut.-Col. Louis Brechemin, deputy surgeon-general, relieved.

Marrow, Chas. E., asst.-surgeon, left from temporary duty at Army General Hospital, Washington Barracks, D. C., en route to rejoin station, Fort Monroe, Va.

Hicks, John R., contract surgeon, granted sick leave of absence for one month.

Brown, Ira C., contract surgeon, ordered to accompany a battalion of infantry from Fort Niobrara, Neb., to Fort McIntosh, Texas, and report for duty at that post.

Hereford, John R., contract surgeon, left Fort Caswell, N. C., and arrived at Fort Moultrie, S. C., for duty.

Cass, William E., contract surgeon, returned from duty at San Francisco, to his proper station, Vancouver Barracks, Wash.

Gardner, Fletcher, contract surgeon, relieved from duty June 20, at Fort Mansfield, R. I., and will then proceed home for annulment of contract.

Carpenter, Alden, dental surgeon, left Fort William H. Seward, Alaska, for duty at Fort Egbert, Alaska.

Rietz, Hugo C., dental surgeon, order for Philippine service revoked; will proceed home, Manitowoc, Wis., for annulment of contract.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, during the two weeks ending June 16, 1906:

Moore, J. M., P. A. surgeon, detached from the Naval Medical School, Washington, D. C., June 15, and ordered to report for examination for promotion, and then to await orders.

Shook, F. M., asst.-surgeon, detached from the Naval Hospital, Mare Island, Cal., and ordered to the Navy Yard, Mare Island, Cal.

Geiger, A. J., asst.-surgeon, detached from the Navy Yard, Mare Island, Cal., and ordered to Washington, D. C., June 15, for examination for promotion, and then to wait orders.

Meyers, G. M., and Backus, J. W., asst.-surgeons, detached from the Naval Medical School, Washington, D. C., June 15, and ordered to report for examination for promotion, and then to wait orders.

Streets, T. H., medical director, detached from command of the Naval Hospital, Naval Home, Philadelphia, and directed to wait orders.

Pickrell, G., surgeon, ordered to the *Franklin*.

Kerr, D. B., surgeon, detached from the Naval Medical School, Washington, D. C., June 15, and ordered to the Naval Recruiting Station, Chicago, Ill.

Von Wedekin, L. L., surgeon, detached from the Naval Recruiting Station, Chicago, Ill., and ordered to wait orders.

Asserson, F. A., P. A. surgeon, detached from the Naval Medical School, Washington, D. C., June 14, and ordered to the *Arkansas* temporarily, and thence home to wait orders.

Webb, U. R., P. A. surgeon, detached from the Naval Medical School, Washington, D. C., June 15, and ordered to the Naval Hospital, Portsmouth, N. H.

Shaw, H., asst.-surgeon, detached from the Naval Medical School, Washington, D. C., June 15, and ordered to the Naval Hospital, Philadelphia, Pa.

Michels, R. H., asst.-surgeon, detached from the Naval Medical School, Washington, D. C., June 15, and ordered to the Naval Recruiting Station, Kansas City, Mo.

Teece, F. W., acting asst.-surgeon, detached from the Naval Recruiting Station, Kansas City, Mo., and ordered home to wait orders pending expiration of term of appointment as acting asst.-surgeon, July 1, 1906.

Myers, G. M., asst.-surgeon, detached from Naval Medical School, June 15, and ordered to Navy Yard, Washington, D. C.

Campbell, F. E., asst.-surgeon, ordered to the *Constellation* and to additional duty at Naval Training Station, Newport, R. I.

McConnon, G. H., asst.-surgeon, detached from the *Constellation* and ordered to the *Missouri*.

Ryder, C. E., asst.-surgeon, detached from the *Missouri* and ordered home to wait orders.

Dennis, J. B., surgeon, detached from the Naval Proving Ground, Indian Head, Md., and ordered to command the Naval Hospital, Puget Sound, Washington, with additional duty at the navy yard at that place.

Munson, F. M., asst.-surgeon, detached from the Naval Medical School, Washington, D. C., and ordered to the Naval Proving Ground, Indian Head, Md.

Drake, N. H., medical inspector, detached from the Naval Academy and ordered to the Naval Hospital, New York, N. Y., for treatment.

Carpenter, D. N., surgeon, detached from duty in command of the Naval Hospital, Puget Sound, Wash., and ordered to the Asiatic Station, sailing from Seattle, Wash., July 6.

Curtis, E. E., acting asst.-surgeon, detached from the *Franklin* and ordered to duty at Camp Harrington Rifle Range, Williamsburg, Va.

Steele, J. M., medical inspector, ordered to the Naval Academy.

Jenness, B. F., asst.-surgeon, detached from the Naval Medical School, June 15, and ordered to the *Constellation* and to additional duty at the Naval Training Station, Newport, R. I.

Langhorne, C. D., surgeon, detached from the Naval Medical School, and ordered to the Naval Academy for temporary duty, and thence home to wait orders.

Decker, C. J., surgeon, detached from the *Alabama* and ordered home to wait orders.

De Valin, C. M., surgeon, detached from the Naval Recruiting Station, Baltimore, Md., and ordered to the *Alabama*.

Marsteller, E. H., surgeon, detached from the Naval Recruiting Station, St. Louis, and to Naval Recruiting Station, Baltimore, Md.

Abeken, F. G., asst.-surgeon, to Naval Recruiting Station, St. Louis.

McGuigan, J. H., pharmacist, detached from the Naval Dispensary, New York, and to the Marine Barracks, New York.

McMahon, J., pharmacist, detached from the Marine Barracks, New York, and to the Naval Dispensary, New York.

Service for the seven days ending June 13, 1906:

Carmichael, D. A., surgeon, bureau letter of May 3, 1906, granting leave of absence for seventeen days, amended to read for fifteen days only.

Cobb, J. O., surgeon, granted leave of absence for ten days from June 25, 1906.

Smith, S. C., surgeon, granted leave of absence for one month from July 2, 1906.

Blue, Rupert, P. A. surgeon, assigned to special temporary duty in Washington, D. C., on board convened by executive order for the purpose of making sanitary inspection of certain public buildings and workshops, on completion of which to proceed to Norfolk, Va., and assume command of service.

Amesse, J. W., P. A. surgeon, granted leave of absence for six days from June 5, 1906, under Paragraph 191 of the Regulations.

Boggess, C. S., asst.-surgeon, granted leave of absence for seven days from June 9, 1906, under Paragraph 191 of the Regulations.

Stimson, A. M., asst.-surgeon, directed to report to medical officer in command, Stapleton, N. Y., for temporary duty.

Hamilton, H. J., acting asst.-surgeon, granted leave of absence for three days from June 12, 1906.

McKay, M., pharmacist, granted leave of absence for two days from June 1, 1906.

Carlton, C. G., pharmacist, granted leave of absence for twenty-nine days from June 10, 1906.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the fourteen days ending June 13, 1906:

Irwin, Fairfax, surgeon, granted leave of absence for one month and twenty-five days, from July 9, 1906.

Carrington, P. M., surgeon, granted leave of absence for three days from June 4, 1906, under Paragraph 189 of the Regulations.

Williams, L. L., surgeon, granted leave of absence for one month and fifteen days, beginning July 16, 1906.

District of Columbia: Washington, May 19-June 9, 20 cases, 1 death.
Florida: General, May 26-June 9, 22 cases; Jacksonville, 7 cases.
Georgia: Augusta, May 21-28, 2 cases; Sapelo Island, June 2-4, 1 case (imported).
Illinois: Cambridge, June 2-9, 10 cases; Chicago, May 26-June 9, 3 cases; Galesburg, 1 case.
Indiana: Indianapolis, May 20-June 3, 2 cases.
Kansas: Topeka, May 26-June 2, 1 case.
Louisiana: New Orleans, May 25-June 9, 36 cases, 1 death.
Missouri: Carthage, April 3-June 4, 10 cases; St. Louis, May 26-June 2, 1 case; Joplin, June 5, 5 cases (imported).
Nebraska: Omaha, May 26-June 2, 1 case.
New Jersey: Jersey City, May 27-June 3, 2 cases.
New York: Monroe, May 14, 1 case; New York, May 26-June 9, 11 cases, 3 deaths; Buffalo, May 1-30, 1 case.
North Carolina: Greensboro, May 26-June 2, 1 case.
Ohio: Cincinnati, May 25-June 8, 13 cases; Toledo, May 19-26, 1 case.
Oklahoma: Oklahoma City, May 26-June 9, 14 cases, 1 death.
Pennsylvania: Philadelphia, May 26-June 2, 1 case; Pittsburg, May 19-26, 4 cases; Lancaster, June 2-9, 1 case.
Tennessee: Memphis, May 19-June 6, 9 cases; Nashville, May 26-June 2, 1 case.
Texas: Houston, May 19-June 2, 2 cases.
Utah: Ogden, May 31, 2 cases.
Wisconsin: Appleton, May 26-June 9, 5 cases; La Crosse, May 19-26, 1 case; Milwaukee, June 2-9, 2 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, April 7-21, 4 cases.

SMALLPOX—FOREIGN.

Africa: Cape Town, April 21-May 5, 13 cases.
Argentina: Buenos Ayres, March 1-31, 68 cases, 52 deaths.
Brazil: Rio de Janeiro, April 22-May 13, 4 cases, 1 death; Pernambuco, April 15-30, 7 deaths.
Chile: Iquique, May 5-12, present.
Canada: St. Thomas, May 26-June 2, 6 cases; Toronto, May 12-June 2, 8 cases; Winnipeg, 1 case.
China: Hongkong, April 7-May 5, 30 cases, 17 deaths.
Germany: Bremen, May 12-26, 2 cases, 1 death.
Gibraltar: May 13-27, 6 cases, 1 death.
Great Britain: Bristol, May 12-19, 2 cases; London, May 29, 2 cases; Newcastle-on-Tyne, 2 cases; Hull, May 19-26, 1 case; Liverpool, 1 case.
Greece: Athens, May 13-28, 4 deaths.
India: Bombay, May 1-15, 8 cases, 16 deaths; Calcutta, April 21-May 5, 131 cases, 99 deaths; Kurachi, April 30-May 13, 48 cases, 16 deaths; Madras, April 28-May 11, 16 cases, 11 deaths; Rangoon, April 21-May 5, 35 cases, 28 deaths.
Italy: General, May 10-24, 59 cases.
Russia: St. Petersburg, April 29-May 12, 14 cases, 11 deaths; Moscow, May 5-19, 22 cases, 8 deaths; Odessa, May 12-26, 24 cases, 3 deaths.
Spain: Barcelona, May 13-30, 11 cases, 5 deaths.
Turkey: Constantinople, May 20-27, 1 death.

YELLOW FEVER—UNITED STATES.

Mississippi: Gulf Quarantine, June 4-6, 3 cases, on S. S. *Whitehall*, from Colon.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, May 6-13, 1 case, 3 deaths.
Cuba: Habana, June 7-12, 2 cases, 1 death.
Honduras: Plumienta, May 19, 2 cases.
Mexico: Coatzacoalcos, May 19-26, 1 case, 1 death; Merida, May 13-26, 3 cases, 1 death.
Santo Domingo: La Vega, June 9, present.

CHOLERA—INSULAR.

Philippine Islands: Manila, April 7-21, 26 cases, 22 deaths.

CHOLERA—FOREIGN.

China: Hongkong, April 28-May 5, 1 case, 1 death.
India: Bombay, May 1-15, 18 deaths; Calcutta, April 21-May 5, 215 deaths.

PLAGUE—INSULAR.

Hawaii: Honolulu, June 3-4, 1 case, 1 death.
Philippine Islands: Manila, April 14-21, 1 case, 1 death.

PLAGUE—FOREIGN.

Australia: Brisbane, April 14-21, 2 cases, 1 death; Rockhampton, April 5-12, 4 cases, 1 death. April 14-21, 4 cases, 3 deaths.
Brazil: Rio de Janeiro, May 6-13, 1 case, 1 death.
China: Hongkong, April 7-May 8, 184 cases, 176 deaths.
Egypt: Beni Souf, Providence, May 11, 2 cases; Minieh Province, May 14-17, 8 cases, 4 deaths; Keneh Province, May 11-17, 7 cases, 10 deaths; Port Said, May 17, 1 death.
India: General, April 21-May 5, 33,747 cases, 28,029 deaths; Bombay, May 1-15, 1,517 deaths; Calcutta, April 21-May 5, 296 deaths; Karachi, April 30-May 5, 465 cases, 415 deaths; Rangoon, April 21-May 5, 125 deaths.
Japan: Formosa, April 1-30, 800 cases, 602 deaths; Kobe, April 14-May 8, 6 cases, 7 deaths.

Association News

THE BOSTON REGISTRATION.

List of Members Who Registered at the Boston Session.

The total registration at the Boston session was over 4,700, the largest in the history of the Association. The largest registration previously was 2,890, at Atlantic City in 1904. In addition to the over 4,700 names below, a few more than a score registered whose names are not given. These either have not forwarded credentials for membership or failed to fill out the card for publication. Below are given two summaries, one by sections and one by states.

REGISTRATION BY SECTIONS.

Practice of Medicine	1,363
Obstetrics and Diseases of Women	307
Surgery and Anatomy	1,006
Hygiene and Sanitary Science	103
Ophthalmology	257
Diseases of Children	160
Stomatology	93
Nervous and Mental Diseases	178
Cutaneous Medicine and Surgery	109
Laryngology and Otology	166
Pharmacology and Therapeutics	76
Pathology and Physiology	92
Registered without specifying any particular section	554
Marked more than one section	248

REGISTRATION BY STATES.

Alabama	28	Louisiana	17	Oklahoma	3

Deaths

George Augustus Ketchum, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1846; a heroic worker during the yellow-fever epidemic of 1847-48; one of the organizers of the Medical College of Alabama, and dean and professor of theory and practice of medicine in that institution; one of the four delegates sent to the convention at Montgomery in 1861, which passed the ordinance of secession; surgeon of the Fifth Alabama Infantry, C. S. A., during the Civil War; a member of the general council of Mobile; a prominent figure in the organization of the Alabama Medical Association; for 35 years president of the Mobile Board of Health, died at his home in Mobile, May 29, after an illness of several weeks, aged 81.

William Martin Findlay, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1867; a member of the American Medical Association, Medical Society of the State of Pennsylvania, Blair County Medical Society, and Altoona Academy of Medicine; one of the most prominent physicians of western Pennsylvania; elected a delegate to the American Medical Association at its Boston meeting; a member of the medical staff of the Altoona Hospital, and for several years representative from Blair County of the State Board of Health; a veteran of the Civil War; twice a member of the local school board, died suddenly at his home in Altoona, from cerebral hemorrhage, June 2, aged 63.

Mary Putnam Jacobi, M.D. Ecole de Médecine, Paris, France, 1871; the first woman to be admitted to the Paris School of Medicine; one of the most distinguished woman physicians of her time; a notable writer on educational and kindred subjects; the first woman to be admitted to membership in the New York Academy of Medicine; some-time professor of materia medica in the Woman's Medical College of New York and in the Post-Graduate Medical School; for 12 years dispensary physician at Mount Sinai Hospital, and visiting physician at St. Mark's Hospital, died at her home in New York City, June 10, after an illness of more than four years, aged 63.

Emerson M. Sutton, M.D. Bellevue Hospital Medical College, New York, 1891; a member of the American Medical Association, Western Surgical and Gynecological Association, Illinois State, Peoria County, Peoria City and Military Tract medical societies; staff surgeon for the Cottage and Deaconess Hospital, Peoria, and local surgeon for the Iowa Central and Chicago & Northwestern Railways; one of the most prominent surgeons and gynecologists of Central Illinois, fearing insanity, committed suicide, June 19, by shooting himself through the head.

Robert Shoemaker Ives, M.D. Medical Institution of Yale College, New Haven, Conn., 1866; a member of the Connecticut Medical Society, New Haven County Medical Society, and New Haven Medical Society; for many years a member of the American Medical Association; consulting physician to the New Haven Hospital; a prominent practitioner of New Haven, died at his home in New Haven, June 9, from appendicitis, a few hours after operation, aged 64.

Samuel H. Lowry, M.D. Bellevue Hospital Medical College, New York City, 1873; a member of the board of censors of the Madison County (Ala.) Medical Society; formerly vice-president and censor of the Medical Society of the State of

Alabama, and for many years health officer of Huntsville, died at his home in that city, June 7, from paralysis, after a long illness, aged 56.

John Davis Hawkes, M.D. Medico-Chirurgical College of Philadelphia, 1904, of Philadelphia; vice-president of the Pancoast Anatomical Society, and member of Pierce Neurological Society, Mann Orthopedic Society and Fox Ophthalmological Society, died at Saranac Lake, N. Y., April 9, after an illness of several months, from tuberculosis, aged 27.

Donald McLean Barstow, M.D. College of Physicians and Surgeons in the City of New York, 1892; a member of the New York State Medical Association; assistant surgeon of the New Amsterdam Eye and Ear Hospital, and a prominent eye and ear specialist of New York City, died suddenly in Portland, Maine, June 9, aged 38.

Jason B. Roach, M.D., for 30 years a practitioner of Augusta, Ohio; a member of the Ohio legislature in 1858; who served three years with the One Hundred and Twenty-sixth Ohio Volunteer Infantry during the Civil War, died at his home in Alliance, Ohio, March 18, from uremia, after an illness of a year, aged 79.

George Hunt Hibler, M.D. College of Physicians and Surgeons in the City of New York, 1904; formerly house surgeon in the Harlem Hospital, and also in the Katonah (N. Y.) Sanatorium, died at the home of his mother in Morristown, N. J., March 31, from tuberculosis, after an illness of a year and a half, aged 27.

Charles Victor Starke, University of Upsala, Sweden, 1889; a member of the American Medical Association; for two years a resident of the Argentine Republic, and since 1892 a practitioner of Rockford, Ill., died at his home in that city, June 10, from nephritis, after a protracted illness, aged 53.

Ephraim McDowell Coffey, M.D. Transylvania University, Medical Department, Lexington, Ky., 1852; division surgeon in the Confederate service during the Civil War; formerly sheriff and treasurer of Platte County, Mo., died at his home in Platte City, June 6, after an illness of two weeks, aged 77.

Henry C. Kasselman, M.D. Universityof Michigan Homeopathic Medical College, Ann Arbor, 1883, for many years a member of the faculty of the Southwestern Homeopathic College, Louisville, Ky., died at his home in Midway, Ky., May 25, from tuberculosis, after a long illness, aged 45.

Morgan M. Lowe, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1885; a member of the parish and state medical societies; a well-known physician of Algiers, La., died at his home in that city, June 4, from appendicitis, after an illness of one week, aged 50.

John Adams Wakeman, M.D. Worthington Medical College, Medical Department of Ohio University, Worthington, Ohio, 1838; Hahnemann Medical College, Philadelphia, 1853; formerly of Centralia, Ill., died at the home of his daughter in Minneapolis, Minn., June 8, aged 91.

Emil H. Klueber, M.D. Medical Department of the University of Iowa, Keokuk, 1863; during the Civil War surgeon of an Illinois regiment; for about 20 years a practitioner of Topolobampo, Mexico, was murdered while attending an Indian patient, Dec. 23, 1905.

Julian Carroll Kendrick, M.D. University of Louisville, Medical Department, 1877; of Downey, Cal.; for two years in the Confederate service during the Civil War; coast surgeon general of the United Confederate Veterans, died at Los Angeles, Cal., May 31, aged 59.

Harry Lee Hinds, M.D. Medical College of Alabama, Mobile, 1904, a practitioner of Jackson County, Ala., died at the City Hospital, Huntsville, April 21, after an operation for tuberculosis of the hip, from which he had suffered for a considerable time, aged 24.

Alexander B. Newton, M.D. Rush Medical College, Chicago, 1867; a member of the La Crosse County Medical Society; hospital steward throughout the Civil War, died at his home at Bangor, Wis., June 6, after an illness of more than a year, aged 63.

James G. La Roe, M.D. Bellevue Hospital Medical College, New York City, 1873, a member of the board of health of Greenpoint, Brooklyn, died at his home in that city, June 2, from cerebral hemorrhage, after an illness of four days, aged 55.

Charles H. Rockwood, M.D. Cleveland Medical College, Medical Department of Western Reserve College, Cleveland, 1869, formerly a practitioner of Amherst, Ohio, died at the home of his daughter in Lorain, Ohio, June 2, from cerebral hemorrhage, aged 65.

Samuel P. Boardman, M.D. University of Wooster, Medical Department, Cleveland, Ohio, 1897; a prominent practitioner of Springfield, Ill., while a sufferer from melancholia, committed suicide by drowning in the Springfield reservoir, June 1.

Frederick W. Deichman, M.D. Eclectic Medical College of the City of New York, 1873; a surgeon during the Franco-Prussian War; a member of the Bristol Medical Association, died at his home in Bristol, Conn., June 6, from nephritis, aged 57.

Arthur Thomas Cheatham, M.D. Jefferson Medical College, Philadelphia, who retired from practice 25 years ago on account of ill-health, died in his home at Atlanta, Ga., March 25, from heart disease, after an illness of 24 hours, aged 74.

James M. McAdams, M.D. Miami Medical College, Cincinnati, 1871, a Confederate veteran, died May 30, at his home in Nevada, Mo., from pneumonia, following an accident in which he suffered a fracture of several ribs, aged 74.

William E. Phillips, M.D. Eclectic Medical Institute, Cincinnati, 1854; Jefferson Medical College, Philadelphia, 1857; a surgeon during the Civil War, died at his home in Wyoming, Ky., May 30, from appendicitis, aged 76.

George Oscar Jobes, for many years a practitioner of Indiana; state sanitary officer during the Civil War, died at the City Hospital, Indianapolis, from arteriosclerosis, February 16, after an illness of two weeks, aged 83.

John Frederick Scoresby Eastgate, M.D. College of Physicians and Surgeons in the City of New York, 1880, died at his home in Ellenville, N. Y., June 2, from pulmonary edema, after an illness of two weeks, aged 49.

Charles A. Hoff, M.D. Miami Medical College, Cincinnati, 1874, some-time on the staff of the Ohio State Hospital, Dayton, died at his home in St. Louis, June 11, from rheumatism, after an illness of five years, aged 56.

Thomas Watkins, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1868, a Confederate veteran, died at his home in Memphis, Tenn., May 31, after an illness of nearly a year, aged 65.

Edwin T. Jones, M.D. New York University, New York City, 1883, of Queens, Long Island, N. Y., acting chief of staff of the Jamaica Hospital, died suddenly in Utica, N. Y., June 11, from cerebral hemorrhage, aged 56.

Henry Austin Carrington, M.D. Harvard University Medical School, Boston, 1848, a member of the Bristol (Conn.) Medical Association, died at his home in Bristol, June 9, after a long period of invalidism, aged 79.

Frederick R. Hodgson, M.D. Saginaw Valley Medical College, Saginaw, Mich., 1900, of Rives Junction, Mich., died at the City Hospital, Jackson, Mich., June 2, from appendicitis, after a short illness, aged 30.

Joseph Fuller Durant, M.D. Eclectic Medical Institute, Cincinnati, 1854, for several years alderman of Quincy, Ill., died at his home in that city, June 5, from heart disease, after a short illness, aged 74.

Arthur S. Sanders, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1881, died at his home in Hot Springs, Ark., June 7, from septicemia, due to a carbuncle of the neck, aged 59.

Sebastian Hiriart, M.D. Tulane University of Louisiana, 1896, of Plaquemine, La., died at the New Orleans Sanitarium, March 17, from pleurisy with effusion, after an illness of several months, aged 59.

John H. Schiermann, M.D. Medical Department of Washington University, St. Louis, 1892, for several years a clinical instructor in that institution, died at his home in St. Louis, June 5, aged 41.

Frank Curtis Dolley, M.D. University of Vermont, Burlington, a member of the Maine Medical Association, was found dead in bed in Casa Grande, Ariz., from heart disease, March 16, aged 50.

Howard Phillips, M.D. Long Island College Hospital, Brooklyn, N. Y., 1882, died at his home in Stillwater, N. Y., April 21, from hemorrhage of the stomach, after a long illness, aged 54.

Warren H. Thomas, M.D. Hahnemann Medical College and Hospital, Chicago, 1877, of Elkhart, Ind., died suddenly from angina pectoris while making a professional call, June 7, aged 63.

Thaddeus E. Sanger, M.D. Hahnemann Medical College, Philadelphia, 1868, of Littleton, N. H., died in a hospital in Boston, June 6, from heart disease, after an operation, aged 74.

Millard F. Lee, M.D. Bellevue Hospital Medical College, New York City, 1876, of Columbus, Ohio, died at the Shepherd Sanitarium in that city, June 4, from tuberculosis, aged 58.

Joseph Bruner, M.D., one of the oldest practitioners of Mecklenberg County, N. C., died suddenly from heart disease while making a professional call near Matthews, May 2, aged 66.

Murdoch McGregor, M.D. Harvard University Medical School, Boston, 1863, a surgeon in the Army during the Civil War, died at his home in River Port, N. S., March 6, aged 70.

Hobart Richardson, M.D. Dartmouth Medical School, Hanover, N. H., 1868, died at his home in Benton, Maine, May 28, from cerebral hemorrhage, after an illness of one week.

John Quincy Adams French, M.D., a practitioner of Hillsboro, N. H., for more than 50 years, died in Hillsboro Upper Village, April 24, two days after an accident, aged 78.

Elisha Ely, M.D. College of Physicians and Surgeons in the City of New York, 1848, a pioneer practitioner of California, died at the home of his daughter in Redlands, May 8.

George B. Harry, M.D. Hahnemann Medical College, Philadelphia, a surgeon in the Spanish-American War, formerly of Dolington, Pa., died recently in Oklahoma, aged 32.

George W. Draper, M.D. Albany (N. Y.) Medical College, 1858, died at his home in Syracuse, N. Y., June 8, from nephritis, after an illness of more than a year, aged 73.

William H. Hugg, a pioneer practitioner of Portland, Mich., died at his home in that place, April 30, from tumor of the intestines, after an illness of one year, aged 80.

Enos S. Swain, M.D. Kentucky School of Medicine, Louisville, 1860, a surgeon in the federal service during the Civil War, died recently at his home in Smithville, Ky.

George Wigg, M.D. Essex Homeopathic Medical Institute, Colchester, England, 1863, died suddenly at his home in Portland, Ore., May 31, from heart disease, aged 68.

Thomas C. Rhoads, M.D. New York University, New York City, 1865, formerly city physician of Weehawken, N. J., died suddenly in New York City, May 30, aged 62.

Frederick Goodwin, M.D. Vermont Medical College, Rutland, 1889, died at his home in Bayfield, N. B., February 11, from nephritis, after a long illness, aged 45.

Gilbert L. Gifford, M.D. Hahnemann Medical College, Philadelphia, 1863, died suddenly at his home in Hamilton, N. Y., from heart disease, June 11, aged 64.

John L. Simpson, M.D. Atlanta (Ga.) Medical College, 1889, died suddenly from heart disease at his home in Houston Heights, Texas, May 19, aged 52.

Paris Shoaff, M.D. Western Pennsylvania Medical College, Pittsburg, 1892, died from tuberculosis at his home in New Castle, Pa., June 6, aged 37.

Moses Hubbard, M.D. Missouri Medical College, St. Louis, 1856, founder of Alla College, Roseland, Texas, died at his home in that city, May 26.

Adam Miesse, M.D. Eclectic Medical Institute, Cincinnati, 1868, a veteran of the Civil War, died at his home in Noblesville, Ind., May 31, aged 65.

King R. Cutler, M.D. Eclectic Medical Institute, Cincinnati, 1892, died at his home in Houston, Texas, May 31, from heart disease, aged 55.

Hall Curtis, M.D. Harvard University Medical School, Boston, 1857, of Boston, died recently at his country place in Beverly Farms, Mass.

Joseph John William Roberts Boyer, M.D., died at his home in Barrie, Ont., February 12, from pneumonia, after an illness of 10 days, aged 51.

Seymour Putnam, M.D. Bellevue Hospital Medical College, New York City, 1876, formerly of Joplin, Mo., died in Kansas City, Mo., May 26.

A. C. Hardin, M.D. Physio-Medical College, Cincinnati, Ohio, died at his home in Elkton, Ky., Dec. 20, 1905, from senile debility, aged 76.

James Miller, Jr., passed assistant surgeon, United States Navy, died in the Cable Station, Midway Island, from appendicitis, May 13.

Harry Haxall, M.D. College of Physicians and Surgeons, Baltimore, 1882, died suddenly at his home in Providence Forge, Va., June 8.

Robert Liston, M.D. Eclectic Medical College of the City of New York, 1875, died at his home in Albany, N. Y., June 1, aged 72.

William T. Brown, M.D. Jefferson Medical College, Philadelphia, 1859, died recently at his home in Altus, Ark., aged 78.

Alexander R. Shaw, M.D. Hahnemann Medical College, Philadelphia, 1857 died at his home in Philadelphia, June 11.

James W. Dupree, M.D. New Orleans School of Medicine, 1870, of Baton Rouge, La., died in Cincinnati, May 25.

I. A. Ketron, M.D. Atlanta (Ga.) Medical College, 1876, died at his home in Clarkesville, Ga., April 12, aged 58.

Jacob Hoke, M.D. Chicago Medical College, 1869, died at his home in Cordova, Ill., May 28, aged 90.

J. T. B. Ford, M.D. (Examination, Alabama), died at his home in Pollard, Ala., May 26, aged 73.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

SOMNOFORM.

DOWAGIAC, Mich., June 5, 1906.

To the Editor:—Where can I get information on the effects of Somnoform, a new dental anesthetic? I wish to find whether or not there have been any fatal or bad effects from its use as an anesthetic. I read an article some time ago in which it was stated that there have been several fatalities from its use. I have lost the article, but think it was in THE JOURNAL. Please send me the required information, or tell where I can obtain it.

W. E. PARKER, M.D.

ANSWER.—Somnoform, prepared by C. De Trey & Co., Berlin, Germany, is said to be a mixture of ethyl chlorid 60 parts, methyl chlorid 35 parts and ethyl bromid 5 parts. The relative value of ethyl chlorid and methyl chlorid as compared with ether and chloroform is still an open question, as also is their relative safety of administration. In a general way they have been found to stand, both in effect and safety, between nitrous oxid and ether. W. J. McCardie (*British Medical Journal*, March 17, 1906, p. 616), cites a number of fatalities from the use of ethyl chlorid and also states that several deaths have occurred from somnoform.

DENATURED ALCOHOL.

LOGANSPORT, IND., June 11, 1906.

To the Editor:—Will you please tell me what denatured alcohol is, or what process it undergoes or what adulterations are made to produce denatured alcohol as referred to in the recent bill passed by Congress? J. Z. POWELL.

ANSWER.—The bill recently enacted authorizing the withdrawal from bond of tax-free denaturized alcohol for certain purposes, specifies that alcohol must be mixed "with denaturing material suitable to the use for which the alcohol is withdrawn, but which destroys its character as a beverage and renders it unfit for liquid medicinal purposes." It further directs that the nature and quantity of denaturing material shall be prescribed by the commissioners of Internal Revenue.

In England, the denaturated alcohol sold at retail contains either 10 per cent. of crude wood alcohol, or else 0.275 per cent. petroleum oil. Under certain conditions alcohol used for manufacturing may be denaturized by addition of other substances.

In Germany, the article offered for miscellaneous sale is denaturized by addition of pyridin and crude wood alcohol, but other additions are authorized for particular lines of manufacture.

Miscellany

Lack of Lime the Basis for Tuberculosis.—P. Ferrier in France and G. Fisac in Spain have recently called attention anew to the importance of lime in the prevention and cure of tuberculosis. The former preaches that the lack of a sufficient proportion of lime in the body is the reason that the tubercle bacilli gain an easy foothold and flourish. Fisac, on the other hand, has been proclaiming the immunity to tuberculosis of persons whose occupation involves the handling of lime and inhalation of lime dust. Ferrier declares that the condition of the teeth is the criterion as to the strength of the resistance that can be offered the bacilli. Tuberculous subjects have poor teeth, as a rule, friable and subject to acute caries. Treatment and prophylaxis should aim to make and to keep the teeth strong and sound, and the tuberculous process will then be found conquered. No acid food, or food inducing acid fermentation, should be allowed, and both food and drinks

should aim to "recalcify the organism." The beverage should be alkaline mineral waters rich in calcium bicarbonates. A glass should be taken half an hour before each meal. This cleanses the stomach and prepares it for the food. During or after each meal he orders a cachet containing 0.4 gm. each of calcium carbonate and tribasic calcium phosphate with 0.35 gm. of sodium chlorid. If the secretion of hydrochloric acid is deficient he prescribes further a teaspoonful of a solution of 2.5 gm. calcium chlorid in 100 gm. distilled water. He is convinced that whenever there is acute dental caries there is phosphaturia, but the latter may be transient and ignored, while the condition of the teeth is a constant and faithful index of the lime values of the organism. The benefit ascribed to country air and to residence at the seashore may possibly be due to the change to water and soil containing more lime. Ferrier's latest communication appeared in the *Bull. Soc. Med. des Hôp.*, xxiii, No. 12, 1906. Sergent's experience during the last eighteen months apparently confirms his assumptions. Rénon also reported a remarkable absence of tuberculosis in a certain town since lime kilns have become numerous there. Some persons who were already tuberculous are now in robust health after working in the kilns.

State Boards of Registration

COMING EXAMINATIONS.

MARYLAND Board of Medical Examiners, Baltimore, June 20-23. Secretary, J. McP. Scott, Hagerstown.

ARIZONA Board of Medical Examiners, Phoenix, July 2-3. Secretary, Ancil Martin, Phoenix.

UTAH State Board of Medical Examiners, Salt Lake City, July 2-3. Secretary, R. W. Fisher, Salt Lake City.

NORTH DAKOTA State Medical Examining Board, Grand Forks, July, 3-5. Secretary, H. M. Wheeler, Grand Forks.

WASHINGTON State Medical Examining Board, Tacoma, July, 3-5. Secretary, C. W. Sharples, Seattle.

RHODE ISLAND State Board of Health, State House, Providence, July, 5-6. Secretary, G. T. Swarts, Providence.

NEW HAMPSHIRE State Medical Board, Concord, July 6-7. Regent, H. C. Morrison, Concord.

ARKANSAS State Medical Examining Board, Little Rock, July 1 Secretary, J. P. Runyan, Little Rock.

BOSTON State Board of Registration in Medicine, State House, Boston, July 10-11. Secretary, Edwin B. Harvey, Boston.

CONNECTICUT Medical Examining Board, City Hall, New Haven. July 10-11. Secretary, Charles A. Tuttle, New Haven.

MAINE Board of Registration of Medicine, State House, Augusta, July 10-11. Secretary, W. J. Maybury, Saco.

OREGON State Board of Medical Examiners, Portland, July 10-12. Secretary, Byron E. Miller, Portland.

VERMONT State Board of Medical Registration, Burlington, July 10-12. Secretary, W. Scott Nay, Underhill.

WEST VIRGINIA State Board of Health, Charleston, July 10-12. Secretary, H. A. Barbee, Point Pleasant.

WISCONSIN State Board of Medical Examiners, Madison (Park Hotel), July 10-12. Secretary, J. V. Stevens, Jefferson.

SOUTH DAKOTA Board of Medical Examiners, Watertown, July 11-12. Secretary, H. E. McNutt, Aberdeen.

DISTRICT OF COLUMBIA Board of Medical Supervisors, Washington, D. C., July 12. Secretary, W. C. Woodward, Washington, D. C.

Georgia April Report.—Dr. E. R. Anthony, secretary of the Regular Board of Medical Examiners of Georgia, reports the written examination held at Atlanta, April 5-6, 1906. The number of subjects examined in was 10; total number of questions asked, 50; percentage required to pass, 75. The total number of candidates examined was 90, of whom 86 passed and 4 failed. The following colleges were represented:

PASSED. College.	Year Grad.	Per Cent.
College of P. and S., Atlanta, (1906), the grades of 77, 79, and 80 were reached by one each, 81 and 82 by three each, 83 by five, 84 by two, 85 by three, 86 by ten, 87 by five, 88 by three, 89 by four, 91 by one, 92 by two, 94, 95 and 97 by one each.		
Atlanta School of Medicine (1906), the grade of 80 was reached by two, 81 by one, 82 by two, 83 and 84 by three each, 88 by one.		
Mebarry Med. Coll.	(1905) 89; (1906) 78, 79, 82, 84, 87, 88	
University of the South	(1905) 77, 79; (1906)	81
University of Nashville	(1906)	85
Leonard Med. Coll.	(1906) 79, 83, 84, 87,	87
Tennessee Med. Coll.	(1905)	88
Chattanooga Med. Coll.	(1899) 85; (1902) 77; (1906)	75
Vanderbilt University	(1893)	80
College of P. and S., New York	(1888)	81
College of P. & S., Baltimore	(1904)	79
Baltimore Med. Coll.	(1897)	86
Maryland Med. Coll.	(1904)	76
University of Tennessee	(1901)	80
Kentucky School of Medicine	(1880)	75

FAILED. College.	Year Grad.	Per Cent.
College of P. & S., Atlanta	(1906)	67, 74
Chattanooga Med. Coll.	(1901)	66
University of Georgia	(1905)	73

Kentucky May Report.—Dr. J. N. McCormack, secretary of the State Board of Health of Kentucky, reports the written examination held at Louisville, May 15, 1906. The number of subjects examined in was 14; total number of questions asked, 110; percentage required to pass, average 70, not less than 60 in any one branch. The total number of candidates examined was 35, of whom 23 passed, including 2 osteopaths, and 12 failed, including 4 osteopaths. The following colleges were represented:

PASSED. College.	Year Grad.	Per Cent.
University of Louisville	(1906) 70, 72, 74, 74, 76, 79, 85	
Eclectic Medical Institute (Cincinnati)	(1906)	84, 84
Medical College of Ohio	(1905)	78, 83
Vanderbilt University	(1905)	75, 83
Louisville Med. Coll.	(1905)	79
Medico-Chirurgical College, Philadelphia	(1905)	78
Kentucky University	(1905)	78
University of Nashville	(1904)	76
College of P. and S., St. Louis	(1906)	76
Meharry Med. Coll.	(1906)	75, 75
New York Homeo. Med. Coll.	(1901)	74

FAILED.		
University of Tennessee	(1906)	64
Eclectic Medical Institute, Cincinnati	(1906)	69
University of Nashville	(1901)	64
Barnes Med. Coll.	(1906)	68
Kentucky University	(1903)	61
University of Louisville	(1906)	66, *74
Kentucky School of Medicine	(1898)	57

* Made below 60 on two subjects.

The following questions were asked:

SURGERY.

1. Differentiate between appendicitis, gallstone colic and renal colic. 2. When would it be necessary to catheterize a male and how would you do it? What difficulties and dangers would you expect to encounter? 3. Discuss the complications of gonorrhea in the female, and tell when you would consider a male cured of this disease. 4. How would you reduce (a) a dislocation of the humerus downward at the shoulder, and (b) a dislocation of the humerus at the hip joint? 5. Differentiate between pleurisy with effusion and empyema. 6. Differentiate between a sprained ankle and Pott's fracture, and give the pathologic anatomy of the latter. 7. Define (a) sepsis, (b) antisepsis, (c) asepsis, (d) volvulus and (e) endothelium. 8. On what symptoms would you establish a diagnosis of syphilis, and describe its secondary manifestations. 9. Describe in detail an inguinal hernia: (b) under what circumstances would you call it strangulated; and (c) describe what steps you would take before deciding that an operation was necessary for strangulated hernia.

MENTAL AND NERVOUS DISEASES.

1. Define (a) mania, (b) delusion, (c) aura, (d) cretinism and (e) idiocy. 2. Describe and give the pathology of anterior poliomyelitis. 3. Describe a section of the spinal cord at one of the following levels—the seventh cervical vertebra, the fourth dorsal or the second lumbar. 4. Tell what you know of the reflex nervous system. 5. Under what conditions would you be willing to state that a person was incapable of writing a will?

CHEMISTRY.

1. What inorganic salts enter into the formation of human bone, and give a method for detecting one base and one acid among them. 2. Define (a) specific gravity, (b) valence. 3. Define glycogen. Where does it occur in the body? 4. Give in detail a test for arsenic in the stomach at a postmortem examination. 5. Define (a) crystallization, (b) efflorescence, (c) organic chemistry, (d) acid and (e) base. 6. Describe in detail two methods for testing urine for albumin. 7. Describe in detail a quantitative test for urea. 8. What is the chemical composition of blood? 9. Name ten elements. 10. Give the chemical constituents of water, air and bile.

ANATOMY.

1. Describe the fourth ventricle. 2. Describe the bladder and give its relations. 3. Describe two of the following: The superior maxillary bone, the os innominatum, the dorsal portion of the vertebral column. 4. Describe the brachial plexus. 5. Describe one of the following muscles: Omohyoid, deltoid, quadriceps extensor. 6. Describe (a) the femoral vein, (b) the trachea. 7. Give the gross anatomy of the pancreas. 8. Describe the transverse colon. 9. Give the histology of the kidney. 10. Describe (a) the circle of Willis, and (b) tell what structures pass through the foramen of Vesalius.

OBSTETRICS.

1. Describe the mechanics of a normal labor. 2. How would you diagnose and manage a breach presentation? 3. Describe the development of the ovum after impregnation and tell what structures develop from each layer of the blastoderm. 4. Tell how to diagnose and how to repair a recent laceration of the perineum. In what proportion of cases are they found? 5. Give the cause, pathology, and symptomatology of milk leg or phlegmasia alba dolens. 6. How would you diagnose placenta previa, and how would you manage a case before, during and after labor? 7. Describe exactly the application of forceps in an occiput posterior case in the superior strait. 8. Under what circumstances would you be called on to do a rapid manual dilatation of the os uteri at full term and how would you do it? 9. A multipara has been in labor several hours, the membranes have ruptured and the right hand and a pulsating cord are in the vagina. Tell exactly what you would do. 10. (a) What is a postpartum hemorrhage? (b) How would you prevent it, and (c) how would you manage an extreme case?

OTOLOGY.

1. Give the causes of deafness and state what may be done to relieve it. 2. Under what circumstances would it be necessary to have an operation done in mastoiditis? 3. How would you diagnosticate acute otitis media and what would you do for it? 4. Describe (a) the labyrinth and (b) the Eustachian tube. 5. How would you remove a bean from the external auditory canal.

ETIOLOGY AND PHYSICAL DIAGNOSIS.

1. Describe the normal heart sounds and give the points of greatest intensity for each of the heart murmurs. 2. How would you differentiate between acute gastritis, ulcer of the stomach, hypertrophy of the stomach and hyperacidity? 3. Give objective and subjective symptoms of pulmonary emphysema. 4. Define bronchial breathing. What is its cause and in what diseases may it be heard? 5. What is the cause of puerperal sepsis and how would you prevent it?

OPHTHALMOLOGY.

1 Describe glaucoma. 2. Describe iritis. 3. Define (a) hypopyon, (b) ophthalmoscope and (c) crystalline lens. 4. Describe ophthalmia neonatorum. 5. Describe trachoma, and tell how you would prevent its spread.

PHYSIOLOGY.

1. Describe the sympathetic (nerve) system. 2. What are the changes in bread during its digestion, and where do each occur? 3. Give the origin, function, and the relative number of the different kinds of blood corpuscles in the healthy system. 4 Define (a) metabolism, (b) secretion, (c) respiration, (d) peristalsis, and (e) coagulation. 5. Describe minute and gross anatomy of the salivary glands and give their functions. 6. Describe the circulation of the blood. 7. How many kinds of muscular tissues are found in the body, describe each. 8. What are the functions of the vagus nerve. 9. Give the physiology of vision. 10. Give the physical properties and chemic composition of normal urine, and name the most important excrementitious products therein.

HYGIENE.

1. How would you prevent the spread of smallpox? 2. How would you disinfect a six-room cottage, each room 14x16 feet and 10 feet high, in which you had treated a case of scarlet fever? Give all steps in detail. 3. If you were treating a case of yellow fever how would you prevent its spread? 4. What advice would you give a patient with acute syphilis in order that he might not infect others? 5. When should water be condemned for drinking purposes?

PATHOLOGY.

1. Give the pathology of tabes dorsalis. 2 State the condition of the blood in leukemia. 3. Give the pathology of rachitis. 4. Differentiate between a chancre and a chancroid. 5. Differentiate between sarcomata and carcinomata and describe the microscopic appearance of two kinds of sarcomata 7. Describe the appearance of the blood in malaria. 8. Give the pathology of the different stages of acute lobar pneumonia, giving the exact microscopic appearance of a section of the lung in each stage. 9. Give the pathology of glioma. 10. Describe the pathologic changes which occur in the spinal cord in amyotropic lateral sclerosis.

MEDICAL JURISPRUDENCE.

1 How would you distinguish human blood stains on clothing? 2 What is malpractice and when is a doctor liable for damages for malpractice? 3. By what physical signs would you establish the fact that rape had been committed. 4. (a) Under what circumstances would a doctor be liable for an overdose of poison in a prescription, and (b) when would the druggist be liable? 5. How would you differentiate between death from acute alcoholism and strychnin poisoning, and describe the postmortem changes in each condition?

GYNECOLOGY.

1 Differentiate between a uterine fibroid and an ovarian cyst. 2 What is a pyosalpinx? 3. Differentiate between pyosalpinx, ectopic gestation and abortion. 4. Give the symptoms, and causes of (a) amenorrhea, (b) dysmenorrhea, (c) metorrhagia, (d) retroversion and (e) endometritis. 5. Describe and give the cause of prolapse of the uterus. 6. Under what circumstances is it justifiable to produce an abortion? 7. Describe senile vaginitis. 8. How would you diagnose a vesico-vaginal fistula, and how would you treat such a case? 9. Define menstruation and describe the menstrual cycle 10. Give the histology of the ovary.

BACTERIOLOGY.

1. Describe the Klebs-Loeffler bacillus. How would you distinguish it? What is diphtheritic antitoxin? 2. Describe the microorganism that causes gonorrhea and tell how to stain it. 3. Describe the mosquito theory of the spread of yellow fever. 4. What is agglutination? What is its practical value in the diagnosis of typhoid fever? 5. Define (a) flagella, (b) karyokinesis, (c) spore, (d) culture and (e) anaërobic. 6. What is Koch's postulate? 7. Give the bacteriology of chronic phthisis, and describe reversion of type. 8. What is phagocytosis? 9. Give the morphology of the *Staphylococcus pyogenes aureus* and tell in what pathologic conditions it is found. 10. Describe (a) a method of making a plate culture, and (b) a stab culture

Louisiana May Report.—Dr. F. A. Larue, secretary of the Louisiana State Board of Medical Examiners, reports the written examination held at New Orleans, May 3 4, 1906. The number of subjects examined in was 10; total number of questions asked, 50; percentage required to pass, 75. The total number of candidates examined was 121, of whom 114 passed and 7 failed. The following colleges were represented:

Mississippi May Report.—Dr. J. F. Hunter, secretary of the Mississippi State Board, reports the written examination held at Jackson, May 8-9, 1906. The number of subjects examined in was 8; total number of questions asked, 64; percentage required to pass, 75 The total number of candidates examined was 231, of whom 118 passed, including 61 non-graduates, and 113 failed, including 72 non-graduates.

Those who passed were from the following colleges: University of the South, 1899, 1905; Toronto Med. Coll., 1899; Marion-Sims Med. Coll., 1895; Northwestern University Woman's Med. Coll., 1882; Memphis Hospital Med. Coll., 1906 (16), 1905, 1904, 1903 (2), 1899; Chattanooga Med. Coll., 1906; Tulane University, 1905, 1906 (4); University of Virginia, 1904; Louisville Med. Coll., 1906; University of Nashville, 1905 (2), 1906 (6); North Carolina Med. Coll., 1906; Meharry Med. Coll., 1906 (4); Atlanta School of Medicine, 1906 (2); Flint Med. Coll. 1906; Leonard Med. Coll., 1906; University of Tennessee, 1897; Barnes Med. Coll., 1906; Vanderbilt University, 1900; Hospital College of Medicine, Louisville, 1905; University of Alabama, 1906; Mobile Med. Coll., 1904.

Those who failed were from the following colleges: Harvey Med. Coll., 1905; College of Med. and Surg., Chicago, 1904; Memphis Hospital Med. Coll., 1900, 1903, 1905 (2), 1906 (8); Tulane University, 1883, 1904, 1906; Med. Coll. of Virginia, 1904; University of Tennessee, 1901; University of Nashville, 1902, 1906 (3); Meharry Med. Coll., 1906 (6); Chattanooga Med. Coll., 1906; Hospital College of Medicine, Louisville, 1904; Leonard Med. Coll., 1905; Flint Med. Coll., 1902, 1904, 1906 4); Kentucky University, 1904; Barnes Med. Coll., 1902; College of P. and S., Chicago, 1889.

Reciprocity with Vermont.—Dr. W. Scott Nay, secretary of the Board of Medical Registration of Vermont, sends us the following:

The Board of Medical Registration of Vermont will endorse the certificate of license of any state medical examining and licensing board in accordance with the following section of the Public Acts of 1904:

Section 14 The board shall issue licenses without examination to reputable physicians and surgeons who shall personally appear and present a certified copy of certificate of registration, or license, which has been issued to said applicant in another state in the union, where the requirements for registration shall be deemed by said board to be equivalent to those of this state, provided such state shall accord a like privilege to holders of a license granted under the laws of this state.

Each applicant for such license shall pay to the board the sum of ten dollars.

The standard of requirements of the Vermont board is as follows:

1 Academic. A high school diploma after four years of study, or its equivalent, that will qualify for entrance without examination to any of the New England colleges.

2. Medical Four courses of lectures of 900 hours each, in four different calendar years prior to graduation from a medical college approved by this board

Practitioners graduated prior to 1901 are exempt from this requirement.

3 Moral Applicants shall present qualifications as to moral character and professional standing from two reputable physicians in the county in which he resides, and from the city or town clerk of his place of residence.

4 Examining The examination in writing shall embrace 12 subjects of 90 questions each: Anatomy bacteriology, practice of medicine and pathology, surgery and medicine, obstetrics, gynecology, physiology, hygiene, materia medica and therapeutics. The general average in at least 75 per cent in order to obtain a license.

West Virginia April Report.—Dr. H. A. Barbee, secretary of the West Virginia State Board of Health, reports the written examination held at Parkersburg, April 10-12, 1906. The number of subjects examined in was 9; total number of questions asked, 180; percentage required to pass, 80. The total number of candidates examined was 44, of whom 12 passed and 32 failed, including 11 non-graduates. The following colleges were represented:

Society Proceedings

COMING MEETINGS.

State Medical Society of Wisconsin, Milwaukee, June 27-29.
American Ophthalmological Society, New York City, June 28-29.

NATIONAL ASSOCIATION FOR THE STUDY AND PREVENTION OF TUBERCULOSIS.

Second Annual Meeting, held at Washington, D. C., May 16-18, 1906.

(Concluded from page 1721.)

Tuberculosis Among the Indians.

COMMISSIONER F. E. LEUPP, Washington, stated that from data collected by 91 field physicians and representing half the Indian population of the United States, there were included nearly 3,000 cases of tuberculosis, one-third of which were of the pulmonary type. He is distributing pamphlets on the subject and has succeeded in gaining the interest of Congress in the project of establishing in the west a sanitarium for tuberculous Indians.

DR. JAMES R. WALKER, Pine Ridge, S. D., said that in that agency in 1896 there were 4,973 Ogalallas, among whom were 741 cases of tuberculosis. The Indians were then impressed with facts concerning the disease, and in five years the number of cases were reduced from 148 to 105 per thousand. After that a physician could not devote his time to the subject and the ratio has now increased to 120 per thousand.

Other papers discussed in the sociologic section were "The Influence of Sanatoria on the Value of Surrounding Property," by W. H. Baldwin; "Effective Methods of Educating the Public," by Paul Kennaday; "Industrial Sickness Relief Associations and Tuberculosis," by Dr. A. C. Klebs, and "Tuberculosis Among the Negroes," by Mr. T. J. Jones, Hampton, Va.

PATHOLOGICAL AND BACTERIOLOGICAL SECTION.

Papers on "Tuberculous Meningitis," "Tuberculosis of the Liver," and "The Kidneys in Tuberculosis," were read respectively by Drs. D. J. McCarthy, Josephus Ullom and Joseph Walsh of Philadelphia.

Clinical and Pathological Comparison of Cavities.

DR. H. R. M. LANDIS, Philadelphia, reported the results of a study of 50 cases in which cavities were present, 76 cavities in all being found. Of the 76, 58 had been recognized before death. Of the unrecognized list all but three were small, the latter being the size of a lemon. The situation more than the size has to do with the diagnosis. Most of the cavities not diagnosed were filled with thick creamy pus. Ten cases were thought to be instances of cavity formation, but were found not to be; five of them showed consolidation around a bronchus. Of the 58 cavities recognized, 53 gave the sign of whispering pectoriloquy, 49 a tympanitic percussion note, and 33 gurgling râles. Whispering pectoriloquy is not pathognomonic of cavity, being absent in 5 and present in 5 cases where cavity was not present, the lesion being around a bronchus.

DISCUSSION.

DR. W. H. WELCH, Baltimore, said it was interesting to note that cavities are almost peculiar to tuberculosis of the lung, only few appearing elsewhere in the body. The connection with the external air permits removal of the dead material, but the mechanical impact of the inspired air must also be a factor. Mixed infection plays a very important part in the formation of cavities, but is not an absolute necessity. The action of autolytic enzymes has not fully been worked out, but this is also an important feature of the process. During the last few years he has found that the influenza bacillus is a common occupant of pulmonary cavities. These analytical studies of different phases of tuberculosis are of great value and should be encouraged.

DR. ALFRED MEYER, New York, has found an expedient of considerable value in doubtful cases of cavity in the lung. The patient usually lies in the position in which he coughs the least and this may be due to the fact that a filled cavity overflows in certain postures and not in others. To drain the cavity and thus to allow it to give the signs of that condition, the patient should be kept for some hours of even days in the position he usually avoids, and in this way the cavity may be located.

Tuberculosis of the Placenta.

DR. A. S. WARTHIN, Ann Arbor, presented a series of lantern slides to show his findings in three cases of this lesion. One was a case of tuberculosis of the tubes in the mother and of the placenta and fetus, a rare condition and not of great importance. A second showed miliary tuberculosis in the placenta, but a number of placentas were confused and the mother could not be located. A third was a case of chronic renal tuberculosis, with following miliary spread of the disease, with abortion at six months. In this the uterus, placenta and fetus were examined. A prominent feature of the lesions in the placenta was the lack of giant and epithelioid cells, necrosis being the constant lesion. The fetal blood was filled with tubercle bacilli, but there were no localized lesions in the fetus.

DISCUSSION.

DR. W. H. WELCH, Baltimore, regards the question of placental lesions as a subject of really fundamental importance in the etiology of tuberculosis. The evidence is becoming stronger and stronger that conveyance from mother to fetus is at least not so very extraordinary, and is probably far more frequent than is commonly supposed. No definite placental lesions are necessary for the passage through that structure of the tubercle bacillus. That tuberculosis in the new born does not more frequently develop has been explained in two ways; first, that the bacilli get in late and hence there is no time for tubercles to develop, and second, that the fetus is relatively insuseeptible. Both reasons are probably active. There is considerable evidence to show that the fetus may harbor tubercle bacilli for weeks without the development of lesions.

DR. L. F. FLICK, Philadelphia, asked if the apparent immunity of children of tuberculous mothers was due to exposure during intrauterine life. Clinically he has noted a resistance to exposure on the part of such children for some time after birth, and he believes that with some this may last throughout life.

DR. WELCH said this was purely a clinical observation which *a priori* has nothing to indicate its impossibility. Here the fetus is acted on by the living bacilli, which, as pointed out by Dr. Flexner, is the only basis of immunity.

DR. J. H. LOWMAN, Cleveland, stated that an examination of 350 school children of tuberculous parents showed that 10 per cent. were tuberculous and a second 10 per cent. were suspicious.

Concerning Bacillus X.

DR. S. J. MAHER, New Haven, detailed experiments with this ordinary harmless bacillus which show the great power of change possessed by it under the proper conditions. When grown in certain ways it becomes acid resisting and produces caseous masses when injected into rabbits. Taken from these masses and injected into a second series of rabbits, caseous nodules are again produced.

Serum Diagnosis of Tuberculosis.

DRS. H. M. KINGHORN and D. C. TWICHELL, Saranac Lake, last year reached the provisional conclusion that the serum method of Arloing and Courmont is not a reliable test in the diagnosis of tuberculosis. Since that time they have made further tests on 247 healthy and diseased persons. Of the 247 persons, 70 were apparently healthy, 155 had tuberculosis, and 22 were doubtful cases of tuberculosis. Of the 70, 84 per cent. reacted; of the 155, there were 87 per cent. positive results, and of the 22, the test was positive in 82 per cent. There is also but little difference in the agglutinating power of the blood from the healthy and the tuberculous, the former being 14.8 and the latter 13.7. The writers conclude that the serum test is not a specific sign of the presence of tubercnlosis, and that it is of no value in the early diagnosis of the disease.

CLINICAL AND CLIMATOLOGICAL SECTION.

State Sanatoria for Tuberculosis.

DR. V. Y. BOWDITCH, Boston, advises that sanatoria be built away from cities and that they admit only incipient or recoverable cases. Advanced cases should be placed in hospitals for that purpose. The sanatoriums should not be made so large that personal supervision will be rendered impossible, as this defeats the aim of the institution. The possibilities of laboratory research should be fully borne in mind in the equipment and administration of all sanatoriums.

Therapeutic Use of Tuberculin Combined with Sanatorium Treatment of Tuberculosis.

DR. E. L. TRUDEAU, Saranac Lake, gave a summary of the impressions derived from the use of tuberculin since 1890. As a diagnostic agent it never should be used, he stated, until the failure of all other methods of arriving at a conclusion. When these have failed it may be used in exceptional cases. No immediate brilliant results accrue from its use as a therapeutic agent, but he has continued its use in spite of the popular clamor against it, partly because certain results in animals are similar to those obtained along the same lines in the treatment of infectious diseases. During later years he has used Koch's products mostly, the old, T. R., and the bacillus emulsion. During the time tuberculin has been used less and less favorable cases have been selected, but at least at first those that promised most were chosen. He has had no experience with febrile cases. Care must be used in its employment, as tuberculin is a powerful agent. Dr. Trudeau advises no physician who values his peace of mind to begin its use.

The method of use is important. A febrile reaction is not necessary, and every effort should be made to avoid its production. The agent not only acts on the disease itself, but stimulates the body cells in their work against the invasion; hence, it is best to continue a mild stimulation for a long period of time. Very small doses should begin the treatment, and if a reaction occurs, never inject again until the signs have disappeared. Six months are almost always necessary for an effect, and a year or more would often be better. Danger from the agent lies wholly in faulty administration. The opsonic index to determine dosage is as yet impracticable of application. In the more advanced cases the immediate result of the use of tuberculin may be striking, but usually this does not occur.

Of the unclassified cases with bacilli in the sputum, 64 untreated and 67 treated, lost the bacilli. Of the classified cases, 24 untreated and 41 treated, showed disappearance of the bacilli. Of incipient cases, 56 per cent. of those treated with tuberculin were apparently cured, and 50 per cent. of the untreated. Of advanced cases, 27 per cent. of the treated and 6 per cent. of the untreated were apparent cures. Of the incipient cases 79 per cent. of the treated and 63 per cent. of the untreated are living at the present time. Of advanced cases 61 per cent. of the treated and 36 per cent. of the untreated are living. The value of these statements depends on two things the accuracy of the figures and the interpretation of the results. Are the results due to the use of tuberculin or to the other factors employed? The selection of cases and the longer average stay of the treated may have something to do with the showing. Be this as it may, Dr. Trudeau many years ago formed the opinion that tuberculin may aid in the sanatorium treatment of tuberculosis and his experience leads him still to hold this view.

DISCUSSION.

DR. LAWRASON BROWN, Saranac Lake, has used the tuberculin treatment in 85 cases, with, on the whole, favorable results.

DR. E. R. BALDWIN, Saranac Lake, spoke chiefly from the laboratory viewpoint. From this view tuberculin treatment is still in the experimental stage. The essence of its effect is in the local reaction. He believes its effect is produced by the action on cells which surround the dead tissue and bacilli, rendering them capable of dissolving and removing these toxic products, and thus limiting the action of the tubercle.

DR. L. ROSENBERG, Bedford Springs, has treated 64 cases with tuberculin during the past year, with results about the same as those given by Dr. Trudeau. Some effect was attained in the early cases, more in the moderately advanced. Subjectively, all were vastly improved by the treatment.

DR. M. P. RAVENEL, Philadelphia, said the agglutinating reaction occurs in those who have no tuberculosis, hence is not due to tuberculosis at all. Dr. Baldwin's suggestion does not explain how the tubercle is walled off by fibrous tissue, which occurs in animal experiments. The whole summary of the question is that we do not yet know the tubercle bacillus or what is in it. Tuberculin differs from bottle to bottle of the same make because there is no standard for it.

Use and Abuse of Pulmonary Gymnastics.

DR. C. L. MINOR, Asheville, from a careful study of a large series of cases, has reached the conclusion that pulmonary gymnasties in selected cases of tuberculosis of the lung, are a very valuable adjunct in the treatment. Observing from time to time the size of the chest by means of the lead tape will show the good effect of the breathing exercises. He dreads the shrinkage of the incipient lung even before other untoward signs make themselves known.

DISCUSSION.

DR. NORMAN BRIDGE, Los Angeles, still believes in the principle of rest to all tuberculous areas.

DR. E. O. OTIS, Boston, mentioned tests which show that at least no harm is done by pulmonary gymnasties in proper cases. Patients all feel better during the exercises.

DR. H. M. KING, Liberty, formerly had his patients practice gymnastics, now he does not. He is not convinced that they do good, even if they do no harm, and he would rather err on the side of safety.

DR. J. H. PRYOR, Buffalo, said that in the state hospital for incipient cases, the superintendent has never seen bad results from gymnastics which have been practiced for two years. An important point in this connection is that many writers in England and some in this country are against sanatorium treatment because it turns out flabby individuals who can not earn their living after going home. Breathing exercises tend to keep up bodily functions and help to put the patient in condition to stand exertion when discharged.

Other papers read in the section were "Diet in Tuberculosis," Dr. H. M. King and Prof. Irving Fisher; "The Relative Value of the Home Treatment of Tuberculosis," Dr. L. F. Flick; "Climate as a Factor in the Treatment of Tuberculosis," Dr. F. I. Knight, Boston; "A Suggestion in the Treatment of Hemoptysis," Dr. L. Brown, Saranac Lake; "Manifestations of Syphilis in Connection with Tuberculosis," Dr. J. H. Pryor, Buffalo; "What May Be Accomplished in Apparently Hopeless Cases of Pulmonary Tuberculosis," Dr. S. G. Bonney, Denver; "A Contribution to Climatic Phthisio-Therapy," Dr. E. S. Bullock, Silver City, N. M.

ILLINOIS STATE MEDICAL SOCIETY.

Fifty-sixth Annual Meeting, held at Springfield, May 15-17, 1906, under the presidency of Dr. H. C. Mitchell of Carbondale.

(*Concluded from page 1788.*)

Treatment of Compound Fractures.

DR. EDWARD H. OCHSNER, Chicago, pointed out in what cases the limb can be saved, and when primary amputation is justifiable. He spoke of the method of disinfection, including prevention of tetanus. He pointed out the indications of plastic work in the repair of bones, tendons, nerves, etc., and discussed the method of drainage and wound closure; also secondary shock and immobilization.

Use of Extension Frames in Treatment of Fractures of Thigh and Leg by Ambulatory Casts.

DR. FREDERICK MUELLER, Chicago, said that the ambulatory plaster cast is the most convenient and natural treatment for all fractures of the thigh or leg. Its application is dangerous in some cases, on account of the possibility of disarranging a fracture once set. The author described a new apparatus which, besides showing all the advantages of the Lorenz apparatus, is especially built for general use in the treatment of fractures. The setting of all kinds of fractures can be accomplished by this apparatus with the greatest convenience for the surgeon as well as for the patient.

Operative Treatment in Fractures Presenting Obstacles to Reduction.

DR. WILLIAM FULLER, Chicago, drew the following conclusions: 1. That the unsatisfactory results hitherto obtained in practically all cases when treated conservatively will not meet the continued approval of surgeons familiar with modern surgical technic. 2. That the indications for radical treatment are postive and certain, and that the safety of the procedure is unquestioned. 3. That the operation offers in this class of cases the only reliable means of arriving at a correct diagnosis, the only basis on which rational and scientific treatment may be enunciated.

Problems in Appendicitis.

DR. H. N. RAFFERTY, Robinson, said that the appendicitis question, although hackneyed, is unsettled in many respects, as shown by bedside contact with individual cases. There is nothing new to offer in the way of diagnosis or treatment. All extremes have been reached in formulating methods of treatment, yet mortality prevails. Difficulty in the conduct of cases is often due to inability to judge the extent of the lesions from either subjective or objective symptoms. The author pointed out how much safer for both patient and practitioner is the doctrine of conservative radicalism over that of radical conservatism.

Angioma and Its Surgical Treatment.

DR. CARL BECK, Chicago, gave a brief historical review of this condition and its treatment, and dealt with the present method of surgery in angiomatous growths. He referred to the Payr and Wyeth method; to excision; the electro-surgical method, and described his own method of subcutaneous excision and suture with the gradual growth of normal neighboring skin.

Shortening of Round Ligaments at Internal Ring for Persistent Retroversion of Uterus.

DR. FRANKLIN H. MARTIN, Chicago, gave a description of the technic of shortening the round ligaments through the internal ring after opening the abdomen by a ventral incision. It is accomplished by making a stab wound through the aponeurosis of the external oblique at the point where it passes over the internal ring. Through this opening is passed a pair of sharp artery forceps, penetrating the peritoneum at the point beneath the internal ring, grasping the round ligament within an inch and a half of its insertion into the uterus, and drawing the same through on the aponeurosis and securing it there by means of a non-absorbable suture. He considers the operation unique in its simplicity; there is perfect security of the round ligaments. He employs the strong ends of the round ligaments and shortens the ligaments in the line of their normal axis.

Complications and Emergencies Met with in Surgical Treatment of Ovarian Cystoma.

DR. GEORGE L. EYSTER, Rock Island, enumerated and described the various complications of ovarian cystoma: Twisting of the pedicle; hemorrhage into the cyst; infection and suppuration; adhesions; displacement due to enlargement of other pelvic or abdominal organs. He made a plea for the split flap method of relieving such sessile adhesions to the abdominal viscera as may endanger their integrity by the ordinary method of enucleation. He reported two cases illustrating some of these complications and emergencies.

How Can We Secure the Co-operation of the General Practitioner in Surgical Treatment of Enlarged Prostate?

DR. CARL E. BLACK, Jacksonville, gave the history of surgery of the prostate, with special reference to surgical failures and their influence on the profession. He said that it is not surprising that it is difficult to have the present operations accepted. What proof is there of the correctness of the present surgical procedures? He spoke of the influence of medical organizations in disseminating information, and their use for postgradnate instruction. He pointed out the apparent conflict between medical and surgical advice, and referred to the weakening influence of the division of the profession into societies and sections of specialists. He discussed the value of papers on surgical topics by general practitioners.

Prostatectomy.

DR. JOHN B. MURPHY, Chicago, pointed out the indications for, the limitations and clinical results of, prostatectomy, saying that the indications are now well accepted and clean cut. The early operation is the one that precedes catheter life, severe vesical infection, not to speak of ascending pyelitis. The technical procedure as to route is always elective in the individual case. The results have been very gratifying as to urinary continence, as to dispensing with the catheter, the cure of suppurative cystitis, absence of fistulæ, prevention of epididymitis, and life-saving. There is no operation that taxes the surgeon's judgment as to the personal resistance equation so much as the operation of prostatectomy.

Vasectomy With or Without Subsequent Anastomosis.

DR. G. FRANK LYDSTON, Chicago, read a paper on this subject which will be published in full in THE JOURNAL.

Treatment of Blennorrhea of the Lachrymal Sac.

DR. W. O. NANCE, Chicago, said that chronic dacryocystitis is an exceedingly annoying process, and a source of danger to the integrity of the eye. The course of the disease is almost invariably obstinate and frequently results in months and even years of treatment by probing, syringing and correction of nasal abnormalities. The removal or destruction of the diseased mucous membrane of the lachrymal duct is positively obligatory as a preliminary operation on the globe of the eye. He pointed out the other indications for extirpation of the sac, and suggested some practical points concerning the technic of operation. He spoke of the essentials of success in operating, and described the changes in the lachrymal gland following the extirpation of the sac.

Operative Treatment of Chronic Discharges from the Ear.

DR. A. E. PRINCE, Springfield, said a very large percentage of cases of middle-ear discharge is due to chronic suppurative mastoiditis. He pointed out the complications which are liable to result when the disease is not controlled. Attention was directed to the results of the efforts of Nature to bring about a spontaneous cure. It is the duty of the surgeon to assist Nature. He spoke of the results of imperfect operations in which the surgeon has failed to remove all the cells, which actually increase the danger of fatality. He summarized the points in the radical operation which are designed to bring about a permanent cure in the least possible time, and cited illustrative cases.

Carcinoma.

DR. GEORGE N. KREIDER, Springfield, spoke of the popular agitation for the early operative treatment in carcinoma. He referred to the remarkable superstitions about the disease, and

said that the affection is not so fatal as is generally supposed. There is great need of teaching physicians and the public the early symptoms. Reference was made to the great number of uneducated persons who are using the strongest, most painful means of treating the disease. Washes and salves are entirely useless. All abnormal growths should be extirpated early. Early extirpation in cancer is absolutely necessary. Inoperable cases should be treated with the *x*-ray, and the patient be given hopes of recovery.

Operative Treatment of Superficial Carcinomata.

Dr. Daniel N. Eisendrath, Chicago, said that by superficial carcinomata are understood those of the lip, tongue, ear, extremities and external genitalia. The reason for recurrence in many of these cases is that no attention, or but little, has been paid to the removal of the secondary deposits in the surgical anatomy of the lymphatic supply of the above regions. He made a plea for a thorough removal of the secondary foci simultaneously with the extirpation of the primary growth, saying that the two operations can be done at one sitting. The extirpation of lymph nodes should precede that of the primary tumor on account of the lesser danger of infection of the operative field. He described the technic as used by him in his surgical work.

Logic of Abdominal Pain.

Dr. J. L. Wiggins, East St. Louis, said that one of the fallacies that is general among the laity and altogether too prevalent among physicians is that the summoning of the surgeon presumes an operation. Another equally vicious is that operations are expedient only as a last resource. Considering the frequency with which these errors obtain, the surprise is not that surgery falls short of perfection, but that it is not altogether discredited. When we consider the safety and simplicity of an operation when a disease is in its incipiency and confined within the lumen of a dispensable organ, and then contemplate the rapid change incident to the escape of infectious material and consequent local or general peritonitis, we feel that the surgeon may be absolved from the charge of excessive zeal in his endeavor to impress on the general profession the vital importance of an early and exact diagnosis, supplemented by an immediate operation whenever an operation is indicated.

Officers Elected.

The following officers were elected for the ensuing year: President, Dr. J. F. Percy, Galesburg; vice-presidents, Drs. L. H. A. Nickerson, Quincy, James H. Stowell, Chicago; secretary, Dr. E. W. Weis, Ottawa (re-elected); treasurer, Dr. E. J. Brown, Decatur (re-elected).

Delegates to the American Medical Association: Drs. George H. Webster, Chicago; J. L. Wiggins, East St. Louis; O. B. Will, Peoria; Charles L. Mix, Chicago. Alternates: Drs. T. N. Rafferty, Robinson; L. C. Taylor, Springfield; J. C. Foley, Waukegan; J. W. Hairgrove, Jacksonville; J. P. Whitley, Petersboro; John C. Cook, Chicago; William Barnes, Decatur, and T. J. Watkins, Chicago.

Resolutions Adopted.

The following resolutions were adopted:

Resolved, That the Committee on Medical Legislation be instructed and the members of the society urged to work for the passage of the bill by the next General Assembly of Illinois, which shall provide that all bottles or packages containing drugs shall bear a statement on the label of the quantity or proportions of alcohol, narcotics or other poisons which may be contained therein.

Resolved, That the Illinois State Medical Society direct its Committee on Medical Legislation and urge its members to do what they can to secure the passage of the Pure Food Bill, now before the House of Representatives, except the amendment introduced into the bill by the house committee, providing for the appointment of a Commission of Experts. It requests that this amendment, which would probably decrease the efficiency of the measure, be eliminated.

Resolved further, That the Committee on Medical Legislation and the members of the society be requested to oppose any amendment to this bill that would essentially change the provision of the bill as it came from the house committee, requiring the labeling of medical packages containing alcohol, narcotics and other poisons.

Resolved, That the Illinois State Medical Society direct its Committee on Medical Legislation and urge its members to do what they can to secure the passage of the bill to increase the efficiency of the medical department of the Army, which is now before the House of Representatives.

Whereas, The American Medical Association, through its Council on Pharmacy and Chemistry and its Journal, edited by Dr. George H. Simmons, has undertaken a campaign of education and of practical work against the nostrum evil in its various phases; therefore be it

Resolved, That the Illinois State Medical Society fully endorses this great work and urges its officers and members to co-operate in every way to further this cause.

HEREAFTER PAPERS TO BE READ BEFORE GENERAL BODY.

Whereas, This is largely a society of general practitioners who are of necessity interested in all branches of medicine and surgery; therefore be it

Resolved, That the Committee on Scientific Work be instructed for the next year's program to provide one day for the medical section, at which papers on purely medical subjects shall be presented; one day for the surgical section, at which papers on purely surgical subjects shall be presented; and one day for a joint meeting, at which papers on borderland subjects and subjects of mutual interest to all shall be presented.

Rockford was selected as the place for holding the next annual meeting, the third Tuesday in May, 1907.

AMERICAN GYNECOLOGICAL SOCIETY.

Thirty-first Annual Meeting, held at Hot Springs, Va., May 22-24, 1906.

(*Continued from page 1792*).

Dilatation Versus Incision of the Gravid Uterus.

Dr. Egbert H. Grandin, New York, said that incision should never be resorted to when the complication calling for intervention justifies delay. Thus induction of labor in a case of pelvic contraction, interference in many cases of impending toxemia, as also in most instances of placenta prævia, call for dilatation. On the other hand, the acute toxemias, the urgent instances of placenta prævia, call for incision. The operative methods to be considered are abdominal and vaginal incision and manual and instrumental dilatation. Broadly stated, in pelvic contraction, whenever it is doubtful that dilatation or vaginal incision will permit of delivery, abdominal incision is called for. In the acute toxemias, where the time element enters as a factor, and in rare acute cases of placenta prævia, vaginal incision is justifiable, else dilatation should be the rule after a prescribed technic. Such devices as the Bossi dilator should receive the unqualified condemnation of American obstetricians. They are needless where the educated hand exists; they are dangerous under any condition. In the event of incision being indicated, the vaginal Cesarean section is to be commended as preferable to the Dührssen incisions. The indication for either is extremely limited.

Vaginal Cesarean Section.

Professor Dührssen, Berlin, Germany, summed up the indications for this operation as follows: Vaginal Cesarean section is indicated when, in the case of an imperfectly dilated cervix, which will not permit of dilatation by gentler means, the life of the mother or the child is brought into danger. The presence of an operator experienced in vaginal operations is required. Imperfect dilatation of the cervix might be caused by pathologic changes in the neighborhood of the lower uterine segment, or danger to the mother and child might arise when the pains had as yet caused insufficient opening of the os. In the first, the case is that of an absolute, while in the second it is that a relative obstruction to delivery. The first must be removed because it leads to danger for the mother and child. In the second the danger is already present and requires the immediate emptying of the uterus. Among the special indications he mentioned that of eclampsia. He first established the principle that on account of the independent nature of eclampsia it is best to empty the uterus by narcotics as soon as the diagnosis is made.

He has collected 376 cases of vaginal Cesarean sections, with 48 deaths, a mortality of 12.7 per cent. This high mortality was not due to the dangers of the operation, but to the serious diseases for which operation was undertaken. This proved that the greater operation, namely, the radical vaginal Cesarean section, has a lower mortality than the conservative vaginal Cesarean section. Of 53 cases of extirpation of the uterus after vaginal Cesarean section only five patients died. This further proves the low mortality of the conservative Cesarean section in clinics where immediate deliveries in cases of eclamp-

sia have been effected according to the author's teachings and directions. Veit had only one death in 33 cases, Bumm only one death in his last 40 cases. He mentioned two deaths in 12 cases of vaginal Cesarean section. One was a woman moribund with heart disease, who died immediately after the uterus was emptied. The other was a case of eclampsia with pulmonary tuberculosis as a complication. She was first cured of the eclampsia; the wound healed perfectly, the uterus was completely involuted, but she died in four weeks of tubercular pneumonia.

The Possibility of the Development of Cancer in the Cervical Stump Following Supravaginal Hysterectomy.

DR. ANDREW F. CURRIER, New York, said that the cases in which this complication might arise are usually those in which the uterus has been removed for myoma. That myoma frequently coexisted with cancer is a matter of common observation. Piquand collected 45 such cases, in 24 of which it was thought that the fibromuscular elements had been transformed into epithelial cells, although in some of them there were preexisting cells which proliferated and developed malignancy. These cells are supposed to have been derived either from the embryonic remains of the Wolffian or Muellerian canal, or to be simply epithelial ingrowths into the fibrous tissue. The author is satisfied from his own experience that the coexistence of cancer and myoma is much more frequent than Piquand seems to think. Noble, in an analysis of 1,188 cases of fibroid tumor operated on by various surgeons, found 29 in which cancer of the corpus uteri was a complication, 12 in which there was cancer of the cervix and one in which there was cancerous infiltration of a fibroid tumor arising from adenocarcinoma of the corpus uteri by metaplasia. The author has not yet seen any conclusive evidence that myoma is transformed into carcinoma, and histologically one would not expect such a sequence.

The suggestions which occur to him in connection with the consideration of this subject are the following: 1. The necessity of more careful clinical and pathologic records, both public and private, in all the cases in which supravaginal hysterectomy is performed. This will probably result in the discovery of cancer of the endometrium in cases in which it was not suspected, and will probably bring to light additional facts in regard to the history of the evolution of cancer. 2. The periodical examination of patients who have undergone the operation in question at not longer than six-month intervals. This is especially desirable for those whose tissues are in a bad condition of nutrition or who suffer from an hereditary taint. 3. Complete removal of the uterus offers greater security from cancer than retention of the cervix. If the patient's history reveals any conditions which suggest the possibility, near or remote, of future degeneration of tissues, complete extirpation should be the invariable rule.

The Search After Truth.

DR. RICHARD B. MAURY, Memphis, in his address referred to the deaths of Dr. A. Palmer Dudley, New York; Dr. James R. Chadwick, Boston; Dr. Arthur W. Johnstone, Cincinnati, and Dr. R. Stansbury Sutton, Pittsburg, which occurred during the year. He then made some remarks on the subject of uterine displacements, and referred to a discussion on ante-flexion before the society in 1888, which was participated in by T. Gaillard Thomas, Graily Hewitt, Sir William Priestley and others, the conclusion having been reached by those men at that time that the man who would not use pessaries in the treatment of antеflexion was unfit to practice gynecology. The intrauterine stem had passed out of the history of gynecology, perhaps forever, and would never again come into favor. The knowledge of pelvic inflammation was so fully disseminated that every practitioner realized the peril to a woman from its use. Maury said that when one considers the various operative procedures which have been devised for the cure of backward displacements and notes that nearly all of them involve the shortening of one set of ligaments or another, or else the suspension of the uterus from above, he must conclude that the present practice is generally accepted by the profession. Maury discussed at considerable length how the uterus is sustained almost entirely by its ligaments, but said that some of the teachings regarding this matter are erroneous, in that the proper supports of the uterus are not the ligaments but the various structures which constitute the two segments of the pelvic floor, as demonstrated by Hart and Barbour.

Results of Vaginal Section and Drainage in Early Cases of Ectopic Gestation.

DR. WILLIS E. FORD, Utica, N. Y., reported 12 cases, which were all seen before rupture had occurred, some of them as early as in the eighth week. In all the cases the incision was made cautiously into the sac, the finger being used to open into it, and the contents examined before the finger was wholly withdrawn, so as not to lose the landmark. In no case was all the blood emptied at the time of the incision, but gauze was carefully passed into the opening and very firmly packed to prevent hemorrhage and allowed to remain for a week before removal. In this way hemorrhage was avoided and the operation was almost trivial in its consequences. The fact that the patients operated on early almost no trace of anything wrong was left in the pelvis afterward, and that the operation was so safe and so certain in its results, impressed him that the society should urge early diagnosis and early operation of all cases of extrauterine pregnancy. If the teaching in the medical schools could be so modified as to impress on medical students a more careful consideration of the subjective symptoms until skill enough has been acquired to enable the verification of the diagnosis to be made with certainty, he is sure that these cases of ectopic gestation would be seen early enough to be operated, and thus prevent rupture and hemorrhage in a large number of instances.

(To be continued.)

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Chorea.

In the treatment of chorea David Inglis, in *Pediatrics*, states that one must keep in mind that it is not a local disease, but one which involves the general impairment of the cerebral functions, and produces motor disturbances. He regards rheumatism as probably the most common cause of this disease. Reflex chorea, however, should not be forgotten. In the treatment, in addition to the removal of the cause, he states that there are practically two things to be done. The first is to stop the waste of nervous energy of the patient, in order to build up nutrition of the neuron bodies, and to lessen the emotional and mental expenditure. Consequently, the patient's time should consist of rest, so far as possible; a nagging mother and an irritable nurse may do a great deal more harm than good in these cases. The amount of sleep should be as great as possible. He makes it a rule to put chorcic patients to bed early and allow them to arise late, and in the afternoon they should be placed in a dark room and allowed to rest for an hour or two, if possible. Sleep, he states, must be obtained at all hazards, and, if need be, chloral may be given for its soporific effects, and he regards it as the surest of all hypnotics, especially as children bear it unusually well. [It must be used with care, however.]

The second important principle of treatment, according to the author, is that of increasing the nutrition of the neuron bodies, and this consists largely in the question of food supply, as most of these patients have but little appetite, and it is not infrequently a difficult matter to secure the ingestion of an abundance of nourishing food. He, therefore, recommends forced feeding when necessary. In this connection he speaks of the mistake of allowing these children to eat three large meals a day, as it weakens the stomach, which is unable to care for so much food at one time. He, therefore, recommends well-cooked nutritious food in small quantities, at frequent intervals. The food should consist especially of fats, which play a great part in cerebral nutrition. Cream, butter, the fats of meat, and, if necessary, cod-liver oil, are valuable

in this disease. In order to stimulate the protoplasm of the cells that they may be able to take up the food supplies brought to them, he recommends arsenic and phosphorus and perhaps strychnia, as of value in stimulating the metabolism of the cell bodies.

He warns against the possibility of over-stimulation by arsenic, as in some cases the same poison which tends to build up may damage the neuron and also the quality of the blood. He recommends, therefore, a combination of iron, arsenic and strychnin in moderate doses rather than heroic doses of arsenic alone. In connection with the dietetic treatment he mentions the use of raw eggs as of value in the formation of fat, because of the lecithin contained in the yolk, and he is of the opinion that it acts in a manner similar to arsenic as a stimulant to the cell metabolism.

Riviere, in the *British Med. Jour.*, recommends ergot and arsenic in chorea. The ergot may be given in doses ranging from 30 to 60 minims of the fluid extract, three times a day, combined with liquor strychninæ (1 per cent. solution) 2 minims (.12). In those cases not improved by the ergot he advises the administration of arsenic. A mixture of the two may be given as follows:

R.	Ext. ergotæ flu	3i	4
	Liq. potassii arsenitis	m. iii	|20

M. To be taken at one dose and repeated after each meal.

The foregoing combination is recommended by Riviere as a very effectual one in all cases.

Hollopeter, in the same periodical, recommends prolonged warm baths in shortening the attacks of chorea. The child should be placed in a bath at a temperature of from 90 to 98 F. and entertained by the mother or nurse by floating toys or by other methods. The entire body except the head and neck should be kept immersed for at least one or two hours. These baths should be given twice daily.

F. M. Pope states that in all suitable cases arsenic should be administered as follows:

1. Administer a mercurial purge.
2. Place the patient on a bland and easily digested diet.
3. Give the arsenic well diluted and in the same dilution throughout, usually giving 2½ minims of Fowler's solution to the ounce of water.
4. Do not discontinue this medication on the first attack of vomiting, as the vomiting is often due to accidental causes.
5. Increase the dose daily.
6. Keep the patient in bed throughout the treatment.
7. If vomiting persists, discontinue the arsenic for twenty-four hours.
8. Examine the patient daily for any toxic action.

Tabes Dorsalis.

In considering tabes dorsalis, F. von Raitz, in the *Medical Record*, states that the treatment must begin by preventing impairment of nutrition and when impairment has already set in by restoring the nutrition, if possible. To prevent any failure of nutrition each patient who has had any infectious disease, who has indulged in sexual excesses, who has been subject to mercury, iodin, lead or any other organic or inorganic poison, should be observed during a period of two or more years, and as soon as any disturbances of the reflexes are shown, the spinal cord and the brain should receive attention by the applications of such methods as are capable of increasing the nutrition to the affected parts. The earlier that tabes is recognized, therefore, the greater the opportunity for a cure. The first step to increase the nutrition of the entire body is to place the patient under the most favorable conditions, such as pure air, sunshine, congenial surroundings, plenty of sleep, and a sufficient occupation of both mind and body. He recommends in this connection the salt brine friction of the body in a warm bath, at a temperature suitable to the patient, and repeated twice a week. This keeps the pores of the skin open and promotes circulation. The clothing must be so adjusted as to keep the patient's body comfortably warm, but not too hot. The diet must be along the lines which will best agree with the patient. The digestive power is, as a rule, impaired, consequently eating slowly and thorough mastication should be enjoined as very essential. Concentrated food should be avoided, as it tends to overload the system with material that can not be oxidized, and it also weakens the muscular power of the alimentary canal and is a factor in the production of constipation and indigestion. Liquids may be taken in sufficient quantities between meals. Alcoholic beverages, as a rule, should be omitted. As regards the medicinal treatment of tabes, he states that there is no preparation in existence which has any beneficial effect on the tabetic lesions, consequently the organs of the individual must be treated as indications arise. For instance, he regards the necessity in some cases of administering strychnin to stimulate the circulation, and in cases of weak digestion rhubarb, gentium and nux vomica, and when the bowels do not act a simple laxative should be administered. When the small intestine has lost its tone, the powdered extract of hydrastis, from 2 to 6 grains (.12-.36) a day is recommended in the majority of cases. And as a general tonic he recommends a capsule composed as follows:

R.	Ferri sulphatis	gr. ii	12
	Sodii carbonatis		
	Extracti gentianiæ, āā	gr. 1/4	|015
	Aloin	gr. 1/8	|008
	Strychninæ sulphatis	gr. 1/30	|002
	Ergotin	gr. 1/5	|012

M. Ft. capsula No. i. Sig.: One such capsule a half an hour before each meal.

Before a lesion like the tabetic lesion can be arrested the whole system must be improved. For this reason he recommends the foregoing outline of treatment.

In connection with this outline of treatment he also recommends the use of electricity, either the galvanic current or the high-frequency current, and in some cases the faradic current. To increase the nutrition of the cord by electricity, he states that both the low and the high tension currents are of value. In the use of galvanism he recommends the positive electrode attached to a large electrode be placed over the abdomen, and the negative electrode placed under the lumbar spine. In other words, he advises the negative electrode applied nearest the seat of the trouble, because under the action of the negative pole fluids are attracted which are alkaline in reaction. He speaks in this connection of the fact that when nutrition fails the normal alkalinity of the tissues diminishes in proportion to this condition.

Beside the polar effects, the constant current, if properly employed, exerts a beneficial influence on the entire body in the way of pacifying the nervous system and strengthening the nerve centers for their duties. To increase the nutrition of the brain he recommends that the positive electrode be placed under the occipito-cervical region, and the negative electrode placed over the frontal area, using a current of from 5 to 10 milliamperes. To stimulate the nutrition at the pathologic foci still more, and to give the tissues rest from the galvanic current, he recommends the use of the high tension current through a Geisler tube, to the spinal cord and brain. To increase the nutrition of the muscular system and peripheral nerves a faradic current should be employed.

The Treatment of Tenia.

The following outline of treatment of tenia is recommended by J. Kingston Fowler in the *British Med. Jour.:* First, the patient must be kept in bed. For two or three, or in some cases for four days, the patient is placed on the following diet: First—Beef tea, 2 pints; port wine, 4 ounces; rusks, 2. Second—During the same period the patient takes extract of cascara sagrada, gr. 2 (.12) three times a day. Third—On the fourth day, early in the morning, the compound infusion of senna, ounce 1 (30) is given, and at 9 a. m. a capsule containing the extract of male fern, minim 15 (1.00), is administered and repeated every fifteen minutes until four doses are given, when the dose of senna is repeated. If by 1 p. m. the worm has not been passed nor the head found a second course of treatment with male fern at intervals of fifteen minutes is begun, and continued for two or three doses, followed in an hour by a purgative. If then the treatment is not successful a third course is prescribed. He does not recommend the continuance of this treatment without interval of a day, as the patient may become exhausted.

Medicolegal

Rules Pertaining to Skill Required of Physicians.

The Supreme Court of Appeals of West Virginia holds, in Dye vs. Corbin, an action for alleged malpractice in the diagnosis and treatment of an injured ankle where a judgment in favor of the defendant is affirmed, that, in an action for damages against a physician, for negligence and want of skill in the treatment of an injury or disease, the burden is on the plaintiff to prove such negligence or want of skill, resulting in injury to the plaintiff. A physician is not required to exercise the highest degree of skill and diligence possible in the treatment of an injury or disease, unless he has by special contract agreed to do so. In the absence of such special contract he is only required to exercise such reasonable and ordinary skill and diligence as are ordinarily exercised by the members of the profession in good standing, in similar localities and in the same general line of practice, regard being had to the state of medical science at the time. A physician does not warrant or insure that his treatment will be successful, in the absence of special contract to that effect. Failure on the part of a physician to effect a cure does not alone establish or raise a presumption of want of skill or negligence on his part. Where a physician exercises ordinary skill and diligence, keeping within recognized and approved methods, he is not liable for the result of a mere mistake of judgment. A physician is liable for the result of an error of judgment, where such error is so gross as to be inconsistent with that degree of skill which it is the duty of a physician to possess.

Referring to the evidence of certain physicians in this case, the court says that it seemed to be directed particularly to the failure of the defendant to give an anesthetic. It was to be observed that these physicians did not say that the failure to give an anesthetic produced a bad result on the injured ankle, or that the treatment of the ankle was improper. The treatment might have been attended with more pain to the patient because an anesthetic was not administered, but the treatment of the ankle might have been the same, whether with or without an anesthetic. It did not follow that the injury to the ankle was increased or aggravated by failure to give an anesthetic. There was no evidence that the injury to the ankle was increased or aggravated by such failure. Such increased or aggravated injury to the ankle could not be presumed without evidence. Besides, it was not shown that, under the standard of skill and diligence by which the defendant was bound, it was his duty to administer an anesthetic, considering time, locality and the condition of the patient.

Again, the court says that proof showing mere conjectural possibility that unfavorable results were due to want of care or skill is not sufficient to make a physician liable. It has also been held that the fact that a physician fails to discover a fracture or dislocation does not alone establish or raise a presumption of want of care on his part.

Undesired Notices and Right of Privacy of Physician.

The Supreme Court of Louisiana says that the accepted statement of facts in the case of Martin vs. the *Picayune* showed the plaintiff to be a well-known and reputable physician, who was a member of a medical society which condemned advertising by physicians in the public press and considered it as unethical. This society adopted resolutions and appointed a committee to interview representatives of the press and request them not to publish the names of members of the regular profession of medicine or place them by publication in the attitude of advertising in any form, as regular practitioners did not resort to advertising. As a member of the committee, the plaintiff called on the defendant's representative, explained why it was that regular physicians did not resort to advertising, and handed him a copy of the resolutions. In a few days the defendant company, he showed, published an article which he deemed injurious and damageable. The article set forth substantially that the case of a young lady named there was unique. That she has been an invalid for years from congenital hip disease, and that owing to the skillful treatment of the plaintiff she had almost entirely recovered. That different physicians had tried their skill on the affected limb and had not met with success. That when Dr. Lorenz visited New Orleans and treated patients, the plaintiff had made a close study of his methods and manner of treatment, which he applied in treating the young lady named. The story appeared to have been obtained from the patient's father, who was, the article stated, in substance, overjoyed, and to whom it afforded delight to say kind things of the physician, the plaintiff.

The conclusion of the district court, after setting forth that the story, if untrue, was enough to irritate and annoy, was that that irritation and annoyance are not of themselves actionable; that it must appear that they are accompanied by substantial injury; that the assertion as a fact that by the use of advanced methods of celebrated surgeons and by his own skillful treatment he had achieved success were not grounds sufficient for the plaintiff to recover damages for injury inflicted; that there was no actionable injury traceable to this publication; that the truth or falsity of the publication was immaterial to the issue presented. Touching the plaintiff's allegation that it put him in the attitude of an advertising quack, thereby bringing him into contempt, the judge said: "Could I satisfy myself that the plaintiff meant to charge and prove that not only such was the effect of the publication, but that it was defendant's purpose to produce on the mind of the public and of plaintiff's friends and fellow-physicians the impression that plaintiff had caused such publication to be inserted in its paper for advertising purposes, I would have no hesitation in concluding that a cause of action had been set forth; for any false impression, produced intentionally or injurious to some one, is actionable libel on him, no matter how the publication or what the purpose used to effect a purpose." Again, it was stated in substance that a cause of action can not be eked out by inference. The intention to be injurious did not appear in the article in question. It should have been specifically alleged. The falsity of the article was not, under the circumstances, sufficient ground of action. It must appear that "defendant meant to produce the impression that plaintiff procured this publication for the purpose of advertising himself, whilst in fact he had not done so."

But the Supreme Court, which reverses the judgment rendered by the district court in favor of the defendant on an exception of no cause of action, says that there is no question, had the plaintiff amended his petition and alleged as before mentioned, that he would have had an indisputable cause of action. But this court really does not think there was downright necessity of going to that extent in order to cover a cause of action. In this court's view, if the publication was malicious, and it was injurious to the plaintiff, it would afford ground for action. True, the words of the article were of praise and congratulation, and no one would seriously contend that they were in themselves actionable. True, words of praise and gratulations are not actionable. But words of praise and gratulations may—on rare occasions, fortunately—lead to injurious consequences, lose their grace and charm, and become actionable. The physician, who by inference finds himself classed with quacksalvers, will be entitled to a hearing, or at any rate should not be turned out of court, unless it appears that he is in error in thus contending. Recently this court held that slanderous words—and, it follows, libelous words—may be actionable, even though they do not consist of an unequivocal and positive assertion. The common law system has not gone as far as the civil law in upholding actions for injurious words spoken or written. Yet even under that system there are decisions which uphold the principle laid down under the latter law.

The Supreme Court thinks that under the circumstances here the cause should be heard on the merits and the right of parties determined after having heard the testimony. In other words, it holds that as the record was made up, the inference from the text of the article complained of, under the asserted facts and circumstances, led to the conclusion that the plaintiff should be heard on the merits. It adds that it is not inclined to fan into greatest importance an issue which can not be thus characterized. At the same time it is evident to the court that there is a principle involved—the right of privacy and its extent, for it has considerable limitations. It can not be decided on an exception of no cause of action.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

Medical Record, New York.

June 9.

1 Circumcision. J. Knott, Dublin, Ireland.
2 *Clinical Observations on Salpingitis and Parametritis in Nulliparæ. S. W. Bandler, New York.
3 *Ionization by Means of the High Frequency Current in the Treatment of Tuberculosis. A. Goss, Adams, N. Y.
4 Fresh-air Homes and Medical Work in Connection with Them. L. R. Williams, New York.
5 *Resection of Stomach for Carcinoma. F. Torek, New York.

2. **Etiology of Salpingitis in Nulliparæ.**—Bandler says that the cause of salpingitis in nulliparæ when there has been no intrauterine manipulation is in most cases a latent unrecognized gonorrhea. He cites a number of instances that have come under his notice, and says that numerous cases of pelvic pain, sterility and ectopic gestation are the result of such cases of salpingitis.

3. **Ionization of Tuberculosis.**—Goss declares that in a state of health Nature seems to furnish in non-susceptible cases protective proteids found in the blood plasma called alexins. He believes the form of the electrode to be of great importance. He uses a vacuum tube for surface application which, instead of having a flat surface, is concave on the bottom with a wire extending lengthwise through the tube and a large disk made concave on the under surface to correspond in shape with the glass electrode and suspended about one-half inch from it. The superficial circulatory apparatus becomes greatly engorged by the application of the high frequency current, and the patient perspires profusely. By this drainage the specific gravity of the blood plasma is changed and there should then be a rapid absorption of the gases retained under the vacuum electrode. In this way the writer attempts to introduce substances into the circulation to take the place of the alexins where they are wanting. He reports a number of cases with favorable results.

5. **Resection of Stomach for Carcinoma.**—Torek believes that although in most cases of carcinoma of the stomach, when the tumor is large, a successful resection is impossible, nevertheless the procedure in each special case depends on its own merits. The operability can not be determined alone by the size of the tumor. Several questions must be considered: the ability to resect well beyond the limits of the disease, the extent of lymphatic involvement, the presence or absence of involvement of the pancreas or other neighboring organs, and the nature of the adhesions.

9 *Critical Analysis of 186 Operations on the Liver and Gall Passages, and the After Results. (To be continued). C. A. McWilliams, New York.
10 *Abdominal Hysterectomy for Fibroid Tumor of the Uterus Complicated with Pregnancy and Prolonged Retention of a Fetus and Placenta. H. T. Williams, Rochester, N. Y.
11 Interscapulothoracic Amputation for Sarcoma of the Scapula. J. Douglas, New York.
12 Exfoliative Dermatitis in the New-Born (Ritter's Disease). B. M. Baker, Norfolk, Va.
13 Abuses of Ether in Abdominal Surgery. J. W. Kennedy, Philadelphia.

6. **Military Hygiene of Japanese Army.** Takaki's paper shows that the medical officers of the Japanese army are governed by rules which take nothing for granted, prescribing directions, in detail, for the preservation of the health of the soldier at all times and under all conditions. The rules of general hygiene are very explicit, considering the care of the finger nails, hair, feet, mouth, teeth, etc.

8. **Dietetic Treatment of Vomiting of Pregnancy.** Kolipinski states that a woman who has vomited incessantly for two or three weeks, who is too feeble to leave her bed, who has received varied and unsuccessful medicinal treatment, whose whole appearance as well as that of her family is one of alarm, who expels everything as if forced by fate, will find to her intense astonishment that the emesis does not occur after a breakfast of fried ham or bacon, that partaking of other solids improves her condition, and that she is able to be up again. Following the daily breakfast of pork in some form, with cocoa, chocolate, and corn bread, a dinner of beefsteak, roast or corned beef with rice, potatoes, spinach, cauliflower, kale or turnips, is offered. Fish, game, fowl and cheese may also be suggested, and they help to make up the evening meal. Foods which induce vomiting are water, taken freely, milk, tea, coffee, soups, and all kinds of fluids, neutral, acid and saccharine, custards, eggs, toast, and fruit. The most unstable combination of a diet is toast, eggs and sweetened tea, things which the stomach of no gravid woman in the early months will tolerate. To offer pork more than once a day is not objectionable, but it should at least be the first food taken each day until the cure is completed. The self-selected regimen in one instance was boiled ham twice a day for more than two months. Kolipinski has used this dietetic treatment in two cases of pernicious vomiting with success, and also in obstinate vomiting of the ordinary variety and believes it worthy of a trial.

9. **Analysis of Liver and Gall Passages.**—It is impossible to abstract McWilliams' paper because of its length and the many points brought out.

10. **Prolonged Retention of Fetus.**—Williams reports a case in which a dead fetus and placenta remained in the uterine cavity for nine months without undergoing decomposition and without causing serious symptoms, except a persistent nausea and gastric distress. The presence of a fibroid suggested a possible cause of the symptoms present and hysterectomy was advised. On opening the uterus after its removal a fetus and placenta, evidently of three months' development, was found in the left side of the uterine cavity in a good state of preservation. The uterine cavity below had been shut off by the encroachment of the fibroid.

24. **Self-Restraint in Surgery.**—Stimson urges deliberation in regard to operative measures with a broad view as to the relations of the diseased structure and careful consideration of the results of the operation. He cautions against the too ready acceptance of new views and suggests that the frequent changes of theory and practice should teach the surgeon not to be overconfident of the value of the procedures that happen to be in vogue. Unnecessary removal of organs is not to be favored because they may subsequently become the seat of disease. The former thorough removal of tuberculous glands is rightly giving way to more conservative measures, and it is possible that with appropriate general treatment operation may be avoided in many cases in which it was formerly deemed imperative. Undue haste in the treatment of granulating wounds is often undesirable. The granulating surfaces may well be allowed to rest. Too active treatment of fractures and of diseased joints is to be deprecated.

25. **Shortening the Round Ligaments.**—Dudley improves Gilliam and Barret's method of drawing the round ligaments through an artificial canal into the laparotomy wound by making an artificial inguinal canal on each side through which the ligament is drawn and anchored intraperitoneally so as to avoid any danger of infecting the peritoneum in case of infection of the superficial wound. If the uterosacral ligaments are lax they should be shortened at the same time. The technic is illustrated.

26. **Malignant Disease of Appendix.**—Rolleston and Jones conclude their article as follows: 1. The disease is one which renders an accurate diagnosis impossible; every case in which the symptoms drew attention to this region exactly imitated appendicitis in some form. 2. Most of the older reputed examples fail to withstand investigation, but as 80.9 per cent. of the 42 genuine examples have been reported since 1900, the disease can not be quite so rare as has been thought. The microscopic size of the growth in some instances makes it probable that many such instances have been overlooked. 3. Pathologically several varieties of carcinoma have been reported, and also sarcoma and endothelioma. The growth is usually, however, a spheroidal-celled carcinoma which is peculiar in the early age-incidence, the slight malignancy, and the resemblance to endothelioma. Colloid change is not common as has been hitherto supposed. 4. The presence of concretions is only mentioned in 3 cases out of the 42. 5. The disease is not prone to affect one sex more than the other. 6. Inflammatory changes, either chronic or acute, frequently accompany the growth. 7. The immediate prognosis and the prospects of freedom from subsequent recurrence after operation are very good, particularly in the spheroidal carcinoma.

30. **Arteriosclerosis of the Aorta.** Ophüls expresses the following view of the process: Anatomically arteriosclerosis of the aorta is a unit. It is a chronic inflammatory process of the vessel wall which attacks all coats simultaneously, but which, as a rule, first produces more noticeable changes in the intima and adventitia. The absence of marked changes in the media in the beginning of the disease, to a certain extent, may be due to the fact that the tissues composing the muscle, especially the involuntary muscle, do not respond so readily to the same irritation which in ordinary connective tissue would produce severe anatomic alterations. The earliest changes in the intima and in the adventitia are a fibrous thickening accompanied in the adventitia by a greater accumulation of cells, probably because of the presence of the vaso vasorum. The fibrous thickening, especially of the intima, is followed by fatty degeneration, which may and often does extend into the media. The author reports 75 cases.

33. **Progressive Softening of the Brain.**—Hunt reports two cases of progressive softening of the brain due to arteriosclerosis or other vascular change in which the clinical course suggested cerebellar tumor. In general the clinical picture was that of a progressive and gradually developing hemiplegia, and the general cerebral symptoms resemble those described by Wernicke as chronic progressive softening without evident vascular lesion. The main trunks of the vessels of the circle of Willis were not occluded, but histologic study demonstrates the obliteration of the central end arteries in the ganglionic and capsular regions. The existence of a progressive softening not dependent on vascular changes may well be questioned. The clinical importance lies in the possible resemblance to abscess, encephalitis and tumor of the brain. Surgical interference in such a case might lead to infection, to which the softened tissues are peculiarly liable.

34. **Gastric Surgery.**—Frank's article is an enthusiastic plea for the more general recognition and extension of the field of gastric surgery.

35. **Leucocytes in Gonorrhea.**—Wile concludes as follows: The polynuclear neutrophiles are highest in acute anterior urethritis and decrease with involvement of the posterior urethra and are lowest in chronic gonorrhea in male or female. The mononuclear leucocytes are increased in the chronic processes and vary inversely with the polynuclear neutrophiles. The eosinophiles are slightly higher in acute anteroposterior urethritis than in acute anterior urethritis. That this is due to involvement of the glands or epididymis, prostate or posterior urethra is very doubtful, as the eosinophiles are comparatively lessened in chronic cases. The basophiles are hardly affected by the disease. There is no relation between appearance of any type of leucocyte in the blood and in the discharged pus. The eosinophiles are of no diagnostic value in gonorrhea.

36. **Urine in Normal Pregnancy.**—Mathews finds that from the fourth to the eighth month of pregnancy the specific gravity of the urine is considerably diminished. This depends on two conditions: 1. The pregnant woman during these months secretes rather more urine than the non-pregnant. 2. The nitrogen elimination is diminished. Three hundred grains of urea (determined by the hypobromite method) is above the average toward the end of pregnancy. This is in part explained by the body's retention of nitrogen and perhaps, in part, by variations in the pregnant woman's diet.

37. **Bacteriology of Conjunctivitis.**—McKee describes the findings in the three most important forms of conjunctivitis, pneumococcus, Koch-Weeks and Morax-Axenfeld. The bacteriologic diagnosis is of great aid to the prognosis and treatment. A pneumococcus infection is not very likely to spread by contagion, while the Koch-Weeks conjunctivitis will go like wildfire through a family. Specific treatment is known for the Morax-Axenfeld infection, and the best treatment for pneumococcus disease is different from that of the Koch-Weeks variety. In the milder forms of conjunctival irritation dependent apparently on errors of refraction, if not relieved by the correction of the refraction and astringent drops, bacteriologic examination will reveal the exact condition and lead to successful treatment.

41 Pathology and Diagnosis of Myocardial Inflammations and Degenerations. J. Daland, Philadelphia.
42 *Beriberi. P. A. Lovering, U. S. N.

38. **Treatment of Compound Fractures.**—Ochsner warns against transporting the patient too far with soiled clothing, directing that it be cut away, the limb wound, superficially cleansed and covered with gauze or other sterile cloth, the limb placed in a blanket splint and the patient taken where the first dressing can be applied. He cleanses the surrounding skin with turpentine to remove grease, etc., and applies to the wound tincture of iodin, which seals the mouths of vessels and lymphatics and prevents absorption. Too much plastic surgery should be avoided; the bone should not be wired, and the wound should not be too tightly closed. If it is desirable to apply plaster-of-Paris the space around the wound between the limb and the plaster splint should be packed with lamb's wool saturated with a solution of rubber in chloroform. When implication of a joint favors ankylosis, rest by immobilization, by limiting the growth of connective tissue, is

the best preventive, and this should be continued for three months, after which, if adhesions have formed, they should be broken up by active motion. If these measures are insufficient, forcible breaking up of the ankylosis, or some other operation, may be necessary.

39. **Vascular Spasm and Fibrosis.**—Hare emphasizes the following points: In cases of high tension due to fibrosis the nitrites can be of but little value, and the iodids with rest and massage the needful. Cases of very high tension are usually those in which the heart escapes sufficiently to help maintain the tension. As fibrosis in the peripheral vessels increases, the muscles of the larger vessels undergo hypertrophy, as does the muscle of the heart. It is quite as possible for vascular compensatory hypertrophy to rupture as for the cardiac compensatory hypertrophy to do so. This rupture of vascular hypertrophy often gives the heart a rest and permits it to recover from its fatigue, and so life is saved. It is possible, if the peripheral fibrosis be arrested, for the vessels also to regain power and a general improvement to ensue. The cardiac stimulants are not needed in these cases so much as rest and the skillful use of alteratives and vascular sedatives.

40. **Arteriosclerosis as a General Disease.**—Stengel recognizes three stages of arteriosclerosis as a general disease: 1. A preliminary one in which the symptoms due to the original etiologic factors are confused with those produced by the arterial disease. 2. A middle period in which the arterial disease is recognizable, but in which secondary organic changes have variable importance. 3. A final stage, circulatory and organic failure and terminal infections. Three types of early arteriosclerosis are observed: nutritional, neurasthenic and nervous. In more advanced stages it may attack the viscera, giving rise to: 1. The thoracic (a) cardiac, (b) aortic. 2. Abdominal, including (a) renal, (b) intestinal, (c) pancreatic, (d) hepatic. 3. Cerebrospinal. 4. Arteriocapillary types.

42. **Beriberi.**—Lovering adopts the infectious theory of the origin of beriberi and divides it into acute, subacute and chronic types. The acute form is always fatal largely in consequence of cardiac involvement. The subacute form shows paralyses, edema and slighter cardiac symptoms. The patients usually recover or else the disease assumes a chronic form. The various symptoms are due to a degeneration of the nerves. There is no specific, but salines are given to relieve constipation and edema, and digitalis seems to be the best drug to sustain the heart. In the chronic cases electricity is useful. Strychnin and other tonics are of value in improving the general condition. Prophylactic measures, isolation, disinfection, etc., should be applied as in other infections.

49 Self-Retaining Trocar and Canula for the Aseptic Evacuation of Distended Viscera. H. Lilienthal, New York.

13. **Affections of the Thyroid Gland.**—Beilby suggests the importance of bearing in mind in diagnosis of thyroid affections the general principle that if the gland is symmetrically enlarged hypertrophy is present, while if a partial enlargement occurs a cyst or tumor is likely to be found. Hypertrophy is a diffuse although not necessarily symmetrical affection, and in some cases the preponderating enlargement of one side may suggest cyst, while occasionally the development of two cysts, one on each side, may simulate hypertrophy. These cases, however, are, as a rule, easily distinguished. Simple hypertrophy usually occurs before the age of 20; exophthalmic goiter between 20 and 30. The early diagnosis of carcinoma is difficult. Age, short duration or sudden increase in size, prominence of dyspnea and dysphagia are prominent factors. The excision of simple hypertrophy should be undertaken for pressure symptoms but rarely for cosmetic reasons. The tendency to the development of carcinomata in hypertrophied glands should be taken into consideration. Partial excision has given good results in cases of exophthalmic goiter unimproved by medical treatment. In the 6 cases reported by Beilby 4 have given excellent results. The best results are those of Kocher, who cured 75 per cent. of 59 cases, with 6.7 per cent. mortality.

45. **Diagnosis of Esophageal Affections.**—Sippy classes these disorders as functional and anatomic. Functional affections may be sensory, as hyperesthesia, or motor, as spasm. Hyperesthesia is indicated by pain especially complained of when a bougie is introduced while the esophagoscope shows a normal mucous membrane. Globus hystericus is an example of esophageal spasm. Inflammation is rare unless caused by the swallowing of caustics. Ulcer seldom occurs, except from carcinoma. The symptomatology of esophageal stenosis is important, as grave mistakes in diagnosis have occurred, the difficulty being attributed to gastric disease and in some cases gastroenterostomy has been unnecessarily performed. If the symptoms indicate and there is no contraindication, the passage of a soft stomach tube should first be used to locate the seat of obstruction. The presence of carcinoma should not be assumed without taking into account other possible causes of stenosis, extra-esophageal, such as aneurisms, tumors, spondylitis, pericardial effusion, diverticulum, or intra-esophageal as tumor, cicatrix, spasm, diverticulum and foreign bodies. The diagnosis of carcinoma is made by considering the course, presence of blood in the feces, characteristic odor on passing the stomach tube, location of the growth (50 per cent. near the cardia, 40 per cent. opposite the tracheal bifurcation and only 10 in the upper part of the esophagus), and finally the appearance as revealed by the esophagoscope. The presence of secondary anemia may be of assistance. Diverticula occurring in the upper part may show a tumor in the neck; in the lower section they may be detected by the course of bougies, the nature of the contents and by the *x*-ray after the ingestion of bismuth suspended in some thick liquid. Cardiospasm is usually easily diagnosed by the fact that while the obstruction is impervious to food, even liquids, it yields to the pressure of a tube or bougie.

46. **Postoperative Ileus.**—Finney concludes his article as follows: 1. Broca's classification into early and late varieties simplifies the diagnosis. In the former class, which so frequently is associated with peritonitis, the differential diagnosis as to variety is always difficult and often impossible. In the latter, which consists almost entirely of the mechanical form, it is usually easy. 2. Adhesions are the chief factor to be reckoned with in the attempt to prevent the occurrence of postoperative ileus, and efforts directed toward this end are likely to be productive of the best results. 3. That drainage exercises a marked influence in the production of adhesions can not be denied. 4. Prompt treatment is indicated in every case after palliative measures have been given a fair trial and have failed. The character of the operation depends on the nature of the obstruction and the condition of the patient. 5. The prognosis is unfavorably influenced by the presence of infection. In its absence it is excellent.

48. **Cutaneous Horns.**—Nietert and Babler report a case in which two horns grew from sebaceous cysts over the parietal region and were accompanied by sebaceous cysts on the face and also by a cutaneous cancer on the right side of the nose. The growths were removed without difficulty. The case suggests the possible relation of these growths to sebaceous cysts and the danger of their being transformed into cancer.

57 Value of the Roentgen Rays in Surgical Diagnosis. (To be continued.) C. Beck, New York.

51. **Excision of Transvere Colon.**—Gant's patient suffered from diarrhea, with frequent discharge of bloody mucus due to a chronic ulcerative colo-proctitis. The rectum had been removed and two artificial ani had been made, one in the left and the other in the right inguinal region, without affording relief. Gant removed the last half of the transverse colon, the descending colon and sigmoid, and made an artificial anus below the umbilicus. The other openings were closed and a very satisfactory result was obtained. The colon showed several constrictions, its lumen being narrowed by thickening of the wall of the intestine.

53. **Intestinal Anastomosis.**—Pleth first unites the serous surfaces of the opposed guts with a running suture of linen thread for a distance of from 7 to 10 cm. This he terms the posterior suture. He then passes an ordinary knitting needle through the gut wall about 1 cm. from the posterior suture, causing it to traverse the lumen of the gut for a distance less than the length of the posterior suture, emerging again on the serous surface. The two needles are brought together, laid parallel, and a straight needle armed with strong silk (or silkworm gut) passes back and forth through the opposite gut walls in such a way that the suture always runs under the needle, the stitches being taken close together. The small bridge of gut wall which overlies the needles is burned or scraped away and the needles are removed. The posterior suture is now continued in the serosa in such a manner as completely to bury the two openings in the opposed gut sections. If desired, another interrupted or continuous serosa-serosa suture may be added. The silk suture is now withdrawn and the anastomosis is completed.

61 *An Experimental Study on the Recurrence of Lymphatic Glands and the Regeneration of Lymphatic Vessels in the Dog. A. W. Meyer, Baltimore.

58. **Stricture of Ureter.**—Kelly reports two cases successfully treated. In the first case the stricture was located at the vesical opening and the ureter was distended into a small cyst from which the urine could be observed to flow drop by drop, but at intervals the cyst became greatly distended and the flow of urine became greater. Incision of the opening with delicate scissors resulted in cure. In the second case the stricture was situated near the pelvis of the kidney and was treated by opening the kidney pelvis and dilating the stricture by passing a small metal catheter. The incision in the pelvis was then closed and the patient made a good recovery. The author also reports two cases of hydronephrosis treated by plication of the pelvis of the kidney.

60. **Diagnosis of Malignant Growths in the Nose.**—The importance of a microscopic examination of all growths removed from the nares is emphasized by Rosenheim. Especially in case of malignant growths is this to be desired because they can be discovered at a time when, on account of their small size, they can be removed by the nasal route; and if this is not feasible a radical operation can be done, at a time when there is the greatest possibility of a cure. Moreover, knowing the nature of the growth removed, we are on the watch for recurrences and are prepared to treat them vigorously. Six cases are reported, three of sarcoma and the other three showing the initial stage of carcinoma or a tendency thereto.

61. **Regeneration of Lymphatic Vessels and Glands.**—Meyer has tried to solve by experimental methods the problem of whether or not the lymphatic vessels and glands regenerate. The evidence, so far as the larger vessels and the glands are concerned, appears to be negative. The possibility of the formation of lymphatic capillaries in granulation tissue for the present must be left undecided, as no conclusive experimental evidence on the subject has been produced. The possibility of regeneration of glands in very young animals must be omitted, but it is probable that the glands found in older animals or in man after operations arise from the enlargement of already existing structures. The author has found that it is very difficult to recognize the smallest glands with the naked eye.

1. **Cancer of the Tongue.**—Butlin says that formerly he divided cancerous lesions of the tongue into three stages: 1. Predisposing conditions, such as leucoplakia, ichthyosis and glossitis; 2. precancerous conditions, such as warty growths, thick plaques and sore places which are not actually cancerous, but which inevitably proceed to cancer unless they are completely removed or destroyed; 3, actual cancer. Recent experience, however, has taught him that many of the conditions in groups 1 and 2 are examples of actually developed cancer in its early stages. He describes 7 cases in which the cancer was found under the following forms: 1. A flat, very slightly raised, smooth, red glazed plaque, feeling like a thin piece of gristle in the surface of the tongue, not thicker than a 10-cent piece, and looking and feeling just like a primary hard sore. 2. A white warty growth, not ulcerated, and scarcely indurated at its base. 3. A slight thickening and hardening of an old leucoplakic area, rather distinguishable to feel than sight. 4. A nodular plaque, red and commencing to ulcerate, with drawing-in of the surrounding tissues.

3. **Propagation of Cancer.**—Bashford illustrates the facts demonstrated by recent experiments on the propagation of cancer in animals. He calls attention to the fact that the first stages of the disease may exist without the production of symptoms. A small piece of mouse cancer transplanted into the subcutaneous tissue, if it grows, ultimately gives rise to a mass of new growth nearly as great as the mouse itself. It produces metastases in the lungs, and leads to the death of the animal. If the tumor be removed by operation, when it has reached the size of an almond, these results do not follow. The mouse remains well indefinitely, although the tumor transplanted into other mice continues to grow. In the same way in the human subject carcinoma and sarcoma are at first local processes taking place in circumscribed areas; their complete removal prevents the further extension of the disease. In this early state, however, the anatomic and histologic lesion constitutes the most reliable criterion of the presence of cancer; symptoms are absent and the removal of a piece of tissue, which can not be shown to be cancerous, or ultimately proves to be non-cancerous, is to be preferred to delay until the naked-eye appearances have raised suspicion to probability. He asks: Are not the consequences of the growth of a small piece of mouse cancer no bigger than the head of a pin sufficient to convince the most skeptical of the justice of this attitude?

6. **Surgery of Sarcoma.**—Neve analyzes the results of removal of sarcomatous growths in the Church Mission Hospital, Kashmir. One hundred and eighty-four growths have been operated on. Of the patients, 80 per cent. were males. The mean age is 40, the ages varying from 5 to 70. Thirty-six per cent. of the tumors were of less than one year's growth. In 2 cases the whole scapula was excised. Many tumors from the flank, abdominal wall or lumbar region were very extensive, and of these few appear to have recurred. Altogether 11 exploratory operations were done; in 12 others the removal was incomplete. In 16 cases there was recurrence, and in 10 others it was doubtful whether extirpation was complete. Three patients died in the hospital or soon after leaving. The remaining 132 are regarded as probably cured, which gives 70 per cent. of successful cases.

7. **Color of Hair in Ovarian Dermoid.**—Shattock believes that ovarian dermoids arise not from a strict parthenogenesis, but from a fertilization of the primordial ova by surplus spermatozoa enclosed in the ovum at the time of conception. In this way he would account for the color of the hair in ovarian dermoids differing from that of the woman bearing the parasite.

11 *Hematoma of the Ovary and Certain Other Closely Allied Conditions. H. W. Wilson.
12 *Hemorrhagic Purpura During Convalescence from Scarlet Fever. A. G. Banks.
13 *Immediate Treatment of Extensive Wounds on Field Service. C. A. Gill.

11. **Hematoma of the Ovary.**—Wilson divides hematoma of the ovary as follows: 1. A group of cases designated as idiopathic. 2. Those due to torsion of the pedicle of the ovary causing obstruction to the venous return. There are three main causes of this: (a) hernia of the ovary; (b) rotation of a slightly enlarged ovary causing twisting of the broad ligament, and (c) the presence of some abnormal predisposing condition in the pelvis—e. g., a broad ligament cyst, the actual twist being brought about by some sudden muscular movement or strain, perhaps associated with a distended bladder. This last variety is analogous to torsion of the testicle seen in cases of imperfect descent. 3. Toxic conditions causing punctiform or more extensive hemorrhage: (a) some of the acute specified fevers—viz., scarlet fever or enteric fever; (b) profound septic intoxication—viz., general peritonitis or puerperal sepsis. It is also seen sometimes postmortem in fatal cases of perforated gastric or duodenal ulcers. 4. Ovarian pregnancy.

Wilson gives the history of 8 cases representing the first and second classes. The greatest interest is attached to the first class. It occurs particularly in young patients and is mostly due to hemorrhage into the cavity of a ruptured Graafian follicle. It is likely to occur at the time of a menstrual period and presents two cardinal symptoms: abdominal pain and uterine hemorrhage. The pain, tenderness and abdominal rigidity may suggest perforating gastric or duodenal ulcer or appendicitis. In certain cases it has been mistaken for ovarian pregnancy. Diagnosis is very difficult before opening the abdomen, and the condition may be overlooked even then if attention has not been directed to its possibility.

12. **Purpura Hemorrhagica in Scarlatina.**—Banks describes a case of hemorrhagic purpura coming on during convalescence from scarlatina and characterized by hematemesis and the occurrence of large petechiæ over the elbows. Under morphin and calcium chlorid the patient, a man, made a good recovery. Albumin appeared in the urine coincident with the purpura, and continued in small quantity until his discharge. The author suggests that the hemorrhagic tendency is due to the same influences which produce nephritis in scarlatina.

13. **Immediate Treatment of Wounds.**—Gill, in considering the immediate treatment of extensive injuries on field service, emphasizes the following points: 1. The immediate application of an antiseptic lotion to large wounds. 2. To provide the necessary antiseptic the addition of tabloids of perchlorid of mercury to the first field dressing packet is suggested. 3. Following the first dressing a period of rest may be allowed, which is highly convenient to the medical staff and conducive to the well being of the patient. 4. Removal by

ambulance transport to field hospital, where operation may be undertaken on a patient whose vital powers have largely recovered from the shock consequent on his wounds.

16 *Beriberi in Sylhet Jail. E. A. W. Hall.
17 Surgery of Sarcomata. A. Neve.
18 Season and Some Diseases in Madras. J. W. Cornwall.

14. **Early Occurrence of Adipocere.**—Vaughan calls attention to the fact that while it is ordinarily believed that a considerable time is necessary for the formation of adipocere, five weeks being the shortest in time in any authentic account, yet it is admitted by Taylor that there is no doubt that the process may take place partially in the dead body within a much shorter period. Vaughan cites 5 cases in which this change had occurred in from two to four days. In 4 of these cases the body had not been buried.

16. **Beriberi.**—Hall discusses the various theories to account for the occurrence of beriberi. In the cases occurring in Sylhet jail, 158 in number, with a mortality of 13.3 per cent., the rice theory is not applicable, as the rice was freshly husked and never more than two days old. In favor of the place theory are: 1. The epidemic affected certain groups of inhabitants of the jail working in definite places and did not affect the other groups to whom the same food and water were supplied. 2. When the prisoners were removed to camps the disease stopped, although they continued to get the same food and water as they had in jail. The theory of the propagation of the disease by bedbugs receives some support from the fact that the bedding of the patients was infested by these vermin, but, on the other hand, the same bedding was issued indiscriminately to the three groups, and when moved to camp the same bedding was used, and for the sick the same wooden beds, yet the epidemic ceased. The author considers that the place theory is the most important and believes that the infection lies in the floor of the building and is inhaled through the mouth and nose; and that the bacillus first lodges in the fauces, producing the faucial redness and tenderness which is so common a symptom in the disease, and passes thence to the stomach and duodenum.

24 *Case of Myasthenia Gravis in Special Relation to Eye and Throat Conditions. G. H. Hogg.
25 Treatment of Cerebral Hemorrhage. J. E. F. McDonald.
26 Fatal Case of Formalin Poisoning. A. Palmer.

20. **Operative Treatment of Enlarged Prostate.**—Maitland summarizes his paper as follows: 1. Clinically there are two forms of enlargement—the soft or adenomatous and the hard or fibrous, but there are many gradations between the two varieties. 2. The operative treatment of the soft variety is by enucleation, preferably by the perineal route. 3. The operative treatment of the hard variety is by cauterization through a median perineal incision. 4. A median perineal section should be the first step in any operative measure on the enlarged prostate. 5. If suprapubic enucleation be performed the perineal section lessens the risk, since it provides the necessary drainage. 6. It is necessary to explore the prostate digitally before being able to decide on the proper operative measure.

22. **Typhoid Fever.**—Millard concludes his paper as follows: 1. Typhoid has very regular recurring seasonal variations agreeing with those of infantile diarrhea, which corresponds closely to those observed in other parts of the globe. 2. The typhoid bacillus is dependent for its dissemination in some way on external conditions, as exemplified in the difference between the incidence rates of the coast and inland districts. 3. The infection of water supplies has not been an important factor in spreading typhoid fever in New South Wales. 4. Infection from a previous case, either directly in the sick room or indirectly from excreta imperfectly disinfected or improperly disposed of, has been a factor of great importance. From this it results that the two essentials in dealing with any outbreak are: 1, To isolate the sick, and 2, to disinfect their excreta.

24. **Myasthenia Gravis.**—Paralysis of the soft palate was first noticed in Hogg's case following a sore throat and suggesting diphtheritic paralysis; it varied much in degree, but continued until the end. Paresis of acommodation of the eye was noticed early; it disappeared in a week or two, returning at a much later stage. Other inconstant paralyses of the eye muscles were ptosis of right side, paresis of right external rectus, and paresis of corrugator supercilli. The pupil reaction, vision for form and color, the field of vision and the fundus were normal. Paralysis of the pharyngeal muscles and probably of the epiglottis varying much in degree were observed; also paresis of the abductors and tensors of the vocal cords. The tongue became affected toward the last so that it could not be protruded from the mouth. The continual remissions and exacerbations in the symptoms were striking. The symptoms were all increased at the menstrual period which was followed by a temporary amelioration. Fatigue seemed to increase the paralysis which was usually worse toward evening. Treatment was without avail. Tubal feeding gave rise to most alarming symptoms of dyspnea and faintness. The pathology of the disease and especially the "lymphorrhages" of Buzzard, collections of small cells resembling lymphocytes between the fibers of muscles or between the cells of a glandular organ, are described.

28. **Delayed Poisoning from Chloroform.**—In THE JOURNAL for Sept. 9, 1905, the occurrence of a tardy hepatic toxemia as the result of chloroform anesthesia was discussed both editorially and in an exhaustive monograph by Bevan and Favill. In the current volume, page 341, West offers an explanation for the delayed poisoning. Tuffier, Mauté and Aubertin here report 2 new cases, demonstrating anew that chloroform accumulating in the organism is liable to induce a subacute hepatitis possibly fatal. The symptoms began in each case about thirty-six hours after the salpingectomy or abdominal hysterectomy, the patients exhibiting prostration and delirium with dilatation of the pupils, weakness, rapid pulse, normal temperature, incessant vomiting, at first bilious, then blood-stained, with subicterus, but no peritoneal reaction or leucocytosis, and the blood sterile. A distinct, constant odor of chloroform in the breath was most significant. Within three days the symptoms gradually subsided to complete recovery in one patient, but progressed in the other to fatal coma. They quote extensively from the articles in THE JOURNAL mentioned above, their conclusions harmonizing with those published. They state that there is now a total of 50 such cases on record, more than half being in children. They ascribe the trouble to an individual defective elimination of the chloroform. The organs retain it for some mysterious reason, and, as the anesthetic continues to exert its injurious action so long as it is in the body, the patient feels the effect the same as if he were being subjected to a constant succession of general anesthesias. They base this assumption on the constant odor of chloroform in the breath during the entire course of the symptoms. Guthrie mentions that the nerve centers smelled strongly of chloroform in a case that came to dissection. These facts emphasize the danger of repeating a chloroform anesthesia before the organs have had time to recover from the effects of the first. Administration of oxygen seems theoretically indicated. The evidences of this delayed poisoning from chloroform aid in restricting the already diminishing number of cases of "operative shock."

29. **When Should Bromids Be Prescribed in Nervous Affections?**—Hartenberg declares that the bromids should be or-

dered in case of nervous affections when there is agitation, excitement, palpitations, spasms, angor, etc., on condition that the nourishment of the general system and of the nerves is satisfactory. Whenever there is fundamental nutritional disturbance it is wisest to refrain altogether from the bromids. Ready fatigue, exhaustion, muscular hypotonicity, arterial hypotension, etc., point to nutritional disturbance, and analysis of the urine will determine the exact state of the nutritional exchanges. If the system needs to be built up, then the bromids are contraindicated, except in epilepsy. He gives them in the form of a cachet at the middle of the meals.

31. **Reduction of Salt in Diet in Scarlet Fever.**—Pater reports the results of salt starvation in 15 cases of scarlet fever. They demonstrate beyond question, he thinks, that this method of treating scarlet fever is absolutely simple and harmless, while it protects against complications, especially on the part of the kidneys. He found that in his cases the course of the disease was shorter than usual, convalescence commencing earlier. If albuminuria was noted at first it subsided as salt was dispensed with. Dopter has also reported similarly favorable experiences, all tendency to nephritis being apparently averted.

41. **Influence of Food of Mother Animals on Development of Fetus.**—Reeb found that Nature produces less substance when the mother is insufficiently fed, but that the elements harmonize in the proper proportions. The maternal organism seems to be drawn on for the lacking elements.

43. **Postoperative Ileus.**—Baisch has studied this subject exhaustively on animals and in the clinic. The prognosis is so grave that the first symptoms of obstruction should sound the alarm. His experience indicates that the presence of blood is the principal factor in the production of adhesions. When the operation is bloodless adhesions do not develop. It is not a mere coincidence that Zweifel, who is the most vehement advocate of "blood dry" operating, has had postoperative ileus in only 2 out of 800 laparotomies, and in these adhesions had been found when the abdomen was first opened. The only means of preventing the formation of adhesions and of breaking up those forming are to place the intestines in their normal position, to stimulate peristalsis early, to refrain from cleaning out the intestines too thoroughly before the operation, and to banish opium from the preliminary and after-treatment. Peristalsis may be stimulated by an enema the second day after the operation and by magnesia or castor oil early the third day and after. If neither flatus nor stools have passed by the fourth day, all food and drink by the mouth should be suspended, and the intestines should be flushed. If there is much vomiting the stomach should be rinsed. He has never found atropin effectual, but advises pouring castor oil into the stomach (50 gm.) as a last resort. If this does not give relief, the situation becomes critical, and after the fifth day—watching the pulse—the necessity for a secondary laparotomy must be considered. The pulse reveals approaching improvement. If it becomes stronger and slower, less tense, this sometimes announces the overcoming of the obstacle before stools and flatus appear. If the pulse grows smaller and faster, waste no more time on symptomatic measures. Do not be deceived by the appearance of a few scybala in the enema water. One patient succumbed on the ninth day, although some feces had appeared in a high enema given the sixth day. The autopsy revealed adhesions and perforation of a gangrenous loop in the small intestine in the small pelvis. The obstacle is generally in the small pelvis, even after a laparotomy. Vaginal intervention will frequently relieve without the necessity for opening the abdomen again. In 4 cases he cured the ileus by placing the patient in the lithotomy position and reopening the colpotomy wound with his finger. The entire small pelvis was then examined, and loops of intestine found adherent were stroked free and lifted. A pad of gauze in the Douglas cul-de-sac keeps the intestines from sliding down. Afterward a high injection is given and the abdomen cautiously massaged. Anesthetics are not required. Thirteen patients were cured by a second laparotomy. In 3 a fecal fistula persisted for a time, but finally healed. The healing proceeded most smoothly when the intestine had been emptied by means of a trocar, but even then there was generally suppuration at one or more points.

47. **Diazo Reaction in Tuberculosis.**—Junker remarks that the results of the diazo test are too inconstant for it to be of much value in early diagnosis. When the findings are constant the physical signs are generally unmistakable.

48. **Resolution in Pneumonia.**—Schläpfer's researches have demonstrated that the resolution and absorption of pneumonic processes and their relics are governed by the tension of the oxygen in the dead tissues. As this is in turn regulated by the condition of the vessels, the final outcome of the process depends on the extent to which the vessels have been injured by the disease. These facts suggest the usefulness of oxygen as a therapeutic measure and of drugs to act on the heart and vessels. The tubercle bacillus finds a favorable soil in the relics of pneumonic processes, and it has further an additionally injurious action on the blood vessels. The benefit of iodin preparations in tuberculous processes may be due to the special action of iodin on the blood vessels. Passive congestion according to Bier may also owe its efficacy to its activation of the blood, including livelier oxidation. It is possible, Schläpfer thinks, that the Bier method might be applied successfully to the internal organs. Tuberculous pneumonia

seems to indicate such treatment, and here, as also in croupous pneumonia, more active treatment seems to promise better results than the hitherto more expectant measures.

52. **Genital Tuberculosis.**—This article fills 100 pages and is the concluding portion of a monograph on tuberculosis of the seminal vesicles. The practical conclusions for the clinician are that a tuberculous process in the genital organs, and especially in the seminal vesicles—contrary to the experience with the more common tuberculous processes in the lungs, intestines, bones and glands—very frequently runs a latent course, and yet is a constant source of danger for the bearer. In all cases of tuberculosis or suspicion of the disease the entire genital apparatus should be investigated, not omitting the seminal vesicles. As the genital apparatus may become infected from the urinary system, the urine should be examined occasionally for tubercle bacilli. Also every discharge from the urethra, even when there is nothing to suggest tuberculosis, should be examined now and then for tubercle bacilli. The tuberculous process displays a tendency to spread along the natural passages, either up or down, and to induce a total affection of the apparatus involved.

53. **Rise of Temperature from Suggestion in the Tuberculous.**—Lorenz relates his experiences with a number of tuberculous patients who were given sham injections of tuberculin. His tables show an almost regular increase in temperature after a sham injection in 44 out of 200 persons tested. The excitement and the suggestion send the temperature up, although none of the supposed tuberculin was really injected. His experience suggests that it might be wise to test the influence of suggestion in this way before really injecting the tuberculin later. A rise of half a centigrade degree can be accepted as a positive reaction to the tuberculin. It should be computed from the temperature noted after the sham injection, allowing for the rise due to the effects of suggestion. The sham injections were liable not only to send up the temperature, but also to affect the general health. It was noticed sometimes that those patients who had the most pronounced rise of temperature after a series of sham injections failed to show any rise when a genuine injection was given. Another fact noticed was that the suggestive reaction was generally more pronounced when the organism was depressed from any cause, a slight cold or inflammatory process in a tooth or the like.

55. **Spread of Tuberculosis by Way of the Lymph.**—Haentjens has long proclaimed that tuberculosis is primarily an affection of the connective tissue and that it spreads by way of the lymphatic system. He regards this conception as very important, for if the danger for the organism from tuberculosis lies in the connective tissue and its juices, it is here that the battle against the tuberculosis virus must be waged. Proceeding on this assumption, he has been producing a prepared curative serum by inoculating animals with specific tuberculosis virus obtained from the blood-forming tissues and bone marrow, thymus juice, spleen extract and lymph. His serum displays both preventive and curative properties. He is preparing a detailed report for publication later.

56. **Transmission of Human Tuberculosis to Cattle.**—In Eber's experiments tuberculous products from the mesenteric glands of children injected into cattle caused virulent tuberculous processes in many instances, although not constantly.

58. **Inhalation Treatment of Tuberculosis.**—Brühl's study of this subject concludes with the statement that it is impossible to exert a direct therapeutic influence on pulmonary processes by means of inhalations. They do no good and are liable to affect the diseased lung injuriously. On the other hand, applied judiciously and at the proper time, they may be very beneficial in treatment of the upper air passages and in catarrh of the large bronchi.

59. **Process for Obtaining Practically Unmodified Cow's Milk Free from Living Germs.**—This communication issues from von Behring's institute at Marburg. It describes the process by which cow's milk is said to be absolutely freed from living germs without altering its taste or modifying its properties. Hydrogen dioxid is added to the milk at once, and after a few hours a ferment is added which destroys the hydrogen dioxid. The milk is rendered absolutely sterile by the dioxid, while neither the dioxid nor the ferment alter its properties in any way. The hydrogen dioxid is placed in the sterile empty milk can and the milk is milked into it. The proportion is 1 to 1,000. The milk is then set aside for from six to eight hours and is then warmed to 52 C. for an hour, after which the ferment is added in the proportion of 0.5 or 1 gm. to the liter. The ferment used is derived from beef blood, with the hemoglobin removed, producing a powerful catalytic ferment, which has a special destructive action on hydrogen dioxid. It was first described by Senter in the *Zeit. f. physik. Chemie.*, vol. 44, who then called attention to its specific action on hydrogen dioxid. He gave it the name of "hämase." It is a yellowish fluid containing 1 or 2 per thousand albumin, which is, of course, a homologous protein with the albumin of cow's milk. The destruction of the hydrogen dioxid in the milk is facilitated by frequent shaking of the vessel. Two hours suffice as a rule. The milk is then ready for use, and when protected from the light keeps fresh for days. The name of "perhydrase milk" has been given to milk thus prepared. The taste is identical with that of pure fresh milk. No germs can be cultivated from it even after twenty-one days. Inoculation of guinea-pigs and mice always resulted negatively even after enormous amounts of tubercle bacilli had been added to the milk with the hydrogen dioxid. Defibrinated beef blood might be used, it is stated, instead of the prepared ferment. The proportion should be 1 c.c. of the defibrinated blood to 1 liter of 1 to 1,000 hydrogen dioxid milk. The warming of the milk might also be dispensed with. The same process may also be found useful for disinfection of drinking water. Experiments in this line are now under way.

60. **Tuberculosis in Relation to Child-bearing.**—Weinberg thinks that the influence of pregnancy on tuberculosis has been exaggerated. He presents statistics to show that the death rate in the year following childbirth is no higher among the tuberculous than among other women. The pregnancy is frequently interrupted by spontaneous abortion or premature delivery. Weakly and tuberculous young women should be advised not to marry. The course of tuberculosis in a pregnancy is not invariably unfavorable, and the disease does not develop with any striking frequency during a pregnancy. Hemoptysis is not especially frequent during the puerperium.

65. **Inguinal Hernia of the Uterus.**—Hilgenreiner reports a case in detail and has collected 39 similar ones in the literature. He gives the details of the last series of 15 cases. In the majority the defect was congenital, and was accompanied by other anomalies. In 4 instances the patients were men and in another a male hermaphrodite. In 8 cases the uterus was pregnant. In the case personally observed the patient suffered from melancholia which subsided completely after the operation. The uterus and right adnexa with some loops of intestines were found in the hernia. They were adherent and, on account of shock, the operation was done in two stages. The psychosis developed during the interval of about nineteen months.

66. **Improved Technic of Experimental Inoculation of Tubercle Bacilli.**—Marmorek states that young cultures are more virulent than those two or three months old. He has also found a difference in the results of inoculation when the bacilli were injected in a fine emulsion or in comparatively large drops. It is also difficult to measure the exact amount injected. In consideration of this difficulty of reproducing always identical conditions in his tests he turned his attention to making the animals more susceptible to the inoculations. He now announces that he has succeeded in this task. He has accomplished this with quinin, which has a paralyzing effect on phagocytosis and thus allows the bacilli to develop unhindered. He injected the bacilli in a 2 per cent. solution of quinin in physiologic salt solution, using white mice for the experiments. By this means the susceptibility of the mice was very much enhanced and the test became much more delicate and reliable.

67. **Physical Measures in Treatment of Acute Articular Rheumatism.**—Laqueur's experience effectually demonstrates that measures to induce artificial hyperemia are valuable adjuvants to the salicylates in treatment of acute articular rheumatism. They can be applied in the form of superheated air or with passive congestion with a constricting band.

68. **Alexander-Adams Operation and Hernia.**—Schickele advises strengthening the anterior wall of the inguinal canal in performing an Alexander-Adams operation. This obviates a tendency to hernia later. The Alexander-Adams operation has been performed in 138 cases at the Strasburg clinic since 1901, and the results are regarded as highly satisfactory. In one instance an old inguinal hernia rendered it difficult to find the round ligament. When found it was sutured between the pillars of the canal, thus preventing any further tendency to hernia.

78. **Results of Roentgen Treatment in General During Last Year.**—Trapp summarizes his review in the statement that the last year has materially enlarged and deepened our theoretical knowledge of the mode of action of the Roentgen rays. They have assumed an important place in the treatment of leukemia, of inoperable malignant tumors and of various cutaneous affections scarcely amenable to other measures. The rays have also attained a place in the treatment of goiter and of enlargement of the prostate.

79. **Artificial Hyperemia in Treatment of Acute Inflammations.**—Lexer calls attention to Bier's recent remark that streptococci, for some reason, are rarely encountered in his clinic. They are seldom found as the causal agents of acute inflammations at Bonn. This fact is contrary to the experiences elsewhere, especially at Lexer's clinic at Berlin, where streptococci are the usual germs found in acute inflammations. He suggests that possibly the fine results obtained by Bier with artificial hyperemia and passive congestion may be due to the absence of streptococci. In any event he urges those applying the new technic to investigate the bacteriology of the lesions as this is important for a better knowledge of its effects.

92 *Zur Prophylaxe der "Katheter-Cystitis." W. P. Richter.
93 Zweimaliges Vorkommen eines Scheidengewölberisses intra partum bei derselben Person (twice lacerated vaginal vault). J. Saks.

86. **Vaginal Speculum.**—The advantages claimed for this speculum are that as it opens the outer end enlarges too, as well as the tip end. The lumen of the vagina can thus be enlarged evenly throughout its entire length.

88. **Etiology and Treatment of Vomiting of Pregnancy.**—Mueller has been declaring for some time that the cause of the vomiting of pregnancy must be sought in some injury of the sympathetic nerve. The vomiting is a reflex neurosis of this nerve from traction or compression of some of its fibers which have been fastened down by relics of some old inflammation. They are thus unable to yield before the enlarging uterus or the congestion of the parts. The site of this abnormal anchoring of the nerve varies in individual cases. He has sometimes found it in the neighborhood of the solar ganglion, with the posterior wall of the uterus adherent near the promontory on the left. After detaching the adhesions at this point the uncontrollable vomiting has frequently ceased in his experience. Sometimes the benefit derived was only transient, but improvement was again realized by breaking up the adhesions anew. Another point whence the reflex vomiting may originate is the region of the internal os. Inflammation around the back of the uterus, with pathologic anteflexion or immovable retroflexion, especially when combined with induration of the vaginal portion of the cervix, are liable to induce the tendency to vomiting. An exceptionally rigid cervix and very solid attachment of the placenta have been observed in some cases. The irritation must have proceeded in these cases from the cervical ganglia, as treatment directed to the environment of the uterus proved ineffectual. The irritation may proceed in rare cases from adhesion of the omentum. Treatment of the reflex hyperemesis must include the release of adhesions or reduction of the tension in parts hardened by chronic inflammation. Massage, stretching the ligaments, raising or lowering the uterus, tamponing the vagina or cervix or the colpeurynter are among the mechanical measures indicated, while rinsing with hot water, enemas, compresses, sitz baths, and absorbent measures in general should be applied as required, with possibly thiosinamin to aid in loosening inflammatory indurations. These measures must be applied cautiously so as not to induce abortion. Hysteria, neurasthenin and autointoxication from the intestines or liver may be predisposing causes. Vomiting occurring during pregnancy is not always the result of the pregnancy. Autopsy revealed cancerous stricture of the small intestine in one case in his experience. Intestinal intoxication is probably the most frequent co-operating factor.

89. **Age at First Menstruation in Sweden.**—To complete the statistics gathered from various countries, Essen-Möller gives the particulars learned from 5,000 women of various social classes in Sweden. The first menses appeared at the age of 10 in .08 per cent.; at 11 in .74 per cent.; at 12 in 4.44 per cent.; at 13 in 9.3 per cent.; at 14 in 21.1 per cent.; at 15 in 26.38 per cent.; at 16 in 16.6 per cent.; at 17 in 9.98 per cent.; at 18 in 6.48 per cent.; at 19 in 2.8 per cent.; at 20 in 1.68 per cent.; at 21 in .26 per cent.; at 22 in .1 per cent., and at 23 in .06 per cent.

92. **Prevention of Catheter Cystitis.**—Richter uses a catheter not more than 5 mm. in diameter, with small openings with rounded edges. A protecting disc which prevents its entering too far into the bladder is mounted on the catheter 5.75 cm. from the tip. The catheter fits on a metal tube which has an extension at right angles to allow influx of the rinsing fluid

when the stopcock at the junction is turned. It prevents injury of the bladder walls from the catheter while it protects against soiling the bed linen.

94. **Antimeningococcus Serum.**—This communication issues from the Institute for Infectious Diseases connected with the Berlin University. It completes the reports of previous research on epidemic cerebrospinal meningitis with the announcement of the production of a curative serum. The serum is obtained from horses inoculated with twenty-four hour agar cultures of meningococci from the cerebrospinal fluid of typical cases. Either the living cultures or extracts of the meningococci are injected into a vein or subcutaneously. The specific action of the serum thus obtained was tested in various ways. The findings, especially by the new hemolytic test, were constant and conclusive. Kolle and Wassermann do not hesitate to advise its use in treatment and also in prophylaxis. They recommend a single subcutaneous injection of 10 c.c. as early in the disease as possible. This proportional dose has proved entirely harmless in experiments on animals.

96. **Principles of Treatment of Disturbances in Speech.**—Among the measures advocated by Gutzmann is reading aloud interesting stories to the child, reading a sentence at a time, quietly and slowly, and making the child repeat the sentence after the reader in the same way. This will almost inevitably cure incipient cases. In the long established ones, the frequent underlying neuropathy requires attention, as also the diet and local lesions.

97. **Roentgen Treatment of Leukemia.**—Flesch does not believe that Roentgen treatment of leukemia is very promising. More than a transient improvement can not be anticipated, and even this is rare in the lymphoid variety. He gives the particulars of 3 cases thus treated.

100. **Pneumococcus or Passive-Congestion Gangrene?**—A young man drove a splinter into his thumb and pulled it out with his teeth. The arm became very painful and swollen, but several punctures failed to reveal pus and a Bier constricting band was applied and left on all night. The next morning the fingers were bluish and cold and gangrene rapidly developed, requiring amputation. Pneumococci were found in the lesion and the gangrene may have been their work, or it may have been the result of the artificially induced congestion superposed on the already intensely swollen condition of the parts. In any event, the case warns that when the soft parts are already very much swollen it is wiser to relieve the tension by an incision to regulate the circulation before applying the constricting band.

102. **Therapeutic Pneumothorax.**—Brauer relates that he has applied Murphy's method of artificially induced pneumothorax in treatment of a girl of 18 with progressive tuberculosis of one lung, the other sound. After each injection of nitrogen the fever abruptly subsided for a long time, an effect not attainable by any other method of treatment known to date. The collapse of the lung caused no disturbances. He has devised an apparatus for injection of the gas. The nitrogen becomes absorbed in time, and it may be found advisable to substitute some other indifferent substance. Experiments in this line are now in progress. The collapsed lung has infectious matter squeezed out of it by the pressure, and the passive congestion aids in its healing. His patient is much improved.

106. **Gastric Secretion in Chlorosis.**—In 23 cases Arneth found hyperacidity in 15 of the patients. In 8 the improvement in the blood findings under treatment was paralleled by the restoration to normal of the gastric acidity. In the severer cases of chlorosis the findings always indicated extreme hyperacidity. He has never encountered subnormal or deficient acidity in any case of chlorosis. The treatment which proved successful was rest in bed at first, sometimes for several weeks in the severer cases, with iron or arsenic subcutaneously. Iron plus arsenic internally was given in the cases in which the number of red corpuscles was very low. If the spleen was enlarged he accepted this as an indication for quinin. His formula for an effective and unirritating iron pill is 7.5 gm. reduced iron with glycerin and gelatin enough to make 90 pills, as soft as possible. He orders one or two pills at first and then three after each meal.

107. **Interruption of Pregnancy in Constitutional Diseases.**—Hofmeier relates his experience in 3 cases of chronic nephritis in pregnant women. The threatening symptoms continued notwithstanding that the fetus had died, but rapid and pronounced improvement followed artificial termination of the pregnancy. In one case the nephritis was very severe and some symptoms are still observed. One woman was delivered by Dührssen's technic of anterior hysterotomy. The condition was critical in all the patients when first seen. These cases teach that it is unwise to allow conditions to reach such a serious pass before interfering. In a case of severe cardiac defect in a primipara of 32 with contracted pelvis, uterus bicornis and transverse presentation, at the tenth month of pregnancy, he safely delivered the patient of a living child by Cesarean section according to Porro. He removed the uterus to prevent future pregnancies and also to simplify the puerperium as much as possible. The results were highly satisfactory, as the childbirth had not taxed the heart unduly. The patient now feels perfectly well except for palpitation and dyspnea when she works very hard. Pregnancy in a diabetic woman is extremely rare for various reasons. In a case recently observed, a woman in the seventh month of pregnancy, had been under treatment for confirmed diabetes; the first symptoms were noted not long after the commencement of the pregnancy. She was artificially delivered of a recently dead fetus. The amniotic fluid contained 0.165 per cent. grape sugar (dextrose). The patient's condition grew progressively worse and she succumbed the fourth day in coma. Hofmeier does not ascribe this fatal termination to the delivery, but to the fact that it was postponed until the disease had gained such headway. If she had been delivered when symptoms were first observed the prospects would have been much better. There is little chance of a viable child from a diabetic mother. In respect to myelitis, a possible connection with pregnancy is generally denied, but in a case in his experience the symptoms improved remarkably after the patient with ascending myelitis had been artificially delivered nearly at term. She succumbed four months later to the effects of a gangrenous decubitus. He discusses in conclusion the psychoses of pregnant women, with a case from his own experience in which melancholia and insomnia accompanied a pregnancy in a woman predisposed to mental affections. In consultation with the physicians who had attended the patient in her three previous pregnancies he induced arti-

tieial delivery. The patient recovered her mental balance and passed through other pregnancies later without psychic depression.

110. **Action of Iodin in Experimental Arterial Affections.**—Twenty-three rabbits were treated with adrenalin and 11 with subcutaneous administration of iodin at the same time. The results showed that the necrosis of the arteries which inevitably followed the injections of adrenalin could be prevented by simultaneous injection of iodin.

114. **Mental Strain for Children.**—Czerny thinks that people exaggerate the importance of "school strain." They ascribe to the school what is really the result of the home environment. The mental strain is intense during the years before the child enters the school if it is much with adults. It is constantly asking questions and learns something from each answer, but no one thinks of measuring or shortening the hours of this activity of the child's brain. Adults sometimes answer a child's questions all day long and merely rejoice in its inquiring little mind. In this way the child soon grows out of its childlike naiveté, and signs of neuropathy develop which are falsely ascribed to "school strain" after the child enters school. The most effectual remedy is to allow children to grow up in the companionship of children, and to reduce their association with adults to the minimum. When children play together the demand for toys and change of amusements is much less than for one child alone, and there is also the possibility of many harmless games and of cultivation of the will. Children playing together have red cheeks while the child associating with adults does not get the same excreise and is pale. This pallor is a sign of mental strain. The excitement that reddens a child's cheeks is harmless. A child with a private tutor has to pay strieter attention in one hour than during the four hours of a public school, and he has more unoccupied time. This aids in developing a neuropathic tendency. The meals, the bath, etc., become important events. Symptoms of hysteria frequently develop in such children in connection with some bodily function.

121 *Suicide with Veronal. Selbstmord durch Veronal. F. Ehrlich.
122 Improved Child's Bed.—Ein neues Kinderspitalbett. Hutzler (Munich).

115. **The Leucocyte Test of Milk.**—Trommsdorf has confirmed Bergey's statements in regard to the diagnostic value of the presence of leucocytes in milk. Whenever leucocytes were found in the milk in large numbers innumerable streptococci were also present.

116. **Spirochetes and Cytorrhyctes.**—Schülz has been making a comparative study of Schaudinn's *Treponema pallidum* and Siegel's *Cytorrhyctes luis*. He call attention to the way in which both are always found together and close to or inside the red corpuscles. Specimens in which there is only a single red corpuscle in the field are especially significant in this respect. He thinks it is possible that they represent merely different phases in the life cycle of a single microorganism.

121. **Suicide with Veronal.**—Ehrlich relates 2 cases of suicide with veronal. Both patients were men of about 57 and generally healthy, although one had suffered from circular melancholia for 20 years. He took 15 gm. of veronal at one time. The other man took 11 gm. Neither recovered consciousness and both died at the twentieth hour. A greenish-yellow tint of the corpse was striking in the first case. Ehrlich comments on the way in which the report in the papers of a suicide with lysol was followed by an epidemic of suicides with this drug. Lysol has since been withdrawn from open sale and can be obtained now only on a physician's prescription. "This way of exploiting new drugs is utterly opposed to common sense," he says. "When a manufacturing chemist puts a new drug on the market he presents testimonials to prove that it is harmless and it is freely offered for sale until cases of severe intoxication and even death gradually accumulate and establish beyond question the fact that the drug is toxic and dangerous. Then it is withdrawn from open sale and regulations are passed restricting its use to physician's prescribing. Thus it fared with antipyrin, sodium salicylate and other drugs. We who are practicing physicians know that the testimonials sent out with the new drugs are often doctored. In the interests of our fellowmen, to protect them against injury to health and death, we physicians must demand that this way of doing things should be reversed. The sale of all the new drugs should be restricted and they should be dispensed only on physicians' prescriptions. Only when a general verdict of physicians as to their non-toxic and harmless properties has been attained should they be allowed to be sold at retail without restrictions. In particular," he adds in conclusion, "veronal should be withdrawn at once from the general market, for veronal in large doses is an absolutely certain fatal poison." In one of the cases reported the patient had bought 30 gm. of veronal, obtaining 15 gm. at one drug store, 10 gm. at another and 5 gm. at a third. The symptoms were cyanosis, unconsciousness, superficial respiration, with occasional complete arrest of the respiration for a few minutes, and retching from time to time. The tip of the nose and the hands and feet were cold, the pupils contracted, the pulse about 90, sometimes imperceptible. The clinical picture simulated that of morphin poisoning. The stomach was rinsed at once and atropin was injected (0.0005 gm. every half-hour, six times). Chemical analysis showed 0.36 gm. veronal in 100 c.c. of urine.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

Address

THE LEGAL RESPONSIBILITY OF THE PHYSICIAN FOR THE UNBORN CHILD.

CHAIRMAN'S ADDRESS IN THE SECTION ON OBSTETRICS AND DISEASES OF WOMEN, AT THE FIFTY-SEVENTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, BOSTON, 1906.

C. S BACON, M.D.
CHICAGO.

INTRODUCTORY.

Since the last session of the Association in Portland, our Section has lost by death two of its Ex-chairmen, Drs. Dudley and Dunning, both of whom were members of the Executive Committee of the Section.

Dr. Augustus Palmer Dudley was born at Phillipsburg, Me., July 4, 1853, and died in Liverpool, England, July, 15, 1905, of tuberculosis, at the age of 53. After completing a high school course he served an apprenticeship in an iron and steel manufactory, where he became a skilled mechanic. Then he began the study of medicine in the office of Dr. Seth Gordon and graduated at the Dartmouth Medical School, in 1877. After practicing four years in Portland, Me., he took the course of an interne in the Woman's Hospital, of New York. After a short service as assistant surgeon in the Woman's Hospital, in San Francisco, he returned to New York in 1884; this city was his home until his death. During this period he was Professor of Gynecology in the Postgraduate Medical School and in the Dartmouth Medical School and was connected with several hospitals.

Dr. Dudley was a skillful operator and a successful teacher. He also made many and important original contributions to the literature of his specialty, the most important of which were his papers on "Conservative Treatment of the Uterine Appendages." He was a Fellow of the American Gynecological Society, the British Gynecological Society and a member of the state and local societies, as well as the American Medical Association. He was also a very active member of the International Congress of Obstetrics and Gynecology and did much for it as the American secretary. Dr. Dudley left a wife and two daughters. He was not only a good physician and a good teacher, but he was also a good citizen and a good fellow, kind to all, loved by all who knew him, a most devoted husband and father. His social qualities were characteristic.

Dr. Lehmann H. Dunning died at his home in Indianapolis, Ind., from heart disease, Jan. 4, 1906, at the age of 55. He graduated at Rush Medical College, Chicago, in 1872. For a number of years he had been Professor of Diseases of Women in the Medical College of Indiana and surgeon in the Indianapolis City Hospital and gynecologist in the Deaconess Hospital. He was a member of the American Association of Obstetricians and Gynecologists, as well as of his county, state and national societies. His numerous contributions to the literature of his specialty were of a practical character. He was a careful, conservative and judicious man, whose influence in the community and in the profession was always for the best.

In the name of this Section I desire to express here the highest appreciation for the earnest and faithful work of these men who have been our worthy leaders, and the deepest and most sorrowful regret for their loss.

THE LEGAL RESPONSIBILITY OF THE PHYSICIAN FOR THE CHILD IN UTERO.

All physicians, as well as other biologists, must regard the child in the womb as much a human being while still in the womb as after its expulsion. Although dependent on its mother for nourishment and for protection from injury and cold, it is still a living being and as much an independent existence as, for example, an intestinal parasite which depends on its host for protection and nourishment. That it lacks some of the functions of the individual *ex utero*, for example, the respiratory does not disprove its independence or its human nature. The infant also lacks functions that are possessed by the adult. The self-conscience of the fetus is only in abeyance because not aroused. The embryo or fetus is then to the biologist a separate human individual and not a *pars viscerum* like the ovary or the appendix.

We must regard this human being as just as independent at the beginning of its intrauterine life as after it has reached a stage where it can live outside of the uterus. The old legal distinction between a fetus *animatus* and *inanimatus* has, of course, no biologic foundation, although the statutes of certain states give a kind of authority for the perpetuation of these terms which are now in reality meaningless. The preception by the mother of fetal movements does not prove or disprove the life of the child any more than would a lack of consciousness of movements of other parasites which exist in her body disprove their existence. Likewise, there is no biologic basis for the ancient legal distinction which gave different vital and human attributes on the fetus *formatus* and the fetus *informatus*.

LEGAL STATUS OF FETUS.

The legal status of the child *in utero* does not conform to its biologic status. All human beings *ex utero* are on the same plane and neither a physician or any one else has the right to take the life of one for the benefit of another or for any reason whatever, unless the state, through its judicial officers, declares the life of an individual forfeited because of his crimes and because its extinction is necessary for the welfare of the state. The unborn child has not the same legal protection. Under certain circumstances its life may be taken. The laws of most states and countries justify feticide when it is necessary to save the life of the mother. The provisions

of these laws are of great importance to the medical profession and should be well known. Every physician should understand his legal responsibilities, rights, and obligations in this connection. The religious and ethical questions involved will not be considered in this discussion or only incidentally.

Surgeons of all kinds are learning to appreciate more and more the importance of having a definite understanding or contract with the patients on whom they operate. If the patient is not in condition to give consent or is not old enough to decide, the contract should be made with the legal representatives of the patient. In case no verbal or written or implied contract is made the surgeon operates at his own risk. When a contract exists he is still liable if he does more or differently than arranged for. Of course under any circumstances he is responsible for his management of the case if it is not skillful or if he is negligent.

The risks of the obstetrician are perhaps still greater. Many of the recent malpractice suits occur in obstetrical cases. The laity are coming to believe that puerperal infection is preventable and that its occurrence is due to malpractice. Obstetrical operations are exposed to the same risks as surgical operations. But operations involving the destruction of life of the fetus introduce a question that is quite different from any that can come before the surgeon and involve an additional risk. It is to this special risk or responsibility of the obstetrician that I wish to call attention as the subjective side of the question.

There is another classification of intrauterine life that might seem more natural and reasonable than those already mentioned, namely, that based on the viability or non-viability of the child. Some may ask, is the destruction of a viable child, especially one near or at term, a more serious matter than that of an unformed embryo, or even than the destruction of a 24-weeks' fetus that can live out of the uterus at most only a few hours? On mature consideration such a question will probably be found to have no biologic basis. As to the juristic side of the question it appears that in most states in this country the law makes no distinction in the legal rights of children *in utero*.

LAWS OF VARIOUS COUNTRIES AND STATES.

We shall be much disappointed if we expect to find that the laws of the country or of any states form a body of well-digested and consistent and logical rules of action. Logical consistency is hardly a characteristic of any law. The law rather expresses the common opinion or judgment of the people, and this expression must conform to the conflicting variety of sentiments held by people of all stages of mental and moral development. If the law is ahead of the people or imposed on them by outside authority, it is apt to be executed indifferently or not at all, or it may raise opposition that leads to its annulment. In this country, as well as in England, whence our laws originally came, the laws are self-made and are generally an index of popular sentiment.

According to the ancient English common law, by which we mean the ancient precedents, the decisions or *dicta* of courts not founded on legislative enactment, the embryo or fetus before the term of quickening had no legal rights whatever. Up to the time of quickening no offense could be committed by an operation that led to the destruction or premature delivery of the fetus. If the woman gave consent, the bringing about of an abortion was not recognized as a punishable offense. Abortion produced without her consent was punishable as assault. The theory of the courts was that life, in contemplation of the law, begins when the child is able to stir in the womb and prior to this time the child does not exist as capable of being the object of criminal intent or action. Hence, when the mother gives her consent, the operation could only be considered as a wrong against something that does not legally exist.

This was the common law till shortly before the separation of the colonies from the mother country. This common law was the basis of the law of this country. In many states, this theory of the legal nonenity of the unquickened fetus was held by the courts to be the law and the early statutes of some states particularly or impliedly approved this theory. Now, however, this provision of the common law has been superseded by the statutes which have been passed by the several states. These statutes, in most of the states, make no distinction between the commission of an offense on the child before or after quickening, although some states still provide a more serious punishment when the act is committed after quickening.

It will not be possible for me to go into an examination of the statutes of the different states, and I must content myself with calling your attention to the practical abrogation of the common law, the substitution of statutary regulations as just outlined, which practically recognize certain rights of the fetus, although they do not place it in the same category with the individual *ex utero*.

I shall pass by a number of interesting questions which do not pertain strictly to the subject, for example, the responsibilities of the mother, and briefly refer to the general provisions that have a bearing on the legal status of the fetus as concerns the physician.

At common law, procurement of an abortion after quickening, with the mother's consent was forbidden, but was not a crime punishable with imprisonment. If, however, the mother died as the result of the abortion the one who performed the act was guilty of murder.

The statutes of the several states generally provide that any attempt to procure an abortion, either by the administration of drugs or by the employment of instruments, is punishable by imprisonment, unless the act is necessary to preserve the life of the mother. When the death of the mother results the crime becomes manslaughter and is punishable as such.

Before considering the question of most interest to us, namely, that of the justification of the act, a moment's attention should be given to a few side questions of importance. For example, how far is one responsible for advice to take medicine or to use means to produce an abortion. It is held that one is responsible for such advice if it is acted on, but not otherwise. The question also arises concerning the efficiency of the means employed. Here it is held that the intent governs. This ruling shows that the object of the law is not only or not so much to protect the fetus as to protect the life and health of the mother from the consequences of the attempts at abortion. This also explains, in part at least, the ruling that the viability of the fetus is not necessary to commission of the crime, although, no doubt, the vitality of the fetus at term, is a very important consideration in determining the justification of an obstetrical operation.

LEGAL JUSTIFIABILITY OF FETICIDE.

We now come to the most vital question of the legal justifiability of feticide. In some wording or other all statutes provide for exemption from punishment for

abortion in case it is necessary to preserve the life of the mother. This provision expressly implies that in the eyes of the law there is a difference in the value of human lives. It is the codification or the reflection of the popular belief or popular conscience that the mother's life is worth more than that of the child *in utero*. Whether this popular opinion or this expression of it in the statutes is morally justifiable or not, is not within the limits of my subject to discuss. We are simply concerned to learn definitely what the law provides. There seems to be no doubt of the far-reaching consequences of this provision concerning the necessity of preserving the life of the mother at the expense of her child. It is on this provision that the physician probably must rely for exemption in case of mutilating obstetrical operations made on the living child.

Just what is comprehended in the provision, "necessary to preserve the life of the mother," must be determined by the court in each case, and decisions have varied in some points. In some states the statutes require that the advice of two physicians be secured to determine the necessity of an abortion. Where such a rule holds it is, of course, necessary to show that the physician acts in good faith, in calling a consultant who is not in collusion with him to perform a criminal act. Where the rule does not hold, consultation is not necessary, but always desirable. It is always necessary to show that the physical condition of the mother requires the abortion. Fear of suicide or of remote results, developing from a possible nervous condition, does not justify the performance of the act. The practice of many physicians who make the probable injury to health an indication for the induction of abortion, is not justified by law and might lead to trouble in the event that such a case were brought before a strict constructionist court. It has sometimes been held that the burden of proving the necessity of the abortion falls on the physician and sometimes that the absence of necessity must be proven by the state. No doubt the circumstances in individual cases would have some bearing here, while in different states the practice varies.

So far, our attention has been addressed chiefly to the rights of the non-viable fetus and to the responsibilities incurred by the physician in its destruction. Neither the statutes nor the decisions of the courts in this country have fixed the status of the viable child *in utero*, except as it has been included with all intrauterine life in the provisions already discussed.

INDICATIONS FOR EMBRYOTOMY.

All obstetrical writers in discussing the indications for embryotomy of the living child have laid down certain rules based on their own conclusions concerning the justifiability of the practice. Nearly all admit that the operation should be done at times. A few, like Pinard, would do away with it entirely. In general, the operation is admitted in cases in which delivery is impossible without Cesarean section or some operation to enlarge the pelvic girdle, and when the latter procedure is refused by the mother. The question is variously discussed from the usual religious and social standpoints, but rarely, or never, is the legal standpoint presented. The individual views of each writer are given and they generally coincide with those of others, so that the two or three sentences devoted to the subject are practically the same in all text-books. I have been able to find nothing authoritative in English concerning the legal status of the operation. Sippel, studying the German criminal law, concludes that: "In practice, the destruction of the life of the child by the induction of abortion or by embryotomy in order to save that of the mother, is not a punishable offense, and modern criminal law practice agrees in this respect. In theory, however, jurisprudence has reached no conclusion as to whether this destruction of fetal life should be allowed or condemned, nor as to how this destruction should be legally construed." Both Kossmann and von Franqué call attention to the fact that in Germany a physician who destroys a living fetus may be in danger from an unfriendly court. In this country, there is little or no doubt that the destructive operation, if necessary to save the life of the mother, would always be justified by the courts.

POINT DECIDED BY MEDICOLEGAL SOCIETY OF FRANCE.

One important point has been discussed and decided by the medicolegal society of France. A physician is not compelled to make a destructive operation against his own judgment or conscience. In other words, if a physician advices a Cesarean secton or a symphyseotomy or pubiotomy and this operation is refused by the patient or her husband or guardian, he can not be compelled to substitute an embryotomy for the operation he proposes, even if he be the only physician in the place. Such a rule would undoubtedly be followed in this country, although I do not know that any case of the kind has ever been decided. It is inconceivable that a court would hold a physician responsible for the death of a woman because he refused to perform an embryotomy on her living child, and he certainly could not be convicted of civil malpractice in such a case. Of course, the physician has no right to leave his patient who has refused his advised conservative operation and he demands an embryotomy until some other physician has arrived, or until he is summarily dismissed from the case.

As to the legal justification of a destructive operation, probably the same can be said as was stated in regard to therapeutic abortion. In some states it might be necessary for the physician to prove that the operation was necessary to save the mother's life, while in most states the burden of proof would be on the state to prove that the operation was not necessary.

INDICATIONS FOR OPERATION.

It is not in my province to enumerate the various indications for the operation, any more than it was my plan to discuss the different pathologic states that required the induction of abortion. In general, it might be affirmed that the indications for destructive operations are becoming contracted and many pathologic states that previously were treated by embryotomy, would not now be accepted as indications.

CONCLUSION.

This review of the legal status of the child *in utero* has led probably to less results than were expected. I have been disappointed in finding less material than was expected. It shows, I believe, that the legal responsibilities of the physician are comparatively simple. No physician need be in doubt in any case. If he believes that the preservation of the life of the mother requires the sacrifice of the child he may operate without fear. It is always better, however, to fortify his opinions by consultation with a reputable colleague. The law does not recognize that the life of the child *in utero* is of equal value with that of the mother.

In deciding on his moral responsibilities, however, the

physician may have much greater difficulty. The statute law is frequently behind or at variance with the ethical law and the variance seems to be marked in this case. Many operations would be legally safe that would be undoubtedly wrong.

It is difficult to deny to the human fetus the innate right of every human being the equal right to life. On the protection of this moral law the child *in utero* must chiefly rely for its preservation. The moral responsibilities of the physician for the child *in utero* are greater than his legal responsibilities. It is hard to dispute Pinard when he holds that neither the father, the mother, the physician, nor any other person has the right of life and death over the fetus. The frequency and boldness with which that right is claimed by the father or by the relatives of the mother should meet with firm resistance. I see no ground on which the physician can stand when he decides to destroy the fetus, except a kind of implied authorization by the state, which agrees to uphold the right of the mother to self-preservation when her life is endangered by that of the fetus.

DENDRITIC KERATITIS OF MALARIAL ORIGIN.*

E. C. ELLETT, M.D.
MEMPHIS, TENN.

Among the less common diseases of the cornea is that known as dendritic keratitis, to apply the name which its appearance suggests, or mycotic keratitis, a name more in accord with its etiology. This disease appears, when fully developed, as a finely branched ulceration of the cornea, running a rather protracted course. In my personal observation it has almost always appeared as a complication of acute malaria, though the same picture has been occasionally seen in patients who had no malarial manifestations, and who had not suffered from malaria at any time sufficiently recent for it to have any possible bearing on the eye trouble.

The disease is not common. Even in malarial districts it is not one of the commoner eye diseases, and when compared with the large number of persons who have malaria, it is seen to be an unusual complication of that disease. I can only state the case thus vaguely, as I have no means of arriving at accurate statistics. The following remarks apply to its characteristics as seen by me:

It is decidedly more common in the late summer and fall, corresponding to the time of the greatest prevalence of malaria. It is rare to have an opportunity to see it prior to the ulcerative stage, though Kipp of Newark has described it as beginning as a series of small subepithelial lymphoid papules, which quickly break down just as phlyctenulæ may do. Judging from the size of the lesions when it is what might be called fully developed, these initial papules must be of almost microscopic size. The rapid coalescence of several lesions results in a fine shallow linear ulcer, with a tendency to branch, this giving the characteristic dendritic arrangement. The amount of infiltration of the surrounding tissue is variable. Often the lesion is merely an abrasion of the epithelium, this being especially true of recent lesions, but frequently it has a gray border or base rendering it more conspicuous. A proper conception of its extent only can be obtained by staining with fluorescin. We might even say that the characteristic arrangement of the ulcer is not suggested until made conspicuous by staining. When seen in the earlier stages, with the ulcer involving the epithelium only, and arrested by Bowman's membrane, the unstained cornea fails to show any more than a little roughness. Later, the infiltration of the substantia propria at least suggests the character and extent of the condition, but at all stages fluorescin definitely outlines the denuded area so clearly and so sharply as to present a picture which can hardly be confused with anything else.

Late in the course of the disease and possibly somewhat influenced by treatment, if energetic, the loss of the epithelium may become very considerable, as much as one-half of the cornea being denuded. I have never seen the lesions suppurate, and while a moderate degree of iritis may occur, it is never more than moderate, and hypopyon is never seen. The lesion is rarely or never multiple. No matter how extensive, it will be found that the ulceration is all a part of a single system or tree, though as healing progresses the bridging of the ulcer here and there may leave separate denuded areas. The history is always given of a preceding chill or chills. It is very rare in chronic forms of malaria and in those unaccompanied by chills. The course tends to be protracted when untreated. In spite of treatment some cases will last for weeks or even months, the corneal picture changing daily. One attack predisposes to others, but one attack is not necessarily followed by others. Still I have seen many patients in whom every attack of malaria "settles in the eye." From the superficial character of the lesions, serious damage to the cornea is not unusual. Nebulæ are usually left, and if central or nearly central, the opacity itself and the resultant irregular astigmatism frequently reduces the vision to from 20/40 to 20/100. That the changes of curvature are a more potent factor in this result than the opacity, is shown by the improvement of vision by cylindrical lenses. It is rare for both eyes to be attacked, even when the disease recurs.

The subjective symptoms are usually marked, the sensation of a foreign body being present, with some deeper aching pain. I have not noticed the supraorbital neuralgia at the beginning, of which Kipp speaks, but neuralgic pains in all the branches of the fifth are not rarely present during the course of the attack. Some patients suffer very little. The ball is injected and photophobia usually marked. It can not be said that there are any characteristic changes in the sensibility of the cornea. The tension is not altered.

It seems to me that this is not the disease described by Horner as herpes corneæ, but is the same, as Kipp suggests, as that described by Hansen Grut and Emmert under the name of dendritic keratitis or keratitis exulcerans dendritica mycotica, respectively. It is convenient to tell the patient he has "fever blisters on his eye," but from the observations which it has been possible to make on this disease in its early stages, and from watching its development and the formation of new buds and off-shoots from the original furrow, I am satisfied that the lesions are not vesicular, but are subepithelial lymphoid collections, resembling phlyctenules, but very much smaller. As far as my personal observation goes, I have only seen this corneal lesion in its typical form in one case where no malarial history was

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

given, and that case ran an unusually mild course. It may or may not be associated with labial herpes, and there is no possibility of confusing it with herpes zoster ophthalmicus. The blood examinations have, with the one exception mentioned, confirmed the existence of malarial infection of the tertian or quartan variety, or in case the plasmodia had been removed by quinin, the equally characteristic corpuscular changes were found.

In common with herpes, the lesions are probably trophic, and could the point be determined, I believe we would find the lesions to develop along the course of the corneal nerves. If we recall the arrangement of the nerve fibers in the epithelium and anterior layers of the cornea, we will be struck with the fact the curved and irregular shapes of the lesions in dendritic keratitis correspond pretty well with the course of these nerve fibers. The fact that the corneal nerves lose their neural sheaths after penetrating about 1 mm. from the cornea-scleral junction, suggests a reason why the lesions under consideration rarely, if ever, reach to the edge of the cornea, but affect the area where the fibers are not protected.

I can add nothing material to what has already been written in regard to the therapeutics of this disease. The general condition always requires treatment, and a change of climate may be necessary. This is not sufficient, in most cases, without local treatment, to relieve the ocular conditions, and I might go a step farther and say that I have seldom, if ever, seen any striking results, as far as the eye is concerned, from the administration of quinin. Yet it is undoubtedly a necessary part of the treatment, not acting as a specific on a specific lesion, but just as a tonic and other similar treatment will do on other forms of corneal ulcers. Similarly, iron may be needed for a postmalarial anemia, and in every way the general condition should be made as good as possible. Very valuable help can be obtained in this direction by blood examinations. Complete removal of the plasmodia from the blood by quinin having been accomplished, the keratitis may still persist for weeks. As far as local treatment is concerned, an antiseptic wash and atropin should always be used and the eye protected. I have not seen any positive results from dionin. The most striking results will often follow the application of tincture of iodin to the ulcer. The eye is well cocainized, the ulcer outlined by staining, and then gone over with a probe armed with a small amount of cotton wet with the tincture. In spite of the cocainization and immediate irrigation, the application is very painful, and is sometimes not at all beneficial. When it does not help matters, the mildest measures are advisable. Hot applications are beneficial and grateful to the patient. A poultice seems to help at times, though the same result can be attained in a more cleanly manner by hot gauze compresses. Some years ago a patient on whom I had tried all the usual methods of treatment without benefit, went on a business trip to a levee camp. On the advice of an Italian laborer he put a garlic poultice on the eye over night. Next day he was practically well, but I have never had another patient who cared to try the same prescription.

As soon as the epithelium is firmly regenerated, the yellow oxid ointment or some similar preparation should be used to lessen the opacity. The refraction should be gone over at intervals, and the corneal changes followed up by suitable changes in the lenses. The astigmatism very frequently causes discomfort on use of the eyes which glasses will relieve.

DISCUSSION.

DR. C. J. KIPP, Newark, N. J., remarked that he found in Dr. Ellett's paper a statement of all that he knew of dendritic keratitis of malarial origin. Dr. Nash, said he, still holds that this form of keratitis is nothing else than the corneal herpes of Norris, but in his opinion this is a mistake. This form of keratitis he had found almost exclusively in persons suffering from malarial poisoning, very rarely in connection with inflammation of the respiratory organs. It was formerly more common than at present when malarial fevers are infrequent. With regard to the treatment he agreed with Dr. Ellett. He might add that in cases in which there is considerable secretion from the conjunctiva he had used with marked benefit a solution of silver nitrate, 1 or 2 per cent., applied to the furrow as well as to the conjunctiva of the everted lids. He had used dionin in some cases with apparent benefit. It certainly seems to give comfort to the patients when used in the form of an ointment, containing 2 to 5 per cent. dionin, put between the lids before going to bed. He still believed that quinin given in pretty large doses has a decided beneficial effect on the corneal disease, especially if combined with iron. There is a class of cases presenting all the appearance of choked disc in which the disease is really a circumscribed retino-choroiditis. In such cases the patch of retino-choroiditis is stretched on the very border of the papilla and causes a papillitis with much edema. He had seen cases in which this swelling amounted to three diopters. The true character of the disease is often not discoverable until the papillitis has subsided. Then you find an atrophic patch with pigment scattered over it, or fringing it, adjoining some portion of the papilla. In such cases, when seen early, there is usually found a deposit of minute particles on Descemet's membrane, and by this the disease may be distinguished from primary papillitis. In the case of a physician seen only a short time ago no cause could be found for the optic neuritis, but when this had subsided an atrophic patch on the edge of the papilla could be seen and there was no further anxiety in regard to the condition of the man's head.

DR. H. MOULTON SMITH, Fort Smith, Ark., said it had been his experience that the disease sometimes follows chronic malaria. He practices in a locality very similar to that in which Dr. Ellett practices. He had sometimes seen these ulcers in which there was a superficial portion of the surface of the cornea with shreds of epithelium about the edges of the dendritic area. He had also seen this particular type become infected and thinks one should not forget that it is possible for these to become infected with pus-forming germs and thus mislead one in diagnosis and prognosis. He had seen some cases in which no improvement occurred until he began the use of quinin. He attached considerable importance to the use of quinin combined with arsenic as a specific cure for this condition.

DR. GEORGE F. KEIPER, Lafayette, Ind., stated that a year ago last spring it was his misfortune to have such a case in which no symptoms of malaria could be found. This induced him to investigate the condition bacteriologically, and as a result he came on a germ which he could not differentiate even with the help of the bacteriologists at the university. They finally submitted the matter to Professor Novy, and the details of that work are reported in the Transactions of the American Academy of Ophthalmology.

DR. JOHN GREEN, JR., St. Louis, called attention to the use of quinin bisulphate in 3 per cent. solution. This was first used for various types of superficial keratitis and especially dendritic keratitis of malarial origin. He uses it by dipping a cotton-wound probe in the solution and passing it over the surface. It is extremely efficacious in controlling pain, and, in addition to other measures, such as irrigations and atropin, seems to start the condition on toward recovery more rapidly.

DR. LEARTUS CONNOR, Detroit, said he did not live in a malarial region, but had seen in the course of the last 25 years about a half-dozen cases that come under this description. While using all the things that have been mentioned and others he was not at all convinced that local treatment has tended recovery; neither could he see that the constitutional treatment was very efficacious. He did think in the last two

cases that he observed a beneficial effect from the use of salicylate of strontium, but the cases are so few and the character of the disease so irregular that he was not at all certain. If he were to have another to manage, however, he should try that remedy early in the case.

Dr. Edward Jackson, Denver, remarked that there was one point in which he would take issue with Dr. Ellett's description; that is, that in a sense it can not be said that there is any characteristic change in sensibility of the cornea. At Denver since the Spanish-American War it has been the policy of the government to bring troops to Fort Logan to recover from certain diseases of the tropics, and he had seen a few cases of this form of keratitis following severe malaria among these patients. The change in sensibility of the cornea is very easily overlooked because the sensibility may be lost in limited sections of the cornea, not over the whole cornea or globe. These cases are sent to this place to recover from the effects of malaria, and on antimalarial treatment and general hygienic treatment recover in the course of a few months entirely.

Dr. S. D. Risley, Philadelphia, said he had seen at the Wills Eye Hospital quite a group of these cases presenting the dendritic characteristics and had come to regard them as a distinct type of keratitis. It is not only possible, but may be probable, that his clinical judgment in this respect is in error, but they seem to get better, and rapidly better, under periodic doses of quinin and arsenic. It may be that these remedies act simply as tonics, but they did not have the same prompt and specific effect in other forms of superficial keratitis. Another characteristic is their tendency to recur at the well-recognized periods for the recurrence of fevers, multiples of the seventh day. This he had seen in three cases. He was, therefore, inclined to feel that there is something specific in this form of keratitis as compared with those forms which are associated with other dyscrasiæ.

RETROBULBAR OPTIC NEURITIS FOLLOWING CHILDBIRTH.*

CHARLES J. KIPP, M.D.
NEWARK, N. J.

Case 1.—A case of recurrent retrobulbar optic neuritis of one eye following successive childbirths, and ending in atrophy of optic nerve, with whitening of part of the eyelashes and eyebrow of same side.

History.—The patient was a strong healthy woman, about 25 years of age, at the time of her third pregnancy when she first came under my observation. I learned from her at this time that her first pregnancy occurred about four years before the third, and the second more than two years before the third. Her eyes have always been good, she has never had an inflammation of the same, and the vision of both was excellent up to the time of her first pregnancy. Shortly after her first confinement she had an attack of transitory blindness in the right eye, from which she recovered completely. She had another temporary loss of vision in the right eye soon after she gave birth to her second child, but this also passed away in a few weeks, and after that, up to her third confinement, the vision of this right eye was very good. I saw her for the first time five weeks after her third confinement. She then complained of pain and a queer feeling in the right eye.

October 1. Third pregnancy. She is nursing the child. Is in good health.

Examination.—The right eye is entirely normal in appearance and the movements of the globe unimpeded in any direction. The ophthalmoscope showed perfectly clear media. The optic papilla was of normal appearance, but the retina around disc and the region of the macula was somewhat less transparent there than elsewhere. She had an absolute central scotoma. The periphery of visual field was not contracted. She had no disease of heart. Urine contained neither albumin nor sugar. Ordered six leeches to right temple. Also potassium iodid., 5 grs., three times daily. On the following day the opacity of the retina around disc and in macular region was less, and she was able to recognize outlines of large objects. Her vision was not tested closely as she was in bed and her eye was sensitive to light.

Clinical Course.—October 4. Supraorbital neuralgia over right eye. Patient can count fingers at five feet. The opacity of the retina has again apparently increased.

October 6. To-day V. 3/60. The opacity of the retina is markedly increased, especially around disc. She has been taking quinin for the supraorbital neuralgia.

October 8. I noticed to-day for the first time that the eyelashes and hair of brow situated in line with supraorbital notch are white, while the rest are of dark color.

October 13. V. 5/9. Opacity of the retina has disappeared, but the disc is now paler than on previous examinations and the retinal arteries are somewhat narrower.

November 1. V. 5/8. Disc very pale, arteries small.

During the following year patient was seen every month. V. 5/8, with V. F. intact at end of year.

Fourth pregnancy two years after third.

Recurrence.—August 27 I was called to see patient again. Learned that she had been confined of a healthy child two weeks previously. She was in good health and was nursing the baby. The urine was free from albumin and sugar. I learned from her that her vision, which had been very good in the right eye up to a few weeks before her confinement, had suddenly become greatly impaired several times in the two weeks preceding the confinement, but had returned after a day or two. Last night, while sleepless in bed, after more or less headache during the last forty-eight hours, noticed that she was totally blind in the right eye. She is confident that she could see very well with this eye yesterday, and that the blindness came on suddenly. She has now pain in an.[1] above the right eye. The attending physician had dropped a solution of cocain in this eye a few hours before I examined the eye on this occasion. Examination showed normal exterior of the right eye. The pupil somewhat dilated from cocain. The media were perfectly clear. The disc was very pale and its outlines quite indistinct. The adjoining retina was cloudy; the retinal veins were smaller than those of the left eye, and the arteries markedly so. Has perception of light only, but in all parts of field. Ordered six leeches to left temple and internally iodid of potassium in gradually increasing doses.

September 22. The only noticeable change in appearance of fundus is a small extravasation of blood of macula, and between this and outer periphery there are several others, of round form and larger size; vision not improved.

October 3. To-day she can count fingers at a foot in outer part of field. The hemorrhages are disappearing. Otherwise as before.

December 20. Marked atrophy of optic papilla. V. 0. This eye diverges.

Later History.—Since then this eye has become totally blind. The hairs in the brow and the eyelashes in a line with the supraorbital notch have remained white and are so to-day, ten years after the change was first noticed. The patient has not been pregnant since her fourth confinement. Two years after last confinement she had photopsies in the left eye, which up to this time had never given her any trouble, but they passed away after a few days and have not returned since. A few months later she had a slight attack of catarrhal conjunctivitis in the left eye, for which her family physician instilled some drops which caused much injection of globe, pains and flashes of light, followed by marked dimness of vision. I saw her on the following day. The eye was still injected, V. 5/5, V. F. intact for form and colors, in daylight and in dimly lighted room.

Ten years later the examination showed the left eye to be entirely normal.

No one will doubt, I think, that the pregnancies or the childbirths were responsible for the development of the eye disease. To me it seems most probable that the pregnancies caused a disturbance in the vascular supply, a congestion at or near the apex of the orbit, and that

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

this produced pressure on the optic nerve and its sheaths and also on the branches of the ophthalmic branch of the fifth nerve. Others who have observed somewhat similar cases following confinement and during lactation have attributed the optic nerve disease to an auto-intoxication. A full account of the views held by different writers as to the causes of this affection, as well as summary of these cases previously published, will be found in a paper by Dr. George S. Derby,[1] entitled "Optic Neuritis During Lactation, Including a Reference to Other Ocular Conditions Observed in This Period."

As regards the whitening of some of the eyelashes and some of the hair of the brow, this has been observed in some severe cases of iridocyclitis mostly of the sympathetic form. So far as I can ascertain, the case here reported is the first one in which this has occurred in connection with retrobulbar optic neuritis. Only a part of the lashes and of the hair of the brow were affected, namely, those in line with the course of the supra-orbital nerve. The absence of the pigment in the hair was undoubtedly due to a change in the hair papilla whereby the supply of pigment to the hairshaft is interrupted. The hairs without pigment seem also to be less thick than the colored ones near them. Although I saw the patient daily, I did not observe any change in the color of the lashes till after a severe attack of supra-orbital neuralgia. I am unable to say that the change in the color of the hair occurred over night, but I am certain that it took place within a few days. The lashes at the place described and the hairs in brow are still white, ten years after the change was first noticed. The lashes of the lower lid of the same eye and the hairs of the brow of the other side are all still of a brown color. An interesting paper on the premature whitening of the eyelashes by Dr. Alfred Vogel will be found together with the literature of this subject in *Klinische Monatsblätter für Augenheilkunde*, Februar und März, 1906, p. 228.

Case 2.—A case of retrobulbar optic neuritis of one eye, following childbirth. Recovery of vision.

History.—Mrs. W. M. D., 35 years of age, was delivered of first child on July 1, 1899, and had convulsions, but no albuminuria, according to her physician. Shortly after confinement she noticed a blur before right eye. This has gradually increased to such an extent that she can only see large objects with this eye at present. The child died a few days after birth.

Examination.—When first seen by me, Feb. 12, 1900, I found that the vision of right eye was less than 6/60. The left eye had S. 6/6. Both eyes were entirely normal in appearance, externally, and the mobility of both eyes was unimpaired. Ophthalmoscopic examination revealed entirely normal conditions in the left eye, and in the right eye a marked paleness of disc was the only abnormality discovered. Examination of the field of vision of left eye showed contraction of about 20° all around for form and a corresponding contraction for colors. The V. F. of right eye was contracted to a somewhat greater extent, blue and red are recognized only close to point of fixation, and green is not recognized at all. The patient, a large, healthy-looking woman, is now in good health. Urine contains neither sugar nor albumin. I prescribed iodid of potassium in 10-grain doses three times daily.

Clinical Course.—During the following months there was a steady improvement and on March 28 (six weeks after her first visit to me) vision of left eye was S. 6/6. The V. F. was of normal dimensions for form and for blue, but was contracted for red and green. A month later the V. F. was only slightly contracted for green, otherwise normal. The ophthalmoscopic examination at times showed a very grayish disc, otherwise normal condition. The right eye was entirely normal, S. 6/6, V. F. intact for form and color.

When last seen by me, March 1, 1903, nearly three years after her first visit to me, I found the sight of each eye to be S. 6/5, the V. F. intact for form and colors. The ophthalmoscopic examination showed marked atrophy of papilla of left eye, the retinal vessels were of about normal caliber. The right eye was normal in every respect.

She has not been pregnant since she gave birth to her first child.

DISCUSSION.

DR. GEORGE S. DERBY, Boston, said that about a year ago he published a paper on this subject, going over the literature very thoroughly, and the impression he got at that time was that no definite etiology could be attached to these cases at all. The condition, he thought, had been very well recognized for a great many years. Reference is made to it in many of the old text-books. Where the neuritis occurs in successive pregnancies it would seem as though prevention of pregnancy should be practiced.

DR. NELSON M. BLACK, Milwaukee, said that in the first case the supraorbital neuralgia would seem to point strongly to the possibility of disease of the sinuses and possibly the increased congestion all over the body accompanying the pregnancy aggravated this condition.

DR. C. J. KIPP, Newark, N. J., said that the cases Dr. Derby referred to are cases attributed to lactation, which was not the case with those of the paper. They followed every pregnancy. Everybody has seen the disease follow pregnancy, but here were four pregnancies, each followed by the same condition.

MEDICAL PHASES OF DENTAL DISORDERS.*

SAMUEL A. HOPKINS, M.D., D.D.S.
BOSTON.

Under this head we have two classes of cases which present themselves for consideration. On the one hand, there are those which, while presenting medical symptoms, are directly due to some disturbance in the teeth or the surrounding tissues; on the other hand, we may have a large number of reflex disorders, the origin of which is not always apparent, but which ultimately we find to be located in a diseased tooth.

Whatever the medical phases of dental disorders may be, or wherever they may be located, in the ears, eyes, throat, nose, in the cervical or the salivary glands or even in more remote organs, it is an unfortunate fact that very many of the cases reported as having their origin in diseased teeth bear with them the confession of failure on the part of the physician to make an early and successful diagnosis.

In going over the meager literature on this subject one is struck by the frequent repetition of such a remark as this: "Everything possible was done for the relief of the patient, but he continued to grow worse until some days after the beginning of the treatment, when attention was called to the condition of the teeth. Then it was discovered that there lay the cause of the disease." In the text-books we find brief allusions to the teeth as disturbers of the neighboring organs, but very little that would be helpful in diagnosis. Fortunately, to become an expert in diagnosing diseases of dental origin, the physician needs only to have the pigeon holes of his memory open so that he will never forget that the teeth may be responsible for many diseases not usually accorded to them. Thus, with a little common sense, he may be able to detect many of these cases almost imme-

* Read in the Section on Stomatology of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

diately. The physician will show uncommon sense, however, if he will keep constantly in touch with a capable dentist to whom he may bring these cases of doubtful origin and with whom he may consult.

Consideration of the disorders of first dentition must be passed over somewhat rapidly. These come at a period of child life when the dentist is not usually employed; and it is quite unnecessary to draw the attention of the physician to this subject, as there has always been a willingness to exaggerate the importance of the erupting teeth as the disturbers of the health of infants. First dentition has long been made the scapegoat to bear the burden of every childish ill. The ignorant or slovenly physician, failing to find the true cause of disease, has been in the habit of referring everything to the teeth. Mothers and grandmothers have caught the infection and have been willing to lay the blame of every disturbance of infantile health on the eruption of the temporary set. Just now a reaction is taking place and a class of men has arisen who, in their contempt for the loose methods of the past, are willing almost to assert that, as dentition is a perfectly normal physiological condition, it can not, therefore, be responsible for any of the disorders of childhood. Perhaps this is swinging the pendulum too far in the other direction. It is probable that we shall miss the exact truth regarding this matter until a more careful study of the development of the digestive tract is made and proper adjustment of the food of the child to his new requirements is accomplished. Not only is the mouth undergoing rapid development during this period of eruption, but the entire follicular apparatus of the alimentary canal is undergoing remarkable developmental changes. These changes are in anticipation of changes in the character of food which the growing system demands. The secretions of the digestive tract are no longer suited for the digestion of that food which alone constituted the diet of the child during the first six or eight months of infantile life. A mixed food is now demanded, and secretions are altered to meet the new requirements. We must remember, too, that not only the alimentary canal, but every organ in the body is undergoing a change; and that the nervous system, particularly the cerebrospinal system, is in a high state of functional activity wherein it responds quickly and in an exaggerated degree to an irritation which would go unnoticed at a less excitable period. If at this period digestive disturbances are brought about by improper feeding or if any departures from hygienic laws are permitted, it is not remarkable that the erupting teeth should be the scene of attack, neither is it remarkable that serious illness should result.

There is no doubt that the eruption of the teeth does, in some cases, create a disturbance. Neither is there any doubt that the disturbance would be minimized and in many cases go unnoticed were there no other causes at work at the same time to upset the delicate equilibrium of the growing child.

Aside from the long list of familiar symptoms coincident with and frequently attributed to the eruption of the first teeth, diseases of the ears and eyes occur with sufficient frequency at this period to warrant most careful examination of the mouth. The fact that many of these eye and ear symptoms clear up when the disturbing tooth is erupted or the gum properly lanced indicates the intimate relationship between these organs.

The teeth are so well recognized as sources of aural disease that it is only necessary to advise that in all cases of aural disturbance a careful examination of the mouth and teeth be made. I want to make an especial plea for the children in our public schools. It is estimated that one-fourth of all the ear aches among these children originate in or are continued by the presence of diseased teeth. These brave little stoics often suffer uncomplainingly, accepting their suffering as an act of God from which relief is not to be expected. Few of us have any idea of the bravery of these children in their struggle with ill health and pains, and I hope the day is near when we shall have provision made for the care of their teeth as a means of relieving suffering and preventing illness.

The disturbing influence of the sixth-year molars is not generally recognized and in the vast majority of cases it is of no importance. If, however, you find the child of five and a half is rather more fretful and cranky than usual; if you discover that sleep is disturbed and that the appetite is not up to the normal, an examination of the mouth will probably reveal a hyperemia of the mucous membrane in the molar region, and perhaps the cusps of the incoming tooth may be seen. Beyond the exercise of a little more patience with the child and a little more care in diet, treatment is rarely necessary. Occasionally, however, the irritation extends to the tonsils and fauces and a mild tonsillitis may result. Occasionally, too, a stomatitis may be set up that will not readily yield to treatment until the teeth are erupted. Less frequently the glands of the neck become slightly swollen. Just here a suggestion of caution might be made. If the swelling is coincident with the eruption of these teeth; if the swelling is slight and no other evidence of tuberculosis is present, it would be well to defer operating on the glands until the teeth have come through and the mouth has returned to its normal state. It sometimes happens that the gland symptoms disappear with the eruption of these teeth and an operation becomes unnecessary.

During the following six or seven years of the life of the child the condition of the mouth and of the teeth is responsible, in a large measure, for the health of the child and its proper development. If the teeth are neglected during this period, loss of appetite, indigestion, ill health and an arrest of development which can not be retrieved will be brought about by the inability of the patient to properly chew his food; while the absorption of vitiated oral secretions and the ptomaines resulting from food decomposition strongly predisposes to disease. A few years ago the writer had occasion to study the difference in virulence of certain pathogenic bacteria in different mouths and in the same mouths under different conditions. The results of those experiments, published three years ago, have been confirmed by further observation, and it may be accepted as proven that not only are bacteria found in greater numbers in uncared for and neglected mouths, but their pathogenic properties are greatly increased in such mouths. This may be explained by the abundant supply of nutrient media furnished by the lodgment of vast quantities of food in and about broken-down and defective teeth and possibly also by the altered secretions of the salivary and mucous glands. The pneumococcus is especially variable in the intensity of its pathogenic properties in different mouths and in the same mouths under different conditions, and the following facts, brought out in the experiments referred to, point to a possible means of reducing the number of pneumonia cases.

The bacterium is found in a large number of healthy

mouths. The exact percentage of mouths in which the pneumococcus is present has been variously estimated and is probably not far from 15 to 20 per cent. In some cases the saliva containing the micro-organism is fatal to small animals, but too much stress must not be laid on this action, as other forms found in the mouth seem to have a similar power.

The organism loses its pathogenic property when grown on artificial media or when the nutrient medium is insufficient, but its pathogenic properties may be revived by passing through susceptible animals. Few organisms are so easily destroyed by antiseptics as the pneumococcus. In the course of these experiments neglected and unclean mouths from which this organism had been obtained were thoroughly cleaned and the teeth put in good condition. For a period of fourteen days or more the teeth were kept scrupulously clean, with the result that in a majority of cases the organism disappeared altogether, and in the remaining cases its virulence was reduced and the saliva became non-pathogenic. This experiment is such a simple and practical one that it can easily be repeated in any dental infirmary with this and other bacteria. As a matter of fact, practically the same results were obtained with the aureus and other forms which were under observation, and the following deductions seemed warranted. Inasmuch as most disease germs enter the body via the mouth, and inasmuch as their virulence is increased when they find lodgment in diseased teeth or in the abundant food material contained in neglected mouths; inasmuch as cleanliness retards growth and reduces the pathogenic property of the bacterium when it does not actually destroy the organism, it behooves the physician and the dentist to regard the teeth and the mouth as important factors in diseases of bacterial origin.

The period between six and twelve years is a time when the teeth especially suffer and when they offer special opportunities for the reception of bacteria and the growth and development of the same. Caries in the first teeth proceeds with great rapidity, and these teeth receive little or no attention except among people of education and large means. Broken down crowns, diseased roots and suppurating inflammations lower the vitality of the child and render him an easy victim to the invasion of infectious disease. It is known that guinea-pigs and other small animals fed on decomposing food or treated with purulent discharges are found to lose their resisting power to disease. Animals kept in pens near the opening of a sewer where the air is vitiated by the sewer gases are found to succumb much more rapidly when inoculated with pathogenic bacteria than animals furnished with a bountiful supply of fresh air, and there is scarcely room for doubt that a child forced to swallow the purulent discharges from an abscessed tooth or the ptomains and toxins resulting from proteid decomposition is no longer able to offer proper resistance to the action of the disease.

Considering the number of contagious and infectious diseases which occur during this period, it is reasonable to believe that the state of the mouth and teeth have an important bearing on the development and spread of infection. Herein is disclosed a possible addition to our knowledge of prophylaxis and a method, still untried, of reducing the cases of infectious diseases in children. While little can be done at present to change existing conditions, except in that small proportion of cases in private practice which we have under our control, there is one phase of disease which occurs in both hospital and private practice which possibly might be improved along the lines indicated. Where one disease follows another, as where pneumonia follows measles or whooping cough, it would seem as if careful attention to mouth cleanliness during the period of convalescence might result in the prevention of many troublesome and dangerous sequelæ.

Reference has been made to the fact that suppurative discharges from temporary molars are frequent in childhood. It happens that the sixth-year molars, so often mistaken for temporary teeth and neglected, frequently break down and a suppurative condition follows. The absorption of pus from these teeth seriously affects the neighboring glands. In the superior maxillary region the parotid group is sometimes affected, but the submaxillary and superficial glands of the anterior triangle of the neck to which the lower teeth drain are more frequently affected. Enlarged glands occur in many cases without dental lesions, and there are a great many more cases of septic absorption from teeth than there are enlarged glands, but from the fact that the glands of the neck and the mesenteric glands are perhaps next to the lungs the most common seat of tuberculosis invasion, it is suggested that resistance to tuberculosis is lessened by the constant absorption of septic matter from diseased teeth. Moreover, many cases are reported of tuberculous glands of the neck where the tubercle bacillus was found in a diseased molar tooth, and we have strong presumptive evidence that in a considerable number of cases the infection found its way into the gland through a diseased tooth.[1] Several cases reported in the *British Med. Journal* confirm this belief, as tubercle bacilli were found in the diseased teeth and in one instance in the abscess sac at the end of the root.

In two cases which have come under my own observation the bacillus was found in the putrescent pulp of the extracted molar, and there seemed to be little doubt that the glands had been infected through this channel.

Ordinarily the eruption of the twelve-year molars is unnoticed. In rare cases it may cause constitutional symptoms of a severe nature. This is more likely to happen where development of the jaw is tardy and where there is insufficient room for the eruption of the tooth between the posterior portion of the first molar and the upright portion of the mandible. If from the tenth to the twelfth year you find the child suffering from fretfulness and loss of appetite, if the eyes and ears are irritated, if anemia with nervousness bordering on hysteria occur, it is just possible that an obstructed second molar is responsible for the symptoms described. An *x*-ray may be necessary to locate the tooth with accuracy and to make the diagnosis, and the treatment must depend on the condition revealed. I deplore most seriously the sacrifice of the six-year molars, yet it may be justified if we become convinced that there is no other way of relieving pressure. I wish to emphasize especially these cases, because they do not occur with any great frequency and few dream of the possibility of these teeth causing such serious illness. If you ever do meet with such a case you will be amazed at the improvement that will follow the relief of pressure.

Disease of the posterior superior teeth is so well recognized as a cause of empyema of the antrum that I will not dwell on this phase except to urge the greatest possible care in examination of the teeth whenever the antrum and associated sinuses are involved. The nasal fossa may also be involved in disease of the superior

1. British Med. Journal, Aug. 20, 1904, p. 385.

incisors. Inflammation extending from one of the third molar teeth or, indeed, from any of the posterior teeth has been known to give rise to inflammation of the nasal mucous membrane, and a discharge from the nose and catarrhal pharyngitis may be caused or continued by the irritation arising from a pulpless tooth. Hyperemia of the turbinated bodies and acute rhinitis may be greatly aggravated by an extension of the irritation from the diseased tooth.

Perhaps no one tooth is capable of giving rise to quite so many severe disturbances as those which may be set up by an erupting wisdom tooth or by the same tooth when inflammation and death of the pulp occurs. From the first condition, case after case of ankylosis may be cited with intense neuralgic pains and severe tonsillitis as premonitory or accompanying symptoms. Inflammation extending along the Eustachian tube from this source gives rise to serious aural disturbances frequently attended with great pain. Unusual and often obscure ocular symptoms may sometimes be traced to this source, while constitutional disturbances are frequently of a severe and serious nature. Either from an erupting or from a pulpless wisdom tooth the formation of pus is always to be dreaded because of its tendency to burrow until some vital part is reached or because general septicemia with grave danger to life may result from the absorption of pus. Suppuration from a third molar should be promptly checked, even if it necessitates the loss of the tooth. Fortunately, the agency of the wisdom tooth in giving rise to disturbances in associated tissues is generally not difficult to detect, but it sometimes happens that an erupting third molar without giving great pain will produce enough irritation and enough pus will be absorbed to give rise to a chain of symptoms puzzlingly like the symptoms of a mild attack of typhoid. It may occasionally save grave anxiety if the third molar region is carefully examined when obscure typhoid or malarial symptoms present themselves.

The action of pulp stones in causing intense pain is now generally recognized, though it must be admitted that the diagnosis is often extremely puzzling. It is safe to say that no diagnosis of neuralgic pain in any of the various ramifications of the fifth nerve can be made without a careful examination of the teeth. As frontal headache generally results from errors in refraction so pains which simulate facial neuralgia originate generally in the teeth.

The influence of erupting and diseased teeth in producing many forms of stomatitis must be passed over without consideration and many nervous reflexes which have their origin in diseased teeth must be neglected. Many other aspects of this subject will occur to the physician who follows this paper, but it is perhaps unwise to carry its consideration further.

It is futile perhaps to expect materially to restrict disease or render our environment innocuous. The laity will persist in unclean habits and will underestimate the value of hygienic living. Commercial zeal, the demands of society, the exactions of school and college and the complexity of life even for the very young will continue to prevent mouth cleanliness from receiving the attention it merits. The self-satisfied physician and the indifferent dentist will continue to neglect this and other forms of prophylaxis, yet the true professional man will always find his greatest satisfaction in the prevention of disease; and it is to him that an appeal is made to practically test the efficiency of the suggestions made in this paper.

If the inspection of school children could be made to include an inspection of their mouths it is believed that a marked improvement would be noticed in public health; and if the knowledge that mouth cleanliness is a potent factor in restricting disease could be made known it is believed that intelligent and progressive people would avail themselves of this knowledge as a protection to health.

DISCUSSION.

Dr. Thomas Morgan Rotch, Boston, said that, with regard to the question of the first molar and its development, he believed in a large degree that those tendencies which develop at this period—many pathologic in character—are simply coincident to a molar appearing at that time. The real trouble lies behind and beyond. In the first place, prenatal tendency to want of development, lack of room, begins to be noted at this period because the other unerupted teeth at this period lie in many different positions, because their change of position in the course of eruption is remarkable. Crowding is manifest in the direction of least resistance, which is naturally on the side nearest. At about this period the child begins to be a mouth-breather, and adenoid vegetations make their appearance, also the result of degeneracy, but aggravated by the fact that there is lack of breathing space, want of oxygenation and the fact that the child finds it necessary to breathe through its mouth. This brings decreased resistance to infection, impaired development of the body generally, particularly in the direction of the bronchi and lungs. Not getting the amount of oxygen necessary, there is a decrease of resistance in this direction, and he believes that at this period chiefly is laid the foundation for great susceptibility to tubercular infection. So far as the pneumococcus is concerned, he agreed with the position of the essayist, and cited as a good example the fact that we do not have pneumonia and bronchitis following the administration of ether as much as we used to. He believes that this is largely due to proper disinfection of the mouth. Again, we do not have pneumonia following scarlet fever, etc. Those who had necrosis as a result of one of these diseases were usually people who were treated under the old methods. Since mouth-breathing has been treated in hospitals there is very little of it. Dr. Rotch emphasized the point that there is little or no treatment that will benefit these patients at the time of the eruption of the first molar. If those little mouths were spread out at this period relief could be given which would be pronounced and real and much more effective than expansion of the arches after the teeth have erupted. What is the use of waiting until there is a narrow arch? Why wait until all the surrounding sinuses have narrowed and become deformed? Direct relief can be given by application to the arches because they widen easily at the median suture, and this gives definite benefit. This not only helps the eruption of the first molar, but lays the foundation for the eruption of the second and third molars.

Dr. M. I. Schamberg, Philadelphia, mentioned the case of a patient who had been suffering from tinnitus aurium and treated by a very able ear specialist in Philadelphia, and who was subsequently sent to him to search for the dental cause of her trouble. Though she had but a few teeth on the affected side, he decided to take a radiograph of several upper teeth that were loosened with pyorrhea, and the picture showed distinctly a communication with the pyorrheal pockets from a small opening in the floor of the antrum. On the removal of those teeth and the syringing of the antrum the ear symptoms were at once relieved.

Dr. Alice M. Steeves, Boston, said that parents should be educated as to the well being of the child. While approving all that is scientific and broad, physicians must go back to the primary cause of the trouble, the care of the child's mouth from the beginning. It is necessary to teach the mother how to clean the child's mouth. Many physicians are too anxious to save their time and turn it to financial profit. They do not seem to consider that teaching the patients and the prophylaxis thereby secured are the elevating things in the profession. Educate the people to appreciate their general health and we will get accordingly better results.

REPORT OF TWO CASES OF INFANTILE SCURVY.*

ALICE M. STEEVES, D.D.S.
BOSTON.

The history of scurvy dates back to 1589, when its most dreaded presence was among sailors and in the armies, where a plentiful supply of fresh meat, vegetables and water were unavoidably limited, and often absent altogether. Much suffering and not infrequently death have resulted from this disease, which has been classed by prominent writers among the diseases of the blood and nutrition.

Scurvy, scorbutus, or Barlow's disease, so called because of the concise and efficient article published by Barlow of London about twenty-five years ago, and elaborated on in later years by Comby of Paris, is not confined to adults, and is equally serious when appearing in infancy or childhood.

Bacteriologic causes have not been satisfactorily proven, and while it seems not unreasonable to believe that further investigation will throw some light on this side of the subject, and although the disease is declared uncommon by modern writers, yet it seems possible that in orphan asylums, and in institutions where children are overcrowded and underfed, that many cases might be found if proper medical inspection were instituted.

A few years ago, a child of 4 years of age was referred to my clinic from a large orphan asylum near by. On examination I found a well-developed case of scurvy. I prescribed treatment and ordered that the patient report to me at stated intervals. After waiting several days for the patient to appear, I called at the institution and found that the child was benefited from the treatment prescribed, and the matron told me they did not get usually so bad as this one. I concluded, therefore, that these cases are not rare in such institutions. On examining the mouths of 180 girls at the Lancaster Industrial School, I found 20 per cent. with thickened spongy gums, saliva purulent and mucoid and with the mucous membrane of the nose, mouth and throat inflamed. These patients invariably complained of rheumatic pains, and while the condition is not strictly scorbutic, it seems to suggest a field for investigation.

GENERAL SYMPTOMS OF THE DISEASE.

Infantile scurvy may appear at any age, but usually about the ninth month a child, anemic, poorly nourished, and living in improperly ventilated rooms becomes gradually weak and irritable. At the same time the muscles gradually become soft, the face becomes pale and assumes a scared expression; the skin is tense, shining, and seems edematous, but does not pit on pressure. The limbs become sore and the child screams if touched. The legs are flexed at first and later are extended. Swelling appears on the shafts of long bones, on the femur first and on the upper end of the tibia, later it may appear on any of the long or flat bones. The lesions are not always symmetrical and may go on to separation of diaphysis of the femur or upper end of the tibia. The eyes are more or less affected; ecchymosis appears in spots on different parts of the body. The lesions of the gums are more marked when teeth are present; the gums become swollen and purple, and bleed easily. The mouth is filled with a fetid sanious exudate. Digestive disturbances are vomiting and diarrhea. The internal organs affected are the spleen and kidneys.

COMPLICATIONS.

Infantile scurvy is not infrequently complicated with acute pulmonary diseases and in such cases there is a rise in temperature, accompanied by respiratory and cardiac disturbances.

TREATMENT AND PROGNOSIS.

Treatment.—This consists of regulation of diet. Milk, beef juice, fruit juice (preferably orange and lemon) and tonics must be given as the case demands. Plenty of fresh air, water and cleanliness are essential.

Prognosis.—Under favorable conditions a gradual recovery may be expected. When complicated with acute pulmonary diseases the case may terminate fatally in a very short time. Scurvy is frequently a complication of rickets.

PATHOLOGY.

Pathologic findings reported by different writers are extravasion of blood beneath the periosteum, separation of the epiphysis of the femur, sub-periosteal, medullary, and muscular hemorrhages, and a diminution of red corpuscles with their hemoglobin. No changes in the leucocytes are reported so far as I can find.

CASE I.—Mary B., aged 7 months, was brought to the dispensary.

Examination.—She had anemia, with swelling of the face and legs. The skin was shiny and tense; the parts did not pit on pressure. The legs were extended, with the toes turned outward. There was ecchymosis over the right eye and some spots on the upper part of the body. The gums were swollen and purple, and the mouth was filled with a fetid exudate. She cried with pain when touched and seemed in constant dread of being handled.

History.—The child's mother had nursed her for two months when all seemed to go well; but the mother was obliged to work and the child was fed on Nestles' food after the beginning of the third month, when it gradually lost strength and suffered from indigestion and loss of appetite, followed by the above described condition.

Treatment.—The patient's mother was instructed to give the child a warm bath and then to wrap her in flannel. The child's mouth was irrigated with a solution of water Oi, glycerin 3i, lemon juice 3ss, castor oil 3i, was given to clean out the alimentary canal. Modified milk, beef juice, and orange juice were ordered.

Result.—The child's mouth cleaned up and she began to retain food, when pneumonia developed and she died in forty-eight hours.

CASE 2.—Alfred G., aged 4 years, was brought to my office.

Examination.—He was nervous and afraid of being touched; he cried when looked at; his attendant gave a typical history of scurvy. The child's gums were purple, mouth filled with fetid sanicus discharge, and face anemic and shiny. The femur was so sore that the child moaned at each step. The joints were swollen, purpura was absent.

Treatment.—I ordered milk with lime water, beef juice, orange juice and lemonade. Castor oil, 3ii was given to clean out the bowels. The mouth was irrigated with water Oi, glycerin 3i, lemon juice 3ss. Treatment was changed as the child improved; he made a slow recovery.

There has been much writing on scurvy, as may be found by referring to the "Index Medicus." The principal authorities consulted in this article were Barlow, Comby, Baginsky, Rotch, Jacobi and Keating.

229 Berkeley Street.

DISCUSSION.

DR. M. L. RHEIN, New York, said that Dr. Steeves has very properly drawn the attention of the profession to the possibility of so much of this condition of infantile scurvy being prevalent in juvenile institutions, and to the great possibilities of its undermining the future strength of the child. The diagnosis of infantile scurvy is of comparatively recent date, and

* Read in the Section on Stomatology of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

should not be confounded with general scurvy, which is a disease that has been recognized for a long time. It is one with which every practitioner should be thoroughly familiar, and Dr. Rhein said that Dr. Steeves did not draw the attention strongly enough to the fact that the main point in treatment of infantile scorbutus is that the diet should be radically changed; that it has been due to improper nutrition, and that while the acids are pre-eminently called for, the main feature is absolute change in the form of diet.

RELATION OF PHYSICIANS TO THE SO-CALLED "ETHICAL" PROPRIETARY MEDICINES.

G. B. KUYKENDALL, M.D.
POMEROY, WASH.

The medical profession is awakening to the fact that it has been made a cat's paw to rake out the proverbial chestnuts for the proprietary manufacturers. The work done by several lay papers and by THE JOURNAL of the American Medical Association and by a few other medical journals is having good results in causing physicians to try to see where they are.

There can be no doubt of the justice of the censure that has been passed on a number of proprietary manufacturers. The exposure of their methods has been so complete and the evidence against them so conclusive that there is no room for question.

There is no language too strong to use in condemnation of crooked concerns and their methods, but the question arises: For how much of this state of affairs are the members of our profession responsible? If not responsible for the sins of the proprietary manufacturer, have we not, to a great extent, aided them in their reprehensible work? There is scarcely one of the proprietary medicines for which the manufacturers do not quote letters of commendation from several physicians, some of them heads of medical colleges, professors, lecturers or writers of medical works or men prominent in the ranks of the profession.

How came these physicians to give their endorsements for publication? For certainly manufacturers did not practice fraud and use these names without authority. While some of the testimonials were not fairly obtained and are not rightly used, it is certain that a good many medical men of more or less eminence have permitted their names to be used to exploit very unethical preparations. We find the names of supposedly reputable physicians, members of medical societies and even of the American Medical Association, endorsing with high praise dozens of proprietary medicines, many of which are advertised in the lay press.

Is it not a fact that some members of our profession have been taken in by the makers and venders of proprietary medicines? We have trusted too implicitly to the honor of these manufacturers; some of them started out with very fine promises, and for a time were ethical to some extent, but after they had obtained the recommendation of physicians they betrayed them and placed them in a very unenviable position. We have listened with too much credulity to the representations of detail men, and have accepted their dictum, with too little investigation. There are many cases, not far to seek, for the present uncomfortable relation of physicians to the proprietary medicines and their manufacturers.

PHYSICIANS' USE OF PROPRIETARIES.

There has been a growing demand for handsome-appearing and pleasant-tasting preparations. The pharmaceutical houses have done much to make the taking of medicine less of a terror than it was formerly. With the bewildering array of elixirs, syrups, cordials, etc., in palatable form, and the glowing accounts of the wonderful virtues of these modern products, we have been hypnotized; certainly, in many instances, have been misled. In addition to the plausible advertisements of these products, the country is infested with representatives of the manufacturing establishments who tell us of the wonderful success these new things are having, how other physicians are "curing" almost every case with them. We are urged to try this or that combination, or mix-up, on the say so of somebody interested only in the sale of the product. If we listened to all of them, the days would be too short and life too brief to arrive at any satisfactory conclusion in regard to half of the wonderful products we are urged to try.

It would seem that not only the laity, but physicians as well, are easily humbugged and, even when scientifically trained, are captivated by the air of mystery thrown around a subject.

The trouble is that we are letting a lot of commercial adventurers do our thinking for us. We do not study materia medica and therapeutics as we should. We allow proprietary-medicine makers to put up compounds, tell us what they are good for and how to use them, without thinking how absurd it all is.

Instead of thoroughly studying our cases and writing our prescriptions, to fit present conditions, we too often consult the list of ready-made proprietaries to find something that will suit, after a fashion, the case in hand. Too many physicians prescribe these remedies because it is easier to do so than thoughtfully to write out their own combinations. For this reason the files of our drug stores are lumbered up with prescriptions for Hancock's bromids, Hayseed's Viburnum, or some fellow's hypophosphites. The promoters of such preparations are becoming millionaires while the poor doctor, poor in more ways than one, wears threadbare trousers and eks out an existence only.

We should do our own thinking and not delegate our head work to interested medicine venders. It may have been true in Cæsar's time that all Gaul was divided into three parts, but it has changed in these days; the drummer has his gall concentrated into one wad, and it takes an iron will to stand up and face down the smooth talk of the modern representative of some of the houses. They want to tell us all about what to give, and how to practice medicine, if we would win success, and too often we let them do it.

MEDICAL JOURNALS AND PROPRIETARIES.

To a very considerable extent we are to blame for the humiliating relation of the profession to the pseudo-ethical and quack remedies. It is not alone the rank and file of the profession who are to blame in giving favorable recommendations to secret proprietary medicines. There are a number of so-called medical journals which devote a large part of their space to advertising and exploiting questionable proprietary products. It would be easy to name a number of notable instances in which these journals do not hesitate to recommend, to those asking for treatment of cases, any of the proprietaries which they advertise.

Some of the journals of this class have large subscrip-

tion lists, and many physicians patronize them. If the demand ceased, the journals would go out of business. How are we ever going to get at manufacturers of nostrums so long as they can exploit their products in the medical journals and so long as medical journals give them their moral support?

The pharmaceutical houses have done much to advance "elegant pharmacy," but many really useful drugs have been manipulated until their elegance far outruns their usefulness. While we have been getting out the bitter, the nauseous and the disagreeable, and getting in syrup, flavorings and aromatics, the real virtues of the drugs have been lost in the shuffle in too many instances, and we have left only nice placebos suitable for persons who have not much the matter with them, but which are dangerous and deceptive things to trust when active drugs are really wanted.

Some of the pharmaceutical houses that we have been used to rely on as ethical in their methods are not altogether free from little transgressions in the matter of appealing directly to the public with their products.

I noticed the other day, standing on the shelves of a drug store, some four-ounce bottles that had on them familiar-looking labels. On examination they were found to contain euthymol, put up by Parke, Davis & Co., and inside of the wrapper of thin parchment paper there was folded on the back of the bottles a pink circular with printing on both sides. One side had a heading reading, "Euthymol, an efficient and harmless antiseptic and germicide," and the formula and an account of its usefulness as a germicide, and at the bottom it reads: "There are many other household applications for euthymol." On the other side there is a heading, "Chief applications of euthymol as a household remedy." Then follows a list of diseases and conditions for which the preparation is recommended, with directions as to manner of using. Will physicians feel like continuing to write prescriptions calling for euthymol when its manufacturers in this way undertake to prescribe for the ailments of the people? Some time ago I wrote to Parke, Davis & Co. in regard to this matter and they have assured me that the objectionable features will be removed from their advertising circulars in the future. I think all will agree that any preparation which is put up for physicians to prescribe should not be advertised to the laity under the same name, with lists of diseases in which it is useful, with manner of using!

Take another instance: In the "literature" left on my desk a few days ago by a representative of the firm of John Wyeth & Brother was a leaflet entitled "Collyrium, Wyeth, an antiseptic eye lotion." On the inside was a detailed account of the benefits of an antiseptic eye lotion "to all persons suffering from congestion or redness of the eyes by using them for near work over a prolonged period." "Sewing women may use this lotion freely, to avoid eyestrain, to which they are subjected many hours daily. Automobilists will find it most valuable in removing fine dust from the eyes, etc.," and then follows a detail of other uses, and at last, "Collyrium Wyeth, aside from its valuable healing properties, will prove an efficient adjunct to any treatment the physician may direct." Collyrium Wyeth, Pepto-Mangan-Gude, Bioplasm-Bower, there is here a similarity in rhythmic flow of words that is very suggestive.

Now this collyrium is designed either for the people direct or for the physician. Which is it? The leaflet accompanying it gives no hint whatever of its composition; hence it would be as wrong for a physician to prescribe it as it would be to recommend Thompson's eye water. If it is for the patient to buy at the drug store and to use "as an efficient adjunct to the treatment of the physician," then there are a good many of us who would prefer either to direct the whole treatment or to turn the case over to John Wyeth & Brother. This thing of manufacturers having one set of advertisements for the physician's eye and another for the public is getting to be too common.

There are before me two advertisements of Marchand's hydrozone. One is clipped from the advertising pages of *Advanced Therapeutics*. This winds up with: "My book, the 'Therapeutical Applications of Hydrozone,' sent free to physicians." The other is cut from the *Spokesman-Review*, a newspaper published in Spokane, Wash. This has printed in large flaring letters: "Hydrozone Cures Sore Throat," and "One 25-cent bottle free. Write for booklet on rational treatment of disease." Here we have the manufacturer of a product that he claims is strictly ethical, appealing to the people with one set of advertisements and to the physician with another. It is the old trick of trying to carry water on both shoulders. Like the old darkey, he expects to "ketch 'em a-comin' and a-goin'." and in the past he has been succeeding.

Let us know what we are giving, and prescribe with a distinct idea of what we expect to accomplish. We should get out of league with these proprietary and "patent-medicine" people and wash our hands of this whole business of prescribing medicines whose exact composition we do not know.

When we get the beam out of our own eyes we will be in better position to ask the removal of the mote from the eyes of others.

Clinical Notes

A NEW METHOD OF MOUNTING MUSEUM PREPARATIONS.

HENRY ALBERT, M.S., M.D.

Professor of Pathology and Bacteriology, University of Iowa; Director of the Iowa State Board of Health Bacteriologic Laboratory and Pathologist to the University Hospital.

IOWA CITY.

Realizing the importance of having a large collection of specimens illustrating the gross pathologic conditions, kept or preserved in their natural shape, size and color, in presenting the subject of pathology to medical students, and being unable to obtain a sufficient amount of material from recent autopsies and operations to meet the needs of a properly conducted course, I have, for the last few years, been paying considerable attention to the different methods of making permanent museum preparations so that whenever a good pathologic specimen is obtained it may be used repeatedly for demonstration.

Although I have repeatedly tried several of the methods recommended by different workers during recent years, none has proved so valuable as the Kaiserling method. When using flat jars, the specimens can be so arranged as to have the principal pathologic part next to the glass and in that way best exposed to view. It often happens, however, that specimens mounted in liquid fall out of position, necessitating constant manipulation to keep them so arranged as to present the diseased part to best advantage.

About four years ago I conceived the idea of mounting pathologic specimens in glycerin jelly in the ordinary

Petri dish used for bacteriologic work. These mounts were very successful, but while waiting to see how long they would remain in the good condition in which they were when first mounted, several articles were published regarding the preparation of specimens in the very manner with which I was at that time experimenting. The author of one of the articles, Dr. W. M. L. Coplin, of Philadelphia, has obtained very fine results by mounting specimens in glycerin jelly, not only in the Petri dishes, but more especially by his Petri-dish-glass-plate method. A number of these specimens were exhibited at the Atlantic City session of the American Medical Association. In endeavoring to make my specimens still more useful and practicable, I conceived the idea about two years ago of mounting stained microscopic sections of the pathologic specimens in the same Petri dish in which the specimen was mounted, so that by placing the Petri dish on the stage of a microscope the histologic features corresponding to the gross characteristics of the specimen could readily be compared. The value of this method will readily be appreciated by all who are concerned in presenting the subject of pathology.

Fig. 1.—Petri-dish-glycerin-jelly preparation of a specimen of cirrhosis of the liver. The stained microscopic section in the lower part of the field was taken from a piece removed from the gross specimen, as seen in illustration.

either to medical students or to practitioners in medical societies. The specimens are prepared as follows:

A small piece (or several pieces) of the gross specimen is removed for microscopic examination. The specimen is then washed free from any blood that may be on its surface and is placed immediately in Kaiserling's solution No. 1,[1] in which

1. Kaiserling's solution No. 1 (the fixative) consists of:
   Formalin (40 per cent. formaldehyd) ..... 800 c.c.
   Potassium nitrate ..... 45 gm.
   Potassium acetate ..... 90 gm.
   Water (distilled) ..... 4000 c.c.

it is left for from a few hours to five or six days, depending on the size of the specimen. This solution fixes the specimen and so hardens it that it will retain its shape. While in this solution the color will disappear. It is then placed in alcohol (95 per cent.), in which it is left for from one to six hours, depending on the size of the specimen. In this solution the color of the specimen again returns. Finally it is placed in Kaiserling's solution No. 3,[2] in which it may be kept indefinitely.

2. Kaiserling's solution No. 3 (the preservative) consists of:
   Potassium acetate ..... 200 gm.
   Glycerin ..... 400 c.c.
   Water (distilled) ..... 2,000 c.c.

If it is desired to mount the specimens in the Petri dish, a gelatin medium consisting of 10 parts of gelatin to 90 parts of Kaiserling's preservative solution[2] is prepared. This is clarified and sterilized just as the ordinary gelatin culture medium is prepared. The addition of a few drops of carbolic acid added to the gelatin while liquid will prevent the growth of moulds which otherwise frequently develop. The same thing may be accomplished by throwing a piece of thymol or camphor on the surface of the gelatin after it has been hardened. This glycerin jelly may be placed in a stock bottle and be used at any time.

Before mounting the specimen a section of the tissue is stained, clarified and mounted in balsam between two cover glasses. It is then mounted on the inner surface of the cover of the Petri dish. The mount is made near the edge of the cover in order that the specimen may be so situated as to be easily examined on any microscopic stage. If the cover of the Petri dish is perfectly smooth (as it should be for this work), the specimen may be mounted directly on the inside of the cover of the Petri dish—the specimen being covered with the ordinary cover glass. When the balsam used for mounting the preparation has become thoroughly dry, the gross preparation may be mounted. This is done by pouring some of the glycerin jelly (liquefied by gentle heat) into the Petri dish, then putting in

Fig. 2.—Petri-dish glycerin-jelly preparation of sarcomata of the intestine and peritoneum secondary to a sarcoma of the uterus. The dotted lines indicate the corresponding parts of the gross specimen and the stained microscopic sections of the same.

the specimen to be mounted, and covering the latter with more of the liquefied glycerin jelly. Enough of the gelatin should be poured into the Petri dish to form a slight convexity above the level of the dish; then a few drops of formalin are added, which assists in preserving the specimen and so acts on the gelatin that it subsequently remains firm, and is not easily broken up. The cover of the Petri dish is then placed over the dish proper and gently forced down in contact with the dish—some of the glycerin jelly necessarily being squeezed out between the cover and the dish proper. When the cover is in contact with the dish a weight is placed on the dish for some hours or until the gelatin has become hardened. Then the gelatin between the cover and the dish is scraped out and a small piece of gauze pressed in. The remainder of the space is then filled by pouring in liquefied hard paraffin. When this hardens the excess of paraffin is scraped off, the specimen is labeled and the preparation is completed.

The mounting of a single preparation requires considerable time and work, but when one sees the quite natural condition in which the specimen may be kept indefinitely and the great value of a preparation when so

mounted that a gross specimen may readily be compared with a microscopic section of the same tissue, it will be readily seen and appreciated that it is worth all the time and trouble required. The illustrations accompanying this article show the results obtained by this method of preparation.

After I had prepared the specimens in this way I thought that there ought to be some way in which the

Fig.3.—View of a hand microscope with the Petri-dish-glycerin-jelly preparation fastened in a special device and so placed as to afford a naked-eye view of the gross preparation. A mounted microscopic section of it is seen at one side.

specimens might be so arranged that when passed around a class of medical students or during a clinic or at medical societies the gross specimen and the microscopic section might be simultaneously compared by the aid of the ordinary hand microscope. To accomplish this I devised a simple attachment, which may be applied to

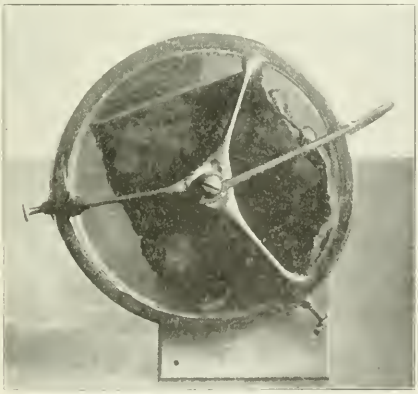

Fig. 4.—View of base of hand microscope with a Petri-dish-glycerin-jelly preparation fastened in special device and so placed that the microscopic section is directly under the objective of the microscope.

the ordinary hand microscope, in which the Petri dish proper may be placed and in which all parts of the specimen may be well inspected by the naked eye and the microscopic preparation then examined by placing it under the objective of the microscope. The device is so arranged that any part of the Petri dish may be placed under the objective and held firmly in place by a spring clamp. A better idea of the device can be obtained from the illustrations.

In my hands this method of preparing and demonstrating specimens has proved invaluable on all occasions when it is either impossible or impracticable to use a large stand microscope, as, for instance, in the clinical amphitheater, in medical societies or in the ordinary recitation room.

I desire to acknowledge the valuable assistance of Mr. L. A. Quaife in carrying out the technic necessary for this work. This method of mounting museum preparation is, of course, just as applicable for anatomic and embryologic specimens as for pathologic material.

A PORTABLE GASTRIC LAVAGE OUTFIT.

JESSE S. MYER, M.D.

ST. LOUIS, MO.

With the modern tendency to simplify therapeutic and diagnostic measures it seems strange indeed that the old method of gastric lavage should be so persistently employed; and this, in spite of the fact that the Leube-Rosenthal method has been so long known to the profession. Surely no one who has employed both methods can consistently maintain that the funnel method is either simpler, cleaner or more efficacious. In fact,

Fig. 1.—Gastric lavage outfit for office or hospital use.

no method may be considered simple which requires the amount of physical exertion necessary in the process of raising and lowering the funnel; no method clean which permits of the possibility of soiling the patient and things about him, and surely no method can be more efficacious than one which permits of the regulation of the in-flow and the out-flow of water, as does the Leube-Rosenthal method. Yet Herschell, though

he considers the apparatus very admirable in the hands of a practiced operator, says it is "too complicated for use in general practice, as almost the skill of a prestidigitator is required to properly manipulate the taps," and then proceeds to describe his "Three-way Tap," a truly complicated procedure. Riegel prefers the 500 cc. funnel, and describes the Leube-Rosenthal method as one applicable only in auto-lavage, which he condemns on general principles. Gillespie describes the method, recommending it in auto-lavage only. Reed recommends the funnel method and warns his readers against procuring "any of the complicated apparatus described in the books" as "troublesome and unsatisfactory." Boas, on the other hand, considers it a most valuable procedure, and uses it in his polyclinic work altogether. "The raising of the big funnel is quite troublesome," says Einhorn, "and I therefore prefer to use in my own practice the Leube-Rosenthal apparatus, which I consider the best means of washing out the stomach." Hemmeter does not recommend this method, but describes one of his own with a continuous current. The continuous current, in my opinion, defeats the chief object of gastric lavage, viz., the elimination of the rugæ, and thereby the removal of mucus and débris from the walls of the stomach.

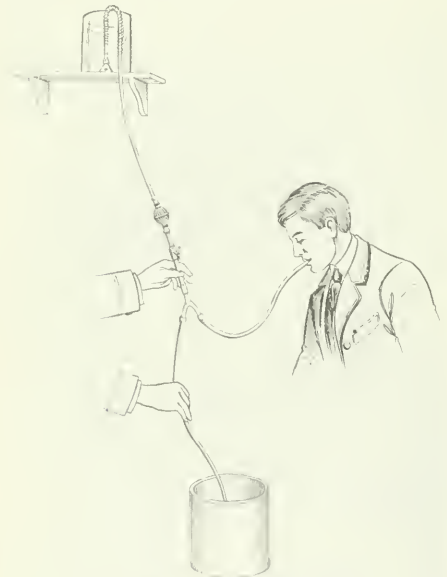

Fig. 2.—Portable gastric lavage outfit.

Strictly speaking, the complexity or simplicity of a method depends not so much on the apparatus used as on the number of movements required to carry out the procedure. In mechanics that appliance is considered simplest and most efficacious which requires least manipulation.

The Leube Rosenthal method consists of a large graduated irrigator, to which is connected a Y-shaped tube, to one arm of which the stomach tube is attached, and to another an outflow tube to a bucket below. Clamps are provided on the arm of the tube leading from the irrigator to the Y, and the one leading to the waste bucket. By manipulating these clamps water is permitted to run into and out of the stomach at one's pleasure.

During the past six years I have employed in my office a modification of this method, as indicated in Figure 1, and it has given me such complete satisfaction that I have discarded absolutely the funnel method, as comparatively impractical and unwieldy. It will be seen that we employ here a double irrigator—not because of its necessity, but because of the occasional desire to use two solutions; as, for instance, nitrate of silver and sodium chlorid. The irrigators are so stationed that they may be readily filled from the water tap. But one clamp is necessary, and that one to stop the flow from the reservoir. The operator stands by the side of the patient and simply manipulates *with his fingers* the tube leading from the reservoir and to the waste bucket; thus regulating the amount of water permitted to flow into the stomach from the graduated irrigators. By compressing the tube leading to the bucket and releasing the one leading from the irrigator, the water flows into the stomach, and on compressing the tube leading from the irrigator and releasing the one to the bucket, the water flows out of the stomach.

For a long time I employed this method in my office and the funnel arrangement when called on to use lavage at the residence or hospital, because of the impracticability of transporting an irrigator. It occurred to me, however, that these same principles might easily be applied to a portable outfit, and the results of the application of these principles are shown in Figure 2. In lieu of the irrigator, this outfit includes a lead sinker, a wire spiral—through which the tube is passed to prevent its collapsing on the side of the vessel—and a small valveless bulb. This outfit may be employed by placing a bucket or pitcher on a mantel or shelf over the patient's head. The flow of water is quickly started by closing the clamp and compressing the bulb two or three times, and after the water starts flowing the procedure is the same as that described above.

This method has been found very useful, too, in producing suction in those cases in which the stomach contents are not readily obtained through expression alone. By releasing both tubes and permitting the water to follow the line of least resistance, flowing rapidly from the irrigator into the bucket below, suction is produced in the tube within the stomach and the contents are readily withdrawn. When the contents are seen to appear at the Y the flow of water may be interrupted by closing the clamp. The stomach tube is then detached and the contents are withdrawn into another vessel. This suction is of such a gradual nature that the contents are more readily obtained than by the use of a bulb or bag.

The chief advantages that may be claimed for this method of gastric lavage are (1) its simplicity; (2) its portability, the whole occupying no more space than the ordinary tube with funnel; (3) but one person is required to manipulate it, and this may be done by a competent nurse or assistant, (4) a large amount of water may be used in a very short period of time without that constant trouble of raising and lowering the funnel and handling a heavy vessel full of water; (5) the removal of the stomach contents is facilitated through suction if desired.

4319 Lindell Boulevard.

A NEW SUPPOSITORY FOR THE MEDICAL AND SURGICAL TREATMENT OF THE NASAL CAVITIES.

EDWARD BAUM, A.B., M.D.

Formerly Assistant Resident Surgeon, Maryland General Hospital; Late Assistant in Surgery, Baltimore Medical College, Baltimore.

BALTIMORE.

Specialists in nose and throat work, especially the former, generally desire to render the effects of applications made to the nose or throat of longer duration than is usually the case with the swab, spray, nebula, ointment, or insufflation.

It is to this end that I have devoted much time and attention, the result of which I desire to submit for consideration.

The shape of the nasal suppository, which I present, conforms to the nasal cavities (Figs. 1 and 2). It is an oblong, oval-shaped body. The inner surface is flat (Fig. 2); the outer one is irregular (Fig. 1). The distal end is rounded and has a handle-shaped proximal end. The outer surface approaching the turbinates is irreg-

ular, with two longitudinal oval ribs corresponding to and fitting into the meati (Fig. 3); the lower rests on the floor of the nose and adapts itself to the inferior meatus. The upper approximates itself to the middle turbinate. These two ribs run parallel the length of the body of the suppository, and join each other at the interception of the body with the neck of the handle, thus forming a pocket or sulcus. Between these two longitudinal oval ribs is a long trough-shaped depression, open at its distal end and terminating in the sulcus, which approximates and admits the inferior turbinate. Immediately above the upper longitudinal rib

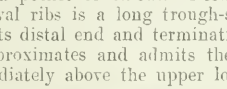

Fig. 1.—Suppositories, outer surface. L., left; R., right.

is another but smaller trough-like groove extending the whole length of the upper rib in which the middle turbinate rests and which continues upward, enveloping the middle turbinate. It then diminishes to a very thin edge, terminating two-thirds distance from the floor of the nose, and extending downward continuous with the septal surface.

The inner septal surface (Fig. 2), from above downward, is flat and smooth, and is interrupted in its continuity by a small oval projection or double-curved rib lying longitudinally from the handle to the oval end, separating (one-third above and two-thirds below)

Fig. 2.—Suppositories, inner or septal surface. L., left; R., right.

the suppository from the septum. This rib or narrow double-curved projection is the only point in contact with the septum, dividing mechanically the current of air, thus permitting free ingress and egress of air in breathing. It also serves to maintain the suppository in position, keeping in apposition the surface of the opposite side, and continually in contact with the turbinates, besides filling in the meati.

The handle-shaped end permits a secure grasp in introducing the suppository, and when in position the handle rests on the inner surface of the lobe of the nose and prevents its expulsion.

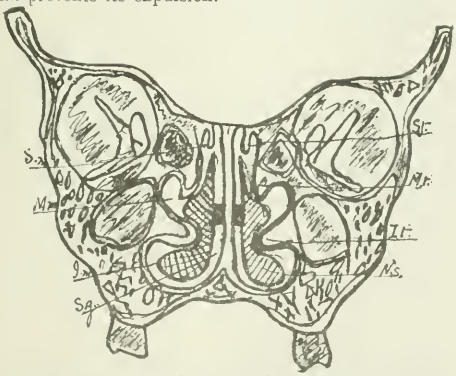

Fig. 3.—Cross section. S., septum; S.m., superior meatus; M.m., middle meatus; I.m., inferior meatus; Sg., air space; N.s., nasal suppository; I.t., inferior turbinate; M.t., middle turbinate; S.t., superior turbinate.

The distal end is rounded from above downward, and is irregular from side to side; it enters the nostril first and is so shaped as to facilitate its introduction.

The forms and conditions in which the nasal suppositories have been used are as follows:

First. The insoluble, unmedicated form in the manner of an internal splint for simple fracture of the nose.

Second. The insoluble form, medicated (antiseptically), as in the first instance with complications, the result of trauma, to maintain the internal conformity of the nasal cavities.

Third. The soluble or melting medicated form, the effects of which by its mere presence in the nose is of a dynamic nature. In relaxed, turgent, flabby turbinates, this effect is prominently noted, causing contraction and retraction immediately. This effect is temporary, but when astringents are incorporated the effect is prolonged.

Fourth. The soluble medicated form; any formulas or combinations can be incorporated for special treatments. Any of the usual sedatives, stimulants, depletives, astringents, antiseptics, anesthetics, deodorants, mild caustics, and escharotics can be combined in a spe-

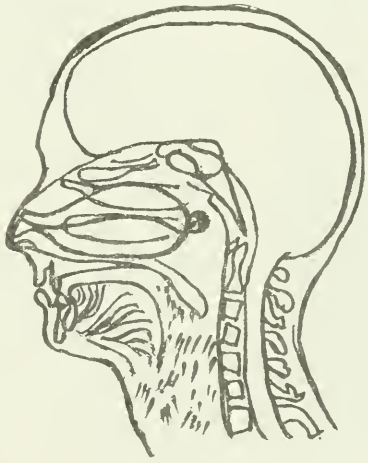

Fig. 4.—Nasal suppository *in situ*.

cial formula as the case may be and for the results desired.

ADVANTAGES.

Advantages experienced with the soluble medicated form: 1, the simplicity with which they can be introduced; 2, the length of time in which the medication can be applied; 3, the melting of the suppository at body temperature, thus setting free its medicant, which lasts from six to eight hours, constantly medicating the affected parts, besides affording a splendid protection against infection; 4, free bathing at all times; the septal surface is the last to disintegrate, this being provided for by the air-spacing between septum and suppository; 5, the suppository can be introduced at any time of day or at bedtime; 6, after surgical operations, this furnishes a splendid dressing; by its constant pressure it prevents oozing and facilitates removal of accumulations in subsequent dressings; 7, it is a valuable protection for mucous membranes from all irritating inhalations of dust, grit, acid fumes, etc.

FORMULAS.

The three formulas below have been used for their respective conditions and good results have been noted.

For catarrhal conditions:

R. Olei cassia.....m. v
Olei eucalypti
Olei gaultheriæ, āā.....m. vii
Camphoræ
Menthol, āā.....gr. iv
Thymol.....gr. iii
Olei theobromæ q. s. ad 3i

M. Ft. suppositories No. xii. Sig.: Insert one in each nostril at bedtime.

For hay fever:

R. Ext. suprarenal
Hydrastini, āā.....gr. i
Camphoræ monobromatis.....gr. xxiv
Menthol cryst.....gr. x
Antipyrini.....gr. xv
Resorcini.....gr. v
Olei theobromæ q. s. ad 3i

M. Ft. suppositories No. xii. Sig.: Insert one in each nostril any time of day or at bedtime.

For acute coryza:

R. Olei cassiæ.....m. ii
Olei anisæ.....m. iii
Olei thymæ.....m. iv
Olei eucalypti.....m. iii
Phenol
Camphoræ
Menthol, āā.....gr. iii
Olei theobromæ q. s. ad 3i

M. Ft. suppositories No. vi. Sig.: One suppository to be inserted in each nostril during the day or at bedtime.

1421 McCulloh Street.

A CASE OF HYPERTROPHY OF THE BRAIN.

JAMES. H. HABERLIN, M.D.

PAWTUCKET, R. I.

Patient.—Matthew B., aged 2, born in U. S.

Family History.—The father, an alcoholic, emotional and excitable, died just after patient's birth, aged 52. Two years before the patient's birth, the father had a painless, nonitching eruption on his legs, thorax and abdomen, and at the same time lost most of his hair and complained of lancinating pains in his head and extremities. The mother was 35 years old when the patient was born. She has always worked hard, always drunk alcoholic stimulants and, of late years, to excess. She married at 18 years of age and has seven living children and one abortion. The second child was born at eight months, lived five hours, and died in convulsions. The fourth born, now eleven years old, is a high-grade imbecile. The abortion was probably due to syphilis.

Previous History.—The patient, the last born child, was delivered with forceps. The head was somewhat larger than the heads of the previous children were at the time of their birth. The child cried as lustily as any of the previous children, and, excepting the comparatively large size of the head, was apparently normal. At three months his mother noticed a disproportionate increase in the size of his head, which continued until his death.

Present Illness.—I saw the baby Feb. 10, 1906, at eight o'clock in the evening. The first symptom that appealed to me was the large size of his head. Noticing a papulo-squamous rash on the forearms and face of his mother, I thought the case very probably one of chronic hydrocephalus of syphilitic origin. The patient had been seized with an epileptiform paroxysm previous to my coming, the mother said, and had just become profoundly prostrated, with twitchings of his face and hands. When I saw him he was comatose, but tossed his head from side to side, grasping in a purposeless way from time to time at things within his reach, and occasionally emitting the hydrocephalic cry. Later the coma deepened, the vacillations of the head gave way to convulsive twitchings of the facial muscles, the movements of the arms and hands became athetoid, and the breathing approached a Cheyne Stokes character. The pupils were asymmetrically dilated and did not respond to light. The tongue was coated with a grayish-brown fur and the teeth were covered with sordes. The pulse was too rapid and feeble to be counted. There was no rash on the body, but over the right, external femoral condyle was a ham-colored, circinate spot as large as a 25-cent piece. The lungs were normal, the abdomen was tympanitic, there were no symptoms of rachitis. The body and extremities were emaciated. Kernig's sign and Babinski's reflex were absent. The knee-jerk and the ankle-clonus were exaggerated.

The head resembled hydrocephalus of the average type. It was pyramidal in shape on the frontal aspect, symmetrical in its enlargement and presented that prominence at the root of the nose which Holt says is seen in no other form of enlargement of the head than hydrocephalus. There was no bulging of the eyes, nor did the interocular distance seem to be increased. The anterior fontanelle was patent and about two and one-half inches in diameter, but there was no separation at the sutures.

The patient died during a recurrence of the epileptiform paroxysm about three hours after the first seizure.

Autopsy.—With the assistance of Drs. W. G. Dwinell and O. G. Ingham, the autopsy was made the following day. The calvarium was removed in a wedge-shaped piece by sawing clear through. The dura was densely adherent to the bone and its removal required great force. The sutures were firmly ossified and the anterior fontanelle was covered with a dense membrane. The meninges were enormously thickened and adhered as one membrane. The superior longitudinal sinus was obliterated. The meninges did not adhere to the brain. The convolutions were not flattened. In removing the brain the cranial nerves were found markedly degenerated. The third, fourth, seventh and eighth nerves were torn easily by pressure of the back of the scalpel. The right occipital lobe was injured by the saw in cutting through the bone. The area of the brain substance thus exposed was pultaceous. The brain, as a whole, was apparently symmetrically enlarged. Very little fluid escaped as it was lifted from its bed. There was nothing especially significant in the thorax or abdomen.

Measurements.	Patient.	Normal Child, 2 Years.
Circumference of head	55 cm.	47.2 cm.
Circumference of thorax	38 cm.	48.4 cm.
Length of body	78 cm.	82.8 cm.
Weight of brain	1712 gm.	1000 gm.

The brain was placed in 80 per cent. alcohol for 9 hours, and later in successive changes of 95 per cent. alcohol. We attempted to examine the brain by Virchow's method, 43 hours after the child's death. Immediately below the surface we found the matter so pultaceous that a satisfactory demonstration was impossible. The following facts, however, were observed: The membranes were not adherent to the brain substance at any part; there was no flattening of the convolutions, no neoplasm, no disproportionate increase in the size of the ventricles. The various foramina were patent. The gray and white matter were developed proportionately.

I have not attempted an exhaustive research of the literature of this subject, but have simply reported this case to add to the literature of an apparently very rare condition, for in the works at my immediate service, among them those of such men as Dana, W. G. Thompson, Potts, Osler and Tyson, I find no mention at all of hypertrophy of the brain.

The case presented no signs by which hydrocephalus could be excluded. If it were not that we were fortunate in obtaining consent for an autopsy, we should yet believe the case to be one of hydrocephalus. The question naturally arises, how many cases like this with the cardinal symptoms of hydrocephalus have been incorrectly diagnosed.

Incentives to Greater Effort.—M. A. Austin, in *Central States Medical Magazine*, states that losing a case, having complications arise, or having unexpected difficulties to overcome, are reasons for constant study, greater care and more vigilance.

A CASE OF POISONING FROM VERONAL.

JOHN GERMANN, M.D.
BROOKLYN, N. Y.

Patient.—E. G., aged 22, male, a school teacher, unmarried, was found in a state of profound coma from which he could not be roused and died 79 hours afterward.

History.—The attending physician makes the following statement: "E. G., a young man of intelligence and a patient of over two years' standing, came to my office on the afternoon of January 13 and stated that he was suffering from insomnia. I advised against the use of any drug, telling him that the drug habit was worse than the rum habit. I advised him to give up a night class he was teaching and to try a hot bath at bedtime. He said that he could not give up the class and that he got home too late to take a bath. After some further talk I was about to write for a simple sedative when he asked me if I would not write for veronal, as his sister was taking it with marked benefit. I said that I had not used the drug, but that Merck's preparations were standard. The statement in the newspapers that I asked him how to spell the name of the drug is untrue. He obtained on my prescription a vial containing fifty 5 gr. tablets, with directions to take two tablets at bedtime. There were no directions to repeat or to increase the dose. So far as is known, he took none at bedtime. According to his father's testimony he went to his room at 9:30 Sunday morning and at 12:30 was found sleeping so soundly that he could not be roused. The vial was empty and none of the drug was found." The patient is supposed to have become impatient and to have taken from 200 to 250 grains instead of waiting for one or two doses to take effect.

Symptoms.—When found, four hours after a hearty breakfast, the pulse was 90, respiration 24. Half an hour before death, 79 hours later, pulse was 152, respiration 44, temperature 108.5. During the last 24 hours the respiration was irregular and stertorous and the man was cyanosed. The heart seemed the least affected; the pulse was of good quality till the last four hours.

Treatment.—Cathartic enemas were given and also high rectal enemas of hot saline solution. Coffee, caffein, diuretics, strychnin, oxygen, adnephrin, and saline solution by hypodermoclysis were all tried but without effect. After 24 hours, the urine contained albumin and a specimen 2 hours before death contained 33 per cent.

Autopsy.—The brain and all the organs were found deeply congested (but only *slight edema* at brain). The organs, especially the abdominal, were dark and the blood was chocolate colored. The stomach, especially, was greatly congested, with a hole 3 inches in diameter—caused by postmortem digestion.

Coroner's Verdict.—"E. G. came to his death on the 17th day of January, 1906, at 90 Norman Avenue, by cerebral congestion and edema, and nephritis caused by taking an overdose of veronal to produce sleep."

Remarks.—If any symptoms could be of an unusual character, I should judge they were the following: 1. Persistence of the coma for a period of 79 hours. 2. The fact that the pulse remained of a good character over such a period of time. 3. The gradual and steady rise of temperature from normal to 108.4 antemortem. 4. The increase of the respirations from 24 to 44. 5. The fact that cyanosis should appear so late in the case. 6. The presence of albuminous urine. 7. The intense cerebral congestion, found postmortem, and the very slight edema. 8. The discoloration of the organs—deep congestion, and the altered blood—dark chocolate color. 9. The intense congestion of the stomach, especially of the cardiac end, and the postmortem digestion of the large space of three and one-half inches in diameter.

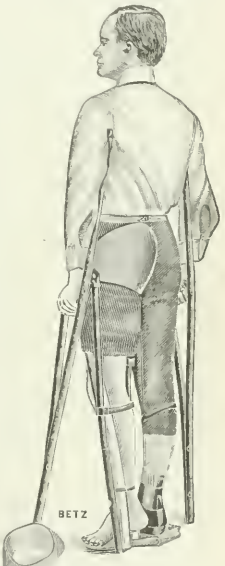
Concerning the manner of prescribing veronal, I can make no comments. The physician ordered 1 bottle of 5 gr. tablets of veronal (Merck). Dose 2 at bedtime. The dispensing druggist, not having a full bottle of 100 on hand, gave the young man 50 tablets. The only remedy, in my opinion, is to wash the stomach thoroughly if the case is seen within 2 or 3 hours after the ingestion of the drug.

A NEW EXTENSION SPLINT.

J. P. HETHERINGTON, M.D.
Surgeon for Pennsylvania, Vandalia, and Wabash Railroad and Union Traction Co.
LOGANSPORT, IND.

I am never called to treat a fracture of the hip or femur without feeling that I wish it could have been some other bone. Many methods of treatment have been tried, almost any one of which means that the patient must remain on his back for from four to six weeks. The pneumatic splint allows a patient to leave his bed, but the yielding air cushions do not give a stable point of extension and the splint is heavy. In bed the roll under the thigh and the rods down the back of the legs lack comfort.

Several years ago I studied the various methods of obtaining the upper bearing. Some surgeons used the perineum and others the axilla for the various extensions and crutch splints. I talked with the makers of artificial legs, and nearly all advised a hard, firm substance, slightly padded, for an artificial leg socket, so I decided that if a solid support were required to sustain the weight of the body it would certainly be sensible to have the same kind of support for a sustained extension of from five to twenty-five pounds on a broken leg. I tried the upper part of an artificial leg socket instead of the perineal band. Then I had half a dozen variously shaped hip and perineal bands hammered out of aluminum, until I finally succeeded in getting quite a comfortable hip-piece. This threw nearly all the weight on the ischium, almost entirely relieving the perineal pressure. The hammered aluminum, however, was brittle and would crack, so I had a light steel band made to fit the hip, and around this placed a shaped mold of fiber and leather. This made a splint that was easy, comfortable, and borne well day after day, but being constructed of steel and leather, it was heavy, and when permeated by various discharges its peculiar odor put it out of use.



I have made several unsuccessful attempts to have the splint cast of pure aluminum, but one maker after another gave it up until recently, when an expert patiently worked at it until he made a set of three sizes, both right and left. The medium size will fit nearly any ordinary person.

I had him make a "skeleton framework" consisting only of adjustable inside and outside rods and footpiece so that I could apply splints between or bandage around them (Fig. 1). Being lightly constructed of pure aluminum it is not strong enough to bear a heavy weight while walking on crutches, but a splint weighs less than four pounds complete. It will not rust, and being of solid metal it can be scrubbed or boiled. I have found it painful to use a bandage or pneumatic pad above the ankle for extension fastening, so I use the adhesive plaster along each side of the leg. The upper part, which I call a "hip housing," fits tightly. The broad thin metal is far more steady and comfortable than a narrow ring, and adds to the comfort in bed. While the pneumatic ring forms a thick pad and undesirably forces the upper fragment upward, the thin housing occupies almost no space between the hip and bed, assists in holding a short upper fragment inward, and, if padded underneath, helps to elevate the sacrum in guarding against bed sores. At the same time it is clear off the median line and aids rather than hinders evacuation of the bowels.

This seems to be another step toward making these patients more comfortable while obtaining the desired extension.

THE INDEX.

In spite of the fact that we have added additional pages in this issue, the index occupies so much space that we are compelled to omit some departments and to reduce the amount of space devoted to others. We do not hesitate again to call attention prominently to this index. We have repeatedly stated that the index to current literature, which occupies the greater portion of the space devoted to the whole index matter, is something entirely different to an ordinary index. It is an index to the current medical literature of the world, but especially to that of the United States. It must be used to be appreciated, and those who have occasion to look up subjects and who are not making use of it are urged to do so. It is not so complete in details as the *Index Medicus* or as the "Index to the Surgeon General's Library," but it will be found to have advantages over these, and peculiar to itself. The explanatory notes at the beginning of the departments should make its use easily understood. As usual, this index will be reprinted[1] in paper cover under the title, "Guide to Current Medical Literature." Included in this reprint will be the names of the journals and the titles of the articles, so that ready reference can be made without using The Journal.

THE EVOLUTION OF SPECIFIC THERAPY.

We are so accustomed to glorify the achievements of modern medical science that we sometimes seem to lose sight of the fact that great discoveries generally are the direct outcome of a gradual development which can be traced far back into the past. To many the discovery of antitoxins and the birth of the idea of a specific etiologic therapy of infectious and toxic diseases, so splendidly realized in the practical use of diphtheria antitoxin, probably appear to have little or no connection with the therapeutic conceptions and efforts of the past, whereas, in reality, in this particular instance, an objective point was reached toward which men had been striving with varying clearness of purpose for centuries and often, no doubt, in despair as to the desired outcome.

In the first place, it is of importance to note that the diseases now known to be infectious appear to have been regarded since the very beginning of history as representing reactions of the living body to special poisons and even in the earliest times epidemic infectious diseases were treated according to general principles similar to those that controlled the treatment of various obvious poisonings, namely, by means that were assumed or expected to destroy and to neutralize the morbific cause. Later, it is true, eliminative forms of treatment were introduced also. There are numerous isolated facts that indicate that the principle of immunization, both in the form now called passive, as well as in the active form, was recognized in very early times and even by uncivilized peoples. Thus, for instance, active immunization against snake-bites is said to have been practiced by African aborigines since time immemorial, and certain historical remedies of early European medicine contained parts of certain animals because those animals were known to be able to withstand poisonous substances. Amulets, the use of which persisted even into the modern era, were employed originally to ward off evil spirits capable of causing disease. Certain forms of amulets suggest efforts at immunization. This is especially true of those that contained poisons of various kinds and which were supposed to protect the bearer by habituating him to the poison. In the middle ages toad-amulets were held to be the best antidote to pest, and they were recommended particularly by Kirchner, one of the first to advocate a parasitic etiology of infectious diseases, because toads were held to originate from the same causes as the pest and were believed to contain in them the pest poison. Amulets were supposed to act also by virtue of a sympathy of poisons which attracted one another and thus to afford protection to the bearer.

In time the idea arose that a substance might be found which would be a universal antidote against the disease-producing poisons of all fevers and epidemics, and for this purpose the celebrated theriac, a mixture of at least 64 different substances, was introduced and used for centuries. Eventually, certain single substances came to be employed as specific antidotes in certain conditions, and the discovery in the sixteenth century that mercury is a specific against syphilis, together with the gradual differentiation of individual infectious diseases, led in the seventeenth century to systematic efforts to discover specific remedies for various infectious diseases, and the plan proposed was nothing less than to attack the special cause or poison of each disease. According to some, this poison was a chemical substance or ferment; according to others, minute organisms, such as worms and mites, later infusoria. Following the demonstration that the bark of the cinchona tree is or contains a direct antibody to the cause of malarial fever—the fermentum febrile—the great Sydenham boldly placed specific therapy as the ideal for medicine. Lange (1655-1701) was an early believer in the theory that infectious diseases are due to minute living things, and he advocated the use in treatment of these diseases of substances that arrest putrefaction or act as vermifuges. Rivinus also urged the use of anthelmintic and antiparasitic agents. It may be not without significance for later developments

1. This reprint is supplied at 50c a copy, or 75c a year.

that the value of antisepsis was early recognized in England, as shown in the following quotation from Francis Bacon: "It is an inquiry of excellent use to inquire of the means of preventing or staying putrefaction; for therein consisteth the means of conservation of bodies; for bodies have two kinds of dissolutions; the one by consumption and desiccation; the other by putrefaction. But as for the putrefactions of the bodies of men and living creatures, as in agues, worms, consumption of the lungs, impostumes and ulcers, both inwards and outwards, they are a great part of physic and surgery."

We must pass over without discussion the influence of the introduction of inoculation of smallpox, practiced for centuries in China and elsewhere, and of the discovery by Jenner of vaccination. In the beginning of the nineteenth century Eisenmann, in Germany, outlined with great clearness the necessary steps in order to discover by way of clinical observation and experiment specific curative agents for the individual infectious diseases, the particular aim being to find substances that would kill the organisms of the contagion without injury to the patient. These necessarily incomplete references will serve to emphasize at once the antiquity as well as the gradual growth in precision of the conception of a specific therapy aimed directly against the essential morbific agent. So far as a small number of diseases is concerned, the problem was solved finally by the discovery in our day of antitoxins, and as for the discovery of specific agents against the many diseases still without direct curative treatment at no time has the outlook been so promising as now.

PRESIDENT-ELECT BRYANT.

Dr. Joseph D. Bryant, President-elect of the American Medical Association, was born in East Troy, Wis., March, 1845, and was graduated from the Bellevue Hospital Medical College in 1868. He has held many important positions, and is now professor of principles and practice of surgery, operative and clinical surgery at the University and Bellevue Hospital Medical College, New York; visiting surgeon to St. Vincent's and Bellevue hospitals, etc. He has long held a high position both as an operator and as an authority on surgical subjects. His "Operative Surgery" took front rank as a standard text-book as soon as it was published, and has become more of a favorite with each edition. His miscellaneous contributions have been many and varied, and always of the highest order.

But it is not alone as a surgeon, or as a writer, but for what he has accomplished in a broader way for his profession, that Dr. Bryant is honored and loved. Without ostentation or display he has been actively interested in the various endeavors the American Medical Association has been making for the betterment of conditions among medical men. To him great credit is due for bringing together the profession of the Empire state and for terminating the differences that had existed there for nearly a quarter of a century. It was during his presidency of the New York State Medical Association, in 1899, that the movement really had its start, and while he was president of the Medical Society of the State of New York he had further opportunity, but both the opportunity and the right man were necessary; and he proved to be the right man.

It was certainly a fitting recognition of his services that the reorganized Medical Society of the State of New York elected him as its first president under the new order of things, although he had just presided for a year over the society.

Dr. Bryant is a genial companion, and his society is sought by men high in other professions. He is a practical man, and as such one of the most successful practicing surgeons in the country. Those who know him well enough to appreciate the energy and enthusiasm, and withal the good judgment which he puts into everything he undertakes, will agree with us when we state that the American Medical Association has honored itself by electing Dr. Bryant its president as much as it has honored Dr. Bryant.

VARIABLE TEMPERATURE THERAPY OF FEVER.

One of the interesting developments in modern therapeutics is the use of fresh air in the treatment of tuberculosis and of all the other diseases that are related to it in their effects on temperature and general health. As the result of the success of these newer methods there has come to be a very general impression that fresh air can also be of great service in the treatment of all febrile affections. It used to be considered necessary that patients suffering from tuberculosis, especially if the disease were running a febrile course, should be kept in an equable temperature without any danger of being affected by draughts or by air that came directly from outside the house. This has been recognized as one of the mistakes of the older method of treatment and, as a consequence, there is coming to be a general impression that other fevers, no matter what their origin, may also be best treated so far as possible in the open air.

The ideal of house and hospital ventilation has come to be that an abundance of fresh air should be supplied, but that this air should always be of a definite temperature, not much below 70 degrees, in order to avoid the supposed dangers of draughts and the exhaustion that might be due to radiation of heat. Is it not possible, however, that this ideal has been founded on a mistaken notion? Under ordinary circumstances, healthy individuals have been accustomed to live under conditions of temperature that represent a variation of from 20 to 40 or more degrees Fahrenheit during the course of the day. This variation of temperature acts as a stimulant to various metabolic processes within the body. It now seems manifest that the reactions by which disease is overcome are to no small extent dependent on these stimulations of metabolism consequent on variations of

temperature. Dr. Burney Yeo has called attention in his book on "The Therapeutics of Mineral Springs and Climates" to the fact that, while a mild equable climate without noteworthy variation between day and night temperature is good for patients suffering from catarrhal symptoms of various kinds, such a climate is only conservative, but never actively curative. It lacks the supreme quality of natural stimulation that is so effective for increasing resistive vitality. Tuberculous patients, Yeo says, do not improve unless there is a daily variation of at least 20 degrees of temperature; hence, it is that, while consumptive patients are often very comfortable along the northern shores of Africa, they do not improve to such a degree as to be able to live out of that climate. On the other hand, it is well known that at a considerable altitude, where the changes between night and day temperature are marked and always represent from 30 to 50 degrees of variation, consumptive patients, according to clinical experiences, are more likely to get well and even to be able to resume their previous occupations than anywhere else.

Certain it is that the ordinary healthy individual would not find himself under favorable circumstances for continued good health in an absolutely changeless temperature. It is a little bit like an absolutely unirritating diet. A certain amount of irritation of the gastrointestinal tract is needed in order to maintain peristalsis. In the same way, the irritation of the skin consequent on variation of temperature stimulates the vasomotor mechanism of the capillary system of the skin and so proves excitant to metabolic activity through the increased circulation. It is in the exhausting processes of continued fever that such stimulation is most needed. The suggestion made by Dr. Walter James at the recent meeting of the Association of American Physicians at Washington[1] that all fever patients should be given the benefit of this important therapeutic factor calls attention to what has been a much neglected feature of physical therapy.

There seems to be considerable clinical experience already at hand to justify the employment of this method of treatment quite apart from recent advances in phthisiotherapy. In New York at the Presbyterian Hospital and at the Fordham Hospital the treatment of pneumonia in the open air, the patient, protected only by a tent even in inclement weather, it is claimed, has given better results than the most careful housing of patients. A distinguished English clinician declared that if he had pneumonia himself he would prefer to be treated under the trees of a park than in the best-appointed hospital of any large city in the world. Pneumonia is one of the diseases in which owing to the inflammation in the lungs it might be thought that warm air would be of more benefit than cold air, yet clinical experience is all against such an impression. In other fevers there is no doubt that patients are much less restless, sleep far better at night and need fewer sedative drugs, and these are practically always depressant to some degree, if they are kept directly in contact with the outer air than otherwise. In fact, it is this feature of the cases that is particularly noteworthy. Sleep depends, so far as we know anything of its physiology, on cerebral anemia, and this does not readily occur unless the blood vessels of the skin have been stimulated by variations of temperature during the day. When cold air baths can be given to typhoid-fever patients there is very little need of cold water baths, and even cold sponges need not be employed so frequently as is ordinarily the case. Cold air is much less depressing than cold water and does not require for its application either the apparatus or the disturbance of the patient necessary for cold bathing.

It would seem, then, that cold air should be admitted much more freely than has been the case, especially to fever patients. It is well known that children suffering from surgical tuberculosis improve rapidly and sleep much better in a room so cold that nurses and physicians need to wear gloves and special wraps in order to keep comfortable. There has been entirely too much dread of cold air and of the effect of draughts. Draughts can only cause congestions when patients' temperatures are already somewhat subnormal. With a temperature above normal there is apparently no danger of the taking of cold from the presence of cold air, while there are apparently very desirable therapeutic effects quite in line with our recent advances in natural and physical therapy that may thus be obtained. Much prejudice needs to be overcome before sufficient clinical experience to determine its value can be secured, but it seems well worth trying faithfully and diligently.

1. The Journal A. M. A., June 2, 1906, p. 1722.

PRIMARY TUMORS OF THE URINARY BLADDER.

Primary tumors of the urinary bladder are relatively rare. Their period of greatest prevalence is between 60 and 70. Men are the victims far more commonly than women. As with new growths in other situations, no special cause has been definitely established, although the predisposing cause is considered generally to consist in some form of irritation. For the purpose of eliciting certain clinical data and of investigating the pathologic anatomy of the simple epithelial tumors of the bladder, also known as papillomata, Dr. Lincoln Davis[1] undertook an analysis of 41 cases observed at the Massachusetts General Hospital during a period of 28 years. In 37 of these the tumor was removed at operation and in 4 it was obtained at autopsy. As the result of clinical and histologic study of these specimens he reaches the conclusion that stone in the bladder is not an etiologic factor of importance in the causation of the tumors under consideration. The condition of the underlying bladder wall in regard to epithelial infiltration is the most satisfactory and reliable guide in the determination of the benign or malignant character of papillary epithelial tumors of the bladder. If the foregoing is

1. Annals of Surgery, April, 1906, p. 556.

accepted as the differential test for these growths, then will the benign forms commonly called papillomata be found at least to equal if not to outnumber the malignant, the papillary carcinomata. Recurrent epithelial tumors are not necessarily malignant. Papillary tumors of the bladder, proved to be histologically benign, may rapidly lead to a fatal result if left alone. Surgical intervention at the proper time in the case of pedunculated papillary tumors of the bladder offers a fair chance of long immunity, if not of permanent cure. The method of surgical intervention to be preferred in these cases is excision of the tumor entirely, with a margin of bladder wall at its base, including mucosa, submucosa and muscularis in part; the section need not penetrate the entire thickness of the wall. In this way a beginning epithelial infiltration of the base, if present, may be circumvented; or if it is not present, the knowledge of the fact is of great value in the important matters of diagnosis and prognosis. The defect in the bladder wall should be closed with sutures, which will at the same time control hemorrhage. The gravity of the operation is not appreciably increased by this procedure.

VIRTUE ITS OWN REWARD AT SAN FRANCISCO.

During the late earthquake troubles in San Francisco the physicians of that city, hard-hit as they were by the catastrophe, were called on as a class more than any other citizens to use their special knowledge and skill in the emergency conditions that resulted. It seems that while others who rendered special services, militiamen, mechanics, plumbers, nurses, etc., received pay for their services—and no one grudges it—there is no provision whatever for any recompense to the physicians. Their services were appreciated as inestimable during the calamity. But the adjective applies also to their compensation and, therefore, the problem is dropped as unsolvable. The general relief committees seem to have no means to pay for their services or are so tied up by legal restrictions that they could not do it even if they had the means. The justice of this is sufficiently obvious, but it is the way things go. As Governor Pardee, who can appreciate the physician's side of the question, says, the medical men of San Francisco were probably the greatest sufferers of any class of citizens, and when the history of the disaster is written "the devotion of the physicians of San Francisco to their duty will receive the prominent place that it deserves." It may seem small comfort to say to a man who is in need that virtue is its own reward, but it may be that that is all the consolation that can be given to the San Francisco physicians at the present time. It is really something, however, to feel that one has acted on the best traditions of his profession and has not dishonored the flag.

Treponema Pallidum and Mercurial Treatment of Syphilis.—*Spitalul* contains an article in the last issue for 1905 describing research on the treponema in syphilitic lesions under mercurial treatment. The number found in the lesions always decreased as treatment progressed, dropping from five or six in each field to one or two before complete recovery. An abstract in the *Muench. med. Wochft.* states that the mercury was injected in the buttocks in the form of 0.03 gm. sublimate every fourth day.

Medical News

CALIFORNIA.

Hospital Opened.—The Whittier Hospital was formally opened with a reception, June 4.

Bequest.—By the will of the late Bartlett Doe of San Francisco, the Fabiola Hospital, Oakland, and the Hospital for Children each receives five-eightcenths of 1 per cent. of the estate, which is valued at more than $2,000,000.

Leper's Home Burned.—By order of the mayor of Santa Ana, the house in which a leper has been living in that city was burned. Three adjoining buildings and vegetable gardens, where the leper had worked, were also destroyed.

Lane Lecture Course.—Cooper Medical College announces that the course of Lane medical lectures will commence August 20, and will continue during five days of the week, two lectures being delivered daily. The lecturer is Dr. John C. McVail, D.P.H., Glasgow, Scotland, and his subject is "Practical Hygiene, Epidemics and Preventive Medicine."

Medical School Rearrangement.—The University of California has transferred from San Francisco to Berkeley all instruction in the first two years of the college of medicine. Students desiring admission to the medical department of the university must have completed certain studies in physics, chemistry, zoology, German and French, which ordinarily require two years of residence at a university or college of good standing. The first two years of the strictly professional work is devoted to anatomy, physiology and pathology. As heretofore, the work of the last two years of the medical course—the clinical years—will be carried on in San Francisco in the affiliated college buildings. The dispensary, heretofore situated in what is now the burned district of San Francisco, will now be established in the medical building.

ILLINOIS.

New Hospital.—A private hospital has been established by Dr. William Blender in Carthage.

Physician Acquitted.—Dr. Robert Emery, Peoria, accused of manslaughter by a criminal operation, was acquitted by the jury, June 8.

Alleged Smallpox.—Dr. Emil Lofgren, health officer of Rockford, has investigated the cases of alleged smallpox at Rockton, and states that the disease is not smallpox.

Medical Fraternity Election.—At the meeting of the Medical Fraternity of Jacksonville, May 8, Dr. John W. Hairgrove was elected president, and Dr. Emma Grace Dewey, secretary.

Smallpox.—A number of cases of smallpox have been reported from Hurricane Township, Fayette County, near Bayle City, and Dr. J. C. Westervelt, inspector for the State Board of Health, has been sent to make an investigation.

Resolutions of Regret.—At a meeting of the Bi-County (Iroquois-Ford) Medical Society, June 5, resolutions were unanimously adopted setting forth the long and honorable career of the late Dr. Daniel L. Jewett, Watseka, first president of the society, and deploring his decease.

Loan to Hospital.—The Oak Park Hospital and Training School for Nurses, of the Sisters of Misericorde, has obtained a loan of $100,000 for 15 years, at 4½ per cent., from the parent organization in Montreal, secured by a mortgage on its property in Oak Park.

Chicago.

Hospital Enlarged.—Grace Hospital, at Sangamon Street and Jackson Boulevard, has been enlarged so that its former capacity is doubled. It now can accommodate from 60 to 70 patients.

Personal.—Dr. Casey Wood was granted the *ad eundem* degrees of M.D. and C.M. by McGill University, Canada, for "services to medical science."——Dr. and Mrs. B. Fantus have gone to Germany to spend the summer.

Clinical School Election.—At the annual meeting of the directors of the Chicago Clinical School, Dr. W. T. Eckley was elected president, Dr. George F. Hawley vice-president, Dr. Arthur M. Corwin secretary and Dr. John S. Nagel treasurer.

Fourth of July Warning.—The *Bulletin* of the Department of Health quotes from the editorial in THE JOURNAL on this subject, and speaks of the improvement of the tetanus situation in the past two years. It urges that all Fourth of July wounds, no matter how caused or when caused, should be kept open to the air until seen by a physician.

Health Conditions.—The death rate last week was equivalent to an annual death rate of 10.76 per 1,000 of population.

The average June rate for 10 years has been 13.04. The hospital population at the close of the week was the lowest in the previous three months. Pneumonia patients are fewer than since the close of last October. Typhoid is less than for many weeks.

Ice Very Good.—The *Bulletin* of the Department of Health reports that of the 167 samples of ice analyzed since Feb. 1, 1906, only 1.5 per cent. were below standard. This is the best showing for years. Although the ice is very good, the methods of handling are reported to be highly objectionable, and a number of dealers and railroads have been notified that the unsanitary conditions must be immediately remedied.

Cocain Sellers.—C. A. Montgomery, a druggist, accused of the illegal sale of cocain and morphin, was fined $100 and costs, June 12.——J. H. Montgomery, a druggist, accused of a similar offense, was discharged on a technicality.——A. Lane claimed that his clerk had sold the drug, and a warrant was issued for the arrest of the clerk.——The case against Charles Cunradi was continued until June 18.——A. C. Brendeke was fined $50 and costs, June 14, for the illegal sale of cocain.

Hospital Asks Injunction.—The Chicago Union Hospital, through its president, has asked the Circuit Court to restrain the building commissioner and the chief of police from interfering with the erection of a new hospital building at Wellington Avenue and Dayton Street. Work on the structure had been ordered stopped by the commissioner of buildings, on the ground that the building was being erected in violation of a city ordinance which forbids a hospital within 400 feet of property used for public school purposes.

Chicago Medical Society.—At the annual meeting of the Chicago Medical Society, June 20, the medicolegal committee made an exhaustive report, showing that 77 suits or threatened suits for malpractice had been brought before it, but that only one judgment had been rendered against a member of the society, and that that had since been set aside. Furthermore, that not a case had been decided or a final judgment rendered against a member of the society for malpractice since the existence of this committee. The organization committee reported that during the year 248 new members had been added to the society, and that one new branch society had been organized, known as the Northwest Suburban branch, District No. 12. Since 1890 the membership of the society has increased from 940 to 1,948. The committee on permanent home reported that the Crerar Library had agreed to furnish quarters for the society as soon as its new building is ready. After the passage of a vote of thanks to the active officers for the efficient service rendered, the election of the following officers was announced: President, Dr. George W. Webster; secretary, Dr. Robert T. Gillmore; counselors for three years, Drs. William A. Evans, Charles S. Bacon, Frank Billings, Louis L. McArthur and Fernand Henrotin; alternates for three years, Drs. William E. Quine, Henry F. Lewis, Winfield S. Harpole, Brown Pusey and Theodore Tieken; alternates for one year, Drs. John E. Rhodes, Heman M. Brown, Jacob F. Burkholder, Frederick Menge and Homer M. Thomas.

INDIANA.

Fined for Illegal Practice.—Robert T. Gamble, Princeton, has been fined $25 for practicing medicine without a license.

Smallpox.—Four cases of smallpox have been reported to the secretary of the Jay County board of health, from Dunkirk. ——Two cases have been reported from Shelbyville.

Disease and Death During May.—In the monthly Bulletin of the State Board of Health, rheumatism was reported as the most prevalent disease. Tonsillitis was reported as most prevalent in the preceding month, an interesting fact in connection with the relationship between tonsillitis and rheumatism. Whooping-cough prevailed unusually. On the whole, the health of the state was better in May than in the preceding month, but no better than in the corresponding month last year. Smallpox still prevails; 112 cases were reported from 14 counties, with no deaths. Tuberculosis caused 376 deaths, including 37 fathers and 73 mothers, all between the ages of 18 and 40. They left 226 orphans under 12 years of age. The disease invaded 372 homes. Diphtheria steadily decreases, causing only 8 deaths. Antitoxin is certainly the principal reducing agent. Cancer caused 128 deaths. About 70 per cent. of all cancer deaths are of women over 50 years of age. One hundred and fifty two deaths were caused by violence, an increase over the preceding month of 28 and an increase of 112 over the corresponding month last year. Of the deaths by violence, 8 were murders, 25 suicides and the remainder accidental. Of the suicides 8 chose carbolic acid, 3 morphin, 4 potash and other poisons, 4 gunshot and 5 hanging. Of the accidental deaths, 14 were caused by railroads, 1 by trolley cars, 30 by crushing injuries, 11 by burns and scalds, 5 by gunshot, 13 by drowning, 5 by horses and vehicles, 12 by poisoning, 4 by lightning and the remainder in various other ways. The total number of deaths was 2,665, rate 11.9; the cities named presented the following death rates: Indianapolis, 16.3; Evansville, 13.6; Fort Wayne, 16.7; South Bend, 16.1; Terre Haute, 21.8; Muncie, 14.8. The average death rate for all cities was 15.2; for the country, 9.8.

MAINE.

Asylum Changes.—Dr. Ezra B. Skolfield, second assistant superintendent of the Eastern Maine Insane Hospital, Bangor, has resigned to enter practice at Charleston. Dr. Forest C. Tyson, Boston, has been appointed successor to Dr. Skolfield.

Many Years in Practice.—Of the 48 physicians who were in practice in Somerset County forty years ago only four are now living, namely: Drs. David S. Hunnewell, Madison; Sirvilla A. Bennett, Norway; Ivory Lowe, Canaan, and Llewellyn Brown, Norridgewock.

Assignments of Medical Officers.—The following assignments of medical officers have been made: To the First Infantry, Major and Surgeon Bial F. Bradbury, Norway, and Captain and Assistant Surgeon Charles L. Cragin, Portland; to the Second Infantry, Major and Surgeon Edwin M. Fuller, Bath, Captain and Assistant Surgeon James F. Hill, Waterville, and Lieutenant and Assistant Surgeon Frederick A. Chandler, Addison; to the Naval Reserve, Lieutenant (j. g.) George H. Turner, Jr., Portland.

Maine Medical Corps.—Under general orders issued by the adjutant general, June 14, the medical officers of the National Guard of the State of Maine are organized as a medical corps, consisting of one surgeon general with the rank of colonel, two surgeons with the rank of major, two assistant surgeons with the rank of captain, two assistant surgeons with the rank of first lieutenant and one assistant surgeon with the rank of lieutenant (junior grade). The hospital corps is to consist of two first-class sergeants, six sergeants, twelve first-class privates and six privates.

Maine Medical Association.—The fifty-fourth annual meeting of the Maine Medical Association was held in Portland, June 13, 14 and 15, under the presidency of Dr. Randall D. Bibber, Bath. The venerable Dr. Alonzo Garcelon, Lewiston, 97 years of age, was the only charter member present. Dr. Walter E. Tobie, Portland, was appointed official reporter. The question of the adoption of the standard constitution for state societies, suggested by the American Medical Association, was decided in the negative by a vote of 45 to 44, as for its adoption a two-thirds vote was required. The annual oration was delivered by Dr. Charles S. Minot, Boston, on "Relation of Embryology to Medical Progress." The following officers were elected: President, Dr. Charles E. Williams, Auburn; vice-presidents, Drs. Charles D. Smith, Portland, and Oscar C. S. Davies, Augusta; censors, Drs. Henry H. Brock, Portland, Bertram L. Bryant, Bangor, Jasper D. Cochrane, Saco, Ellery M. Wing, North Anson, and William L. Haskell, Lewiston; committee on publication, Drs. Walter E. Tobie and Stanley P. Warren, Portland, Louis L. Hills, Westbrook, Joshua W. Beede, Auburn, and Langdon T. Snipe, Bath.

MARYLAND.

Improvement.—The publicity recently given to such matters has worked great improvements in our slaughter houses, according to the statements of city and state health authorities. Some of the establishments were found in such a condition that they will have to be closed entirely.

Personal.—Dr. S. W. Page, late of the house staff, City Hospital, and resident physician of Bayview Asylum, has returned to his home in Anderson, S. C., where he will practice.——Dr. Howard A. Kelly received the honorary degre of LL.D. at the commencement of Washington and Lee University, June 20.——Drs. Hugh H. Young and Gordon Wilson sailed for France, June 20.——Dr. J. S. Woodward, Jr., assistant surgeon, United States Navy, who has been stationed at Panama for several months, is visiting this city.——Dr. Conrad K. Uhlig has been appointed lecturer on chemistry at the Woman's Medical College.——Drs. J. M. Hundley and R. Winslow sailed for Europe June 21.

Baltimore.

Fined for Illegal Practice.—Theodore J. Taylor, colored, was fined $75 and costs in the criminal court, June 12, for practicing medicine without a license. The defendant claimed that he gave his patients only herb teas and did not pretend to be a physician.

Hospitals for Consumptives.—The annual report for the Hospital for Consumptives shows that 115 patients were treated during the year, of whom 46 were discharged benefited, 16 showed no improvement, and 9 died. An additional building and mountain sanatorium were added to the institution.

Hospital Appointments.—The following appointments are announced on the staff of St. Joseph's Hospital for the year beginning June 1: Pathologist, Dr. Eugene H. Hayward; radiographer, Dr. Howard E. Asbury; resident staff, Drs. Hamner C. Irwin, senior resident and surgeon, and Bernard J. West, gynecologist and oculist, both reappointed; Drs. George H. Pfueger and Charles L. Jennings, physicians, and Drs. V. F. Cullen and Newton W. Hirshner, surgeons. The following dispensary appointments have been made: Medical, Dr. John S. Fischer; surgical, Drs. Joseph E. Gately and J. M. Lynch; eye and ear, Drs. J. J. Carroll and Otto S. Duker; nose and throat, Drs. Frank E. Brown and J. P. Robinson; pediatrics and skin, Dr. E. L. Crutchfield; gynecology and obstetrics, Drs. L. E. Neal and E. L. Crutchfield, and protology, Dr. Arthur Hebb.

MASSACHUSETTS.

Establishes Chair in College.—Mrs. Louisa N. Bullard has given Harvard University Medical School $52,000 to establish a chair of neuropathology.

Sentenced to Penitentiary.—David H. Richmond, Brockton, on June 15 was sentenced to imprisonment in the penitentiary for a period of from six to ten years for causing the death of a woman by an illegal operation.

Bequest.—By the will of Miss Ella A. Bartlett, Kingston, N. H., Hale Hospital, Haverhill, is given $5,000 as an endowment for a free bed for the use of Kingston people, and $3,000 is devised to the Exeter College Hospital, to be known as the Sandborn Stevens fund.

Require Five Years' Course.—At the annual commencement exercises of the College of Physicians and Surgeons, Boston, it was announced that in future, in order to obtain the degree of doctor of medicine, a five years' course of study will be required, together with one year's hospital work after the completion of the course.

Medical Care for Employés.—In connection with a new building to be constructed for the W. L. Douglas Shoe Company, of Brockton, there is to be a thoroughly equipped medical emergency room, with a physician in constant attendance, who will also make professional calls in the homes of such of the employés as may so desire.

MICHIGAN.

Hospital Opened.—The Hubbard Memorial Hospital, given to Huron City by Frank W. Hubbard, Bad Axe, was formally opened May 30.

To and from Europe.—Dr. and Mrs. Charles B. Nancrede, Ann Arbor, are spending the summer in Europe.——Dr. Walter R. Parker, Detroit, has sailed for London.——Dr. and Mrs. R. Adlington Newman, Detroit, who have been in Europe, sailed for home June 8.——Dr. George F. Inch and wife, Kalamazoo, have sailed for England.——Dr. James A. Ardiel, Grand Rapids, started for Europe June 11.

Communicable Diseases.—Greenville is reported to have had 14 cases of smallpox.——Two cases of smallpox are reported in Chapin. No spread of the disease is anticipated.——Measles is reported to be epidemic at the Michigan Home for Feeble-minded and Epileptic, Mount Clemens.——On account of the prevalence of diphtheria in Coldwater the Board of Health has closed the city schools and churches and prohibited public gatherings.

Personal.—Dr. Theodore A. Felch, Ishpeming, has been appointed a member of the State Board of Medical Registration, vice Dr. Joseph B. Griswold, Grand Rapids, resigned.——Dr. Zygmont L. Kadlubowski has been appointed city physician of Detroit, vice Dr. Boleslaus W. Pasternacki.——Dr. Henry M. Joy, Calumet, is in Ann Arbor under treatment for septicemia.——Dr. Henry B. Gammon, Hastings, recently underwent operation for nephrectomy and is reported to be improving.——Dr. Ziba H. Evans, Traverse City, has been adjudged insane and committed to the State Hospital, Kalamazoo.

MINNESOTA.

"Patent Medicines" in Minnesota.—Under a law of Minnesota a state medical board is constituted with directions to procure samples of all the "patent medicines" sold in the state and to subject them to a careful analysis. The results of each analysis are to be published in a weekly bulletin to be issued by the department. If the preparations contain opiates, alcohol or other deleterious substances, that fact will be published, together with the quantity.

NEW JERSEY.

Election of Officers.—At the one hundred and fortieth annual meeting of the New Jersey State Medical Society, held in Atlantic City, June 19-21, the following officers were elected: President, Dr. Alexander Marcy, Jr., Riverton; vice-presidents, Edward J. Ill, Newark, David St. John, Hackensack, and Benjamin Waddington, Salem; corresponding secretary, Daniel Strock, Camden; recording secretary, William J. Chandler, South Orange; treasurer, Archibald Mercer, Newark. It was decided to meet next year at Cape May in the last week of June.

NEW YORK.

New York City.

Funds for St. Mary's Hospital.—A garden party netted $6,000 for St. Mary's Hospital. This is more than was secured at any of the 16 previous functions of this sort.

Library for Fordham.—It has been announced that Dr. Thomas Addis Emmet has given his medical library, said to be the finest nucleus around which a medical library could grow, and valued at more than $25,000, to the Medical Department of Fordham University.

A Million for Hospitals.—The board of health has applied for an appropriation of $1,000,000 to continue the additions being made to the contagious disease hospitals on North Brother Island, at the foot of East Sixteenth Street and on Kingston Avenue, Brooklyn.

Ambulance Accident.—An ambulance belonging to the Long Island College Hospital was struck by a trolley car and upset, injuring the driver and a bystander. Dr. Williams, the surgeon, was picked up unconscious, badly cut and bruised about the head, and showing symptoms of internal injuries.

Seaside Hospital Open.—The Seaside Hospital belonging to St. John's Guild has opened for the summer two weeks earlier than usual. Tickets for admission have been distributed to hospitals, dispensaries and other organizations working among the poor, and will be given to mothers of sick babies needing treatment.

Personal.—Dr. Francis J. Quinlan has been the recipient of the Laetare medal, which is conferred once a year by Notre Dame University on a Roman Catholic layman who has won distinction by service to mankind.——Dr. Charles L. Gibson has been elected professor of clinical surgery in the Cornell Medical College.——Dr. and Mrs. G. S. Munson sailed on the *Koenigin Luise* June 23.

Contagious Diseases.—There were reported to the sanitary bureau for the week ending June 16, 669 cases of measles, with 30 deaths; 416 cases of tuberculosis pulmonalis, with 157 deaths; 297 cases of diphtheria, with 26 deaths; 133 cases of scarlet fever, with 10 deaths; 58 cases of whooping cough, with 3 deaths; 38 cases of typhoid fever, with 6 deaths; 14 cases of cerebrospinal meningitis, with 14 deaths; 108 cases of varicella, and 4 cases of smallpox, making a total of 1,737 cases, with 246 deaths.

Result of Caisson Inquests.—The inquest on the deaths of four men from caisson disease contracted in the Pennsylvania Railroad tunnel has been concluded. The jury recommended more care in allowing men to enter and leave the air locks, and advised that men should not be allowed to exchange passes, thus permitting some to go in without physical examination. The jury recommended that the board of health take adequate action to prevent further needless loss of life. It was stated officially that the board had made inspections and would repeat such inspections in consequence of the recent accidents.

St. Mark's Hospital.—The sixteenth annual report of this institution shows that 4,676 patients have been treated during the past year. The total receipts for the year were $46,221.46 and the expenditures $43,254. The average daily cost of maintenance per patient was $1.80, a sum below that reported by many other hospitals. One feature of this institution is to give a free meal to every poor person applying for it at the doors; during the past year 5,609 free meals have been dispensed. This hospital is not connected with any religious organization, but is entirely dependent on voluntary contributions.

Object to New York Garbage.—Complaints have been received that the beaches of Long Island and New Jersey have become a dumping ground for New York garbage. This indicates that the 15 mile limit is not far enough and Commissioner Woodbury proposes to have the scows taken 25 miles out. The commission which the legislature authorized the

mayor of New York City to appoint to devise means for keeping the waters of New York harbor from becoming polluted will consist of Dr. Daniel Lewis, ex-president of the State Board of Health; Prof. Olin H. Landreth, Dr. George H. Soper, Mathew C. Fleming and A. J. Provost. The commission is requested to ask the co-operation of the authorities of New Jersey and to make a report within two years.

OHIO.

Free Diphtheria Antitoxin.—Commencing July 1 the city of Cleveland will distribute diphtheria antitoxin to the needy free of charge.

Personal.—Dr. Wade MacMillan, surgeon to Christ's Hospital, Cincinnati, has been appointed on a commission by the governor to build a state hospital for crippled children. Dr. Frank Bunts, Cleveland, is the other medical member of the commission, while the third is a layman.——Dr. and Mrs. A. Judson Quimby, Blaine, have sailed for Europe.

Cincinnati.

Commencements.—Miami Medical College and the Medical College of Ohio held their annual commencement exercises June 1. The former graduated a class of 24, of which 18, or 75 per cent., secured hospital positions. The Medical College of Ohio, out of a class of 33, secured hospital positions for 22, or 67 per cent.

Personal.—Dr. Frank B. Cross is in Vienna, in Fuch's clinic. ——The Cincinnati Board of Public Service has appointed Dr. Louis P. Heyn city bacteriologist in place of the late Dr. W. H. Crane. Dr. Crane's other position, city chemist, has been awarded to Dr. Fred Sampson.——At a recent meeting of the board of trustees of the Chicago Home for Destitute Crippled Children, Dr. Gilbert L. Bailey, formerly of Cincinnati, was appointed assistant orthopedic surgeon.——Drs. Emmett, Fayen and Streitman, who have just finished their terms of service as internes to the Good Samaritan Hospital leave shortly for Europe, to be gone a year.

PENNSYLVANIA.

Personal.—Dr. B. F. Wagonseller, Selins Grove, has been selected as a candidate for Congress from Snyder County.

Portrait of Dr. Penrose for University.—At the annual commencement exercises of the University of Pennsylvania, June 13, Dr. Edward Martin presented to the Medical Department of the university a life-size portrait of Dr. Charles B. Penrose, a former professor of gynecology.

Formaldehyd in Milk.—At Pottsville a test was made of local dairy products before Justice of the Peace Conrad, which disclosed the presence of formaldehyd as a preservative. It was asserted that the milk had been kept sweet for six weeks. State Food Commissioner Simmers will enter prosecution.

Vaccination for State Cattle.—Dr. Leonard Pearson, state veterinarian, assisted by Drs. M. P. Ravenel and S. M. Gilliland, has made experiments during six years to guard against tuberculosis in cattle. Dr. Pearson has been led to state that perfect immunization can be obtained in healthy cattle and that the disease can be arrested in those already attacked. As a result of these experiments, it is said, the vaccination of cattle to prevent tuberculosis is about to be put in practice throughout the state.

Tablet in Honor of John Morgan.—A memorial tablet to the memory of John Morgan, founder of the Medical Department of the University of Pennsylvania, has been secured and will be placed in Houston Hall of the university. The tablet contains the following inscription:

JOHN MORGAN. College, 1757. F.R.S., 1762.
Edinburgh University, M.D., 1763.
Physician-in-Chief of the American Army, 1775-77.
Founder of the Medical Department of the University, 1765, and first in America to hold a Chair of Medicine.
Erected by the Class of 1906, Medical.

Alumni Reunion.—The twenty-fifth anniversary of the graduation of the class of '81 of the Medical Department of the University of Pennsylvania was celebrated by a reunion and dinner at Essington, Pa., June 13. Twenty-two members of the class were present, with Drs. James Tyson, J. H. Musser and H. R. Wharton as invited guests. The former officers of the class were re-elected: Dr. G. E. de Schweinitz, president; Dr. W. Easterly Ashton, vice-president, and Dr. D. W. Nead, 3222 Spencer Terrace, Philadelphia, secretary and treasurer. It was decided to hold reunions every five years, or oftener, at the discretion of the officers, and a resolution was adopted fixing the annual dues of the members of the class at $1.00.

Philadelphia.

Public Baths Open. The 18 public bath-houses throughout the city were opened to the public for the summer June 18. The houses will be open daily from 6 a. m. to 9 p. m., except Sunday, when the hours will be from 6 to 9 a. m. Two new bath-houses have been added to the list since last summer. Last summer 4,602,729 baths were taken.

Money for Hospitals.—By the will of the late Joseph A. Seffarlen, St. Vincent's Maternity Hospital receives $5,000.—— By the will of the late Hettie W. Swire, $500 is given to the Philadelphia Home for Incurables, and $500 to the Sanitarium Association.——The Germantown Hospital will realize about $2,000 as a result of a benefit garden party.

English Surgeons Visit.—Messrs. Charles A. and Hamilton Ballance, surgeons to St. Thomas Hospital, London, who had been attending the Boston session of the American Medical Association, were entertained by Dr. Robert G. Le Conte at the Rittenhouse Club, June 12. While in the city they were the guests of Dr. W. W. Keen and visited the principal medical schools and hospitals.

City Milk Supply.—The report of the milk inspectors, detailed by the board of health to investigate the milk supply of the city, reports that the milk was found to be fresh, wholesome and not contaminated. The improved condition of the city's milk supply is attributed to the observance by the milk dealers of the regulations issued by the department of health and adopted by the Philadelphia milk exchange.

Vacation Suspension.—During July and August there will be no meetings of Philadelphia medical organizations exceept the Medicolegal Society. The *Weekly Roster* will also suspend. During the first season of the roster it has aided in the formation of two branches of the County Medical Society, has increased the number of particiapating organizations to 28, and its weekly circulation from 1,300 to almost 2,400.

Personal.—Drs. Clara Marshall, Francis White, Donnel Hughes, Morris Longstreth, John M. Swan, Walter Ziegler and Daniel Hoyt have sailed for Europe.——Dr. W. W. Maries has resigned as assistant medical inspector from the board of health.——Dr. William E. Hughes, pathologist to the Presbyterian Hospital and late professor of medicine in the Medico-Chirurgical College, was operated on for appendicitis in the German Hospital, June 21.

Hospital Report.—The report of the Medico-Chirurgical Hospital shows that there were treated in the hospital during May, 311 cases; in the accident room, 701; medical dispensary, 280; surgical dispensary, 1,288; gynecologic dispensary, 162; orthopedic dispensary, 40; genitourinary dispensary, 490; skin dispensary, 111; nervous dispensary, 177; pediatric dispensary, 42; eye dispensary, 1,480; ear dispensary, 416; nose and throat, 257; therapeutic, 138; electrical, 178; *x*-ray, 162, making a total of 6,283.

Fire Ambulance Service.—The plan to have regular ambulance service at all fires throughout the city has been arranged and the new service will be placed in effect during the present week. The city has been divided into five districts, corresponding to the chief police districts. The ambulances to the hospitals in the district in which a fire occurs will respond to a single fire alarm; when two or more alarms are sent in the ambulances more remote will also respond. Twenty-five free and four paid ambulances constitute the service.

Health Report.—The total number of deaths reported for last week reached 429. The principal causes of death were: Typhoid fever, 18; measles, 2; pertussis, 4; diphtheria, 8; pulmonary consumption, 59; cancer, 30; apoplexy, 16; heart disease, 33; acute respiratory disease, 31; enteritis, 46; hepatic cirrhosis, 6; Bright's disease, 34; suicide, 2; accidents, 18; and marasmus, 7. There were 219 cases of contagious disease reported, with 27 deaths. The death rate is of the normal average and contagious diseases have decreased in comparison with the preceding week.

Slaughter Houses Insanitary.—The report of the medical inspectors of the Bureau of Health shows that the city's slaughter houses are in a dangerous condition. Out of 76 houses inspected, 50 were declared insanitary. Each proprietor is notified by the Board of Health to put his place in a sanitary condition or to take his chances of having his business condemned. Several arrests have been made of men who have failed to comply with the warnings issued by the health bureau. Fifteen per cent. of the slaughter houses and large abattoirs were found in an excellent sanitary condition.

Venereal Prophylaxis. The Philadelphia Society for the Study and Prevention of Social Disease is now thoroughly organized and plans a large hospital as well as a widespread

educational movement. The officers are: Hon. Abraham M. Beitler, president; Dr. W. W. Keen, Charles C. Harrison, Esq., and Col. R. Dale Benson, vice-presidents; Dr. Robert N. Willson, secretary, 1708 Locust Street; Dr. Jay F. Schamberg, treasurer. The society is sending out the following statement in connection with an appeal to physicians to join the movement:

It is proposed to attack the problem of venereal disease along the general lines that have been followed in combating other infectious conditions, and conspicuously in the fight against tuberculosis. At present neither the medical profession nor the lay public should be asked to sanction measures other than those of an educational nature. It would seem just, however, in the presence of a widespread venereal infection, which spares no class even when free from misdoing, that laymen should be placed in possession of their only safeguard, the facts, to which they have a clear title. Women, rich and poor, stand the brunt of the storm. They suffer disease and sterility in silence and in ignorance that the cause is often the double standard of morals that admits of male license, yet requires the female to be pure. This society hopes primarily to present the facts regarding normal sexual hygiene. Much will be accomplished if the laity, male and female, be informed with authority of the need for early education in the home, especially regarding Nature's laws, and later as to her imperative demand for chastity in both sexes. Thus only will the health of the community be safeguarded.

Practical evidence of the existing state of affairs is afforded fathers and mothers in the report of nearly one thousand cases of venereal disease treated annually in the Philadelphia Hospital alone, with as many more in the wards in a chronic state. From this and every focus proceeds a danger of both innocent and criminal infection that should not be ignored. Though the poor man and the poor man's daughter suffer most, the statistics among the so-called higher classes afford the physician a no less certain cause for reflection and regret. Adequate provision for the hospital treatment of venereal disease, the education of private and hospital patients concerning the means of its transmission, and the importance of sexual health as a prerequisite to marriage, are all matters that should interest you.

VIRGINIA.

Personal.—On May 29 the citizens of Portsmouth presented a silver loving cup to Medical Director Remus C. Persons, U. S. Navy, in charge of the Norfolk Naval Hospital, who has been transferred to the Mare Island Navy Yard.——Dr. Charles R. Robins, Richmond, recently advanced from adjunct professor to professor of gynecology in the Medical College of Virginia, in accordance with the custom of that institution, gave a banquet to the adjunct faculty, May 31.

WASHINGTON.

Medical Women Organized.—The Medical Women's Club of Seattle was recently organized with 15 charter members and the following officers: Dr. Sarah J. Dean, president; Dr. Sarah A. Kendall, vice-president, and Dr. Marietta Marsh, secretary and treasurer.

Hospital Plans New Building.—St. Mary's Hospital, Walla Walla, has decided to build an addition which will double the present capacity of the institution. The new building will be three stories in height, will accommodate 150 patients, and will cost about $100,000.

Fined for Illegal Practice.—E. W. Colgrave, Walla Walla, on April 25, pleaded guilty to practicing medicine without a license and was given a minimum fine of $50. The defendant pleaded ignorance of the law, stating that he supposed he was entitled to practice on filing notice with the state board of his intention to take the examination.

WISCONSIN.

Hospital Opened.—A new hospital with 14 rooms was opened in Stevens Point June 2.

Leper in Soldiers' Home.—A case of leprosy was reported June 5 from the Soldiers' Home, Milwaukee,

Itinerant Physician Not Guilty.—In the case of J. Austin Larsen, Eau Claire, charged with practicing medicine without a license, the jury, on May 28, found the defendant not guilty.

Proposed Consolidation.—At the banquet following the commencement exercises of the Milwaukee Medical College, May 31, Dr. William J. Cronyn, professor of medical jurisprudence in that institution, strongly advocated union of the two medical colleges of the city.

Must Pay License.—Physicians of Stillwater, Minn., have received notice from the Wisconsin State Board of Health that if they desire to practice in that state they must pay a license fee of $25. For many years it has been the custom for Stillwater physicians to answer calls in the small towns on the Wisconsin side of the St. Croix river.

Anti-Nostrum Resolutions.—At a recent meeting of the physicians of Manitowoc, Calumet and Sheboygan counties, at Brillion, the following resolutions regarding proprietary and "patent medicines" were unanimously adopted:

WHEREAS, The use of proprietary and "patent medicine" is a danger to the health of the community and derogatory to the position of the physician as a good citizen and guardian of the people's health.

Resolved, That we as a party and as individual members of the profession put ourselves on record as opposing the use of such remedies advertised through either as the newspaper's or in any such form, or in the form in which they are placed before the physician.

Resolved, Further, that we commend the efforts of such newspapers or journals that are making an effort to destroy the "Great American Fraud."

GENERAL.

New York Quarantine Regulations Against Cuba.—The New York quarantine against Cuba went into effect June 23. Under these regulations all passengers on steamships from Havana and other Cuban ports must on arrival produce certificates showing that they are immune from yellow fever. Their failure to do so will mean that they will be held for observation until five days have elapsed since their departure from Cuba.

Dr. White Convalescing.—Dr. J. William White, Philadelphia, professor of surgery in the University of Pennsylvania, underwent an operation at Rochester, Minn., June 21, for the removal of the sigmoid flexure of the colon on account of a tumor, which proved on pathologic examination to be of an inflammatory origin, caused by an intestinal diverticulum containing an enterolith. On June 26 he was reported to be convalescing satisfactorily with every reason to expect permanent recovery.

Red Cross Prizes.—The central committee of the American National Red Cross has received notification that the Empress Marie Feodorovna, who is patroness of the Russian Red Cross Society, has given $40,000 to establish a fund, the interest of which is to be given each five years in prizes for inventions which will facilitate the removal of the wounded from battle fields and from scenes of action at sea. The awards will be made by a special international jury. Three of these prizes will be given in 1907. The central committee of the American National Red Cross, War Department, Washington, offers at the proper time to receive and forward, without expense, the plans and models of American competitors for these prizes.

Health Report of the Isthmus for May.—The report of the sanitary department of the Canal Zone for May states that during the month one case of yellow fever occurred in Colon. The patient was an Italian who had been living in Colon for two months. He died after an illness of 5 days. The general health of the canal employés is excellent. The death rate was the smallest for the last year. Pneumonia continues to be the greatest cause of death; during the month there were 15 deaths among the blacks and 2 among the whites from this cause. Malaria caused 5 deaths. The report states that while the health conditions among the civil employés population is not so good as among the laborers, it is improving. Beriberi is decreasing; a year ago the deaths from this disease averaged 16 or 17 a month. During May, 1906, there were only 2 deaths from this cause.

B. & O. to Fight Bacteria.—The Baltimore & Ohio Railroad has started a campaign against propagation of bacteria by thorough disinfection of their cars. An order has been issued by the general manager that all passenger cars shall be equipped with cans of disinfecting material and train porters are being instructed as to their use. Each porter is required to keep his car antiseptically clean, and similar orders have been issued to the employés in charge of passenger stations. Disinfection of cars and stations is done under the direction of the medical inspectors of the relief department of the road. When it is learned that any one on the train is suffering from a contagious or infectious disease the conductor is instructed to notify his division superintendent by wire, so that the car can be promptly disinfected at the end of its run. Formaldehyd gas is used and the car subjected to the action of these fumes for a period of seven hours.

CANADA.

Contagious Diseases.—During May there were 33 cases of diphtheria in Toronto, 25 of scarlet fever, and 8 of typhoid fever.——There were 37 cases of typhoid fever in St. John, N. B., during the last week of May, all traced to milk.

Hospital News.—The York County Council, Ontario, is making a grant of $15,000 to the Toronto General Hospital.——The Toronto General Hospital and the Hospital for Sick Children will periodically make interchanges in their nursing staffs.——The new wing for patients with nervous diseases in connection with the Toronto General Hospital was formally opened June 14. It contains two private wards and two public wards, with accommodation for 12 patients.——The Commercial Travelers' Association of Montreal has endowed a bed in the Montreal General Hospital at an expense of $2,000.

Personal.—Dr. William Oldright, Toronto, who attended the International Medical Congress, was robbed at Padua of his purse, personal papers and a letter of credit for $1,500.——Dr. McLaren, formerly superintendent of the Hamilton City Hospital, has been appointed sub-inspector of ophthalmic hospitals under the government of Egypt and is on his way to Cairo.——Dr. Louis de Lotbiniere Harwood has been appointed medical superintendent of the Notre Dame Hospital, Montreal. ——Dr. Helen MacMurchy, Toronto, has been appointed by the Ontario government to take a census of the feeble-minded people of the province of Ontario other than those confined in provincial hospitals and houses of refuge.

FOREIGN.

German Appropriation for Research on Syphilis.—The German Reichstag has appropriated $25,000 to further the research on syphilis, especially Neisser's work with monkeys in Java.

Ibsen a Student of Pharmacy and Medicine.—Our foreign exchanges state that Henrik Ibsen was a graduate pharmacist and served at Grimstadt for three years as pharmacist's assistant. He then left this town to take up the study of medicine, but did not continue it long, turning then permanently to literature.

Prize for Work on Tuberculosis.—It is reported from Budapest that Prof. F. Koranyi offered a prize of $250 for the best Hungarian work on tuberculosis that has appeared in the last five years. The prize was unanimously awarded to Prof. O. Pertik for his important monograph on tuberculosis, based on personal research, which forms the second part of the Lubarsch-Ostertag "General Pathology and Pathologic Anatomy."

Appropriations for Special Research in France.—About $31,600 was appropriated by the French government during 1905 to aid scientists in special research. Among the beneficiaries was Calmette of Lille, director of the experimental institute where antivenin, to protect against snakebites, and serums of various kinds are prepared. He also established the first special dispensary for tuberculosis. His scientific zeal won for him also the Audiffred "devotion prize" last year. Achard of Paris was another beneficiary, his research being especially on "salt starvation" in treatment of various diseases. Arloing of Lyons received financial aid in his studies on vaccination against tuberculosis, R. Dubois on the "radiobes", F. J. Bose on the bryocytic diseases," and J. Ray on cancer.

Physicians in Politics.—The *Semaine Médicale* of Paris comments on the exceptionally large representation of the medical profession in the French parliament, saying that it is out of proportion to the population and to other professions. It says also that experience has shown that when a physician is elected to the national legislature in France he seems to lose all concern for the material interests of the profession and even for everything connected with medicine. It adds that it could cite the names of several confrères, long subscribers to the *Semaine Médicale*, who say they no longer have leisure to read it as their time is so occupied with their legislative duties. France suffers very much from irregular practices, and quacks of all kinds, even to the extent of having an irregular "School of Massage and Magnetism," conducted by one Durville, officially sanctioned by the state and duly registered. The Congress for the Repression of Quackery, recently held at Paris, is mentioned below.

Organization of the Profession in France.—It is now 25 years since Dr. G. Mignen of Montaigu, a small town in northwestern France, conceived the idea of urging the physicians of his district to combine for the purpose of promoting their material interests. The association thus formed was the first "syndicat médical" in France. Now there are 157, and they number more than 8,000 members, with only a few departments still without an organization of the kind. The anniversary was celebrated on May 16, when a bronze tablet was presented to Dr. Mignen, bearing an allegorical device and the motto: "Credo, Spero, Expecto." The *Progrès Méd.* remarks that the members say their "Credo" full of faith in the future of the organization of the profession, their "Spero" full of hope in the results of the work, shoulder to shoulder, which has scarcely as yet begun, and their "Expecto" looking forward with confidence to the day when the physicians of the land will be able to take the useful and honorable place in modern society which membership in the organized and well directed profession will insure for them.

The Cancroin Suit.—Professor Adamkiewicz, formerly of Warsaw, now of Vienna, has instituted proceedings against the manufacturing chemists, Merck & Co. of Darmstadt, claiming $60,000 as the forfeit agreed on in a contract for the manufacture and exploitation of his "cancer remedy, cancroin." The contract was signed in 1901 and the firm agreed to manufacture and push the remedy and not to withdraw from the agreement until after five years, under penalty of forfeiting the above amount. He further claims that the firm did not make the cancroin according to his directions, but purchased the neurin, the principal ingredient, instead of supervising its production. The firm contend that Adamkiewicz misled them with his statements that cancroin was an actually effectual remedy against cancer. They state that the reports of prominent physicians have been unfavorable, and that they have lost money on the venture. To this the plaintiff, according to the Vienna letter in the *Deutsche med. Wochft.* for May 31, retorts that "if the firm lost money it was due solely to the lack of the advertising necessary for the introduction of a new remedy."

Plague in India.—The Indian correspondent of the *Lancet* states that the epidemic of plague in India this season is pursuing a very unusual course. While it has been comparatively mild and has developed later in nearly all parts, the city of Bombay is suffering to an intense degree and about a thousand deaths a week are being recorded. Calcutta, on the other hand, has this year escaped with a very modified outbreak. There has not yet been any official announcement with regard to the results of the work of the scientific investigations on plague, but it is rumored that the rat-flea theory has been accepted, and great efforts have been made in many towns to exterminate these pests. Scores of thousands of rats have been destroyed in Rangoon, Calcutta, and Bombay, but anything approaching extermination has not been realized. The milder outbreaks this year can hardly be attributed to this measure, because the lessened severity has been equally marked in places where the rats have been left undisturbed. It is interesting to note that the recrudescence in Bombay city is a month later in the season than heretofore and has developed to its present intensity in the hottest part of the year. No more ought to be heard of the annual decline being brought about through the advent of hot weather.

Congress for the Repression of Illegal Practice of Medicine.—The long-heralded French congress to discuss ways and means for repressing irregular practices opened at Paris, May 28, with 300 physicians in attendance. The ministers of public instruction and of the interior and the prefect of police were also present, and a number of lawyers were among the speakers. Professor Brouardel opened the session, but was compelled to retire early on account of his feeble health. The walls were decorated with quack advertisements, posters, etc., but perhaps the most striking example of quack effrontery was the distribution to the members of the congress, as they approached the building, of a circular entitled "Aux Congressistes." It proved to be a virulent diatribe against regular medicine, a manifesto issued by the quack *Journal de Santé*. Special emphasis was laid by many speakers on the necessity for collecting all the cases of injury from quack practices that are known. Each local medical society was urged to have its members on the alert for such occurrences. Among the resolutions adopted by the congress was one to the effect that the medical syndicates should co-operate in the production of a work showing the danger and damage from irregular practices and ask that the subject should be presented in the schools. A number of resolutions were adopted, some advocating the restriction of massage and of the fitting of eyeglasses to registered physicians, others urging that massage should be taught in the medical colleges. The French law regulating the practice of medicine was shown to be capable of much more rigorous application. The delegate from the Berlin Medical Chamber expressed a wish that Germany might have legislation like it. Levassort urged the organization of a central office, to be supported by contributions from the various medical societies throughout the country, the official title to be the Central Office for the Protection of the Public Health Against the Illegal Practice of Medicine. This office should centralize the efforts of physicians in the repression of quackery and education of the public, collect and classify data in regard to illegal practices, and supply information. This motion was adopted and also another by the same speaker, urging the collecting of data for an official directory of all the legally qualified practitioners of medicine in France. An able article on the congress as a whole, in the *Semaine Médicale* for June 6, sums up its work as not productive of much that was new, but as pointing with increasing clearness to the fact that the way to suppress quack practices is by education of the public. Little can be hoped from the public authorities until they are forced to act by the coercion of public opinion.

VIENNA LETTER.

The New Hospital for Clinical Teaching.

The Vienna General State Hospital having proved entirely inadequate to the needs of modern medicine and modern teachings on account of its restricted localities, a combined action by municipal and governmental authorities was initiated by the senate of the Vienna University with a view to building a suitable hospital on modern principles. Thus a vast area of garden ground has been bought up by the respective representatives, and now 200,000 square meters are at the disposal of the building committee. The new hospital will consist of 21 large pavilions, each pavilion being devoted to the needs of one clinic and comprising all facilities and opportunities for conducting scientific and curative researches. Vast, commodious wards, laboratories furnished with all necessary apparatus, and completely fitted out according to the wishes of the directors of the respective clinics, are planned, and three pavilions are already in course of erection. They will be completed in September, when they will be opened. The plans comprise three clinics (pavilions) for internal diseases, two surgical, two gynecologic and obstetric, two each for ophthalmologic, otologic, dermatologic, laryngologic and neurologic purposes, besides a chemical institute and a pavilion for morbid anatomy, besides another building for administrative purposes. Cases which do not seem suitable for clinical demonstration will be directed to another hospital, situated more on the outskirts of the city, while the state hospital will be situated in the center of the town, near the present hospital. The capacity of the wards will be 2,400 beds, and the costs are estimated at 20,000,000 kroner ($4,000,000). It will be not the most expensive, but the largest and best equipped clinical hospital in Europe, perhaps in the world.

The Winter Session at the University.

The last winter semester of the University of Vienna lasted until the end of April on account of the numerous courses and lectures which were delivered by the professors and their assistants. The postgraduate lectures are delivered monthly during the time of Easter holidays and after the summer term, so as to enable the practitioners to make use of these classes. There were 52 physicians from England and America, and numerous others are still working in the wards of the hospitals. English courses are being held by several professors for the convenience of foreign visitors, thus offering them a great advantage, at least, for their first few weeks in the city.

Insurance Fees and Lodge Practice

Some Companies Allow Mileage.

WHITING, IOWA, June 13, 1906.

To the Editor:—I wish to add my mite to the discussion going on in regard to life insurance examination fees. It may not be generally known to examiners that some companies allow a mileage fee in addition to the regular examination fee in cases in which the physician has to make a trip to the applicant's place of residence. As so many life insurance companies seem to reveal a disposition to exploit their medical examiners, the latter ought to be on the watch to get all that is coming to them, and should always include a bill for mileage in cases in which they have had to make examinations away from their offices. F. S. SPEARMAN, M.D.

One Insurance Company Voluntarily Raises Fees.

DALLAS, TEXAS, June 8, 1906.

To the Editor:—While individual physicians and medical societies are protesting through THE JOURNAL against the cut in fees of some large eastern insurance companies, it is gratifying to state that the Pacific Mutual Life Insurance Company of California has voluntarily raised the fees for medical examinations from $3 to $5, independent of the size of the policy.

EMILE ARONSON, M.D.

Societies Take Action.

OTHER SOCIETIES.

The Chickasaw County (Iowa) Medical Society adopted resolutions making it dishonorable for any member to accept less than $5 for making an examination for life insurance. Similar resolutions were adopted by the Randolph County (Ga.) Medical Society, the Obion County (Tenn.) Medical Society, the Spartanburg (S. C.) Medical Society, the Sixth District (N. D.) Medical Society, the Whitley County (Ind.) Medical Society, the Indiana State Medical Association, and the North Carolina State Medical Society.

The Recent Cut in Insurance Fees.

HERMAN, MINN., June 5, 1906.

To the Editor:—The physician who examines an applicant for life insurance immediately assumes the position of a corporation lawyer, that is, his ability is bought to ascertain the practicability of a company investing in the applicant's chance to live. Is the applicant a business proposition? Is his earning capacity—physical health—good for the maximum of his expectancy? In other words, the physician is the "grader" of risks, the governor which keeps the mortality from "blowing off."

If it were a matter of mere questioning and the search for albumin a notary public would suffice and his seal and 25 cents might close the incident. But, would his acceptance satisfy the discriminating insurance company as to the soundness of such "bucket-shopping"? No; the company insists on a qualified physician with hospital experience, a member of a medical society, possessed of the means and knowledge of complete urinalysis. And even then the physician is most carefully selected from many of his kind because of individual adaptability. This is the man that is asked to apprise the company as to the physical soundness of their agent's catch.

If, then, you are examining for old-line companies—an acknowledgment of your superior ability—and accept a reduction in fees you not only flatly contradict their opinion of you, but your reduction is added to the very profits which your examination has made possible—the premium-bearing applicant. Or, to strike nearer home, you—a trained man—are cut $2 to defray the expenses of the untrained—the agent—usually a man who has failed in all other lines of business attempted! J. T. LELAND, M.D.

Correspondence

The Advertising of the Battle Creek Sanitarium Company.

CHICAGO, June 25, 1906.

To the Editor:—In view of the fact that Dr. Kellogg says in his letter, printed on page 1941 of your last issue, that "I consider Dr. Pusey's censure entirely just in every particular with the one exception that it does not apply to the Battle Creek Sanitarium, but rests wholly on the management of the Battle Creek Sanitarium Co., Limited," there seems to be no occasion to call further attention to my letter (THE JOURNAL, May 12, 1906, p. 1462). There is, however, a slight error in his statement when he speaks of my criticising the Battle Creek Sanitarium because of certain advertisements which are published in the newspapers over the name of the Battle Creek Sanitarium Co., Ltd. I used no names in my criticism except the name which occurred in the advertisement, the "Battle Creek Sanitarium Co., Ltd.," and if in criticising that concern I was unavoidably criticising the sanitarium, the mistake lies with the sanitarium in allowing its name to be used by an independent concern in such a way as to leave the impression with readers that it is the Battle Creek Sanitarium.

I accept fully the disclaimer of Dr. Kellogg that neither he nor the Battle Creek Sanitarium is intentionally responsible for the actions of the Battle Creek Sanitarium Co., Ltd., but it seems to me that the Battle Creek Sanitarium cannot hope to escape from any criticism which may result from the actions of a company that has the name "Battle Creek Sanitarium" as part of its title. The name inevitably suggests connection with, if not proprietorship of, the sanitarium, and it is a name which surely no corporation could adopt without the acquiescence of the sanitarium. The public cannot be expected to go to the incorporation papers of the Battle Creek Sanitarium Co., Ltd., or to know that it is not the company controlling the Battle Creek Sanitarium, without some such statement as Dr. Kellogg's. Until the publication of Dr. Kel-

logg's explanation, I think the very large majority of the medical profession must also have lived under the error that the Battle Creek Sanitarium Co., Ltd., was a corporation owning the Battle Creek Sanitarium or was a subsidiary corporation.

After writing my letter to THE JOURNAL, I had an agent answer an advertisement of the Battle Creek Sanitarium Co., Ltd. In reply I received a symptom blank to be filled out and a request to send $5.00 for a supply of food, "which our expert dietitians will select." I filled out this blank *showing a person in normal health without bad habits*, and sent it and the $5.00. The only answers which possibly could have been distorted into evidence of dyspepsia were, "Sometimes sleepy," in reply to "Have you pain or heaviness after eating?" and "Drowsiness at times" in reply to "Do you suffer after eating from headache, drowsiness, etc., etc.?" Do you suppose there is a person living who is not sometimes sleepy, or who is not drowsy at times after eating!

In reply to this symptom blank I received a supply of foodstuffs and various literature. One letter which purported to be an individual letter addressed to the patient, began "The foods have been selected by our dietitians for your particular use." In addition there was a twenty-page letter, apparently a personal typewritten letter, in which there was a lot of instructions and advice addressed to the patient. This began, "From the statements made on your information blank, it appears that you are suffering from delayed digestion resulting in mal-assimilation, etc." There was also included "A blank report of progress for the dietetic department," to be filled out by the patient and returned, presumably for further information. In about ten days there came a follow-up letter containing, among other things, "Let us know at once any symptoms which are indicated on the report blank."

This, of course, is making an effort to treat people by mail; but it is more than that. By reverting to their advertisement it will be seen that they request replies both from the sick and those who wish to remain well, and in my particular case they were notifying a person, whose symptom blank showed normal health, that he was suffering from "mal-assimilation"—and a lot of other big words—and were then going ahead to treat him. This comes precious near trying to persuade people that they are sick, in order to cure them, or at least in order to have them for patients, or, we will say, purchasers of their goods; and in so doing it comes very close to the practices of the worst types of medical charlatans. To undertake to prescribe for people by mail is bad enough from the standpoint of the medical profession, but to tell them that they are sick in order to sell them things is the limit.

Now, as to the confusion with the Battle Creek Sanitarium—not *my* confusion, because, although I knew no better, I referred to nobody but the signer of the advertisement—but as to the confusion which must inevitably take place in the minds of the people who read these advertisements and get this literature. The letters sent out with their foods, and advice, were written on stationery with letter heads like "Battle Creek Sanitarium Company, Ltd., Battle Creek, Michigan, Department of Dietetics," with pictures of the sanitarium as part of most of the letter-heads. There was enclosed a book entitled, "The Simple Life, . . . The Battle Creek Idea." In this there was a two-page illustration of the Battle Creek Sanitarium. The third sentence on the first page of the letter-press of this booklet is "The expenditure of over a million and a half dollars in the creation of the Battle Creek Sanitarium was possible only because of the wonderful results secured." All through this booklet are references to the "Battle Creek Idea," the "Battle Creek System," and more than once reference is made to the "Battle Creek Sanitarium," not to "The Battle Creek Sanitarium Co., Ltd." There is nothing in this booklet that I found to indicate that all this stuff is not put out by the Battle Creek Sanitarium. On the contrary, I could get no other idea from the booklet, from the other literature, and from the labels on most of the packages, than that the design was to make the credulous believe that these things were issued by the Battle Creek Sanitarium.

Another leaflet which I received is chiefly an advertisement of a book by Dr. Kellogg, "The Stomach." "Dr. Kellogg, superintendent of the great Battle Creek Sanitarium, wrote this book. . . ." On one of the symptom blanks which they sent out, with an offer to furnish a supply of proper foods for $5, is stuck an insert in red ink, saying, "Use this blank and secure 'The Stomach' free." On the fourth page of this leaflet advertising "The Stomach" there are several testimonials. In one of them occurs the following sentence: "I can not say but one thing of all that has been sent me from the Battle Creek Sanitarium." I can not resist quoting another sentence from this same testimonial: "The 'Good Health' came last night, and like all else it is beautiful, good and true." (How true this rings to the average medical testimonial with its bad grammar and bathos).

Now, unless the Battle Creek Sanitarium proposes to stand for such methods, it seems to me absolutely necessary that its name be eliminated from the company issuing these food products. If there is any criticism from the professional standpoint to be attached to what the Battle Creek Sanitarium Co., Ltd., is doing, it is inevitable that this criticism must reflect on the Battle Creek Sanitarium, so long as the food company does business under its present name; the only way the Battle Creek Sanitarium can escape the conviction that it is behind this food company is to take its name entirely out of this company.

The logic of the situation indeed, compels me to go further, and to believe that neither the Battle Creek Sanitarium nor the medical men in association with the sanitarium can maintain their ethical character in the eyes of the profession, unless the sanitarium is able in some way to stop the exploitation of its reputation in the way it has been exploited by the Battle Creek Sanitarium Co., Ltd., or, better, make the company selling its products radically change its methods.

I am as glad as anybody that Dr. Kellogg and the Battle Creek Sanitarium are independent of the Battle Creek Sanitarium Co., Ltd., and I deplore as much as any one the fact that they are unwittingly laid open to what Dr. Kellogg calls "censure entirely just." And I hope that in the interest of their professional dignity they will be able to prevent the further use of the reputation of the Battle Creek Sanitarium in the ways which I have described above. W. A. PUSEY.

The Country Doctor.

GUM SPRING, VA., June 16, 1906.

To the Editor: I am very glad to note in THE JOURNAL, June 2, 1906, page 1711, Dr. M. W. Pearson's reply to Dr. John C. Wilson on "The Country Doctor." I am confident that Dr. Wilson's article is calculated to do great mischief, for it may be the means of stimulating other young and over-confident practitioners to undertake operations which they are incapable of performing except in a third-rate or fourth-rate manner, thus not only jeopardizing human lives without warrant, but bringing scientific surgery into disrepute with the non-discriminating public. I am myself a country practitioner, and I know whereof I write.

In my judgment, the country doctor (or any other general practitioner), who does major surgery, except in the most extreme emergencies, deserves to have his license to practice revoked.

To me it seems the baldest nonsense to talk of the country doctor doing refraction work, for any one who has tried country practice knows that, were the doctor never so well qualified, he would lack the time, and no man can become specially skilled in a special field without devoting most, if not all, of his time to it. W. K. McCOY.

Ocular Complications of Measles—The Country Doctor.

KALAMAZOO, MICH., June 11, 1906.

To the Editor:—In THE JOURNAL, May 26, there appears an item in Therapeutics on "The Ocular Complications in Measles." While in many respects there is a great deal of good advice in the article there are one or two things which it seems to me few oculists would advise. First, I am pretty sure that no one would think of using solution of cocain when intense photophobia is present. This symptom is most usually due to erosion of the cornea, and one of the great objections to

cocain solution is just this propensity to bring about such conditions. It is better to use 5 per cent. dionin or 0.5 per cent. solution of atropin sulphate p. r. n. Second, when intense itching of the eyelids occurs, it has not been my fortune to see any good result from the Pagenstecher ointment. I should think that better results would follow the use of phenol ointment, 10 per cent.

As to the use of the spray in general catarrhal conditions, I don't believe that one child in a hundred ill with measles will let the physician use a spray, and even if it did, if there is one thing that is decidedly *passé*, it is the spray. A very much readier way to wash the nares of these little patients is to use the ordinary nasal douche. It is simple, effectual and cleanly. Moreover, after using it or any other form of cleansing agent (and, by the way, a simple solution of salt and baking soda—a pinch each in the douche of warm water, is the easiest, handiest and best in my judgment), the child should not be permitted violently to blow the nose, for fear of carrying these secretions up the Eustachian tubes.

While I am correcting what seems to me to be an error, permit me to correct another error which appeared in THE JOURNAL, May 19, in a very excellent article on "The Country Doctor." There was much to commend in this article, and no one can have a higher respect for the capabilities of the country doctor than I, nor do I forget for one moment that Ephraim McDowell and Marion Sims were country doctors. The point which seems self-evident to me is the error in fancying that the specialist exists simply to impress his wonderful prowess on the non-specialist, or that the work specialists do is so unimportant that any country doctor can correct errors of refraction as well as the trained oculist. I have my doubts about this, that he can do as well and better than the average spectacle dealer (who, by the way, is not an optician even) goes without saying, but if the average physician with no preparation, or with a six-weeks course, can do as well as the thoroughly prepared oculists, than the ranks of the American ophthalmologic societies must be made up of some very poor timber. As a matter of fact, there is hardly a problem in medicine which calls for a more accurate and painstaking piece of work than the correction of refraction. That the doctor—country or city—should be able to tell whether or not an error of refraction exists is most necessary. I would go further and say that it is most desirable that he should be able properly to use the ophthalmoscope in his daily work. It will be of inestimable value to him. Among other things he should be able to recognize adenoids and, if need be, to operate for their removal. He can do that infinitely better and to more advantage to his patients than to correct refraction. It is remarkable how much shockingly bad work is foisted on a poor, deluded public by men with a smattering of ophthalmic knowledge.

ED. J. BERNSTEIN.

Dr. MacCormack in Lincoln County, Kentucky.

STANFORD, KY., June 1, 1906.

To the Editor:—In the language of the "sport," Dr. J. N. MacCormack, of Bowling Green, the representative of the American Medical Association, has been "going some" during the month of May. Except it be one in the flush of full health, as is usual with Dr. MacCormack, he could ill withstand the mental and physical strain through which he has recently gone. Meeting with recognition and encouragement everywhere enables him to keep young. His itinerary, arranged for him by the council of the Kentucky State Medical Association, began on May 1 and ended on the evening of May 26. He delivered in the 26 days (Sundays excepted), 38 addresses, which, like the stories of the sea god's daughters, are neither the same, nor yet different, but as sisters should be.

I would not presume to speak for other sections, but am able to compute for the profession of Lincoln County the gain which has accrued from his recent visit to Stanford, May 16. He was announced to speak at 10 a. m., not a convenient hour, being rather early for business people to "drop everything," even to hear a political harangue, of which Kentuckians, generally, are so fond; but the large, old-fashioned court-house, one of the most ancient in the commonwealth, was filled to overflowing with gentle folk, old and young, big and little, all anxious to listen to a new rendering of "The Relations of the Medical Profession to the Public," by a gentleman whom they had not seen, but of whom they had heard much. Suffice it that all were highly pleased as well as edified.

With the exception of three or four, who were unavoidably detained, every doctor in the county graced the occasion with his presence, and Casey, an adjoining county, sent a coterie of representative physicians.

Dr. MacCormack is so modern, so well equipped, his qualifications are so numerous, his manner and methods so fetching that to hear him before an audience is the rarest of treats. He does not indulge in polemics; his sentences mean something, he puts wit into them, emotion and satire, and when necessary, metaphorically speaking, "spanks" both the layman and the doctor—just for their own good. He is earnest, alert, open-eyed, and his eagerness is so patent that every one observes his desire to do good for the great common people by his sensible, practical remarks; and the members of the profession the boys in the trenches—feel, too, the higher and more ennobling life he pictures to them.

He wants the doctor not to neglect to-day, but to make the most of every passing hour, to fulfill his own hopes or the hopes of his friends, to be accomplished in his art, and above all, to observe the sweet amenities of life toward his fellow-practitioners.

Now, that the itinerary of Dr. MacCormack is over and gone, the aftermath is bound to be fine. We, in Lincoln, can hear flattering testimony to the efficiency of the good work done here. May harmony and peace, like a flowing river, ever be with us, as it is to-day.

Dr. MacCormack touched on a wide range of topics, but one in particular, "the mustard in the salad dressing," was that of fees for the examination of subjects for life insurance. He enumerated the $5 and the $3 companies. This matter is now interesting the whole profession. I may emphasize the fact that the Lincoln County Medical Society recently legislated on this question with unanimity, resolving that no member shall in the future, make an examination for an old-line company without charging and receiving therefor the fee of $5. Verily justice should be meted out to the doctors as is done to others—they deserve it. The recently promulgated plan of our metropolitan life companies compelling the physician, the man of standing and ability, to examine an applicant, then pass judgment on a risk of $1,000 and paying him only $3 for his service is an outrageous travesty on equity and justice, driving him, as it were, like sheep to the shambles; but still there are some, like Barkis, who are "willin'."

This should not prevail! Only organized effort will bring the companies "to taw" and cause them to pay a decent fee. But should they hang fire, not willing to accede to the demands of the profession, attempt the expedient, which is threatened, of doing without the doctor in $1,000 policies, or employ (and they may find them) cut-rate examiners for this work, discomfiture may and doubtless will overtake them within a few years.

In this tour the national organizer is dealing with this subject in an emphatic way, and his advice will overcome the obstacles now confronting us, or at least, so alleviate them as to make them tolerable. He is for the doctor in and out of season. It remains with him, then, to stand stanch and true like a pig's foot. If he shies at the fear of losing a job, he should have pasted in his chapeaux this sentiment:

"Our doubts are traitors
And make us lose the good we oft might win
By fearing to attempt."

STEELE BAILEY, M.D.

Presentation of Papers—A Just Criticism.

CHICAGO, June 16, 1906.

To the Editor:—While we are still enthusiastic over the wonderful success of the Boston session and thoroughly impressed with the dignity and great efficiency of the machinery of the American Medical Association, would it not be well to consider some of the factors which have operated to qualify the complete satisfactoriness in some directions?

It is obvious that the growth and general development of the Association is to present new problems which so far as may be should be anticipated. The sections, particularly in medicine and surgery, are and are destined to be still more attended to a degree that makes the complete usefulness difficult to achieve.

The presentation of the formal paper necessarily is acquiring a greater prominence and the discussion by the general profession, which in former days was one of the chief pleasures, to say the least, of the session, is becoming more difficult and distinctly less a feature. It serves to direct attention very distinctly to the character, not only of the papers produced, but also of the presentation thereof.

It is common observation that many members who read papers have entirely neglected the rhetorical quality necessary to present their views. One does not refer to the matter of startling impression through rhetoric, but to the desirable end of being comprehensible. For the most part this is due to faulty reading. Many elements enter into this. Many men are inexperienced, many are unfamiliar with their subject matter, and few have naturally insufficient voice, but most have tricks of enunciation and modulation of the voice which are utterly unsuited for presentation of serious matter to large gatherings in large spaces.

This is not a trivial matter, but a matter of the deepest importance, not only so far as regards the individual, but as concerning the rights of the audience to entertainment and instruction. No one has the right to take the time of a section or a general meeting in presenting a paper read either so rapidly, so indistinctly, or so stumblingly as to be painful to the great majority of the audience trying to listen.

No man need be so embarrassed as to make his inexperience an insuperable obstacle; no man need be at all unfamiliar with his paper, and there is no voice which under proper and considerate management can not be made to do effective service.

This does not apply to the members of minor prominence in the Association. If one could mention names it would be found to touch most pointedly many of the members whose opinions and influence in medical affairs are most sought for and needed.

Let every individual who has participated in the Boston session take it to himself and consider whether, in presenting his contribution, he has done full justice to the audience in this respect.

B.

An Ohio League.

SIDNEY, OHIO, June 11, 1906.

To the Editor:—The letters and other matter in recent numbers of THE JOURNAL which refer to the practice of church papers in giving place to advertisements of nostrums indicate a commendable interest.

It seems difficult to account for the apathy of clergymen of all denominations on this subject. The only rational explanation is that these men have not been aroused to a proper sense of the enormity of the evil. Either the family physician has not taken his brother of the clergy in hand and given him proper information, or individual effort has counted for little. Believing the latter to be the true reason, an effort was made at the annual meeting of the Ohio State Medical Society, held at Canton, to effect an organization of medical men who are interested in church work, for the purpose of doing by united action what can not be done by individuals alone. It is called "The League of Members and Adherents of Churches for the Suppression of Fraudulent Advertising in Church Publications."

In its constitution or declaration of principles the league states its object to be the enlistment of all moral and religious forces for the protection of the people, and the enforcement of such legal measures as seem necessary and proper.

Its aim is to organize auxiliary societies in every county of the state, to be composed of physicians, lawyers, ministers, teachers and other educated persons, women's clubs and other societies. These local associations are expected to distribute literature and to secure lecturers, and in every legitimate way to seek to enlighten the minds of the people and to prevent their exploitation by charlatans and fakers. In this way every clergyman will be brought to face the fact of his responsibility in permitting his own people to be defrauded and deceived. Church organizations, conferences, presbyteries, synods, associations, and other courts will soon take such steps as will reform this blot on our Christian civilization.

If this plan of campaign appeals to medical men in other states as it does to those of Ohio, a great impetus to the work will be given by early organization in every county in every state in the Union. United efforts alone can bring success—especially when the attack commences as it must ere long—on secular papers. The Great American Fraud is too strongly intrenched behind a fortress of unlimited capital to surrender without a gigantic struggle.

The condition which confronts us is one largely of our own making. Too long have we neglected the education of the people. Our allegiance to God and our duty to humanity calls for this work of redemption.

Already a large number of members of churches and others have joined this league.

Correspondence is invited by the executive committee:

Nitroglycerin in Pneumonia.

ST. LOUIS, June 20, 1906.

To the Editor:—The caustic criticism of the practice of using nitroglycerin in the treatment of pneumonia, in the article on "The Treatment of Lobar Pneumonia," by E. Russell Zemp, in THE JOURNAL, May 26, calls for some defense of a valuable but much abused and misused drug. Dr. Zemp states dogmatically that "nitroglycerin most certainly paralyzes the pneumogastric and the respiratory and vasomotor systems," also that "no one who clearly understands the physiologic action of this drug can be excused for killing a patient with pneumonia by its use."

As a matter of fact, the physiologic action of nitroglycerin has not as yet been clearly established. The recent study of the drug by Dr. H. P. Loomis, "Limitations of the Value of Nitroglycerin as a Therapeutic Agent," *Med. Record*, 1905, No. 11, p. 411, corroborates the commonly accepted opinion that it causes an acceleration of the heart's action and a dilatation of the peripheral arteries. The notion that it causes a fall in blood pressure, he proves to be unfounded and erroneous. His experiments show that instead of a fall a slight rise in pressure is recorded by the sphygmomanometer.

I do not wish to be understood as advocating the routine use of nitroglycerin in the treatment of pneumonia, but I am convinced that it is of great benefit in the collapse following the crisis. It is especially indicated in the extreme cases in which the medullary centers are obtunded and pulmonary edema ensues, the heart muscle weakens, the extremities become cool and the skin cyanosed. In a number of cases in this condition, while full doses of strychnin, digitalin and normal saline solution were being administered, I have observed remarkable improvement to follow the addition of nitroglycerin. It should be given in the form of spirits of glonoin (U. S. P., 1890) dropped on the tongue every half hour (average dose, three drops), gradually withdrawing the drug after the desired result is produced.

As to the manner in which it acts, Dr. Loomis suggests that "it causes intrinsic changes in the circulation, increasing the supply of blood to the respiratory centers in the medulla, thus stimulating them."

I believe it to be a safe, quickly absorbed, rapidly diffused stimulant, tending to restore the circulatory equilibrium and especially valuable in the treatment of collapse.

HORACE W. SOPER, M.D.

Association News

A Correction to the Minutes of the House of Delegates.

Dr. Alexander R. Craig of Pennsylvania, chairman of the Reference Committee on Amendments to the Constitution and

By-Laws, has called attention to the fact that in the minutes of the Boston session of the House of Delegates, printed in THE JOURNAL, June 16, page 1875, in the report of the Reference Committee, the amendment to Chapter 10, Section 7, of the By-Laws was inadvertently printed as a part of the report of the committee. This amendment was proposed at the Portland session and was referred to the Reference Committee on Amendments to the Constitution and By-Laws. On investigation this committee found the amendment to be in conflict with the Constitution and reported instead the substitute amendment to Article 8 of the Constitution, which, under the rules, was held over for one year before action. At the Boston session the committee reported in favor of this amendment to the Constitution and it was adopted. In making up the minutes the original amendment, which had been discarded in favor of the substitute, was unintentionally included in the report of the committee.

Marriages

LEWIS M. EASTMAN, M.D., to Miss E. May Hines, both of Baltimore, June 5.

J. LEO DEVINE, M.D., to Miss Marie E. Davis, both of Lansford, N. D., June 6.

GRANT GOODWIN, M.D., to Miss Eva H. Sidle, both of Monticello, Ind., June 6.

CHARLES A. KREUTZER, M.D., to Miss Helen Kramer, both of Milwaukee, June 27.

LEWIS B. GAINES, M.D., to Miss Ethel Alexander, both of Atlanta, Ga., June 12.

J. ROBERT CAYWOOD, M.D., to Miss Elizabeth Barber, both of Piqua, Ohio, recently.

EDGAR BOONE WILCOX, M.D., to Miss Margaret Bevan, of Oskaloosa, Iowa, June 12.

JOHN B. HALL, M.D., Boston, Mass., to Miss Mary Harriet Curtis of Chicago, June 27.

FRANK M. RIDLEY, M.D., JR., La Grange, Ga., to Miss Mabel Hood, of Baltimore, recently.

ROY C. GLANN, M.D., Bronson, Iowa, to Miss Bertha Shedd, of Holly Springs, Iowa, June 6.

WILLIAM A. HACKETT, M.D., to Miss Adele Hagemeister, both of Detroit, Mich., June 14.

LOUIS PROUDFIT, M.D., Osceola, Ind., to Miss Grace B. Sawyer, of Mishawaka, Ind., June 14.

VICTOR J. LA ROSE, M.D., Mandan, N. D., to Miss Rose McHugh, of Bismarck, N. D., June 12.

GEORGE CARROLL LOCKARD, M.D., to Miss Louise Cummings Wright, both of Baltimore, June 12.

JOHN WALTER MARTIN, M.D., Colfax, Iowa, to Miss Fannie Leonore Benson, of Chicago, June 20.

ADONIRAM JUDSON QUIMBY, M.D., to Miss Gertrude Seabright, both of Blaine, Ohio, June 13.

THOMAS A. BURRAGE, M.D., Portland, Maine, to Miss Harriet G. Dyer, of Providence, R. I., June 12.

WALTER E. KEEHL, M.D., Battle Creek, Iowa, to Miss Sylvia Duncan, of Iowa City, Iowa, June 14.

LUTHER EMERICH, M. D., Saugerties, N. Y., to Miss Cordelia E. Parish, of Maryland, N. Y., June 13.

JOSIAH MEDBERY, M.D., Columbus, Ohio, to Miss Frances B. Lodwig, of Portsmouth, Ohio, June 19.

HARRY L. CRUTTENDEN, M.D., Morris, N. Y., to Mrs. Claudine S. Johnston, of Otsego, N. Y., June 12.

A. E. LEMON, M.D., Fresno, Cal., to Miss Daisy Mitchell, of Clinton, Mo., at Topeka, Kan., recently.

JAMES HAWLEY BURTENSHAW, M.D., to Mrs. Susan Dewey Holman, both of New York City, June 9.

PRENTISS BOWDEN CLEAVES, M.D., Cherokee, Iowa, to Miss Jane Delaplaine, of Tipton, Iowa, June 9.

WINFRED LEMAN POTTER, M.D., Homer, N. Y., to GEORGETTA ALLER, M.D., of Brooklyn, N. Y., June 12.

CHARLES SUMNER ROCKHILL, M.D., Cincinnati, to Miss Margaret Hackedorn of Toledo, Ohio, June 27.

JAMES KNIGHT QUIGLEY, M.D., Rochester, N. Y., to Miss Genevieve Searl, at Franklinville, N. Y., June 20.

Deaths

Oscar L. Dales, M.D. Cleveland Medical College, Medical Department of Western Reserve University, 1880, of Grand Rapids, Mich., a member of the American Medical Association, city health officer in 1897, a member of the board of health in 1903, and president of the board for a year and a half thereafter, a member of the Michigan State Medical Society, and of the Grand Rapids Academy of Medicine, and one of the most prominent physicians of central Michigan, died at the Union Benevolent Association Hospital, Grand Rapids, June 12, after a long illness, aged 49.

Henry C. Willison, M.D. New York University, New York City, 1872, superintendent of the Western Washington Hospital for the Insane, Stellacoom, and thereafter a resident of Port Townsend, for several terms president of the Washington State Medical Association, and twice a member of the State Board of Medical Examiners, died at his home, June 12, aged 61.

Charles Lee Fisk, M.D. College of Physicians and Surgeons in the City of New York, 1856, a member of the Massachusetts Medical Society, once vice-president of the Franklin District Medical Society and chairman of the local board of health, died at his home in Greenfield, Mass., April 21, from angina pectoris, after an illness of three weeks, aged 74.

Joseph Henry Widdifield, M.D. University of the Victoria College, Coburg, Ont., 1869, M. R. C. S., England, 1870, licentiate Royal College of Physicians, Edinburgh, 1870, member of the College of Physicians and Surgeons, Ontario, 1870, sheriff for the County of York since 1888, died suddenly at his residence in Toronto, June 3.

Francis Root Day, M.D. Rush Medical College, Chicago, 1883 a member of the American Medical Association, who went to the Sandwich Islands in 1890, and was soon after appointed physician to King Kalakaua, and became one of the foremost practitioners of Honolulu, died at his home in that city June 1, from pneumonia.

Tighlman Hunt, M.D. Medical College of Indiana, Indianapolis, 1872, a member of the American Medical Association, a prominent practitioner of Indiana for more than 40 years, died at his home in Plainfield, June 12, from cerebral hemorrhage, after an illness of two months, aged 68.

Daniel H. Hardaway, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1861, surgeon in the Confederate service during the Civil War, died at his home near Blackstone, Va., June 7, from nephritis, after a short illness, aged 67.

Andrew D. Blanchard, M.D. Harvard University Medical School, Boston, 1846, surgeon during the Civil War stationed at Fortress Monroe, Va., for several years a practitioner of Lawrence, Mass., died at his home in Melrose, Mass., June 11, aged 83.

Heman D. Ure, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, formerly of Lexington, Ky., died in St. Louis, April 26, four hours after an accidental fall in which he sustained a fracture of the skull, aged 60.

James McGovern, M.D. University of Nashville, Medical Department, 1905, of Pom Nolen, Miss., died Feb. 16, from concussion of the brain, the result of a fall from his horse, while making a professional call five days before, aged 25.

James Morris Madden, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1860, of Brunswick, Ga., died in that city March 14, an hour after having been thrown from his buggy in a runaway accident, aged 63.

Edward Payson Jeffries, M.D. Harvard University Medical School, Boston, a surgeon in the army during the Civil War, died suddenly at his home in Avalon, Catalina Island, Cal., March 14, aged 70.

Henry R. Hundley, M.D. Hospital College of Medicine, Louisville, Ky., 1905, of Clay County, Ky., died in Flora Vista, N. M., recently, from tuberculosis, after an illness of one year, aged 28.

Charles Newton Mayson, M.D. Medical College of Georgia, Augusta, 1843, died at his home in Kingston, Ga., February 6, from senile debility, after an illness of sixteen months, aged 82.

Robert H. Richards, M.D. Manitoba Medical College, Winnipeg, 1901, surgeon of the steamer *Miowera*, committed suicide by shooting himself in his cabin on the steamer, June 16, aged 27.

Timothy J. Caldwell, M.D. Medical Department of the University of Iowa at Keokuk, 1861, formerly state representative and state senator, died suddenly in his apartment in Adel, Iowa, June 16, from senile debility.

Jennie B. Allen La Tourrette, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1892, died in New York City, March 15, from cancer, after an illness of two years, aged 58.

Clara Hazard, M.D. State University of Iowa, College of Homeopathic Medicine, Iowa City, 1897, died at her home in Iowa City, June 14, after a short illness from uremia.

Charles Augustus Lampanius, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1878, died suddenly from cerebral hemorrhage, June 13, at his home in Catonsville, Md., aged 53.

John C. O'Haire, M.D. Albany (N. Y.) Medical College, 1891, of Nassau, N. Y., died at the home of his mother in Watervliet, N. Y., June 16, after an illness of about three months.

Paul S. Sue, M.D. Detroit Medical College, 1869, for 37 years a practitioner at Fenton, Mich., died at his home, June 2, from paralysis, after an illness of five years, aged 59.

William Parker, M.D. College of Physicians and Surgeons of Ontario, 1877, died at his home at Westport, Ont., from anemia, June 6, aged 65 years.

Levin D. Collier, M.D. Department of Medicine of the University of Pennsylvania, a practitioner until 1871, died at his home in Salisbury, Md., June 12, aged 75.

G. W. Miller, M.D. Medical Department of Western Reserve University, Cleveland, 1881, was burned to death at his home in Brush Valley, Pa., June 15.

John Cooke Laurens, M.D. Louisville Medical College, 1896, died at his home in Mantoe, Va., June 14, aged 32.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending June 23, 1906:

Bradley, A. E., surgeon, left Fort Sheridan, Ill., on fifteen days' leave of absence.

Bevans, James L., asst.-surgeon, advanced to rank of captain.

Birmingham, H. P., surgeon, will take temporary charge of the office of the chief surgeon, Department of the Gulf, and of the attending surgeon, during the absence of the latter on sick leave. Major Birmingham will retain station at Fort McPherson, Ga., and make such visits to Department Headquarters and return as may be necessary.

Skinner, Geo. A., asst.-surgeon, granted twenty days' leave of absence on completion of his examination for promotion.

Kirkpatrick, Thos. J., asst. surgeon, reports for duty at U. S. Target Range, Waco, Ga., from temporary duty at Fort McPherson, Ga.

Kneedler, Wm. L., surgeon, ordered to report in person to Brigadier General Frederick Funston, U. S. Army, president of an Army retiring board at San Francisco, Cal., at such time as he may designate, for examination by the board.

Gilchrist, H. L., and Davis, Wm. T., asst.-surgeons, left from temporary duty at San Francisco, Cal., en route to rejoin station, Army General Hospital, Washington, D. C.

Wadhams, S. H., asst.-surgeon, left Fort Slocum, N. Y., on seven days' leave of absence.

Metcalfe, R. F., asst.-surgeon, left Columbus Barracks, Ohio, with recruits, en route to Fort Lawton, Wash.

Duval, Douglas F., asst.-surgeon, granted twenty days' leave of absence on account of sickness, to take effect on the expiration of present leave.

Ford, Clyde S., asst.-surgeon, ordered to proceed from New York City, N. Y., to Philadelphia, Pa., on official business pertaining to the inspection of certain articles manufactured for use of the Medical Department of the Army.

Ferguson, James B., contract surgeon, granted leave of absence for three months.

Hutson, T. Ogier, contract surgeon, relieved from further duty in the Philippines Division, and ordered to Fort McPherson, Ga., for temporary duty.

Campbell, George F., contract surgeon, sailed from San Francisco, Cal., June 15, on the *Thomas*, for Philippine service.

Hardis, Herbert I., contract surgeon, arrived at San Francisco, Cal., June 17, on the *Sheridan*, for leave of absence from the Philippines Division.

Baker, Charles L., contract surgeon, arrived at San Francisco, Cal., June 17, on the *Sheridan*, for leave of absence from Honolulu, H. T.

Whitaney, Jean C., contract surgeon, left Boise Barracks, Idaho, and arrived at Fort Casey, Washington, for duty.

Rhoades, Rex H., dental surgeon, arrived at Fort Sheridan, Ill., for duty.

Ware, William H., dental surgeon, left Fort Apache, Ariz., and arrived at Whipple Barracks, Ariz., for duty.

Daywalt, George W., contract surgeon, arrived at Key West Barracks, Fla., for temporary duty.

Watkins, Victor E., contract surgeon, left Fort Mansfield, R. I., and arrived at Plattsburg Barracks, N. Y., for duty.

Richardson, George H., contract surgeon, reported for temporary duty as surgeon of the transport *Buford*.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending June 23, 1906:

Woods, E. L., asst.-surgeon, detached from the Naval Academy and ordered to the *Kearsarge*.

Gill, J. E., asst.-surgeon, detached from the *Kearsage* and ordered home to wait orders.

Warner, R. A., surgeon, asst.-surgeon, detached from the Naval Academy and ordered to the *Louisiana*.

Butts, H., Garrison, P. E., Raison, T. W., asst.-surgeons, appointed asst.-surgeons, with rank of lieutenant (junior grade), from June 1, 1906.

Lee, A. E., asst.-surgeon, ordered to the Naval Hospital, Mare Island, Cal.

Steadman, W. G., Jr., Dollard, H. L., acting asst.-surgeons, ordered to the Naval Hospital, New York, N. Y.

Plummer, G. R., acting asst.-surgeon, reappointed acting asst.-surgeon for three years from July 1, 1906.

Parker, E. G., P. A. surgeon, detached from the *Pensacola*, July 9, and ordered to Washington, D. C., July 16, for examination for promotion, and thence home to wait orders.

Freeman, G. F., P. A. surgeon, ordered to special duty with the Surgeon General of the Navy.

Wheeler, L. H., asst.-surgeon, detached from the Naval Station, Cavite, P. I., and ordered to the *Helena*.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and noncommissioned officers of the Public Health and Marine-Hospital Service for the seven days ended June 20, 1906:

Amesse, J. W., P. A. surgeon, relieved from duty at Ellis Island, N. Y., and directed to proceed to Gulfport, Miss., for temporary duty.

Stimson, A. M., assist.-surgeon, directed to rejoin station at Ellis Island, N. Y.

Collins, G. L., asst.-surgeon, granted leave of absence for three days from June 25, 1906.

de Valin, Hugh, asst.-surgeon, granted leave of absence for one day, June 16, 1906, under Paragraph 191 of the Regulations.

Bailey, C. Williams, acting asst.-surgeon, granted leave of absence for seven days from June 27, 1906.

McConnell, E. F., acting asst.-surgeon, granted twenty-two days leave of absence on account of sickness and three days annual leave from May 17, 1906.

Mason, W. C., acting asst. surgeon, granted leave of absence for five days from June 25, 1906.

Riemer, H. B. C., acting asst.-surgeon, granted leave of absence for seven days from June 14, 1906, under Paragraph 210 of the Regulations.

Stevenson, J. W., actlag asst-surgeon, leave of absence granted for thirty days from June 11, 1906, amended to be effective from June 18, 1906.

Walker, T. D., acting asst.-surgeon, granted leave of absence for eight days from June 8, 1906.

Achenbach, John, pharmacist, granted leave of absence for thirty days from May 3, 1906, on account of sickness.

Brown, F. L., pharmacist, granted le vaeof absence for one day, June 16, 1906, under Paragraph 210 of the Regulations.

Richardson, S. W., pharmacist, leave of absence granted for ten days from June 3, 1906, amended to read five days only

Troxler, R. F., pharmacist, granted leave of absence for seven days from June 13, 1906, under Paragraph 210 of the Regulations.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended June 22, 1906:

SMALLPOX—UNITED STATES.

Alaska: Nome, June 14-15, 6 cases (on schooner *Monterey*).
California: Los Angeles, June 2-9, 1 case.
Florida: General, June 9-16, 6 cases; Jacksonville, 3 cases.
Georgia: Augusta, June 4-11, 3 cases; Sapelo Island, to June 12, 6 cases.
Louisiana: New Orleans, July 9-16, 5 cases.
Michigan: Detroit, June 9-16, 2 cases.
Montana: General, May 1-31, 6 cases.
New York: Monroe, June 19, 1 case; Saratoga Springs, 1 case; New York, June 9-16, 4 cases.
North Dakota: General, April 1-30, 25 cases, 4 deaths.
Ohio: Cincinnati, June 8-15, 12 cases; Hamilton, May 12-19, 1 case; Youngstown, May 16-June 15, 3 cases.
Oklahoma Territory: Oklahoma, June 2-9, 8 cases, 1 death.
Oregon: General, May 1-31, 36 cases, 1 death.
Pennsylvania: Allegheny, June 9-16, 1 case; Pittsburg, May 26-June 9, 5 cases, 3 deaths.
Tennessee: Knoxville, June 9-16, 1 case; Memphis, June 2-16, 5 cases.
Utah: General, May 1-31, 79 cases.
Wisconsin: Appleton, June 9-16, 2 cases.

SMALLPOX—FOREIGN.

Africa: Cape Town, May 5-12, 4 cases; Freetown, May 11, present.
Belgium: Liege, May 19-26, 1 case, 1 death.
Brazil: Pernambuco, May 8-15, 5 deaths.
Chile: Antofagasta, May 20, present; Coquimbo, present; Iquique, epidemic; Talkahuana, present.
France: Paris, May 12-26, 16 cases.
Gibraltar: May 27-June 3, 2 cases.
Great Britain: Liverpool, May 26-June 2, 2 cases; London, May 26-June 2, 3 cases.
India: Bombay, May 15-22, 5 deaths; Calcutta, May 6-12, 57 deaths; Karachi, May 13-20, 15 cases, 11 deaths; Madras, May 12-18, 11 deaths; Rangoon, May 6-12, 23 deaths.
Italy, General, May 25-31, 27 cases.
Peru: Callao, May 12-19, 1 case.

CHOLERA—FOREIGN.

India: Bombay, May 15-22, 20 deaths; Calcutta, May 6-12, 42 deaths; Rangoon, May 6-12, 4 deaths.

YELLOW FEVER.

Costa Rica: Limon, June 20, 1 case.
Cuba: Habana, June 18-21, 2 cases.
Honduras: Pimienta, May 19-23, 20 cases.
Mexico: Merida, May 27-June 9, 3 cases, 1 death.
Case reported at Coatzacoalcos in report for June 8, 1906, found not to be yellow fever.

PLAGUE—INSULAR.

Hawaii: Honolulu, June 15, 1 death.

PLAGUE—FOREIGN.

Australia: Brisbane, April 28-May 5, 1 case, 1 death; Rockhampton, April 28-May 5, 1 case.
Brazil: Pernambuco, May 1-15, 1 death.
Egypt: General, May 17-31, 34 cases, 12 deaths; Alexandria, May 29, 1 case; Port Said, May 26, 2 cases, 1 death.
India: Bombay, May 15-22, 511 deaths; Calcutta, May 6-12, 92 deaths; Karachi, May 13-20, 144 cases, 135 deaths; Rangoon, May 6-12, 69 deaths.
Peru: Lambayeque, May 6-13, 2 cases; Lima, April 30-May 13, 9 cases.

Book Notices

TEXT-BOOK OF MATERIA MEDICA FOR NURSES. Compiled by L. L. Dock. Fourth Edition, Revised and Enlarged. Cloth. Pp. 330. Price, $1.50 net. New York: G. P. Putnam's Sons, 1905.

This well-known text-book for nurses has been revised to conform to the new United States Pharmacopeia. Chapters have been added on serum therapy and on mineral springs and waters. The table of solutions is practical; it gives the name of the drug used and its usual form, percentage, strength, i. e., 1-1,000. grains to the fluid ounce, and amount per liter.

HANDBOOK OF SURGERY. By G. B. Buchanan, B.A., M.B., C.M., F.F.P.S., Assistant-Surgeon, Western Infirmary, Glasgow, etc. Cloth. Pp. 547. Price, $2.75 net. New York: William Wood & Co.

This is intended as a manual for students and is chiefly a work of compilation. The subject matter is divided into three sections: 1. General Surgery. 2. Surgery of Special Tissues. 3. Injuries and Diseases of Special Regions. Each of these is in turn subdivided. There is a lack of detail regarding the technic of the surgical measures indicated in the various conditions discussed, and, as the book is intended for students, the omission is a grave one.

DIE KRANKHEITEN DES VERDAUUNGSKANALS (Oesophagus, Magen, Darm). Ein Leitfaden für praktische Aerzte. von Dr. Paul Cohnheim, Spezialärzt für Magen-und Darmkrankheiten in Berlin. Mit 17 Abbildungen. Paper. Pp. 247. Price, 5.60 m. Berlin: Verlag von S. Karger. 1905.

Cohnheim divides his book into two parts—general and special. In the first he considers the history of the patient, the physical and chemical examination, and the various methods employed for conducting these and apparatus needed. Stress is laid on the importance of the history and a thorough and painstaking physical examination which often leads to a correct diagnosis. In the second part are discussed the diseases of the several parts of the digestive tract. The book abounds in many excellent diet lists and useful prescriptions.

RELATIONS OF DISEASES OF THE SKIN TO INTERNAL DISORDERS, with Observations on Diet, Hygiene and General Therapeutics. By L. D. Bulkley, A.M., M.D. Cloth. Pp. 175. Price, $1.50. New York: Rebman Co., 1906.

This consists of a series of lectures delivered at the New York Skin and Cancer Hospital during the spring of 1905. Bulkley believes that by the separation of dermatology as a specialty attention has been directed from the relations existing between the skin and the general economy to the microscopic details and the study of local features. The predisposing and exciting causes of skin lesions are briefly considered, and the urticaria resulting from gastrointestinal derangements. He mentions copaiba, quinin, aconite, belladonna, ergot, opium and turpentine as vegetable drugs which may cause skin eruptions, and iodin and bromin and their compounds, arsenic and certain of the coal-tar preparations such as antipyrin, phenacetin, sulphonal as mineral drugs which may cause skin lesions. Digestive, excretory, respiratory, nervous and cutaneous disturbances are discussed in their relation to skin diseases. Lecture IV, the last, is devoted to a consideration of the diet in these cases and to hygiene and the general therapeutics of skin diseases.

LABORATORY GUIDE IN EXPERIMENTAL PHARMACOLOGY. Directions for the Course Given in the University of Michigan. By C. W. Edmunds, A.B., M.D., and A. R. Cushny, A.M., M.D. Cloth. Pp. 246. Price, $1.50. Ann Arbor, Michigan: George Wahr, Publisher.

This work serves as a guide for the student in making laboratory experiments along the line of pharmacology. Experiments with many drugs are carried out and observed on animals. Only those preparations with which the student most commonly comes in contact are included in these experiments, such as the more important hypnotics, the cerebral and spinal excitants, the heart stimulants and depressants as demonstrated by their action on the heart of the turtle and dog. The effects of the suprarenal extract and the nitrites on the blood pressure may be demonstrated. The experiments for the most part are simple and practical and are of value in impressing the student with an accurate knowledge of the physiologic action of a drug in order that he may prescribe it in a proper therapeutic manner.

INTRODUCTION TO MATERIA MEDICA AND PHARMACOLOGY, Including the Elements of Medical Pharmacy, Prescription Writing, Medical Latin, Toxicology, and Methods of Local Treatment. By O. T. Osborne, M.A., M.D., Professor of Materia Medica, Therapeutics and Clinical Medicine in the Yale University. Cloth. Pp. 167. Price, $1.00 net. Philadelphia: Lea Brothers & Co., 1906.

The object of this book, as stated by the author, is to introduce the student to the study of pharmacology and therapeutics, "with the purpose constantly in mind of preparing him for the practice of medicine, i. e., to care for the sick", and this worthy aim is carried out in the book. Chapter 5 on special treatments and Chapter 6 on simple food preparation contain valuable information on matters in regard to which the medical student's education usually is neglected. The book is practical in every way and will be found helpful to those who feel themselves weak in pharmacology. While errors are few, it should be noted that nitroglycerin is not a nitrite (p. 33), and that calomel is not a synonym for mercuric chlorid.

DISEASES OF INFANCY AND CHILDHOOD. Designed for the Use of Students and Practitioners of Medicine. By H. Koplik, M.D. Second edition, thoroughly revised and enlarged. Illustrated with 106 engravings and 33 plates. Cloth. Pp. 885. Price, $5.00. Philadelphia: Lea Brothers & Co., 1906.

This work has been revised, many chapters having been entirely rewritten. The chapters on "Management and Hygiene of the Normal Infant" and "Methods of Examination" are very practical. Section II of the book is devoted to the subject of infant feeding and this section alone would make the book a valuable one. Tables are given showing the composition of colostrum, normal breast milk, cow's milk, etc., and the differences in composition in human milk and that of the cow, goat and ass. Methods of modifying and Pasteurizing cow's milk are discussed in detail, and the disadvantages of sterilization as compared with Pasteurization are noted. Directions are also given for preparing the various artificial foods. Contraindications for maternal nursing are noted and the qualifications for a good wet-nurse stated. The various diseases of infancy and childhood are considered, including congenital syphilis. The illustrations are good, especially the colored ones.

Society Proceedings

COMING MEETINGS.

American Orthopedic Association, Toronto, Canada, Aug. 20-21.
British Medical Association, Toronto, Canada, Aug. 21-25.
American Roentgen Ray Society, Niagara Falls, Aug. 29-31.

AMERICAN SURGICAL ASSOCIATION.

Annual Meeting, held at Cleveland, Ohio, May 30, 31 and June 1, 1906.

The President, DR. ALBERT VANDER VEER, of Albany, New York, in the Chair.

Surgery of the Large Intestine.

DR. GEORGE E. ARMSTRONG, Montreal, Canada, said that in a very large percentage of cases of early malignant disease of the intestine there is a regular daily rise of temperature, amounting to two or more degrees, and that if this proves to

be a general rule, it will be a valuable sign. Another symptom complex referred to was the frequently recurring colicky pains associated with constipation; and when the cancer is situated in the rectum, the sudden development of hemorrhoids. These tumors sometimes lie under the liver, or under the spleen, so that they cannot be detected with the patient in the recumbent position, and yet become apparent when he stands up, or they may be discoverable one day, and the next be impalpable in any position that the patient may assume. A distinguishing feature of these tumors is their mobility, particularly mobile under the hand, and most marked when situated in the transverse colon and sigmoid.

The treatment of these cases was discussed from two points of view. First, the relief of intestinal obstruction; second, the radical removal of the growth. In the former good judgment has more to do with the results than manual dexterity or knowledge of technic, and in the case of patients with distended abdomen, stercoraceous vomiting, general peritonitis, and intestinal walls sodden and friable, nothing more should be attempted than drainage of the bowel through the appendix or an appropriately placed Paul tube. Many deaths occur through trying to do too much under such circumstances. Ideal surgery should not be considered; it is a question of expedience and of temporizing, and of giving a patient time to recover from the toxemia present. Short circuiting of the growth and its removal at the same or some subsequent time is a cleaner and more satisfactory procedure than colostomy, and a method which offers opportunity for the removal of glands. The delivery of the growth, drainage of the bowel with a Paul tube, subsequent removal of the tumor, and the establishment of anastomosis by Mikulicz's kentrotribe is commended as a safe procedure, but by no means ideal, as it is dirty, and does not generally permit thorough removal of glands.

In the so-called high cancer of the rectum good results have been obtained by the sacral methods. By this route the disease may be removed at a high level and the operation is comparatively bloodless. On the other hand it opens up a large field which too often becomes infected in spite of all precaution. The combined abdominal and perineal method is the most conservative, the safest and most radical of the methods so far employed. Through the abdominal incision the operator can get as far above the disease as is necessary. The glands may be thoroughly removed and involvement of the peritoneum or bladder, if present, may be recognized and dealt with as may seem best. The greater part of the operative work may be accomplished before the intestine is opened or the peritoneum exposed to infection. If there is sufficient of the lower end left after the removal of the disease, the intestinal canal may be restored by a sigmoidorectostomy, or an ileosigmoidostomy. If this is impossible, the upper end may be brought out through a colotomy wound, and a permanent artificial anus established. The lower end can then be separated by blunt dissection, pushed down behind the bladder, and the peritoneum closed over it much in the same way as after extirpation of the uterus. The lower end may then be removed by the perineal route. If the patient's condition is not good, the removal of the lower end of the rectum may be delayed for a few days, but in four cases in which the author removed high rectal disease by this method the patients have been remarkably free from shock, and have left the table in good condition.

Cancer of the Sigmoid and Rectum.

DR. CHARLES H. MAYO, Rochester, Minn., said that cancer of the colon is a disease in a removable structure which may remain essentially local for a long period. In the sigmoid, if the tumor is not removable, short circuiting the bowel is advisable. Low cancer of the rectum can be removed by the perineal route. Those cases which lie above easy reach are best removed by a combined operation, abdominal and perineal. If the muscular and nerve tissue can be preserved, the anal outlet is maintained; if it must be destroyed, an inguinal anus is made. If within (easy) reach and inoperable, curetting and cautery is preferable to colostomy. In five years Drs. W. J. and C. H. Mayo operated on 26 patients by the combined method. 7 died from the operation or within one month; 10 were operated too recently to be of value, but are alive and well; 7 lived over one year, 5 are alive now; 5 lived over two years, 3 are alive now; 3 lived over three years, 2 are alive now. Only 4 survived the operations made over three years ago, and 50 per cent. are alive and well, so that the results of cure are favorable, although the operative mortality is high.

Cancer of the Colon.

DR. WILLY MEYER, New York, pointed out the paramount importance of early diagnosis and timely operation, at the same time admitting the great difficulty in reaching such a consummation, chiefly on account of the usually latent development of the disease. He cited a case in which the patient had apparently been in perfect health up to within a few weeks of his death. The symptoms then developing pointed to malignant tumor of the anterior mediastinum. Postmortem showed primary carcinoma of the colon at the splenic curvature, with metastatic involvement of the mediastinum. Of the subjective symptoms that of greatest value is periodic contraction within the abdomen. It occurs usually in more or less the same locality, and, in an advanced stage of the disease, is frequently followed by a distinctly audible gurgling sound. He calls this sign "subjective stiffening" of the gut, in contradistinction to the "objective stiffening," or tetanic recurrent peristalsis of the gut proximal to the seat of the disease. In one of his own cases, a carcinoma of the transverse colon, this "subjective stiffening" of the gut represented the only symptom complained of during many months. Among the objective signs the author mentions the appearance of a palpable tumor in 40 per cent. of the cases only, chronic circumscribed meteorism, objective stiffening of the gut, and the sudden formation of capillary angiomata and pigmented warts in the skin of the abdominal wall, the latter an unfailing pathognomonic sign of cancer of the colon, provided the history and palpation point to this disease.

The age of the patient is not a contraindication to radical operation, so long as his general condition is still good. In greatly debilitated patients, palliative operation only can be performed, but if done at an early stage of the disease the objectionable artificial anus, otherwise unavoidable, may be obviated by way of a lateral anastmosis.

Surgery of Tuberculosis of the Colon.

DR. L. L. MCARTHUR, Chicago, submitted the following propositions: 1. Intestinal tuberculosis is far more frequent than has been in the past accepted. 2. Its primary nature is admitted to be 5 per cent. by the pathologists, who also claim that 25 per cent. of all human tuberculosis gains its entrance through the intestinal mucosa. 3. Either the "ulcerative" or the "hypertrophic" type of this disease is (at some time) amenable to surgical interference. 4. Interference should be either by excision or exclusion. 5. Surgical intervention in these forms of intestinal disease is better borne than in any other. 6. Early recognition by the internist and interference by the surgeon will eliminate a large proportion of cases now classified as tabes mesenterica.

Myomata of the Large Intestine.

DR. W. L. ESTES, South Bethlehem, Pa., said that true myomata of the large intestine are almost unknown. So-called myomata of the large intestines are histologically fibromyomata and they are practically always fibroleiomyomata. The rectum is the part of the large intestine which in the great majority of the cases is involved, although there are a few cases on record of myomata of the cecum, of the ascending and of the descending colon. Estes gives the history of a very remarkable case of stenosis of the sigmoid flexure, which resulted from enormous and symmetrical hyperplasia, chiefly of the muscular coats of the gut, and which formed a well-marked tumor of the intestine. The intestine was strictured, almost entirely closed, within the area of the tumor, not above it, nor below it, and the stenosis was produced by the bulk of the hyperplastic muscular layer. Histologically, it was classed as a myofibroma. He has not been able to find any mention in the literature of a similar case. He believes that his case is very rare, and that it indicates the possibility of a fourth class of tumor of the large intestine, which belongs to the myomatous groups.

Surgery of Carcinoma of Rectum and Sigmoid Colon.

DR. JOS. C. BLOODGOOD, Baltimore, Md., stated that in the majority of these cases the hope of future progress depends more on earlier recognition than on improvement in operative technic. The only partially settled problem is in regard to the extent to which glandular dissection shall be carried. At the present time the majority of authorities favor a restricted glandular operation in view of the higher mortality of the more extensive dissection and the slight probability of a cure if these more remote glands are involved. In planning for the complete extirpation of these growths one should resect a very generous portion of the apparently uninvolved intestine on each side of the palpable tumor, because infiltration of the new growth along the submucosa beyond the open ulcer is a common occurrence. The next most important step is to include with this portion of the bowel a large area of mesocolon, whether the glands be palpable or not.

In selecting the point for the division of the bowel above and below the tumor one should have in mind not only the complete removal of the tumor, but to select a point for division which shall have, after the resection of the mesenteric area, a proper blood supply. The decision as to the method of suture after the resection is a somewhat difficult one. As a rule, closure of the two ends with a lateral anastomosis is the safer procedure. As the tumor of the colon approaches the promontory of the sacrum new problems arise. In some instances there is sufficient healthy bowel below the tumor to allow a resection and suture within the abdomen. In other cases, on account of the position of the tumor, or its infiltration analwards, the resection can only be accomplished completely by a combination of an abdominal and extra-abdominal or sacral incision. He has endeavored not only to fulfill the requirements of a complete removal of the malignant disease, but to attempt, after its removal, a restoration of the continuity of the bowel by an end to end anastomosis. In one case he was able to perform the complete resection of a carcinoma situated just above the promontory of the sacrum entirely within the abdomen. The condition of the patient, however, forbade at that time an attempt at suture. At the present writing, eighteen months since operation, the patient is content with the colostomy. In a second case it was necessary to finish the resection through a sacral incision. In this instance it was possible to save, with a good blood supply, eight inches of the lower end of the rectum, which rendered an end to end suture in the sacral wound possible. The result at the present time is unusually satisfactory. In the third and most recent case it was possible to resect and suture entirely within the abdomen.

A careful study of the cases in the literature appears to justify the following criticisms: First, colostomy has been performed too frequently as a primary operation. He believes that colostomy is not indicated unless the patients are first seen in the condition of an acute obstruction, or their condition is so critical from chronic obstruction that a prolonged operation is contraindicated. If possible, the entire operation should be performed at one sitting. Second, it is unnecessary to ligate the vessels so far from the mesenteric border of the colon. Resection of the glands up to this point is not indicated. If they are involved, his experience demonstrates that the condition is hopeless for an ultimate cure. The disadvantage of ligation of the vessels so far from the colon is due to the fact that, after such a ligation, a more extensive resection of large intestine is necessary in order to leave the bowel with proper circulation. Third, too much bowel below the tumor is removed.

(To be continued.)

MASSACHUSETTS MEDICAL SOCIETY.

Annual Meeting, held in Boston, June 12-13, 1906.

(Continued from page 1937.)

Owing to the recent session of the American Medical Association the subject of "Diseases of the Bile Passages," including the liver, gall-bladder and pancreas, was the only scientific topic presented for discussion.

DR. VICTOR C. VAUGHAN of Ann Arbor, Mich., in the "Shattuck Lecture" considered "The Chemistry of the Bacterial Cell," and in the "Annual Discourse," delivered this year by Dr. John L. Hildreth, of Cambridge, "The Relation of the General Practitioner to the Specialist" was discussed.

The question of amending the by-laws relating to membership in the society provoked an animated discussion. For thirty years or more the society has forbidden its members to practice "spiritualism, homeopathy, allopathy, Thomsonianism, eclecticism or any other irregular or exclusive system, generally recognized as such by the profession, or declared so by the councillors of the society." Practically, homeopaths formed the class chiefly under discussion, and a committee, of which Dr. F. C. Shattuck, of Boston, was chairman, after calling attention to the demise of some of the other sects, presented an amendment allowing, under strict educational qualifications, one to become a member, provided he "does not profess to treat disease by, or does not intend to practice any exclusive system, generally recognized as such by the profession, or declared so by the councillors of the society." After considerable discussion the amendment was adopted.

More than twelve hundred members sat down at the annual dinner at which addresses were made by President Charles W. Eliot of Harvard University, and Judge Henry N. Sheldon, one of the trial justices in the Tucker murder case, who presented some considerations on the value of circumstantial evidence.

AMERICAN GYNECOLOGICAL SOCIETY.

Thirty-first Annual Meeting, held at Hot Springs, Va., May 22-24, 1906.

(Concluded from page 1967.)

Surgery of Female Pelvic Organs.

DR. SETH C. GORDON, Portland, Me., presented the following conclusions: "1. The Battey operation does much good in the practice of men of experience and skill in operating. The results in many cases are often delayed for obvious reasons. Undoubtedly much more harm than good is done because of inexperience in pathology and operative skill. 2. So-called conservative gynecology in too many instances is but a conservatism of diseased organs, in whole or in part, and not conservative of the health of the patient. 3. The sentiment is changing from this extreme conservatism to a more careful consideration of the future condition of the patient, as instanced in a more general belief in hysterectomy for fibroids of the uterus instead of myomectomy. 4. In resections of the adnexæ regard should be paid to the history of the cause of infection rather than to the macroscopic condition, as the virulent germs produce changes that require total removal, together with the uterus, as the only safety to the patient. 5. In malignant disease of the uterus efforts should be made to discover it early, when panhysterectomy might be done to advantage. Advanced cancer may be treated tentatively by curettement and actual cautery. The extremely extensive operations of attempting removal of a wide margin around the uterus have produced unsatisfactory results, with a very high mortality and early recurrence. 6. Surgical measures for displacements are still *sub judice* so far as any agreement as to any special method is concerned.

Conservative Operations on the Ovaries.

DR. J. MONTGOMERY BALDY, Philadelphia, said that senile sentiment has no place in deciding what should be done in the presence of a diseased ovary. Nor is the anatomic limit of disease and health in this organ the only thing to consider. It is difficult to tell what is and what is not disease in the ovary, even microscopically, and in a very large number of instances it is necessary to decide the question by the symptoms and not by the makeup of the organ. Conservative operations on the ovaries are so commonly mixed up with the removal of adhesions, replacement of the uterus and other accompanying procedures that it is utterly impossible to distinguish between results. Immediate results and end results are different. End results are not always reliable. It is only by the survey of the whole case, general as well as local, together with a profound practical knowledge of human nature, as well as a sublime respect for the vagaries of women's nerves, that one appreciates the full truth. Again, end results are important in that large

numbers of women are operated on, the lesions corrected, and yet no good results or only temporary results are obtained.

Putting the facts squarely before the ordinary woman, giving her full, unprejudiced freedom of decision, in twenty-four cases out of twenty-five she will decide for a complete operation. Sentiment exists largely in the physician, not in the woman, and the few who are influenced by it have been educated up to that point by physicians who object to the removal of the ovaries because they have found on analysis of a group of cases that "78 per cent. subsequently suffered a notable loss of memory, 60 per cent. were troubled with flashes of heat and vertigo, 50 per cent. became irritable, less patient, and some so changed as to give way to violent and irresponsible fits of temper; 42 per cent. suffered more or less from mental depression, 35 per cent. increased in weight, and some became abnormally fat," the general intelligence being such as not to appreciate that the picture drawn as one of bad results following faulty judgment consists merely of the symptoms of the natural and inevitable menopause and which would in a short time leave the woman as surely as they came to her.

End Results in One Hundred Cases of Conservative Operations on the Uterine Appendages.

DR. WALTER P. MANTON, Detroit, Mich., said that in order to ascertain his own experience along conservative lines he had taken 100 cases from his notebooks. Of the 100 women, 30 were single, 64 married and 6 not noted. The following operations were done: On the ovaries, resection of both ovaries in 17 cases, right ovary in 26 cases, left ovary in 13 cases. Puncture of both ovaries in 22 cases, right ovary in 8 cases, left ovary in 14 cases. In 19 women the ovary of one side was found to be so largely involved as to require removal, the right in 6 instances, the left in 13. Resection was done in both tubes in 13 cases, right tube in 4 cases and left tube in 9 cases. It was found necessary to remove one tube in 10 of the patients, the right in 4 and the left in 6. The opposite ovary was left untouched or was resected.

In the 100 women the immediate results were entirely satisfactory, that is, all the patients recovered from operation and were relieved from the sufferings of which they formerly complained. The mortality was, therefore, *nil*, and the results temporarily perfect. The majority of these patients remained under observation for at least three months. Following this quarter year, 61 are known to be well at present, 31 have been lost sight of, 5 are doubtful, complaining of pelvic pain referable to the resected ovary, but in which no change could be detected on examination, and 3 required a second operation for the removal of the conserved organ, which in each instance had undergone further cystic degeneration. Of the 64 married women, 55, or 85 per cent., and of the 30 single women, 23, or 75 per cent., were well a year following operation. Of 64 patients of whom knowledge was had a year or more following operation, 41 were married. Of this number, 6, 14 per cent., subsequently became pregnant; 4 of these were delivered at term, 1 aborted at the third month and 1 is still pregnant.

From the foregoing he maintained that his own statistics and those of others show that the conservative surgery of the ovaries and tubes, having passed the experimental stage, has established itself as a legitimate and successful operation in all the conditions to which it might be applied properly, and that it should be the operation of choice in all instances during the child-bearing age, in which the diseased state of the organs admits of its employment.

Technic of the Repair of Large Vesical Fistulae.

DR. WILLIAM S. STONE, New York, summarized his paper as follows: 1. The basic principle in the repair of large fistulæ is an extensive separation of the bladder walls, especially of the upper part in front of the cervix, by means of which it is readily sutured to the more fixed lower portion. 2. The uterus, which has been made movable by the free dissection entailed in the separation of the bladder, or by an additional incision posteriorly in some cases, is a most valuable supplement in filling up the opening in the vaginal wall. 3. With these principles applied it is a matter of little importance what kind of suture material is used or what relation the vesical and vaginal suture lines have to each other.

Treatment of Vesico-Vaginal Fistulae.

DR. I. S. STONE, Washington, D. C., said experience has shown that wounds of the bladder made during the performance of a surgical operation heal readily after careful application of sutures. This occurs after injuries at the base, as in vaginal hysterectomies, as well as in those at or near the fundus, which are comparatively frequent in operations on the uterus for the removal of tumors. Two principal causes contribute to this result. One is the healthy condition of the bladder itself and another is the ease with which the muscular wall of the organ can be approximated when absolutely free from the uterus or vaginal wall. It has been his experience that the very large fistulæ afford such free drainage as to secure perfectly healthy mucus surfaces of both bladder and vagina, the only exception being in one bedridden patient who had been indifferently cared for and whose fistula was covered with incrustations. It will be found in many instances that large fistulæ persist because they are associated with injuries of the vagina, of a serious character, which produce extensive cicatricial contraction. Such an injury is more than a mere incision or laceration of the vaginal wall, and includes the connective tissue also, which becomes a permanent retractor to the margins of the fistula and prevents its closure until surgical relief is afforded.

He feels confident that any fistula can be closed satisfactorily by first liberating the bladder from any adherent surface or organ which prevents its closure, and then by uniting the margins of the fistula with catgut, and afterward, at the same sitting, by utilizing the vaginal wall of the uterus as might be needed to support the line of sutures in the bladder wall. This is opposed to the contention of those who favor suture of the supporting base only the vaginal wall, for example. Finally, one might draw the vaginal walls forward after suitable dissection, or he might utilize the uterus, as suggested by Kelly, or by using the Freund method of turning the fundus downward and then forward into the opening. This last method is objectionable because it necessitates a new opening into the cavity of the uterus to provide for the escape of the menstrual flow. He has overcome the disadvantages of Kelly's method and has obtained abundant mobility by drawing down the uterus, cutting away the anterior vaginal wall and dividing the broad ligaments so as to cause less traction on the sutures. This has also been accomplished by separating the bladder from the uterus and broad ligaments through an abdominal incision and by a division of the broad ligaments at their upper border, where they are attached to the uterus. This method has been used for the relief of fistula of any description, and the profession owes acknowledgment to Mackenrodt for priority and for clearly establishing its usefulness in almost any fistula of whatever shape, position or size. In the treatment of small fistulæ the vagina is divided longitudinally, the bladder is separated from the vaginal wall, then united, and the vaginal wall closed, each independently. He has found its best and most useful application in the closure of large fistulæ and where failure has resulted after previous attempts at cure.

Shortening of Round Ligaments Within Inguinal Canals Through a Single Suprapubic Transverse or Median Longitudinal Incision.

DR. REUBEN PETERSON, Ann Arbor, Mich., said that in his hands the Alexander operation for shortening the round ligaments has proved the most satisfactory of all the operations for backward displacement of the uterus. However, the operation has two great disadvantages: It is limited to freely movable uteri and it necessitates two incisions. In the operation now employed by Peterson the work is performed (1) through a single incision, preferably through a suprapubic, transverse incision not more than three inches in length; (2) the external rings are easily exposed by such an incision; (3) they can be readily, although not so easily, exposed by the ordinary median longitudinal incision; (4) the operation is applicable to adherent as well as movable uteri, since the abdomen is opened in every instance; (5) by following out a certain technic the round ligaments can be definitely and quickly located in every instance.

Hypernephroma Renis.

DR. J. WESLEY BOVÉE, Washington, D. C., reported two such cases and said that hypernephroma is the commonest form of

kidney tumor. Many kidney tumors formerly thought to spring from kidney structure are now known to originate in islands of suprarenal tissue included in the kidney, the so-called renal nests. Such deposits of renal tissue are common along the genitourinary tract, are usually benign in character, but may become malignant. The treatment consists of removal when they cause symptoms.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

The Removal of Foreign Bodies from the Eye.

Among the most frequent minor accidents that mankind is heir to, according to A. R. Baker, in the *Cleveland Medical Journal*, is the danger of the introduction of foreign bodies in the eye. In the removal of these bodies Baker states that the cornea should be exposed to a good light and that the physician should have perfect eyesight, a steady hand and good judgment. Before attempting to remove a foreign body two or three drops of a 2 per cent. solution of cocain should be instilled into the eye at intervals of one or two minutes. He speaks of the importance of having on hand a freshly prepared solution of cocain, and says that no solution should be used which is more than twenty-four hours old. Consequently he advises the method of preparing solutions from hypodermic tablets. A tablet containing 2 3/5 grains to the dram of boiled water will make approximately a 2 per cent. solution. In cases in which the eyes are irritable or sensitive to light, a drop of the cocain solution in the uninjured eye will greatly facilitate the ease of the removal of the foreign body from the effected eye. The lids should be thoroughly cleansed, as well as the surgeon's hands and all instruments used in this connection.

The great danger lies not infrequently in the fact that the patient immediately rubs the eye when a foreign body has entered it, with his dirty fingers or a dirty handkerchief, thus increasing the probability of infection. On the other hand, if it were let alone, profuse lachrymation in a great many instances would dislodge the body.

The most frequent form of infection is that of an acute catarrhal conjunctivitis, generally brought on by the application of bread and milk, flaxseed or other poultices. These substances usually contain numerous pathogenic bacteria placed on a splendid receptacle, which is the conjunctiva. If these cases are not of long standing, or if the secretion is of a purulent character, the eye may be washed out with sterile water or a saturated solution of boric acid, followed by a 2 per cent. solution of some silver preparation, and this followed by repeated flooding of the eye with a boric acid solution. If an ulceration of the cornea should arise, the prognosis, of course, is more grave. If this ulcer shows a "dirty" appearance, all the shreds of the broken-down epithelium should be scraped off with a needle, or any other instrument used for removal of foreign bodies, then a fine probe or toothpick wrapped in a piece of sterilized cotton should be dipped into a solution of bichlorid of mercury (1 to 250 to 1 to 500), and applied to the ulcer; at the same time giving the cotton a slightly rolling motion, so as to touch every particle affected. Great care should be used to prevent an excess of the bichlorid in order to avoid coming in contact with the healthy cornea. If there are no conjunctival complications, a compress bandage with dry dressings may be used, but if there is any suspicion of a conjunctivitis, past or present, the eye should be left open. If pain is present, even though there be no evidence of an iritis, he recommends that a solution of atropin, 4 grains to the ounce, be dropped into the eye two or three times a day. The use of hot fomentation is, as a rule, the most valuable adjunct to this treatment. They should be used for from twenty minutes to an hour, and repeated two or three times a day, or more frequently if the pain persists.

The Treatment of Psoriasis.

P. S. Abraham, in the *British Medical Journal*, states that if he were asked as to the comparative efficacy of external and internal treatment of psoriasis, he should prefer the external treatment. In his experience the eruption of psoriasis practically always disappears under application of some tar preparation, especially chrysarobin; even where no internal medication has been carried out. However, he advises both external and internal medication, although there is no specific for psoriasis. He regards arsenic of benefit as a nerve tonic, especially in those patients who have a neurotic tendency, when it may be pushed to its toxic effects and cause a temporary disappearance of the eruption. Another substance which influences the nutrition of the skin and sometimes has a beneficial effect on psoriasis is thyroid extract. He remarks, however, that after the treatment of some 65 patients, extending over a period of several months, that only a few showed improvement. In more than half the cases the result was either negative or the eruption actually increased while the preparation was being administered. He advises the administration of magnesium sulphate with a little iron and some bitter tonic as of value in regulating the bowels, promoting excretion and improving the general nutrition. In every case in which there is the least suspicion of a uric acid diathesis, he recommends the administration of salicylates, salicin and alkalies. As regards external remedies, he, as a rule, orders a thorough soaking of the skin for at least ten minutes in a weak tar bath every day, followed by a copious inunction with some ointment containing a tar preparation. He does not consider the exact preparation of any material importance. In this connection he prefers creolin as a preparation which will answer the purpose. He recommends as a bath 3i (4.00) of this preparation to six gallons of water, and as an ointment for the indurated patches on the extensor surface the following combination:

℞ Creolin 3i-ii 4-8
Acidi salicylici
Hydrargyri ammoniati, āā ..... gr. x .65
Lanolini q. s. ad 3i 30

M. Ft. unguentum. Sig.: Apply locally to the affected areas.

In some cases the addition of soft soap, 3ii-iii (8.-12.), and occasionally precipitate of sulphur gr. xv (1.00), to the foregoing combination, is recommended by the author.

He states in this connection that the proportion of the ingredients must be varied, either diminished or increased, or some of them perhaps entirely omitted, depending on special circumstances of the case, the idiosyncrasies of the patient and the parts affected. Good results, as a rule, are obtained from this outline of treatment within a few weeks. In those cases in which the progress is slow he adds chrysarobin, gr. x-xx (.65-1.30) to the foregoing ointment, especially when the case can be properly watched. In cases of psoriasis of the scalp he recommends the following combination:

℞ Hydrargyri ammoniati
Saponis mollis, āā 3i 4
Liquid petrolati 3i 30

M. Ft. unguentum. Sig.: Apply locally to the scalp.

He sometimes recommends the addition of resorcin or some tarry oil to the foregoing combination.

Diarrhea in Infancy.

The following combinations are recommended by Yeo in the treatment of diarrheas occurring in infancy:

℞ Sodii bicarb. ..... gr. iv .25
Pulv. rhei ..... gr. iss .09
Pulv. cinnamomi ..... gr. i .06

M. Ft. chart. No. i. Sig.: One such powder to be taken twice a day.

When curds of milk are present in the stools the following combination is recommended:

℞ Pulv. ipecac. et opii ..... gr. xv 1
Pulv. guaranæ ..... gr. 3 4 .05
Pulv. sacchari albi ..... gr. xlv 3

M. Ft. chart. No. x. Sig.: One powder every two or three hours.

In cases of profuse diarrhea without dyspeptic symptoms the following combination is recommended:

R.	Tinct. krameriæ	3ss 2 |
	Tinct. opii	m. iss |09
	Syr. simplicis	3iiss 10 |
	Aquæ destil	3iii 90 |

M. Sig.: One dessertspoonful every two hours.

In cases in which anemia is a factor following chronic diarrhea the following combination is of service:

R.	Ferri carb. sach.	|
	Pulv. ipecac. et opii, āā	gr. iss |09

M. Ft. chart. No. x. Sig.: Three or four powders daily.

In cases of fetid diarrhea, in which there is marked evidence of putrefaction with foul odor, the following is recommended:

R.	Ferri sulphatis	|
	Sodii salicylatis, āā	gr. xx 1 |30
	Glycerini	3iii 12 |
	Aquæ	3iii 90 |

M. Dissolve the sulphate of iron and the salicylate of soda separately and then mix. Sig.: One tablespoonful every three hours until the stools are blackened.

In summer diarrhea the following is of value:

R.	Decoct. hematoxyli (5 per cent.)	|
	Acidi sulphurici arom., āā	3ii 8 |
	Spiritus chloroformi	3vi 24 |
	Tinct. opii camph.	
	Tinct. card. comp., āā	3i 30 |

M. Sig.: One teaspoonful in water after each movement of the bowels.

In cases of ulcerative colitis Yeo recommends the following combination as a rectal injection:

R.	Argenti nitratis	3ss-i 2-4 |
	Aquæ dest.	Oi-ii 500-1 000 |

M. Sig.: Elevate the hips and allow the water to flow in slowly from a syphon bag.

In some cases of chronic diarrhea in adults the following is recommended:

R.	Tinct. catechu	|
	Tinct. kino, āā	3ii 8 |
	Tinct. opii	3i 4 |
	Spts. camphoræ	3iss 6 |
	Misturæ creta q. s. ad	3iii 90 |

M. Sig.: Two teaspoonfuls every four hours.

When the diarrhea is accompanied by flatulency the following combination is advised in adults:

R.	Tinct. opii	m. xv 1 |
	Ext. hematoxyli	gr. lxxv 5 |

State Board Law Valid—License Revocation and Review.

The Supreme Court of Nebraska holds, in Munk vs. Frink, that the act of 1891 creating a State Board of Health is not rendered void by the fact that it provides for compensation of its secretary by fees which are not required to be accounted for or paid into the state treasury.

A complaint filed before the State Board of Health for the purpose of procuring an order revoking the license of a physician is sufficient if it informs the accused, not only of the nature of the wrong laid to his charge but of the particular instance of its alleged perpetration. By section 580 of the Code of Civil Procedure the district court is given jurisdiction to review, by proceedings in error, an order of the State Board of Health revoking the license of a physician.

The Supreme Court commissioners in writing the opinion of this case say that a licensee does not necessarily have a property or contractual right in his privilege, so as to render a revocation of his license a judicial act, but they think that the legislature confers a quasi property or contractual right by providing that revocation shall be only for specified cause or causes arising out of the conduct of the licensee and analogous to a forfeiture, the declaration of which is essentially a judicial act. This view does not, of course, involve a limitation of the power of the legislature to revoke the license by direct enactment.

Death from Compressed Air Being Turned on Person.

The Court of Civil Appeals of Texas says that what is now entitled the case of the Galveston, Harrisburg & San Antonio Railway Co. vs. Currie was brought to recover from the company for the death of an employé alleged to have been caused by compressed air being injected into his bowels from a compressed-air hose turned on him by his foreman. It was true that this seemed to have been a result of an application of compressed air to a person that staggered the comprehension of the physician who testified in the case, who said he did not believe it possible for a hose of the size of the one in question to so overcome the sphincter muscle as to allow air to rush into the bowels of the employé, but he went on to say that it did. It was probably safe to say from the evidence that the foreman did not expect the air to penetrate the employé so as to cause his death or do him any real harm. But the act was the direct and proximate cause of the employé's death, and in such cases it does not affect the liability of the wrongdoer that the consequence of his act was something unforeseen or improbable. The act was calculated or likely to do some injury, and as this was the case it was necessary that injury in the precise form in which it in fact resulted should have been foreseen. Moreover, the court considers that under all of the circumstances the railway company could be held liable for the death, and so affirms a judgment against it for damages therefor. And it says that it was immaterial that in turning the hose on this employé the foreman was prompted by a spirit of fun.

Relative Powers of Examining Board and Courts.

The Supreme Court of Idaho holds, in the case of Raaf vs. State Board of Medical Examiners, that, under the act approved March 3, 1899, known as the "State Medical Law," the State Board of Medical Examiners, in the examination of applicants for a license to practice medicine and surgery, is required to exercise judgment and discretion in granting or refusing licenses to such applicants, and in so doing exercises quasi judicial functions. The state medical law contains no provision granting the right of appeal from the action of the board of examiners in refusing a license to an applicant, but by the terms of section 9 of the act it is provided that the action of the board in refusing to grant a license under the provisions thereof may be reviewed by the district court on certiorari, as it is called, provided proceedings therefor are instituted within ten days after notice of such refusal. By conferring the right to have the action of the board in refusing to grant a license reviewed, as provided in section 9 of the act, the legislature has indicated an intention to limit and confine the authority and jurisdiction of the courts in considering the action of the board to the procedure and scope of investigation and inquiry usually and ordinarily pursued and exercised by the courts in the issuance and consideration of writs of review. The legislature has provided for a board of experts learned in medicine and surgery for the purpose of examining applicants for license to practice within the state, and the language of the medical act and the purposes and objects thereof preclude any inference that the legislature ever intended that a disappointed applicant might apply to the court and there have his answers re-examined, marked, graded and passed on as to their correctness by the court. The courts are open to compel action by the State Board of Medical Examiners when they fail or refuse to act, and to review their authority where they have assumed to exercise powers not conferred; but the courts will not review and re-examine matters in which the board is called on to exercise judgment and discretion, and perform quasi judicial functions in reference thereto.

The legislature, the court says, had in view the protection of the health of the people of the state, and, as a means to effect that end, determined that all persons thereafter intending to enter the practice of medicine and surgery should

be examined as to their fitness, learning and qualifications by a board of experts learned in the science and art of that particular profession. Is it at all probable that the legislature ever intended that a disappointed applicant might apply to the court and there have his answers re-examined and passed on by one unlearned, perhaps, in a single one of the branches of this science? Courts are neither required nor expected to be experts in therapeutics, gynecology, toxicology, diagnosis, etc., and for them to undertake to examine and grade physicians on such branches would be an unwarranted assumption of jurisdiction. The layman, wandering among the puzzling mazes of materia medica and the speculative bewilderments of pathology, might with equal assurance and conscientiousness grade an applicant who had correctly answered all the questions at 10 per cent., and one who had correctly answered none at 100 per cent. As to the plaintiff's contention that, since he had introduced in evidence what he claimed were correct text-book answers to the questions, the court could have a standard by which to examine and grade answers, the court says that this would hold good so long as the answers of the applicant might be in the same language as the answers which were shown to be correct, but the moment the applicant's answer branched out into different language, and his own mode of expression, a court, not proficient in the science of a profession characterized by abundant technical language and phraseology, would encounter perplexities and difficulties unnumbered.

Again, the court says that there are no set, fixed or inviolable rules by which such a board must determine whether a question has been answered correctly or incorrectly. Knowledge must be brought to bear and judgment must be exercised. The science of medicine is not such an exact and immutable science but that those who are eminent and learned in the profession often differ in a diagnosis, or as to what would be an absolutely correct answer to a given question. It is a progressive science. This is one of the chief considerations for requiring such examinations to be conducted by those who are proficient and learned in the profession. If the board should fail to act when it is its duty to act, the courts are open to enforce action. If it acts without jurisdiction, the courts are open to inquire into and review the authority they have assumed to exercise. The court can not, however, under the medical law of Idaho, be converted into a board for the examination of applicants for a license to practice medicine and surgery. Questions of bias or prejudice existing in the mind of any member of the board against an applicant or of incompetency of a member, or of errors and mistakes of judgment or unfairness in marking and grading an applicant's papers are matters that may be properly addressed to the executive authority from which they receive their appointment, who may take such action thereon as the best interests of the public demand.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

Medical Record, New York.

June 16.

1 Neurons and Neurofibrills. J. Collins and G. E. Zabriskie, New York.
2 *The Lenhartz Treatment of Gastric Ulcer at the Eppendorfer Krankenhaus. J. V. Haberman, Hamburg, Germany.
3 *Treatment of Stammering. E. L. Kenyon, Chicago.
4 *The Stomach Douche and Its Application. M. Gross, New York.
5 *Diphtheria Antitoxin in Chorea. B. F. Hamilton, Emlenton, Pa.
6 Reichenhall, Bavaria: A Climatic Resort. L. Gruenwald, Munich, Bavaria.

2. **Lenhartz Treatment of Gastric Ulcer.**—Haberman gives the following treatment of gastric ulcer: Absolute rest in bed for at least four weeks; avoidance of all mental excitement; the almost continual use of an icebag over the stomach for two weeks; the administration of between 200 and 300 c.c. of iced milk, given in spoonfuls and from two to four beaten eggs; the administration, for 10 days, of 2 gm. of bismuth subnitrate at a dose. The eggs are beaten up entire, with a little sugar and the dish containing them is placed in a receptacle filled with ice; sometimes a little wine is added. This food at once "binds" the supersecretive acid, mitigates the pain, and causes the vomiting to cease. After a few days some raw chopped meat is given. In the third week quite a mixed diet is allowable.

3. **Treatment of Stammering.**—Kenyon advances three main ideas in his discussion of the treatment of stammering: First, education that the patient may consciously learn how to handle his speech apparatus; second, discipline, that he may overcome a firmly-rooted and stubborn habit; and, third, correction of general organic disability, and of peripheral abnormalities, in order that the delicate mechanism of speech may not be physically interfered with. The patient must at once be made a student of normal speech from the standpoint of the technic of its production. This new knowledge must be immediately put into practice. Speech is now no longer automatic, but becomes a function governed in detail by the consciousness and the will. The patient will gain control of his speech mechanism and direct it in detail. But even then the subconscious nervous structures must be held well in hand until they can be entrusted to assume control. This defect should be corrected at an early stage and firmness of purpose on the part of the patient is one of the important elements in its successful treatment.

4. **Application of Stomach Douche.**—Gross gives as the strict indications for the introduction of the stomach tube for therapeutic purposes: Acute toxic inflammations, intoxications, and ileus; old mucous or non-mucous gastric inflammations; a small number of sensitive neuroses, hyperesthesias, chronic ulcerative affections, erosions; anomalies of secretion, or chylorrhea; and disturbances of motility in both atonic and mechanical gastrectasia. The tube which Gross has used during the last few years differs from the ordinary stomach tube in that it is provided with an end opening and a number of small, pinhead-sized lateral holes which perforate the walls of the tube in different directions. The action of this stomach douche is mechanico-chemical, thermic, or both. A loose hard rubber valve is placed at the large end aperture, which it tightly closes as the fluid is injected. As the upper end of the tube is lowered, the outflowing stream pushes the valve up.

5. **Diphtheria Antitoxin in Chorea.**—Hamilton saw a case of diphtheria in a boy 15 years old, about nine years ago. The patient had suffered from an aggravated form of chorea for several months. He gave the boy full doses of diphtheria antitoxin, after which the choreic symptoms disappeared and did not return. The boy lived only one week. Recently Hamilton attended a young man who suffered from chorea following rheumatism. Delirium developed into a violent mania, and it was plain that unless relief was soon afforded, death was not far distant. Three thousand units of diphtheritic antitoxin were administered, after which the choreic symptoms were so much relieved that all restraint was removed. After two more doses, the first of 1,500 and the second of 2,000 units of antitoxin, all irregular muscular symptoms subsided and have not yet returned. It is now over a month since this treatment was instituted.

14 *An Unmentioned Means of Puerperal Infection. G. W. Greene, Auburn, N. Y.

9. **Surgical Treatment of Indigestion.** According to Deaver, the problems of the proper treatment of chronic indigestion can only be worked out by the physician and surgeon together.

Very many cases of chronic indigestion—gastric, biliary or appendicular—are really a form of surgical disease, and those which do not yield within a reasonable time to rational medical treatment, Deaver believes can almost without exception be promptly and permanently cured by surgery. The surgeon, if called into consultation early, may decide with the aid of his medical colleague not only which are proper cases for surgical intervention, but also at what period of the disease surgical remedies had best be advised.

11. Bier's Method in Acute Purulent Otitis Media.—Kopetzky claims that the Bier bandage applied early in cases of acute otitis media, with or without complicating mastoiditis, is a measure productive of good results in cases selected among the young and the otherwise healthy.

14. Puerperal Infection.—Greene reports a rather unique case of puerperal infection the result of an infection conveyed by the husband, who was in the habit of making almost daily vaginal examinations for the purpose of noting the course of the pregnancy. At that time the husband was handling hides for a hide merchant, but as his ambition was to become a physician, he had in some way gained possession of a book on obstetrics, which he had read. The labor was perfectly normal, but two days later the patient was taken with a chill, which was followed by a terrible attack of puerperal fever. The woman eventually recovered, but was perfectly blind in one eye and partially so in the other from an intercurrent attack of optic neuritis. Greene is convinced that the germs were carried from the filthy hides which the husband handled to his wife's genital tract.

22. Etiology of Puerperal Sepsis.—Voorhees concludes that the etiology of puerperal fever can be traced, in almost all cases, to external infection—imperfect technic; but that there are a few cases for which the medical attendants are in no way responsible and that must be attributed to so-called autoinfection.

24. Treatment of Puerperal Infection.—Cragin calls attention to extragenital sources of infection during the puerperal period, such as appendicitis, pyelitis from the colon bacillus and mastitis. If a rise of temperature does not subside as the breast improves, the uterus should be investigated. Two conditions must be recognized. First, a toxemia due to the absorption of (1) a product of putrefactive bacteria, or (2) the toxins of distinctively pathogenic bacteria. Second, a bacteriemia, in which bacteria circulate in the blood. Every case should be considered as a toxemia until evidence to the contrary is obtained. The uterus should be emptied, if possible, by the intrauterine route; if not, by the finger or the curette, the finger being preferred. A form of toxemia is due to the retention of the uterine flow by marked anteflexion. The treatment of puerperal bacteriemia is chiefly that of the general condition. Of drugs, alcohol and strychnin have given Cragin the best service. The use of silver preparations appears to be harmless but inefficient, and the same may be said of antistreptococcus serum. The author makes it a rule never to perform a hysterectomy for puerperal infection during the puerperium unless he can obtain evidence of the localization of the infection with pus formation either in the uterine wall or in the appendages.

27. Tuberculous Infection of Uterine Myomata.—Dickson reports a case in which a myoma of the uterus was tuberculous, the infection having reached the tumor probably from the endometrium. The tuberculosis of the tube was apparently primary and a descending infection of the endometrium.

29. Surgical Operations on the Insane.—Broun concludes that if the operation, when needed, has been properly done and the patient is not mutilated by an uncalled-for castration, the mental condition is never exaggerated. Under the stimulus of the improved somatic state resulting from surgical relief and hygienic treatment some of the patients show greater mental changes under the moral and therapeutic care than was known before such relief was given. At times this improved mental state continues to one of recovery. The primary object of surgical operations on the insane should be to improve the physical status of the patient with one end only in view—that of relieving them of physical suffering and nervous disturbances. If as a result of this relief they are mentally improved it is a welcome sequel, one for which the surgeon feels doubly repaid.

FOREIGN.

Titles marked with an asterisk (*) are abstracted below. Clinical lectures, single case reports and trials of new drugs and artificial feeds are omitted unless of exceptional general interest.

British Medical Journal.

9 Severe Punctured Wound of Lower Jaw. E. G. Wales.

3. Abdominal Section for Rupture of Uterus.—Cripps reports three cases. The first patient, a multipara, had a placenta previa which was followed by rupture of the uterine wall, the tear being in the right lateral aspect posteriorly. It included the entire length of the cervix, extending upward for several inches into the lower uterine segment and downward into the upper aspect of the vagina. The patient died immediately after the last suture had been inserted. At the autopsy the uterine wall showed evidence of considerable fatty infiltration of the muscular fibers. The second patient, also a multipara, had a tear about four inches in length, extending from the vaginal fornix upward to nearly the site of origin of the Fallopian tube. The case was one of breech presentation and the rupture occurred before the birth of the child. The patient was operated on immediately and made a perfect and uninterrupted recovery. In the third case the tear extended from immediately below the fundus to the neighborhood of the internal os. This patient also recovered.

4. Tubal Pregnancy. The first case reported by Whiteford is an example of the variety in which after rupture of the tube the blood being slowly and intermittently poured out is limited to the lower abdomen by adherent omentum and intestines, from which are derived the bacteria which infect the blood clot. The second case is an example of the fulminating type of hemorrhage following rupture. The third case illustrates what is probably the most usual condition found after

rupture of the tube, not involving the death of the fetus, which continues to develop between the layers of the broad ligament.

18 Case of Angioneurotic Edema. C. A. P. Truman.
19 Hygiene of the Tissues; Hygiene of the Alimentary Canal. E. Metchnikoff.

13. **Malignant Disease of the Appendix.**—Rolleston and Jones have collected 62 supposed examples of primary malignant disease of the appendix. After carefully excluding those not confirmed by the microscope and those which may have been primary in the cecum, the number is reduced to 42, of which the diagnosis was carcinoma in 37 cases, endothelioma in 3, and sarcoma in 2. In most of these the condition was found during an operation, but 9 examples were discovered at necropsy or as the result of a routine examination of the appendix afterward. In only 5 of the 42 cases were secondary growths described as being present.

14. **X-Ray Diagnosis of Kidney Stone.**—Holland sums up his paper as follows: 1. When a stone or stones are present in such size as to produce symptoms suggesting the desirability of operation, if a careful and thorough examination is made such stone or stones can nearly always be shown by *x*-rays. And this would also apply to the presence of stone even if the symptoms alone were not sufficient to demand operation. 2. In most cases when shadows are shown the size, shape and position can be relied on in diagnosing them as from kidney or ureteral stones. In other cases when doubt may arise as to the cause of the shadows the experience of the examiner will often settle the matter and in some cases stereoscopic radiography, the use of ureteral bougies, etc., can be used as a help. 3. The negative diagnosis can be relied on only when the whole region on both sides is carefully examined and when the plates are taken under the essential condition for successful examination and when they are of the necessary quality in showing sufficient differentiation of the soft structures in the kidney and ureteral regions. 4. There can be no justification for operation or prolonged medical treatment without an efficient *x*-ray examination being made.

16. **Rare Injury to Wrist.**—The case reported by Moreley was one of complete fracture of the scaphoid bone with forward dislocation of one of the fragments, necessitating its removal. The outer half of the bone remained in articulation with the trapezium and trapezoid.

Bulletin de l'Académie de Médicine, Paris.

20 (Year LXX, Nos. 19-20.) Improved Mask for Ethyl Chlorid General Anesthesia. L. Camus.

23 First-Aid Package.—Boîte de secours immédiat. Quidet.
24 Glycerin Aging of Vaccine.—Vieillissement glycériné du vaccin. Kelsch.

21. **Aneurisms Cured by Reducing Arterial Tension.**—The three aneurisms described were in the left subclavian in the first case, and involving the brachial and cephalic arteries and the aorta in the second and the thoracic aorta in the third. Treatment included rest in bed, regulation of the diet and drugs to reduce the arterial tension and to dilate the vessels. The diet was restricted to milk, or milk and vegetables, avoiding everything that could generate toxins. Drugs were given to keep the arterial tension continuously below normal. The trouble, Huchard says, is in the aorta and arterial system, but the danger lies in the kidneys. When the kidneys become affected with sclerosis, arterial hypertension follows. Appropriate preventive treatment of the kidneys, including restriction to a more or less rigorous milk diet, favors the elimination of the vasoconstricting toxins and aids in preventing hypertension. The benefits in the 3 cases reported were prompt and durable, the patients having been under observation for from four to eight years. One was a syphilitic of 61, the others were a woman of 45 and a man of 37.

22. **Research on Medicinal Prophylaxis of Syphilis.**—This communication was summarized in the news columns on page 1779. It seems that several persons volunteered for the experiments, and the one selected intends to relate his experiences as his thesis. Neisser was not always successful in preventing the development of syphilis in monkeys after inoculation followed by application of the mercurial salve. Metchnikoff's experiments all resulted positively. He aimed to reproduce the natural conditions so far as possible, although the inoculations were necessarily much deeper and more intensive than under natural conditions. Neisser made them much less superficially than in the Paris experiments. The results of the prophylactic inunctions were positive in 50 per cent., even under these extreme conditions.

Presse Médicale, Paris.

29 *Origine intestinale des adénopathies trachéo-bronchiques tuberculeuses. A. Calmette, C. Guérin and A. Delearde.

25. **The Senile Kidney.**—Létienne concludes his study of this subject with the remark that it is not age that induces senility in the kidney, but the vicissitudes which it has to undergo. It may be long undermined without any clinical manifestations, and succumb abruptly to some "last straw." He relates a few case histories to show the great benefit to be derived from a milk diet in arterial atheroma and the concomitant nephritis in the aged. In some cases the symptoms developed suddenly in the midst of apparent health in men of 67 or 72. In one instance after getting chilled one night in coming out from a warm room, a sudden, subacute edema of the lung developed in the course of a few minutes, rapidly fatal, revealing the hitherto unsuspected kidney changes.

26. **Splenic Anemia.**—This communication from Constantinople describes 3 cases of "Banti's disease" in which the patients were cured by treatment as for malaria.

27. **Intestinal Occlusion.**—Roger and Garnier have succeeded in isolating toxic substances from an extract of the small intestine which induce convulsions and reduce the arterial pressure when injected into the veins of animals. The existence of these toxic substances in the walls of the intestines explains certain clinical phenomena observed in case of intestinal occlusion. The liver is able to neutralize moderate amounts of these intestinal toxins for a certain length of time. When the amount is excessive the liver proves inadequate for the task and symptoms appear. Intravenous injection of the toxins causes no symptoms so long as the liver is taking care of them, but the moment finally arrives when it becomes exhausted and symptoms develop exactly similar to those observed in human intestinal occlusion. The experiments have demonstrated that the symptoms observed can not be due to microbian putrefaction.

29. **Intestinal Origin of Tuberculous Tracheo-Bronchial Glandular Affections.**—In this article Calmette and his co-workers relate that inoculation of laboratory animals with mesenteric glands from children presenting tuberculous tracheobronchial glandular affections always revealed the presence of tubercle bacilli in the mesenteric glands, even when the latter were apparently sound. They found that a single small dose of bovine tubercle bacilli given to calves and kids in their food passed through the intestinal wall and were retained in the mesenteric glands for a time. Sooner or later, however, the tracheo-bronchial or retropharyngeal glands became enlarged with or without pulmonary lesions. During all this time the mesenteric glands remained apparently sound. Inoculation of guinea-pigs with these glands, however, revealed the presence of tubercle bacilli. In the cadavers of 3 children who had not presented any clinical evidences of tuberculosis, inoculation of animals likewise revealed tubercle bacilli in the mesenteric glands. The authors conclude that as the mesenteric glandular infection

precedes the development of the glandular lesions in the respiratory apparatus, the latter, as well as pulmonary tuberculosis in children and in adults, must be regarded as the result of infection with tuberculosis by way of the intestines. The hypothesis of infection by inhalation has not yet been positively proved, but it is becoming more and more evident that children and adults contract tuberculosis by ingesting the milk of tuberculous cows or from food contaminated with bacilli or with particles of tuberculous sputa of human origin.

Semaine Médicale, Paris.

30 (XXVI, No. 22.) *Les pseudo-perforations de l'utérus au cours des opérations intra-utérines. R. de Bovis.

30. **Pseudo-perforations of Uterus.**—That relaxation of the uterine musculature can occur, with or without enlargement of the uterine cavity, is an established physiologic fact. When observed in course of a gynecologic operation it appears as if the uterine wall had been perforated by the instrument. This deceptive appearance is particularly apt to occur when there is some adjuvant factor such as the weakening or especial thinness of the uterine wall, special reflex inhibitions, such as are liable in case of dilatation of the cervix, and negative intra-abdominal pressure. A number of cases have been related in which a sound was inadvertently passed into one of the tubes. In case of an actual perforation, the tip of the instrument can be palpated through the abdominal wall and palpation causes a pricking sensation. This sensation is absent in case of a pseudo-perforation, as the uterus and its walls have no actual sensibility while the parietal peritoneum is extremely sensitive. In case of true perforation the peritoneum is liable to react instantaneously with signs of irritation. In Pollak's case there was a chill at once and the pulse ran up to 160 and became almost imperceptible. Mauclaire also observed in one case an almost immediate change of expression and sudden increase in the pulse rate. The international literature on the subject is reviewed.

38 Ueber den histologischen Bau der kindlichen Eihäute bei normalem, vorzeitigem und verspätetem Blasensprunge (fetal membranes). A. Hauptmann.

37. **Gastric Inhibition of Labor.**—Kehrer is convinced that when the digestive energies of the stomach are taxed much the force of the uterine contractions is correspondingly reduced. His research has demonstrated this to be a general law, and he discusses the causes for it. One plausible hypothesis is that the hyperemia in the stomach, the consequence of the ingestion of food, diverts the blood from the uterus. This hypothesis is sustained by certain phenomena he has observed in animals. In the clinic he has found that a heavy meal is frequently followed by subsidence of the labor pains. He has found further that if the stomach can be hastily emptied by induced vomiting, the labor pains acquire new energy. These facts confirm the importance of eating lightly as labor is impending. He advises small frequent meals, mostly if not entirely restricted to fluid foods. He adds that the rarity, in Germany, of the onset of labor during the afternoon may possibly be explained by the usual heavy noon dinner.

Deutsche medizinische Wochenschrift, Berlin and Leipsic.

39 (XXXII, No. 18.) *Ueber eine örtliche Giftwirkung des Phenylhydroxylamin (local toxic action). L. Lewin.
40 *Ueber die Prophylaxe der Magenblutungen (gastric hemorrhages). L. Boas.
41 *Stretching the Palate in Treatment of Mouth Breathing and Occlusion of Tubes.—Gaumendehnung nach Schröder in Kassel. Löhnberg.
42 *Treatment of Inflammation with Partial Congestion and Compression.—Ueber partielle Stauung und Druckbehandlung bei Entzündungen. Heermann.
43 *Exploratory Drilling.—Probebohrung als diagnostisches Hilfsmittel. J. Plesch.
44 *Salt Solution Ready to Infuse.—Infusionsbomben. H. M. Marcus, Vienna.

39. **Spread of Poisons by Way of the Lymphatics.**—Lewin used his thumb as a stopper in shaking a vial containing a concentrated solution of phenylhydroxylamin, a blood poison. The thumb swelled thereafter, as also the adjacent parts, and there was a painful inflammation which did not subside for eight weeks. The swelling and pain followed the superficial lymphatic vessels of the region.

40. **Prophylaxis of Gastric Hemorrhage.**—Boas' assertions in regard to the great diagnostic value of minute traces of blood in the stools and stomach content have been chronicled in these columns. (See pages 433 and 1348 of vol. xliii, 1904.) He has found that these occult hemorrhages, as he calls the presence of invisible traces of blood, are the precursors of large hemorrhages in the majority of cases. It is extremely important, therefore, to detect this premonitory bleeding. He preaches that physicians should examine for it as systematically as they now examine the urine for albumin or sugar. Discovery of the occult blood is an alarm signal and should be met by prompt measures. The patient must stay in bed until the blood vanishes from the feces. This is hastened by a strict milk diet. In the severer cases, ice to the stomach region and rectal injections of a 10 or 20 per cent. solution of calcium chlorid are indicated, with cold packs and possibly injections. The Leube-Ziemssen treatment with hot applications he would positively restrict to cases of ulcers past the hemorrhagic stage. He has witnessed injury from them while the ulcer was still bleeding. Examination for the occult blood in the stools or stomach content is also a most valuable index of the success of treatment and the progress toward recovery. The only trouble is the difficulty of deciding whether the traces of blood found proceed from the tissues or from food. The technic for the detection of the blood has not yet been perfected to such a point as to differentiate human from animal blood, but even with this drawback the guaiac-turpentine and the aloin tests are exact enough for practical purposes. He mentions also the benzidin test described by Adler, Schumann and Westphal (*Zeit. f. physiol. Chemie*, XLI and XLVI), which is based on the same principle of oxidation.

41. **Treatment of Mouth Breathing by Stretching the Palate.**—Löhnberg regards stretching the palate as a notable advance in the treatment of mouth breathing and of chronic occlusion of the tubes. It enlarges a congenitally narrow passage and one that has become occluded from disease. He describes in particular the case of a child of nearly 5 who was cured of the adenoid expression and was able to breathe through its nose and to hear better after the palate was stretched. The growth of the teeth under normal conditions was also favored

42. **Partial Passive Congestion and Compression in Treatment of Inflammations.**—Heermann states that he has been much pleased with the results of applying loose constriction above an inflammatory focus. The constriction should not be tight enough to induce actual passive congestion, but only to cause a partial arrest of the circulation. He had noticed that inflammation did not spread if the part were thus partially shut off from the general circulation. This technic might be combined with the Bier technic, but it has the advantage that it does not require the close supervision necessary with the latter. In addition he mentions that the healing of fistulas and abscesses past the acute inflammatory stage is promoted by pressing the walls together at the bottom of the cavity. He has also derived great benefit from a method of tamponing an inflammatory focus after incision. The incision is left open and the pressure applied around it, the results being more rapid healing and better restitution.

43. **Exploratory Drills.**—The useful little drills for boring into the bones and soft parts are no larger than an exploratory puncture needle.

44. **Salt Solution Ready to Use.** The bulb holds a pint or quart of sterile salt solution ready for infusion; the projecting glass tubes are fused.

GENERAL INDEX.

All reading matter in THE JOURNAL from January to June, inclusive, 1906, is indexed here. (For Current Medical Literature Index see pages 2050 to 2092.) All societies, congresses, etc., are grouped under the general subject of "Societies" at the end of the letter "S." Similarly, all "Deaths" and all "Book Notices" are indexed under those titles at the ends of the letters "D" and "B," respectively. Matter pertaining to the Association is under "Association News." With the above exceptions, all matter is indexed under the most important word of the heading that was used in THE JOURNAL. It is, therefore, well to remember that in looking up a certain subject, related words should be consulted, for example, nostrum, patent-medicine, proprietaries, proprietary medicines. The letters used to explain in which department the matter indexed appeared are as follows: "E", editorial; "O", original article; "T", therapeutics; "P", pharmacology; "Ml", medicolegal; and "ab" denotes an abstract of an article that has appeared in full elsewhere.

CURRENT MEDICAL LITERATURE

INDEX OF TITLES

Explanation: The reading matter which appeared in THE JOURNAL is not indexed here, except the original articles and the abstracts of original articles. This index includes the titles and the subjects of original articles published in the leading medical journals of the world during the past six months. The titles and the names of the journals in which they appeared were published weekly in the Current Medical Literature Department, to which references are made. The figures in parentheses refer to the paragraph; the number following, to the page in THE JOURNAL. For instance, "Hernia, results of operation for radical cure of, (12) 1402—ab" refers to page 1402 of THE JOURNAL, on which is found opposite paragraph 12 the title of the paper and the name of the author, viz., "Results of Operation for Radical Cure of Hernia. J. Hutchinson." This title is listed under the journal in which the article appeared, *The Lancet*, London, April 7. The "ab" indicates that an abstract of the article appeared in THE JOURNAL, which will be found below the title on page 1402. Titles of articles which appeared in THE JOURNAL are indicated in the index below by an asterisk (*) before the page number. For instance, "Calculus, Diagnosis of Renal. *851," refers to page 851 of THE JOURNAL, on which is found the following: "The Diagnosis of Renal Calculus. Guy L. Hunner." Index to authors of all the articles below is on pages 2080 to 2092 of this index.

Shoes and feet (18) 303

CURRENT MEDICAL LITERATURE

INDEX OF AUTHORS

In this index are the names of the authors of articles which have appeared in THE JOURNAL of the American Medical Association and of articles which have been listed from week to week in the Department of Current Medical Literature as having appeared in other journals. Thus it practically includes the names of all who have published articles in the leading journals of the world during the past six months. The * preceding the page reference indicates that the article appeared in full in THE JOURNAL. The numbers in parentheses indicate the numbered paragraphs on the page referred to. The numbers not in parentheses indicate pages.
