

THE PHARMACEUTICAL JOURNAL.

THE
PHARMACEUTICAL JOURNAL

ESTABLISHED 1841.

A Weekly Record of Pharmacy and the Allied Sciences.

VOLUME LXIV.
FOURTH SERIES—VOLUME X.
JANUARY TO JUNE, 1900.

LONDON:
PHARMACEUTICAL SOCIETY OF GREAT BRITAIN,
17, BLOOMSBURY SQUARE, W.C.

70

INDEX TO VOLUME X.

(FOURTH SERIES.)

A

- Abelous, B., and E. Gérard—Animal experiments, 41, 357.
- Aberdeen Pharmaceutical Association (Annual meeting), 295, 650*a*.
- School of Pharmacy, Gordon's College (Annual Supper), 85.
- Acaciæ Arabicæ Cortex, 187.
- Gummi, B.P., 19, 233.
- Acalypha, 187.
- Accuracy, The Inaccurate on (An Ordinary Pharmacist), 3.
- Acetates, Phenolic, Conversion of into Benzoates (Bodroux), 225.
- Acetic Extract of Belladonna (Squibb), 59.
- Acetylene Generation and Purification on a Small Scale, 646.
- Proposed Order in Council *re*, 132, 153.
- Tetrabromide, 463.
- Acid Fixing Bath (Photographic Supplement, April 7), 6.
- Acids and Alkali, A New Indicator for (Reigler), 21.
- Effect of, on Fungi (Clark), 567.
- Fatty, Quantitative Separation of (Farnsteiner), 636.
- from α -Dibromocamphor, Some (Lapworth and Chapman), 297.
- Acidum Aceticum Glaciale, B.P. (Umney), 8.
- Acne Rosacea, Ointment, 508.
- Aconite Root, Commercial (Holmes), 278.
- Aconiti Radix, B.P., 8, 19.
- Aconitic Acid, Synthesis of (Ruhemann and Stapleton), 659.
- Aconitina, B.P., 20.
- Actææ Racemosæ Radix, B.P., 387.
- Addendum to the British Pharmacopœia, Indian and Colonial, 187, 201, 231 (Dr. Atfield's Report), 629.
- Adeps, B.P., 39.
- Lanæ, B.P., 39.
- Adesekanchie (J. S. Ward), 280.
- Adhesol Varnish, 229.
- Adie, R. H., and T. B. Wood—Volumetric Determination of Potassium, 171.
- Adrian and Trillat—Colouring Matter of Digitalis Lutea, 69.
- Adulteration by Chemists, *Medical Press* on, 238.
- Laws (Glyn-Jones), 71.
- Adurool Developer (Photographic Supplement, April 7), 5.
- African Drugs, Some West (J. S. Ward), 279, 286.
- West, Balsam, 227.
- Agriculture, Science and (E. M. Holmes), 77.
- Air, Liquid, and Bacteria (MacFadyen), 333, 617.
- Liquid, Clinical Uses of (Pearce), 76.
- Liquid (Hampson), 107.
- Pathogenic Organisms in the (Deeleman), 1.
- Airol Solution, 364.
- Ajowan, Oleum, 232.
- Akakia (Hooper), 591.
- Akotompoteng (J. S. Ward), 279.
- Albo, G.—Function of Solanine, 639.
- Albumin, Coagulability of (Farmer), 591.
- Living, Formation of, and the Process of Respiration in Plants (Palladin), 1.
- of Strychnos Seeds (Bourquelot and Laurent), 687.
- Albuminoid from Snails (Paderi), 639.
- Albuminoids, Insoluble, Regeneration of (André), 663.
- Synthesis of (Palladin), 143.
- Albumins, Egg, Nomenclature of (Panormof), 225.
- Alcock, F. H.—Assay of the Official Nux Vomica Preparations, 174; Tannin in Kino, 267; Assay of Official Antimony Compounds, 362; Experimental Apparatus for Making Potassium Bicarbonate, 416; Potassium Ferrate, 464; Toughening Filter Papers; The Purification of Calcium Chloride, 524; Remarks on a Prescription: The Separation of Antimony and Arsenic, 640.
- F. H. and H. W. Green—B.P. Test for Phenacetin, 317.
- Alcohol an Antidote for Carbolic Acid Poisoning (Kelly), 1.
- Dressings in Psoriasis (Lau), 57.
- Production of, by Plants (Mazé), 495.
- Unprecedented Accumulation of, in Japan, 492.
- Alcoholism, Serum Cure for (Sappelier and Thiébauld), 17.
- Algæ, Fresh-Water, Absorption of Arsenic by (Bouillhae), 210.
- Alkali and Acids, A New Indicator for (Reigler), 21.
- Nitrites, Colour of, 219.
- Alkalies, Action of Iodine on (Taylor), 315.
- Alkalimetry of Amines (Astruc), 91.
- Alkaloid of Pomegranate, New (Piccini), 249.
- Alkaloidal Assays, Directions for Certain (Gordin and Prescott), 5.
- Salts, Action of Chloroform and Similar Solvents on (Schaer), 308.
- Alkaloids in Leaves of Datura Stramonium, etc., Quantitative Determination of (Schmidt), 22.
- in Plants, Determination of (Dewhirst), 358, 383.
- of Wallflower (Reeb), 639.
- Alkaptonuria, A Curious Condition of Urine, 171.
- Alkylating by Means of Alkylodides and Dry Silver Oxide (Lander), 432.
- Allen, A. H.—Annual Report on Drug Adulteration in Yorkshire, 295.
- C. B.—A Pharmaceutical Caucus, 421, 477.
- Almond and Peach Kernel Oils, B.P. Test for (Umney), 8.
- Cream, 274.
- Essence, Bitter, 689.
- Meal, Cosmetic, 392.
- Almonds, Bitter, and Sweet, B.P., 67.
- Aloe Barbadosensis, B.P., 40.
- Socotrina, B.P., 40.
- Aloes, Natal, Source of, 61.
- Aloinum, B.P., 66.
- Alepecia, Treatment of (Balzer), 598.
- Alstonia Scholaris, 233.
- Aluminium Phosphide (Fonzes-Diacou), 687.
- Solder for, 68.
- Amantia Muscaria, Pigments of (Griffiths), 115.
- Amber and Copal (Roessler), 277.
- American Blight, Spray for, 364.
- Conference of Pharmaceutical Faculties, 633.
- News, 608, 632, 656.
- Pharmaceutical Association, Richmond Meeting, 632.
- Amines, Alkalimetry of (Astruc), 91.
- Amino Chloro Pyridines, Some New (Sell and Dootson), 167, 586.
- Ammonia and Nitrogen, Determination of (Villiers and Dumesnil), 333.
- and Sulphur Dioxide, Interaction of (Divers), 518.
- Aromatic Spirit of (White), 144, 158, 163; (Dudderidge), 235; (White), 267.
- Linimentum, B.P. (Clower), 689.
- Ammoniacum, B.P., 66.
- Examination of (Dieterich), 647.
- U.S.P., 524, 669.
- Ammoniæ Aromaticus, Liqueur, 196.
- Ammonii Acetatis Conc., Liqueur, 372; (Clower), 689.
- Ammonio-Arsenio-Citrate of Iron, 497.
- Ammonium Acetate, and Quinine Solutions (Kidd), 94, 112.
- Amido-Sulphite (Divers and Ogawa), 219.
- Imido Sulphite (Divers), 586.
- Carbonate (White), 144, 163.
- Sulphites, Thiosulphates, and Trithionate, Products of Heating (Divers and Ogawa), 219.
- Amygdala Amara, B.P., 67.
- Dulcis, B.P., 67.
- Amyloid Sections, Mounting (Green), 145.
- Amylum, B.P., 113.
- Analysis of Drugs at Exeter (Moor), 84.
- of Drugs, Local Government Board and the, 16.
- Taking of Samples for (High Court decision), 628, 630.
- Analyst, Qualification for, 650.
- The Automatic, 56.
- Analysts, Public, The L.G.B. and the Competency of, 293.
- Society of Public (Annual Dinner), 88.

- Analytical Books, 90.
— Notes, 312, 636, 682.
Anderson, F. A.—Oil Extraction Flask, 91.
André, G.—Transformation During Germination, 663.
Andrews, C. R. P.—Non-British Grasses in the Channel Islands, 171.
Andrographis, 187.
Anethi Fructus, B.P., 113.
Angiosperms and Gymnosperms (Bernard), 91.
Angostura Balsam, 227.
— Bark, B.P., 518.
Anhalonium Lewinii, 191.
Aniodol, 463.
Anglo-Colonial Chemical Company, Limited (Winding-up Petition), 58.
Animal Ferments (Abelous and Gérard), 41, 357.
— Organs, Arsenic in (Gautier), 41.
Anisi Fructus, B.P., 114.
Annual General Meeting and Dinner of the Pharmaceutical Society (Date), 451; 535, 547.
Alogeissus Latifolia, 233.
Anonymity, Red Rag of (An Ordinary Pharmacist), 46; (C.A.A. Discussion), 112.
Anopheles, Malaria and (Spurrier), 350.
Answers to Queries, Remarks on the, 12.
Arthemidis Flores, B.P., 140.
Anthocyan, Original Colour of (Keegan), 21.
Anthrax, Russian Method of Treating, 57.
Antimony Compounds, Assay of Official (Alcock), 362; (Dudderidge), 399; (Alcock), 640.
Antiperiodic, A Valuable, 497.
Antiphlogiston, 76.
Antiseptic Dressing, Methyl Salicylate as an (Gallois), 183.
— Gauzes (Debuchy), 171.
— Intestinal, for Infants (Rochkovsky), 330.
— Soaps, 616.
— Varnish, 214.
— Water, 575.
Antithermalin, 76.
Apigenin, Action of Nitric Acid on (Perkin), 225.
Apiin, Action of Nitric Acid on (Perkin), 225.
Apothecaries Act, 1815 (Glyn-Jones), 70, 87.
— Hall, A New, Wanted (An Ordinary Pharmacist), 75.
— Hall Examination, 448.
Apotheker Verein, Address of the, 448.
Apotheker-Zeitung, Resignation of the Editor of the, 513.
Apparatus Constructed of Vitreous Silica (Shenstone and Lacell), 500.
— for Making Potassium Bicarbonate, Experimental (Alcock), 416.
Apple Essence, 689.
— Tree Canker, Remedy for, 229.
Apprentice's Idea of the Retail Trade, An (Murdoch), 65.
Apprentices' Indentures in Australia, 603.
Apprenticeship, *re*, 128.
April Minor Examination, 158.
Aquatic Plants (Wallis), 136.
Araroba, B.P., 141.
Arcangeli, Prof. G.—Is *Pleurotus Olearius* a Poison? 389.
Architects' Registration Bill, 546, 583.
Argonin Solution, 364.
Aristolochia, 188.
Armoracæ Radix, B.P., 141.
Armstrong, Professor—Bach's Hydrogen Tetroxide, 663.
Army Contract Scandals, 323.
— Medical Compounders, Woes of (An Ordinary Pharmacist), 47; (*Truth*), 83; (C.A.A. Discussion), 112; (*Truth*), 133.
— Pharmacists Ranking as First Lieutenants (New York), 657.
— Surgeons, Unregistered, 205.
Arnica Rhizoma, B.P., 141.
Arny, H. V.—Resin in Beeswax, 591.
Aromatic Spirit of Ammonia (White), 144, 158, 163; (Dudderidge), 235; (White), 267.
Arrow-Poisons (Wakamba), 1; (Wagogo), 413.
Arsenate, Potassium (Lothian), 183, 191; (J. R. Hill), 184, 235.
Arseniate, Ferrous (Cowley), 108.
Arsenic, Absorption of, by Freshwater Algæ (Bouillhac), 210.
— Alleged Conversion of Phosphorus into (Winkler), 663.
— and Antimony, Separation of (Alcock), 640.
— and Iron Wine, Solution of (A. Currie), 418, 430; (Peck), 448; (A. Currie), 478.
— and Tincture of Nux Vomica, Hydrochloric Solution of (Kidd), 94, 112.
— Caseinate, 121.
— in Animal and Human Organs (Gautier), 41, 61.
— in Phosphate of Soda (Editorial), 675; 680; (An Ordinary Pharmacist), 695; (Editorial) 699.
— Sale of Preparations of, 236.
— Solution of (Duncan), 329.
— Sulphide of, A New (Scott), 315.
— Tests for (Paul and Cownley), 688.
Arsenical Contamination, Editorial Remarks on, 699.
— Wall-Papers, Mould-Fungi and (Schmidt) 389.
Arsenicalis, Mistura Ferri (St. John's), 626.
Artemisia Absinthium, Oils of (Charabot), 567.
Asafetida, B.P. (Umney), 8; 142.
Asarum Canadense, An Adulterant of Hydrastis, 236.
Ash Percentage of Commercial Cochineal (Merson), 309, 314.
Ashton, C. S.—Glaucium Luteum, 344.
Asparagus as a Diuretic (Hare), 57.
Assay of Drugs by the Use of Living Plants (Kraemer), 620, 667.
— of Ipecacuanha, Belladonna, and Nux Vomica, Official Processes for the (Bird), 175, 306, 334, 414, 532, 690.
— of the Official Nux Vomica Preparations (Alcock), 174.
Assays, Alkaloidal, Directions for Certain (Gordin and Prescott), 5.
Assimilation, Chlorophyll, by Leaves (Griffon), 143.
— of Atmospheric Nitrogen (Hiltner), 383.
Assistant, Absence of an, Without Leave, 492.
Assistants and the War, 700.
Assistants' Salaries: A Suggestion ("Labor"), 698.
— Testimonials—A Warning (Cummings Brothers), 54.
Astruc, A.—Alkalimetry of Amines, 91.
Asylum Dysentery, Micrococcus of (Durham), 171.
Atkinson, Dr. Edmund, Death of, 563.
Atomic Theory, Paper on, 90.
Atoms and Ether (Fleming), 131.
Atropa Belladonna, etc., Leaves of, Quantitative Determination of Alkaloids in (Schmidt), 22.
Atropinæ Sulphas, B.P. (Umney), 8.
Atropine (Hesse), 116.
— in Datura Seeds (Thomann), 249.
— Smallest Known Fatal Dose, 698.
Atroscine (Hesse), 117.
Atsunobie Bark (J. S. Ward), 280.

PHARMACEUTICAL JOURNAL

VOLUME 64 (FOURTH SERIES, VOLUME 10).

LONDON: SATURDAY, JANUARY 6, 1900.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

PATHOGENIC ORGANISMS IN THE AIR.

By exposing plates to the air, washing off the colonies when those have developed, and injecting the washings intravenously into a rabbit, pathogenic organisms when present can be readily detected, according to Deeleman (*Centr. f. Bak.*, xxvi., 492). The pathogenic organisms which are found in the air are, in the order of their frequency, the *Staphylococcus pyogenes aureus*, the *Staphylococcus pyogenes albus*, the colon bacillus, and the *Diplococcus pneumoniae*. The pathogenic organisms occur in the air much more numerous in dirty surroundings than in clean ones.

PRODUCTION OF PROTEIDS IN-SOLUBLE IN THE GASTRIC JUICE.

W. Palladin continues his investigations on the connection between the formation of "living albumin" and the process of respiration in plants. The amount of nitrogen in the indigestible residue is used as a rough test for the amount of living albumin. The formation of fresh substances at the expense of sugar takes place much more energetically in the light than in the dark; and this is also the case with the regeneration of the proteids. The more refrangible rays of the spectrum favour the regeneration of albumin more than the less refrangible rays. Undigestible proteids are abundantly formed, even in the dark, when sugar is present, but in still greater quantities in the light. In the blue half of the spectrum a larger quantity of undigestible proteids is formed than in the yellow half. The energy of respiration in leaves supplied with sugar is twice as great in the light as in the dark. The proportion between the amount of carbon dioxide produced, and the amount of undigestible proteids is nearly constant. The experiments were made on etiolated leaves of *Vicia faba*.—*Bot. Centralblatt*, 79, 193.

CARBOLIC ACID POISONING.

Dr. J. Austin Kelly reports the following case:—A child twenty-one months old accidentally swallowed at least one ounce of Schering's carbolie acid. It was hurried to a drug store and there was given olive oil.

The doctor arrived five minutes later; he first gave an emetic of zinc sulphate to remove the oil, and then gave six to eight drachms of pure alcohol, following this in six minutes with a hypodermic injection of apomorphine, $\frac{1}{30}$ grain. When the apomorphine had produced emesis, one drachm of undiluted whiskey was administered every ten minutes for eight doses. "Pain was relieved immediately upon the administration of alcohol, in thirty minutes the patient rallied, and the next day the little fellow was playing about as usual with very slight destruction of tissue resulting from the ingestion of the acid." From this and other cases Dr. Kelly concludes that:—(1) Alcohol is undoubtedly the best antidote in all cases of carbolie poisoning, and, indeed, is an absolute antidote; (2) Where possible, lavage of the affected tract and stomach

with alcohol should be resorted to in preference to all other methods; (3) Where lavage is not practicable then give alcohol or whiskey, preferably the former, followed by apomorphine as an emetic.—*Merck's Archives*, through *Bulletin of Pharmacy*, 13, 517.

MERCUROUS NITRITE AND ETHYL IODIDE.

Dr. P. C. Rây finds that when mercurous nitrite acts upon ethyl iodide, about equal quantities of nitroethane and its isomeride, ethyl nitrite, are formed. The yield is, however, somewhat poorer than when silver nitrate is used, owing to the formation of very compact lumps of mercurous iodide, which prevents the reaction from becoming complete.—*Proc. Chem. Soc.*, 15, 239.

ARROW-POISON OF THE WAKAMBA.

Von Brieger has investigated this heart poison, the action of which closely resembles that of digitalis. Its toxicity is extraordinary, 0.05 Mgm. of the pure substance being fatal to guinea-pigs of 300 Gm. weight, in fifty minutes, while 0.3 Mgm. to each kilo. of body weight was fatal to dogs. Analysis points to the formula $C_{20}H_{46}O_{19}$. The active principle crystallises in anhydrous needles, melting at 182-184° C., but crystals containing 20 per cent. of water separate in larger plates, which melt at 93°-94° C. It is insoluble in ether, acetic ether, chloroform, and benzene; soluble with difficulty in cold, more soluble in hot, alcohol or water. The solution is laevogyre. The pure substance does not reduce Fehling's solution. By long heating with mineral acids, a yellow, amorphous, non-poisonous body separates, which is easily soluble in alcohol. The aqueous solution after the removal of this body reduces Fehling's solution, and gives an amorphous glucosone. The glucoside dissolves in concentrated sulphuric acid with a reddish-brown colour and green fluorescence. With tannic acid and the usual alkaloidal reagents the substance gives no precipitate.—*Chem. Zeit. Repert.*, 23, 315, after *Deutsch. med. Wochenschrift*.

IDENTIFICATION OF NICOTINE.

Nicotine is one of the few alkaloids which give no distinctive colour reactions, and is, therefore, distinguished from conine with great difficulty. J. Schindelmeiser proposes the following reaction, which may be obtained with 0.0005 Gm. of nicotine, and does not occur with conine. A trace of the alkaloid is treated with a drop of 30 per cent. formaldehyde solution, free from formic acid, and allowed to stand for several hours, when, on the addition of a drop of nitric acid, the solution is coloured crimson; if from 0.005 to 0.01 Gm. of nicotine be taken, the colour is dark red. The amount of formaldehyde indicated should not be exceeded, as with an excess, the solution becomes green, and the addition of nitric acid causes violent decomposition; nor should the mixture of nicotine and formaldehyde be heated. In place of formaldehyde, the author has tried concentrated formic acid, which reacts very well, also acetaldehyde and concentrated acetic acid; the last two require more nicotine, and give less definite reactions. Neither piperidine, trimethylamine, pyridine, chinoline, picoline, nor aniline gives the reaction.—*Pharm. Centralhalle*, 40, 704.

THE PHARMACOPŒIA IN ITS RELATIONS TO PHARMACISTS.

BY CHARLES UMNEY.

Dr. Nestor Tirard, a member of the General Medical Council, and a prominent worker in connection with the compilation of the British Pharmacopœia, has recently delivered a series of lectures on "Pharmacy and the British Pharmacopœia" before the Society of Apothecaries of London. His last lecture (*vide British Medical Journal*, Dec. 30, 1899, page 1785), entitled "The Pharmacopœia in its Relation to Pharmacists," is an excellent and concise commentary on the important changes that were made in the Pharmacopœia, 1898.

Dr. Tirard in summarising, asks "how the changes affect the chemist, the dispenser, and the manufacturer?" and follows with extracts from various journals, giving individual opinions as to the value of the work, then alludes to the dissatisfaction of the Irish representatives at the lack of opportunity they had of taking part in the production of the pharmacy portion of the work, and finally asks a question as to whether it is not desirable that the compilation of the Pharmacopœia should be in the hands of medical men. The lecturer concluded his third and last lecture with the following:—

If we consider the way in which trade interests are affected by the Pharmacopœia, if we consider that the volume deals with things bought and sold, it is impossible not to realise the risks of trade competition, of trade influence and the constant danger of introducing a standard which might create a monopoly. I would ask you whether, with this in view, it is not better that the compilation should be in the hands of those whose motives cannot be assailed, that the final responsibility should rest with those whose interests are not at stake?

As a pharmaceutical chemist, a manufacturer, and a member of the Pharmacopœia Revision Committee, I decline to believe, notwithstanding the official position Dr. Tirard holds on the General Medical Council in connection with the Pharmacopœia, that he is acting as the mouthpiece of the Pharmacopœia Committee of the General Medical Council. One would have fancied that a new era would not have dawned so late in the nineteenth century, and that the pharmacist, who the century thought had been accredited with honesty, would not in these latter days have so degenerated that such whisperings should be heard concerning him as "let no such man be trusted."

What a forlorn hope, too, for the Council of the Pharmaceutical Society when called upon to elect its Pharmacopœia Revision Committee from such material. Possibly those who knew their *confrères* best thought "Peradventure ten shall be found" that would not (as Dr. Tirard says), "introduce standards which might create a monopoly."

To comment in detail upon the several points embodied in the lecturer's concluding paragraph would probably be unprofitable and assuredly irritating, and I will dismiss the subject by saying that there are pharmacists out of Great Britain—and that in all civilised countries (England only excepted) pharmacists have a well-defined and important share in pharmacopœia publication and revision.

Having dissented thus much from the suggestions of Dr. Tirard, I venture to state that in my opinion there will always continue to be an unsatisfactory and incomplete revision and publication of our national Pharmacopœia, from a pharmacist's point of view, until a well-planned scheme be agreed upon, and the devising of such scheme should not, as on previous occasions, be put off for another seven years, but should be taken in hand at once. There should be no secrecy in pharmacopœia making—each new year should find us "up to date," aided by the editor's annual report—but such a report in perfection is impossible without proper equipment and thorough organisation. My suggestions are sub-joined.

1. That there should be a decennial revision of the British Pharmacopœia.

2. That the next edition should be published January 1, 1910, and that prior to its publication there should be an attempt to make such issue "Statute Law."

3. That six months prior to its publication (July 1, 1909), the book in its entirety should be exhibited at ten centres in Great Britain and Ireland (say five in England, three in Scotland, and two in Ireland).

4. That the General Medical Council should appoint an editor of the Pharmacopœia, and retain his additional services as reporter.

5. That the General Medical Council should request the Pharmaceutical Societies of Great Britain and Ireland to nominate a committee of ten pharmaceutical chemists, five to be nominated for England, three by Scotland and two by Ireland. Such committee to be a permanent one, and have a secretary.

6. That the Pharmacists' Committee should meet at not less than three-monthly intervals, and furnish annually complete data to the editor, who should be empowered to report on the same and publish and circulate such report in a manner to be agreed upon by the Medical Council.

7. That once in six months, at least, and at such time as the Medical Council may think fit, a sub-committee of the Pharmacists' Committee should have a conference with the Medical Council Pharmacopœia Committee and the editor. The Pharmacists' sub-Committee referred to should not consist of more than four, two of such sub-Committee to be representatives of England and one each of Scotland and Ireland.

8. That no fees be paid to pharmacists for any research or other work, and that particulars of all material used in Pharmacopœial work be furnished annually to the Committee's secretary, all charges for the same being at cost price.

9. That the General Medical Council pay all travelling expenses of members of the Committee meeting in London quarterly or oftener, also the salary of the permanent secretary of the Committee, and all amounts disbursed by the secretary for material used.

10. That the Pharmaceutical Society of Great Britain do undertake to give the Committee every facility to carry on its work in its buildings free of charge, and if requested, place its Research Laboratory at the Committee's service.

If the General Medical Council would deal with the whole subject and in its deliberations give due weight to the entire conditions under which the pharmacopœias of Germany and United States of America are produced, it would rid itself at once and for all time of that objectionable friction that has been going on more or less for a generation and would do justice to pharmacy, no injustice to medicine, and cause no loss of dignity to the medical profession.

MERCURIOL.—Broomquist, of Stockholm, has applied this name to an amalgam of aluminium, magnesium, and mercury, the last-named being present to the extent of 40 per cent. It forms a very fine greyish amorphous powder, from which the mercury readily volatilises under the influence of warmth, air and moisture. It is recommended for the treatment of syphilitic affections, the patient wearing a small sachet containing 5 Gm. of mercuriol next to the skin for five to ten consecutive days, during which one sachet suffices. The absorption of the mercury is effective, and its elimination very active. It is also useful for mercurial inhalations.—*Nouv. Rem.*, 15, 497, after *Arch. für Derm. und syph.* [Care should be taken not to confound the preparation mercuriol with mercuriol, a combination of mercury with nuclein. The close resemblance of those names well illustrates the danger which may arise from the use of similar empirical titles for totally diverse specialties.—Ed. P.J.]

FACTS AND FANCIES,

BY AN ORDINARY PHARMACIST.

The President and the Companies Bill.

Mr. Martindale's move, in placing before the President of the Board of Trade a general expression of the views of the pharmacists of Great Britain with regard to the company pharmacy problem, must be described as being decidedly diplomatic, more especially in view of the difficulty he has apparently experienced in keeping what Mr. Carteighe would call his "team" well in hand. Whilst necessarily lengthy, the letter is a skilfully drafted summary of the whole position, committing the President and Council to no particular policy so far as details are concerned. At the same time, it is a dignified protest

(1) Against the assumption and use of pharmaceutical titles by other than duly registered individuals;

(2) Against the retailing, dispensing, or compounding of poisons by unregistered persons.

It will be noticed that the wording of the essential paragraph in Mr. Martindale's letter—printed in bolder type at page 607 of the *P.J.* of December 23—is almost identical, so far as it goes, with the text of the resolution suggested in my article of November 25 (see *P.J.*, p. 503). Greater weight would probably have attached to it if it had been in the form of a resolution adopted by the Council, especially if there had been unanimity on the subject. But, I imagine, Mr. Ritchie may rest assured that not a single member of the executive body will dissent from the views expressed by Mr. Martindale; that being so, the fact of a formal protest against the existing state of affairs having been officially placed on record should suffice for all practical purposes. It is now matter of history that the pharmacists of Great Britain, as represented by the President of the Pharmaceutical Society, have formally protested against the misuse of their titles and the consequent prejudice of public interests which were supposed to be protected by the provisions of the Pharmacy Act of 1868. The Government must now act or be further spurred on to do its duty.

The Inaccurate on Accuracy.

It is amusing to note, by the way, that a trade journal which published an incorrect version of the Lord Chancellor's speech delivered on August 3, ventures to chide Mr. Martindale for adopting what it is pleased to term "an uncorrected version" of that same speech. As a matter of fact, there is no published report of the Lord Chancellor's speech, for the simple reason that the reporters in attendance at the House of Lords on the occasion referred to found it utterly impossible to hear what was said. Subsequently, however, when his Lordship's attention was directed to the inconvenience likely to result from that unfortunate occurrence, Lord Halsbury kindly dictated the gist of his remarks to the reporters, and a fully and authoritatively corrected version of that statement appeared in the *P.J.* of August 12. That was the version quoted by the President in his letter to Mr. Ritchie, and whatever any trade journal may say "authoritatively" on the subject, its assertions must be regarded as inaccurate and unconvincing unless they accord with what is stated there. Whilst on this subject, it may not be amiss to remark that, in my opinion, since the *P.J.* is the official gazette of the Pharmaceutical Society, only such records of matters connected with the Society as appear therein can be regarded as strictly official, and beyond question. Other newspapers are doubtless welcome to copy those records, though I have observed that they do not always acknowledge the source of their information; but—judging from what personal observation teaches me with regard to the circulation of the different journals in London and the provinces—there is not the slightest occasion to publish anything of importance to British pharmacists elsewhere than in the Society's official organ. It cir-

culates more widely amongst "persons who are entitled to practise pharmacy in Great Britain" than any other newspaper devoted chiefly to pharmaceutical topics, and it is not too much to assert that it is carefully read, week by week, by every chemist on the Register who has a soul above that of a mere trader. For the rest, anything will serve.

Mr. Hills on the Situation.

It has been whispered that the paper read by Mr. Walter Hills at the meeting of the Western Chemists' Association a fortnight ago embodied what he would have liked to say when addressing the same body at its annual dinner thirteen months earlier. What he did say then was virtually to the effect that, unless 90 per cent. of the trade belonged to the Pharmaceutical Society, he would not take the lead in any attempt to suppress company trading in pharmacy. The number required to make up the 90 per cent. did not join the Society; perhaps they are not likely to do so, lack of public spirit and superabundance of small-mindedness being sadly too prominent in the ranks of the outsiders. Meanwhile Mr. Hills has burnt his boats, as irrevocably as Messrs. Atkins and Glyn-Jones, and committed himself to the proposal that the use of pharmaceutical titles should be restricted to duly qualified individuals and that all open pharmacies owned by companies should be *bona fide* under the control of persons registered under the Pharmacy Act, 1868. It is true that he has stated his preference for the prohibition of company trading in pharmacy, but only to follow up what he said on that point by an expression of utter hopelessness with regard to anything of the kind being feasible. I would direct special attention to the fact that the somewhat despairing position now taken up by Mr. Hills is the direct outcome of the lack of support which he might reasonably have expected to receive, when he occupied the position of President of the Pharmaceutical Society. The members of the Western Chemists' Association appear, generally to have inclined to the views expressed by Mr. Hills, and, so far, no protests have been heard, not even from Lancashire, where dwell the sternest opponents of the policy of surrender. Can it be that all the local pharmaceutical volcanoes are played out? or is it only somnolence, such as accompanies much Christmas fare, which is responsible for the refreshing sense of quietude that pervades the columns of all the journals at present.

The Pharmaceutical Qualification.

I must confess to a feeling of considerable sympathy with the view recently expressed by a writer in these columns (see *P.J.*, December 16, p. 578), to the effect that, so far as the best interests of pharmacists and the public generally are concerned, the essential thing to aim at is for each separate establishment where pharmacy is practised to be personally controlled by a duly registered person. That controlling person, as I understand the suggestion, would be expected to give his undivided attention to a single place of business, and he would in all respects be absolutely responsible—in relation to the public—for everything that occurred in connection with the conduct of the business. Many registered chemists—possibly Mr. Lord Gifford among the number—may be expected to object to that method of securing acceptance of the principle of "qualified proprietorship," because it would interfere to a considerable extent with the present free and easy methods of carrying on branch establishments and possibly also with that even worse practice—the supply by registered chemists of drugs and galenicals to hucksters. More than that, it might even, in many instances, have the effect of compelling the actual proprietor of a business to attend to it personally. But the public interest must be considered before personal convenience, and even though Dinneford and Co., John Bell and Co., Savory and Moore, and other firms should be compelled to put up the names of the pharmacists actually in charge of the business at each of their establishments, "just like a common public house," I quite fail to see that any loss of professional prestige or business profit need follow. And, after all, is not the pharmaceutical qualification one and indi-

visible? Medical men and lawyers cannot throw the mantle of their qualification over the shoulders of unqualified individuals, nor mask it under the name and style of long defunct predecessors, why, therefore, should pharmacists wish to do so? As professional men their chief capital is in themselves as legally-qualified individuals; let the individuality be manifest at all times, and the worst that unqualified competition can then do will be to show that there is quackery which apes pharmacy as well as other professions, and that medicine which is low-priced is not cheap unless accompanied by the personal guarantee of an individual who is fully alive to the fact that he has a professional reputation to lose.

Shall the Qualifying Examination be Divided?

Division of the qualifying examination, as recently suggested by Mr. Peter Boa (see last volume, p. 524), is, doubtless, a very desirable thing, in view of the great pressure now put upon candidates in having so much to prepare for a single test. But, as Mr. Lennox pointed out in last week's Journal, in a letter which reveals an unduly perturbed state of mind on the part of the writer, very little interest has been manifested in the subject recently, except by a few individuals. The fact of the matter is that the question of dividing the examination can hardly yet be regarded as coming within the sphere of practical politics. When it does there will be much more to consider than the method of division or how best the students' burden can be lightened; the candidate's knowledge will naturally require to be more deeply probed, the manner in which he has acquired it will need to be considered, and it is doubtful if a hard-and-fast line should be drawn between the subjects to be taken in the two parts of the altered examination. Bearing in mind that, shortly after August next, all who present themselves for the qualifying examination may be assumed to possess a knowledge of mathematics, which is not now required, it is easy to recognise in what direction the examination in physics and physical chemistry may develop. How others may be affected if the examination should be divided remains to be seen. The method of division would probably be, broadly speaking, as Mr. Boa indicates, the scientific subjects being taken first and the technical subjects, with practical work based thereon, subsequently. But the scientific subjects must also be treated practically, and it would not be advisable to separate the examinations in theory and practice more than at present. It might be found desirable, therefore—not less than three years after passing a preliminary examination, and on production of proof that a proper course of study has been followed—to permit candidates to enter for an intermediate examination—oral and practical—in prescription Latin, chemistry, physics and botany, the standard for the scientific subjects approaching, if not equalling, that of the present Major examination. A period of six months might then elapse before the successful candidate was permitted to enter for the final examination—covering at least two days—in practical dispensing, prescription-reading, pharmacy, pharmacography (including the histology of drugs), and advanced chemistry; possibly it might be found desirable to add a written paper in advanced chemistry and physics. In that case, the way would be prepared for conferring the title of "pharmaceutical chemist" on the successful candidates at the final examination, if even the rearrangement suggested did not at once justify such a course. But that is another story; for the present it must suffice to educate pharmaceutical opinion up to the point of deciding that division of the qualifying examination is a desirable and a necessary step.

The Botanical Incubus.

The perusal of Dr. Bryan's paper in last week's *P.J.*, on the crippling of botanical science by words, has given me much satisfaction, for of all the possible ways of making the study of natural science inexpressibly wearisome commend me to the overloading of facts with technical terms and especially terms derived

unnecessarily from other languages than English. The average pharmacist finds the study of botany sufficiently troublesome under any circumstances; he thinks his examinations are unduly burdened with the subject, finds botanical examiners more or less unreasonable in their estimate of what a pharmacist ought to know of their particular science, and probably ends by arriving at the conclusion that the study of botany by pharmacists is altogether a mistake. Such being the state of affairs it would appear desirable to make the study as little repulsive as possible, and, as a first step in that direction, Dr. Bryan's proposals for simplifying the descriptive terms used in botany might well be acted upon. There is no sound reason why an English-speaking student should be compelled to learn Latin and Greek before he studies botany, and as little reason why he should be troubled to memorise what are to him more or less meaningless terms of foreign derivation when his own language is quite capable of furnishing self-explanatory terms every whit as suitable. The study of classical languages tends to diminish rather than increase, and it is simply absurd to keep up a restriction that can only end by reducing the number of all-round botanical students to a minimum. The somewhat drastic remedy proposed by Dr. Bryan should, therefore, be applied as promptly as opportunity may permit, foreign technical words in botany being replaced, as far as possible, by self-explanatory English words, and those which cannot be so replaced treated in such a manner as to distinguish their component parts. The brief list given as an illustration by Dr. Bryan suffices to show how readily a large number of terms can be replaced by simple equivalents, and I am quite of his opinion that a very large number can be similarly replaced without loss of accuracy in description and with much gain in point of time.

Pharmacists and the War.

The proposal in last week's *P.J.* (see p. 640) that a School of Pharmacy Drill and Rifle Corps should be formed, is based on a totally inadequate idea of the necessities of the situation, but, nevertheless, it comes opportunely, in view of the fact that the Earl of Mount Edgcumbe has just suggested a novel scheme for drilling and arming men who would like to receive some military training, yet find it inconvenient to spare the amount of time required of those who join a volunteer corps. It is proposed that in the neighbourhood of a garrison or volunteer headquarters, classes might be formed for instruction in drill and rifle practice, arms being lent to those attending the classes, and instruction given by non-commissioned officers capable and willing to undertake the duty. The idea underlying the scheme is that a large number of men might thus be preparing themselves for military service, without cost to the country or leaving their employment, and so become better fitted at short notice to join some corps and fill the place of those who have been sent abroad. Before any further steps are taken in the direction of constituting the proposed School of Pharmacy Corps, it might be well to ascertain what prospect there is of the Earl of Mount Edgcumbe's scheme being taken up. It is worthy of note that his Lordship is brother-in-law of the Minister for War, and that he says he has been "unofficially encouraged" to publish his suggestions. With regard to the enlistment of army compounders, it will be interesting to know how many properly qualified individuals enlist in that capacity for service in South Africa. Assuming that the campaign does not last longer than a year, each compounder of medicine will receive rather more than seventy-four pounds in cash, plus any general gratuity that may be granted to the troops, possibly about eighty pounds altogether. Free rations, kit, and passage to and from South Africa are also promised, but it may be anticipated that the out-of-pocket expenses incurred by each individual during the campaign will be far from trifling, since famine prices may be expected to prevail

in South Africa for some time to come. On the whole, therefore, the post of compounder of medicine for the army cannot, even with the present exceptional terms, be regarded as a tempting one—except to adventurous or ultra-patriotic spirits—but the advice offered to pharmacists by a correspondent whose letter appeared in last week's *P.J.* (see p. 639) is not likely to be acted upon generally, for it is reported that there has been quite a rush of applications from both Minor and Major men, many more applications having been received, in fact, than there are vacancies.

DIRECTIONS FOR CERTAIN ALKALOIDAL ASSAYS.

BY H. M. GORDIN AND A. B. PRESCOTT.*

A General Method for the Extraction of Alkaloids in Assays.

I.—AS A METHOD¹ BY PERCOLATION.

One to 4 Gm. of the finely powdered drug is weighed into a low, wide-mouthed vessel, with a round bottom, holding eight or ten ounces, and having a well-fitted cork, such as a screw-top ointment-jar.² The powder is rubbed up with a small pestle to a fine paste, by adding a little of a solvent mixture, composed of stronger ammonia water and alcohol each 5 C.c., chloroform 10 C.c., and ether 20 C.c.³ Then a few more cubic centimetres of this mixture are added, so as to have the drug well covered with the liquid, using in all about five times the amount of the drug taken. The vessel is corked, with the pestle inside, and is set aside for about four or five hours, taking care to agitate by circular movement very frequently during that interval. After that time the cover is removed, and the vessel kept in a current of air, stirring frequently till all odour of ammonia has disappeared. With a good draught and frequent stirring, the powder will be almost perfectly dry in about one hour. The vessel is then put into a vacuum desiccator over sulphuric acid for about four or five hours.

An amount of powdered sodium chloride,⁴ equal to about five or six times the amount of drug employed, is carefully mixed in, with use of the pestle, and the whole thrown into a small percolator, one provided with a glass stop-cock and having a plug of cotton at the bottom.⁵

The vessel is then cleaned out several times with small quantities of sodium chloride, and the cleanings added to the percolator. The mixture in the percolator is then covered with a little of the cotton, which is pressed down with a piece of glass, and a suitable menstruum, usually chloroform, is poured slowly into the percolator

NOTE.—Analytical results in support of these directions are given in an accompanying paper, "Further Work Upon the Estimation of Alkaloids and the Assay of Alkaloidal Drugs," presented in this Association at this date. Also in the paper entitled, "Certain Alkaloidal Periodides, and the Volumetric Estimation of Alkaloids as Higher Periodides," by the same authors, *Proc. Am. Pharm. Assoc.*, 1898, p. 340; *Pharm. Arch.*, i., p. 121; *J. Am. Chem. Soc.*, 1898, p. 724. A paper on "Hydrastine Hexiodide and Assay of Hydrastis," *Am. J. Pharm.*, 1899, p. 257. Further, see the article, "The Periodides of the Alkaloids as Molecular Forms for Estimation," etc., by A. B. Prescott, 1897; *Pharm. Review*, vol. xv., and other papers since 1895.

* In the work of Research Committee D, Section 2, Committee on Revision and Publication of the Pharmacopoeia of the United States, 1890—1900. Read before the *American Pharmaceutical Association*, September, 1899.

¹ These directions were published, nearly as here given, by the authors, in an article, "Emetine Octoiodide," etc., *Pharm. Review*, vol. 17, 1899. This general method is not applicable to Ipecacuanha. See under "Assay of Ipecacuanha" further on.

² An ordinary teacup fitted with a specie cork answers well.

³ In the case of *Hydrastis canadensis* the chloroform is replaced by an equal volume of ether.

⁴ In the case of hydrastis the sodium chloride is replaced by barium nitrate.

⁵ A suitable percolator is easily made out of an ordinary piece of glass tubing fitted with a perforated cork, through which passes a tube having a glass stop-cock.

till the menstruum reaches the stop-cock. The latter is then closed, the percolator covered, and set aside for five or six hours. After that time the stop-cock is opened, and the drug exhausted with the menstruum, percolating until, ten drops of the percolate being evaporated on a watch-glass and the residue taken up with a few drops of acidulated water, the solution shows no turbidity whatever on adding a few drops of the solution of iodine. When finished, the percolate, which is received in a flat evaporating dish, is placed in a good draught at a temperature of about 30° C. When the liquid is reduced to a very small volume, 10 C.c. of acidulated water⁶ is added, and then a few cubic centimetres of ether, or petroleum ether, so as to have an ethereal liquid cover the aqueous solution,⁷ when the whole is stirred with a glass rod until all the ethereal liquid is driven off. The liquid is then filtered, and the evaporating dish and filter washed several times with acidulated water. In this way is obtained a colourless solution of the alkaloid which can be worked up for any method of determination.⁸

II.—AS A HOT EXTRACTION METHOD.

Instead of the cold percolation, as above directed, hot extraction in any suitable apparatus may be used, all other features of the operation being the same. If a Soxhlet tube is used, care should be taken that the syphon works intermittently, as otherwise the extraction is very incomplete; if Dunstan and Short's apparatus⁹ is used, the boiling of the solvent should be so regulated as to have always a layer of about two centimetres of it on the top of the drug. Our experience has taught us that for quantitative work cold extraction by percolation requires less skill and care than hot extraction in a Soxhlet tube, though with careful operation the latter method is preferable.

Volumetric Assay of Alkaloids by Precipitation with Free Iodine.*

In this method so far applied to Atropine, Morphine, Strychnine, Brucine, Emetine, Hydrastine and Caffeine, the determination depends upon the formation of a Periodide.—For opium assay, the assay of nux vomica with separation of strychnine from brucine, assay of ipecac., and determination of berberine in assay of hydrastine, see below. For determination of caffeine, the alkaloid solution must be invariable acidulated (Gomberg, 1896). For assay of kola, see Knox and Prescott, 1896-7, *Proc. Am. Phar. Assoc.*, 44, p. 128, and 45, p. 131; *J. Am. Chem. Soc.*, 19, p. 63; 20 p. 34.

REAGENTS AND UTENSILS REQUIRED.—(1) A standardised solution of iodine dissolved in water with potassium iodide to be of about decinormal strength (12.653 Gm. of free iodine in 1,000 C.c.). The solution may be made as the volumetric test solution of iodine of the U.S.P., and used with the exact decinormal factor of iodine if preferred.

(2) A solution of sodium thiosulphate, of about decinormal strength, standardised to known ratio with the iodine solution. The volumetric test solution of thiosulphate of the U. S. P. may be used.

(3) The starch test solution of the Pharmacopoeia.

(4) The burettes and centesimal measuring vessels for any volumetric work in analysis.

* These directions were given in substance in an article entitled, "Emetine Octoiodide and the Estimation of Alkaloids Generally," by the authors of this paper in *J. Am. Chem. Soc.*, 21, p. 234, March, 1899; *Pharm. Review*, vol. 17, 1899.

⁶ If an alkalimetric assay is intended, the acidulated water in the operation should be closely standardised and taken in definite quantities.

⁷ If the menstruum is all evaporated off it is sometimes difficult to dissolve out the alkaloids with the acidulated water. If chloroform be used, coming below the aqueous layer, it evaporates too slowly.

⁸ The method of extraction described above presents particular advantage in those cases where several alkaloids soluble in different menstrua are present in the drug, as by using these menstrua successively, a separation of the alkaloids can be easily effected. This principle we have applied to the assay of opium, and to that of *Hydrastis canadensis*.

⁹ *Pharm. Journ.* [3], 13, p. 664.

THE VOLUMETRIC OPERATION.

The final alkaloidal solution obtained by whatever mode of extraction ^{9a}, but always representing a definite quantity of the drug to be assayed, is poured slowly and with constant stirring into a flask holding 100 C.c., in which has been previously drawn 20 to 30 C.c. of the standardised solution of iodine, and 1 or 2 C.c. of dilute hydrochloric acid¹⁰ (U. S. P.). The flask is then filled up to 100 C.c., stoppered, and well shaken till the periodide has separated out. The supernatant liquid is to be perfectly transparent, but of a red iodine colour. Fifty C.c. is then filtered off, and in this portion the excess of iodine determined by means of standard sodium thiosulphate. The amount of iodine consumed, multiplied by the proper factor, gives the amount of alkaloid present in the quantity of drug taken.¹¹

In case more than one alkaloid be present in the drug, a mean iodometric factor can be drawn, as shown for strychnine and brucine in the list of factors. In alkalimetric determinations a mean factor is often used in assay for total alkaloids, and the same is equally justifiable in iodometric work, when the data are known.

Should there be no precipitate with iodine, but only a slight turbidity, then the drug is extremely poor, and for the assay a much larger quantity than has been used should be taken. On the other hand, should the supernatant liquid, after adding the alkaloidal solution to the solution of iodine and separating the periodide by shaking, have very little colour, or be almost colourless, then it is certain that the drug is very rich, and either a smaller quantity of the drug or a larger quantity of the iodine solution must be employed in the assay.

Generally, if the drug contains as much as 3 per cent. of the alkaloid, 1 Gm. should be taken for the assay; if it contains less than the above amount, but not less than two-tenths of 1 per cent. of alkaloid, then a quantity between 1 and 5 Gm. should be

THE IODINE FACTORS.

Assay of Opium.

THE MATERIALS AND UTENSILS FOR THE ASSAY.

Opium in very fine powder; powdered sodium chloride, such as is used for the table; an ethereo-ammoniacal mixture composed of stronger ammonia water (U. S. P.) and alcohol, of each 5 C.c.;

^{9a} Directions for extraction are given further on. Other procedure for extraction is given in Lyons' 'Handbook of Assaying,' 1899. Detroit: Nelson, Baker and Co. Pp. 24 to 30.

¹⁰ It is always to be remembered, that this estimation by formation of higher periodides, requires the alkaloid to be added slowly to the iodine, with excess of the latter. Except in the case of morphine an excess of acid is not hurtful, and even promotes the separation of the periodide. Hydrochloric is to be preferred to sulphuric acid.

¹¹ For example: If operating upon two Gm. of powdered ipecac root, the iodine consumed be 0·957764, then the percentage of emetine in the drug equals $0·957764 \times 0·55 \times 100 \div 2 = 2·63$.

¹² If the analyst prefers to standardise his volumetric solution of iodine to exact decinormal strength, or to adjust the consumption of iodine to this strength by use of a correcting factor, then he will multiply the C.c. of iodine solution consumed by the proper factor in this column. (1 C.c. decinormal solution contains 0·012653 Gm. of iodine.) The more simple way, however, is to register the actual quantity of iodine in 1 C.c. of the solution, be the same above or below the 0·012653 Gm., and multiply this actual quantity by the number of C.c. used up, so as to get the weight of iodine consumed. This, multiplied by a factor of the first column above, gives the quantity of alkaloid estimated in grammes.

¹³ That is, a provisional representative of the total alkaloids of ipecacuanha.

chloroform (U. S. P.) 10 C.c., and ether 20 C.c.; benzol boiling at about 80° C.; a mixture of one volume of absolute alcohol and five volumes of chloroform; twentieth-normal sulphuric acid and twentieth-normal potassium-hydrate solution; neutral methyl-orange paper; standard solution of iodine, of any known strength in the neighbourhood of 1 per cent.; and standard solution of sodium thiosulphate of about twentieth-normal strength.

A 4- or 6 ounce screw-top ointment jar, having a bottom concave within; a small pestle, just long enough to rest half upright within the jar when it is closed; a small glass percolator provided with a stop-cock, and of the length of about 22 centimetres and inner diameter of about 1·3 centimetres.¹⁴

DIRECTIONS FOR THE ASSAY.

Weigh out 3 Gm. of the opium into the ointment jar, rub it up by means of the pestle with a few C.c. of the ethereo-ammoniacal mixture to make a fine paste, taking care not to smear the sides of the jar unnecessarily; then add about 2 C.c. more of the same mixture, so as to have the opium well covered with liquid; screw down the top, leaving the pestle inside, and set the jar aside for five or six hours. After that time the jar is opened, about 10 Gm. of the sodium chloride thoroughly mixed in with the opium, and the open jar placed in a good current of air, stirring frequently with the pestle in order to prevent formation of lumps. In about an hour the powder will be nearly dry. The jar is then placed in a vacuum desiccator containing, besides sulphuric acid, a vessel of paraffin, and left there over night. The jar is then taken out, any lumps in the powder carefully crushed with the pestle, and the mixture transferred first to glazed paper, and then to the percolator, in the bottom of which a plug of cotton has been placed. The jar is rubbed out several times with small quantities of the sodium chloride, the rinsings added to the percolator, and, having placed a plug of cotton and a piece of glass on the top of the powder, the opium is extracted with benzol by percolating very slowly, until, upon evaporating ten drops of the percolate on a watch-glass, and taking up the residue with ten or twelve drops of very slightly acidulated water, no turbidity appears by the addition of two drops of the iodine test solution. After the narcotine, thebaine, codeine, and most other alkaloids have in this way been completely removed by the benzol, the receiver is taken away¹⁵ and a shallow evaporating dish placed under the percolator.

The percolation is now continued slowly with the mixture of alcohol and chloroform,¹⁶ until ten drops of the percolate tested as above give no reaction for alkaloids. The evaporating dish is now put into a good current of air, and left overnight,¹⁷ or until the solvent has disappeared. The bottom of the dish will then be found to be covered with a good crop of crystals intermixed with a little resinous matter.

DETERMINATION IN THE ALKALIMETRIC WAY.

Fifty C.c. of the twentieth-normal sulphuric acid is now carefully run out from a burette into the evaporating dish, the contents rubbed well with a pestle till everything is detached from the bottom and sides of the dish, and then, without filtering, poured into a tall, narrow measuring cylinder. The dish is then carefully washed several times with small quantities of water, the washings added to the cylinder, and the latter filled up to make 90 C.c. After shaking well a few minutes, and setting aside till solid particles have settled down,¹⁸ 75 C.c., representing 2½ Gm. of the opium, is filtered off into a beaker holding some 250 or 300 C.c.,

¹⁴ The lower part of a burette cut in two answers very well.

¹⁵ The benzol, of course, can be recovered by distillation and over and over again.

¹⁶ See Burg., *Ztschr. anal. Chem.*, **19**, p. 222.

¹⁷ This makes the whole assay occupy about two days and two hours be started in the morning.

¹⁸ The filtration is much accelerated if the waxy particles are prevented from entering the filter.

about 50 C.c. of water added, and then 35 or 40 C.c. of the twentieth-normal potassium hydrate run out from a burette into the beaker. Twentieth-normal sulphuric acid is now carefully added, 1 C.c. at a time, stirring with a glass rod and testing the liquid after each addition by immersing for about fifteen seconds small strips of neutral methyl-orange paper. As soon as the paper becomes reddish, 1 C.c. of the potassium hydrate solution is added, and then again of the sulphuric acid, adding now one-tenth of a C.c. of the latter at a time, till the paper becomes reddish. In order to get exact results, the acid and alkali solutions should be standardised in nearly the same conditions under which the titration of morphine takes place; that is, using about 175 C.c. of liquid, and noting the appearance of the reddish tint upon the test paper at the point of neutrality. The strips of reagent paper should, of course, be wet with the wash bottle before immersion in the beaker. Though the solution of morphine has a yellow colour from some extractive matter, so that the end reaction cannot be found by adding a liquid indicator to the solution, there is not the slightest difficulty in noting the appearance of the reddish tint upon the cream-coloured methyl-orange paper. Of course, other indicators, like iodo-eosine in ethereal solution, etc., might be found to give equally good results, but having found the dip test with methyl-orange paper to give sharp and definite results with this alkaloid, we have not experimented upon other indicators.

One C.c. of twentieth-normal acid being equivalent to 0.0142 Gm. of anhydrous morphine, the number of C.c. of the acid consumed by the alkaloid from $2\frac{1}{2}$ Gm. opium, multiplied by 0.568 (= 0.0142, $\frac{1.00}{1.75}$), gives the percentage of morphine in the opium.

DETERMINATION IN THE IODOMETRIC WAY.—When it is desirable to control the alkalimetric assay with an iodometric one, the contents of the beaker are emptied in a 250 C.c. measuring flask, washing the beaker two or three times with small quantities of water, the flask filled up to 250 C.c. about 3 or 4 Gm. calcium hydrate added, and the mixture shaken for about an hour. This treatment removes a good deal of the colouring matter, but keeps the morphine in solution. Fifty C.c., which represents $\frac{1}{2}$ Gm. of opium, is now filtered off into a 100 C.c. flask, and the liquid slightly acidified with hydrochloric acid. The liquid will now be only slightly coloured. Twenty C.c. of the standard iodine is now run out from a burette into the flask, the latter filled up to 100 C.c., and the flask well shaken till the supernatant liquid becomes perfectly transparent, but has a dark-red iodine colour.¹⁹ Fifty C.c. is now filtered off and the excess of iodine determined by the standard sodium thiosulphate, using starch as indicator. The amount of iodine consumed by the $\frac{1}{2}$ Gm. of opium, multiplied by $149.8 = 0.749 \times 100 \times 2$,²⁰ gives the percentage of morphine in the opium.

If only an iodometric assay be desired, but 1 Gm. of opium need be taken for the assay, and the latter conducted exactly as described above up to the point where the chloroform-alcohol has been removed by evaporation. At this point the residue is taken up with good lime water by rubbing the evaporating dish thoroughly with it, pouring the mixture in a 100 C.c. flask, filling the latter up with lime water to make 100 C.c., shaking the flask about an hour, filtering off 50 C.c. into another 100 C.c. flask, acidulating and then finishing up as above.

Assay of Nux Vomica.

The acidulated-water solution of the total alkaloids of the drug, as obtained by the directions on page given above, or other method of extraction, is made up to a definite volume, say 100 C.c. If 4 Gm. of the drug has been taken, then 25 C.c. will represent 1 Gm.

¹⁹ See our article in *J. Am. Chem. Soc.*, 1893, p. 722; *Proc. Am. Phar. Assoc.*, 1898, p. 368.

²⁰ 0.75 is here taken instead of 0.74914, which is the factor for morphine (*loc. cit.*, p. 724).

of the drug, and will be sufficient for one estimation. This volume, then, is run from a burette into a 100 C.c. flask in which has been placed 20 C.c. of the decinormal iodine solution and 2 C.c. dilute hydrochloric acid, when the amount of iodine consumed by the total alkaloids in that 1 Gm. of nux vomica is reached in the way described above. Let that amount be *a*. If only the amount of total alkaloids in the nux vomica is desired, it is sufficient to multiply *a* by 47.8, which is equal to 100 times the mean factor of strychnine and brucine, and the percentage of total alkaloids is at once obtained.

For the separate determination of strychnine and brucine a modification of Dunstan and Short's²¹ method of separation by ferrocyanide, we have found to work fairly well as follows: Another portion of the alkaloidal solution, representing 2 Gm. of the nux vomica, that is, 50 C.c. is run out from the burette into an Erlenmeyer flask of the capacity of about 300 C.c., and to the contents of the flask 10 C.c. of a 2 per cent. solution of sulphuric acid is added, and then water enough to make in all about 200 C.c. Then pour in 25 C.c. of a 5 per cent. solution of potassium ferrocyanide, stopper the flask, and shake continuously for about half-an hour. Now filter, wash the precipitate on the filter repeatedly with water containing 1 per cent. of sulphuric acid till a few drops of the filtrate diluted with a little water have no bitter taste. The filter is then pierced, and the precipitate rinsed with use of the wash-bottle into a 100 C.c. flask. To the contents of the flask is then added 20 C.c. of a 5 per cent. solution of zinc sulphate, and the flask kept on a boiling water-bath for about fifteen minutes. The zinc sulphate decomposes the strychnine ferrocyanide, zinc ferrocyanide is precipitated, and strychnine sulphate remains in solution. The flask is then completely cooled, and water enough added to make 100 C.c. Of this 50 C.c. representing again 1 Gm. of nux vomica, but deprived of the brucine, is then filtered off and run out from the burette into a 100 C.c. flask containing 20 C.c. of decinormal iodine solution and about 2 C.c. of dilute hydrochloric acid. The amount of iodine consumed by the strychnine alone is then determined as above. Let it be *b*. Then $b \times 43.9$ (100 times the strychnine factor) gives the percentage of strychnine, and $(a-b) \times 51.8$ is the percentage of brucine in the nux vomica.²²

Assay of Ipecacuanha.

For extraction of the drug use one of the methods given in Lyons' 'Assaying.' The cold percolation process of extraction previously directed, as already remarked, does not work well with this drug.²³

In iodometric estimation the total acidulated alkaloid solution is made up to a definite volume, an aliquot portion taken, and added to a measured excess of the iodine solution, as directed heretofore. The iodine factor of emetine is taken as fairly near the mean factor of the total alkaloids.

²¹ *Pharm. Journ.* [3], 14,290; *Am. J. Pharm.*, 1883, 579. Any other method of separation of strychnine and brucine may be used with the iodometric estimations.

²² To test the exactness of this method, we prepared a solution containing known quantities of each of these alkaloids, and determined the same by the described method. The results, as can be seen from the following statement, are fairly satisfactory, if we consider the well-known difficulties of this separation. The solution contained 0.16 per cent. strychnine and 0.22 per cent. brucine (anhydrous).

Iodine consumed by 10 C.c. before removal of brucine.	Iodine consumed by 10 C.c. after removal of brucine.	Found Strychnine.	Contained Strychnine.	Found Brucine.	Contained Brucine.

²³ Ether, chloroform, and acetone were tried as menstrua in the cold percolation, but the results were too low. The ammoniated mixture fails to yield all the alkaloid. This possibly explains why Flückiger (*Pharm. Ztg.*, 1886, p. 30), extracting by ammoniated chloroform, obtained exceptionally low results. See also Guareschi, 'Alkaloide,' 1896, p. 527.

Assay of Hydrastis.

In the assay of *Hydrastis canadensis*, for berberine and for hydrastine, the directions for the assays are given in our other paper entitled, "Further Work Upon the Estimation of Alkaloids," etc. In the plan of the assay the hydrastine is dissolved with absolute ether, and estimated iodometrically, as a hexiodide. The berberine, undissolved by the absolute ether, is estimated volumetrically by precipitation as berberine hydriodide, the excess of the precipitant, potassium iodide, being determined by silver nitrate with sulphocyanate. But before the berberine is precipitated as hydriodide it is separated in its acetone compound. And before the alkaloids are acted upon by the reagents they are liberated from the powdered drug by maceration with an ethereo-ammoniacal mixture.

A FEW DIFFICULTIES OF THE BRITISH PHARMACOPŒIA, 1898.*

BY JOHN C. UMNEY.

ACIDUM ACETICUM GLACIALE.—The Pharmacopœia states that glacial acetic acid containing 99 per cent. by weight of hydrogen acetate should remain crystalline until the temperature rises above 15°·5 C., but acid having a melting point of 15°·5 C. will have a real hydrogen acetate strength of over 99 per cent., whilst an acid containing 99 per cent.—or 89·9 per cent., the amount actually indicated by the titration in the B.P.—will have a melting point of 14°·7 to 14°·8 C.

ACONITI RADIX.—In view of the fact that there is not sufficient *Aconitum napellus* cultivated in Britain to supply the root required for making pharmaceutical preparations, it is necessary to make use of foreign supplies, taking every possible precaution to insure the identity of the plants from which the root is taken, and that the drug contains a high percentage of crystallisable aconitine.

ATROPINÆ SULPHAS.—Considerable difficulty is experienced in obtaining atropine sulphate melting at 183° C., the removal of all traces of hyoseyamine sulphate being costly and of but little advantage. Practically all the atropine sulphate of commerce melts at 186° to 187° C., but otherwise it corresponds to the official characters and tests, and yields a base melting at 115° C.

ASAFETIDA.—There is little, if any, asafetida now in the market, which meets the B.P. requirements, the addition of earthy matters as adulterants in the country of collection prevailing to such an extent that in no instance could average samples be obtained during the past eight years which came up to the B.P. standard. When a whole case of asafetida was examined the ash was not usually less than 16 or 17 per cent., making due allowance for loss of weight (10 to 11 per cent.) in drying and powdering. As regards solubility in alcohol, that varied from 24 to 80 per cent. Though tears of asafetida answering the B.P. requirements could be picked, a case of the finest drug entering the port of London would not yield 5 per cent. of B.P. asafetida. To meet the difficulty, so far as concerns the tincture, nearly double the proportion of asafetida ordered in the B.P. should be used for preparing it, and the tincture should be standardised so that 100 C.c. would yield 12 Gm. of extractive. Otherwise, a purified strained asafetida should be used, though in that case there would be a considerable loss of the volatile constituents of the drug, and that would be a disadvantage, since the medicinal value of the drug depends largely upon those.

CREOSOTE.—The Pharmacopœia states that creosote should rotate a plane of polarised light to the left, but, as a matter of fact practically all the beechwood creosote found in commerce is either slightly dextro-rotatory or devoid of optical rotation.

EXTRACTUM CASCARÆ SAGRADÆ LIQUIDUM.—In order to keep this preparation, under all conditions of storage, it appears necessary to add to it 25 per cent. more alcohol.

GLUSIDUM.—The saccharin of commerce (of so-called 330 strength) does not comply with the official test for the absence of sulphamido-benzoic acid; in fact, it may contain as much as 40 per cent. Saccharin of so-called 550 strength, however, appears to answer all the B.P. tests.

IPECACUANHA.—Deterioration takes place in the alkaloidal value of the liquid extract of ipecacuanha, and even more rapid deterioration in the wine.

JABORANDI FOLIA.—At the present time the leaves of *Pilocarpus jaborandi*, Holmes, are not obtainable in commerce, the principal supplies consisting of the leaves of *P. selloanus* or *P. microphyllus*.

LIQUOR PANCREATIS.—This preparation retains its activity better when glycerin is present, but that addition is not officially ordered.

OLEUM AMYGDALÆ.—The B.P. test for distinguishing almond and peach kernel oils is somewhat at fault, as both oils will separate into a solid white mass and a nearly colourless liquid when treated with fuming nitric acid. Apricot kernel oil, however, behaves differently, and its possible presence as an adulterant of almond oil should be borne in mind.

OLEUM RICINI.—As castor oil of undoubted purity may assume a slight brownish colour on the application of the sulphuric acid test of the B.P., it is suggested that the wording of the test be altered from "brown" to "blackish brown," and that the percentage of potassium hydroxide required for saponification, viz., 17·6 to 18·5, should be added.

SCAMMONIUM.—The majority of samples of scammonium met with in the London market yield slightly more than three per cent. of ash on incineration, but that is a matter of very little importance so long as the correct proportion of ether-soluble resin is present, a requirement which is easily met, as the official standard is decidedly low.

SPIRITUS ÆTHERIS COMPOSITUS.—Difficulties arise in connection with the sale of so-called "oleum æthereum"; on account of its giving indications of contamination with methyl compounds, it appears desirable, therefore, to obtain a guarantee that only pure ethylic alcohol has been used in its preparation.

TEREBENUM.—It is difficult to obtain terebene which is optically inactive—or which, if so when freshly made, will remain so—and it might be well to allow a limit of 1 to 1·5 degree, in either direction, provided stringent requirements as to limit of boiling point were maintained. Portions of terebene boiling over the maximum seem to originate through the use of turpentine which has been kept for a long time.

UNGUENTUM CONIL.—It seems desirable to continue to use boric acid in this preparation, as required by the B.P. Addendum, 1890.

PHARMACEUTICAL SOCIETY.

MAJOR EXAMINATION QUESTIONS.

PHYSICS.

Thursday, December 28, 1899.—From 10 a.m. to 1 p.m.

[Six questions only to be attempted.]

1. Describe the necessary apparatus and give an account of the procedure to be followed in determining the vapour density of a substance by Hofmann's method. State clearly the way in which the results of vapour density determinations are employed in fixing the molecular weights of substances.

2. Explain the difference between "sensible" heat and "latent" heat. What are the general effects of heating a body? Describe these effects (a) on heating water from 3° C. to 5° C., (b) when a bar of iron is heated in air, (c) when a gas is heated in a cylinder with a movable piston.

3. Describe carefully the construction of any form of secondary battery, and state the chemical changes which take place within the cells during charging and discharging.

4. Define "specific heat." A piece of platinum of specific heat 0·32 is heated to 1000° C. and dropped into eight times its weight of water at 12° C.; what will be the final temperature?

5. Instance three illustrative cases of the chemical influences of light, and discuss the chemistry of the changes that occur in each of the cases you select.

*Abstracted from "Notes on Current Chemical and Pharmaceutical Topics," published January 1, 1900.

6. Calculate the focal distance of a crown glass meniscus lens, the radius of curvature of the concave face being 45 M.m., and that of the convex face 30 M.m., and the index of refraction being 1.5.

7. Explain the construction of the electric furnace, and describe the carrying out in actual practice of any manufacturing process in which it is employed.

8. Explain with the aid of a diagram the refraction of a beam of white light by a glass prism. Show what observations would have to be made in order to deduce the refractive index of the glass for a particular coloured ray.

CHEMISTRY.

Thursday, December 28, 1899.—From 2 p.m. to 5 p.m.

[Six questions only are to be attempted, and of these at least two must be taken from Part II.]

PART I.

1. Explain and illustrate the sense in which the word *equivalent* is employed in modern chemistry. In what other chemical senses has this word also been employed?

2. Write in order the symbols of the elements which form the first two small periods in the natural system and discuss the consequences of this arrangement.

3. What are the natural sources from which the various lithium compounds are derived? Describe how lithium carbonate can be prepared in quantity from lithium compounds which occur in nature.

4. How would you prepare specimens of the following substances, common materials, with the exception of the salts named, being placed at your disposal? Potassium iodate, cuprous chloride, sodium hydrogen sulphite, dipotassium hydrogen phosphate.

5. What products are obtained upon the decomposition of each of the following substances by the aid of heat:—Potassium ferrocyanide, potassium bichromate, ammonium bichromate, hydrogen sodium ammonium phosphate (micro-cosmic salt), arsenic acid, oxalic acid?

6. Describe two methods for the separation of arsenic from antimony, using equations to express all the important chemical changes which occur.

PART II.

7. State the various steps that it would be necessary to take in order to prepare synthetically a specimen of oxalic acid.

8. Write an account of the properties and principal reactions of ethylamine and describes three methods by which this substance could be obtained.

9. What is uric acid? How does it differ from an ordinary carboxylic acid and why does it form salts from basic hydroxides?

10. A hydrocarbon derived from benzene has the molecular formula C_8H_{10} . Give the possible constitutional formulæ of such a compound and indicate a method by which its constitution might be determined.

MATERIA MEDICA.

Friday, December 29, 1899.—From 10 a.m. to 11 a.m.

By what chemical or physical characteristics could you identify the following substances:—Almond oil, cod liver oil, codeine, podophyllum resin, salicin, thymol, jalapin, and benzoic acid? State what you know about the mode of preparation of each.

BOTANY.

Friday, December 29, 1899.—From 11 a.m. to 1 p.m.

1. Describe fully the phenomenon of transpiration in plants, and point out the various conditions which govern it.

2. What is Latex? Give some account of its occurrence in plants.

3. Write a detailed account of the morphological differences between Gymnospermæ and Angiospermæ.

PRACTICAL MATERIA MEDICA.

Friday, December 29, 1899.—From 2 p.m. to 3.30 p.m.

1. Prepare a transverse section of the Calumba root. Draw and describe your section, pointing out anything characteristic observed.

2. Report on the two samples of powdered Calumba root.

PRACTICAL BOTANY.

Friday, December 29, 1899.—From 3.30 p.m. to 5 p.m.

1. Make preparations to demonstrate the microscopic structure of the leaf provided (A).

2. What is B? Give a drawing of its internal features and indicate by references on your drawing the value of its various parts.

3. Refer the plants C and D to their natural orders, giving reasons for your references.

LETTERS TO THE EDITOR.

The Society's Examinations.

I noticed with pleasure the letter from Mr. Lennox on the above subject. It strikes a chord which must find response in the hearts of all those who are interested in the future of our calling. I take it for granted that the only true aim of pharmaceutical as of all other examinations is that we may send out a body of men thoroughly capable of the duties which they have in hand, and of lending dignity to a calling which has already been dragged in the mire too long. If this be so, it would seem that our inaction as a Society on the subject of examination reform is almost inexplicable, for while I am ready to admit that examinations at their best are but faulty, still I think there is no parallel to the methods of our pharmaceutical system. I should never be one to advocate the lowering of our examination standard, rather the reverse, but to anyone who will give it thought our system must appear as absurd as it is unjust. It is not so much the stiffness as the unfairness of our qualifying examination which frightens young men who enter the pharmaceutical arena to-day. There is something more than the usual element of chance about it. I have sometimes wondered whether there could be any moral sense or real personal kindness about our examining board, that they can treat so lightly a matter of such importance to those aspiring pharmacists, many of whom find it unusually difficult to acquire funds for repeated failures.

Now, allow me to emphasise a few points which have already been suggested as reforms. A man presents himself and, having been successful in his practical examination, finds that on the second day, perhaps in his last subject, he is "plucked." He is now required to plod all through the work already done successfully, and in which the examiners have expressed themselves as satisfied. It is no uncommon thing to meet with a man who has passed in the same subject three or four times and then been "plucked." Surely it makes the position of an examiner very absurd, to express satisfaction as to a man's capabilities in a subject to-day and three months hence declare him unfit to pass, but it has a much more serious side for the unlucky student, who is, perhaps, better up in his work the second time than the first, but by a series, it may be, of quite unusual questions, is staggered, and loses his head. I am certainly of the opinion that a subject once passed should stand to the candidate's credit. Make the examination searching, more so than at present if you will, but do not compel a man because he is weak in botany to pass in practical dispensing half-a-dozen times. This is not a new idea. I believe it obtains in most professional examinations but our own, and it seems to me the only common-sense method. I regard the idea of dividing the examination into two parts as a decided move in the right direction. The Minor covers far too wide a field for one examination; to divide it, I think, would ensure greater thoroughness in work and at the same time remove a strain from the minds of students, which is not due to reading but to cram in its worst form.

One other point and I have done. It has always seemed to me that a system of oral examination by one individual examiner is a mistake. Without venturing a word against the Society's choice of examiners, I think it often happens that the examiner, be he the highest authority on the subject with which he is dealing, is still quite without tact in dealing with candidates, and often puts his questions in such an obscure fashion as to muddle the unhappy victim before him. Again, the candidate is subject to the changing moods and temperaments of examiners, as well as to their pet theories. What I suggest, and what I believe is adopted by another examining body, is that a second examiner shall set

and hear the questions, and award the marks, and shall have the right to explain more fully any question that seems to him to be put in a somewhat obscure fashion. As one who has been through the mill, I offer these perhaps feeble suggestions, but this I feel strongly, that any effort made by the Society to make its examinations less of a bore and more a test of knowledge, and thus to place them on a more just footing, would be highly appreciated by students, and would conduce more than anything else to strengthen the Society. I do not believe a lower educational standard is wanted, but present-day students feel very keenly the injustice of the present system, and any effort the Society may take to remove that feeling will be amongst the most humane, as well as the most progressive, movements it has ever undertaken.

Newcastle-on-Tyne, January 1, 1900. THOS. HY. FLEMMING.

Liquor Bismuthi.

Whilst fully recognising the exhaustive manner in which Messrs. Cowley and Catford have treated the subject of liquor bismuthi in their recent paper, may I be allowed to point out that in a paper on the same subject by myself, read at the Plymouth Conference, and published in your report of that meeting, and in the 'Year-Book of Pharmacy,' p. 451, I described a method by which the loss of bismuth due to unneutralised nitric acid may be minimised, and the presence of oxy-nitrate, rendering the precipitated citrate partly insoluble, may be prevented. For this method I claim the advantages of more simplicity in manipulation, and less departure from the B.P. directions, as well as priority of publication, over the method devised by those gentlemen.

Newcastle-upon-Tyne, FRANK R. DUDDERIDGE.
January 1, 1900.

Pharmacists and the War.

Your correspondent of last week, Mr. J. B. Guyer, has done a useful service in drawing attention to the Government regulations for the employment of dispensers during the war. It is to be hoped that the Pharmaceutical Society will address a remonstrance on the subject to the War Office. The pay offered is about that of a "Sergeant (Corporal) Cook" in the Artillery, and not much more than half that of a sergeant-major. In position, I suppose, the dispenser would rank somewhere on a level with a corporal, and far below a sergeant. It is instructive to compare this pay and position with those accorded to the Volunteer medical men serving in the war. They receive £1 a day, more than a major's pay and more than that of an infantry lieutenant-colonel; in position they are ranked with captains. These anomalies are illustrative of what has long been one of the curious features of pharmacy—the position of dispensers. It is scarcely an exaggeration to say that the Pharmaceutical Society exists for little else than the promotion and protection of the dispenser's art. Take from the average pharmacist his ability to dispense and there is little to distinguish him from the ordinary tradesman. Dispensing is only purely professional side of his calling, yet it is a truth, and one which might furnish an ironical comment on the aims and position of the Pharmaceutical Society, that those of its licentiates whose sole business it is to dispense, and who cannot in any way be regarded as tradesmen, are the worst paid and the least regarded of the pharmaceutical community. It is needless to give facts in support of this statement. A glance at the pay-sheet of any public institution employing dispensers, or an appeal to the personal experience of any public dispenser, will satisfy the most sceptical of its truth.

London, January 2, 1900.

A. CAMPBELL STARK.

PRACTICAL NOTES AND FORMULÆ.

Apparatus for Filtering Liquids.

In the *Pharmaceutical Journal* for December 30, 1899 (p. 623), Mr. E. W. Lucas recommends the use of a special apparatus for the filtration of small quantities of liquids. I find it preferable to use an ordinary filtering flask and to fit a test tube to the stem of the funnel by means of a cork with sides grooved to allow free passage of air. This method is the simplest possible one; it has been in use in my pharmacy for some months past for filtering small quantities of animal substance solutions.—HAROLD E. MATTHEWS, Clifton.

The Assay Process for Ext. Cinchonæ Liq.

The analytical process given in the B.P. for standardising Ext. Cinchonæ Liq., as also Tinct. Cinchonæ, is far from being an ideal one. The benzolated amylic alcohol at once forms an emulsion when shaken with the alkaline liquid extract, and the various methods adopted to overcome this emulsification not only lead to loss of time, but, what is more important, to loss of alkaloid. The following method of assay, which has nothing very original about it, but which naturally suggested itself in view of the above trouble was found to work satisfactorily and gave concordant results; it may be found useful by many pharmacists wishing to standardise the aforesaid cinchona preparations, and who have difficulty in carrying through the benzolated amylic alcohol process:—Introduce into a separator 5 C.c. of the liquid extract or 10 C.c. of the tincture, mixed with 10 C.c. of water, add excess of ammonia, and shake the alkaloid out with three successive portions of ether-chloroform (9 of ether to 1 of chloroform). Dissolve out the alkaloids from their ether-chloroform solution by agitating in the separator with 20 C.c. of dilute sulphuric acid (5 p.c.), and twice more with 10 C.c. of acidulated water. The aqueous solution of acid sulphates of the alkaloids is then rendered ammoniacal, and the alkaloid removed by agitation with 3 × 10 C.c. of chloroform. The mixed chloroformic solutions are evaporated in a tared dish and the residue of alkaloid dried to constant weight at 110° C.—J. STENHOUSE, Edinburgh.

Dispensing Bromoform.

The following, which I have had to dispense recently, may be useful to W. R. K.:—

R Bromoform 1 drop.
Fiat Emulsio \mathfrak{z} i. To be given every three hours. Mitte \mathfrak{z} iv.

The bromoform (32 drops) was dissolved in \mathfrak{z} ss. almond oil and emulsified with mucilage of acacia, and \mathfrak{z} ss. syrup of tolu added to flavour the mixture. In another prescription, the doctor ordered the emulsifying agent.

R Bromoform \mathfrak{z} ss.
Tr. Senegæ \mathfrak{z} ii.
Syr. Aurantii \mathfrak{z} ss.
Aq. Chloroformi ad \mathfrak{z} vi.
Ft. Mist. \mathfrak{z} i. every ix hours.

In this case the bromoform was mixed with the tincture of, senega in the bottle, and the chloroform water added, the syrup of orange being added last.—W. JOSTY, London.

Coloured Gold Alloys.

Green gold—Fine gold, 2 to 3; silver, 1. Brass yellow gold—(1) Fine gold, 1; silver, 2. (2) Fine gold, 4; silver, 3; copper, 1. Pale red gold—Fine gold, 1; copper, 1. Grey gold—(1) Fine gold, 30; silver, 3; steel filings, 2. (2) Fine gold, 4 to 5; steel filings, 1.—*Pharm. Centralh.*, 40, 406, after *Journ. d. Goldschmiedek.*

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany,
Austria, Italy, Russia, Switzerland, Canada, the
United States, South America, India
Australia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.
Publishing and Advertising Office: 5, SERLE STREET, W.C.

Members of the Pharmaceutical Society must address all communications with reference to the transmission of the Journal, to the Secretary, 17, Bloomsbury Square, London, W.C.

LONDON: SATURDAY, JANUARY 6, 1900.

◊ 1899. ◊

THE year just closed will certainly be notable in connection with the history of pharmaceutical affairs in this country, as being the period when the original project of the Pharmaceutical Society was at length completely provided for. The conditions prevailing at the time when the Society was founded, did not permit of such a union of all persons engaged in business as chemists and druggists as the founders of the Society considered to be desirable. The exercise of the business was then free from any conditions, while it was a first principle with the founders of the Society that membership should be subject to the condition of being, in every instance an indication of capabilities to be trusted by the public and creditable to the general body. Identification of the trade with the Society was therefore impossible at that time, though that was the ideal of WILLIAM ALLEN, JACOB BELL, and all their colleagues, towards which their efforts were directed, and have been followed up by their successors even to the present day. To remove the obstacles that stood in the way of bringing about that great desideratum has been the work of nearly sixty years, and the present representative of the historic house of JOHN BELL and Co. may well be congratulated that in the previous year he was successful in carrying through the Legislature a Bill which provided eventually for the possible association of all legally recognised chemists and druggists, as members of the Pharmaceutical Society, upon terms of perfect equality. That was an achievement of which the present successor to JACOB BELL may well be proud, inasmuch as it is a worthy continuation of the work of his illustrious predecessor, which should be a source of satisfaction to every member of the pharmaceutical body—some reward for adherence to the sound principles of the Society and for the frequently difficult task of according those principles the support and justification rendered necessary by untoward circumstances, and a success of special importance in connection with impending questions.

As a result of the additional powers conferred upon the Society by the Pharmacy Act Amendment Act of 1898, the bye-laws relating to membership were altered, so that every person legally qualified to use the title of chemist and druggist in connection with the business was made eligible as a member of the Pharmaceutical Society without any of those reservations which had formerly been unavoidable. The objection to association with the Society which had previously been urged by many—not without some plausibility—viz., that they could not take any other than a subordinate position in the Society, has now been entirely done away with. The not unnatural claim of the pharmaceutical chemist to precedence has no longer the weight or the attention that it could formerly command, and whether that circumstance is to be matter of regret or not at the present time is merely a question to be determined by the action of those on whose behalf the preferential claim of the pharmaceutical chemist has been put into the background for the sake of ensuring thorough consolidation. The preparation that has been made for that desirable consummation during the preceding year may now be considered from the point of view of its efficacy, after a full twelve months have lapsed since the period at which association with the Society usually commences. Within that space of time the number of members joining the Society has been 2,196, exclusive of the number of those who were associates in business last year, and, of course, came to rank as members without election. That addition to the total number of members of the Society is considerable in itself, and it has been brought up very well by what might have been expected from associates not in business taking up a position as members. But when that accession of members is compared with the number of legally qualified persons, the effect of the legislation of 1898 appears in a less favourable light, since the addition to the Society appears to amount to only about one-tenth part of the number of legally qualified persons who were unconnected with the Society but were made eligible to the position of membership.

In directing attention to this effect of the long-deferred provision for according to legally qualified chemists and druggists, the full privileges of association with a Society incorporated by Royal charter and empowered by subsequent Acts of Parliament to promote the interests of persons engaged in that calling, the peculiarity of present conditions may be pleaded as some justification. Changes in the mode of conducting business of all kinds have, during the past twenty years, affected almost every occupation, and the business of the chemist and druggist has been no exception, either in its trade or professional aspects. Under the domination of free trade doctrines protection is obtainable only for public interests; classes and individuals must provide it for themselves. In view of the question that will probably be raised in Parliament as to the competence of companies to carry on the business of chemists and druggists, the need of agreement among the members of the body that is to some extent represented by the Pharmaceutical Society will become more imperative than ever it has been. The possibility of influencing action on their behalf, through the position of membership, should be more generally regarded as a privilege necessary for securing existence, if not for bringing forth more favourable conditions.

Members of the trade require to take cognisance of the possibility that has been presented to them for consolidated co-operation, in their own interests and for their mutual protection. To use the words of a German contemporary, which takes a sympathetic interest in our affairs, the main provision of the measure passed last year should be regarded as one for which there is the greatest necessity that chemists and druggists should take the fullest advantage of it, in order to prevent the ground from being taken from under their feet by the onward sweep of modern developments in trade and competition.

DEFINITION OF THE WORD "CONTROLLING."

AMONG the many suggested remedies for the "company" problem which have reached us from chemists and druggists' that one which advocates the compulsory qualification of the "controlling" shareholders of a company seems to have a fair measure of support. Perhaps there may be good grounds for this backing; but the thought will obtrude itself that a primary essential to favourable criticism is a clear definition of the word "controlling." When and how does a shareholder control the concern in which he has his holding? Take a concern with a capital of £10,000 in £1 shares; suppose three persons each held 500 of such shares, another person 1,000, and the remaining capital to be in the hands of say, 100 members of the general public—a not very improbable case to state. Who would be the controlling shareholder? The natural answer is, of course, "the man who holds the largest number of shares." But what sort of control can he exercise? The three holders of 500 each could swamp him if they acted conjointly, and the four principals could, in turn, be out-voted by the remaining proprietors.

The difficulty of devising a workable definition of the term that would be applicable to the kind of "control" to be exercised in the case of a pharmaceutical business, seems to be the weak point in the proposal, if not a fatal bar to its adoption. When one comes to consider in addition the subtleties of debenture capital, preference, deferred and ordinary shares, and their degrees of priority, the difficulties begin to thicken, and the task of finding the responsible individual becomes almost hopeless. Then, again, it must always be borne in mind that a responsibility based upon a financial holding is a most illusory form of security—the rottenest of hollow reeds; for shares may be, and very often are, manipulated to fit certain exigencies. They could and would be "rigged" without much difficulty to escape the consequences of the "controlling shareholder" proposal.

But perhaps financial control is not what our correspondents have in mind. They may intend to hit the person virtually conducting the business; if this be so they cannot logically withhold support from the thorough-going proposal of a compulsory proprietorship which must be both financially and pharmaceutically qualified. These observations are made in no carping spirit, but solely with a view to inducing those who take sufficient interest in pharmaceutical affairs to offer suggestions on the great problem of the day to meditate a little respecting the probable effect of their proposals if carried into practice.

ANNOTATIONS.

THE CONFERENCE BLUE LIST is no more, the Executive Committee of the B.P.C. having decided that sufficient publicity can be gained for its list of suggested subjects for investigation through the medium of the weekly press. The Research List, therefore, as it is now called, duly appeared in our pages last week (see page 628), and is there displayed for the benefit of all anxious investigators or would-be investigators. The number of subjects suggested has been reduced to thirty-eight, but those, if properly taken up, should suffice to keep all the regular pharmaceutical investigators in the United Kingdom busy until the Conference assembles in London. At least a fortnight would then be required to have the reports properly read and discussed. But, in addition, the President of the Conference has suggested an almost limitless subject, by asking pharmacists generally and members of the Conference in particular to keep records of all difficulties met with in preparing the galenicals of the British Pharmacopœia. Those records they are desired to communicate at the London meeting, with any suggestions for possible improvements in the official processes and tests. Assuming that this invitation, as well as that of the Executive Committee, is accepted as literally as it is given, and that new investigators also arise, whilst older ones bring up papers on subjects of their own, the business of the annual meeting of the Conference next year may quite conceivably require a full calendar month for its disposal. Fortunately, however, human nature is still an important factor in influencing the actions of pharmacists, and, after all, we may reasonably anticipate that all the communications will be crowded into the usual insufficient two days.

PROFESSOR NESTOR TIRARD has been lecturing before the Society of Apothecaries of London on "Pharmacy and the British Pharmacopœia"—his third lecture dealt with the Pharmacopœia in its relation to pharmacists, and appears to have been intended to show that the work is a success, as proved by its influence on prescribing and dispensing. As a matter of fact, so far as can be judged from the report in last week's *British Medical Journal*, the lecture was but little more than a running commentary on the alterations in nomenclature, strength and composition of official preparations. What there was beyond that was embodied in the lecturer's conclusions, wherein he attempted to show how all the changes in the Pharmacopœia affect "the chemist, the dispenser, the manufacturer." Apparently—but, we fear, without sufficient reason—everyone, or practically everyone, is assumed by the lecturer to be satisfied with the results. Referring to the suggestion published in the *Pharmaceutical Journal* for August 20, 1898 (p. 229), that, in future, pharmacists should decline to assist in the revision of the Pharmacopœia, unless they are to receive full recognition as co-workers on the Pharmacopœia Committee, Dr. Tirard ended his lecture with the following cryptic utterance:—"If we consider the way in which trade interests are affected by the Pharmacopœia, if we consider that the volume deals with things bought and sold, it is impossible not to realise the risks of trade competition, of trade influence, and the constant danger of introducing a standard which might create a monopoly. I would ask you whether, with this in view, it is not better that the compilation should be in the hands of those whose motives cannot be assailed, that the final responsibility should rest with those whose interests are not at stake?" Objection is rightly taken to this offensive passage by Mr. Charles Umney (see p. 2), and we do not hesitate to add our strong protest to his. It is much too late in the day for medical practitioners to claim superiority in this matter, and it would be equally out of place for them to pose as ethical examples to pharmacists.

THE ANSWERS TO QUERIES, which are published in the Journal most weeks, appear to be widely read by many besides those for whos

especial benefit they are intended, and, as a result, misconceptions seem occasionally to arise in the minds of some who are not addressed in those answers. The latest illustration of that is afforded by an answer in last week's issue, where a correspondent was informed that a particular certificate he inquired about would not be accepted by the Board of Examiners, from a candidate for the Minor Examination, after August next. The reply dealt with that particular certificate and nothing else, but immediately another correspondent wrote to ask if it referred to a certificate of the Pharmaceutical Society's First Examination, which he passed three years ago. In answer to that, it should hardly be necessary to explain that, having once been registered as a "Student," no one will be expected to show further proof of having passed an approved scholastic examination. Another inquirer asks a question about books for Major Examination work, a full list of which he will find in the "Students' Number" of the *Pharmaceutical Journal*, published on September 9 last. Whilst both willing and anxious to help readers in every possible way, the Editor must request those who are in need of information to refer to back numbers before giving themselves the trouble of writing a letter of inquiry. A little search through the very full indexes to back volumes will often save much time and trouble, both to the editorial staff and to those who require the information. In addition to that, the space which would be occupied by needless repetitions will frequently be saved.

THE CHEMISTS' BALL will be held at the Portman Rooms, Baker Street, W., on Wednesday, January 17, *i.e.*, less than a fortnight hence. As it will be the last ball of the nineteenth century, the Hon. Secretary is naturally anxious to establish a record for the century. He will therefore be glad to receive a further large number of applications for tickets at an early date. The tickets (lady's, 12s. 6d.; gentleman's, 17s. 6d.) are inclusive of refreshments, supper and wine, and can be obtained of Mr. Warren, at 24, Russell Street, Covent Garden, W.C. The profits of the ball, as is well known, are always devoted to charitable objects, the Benevolent Fund of the Pharmaceutical Society having profited largely in that way for many years past. In spite, therefore, of the many calls upon all and sundry at the beginning of the year—this last year of the century more particularly—it is hoped that one of the pleasantest pharmaceutical gatherings of the year will not suffer from lack of interest on the present occasion.

THE SALE OF INSECTICIDES is again referred to by the *Gardeners' Chronicle*, in its review of the past year. It is there suggested that an attempt has been made by the Pharmaceutical Society to restrict the sale of such substances as weed-killers, insecticides, and other compounds, containing in some cases enormous amounts of the most deadly poisons. It would be more correct to say that it is the law which restricts the sale of such things to persons who have been specially trained to deal in poisons, and the duty of enforcing the law is imposed upon the Society. We quite agree with our contemporary's remark that some people are so incautious that no regulations will save them from the consequences of their own want of care, but that other people may, nevertheless, fairly demand that the sale of such substances should be carefully regulated so that, although accidents cannot wholly be prevented, every reasonable precaution should be taken to avoid them. "Suppose a drop or two of some of these more potent insecticides were by accident to be introduced beneath the skin, or into an open wound, a mere scratch would be enough, the consequences would be most lamentable." So says the *Gardeners' Chronicle*, and that, we think, is ample reason why horticultural requisites of a poisonous nature should not be obtainable from traders connected with horticulture, except under the identical conditions that are imposed upon the druggist. "The encroachment on the liberty of the subject is here only a means for securing the preservation of the

liberty of the multitude." That is well said and cannot be improved upon here.

ENGLISH GRAMMAR is, apparently, not a subject to which any special prominence is given in the modern system of elementary education, otherwise English "as she is spoke" would be much more elegant, and the written work of students would be much more intelligible than it now is. This fact was rather startlingly brought home to the examiner of an English paper set some little time back in one of the many non-official supplementary schools of the metropolis, whose special function is to try to remedy the omissions of the national system of education. An essay had been written, and it occurred to the examiner to ascertain how far the budding authors understood the meaning of the words he employed. He therefore asked certain of the students to write down the usual signification of a few of the words which he selected. The result was sufficient to shake the profoundest faith in the divine right of the constituted order of things, and even warranted in the mind of the examiner a suspicion that modern methods of preliminary training seem chiefly to tend towards converting the brains of students into a hopeless jumble of half-digested scraps. One of the words was "coalition." This was translated by "the act of coal-ing," and by the not less brilliant definition "when two meet together with great force." "Magnanimous" was "something which is very large." Another humourist gravely stated in black and white that "fomentation" meant "to foam at the mouth," whilst a companion evolved a specially happy idea by declaring it to stand for something which "fisses." But, perhaps, the cream of the whole collection was the truly rich description of consonants as being "letters of the alphabet which cannot be pronounced with either the lips, the teeth, or the throat." There is good reason for supposing that the vocabulary of the examiner was for a time wholly composed of that class of consonant.

THE DEATH OF SIR JAMES PAGET, on December 30, removes one of the most eminent members of the medical profession. He was a younger brother of the late Sir George Paget, K.C.B., Regius Professor of Medicine at Cambridge, and received his early medical education at St. Bartholomew's Hospital, where he distinguished himself by winning nearly all the prizes that were then given. He became successively Hunterian Professor of Surgery, Member of Council, and President of the Royal College of Surgeons. He was also Serjeant Surgeon to the Queen, and Surgeon to the Prince of Wales; a member of the Senate and Vice-Chancellor of the University of London; a Member of the Institute of France; a Fellow of the Royal Society; a D.C.L. of Oxford, and LL.D. of Cambridge; and was President of the first Medical Congress held in England. He was created a Baronet in 1871; and sat upon two Royal Commissions, one to inquire into the condition of the London small-pox and fever hospitals, the other on small-pox and vaccination. He was President of the Clinical Society in 1869; of the Royal Medical and Chirurgical Society in 1875, and of the Pathological Society in 1887.

THE ISLE OF MAN PHARMACY BILL has been referred to a Committee of five members of the House of Keys, on the motion of Mr. J. T. Cowell, who said statements in the *Pharmaceutical Journal* led him to believe that the measure was faulty, and would not meet the object the chemists of the island had in view when they asked for the Bill. It was said to place grave restrictions upon chemists, which are not placed upon them across the water, and it was therefore suggested that the best plan would be to do what was done in the case of medical men—when a Committee took evidence and reported to the House—as Mr. Cowell thought the decision of that Committee was probably of some use when the matter came to be decided. The members appointed on the Committee are Messrs. J. T. Cowell, J. J. Goldsmith, Kerruish, Crellin, and Mylrea.

SALE OF FOOD AND DRUGS ACT, 1899.

CIRCULAR FROM THE BOARD OF AGRICULTURE.

This enactment came into operation on the 1st instant, and signs are not wanting that a crusade against the offences punishable by the Act is about to be actively inaugurated under Departmental auspices. On the last working day of the old year a circular was addressed by the Board of Agriculture to the clerks of all the local authorities in Great Britain, directing attention to the provisions of the new Statute, and delicately, but quite unmistakably, showing the nature of the duties thereby imposed upon such authorities. One of those duties, and perhaps the one to which the Board of Agriculture attaches particular importance, is the appointment of a public analyst. Every local authority is specifically enjoined to appoint a public analyst, together with proper officers to take samples for analysis, and generally to put into force the law relating to adulteration.

It appears fully evident by this action of the Government Department that the statutory obligations resting upon Local Boards and Vestries will not be allowed to remain unfulfilled; indeed, it is probable that not only a nominal, but an adequate and efficient discharge of those obligations is to be required. The official circular to town clerks and others, after referring to the fact that there were, in the year 1898, forty-two English boroughs in which not more than twenty samples were taken during the twelve months, pertinently proceeds to inquire whether the Local Board receiving that particular copy considers that its own district is fully equipped with inspectors who have experience as sampling officers—men who are able to exercise economy and discrimination. It may naturally follow that, as each Local Board will put its own valuation on its own appointments, very few replies in the negative will find their way to Whitehall; but, as the inquiry is accompanied by a request for an early intimation of what steps have been taken to carry out the provisions of the Act, the Department appears determined to find out, for itself, the real truth and to insist that the intentions of the Legislature, so far as the purity of foods is concerned, shall be carried into vigorous practice.

The Treasury has appointed additional inspectors under the Act, and those are to be available to confer with local authorities as to the best methods for securing an efficient regard for the law; their further but unspecified charge is, no doubt, to report to the Department lax Local Boards who do not take steps to give effect to the "extended vigilance" in the detection of fraudulent practices which the new Act requires. The quoted words supply the key to the whole situation, and it is not at all improbable, in the ordinary nature of things, that the "extended vigilance" may find practical expression in increased raids on chemists. For inspectors, even the most discriminating variety, have an appreciable amount of human nature as well as intelligence, and they will not confine their operations to sampling foods, while pharmaceutical practice, by its very character, affords so ready a field for attack. It therefore behoves pharmacists to be especially careful henceforth to satisfy themselves that their medicines are of official standard and their drugs of unimpeachable purity, so that, so far as regards registered men, the poet's dictum that "things are not what they seem" may cease to have authority.

In order that the statutes relating to Food and Drugs may be read and inwardly digested, as they ought to be, by chemists, the Pharmaceutical Society publishes them almost *in extenso* in the annual editions of the Calendar and—as a source of information on that subject, as well as concerning other Statutes affecting chemists—a copy of that compilation becomes almost as essential to the calling as the Pharmacopœia. Every chemist in business on his own account should, therefore, take steps to procure a copy of the new edition, to be published shortly.

ENGLISH NEWS.

HULL CHEMISTS' ASSOCIATION—At the annual meeting of this Association, held at the Imperial Hotel, on December 19 last, Mr. A. Sheffield, President, in the chair, the following resolution, proposed by the President and seconded by Mr. W. Staning, was carried unanimously:—

That in the opinion of this meeting it shall be unlawful for a company or other corporate body to carry on the business of a pharmaceutical chemist, or chemist and druggist, or to use any description implying qualification under the Pharmacy Acts unless all the directors and controlling shareholders of such company shall be qualified chemists under the Pharmacy Act, 1868.

It was also resolved to send a copy of the resolution to the Pharmaceutical Society and one to the Secretary of the Federation of Local Pharmaceutical Associations.

MANCHESTER PHARMACEUTICAL ASSOCIATION.—In response to the feeling of several Members of this Association, the Ball Committee has held a meeting to consider the advisability of postponing or cancelling the ball announced to be held on January 24, 1900. As a result it has been decided that, owing to the anxiety caused by the state of affairs in South Africa, and the suffering of so many fellow-countrymen, it is advisable to abandon the proposal. The ball, therefore, will not take place this session.

CITY OF LONDON IMPERIAL VOLUNTEERS.—Messrs. Wright, Layman, and Umney, of Southwark Street, S.E., have addressed the following letter, dated December 23, to the Lord Mayor of London:—"Dear Sir,—We notice with the greatest possible satisfaction the raising of the above corps (1,000 men) for service in South Africa, and the generous response that has been accorded to your appeal to aid in its equipment. Although our business is not within the precincts of the City, still we are desirous of contributing to make such equipment of the City of London Volunteers as perfect as it well can be. We imagine that medicines will be required, and as we have had considerable experience in this direction, gained while we had the honour of holding the contract for their supply to the whole of the British Army during a period of three years—1894 to 1897, we shall be very glad to place ourselves at your service, and to supply free of charge all medicines (not surgical appliances) that the medical staff connected with this corps may think necessary to forward to South Africa."

THE LIVINGSTONE EXHIBITION.—The exhibition which has been held during this week at St. Martin's Town Hall, London, W.C., has been organised under the auspices of Livingstone College, and was decidedly unique and interesting. It is intended as a help towards the solution of the health question as it affects residents or travellers in unhealthy climates. Instruction on those lines has for the past six years been given to missionaries at the College; it is hoped by means of the exhibition and its official organ "Climate," to lead to a much larger consideration of the common-sense precautions which should be taken in connection with all kinds of enterprise in foreign climes. The exhibition comprises all kinds of devices for making the work of the explorer easy, and for reducing to a minimum the transport of a military expedition or a missionary party. Among the firms exhibiting were several well-known manufacturers of food specialties, including Allen and Hanburys, Limited; Bovril, Limited; Cosenza and Co. (Maggi's Consommé), and others. Messrs. Allen and Hanburys, Limited, were also represented in the medical department, together with Aërotors, Limited (Sparklets), Burroughs, Wellcome and Co., Howards and Sons, Aliène Co., B. Kühn (Chinosol), Oppenheimer, Son and Co., Limited, and T. Howard Lloyd and Co. Filters and applications for the purification of water, general sanitary fittings, and disinfectants were exhibited by the Berkfeld Filter Co.,

Limited, and Newton, Chambers and Co., Limited (Izal). In addition to the trade exhibit there was a very interesting collection of Livingstone relics—his sextant, Bible, journals, pistols, surgical instruments, autograph maps, and a number of objects connected with the life and work of the great missionary and explorer. There were also a number of other interesting relics of great travellers, many of which were lent by the Royal Geographical Society. Lectures were given on "The Malarial Mosquito," by Major Ross, of the Sierra Leone Malarial Commission, and by Miss Kingsley. The patron of the exhibition was H.R.H. the Princess Christian, the president being Sir George Goldie.

BORIC ACID AS A PRESERVATIVE.—The adjourned case against Messrs. Hudson Brothers, Limited, for selling clotted cream alleged to be adulterated with boric acid (see *P. J.* [4], 9, 484), was resumed at Westminster Police Court, on Thursday, December 28.—Evidence for the defence having been given, the magistrate (Mr. Shiel), said there was no law in the case; it was purely a matter of fact. The onus of proof lay on the defendants to satisfy him that the compound used as a preservative was not injurious to health. They had not so satisfied him, therefore he must decide the case in favour of the prosecution (the St. George's, Hanover Square, Vestry), and impose a fine of £10, and twenty guineas costs.—Counsel for the defence said defendants would consider the question of appealing to quarter sessions.

SALE OF CAMPHORATED OIL.—At Coalville Petty Sessions, on December 22, Thomas Dodd, of Whitwick, was fined £1 12s., including costs, for selling camphorated oil which was not compounded in accordance with the B.P., 1898.—At Loughborough Petty Sessions last week, Charles J. Wathes, chemist and druggist, Kegworth, was fined 2s. 6d. for selling camphorated oil deficient in camphor to the extent of 3 per cent. Defendant said that the compound was made by a qualified chemist, and with the full ingredients; the deficiency was doubtless due to volatilisation.—At Lambeth Police Court, on January 2, Annie Wolff, described as a medical herbalist, of Choumert-road, Peckham, was summoned by the Camberwell Vestry for selling camphorated oil deficient in camphor to the extent of 74 per cent. The defence was that defendant had only had the business a short time, and had made the oil in accordance with a recipe left by the previous owner of the business.—Fine, £1, and 17s. 6d. costs.

"SILVERINE" FOR PEPPERMINT.—On Tuesday, January 2, the Stockport coroner held an inquest with regard to the death of Rosa Langley (15), daughter of a hatter.—It appears that the girl was not well on Christmas Day, and her mother advised her to take a dose of peppermint. Instead of peppermint she took some "silverine," which was in a similar bottle without a label. She immediately became ill and died. It was proved that the "silverine" had been purchased by the deceased's brother from a hawker, and the coroner expressed the opinion that hawkers should be prevented from selling poisons. He further stated that he should communicate with the Chief Constable to ask him to put a stop to the sale of the fluid, which is said to contain nitric acid and mercury, and is used for "silvering" articles.

OVERDOSE OF LAUDANUM.—The Sheffield City Coroner held an inquest, on December 28, upon the body of Daniel William King (85), of 163, Alexandra Road, Heeley, who died on the previous Monday night from the effects of laudanum poisoning.—Evidence was given to the effect that deceased had been in the habit of taking laudanum to procure sleep.—A verdict was returned to the effect that deceased died from an overdose of laudanum, administered by himself, but for what purpose there was not sufficient evidence to show.

Obituary.

GILL.—On December 20, Joseph Gill, Chemist and Druggist, Liverpool. Aged 71.

LOWE.—On December 29, Charles Lowe, Pharmaceutical Chemist, Surbiton. Aged 83. Mr. Lowe had been a member of the Pharmaceutical Society since 1853.

PICKLES.—On December 18, William Thompson Pickles, Chemist and Druggist, Queensbury, near Bradford. Aged 76.

SIMPSON.—On December 25, Thomas Simpson, Chemist and Druggist, Croydon. Aged 70.

STEVENSON.—On December 23, Stephen Stevenson, Chemist and Druggist, Rochdale. Aged 66.

THORNE.—On December 28, Henry Courtney Thorne, Chemist and Druggist, Brighton. Mr. Thorne had been connected for many years with Messrs. Headland and Co., chemists, of Brighton and Hove, and became a director when the business was turned into a limited company at the beginning of 1899. He was very highly esteemed amongst pharmacists in the town, and was a prominent member of the Brighton Association of Pharmacy.

TUNLEY.—On December 12, William Henry Tunley, Chemist and Druggist, late of Rowlands Castle. Aged 45.

WOODHEAD.—On December 23, Herry Charles Woodhead, Chemist and Druggist, Liverpool. Age 64. Mr. Woodhead had been a member of the Pharmaceutical Society since 1892.

WORFOLK.—On December 24, Francis Worfolk, Chemist and Druggist, late of Bolton. Aged 86.

YATES.—On December 26, Samuel Pearce Yates, Pharmaceutical Chemist, Boscombe. Aged 55. Mr. Yates, who had been a member of the Pharmaceutical Society since 1871, had resided in Boscombe for about nine years, and was very well known. He had been ailing for a month or six weeks, but was attending to his business till within a few days of his death, the cause of which was asthma.

SCOTTISH NEWS.

GLASGOW CHEMISTS' AND DRUGGISTS' ASSISTANTS' AND APPRENTICES' ASSOCIATION.—A conversazione was held under the auspices of this Association in the Mid-Masonic Hall, West Regent Street, on December 29. There was a large gathering, and an attractive programme of dances, songs, etc., was carried out with great zest and success. The party did not break up until an early hour in the morning.

A LIBEL ON CHEMISTS.—In a recent Glasgow case where a man was convicted of drugging with chloral, Sir Henry Littlejohn, who was one of the witnesses, said "there was so much competition that druggists would sell that most potent drug to anyone without taking the buyer's name; so much facility was a perfect disgrace to society." It is to be hoped that Sir Henry Littlejohn's facts are weak, and that his assertion is only one more baseless slander against a class of men who deserve more commendation than blame.

PROCEEDINGS UNDER THE PHARMACY ACTS.—At Glasgow Sheriff Court, on Wednesday, January 3, before Sheriff Guthrie, David Stirling, assistant in the shop of Dr. R. Davidson, 255, Main Street, Shettleston, was charged with selling a quantity of opium, contained in a quantity of laudanum or tincture of opium, to an agent of the Registrar of the Pharmaceutical Society of Great Britain, on December 2, 1899.—Mr. Peter Morison, jun., of Messrs. P. Morison and Son, solicitors for the Society in Scotland, appeared for the complainer, and Mr. J. C. Brock, writer, Glasgow, for the accused.—Mr. Morison explained that this was only a pleading diet, and asked that a day might be appointed when evidence could be given.—A long discussion then took place

between the solicitors, with an occasional remark by the Sheriff, on a question of procedure, Mr. Brock arguing that as his client was not aware that it was only a pleading diet, the case should be disposed of that day.—Finally the case was adjourned until Wednesday, February 14, at one o'clock.

IRISH NEWS.

A DOCTOR'S FATAL MISTAKE.—The people of Bandon have been startled by the death of a very popular local doctor, Dr. William J. Belcher, the medical officer to the Bandon Workhouse, who has accidentally poisoned himself. He had visited the workhouse, as usual, and having seen the patients, he went to the surgery to make up their medicines. In this he was assisted by the hospital nurse, and, whilst giving some directions to her, he set about preparing a draught for himself. Apparently, he inadvertently took up a bottle containing carbolic acid in mistake for one containing solution of magnesia, and, having mixed some of the contents with chloroform water, swallowed the draught. He immediately realised the mistake he had made, and medical assistance was sent for, but too large a quantity of the poison had been taken, and, in a very short time, the victim of his own error was dead. It appears that the carbolic acid and the solution of magnesia were kept in bottles of the same shape and size, and that both were standing on the dispensing counter at the time of the accident.

THE ANALYSIS OF DRUGS.—At the last meeting of the Macroom, Co. Cork, Guardians the Local Government Board forwarded a copy of a letter which had been received from Dr. Crowley, medical officer, Clonmoyle Dispensary District, relative to the analysis of samples of drugs supplied for use in that district. Dr. Crowley, in his communication to the Local Government Board, stated that the Guardians of Macroom Union had never asked him to send the medicines to be analysed, nor even informed him that they had an analyst. It was only the Local Government Board Inspector, Dr. Browne, who told him that a Mr. O'Mahony, of Cork, had been appointed analyst of medicines and drugs for the Union. He did not even know how to forward samples of the drugs for analysis, but, of course he would obey the instructions of the Board. Several Guardians expressed the opinion that Dr. Crowley must have known how to forward the drug samples, while others maintained that he should have been informed that an analyst for the Union had been appointed, and that he should be instructed as to how the drugs should be sent on for analysis. The Clerk of the Union said that he had received the drug samples for other doctors of the Union, and had duly forwarded them for analysis. It was decided by the Guardians to send all necessary information on the subject to Dr. Crowley forthwith.

MR. ROBERT G. DOWNES, President of the Pharmaceutical Society of Ireland, has sent a letter to the Council, resigning the Presidency on the score of ill-health. Mr. Downes entered three months ago upon his third year of office. We are informed that his determination to resign is due solely to his continued indisposition, which prevents him taking that active part in the affairs of the Society which is necessary to the proper carrying out of the objects for which it was formed 25 years ago. The regrettable electric tramway accident which befell Mr. Downes a short time ago, and of which we made mention at the time, has contributed in no small degree to his present bad state of health. It is not improbable that a successor to Mr. Downes will be found in the person of Mr. G. D. Beggs, the esteemed Vice-President of the Society, and should that gentleman consent to act, the duties of the onerous position will be in extremely able hands.

FOREIGN NEWS.

BRITISH CHAMBER OF COMMERCE OF PARIS.—An arrangement has at last been arrived at between the English and French Governments, under which no charge will be made from the 1st January, 1900, for consular visa to certificates of origin. This reform, which the British Chamber of Commerce of Paris has for a long time been endeavouring to obtain, and has finally been instrumental in securing, means a saving of six francs to British firms for every certificate of origin which they take out for France, and as in practice certificates are taken out for almost every invoice, the benefit secured for British firms is a very substantial one.

MICROBES AND THE TELEPHONE.—The Under-Secretary of State for Posts and Telegraphs, Paris, having received numerous complaints of the fear of infection by the use of the public telephones, instructed Drs. Roux, Grencher, Nocard and Marc Sée to institute an inquiry. The result of the inquiry shows that the complaints are well-founded. The report states that "considering that as far as those telephoning are concerned, microbes may be thrown on the vibrating plate by the saliva of the person who is speaking, and that, in an extreme case, those may be diffused as dust, under those circumstances the whole box becomes contaminated, yet the usual precautionary measures are sufficient. So far as the receivers of telephonic messages are concerned, the transmission of diseases is considered to be highly improbable. In any event, the ordinary precautions are considered to be enough to avoid it."

FATAL MISTAKE IN READING A PRESCRIPTION.—A very interesting poisoning case, resulting from a husband's misinterpretation of a doctor's prescription for his wife, is just now being investigated by the Paris police. According to details gleaned, it appears that a Madame X, of the Rue d'Amsterdam, was suffering from a serious stomach complaint, respecting which she called in a medical man, who, after a consultation, gave the following prescription: "Purgatif—Gouttes amères de Baumé, 30 gr." Monsieur X had his prescription for the drops dispensed at a pharmacy near the Gare St. Lazare, and gave the whole 30 grammes to his wife as a purge. Madame X died almost immediately after taking the dose. The "Gouttes amères de Baumé" is a French Codex preparation made by macerating 500 grammes of St. Ignatia bean in 1,000 grammes of alcohol at 60°, hence the dose swallowed contained a large quantity of strychnine. The doctor contends in his defence that the dash between the words "purgatif" and the words "Gouttes amères de Baumé" indicated plainly that a purge was to be taken, and afterwards, a dose of the drops. No dose, however, was indicated upon the prescription. That given in the Codex is "from 1 to 8 drops." The chemist declares he dispensed the prescription not as a purge, but to be given by drops. The husband contends that it ought to have been specified on the prescription at what dose, and under what conditions the "drops" should have been taken. The question as to whom shall be held responsible for the death of Madame X has not yet been solved. Clearly upon the face of the matter the doctor is guilty of the grossest carelessness for not at least "specifying" a purgative, for had he done so no such misinterpretation would have been likely to occur.

THE LATE DR. EVANS' MS.—Monsieur Symonds, a Paris bookseller, has been sentenced in default by the Eleventh Chamber of the Correctional Court, on the charge of "abus de confiance" for refusing to restore to the heirs of the late Dr. Evans the manuscript of the latter's book, "The Fall of the Second French Empire." The sentence is eight days' imprisonment, 100 francs fine and 500 francs damages. The late Dr. Thomas Evans, formerly a dentist of much repute practising in the Rue de la Paix, Paris, made a great name for himself during the Commune. It was he who

succeeded in getting the Empress Eugénie safely away in his carriage from the Tuileries, finally conducting her to England. He was mixed up in all the political and court intrigues during the Second Empire, and his book, of which only a limited number was printed, deals chiefly with the events in which he played a prominent part himself.

USES OF TOBACCO JUICE.—“Tobacco juice, rich in nicotine, and warranted,” is kept for sale at nearly all tobacconists in France. It is tested by the Government, and contains from 5 to 6 times the proportion of nicotine found in ordinary tobacco juice. For spraying plants it is mixed with 100 parts of water. The spraying is done after sunset, and the plants are sprinkled the next day with fresh water. As a lotion to kill parasites on cattle it is mixed with 20 parts of water, and applied gradually to parts of the skin, avoiding sores. The above mixtures are improved by adding $3\frac{1}{2}$ oz. of soda crystals to every $1\frac{3}{4}$ pints of diluted juice. “Le Noir,” a sooty parasite of the orange, lemon, olive, and other trees of the Mediterranean, as well as potatoes, beans, peas, tomatoes and other vegetables, is killed by the juice.

MANUFACTURE OF ARTIFICIAL SPONGES.—The process, patented by Dr. Gustav Pum, of Graz, Germany, consists principally in the action of zinc chloride solution on pure cellulose. The results are amyloid and hydrocellulose, which swell up with water but turn horny and hard on drying. In order to retain for the product the property of also absorbing water after drying, alkali-haloids are employed in treating the cellulose with zinc chloride, and finally the product is subjected to a mechanico-plastic treatment. Thus, for example, 2,000 grammes of concentrated zinc chloride solution and 2,000 grammes of sodium chloride are used for 100 grammes of cellulose, whereby a pasty, viscous mass is obtained, which is mixed with about one kilogramme of coarse rock salt. The plastic mass thus obtained is pierced in a press mould with pins, after whose removal the pressed material appears traversed by small canals in all directions. The excess of salts is removed by washing for one or two days with alcohol and water. The product thus obtained can take the place of natural sponge in all its uses, and may especially serve for filtering water for sanitary and industrial purposes. It is also suitable for filling up life-preservers, and for the production of anchor-buoys, as well as in surgery for absorbing secretions, or in pharmacy for clearing mixtures and thus replacing cotton wool.

SENSATIONS OF PRUSSIC ACID POISONING.—A French journal of pharmacy reports that Professor Willis G. Jackson, of the Maryland Agricultural Experiment Station, proposes the use of hydrocyanic acid gas as a lethal agent to be used for capital punishment in the place of hanging or electrocution. It is not a novel idea, but he describes his own experience of the poison. He felt a pleasant drowsiness, relaxed muscles, and a feeling of indifference as to what happened. There was no pain, and his sensation was rather soothing than disagreeable. On the other hand, Mr. E. Murray-Aaron, who came near death through inhaling the hydrocyanic fumes from an insecticide jar, and was restored to life with difficulty, states that he felt “intense intercostal agony, unthinkable mental distress, and a horrible consciousness of all that was going on, without the power to give any sign of life.”

SERUM CURE FOR ALCOHOLISM.—The discovery of a new serum, injection of which is said to give the patient disgust for alcohol has been reported to the Académie de Médecine, by Drs. Sappelier and Thiébault, in conjunction with Monsieur Broca, a chemist of the Rue Saint Denis. This matter is creating a considerable sensation in Paris. Briefly, the curative serum is extracted from the blood of a horse which has previously been alcoholised. Injections of this serum will give an alcohol-maniac an absolute disgust and

repugnance for alcoholic liquors. Dr. Thiébault, when interviewed by our correspondent at Paris, remarked “That the matter cannot be discussed at present. It is like a legal case, *sub judice*, for that is how the present position of the discovery may be now properly described. Our discovery is in the hands of Messrs. Lancedreaux, Mottet, and Laborde, the Committee of the Academy, who will, in time, draw up their report. But, naturally, time must be allowed the Committee for making the necessary experiments, and establishing our claim. Understand clearly what our cure really is. To suppose that we can take a man in the last stages of alcoholism, who is actually tottering into a drunkard’s grave, and raise him to life, is absurd. On the other hand, what we can do is this: We can cure alcoholomania if there be no organic lesions. Be careful to distinguish between dipsomania and alcohol-mania. A dipsomaniac may find in turpentine, for instance, something to satisfy his dreadful craving; it is certainly depraved taste, but many a chemist knows that methylated spirit and bay rum and Florida water have been consumed by the tippler—more rightly called a ‘dipsomaniac.’ An alcohol-maniac, however, only has the appetite for alcohol, as the word implies. Now our cure is applicable to those who are addicted to the abuse of alcohol under the conditions already laid down—that is to say, if the patient’s liver and other organs be not destroyed by drink. At present, the question, so far as we are concerned, is purely and absolutely scientific, and all interviews must be declined until the Academy has pronounced upon it.” “But suppose the Académie de Médecine decides adversely, will that be final for you and your collaborators?” Dr. Thiébault shook his head, and said: “Ah, in that case (which is not likely) then there is another court of appeal, but we shall not talk about that just yet. We know what we are capable of, and actions speak louder than words.”

PHARMACY IN AUSTRALASIA.

(From Our Melbourne Correspondent.)

THE PROPOSED RECIPROCITY CONFERENCE.—The proposal to hold a “reciprocity” conference in Melbourne during January, when the eighth annual meeting of the Australasian Association for the Advancement of Science takes place, has led to some interesting correspondence between several of the Pharmacy Boards interested. At the November meeting of the Victorian Board, for instance, a letter was received from that of New South Wales, intimating that before joining in the movement they would be glad to come to an understanding in reference to the recognition of the different existing Registers of Pharmacists, and submitting the following questions for consideration:—(1) Will the Pharmacy Board of Victoria register all those persons who hold, or are entitled to hold, the New South Wales certificate of registration as pharmacists under Sections A, B, C, D, E, and F of clause 11 of the Pharmacy Act 1897, on their coming to live in the colony? No registrations have been made under Sections E and G of the said Act. (2) If the Board is not prepared to register all the above-mentioned persons, kindly state, which of the certificates of New South Wales you are prepared to accept, pointing out the sections of clause 11 to which you agree. (3) If the Board should object to some of the sections of clause 11, will the Board be good enough to say under which conditions the Board would be prepared to accept these persons? Would it, for instance, accept pharmacists under Sections A, B, C and D if they have passed a pharmaceutical examination of a modified nature, such, for instance, as adopted by the Pharmaceutical Society of New South Wales, which is a copy of the modified examination provided by the Victorian Board? The subject was not definitely disposed of at the meeting in question, pending a reply to a communication addressed to the N.S.W. Board, requesting information as to how that body would be enabled to impose a

modified examination, as there was no provision for doing so in the present N.S.W. Pharmacy Act. So the matter stands at present between the two leading colonies.

A SIMILAR COMMUNICATION to the foregoing, from New South Wales, was under consideration at the November meeting of the Pharmacy Board of South Australia, when the following opinion was arrived at:—(1) That it would be inadvisable to recognise all registrations under the New South Wales Act. (2) That sections other than D were agreeable. (3) That a modified examination added to a D qualification would meet the objection to this. So far, therefore, South Australia seems prepared to accept what New South Wales appears willing to give—a modified examination added to certain qualifications. Western Australia has also replied in similar strain. It remains to be seen how it is proposed to get over the difficulty, attention to which has been directed by the Victorian Board. Tasmania has definitely announced that examination is the only basis it will agree to, but should an agreement be arrived at among the others it would no doubt be induced to come in.

THE WEST AUSTRALIAN PHARMACY BILL.—From the Federal point of view the Pharmacy and Poisons Amendment Bill which has just passed through the West Australian Assembly is fairly satisfactory, as among other things it provides for the recognition of apprenticeship and examinations passed in other colonies. The principal alterations introduced are as follows:—Poisons licences may be issued to persons distant five miles from the nearest pharmacy (the present Act prescribes twenty miles as the limit); the word "poisons" in section 29 (b)—which prescribes that the name, etc., of purchaser of poisons, etc., shall be entered and signed for—is now to apply only to poisons specified in Part I. of the new schedule; and the Act also restricts the application of the section 30 of the Act (providing that no person shall sell any poison ordered by letter, etc., to any person with whose signature he is unacquainted, unless such signature has been witnessed by a Justice of the Peace, legal practitioner, or notary public, or is otherwise authenticated by some person known to the vendor). Section 31 (No person shall sell any poison unless the bottle, etc., containing the same bears the word "poison," together with name of article and name and address of vendor) is now to be supplemented with the words: "Together with the address of the shop or premises from which the poison was obtained." The Act also amends section 36 (Exemptions) by extending the exemption of the Act to "the sale for mining purposes of cyanide of potassium, strong mineral acids or other metallurgical chemicals required in the mining industry." The fifth schedule has now been repealed, and a new one substituted, the effect being that the poisons now constituting the fifth schedule are to form Part I. of the new schedule, and Part II. gives an additional list of poisons. The new sections are mandatory that the business of a pharmaceutical chemist must be carried on by the principal or qualified assistant; and that chemist must have his name legibly painted on the front of his business premises; every person licensed to sell poisons must produce his sales of poisons record book to the Council or Registrar or person authorised in writing by the President or Registrar whenever required; in any prosecution under section 38 of principal Act the fact that any person is apparently employed in any drug shop or acts in the capacity of salesman, shall be *prima facie* proof that such person carries on business as a pharmaceutical chemist in such premises.

BEFORE THE BILL EMERGED from the Committee stage a final clause was adopted as follows:—"Nothing in this Act contained or in the principal Act shall prevent any person carrying on the business or occupation of a pharmaceutical chemist in Western

Australia, who at the passing of this Act is possessed of any qualification legally recognised in any of the Australasian colonies, and who has been a resident in Western Australia for a period of three months immediately preceding the passing of this Act, and is engaged as manager, managing owner, or assistant in the business of a pharmaceutical chemist or company registered in accordance with the provisions of the principal Act, keeping open shop in the colony of Western Australia, and such manager or assistant being at the time of the passing of this Act engaged in the dispensing of prescriptions of legally qualified medical practitioners: Provided that such person shall apply to be registered under the provisions of this Act within three months after the passing thereof; and if such person shall not so apply he shall be excluded from the provisions of this section."

THE FOLLOWING IS THE POISON SCHEDULE AS FINALLY ADOPTED:—

PART I.	
Aconite	Digitalis and its preparations
Arsenic and its preparations	Ergot of Rye and its preparations
Arsenical preparations, except green and other paints and pigments	Essential Oil of Almonds, unless deprived of its prussic acid
All poisonous vegetable Alkaloids, and their salts	Iodine
Belladonna and its preparations	Laudanum
Cannabis Indicus (hemp)	Nux Vomica, bean or powder
Cantharides	Opium and all preparations of opium or poppies
Chloral Hydrate	Phosphorus
Chloroform	Prussic Acid and its preparations
Cocaine and its preparations	"Rough on Rats"
Conium and its preparations	Savin and its oil
Corrosive Sublimate	Strychnine and its preparations
Croton Oil	Tartar Emetic
Cyanides of Potassium and all metallic cyanides	
PART II.	
Butyr of Antimony	Oxalic Acid
Carbolic Acid	Patent and Proprietary Medicines containing any poison mentioned in Part I. of this Schedule
Chlorodyne and Soothing Syrups and Powders	Red Precipitate
Colocynth Pulp	Strong Mineral Acids
Ether	Sugar of Lead
Iodoform	White Precipitate
Mercury Subchloride	

THE NEW ZEALAND PHARMACY BILL.—The "Act to amend the Pharmacy Act, 1898," has just passed through the New Zealand Legislature. It is equally short and (from a Federal point of view) unsatisfactory, as witness the text:—"An Act to amend the Pharmacy Act, 1898. Be it enacted by the General Assembly of New Zealand in Parliament assembled, and by the authority of the same, as follows:—1. The short title of this Act is 'The Pharmacy Act Amendment Act, 1899.' 2. The provisions of sub-section 5 of section 27 of 'The Pharmacy Act, 1898' (entitling certain persons to be registered as pharmaceutical chemists without examination) shall apply only in cases where the person claiming to be entitled to be registered under that sub-section was, as owner or manager, keeping open a shop in New Zealand as a dispensing or homœopathic chemist at the time of the coming into operation of that Act." As the *Australian Journal of Pharmacy* inferentially remarks, this practically puts all the other colonies in quarantine, so far as New Zealand is concerned.

A "WESTERN AUSTRALIAN DENTISTS ACT AMENDMENT BILL" has just been passed through the Legislative Assembly of the Colony indicated. It was introduced on the suggestion of the Dental Board (of W.A.), and reduces the period for which a student has to practice dentistry before being registered from seven to four years. It also provides an annual registration fee of £2 2s., and that appeals against the findings of the Dental Board should be direct to the Supreme Court, instead of to the Minister, in the first case.

THE STUDENTS' COLUMNS.

THE MATERIA MEDICA OF THE PHARMACOPŒIA.

INTRODUCTORY.

The following notes are intended to serve the same purpose in connection with the vegetable and animal materia medica of the British Pharmacopœia, 1898, as the recently concluded series of notes in the Students' Columns have served in connection with the chemistry and pharmacy of that work. The object kept in view in compiling the notes has been the full explanation of what is not self-explanatory in the official monographs, and yet appears capable of explanation. Naturally a large number of sources of information have been drawn upon, including Squire's 'Companion to the British Pharmacopœia,' Hanbury and Flückiger's 'Pharmacographia,' Greenish's 'Materia Medica,' Ransom's 'Medicinal Plant Names,' and others, too numerous to mention. As in the case of the former series, any comments or suggestions will be gladly received by the Editor.

Acaciæ Gummi.

GUM ACACIA is a dried exudation from the stem and branches of various species of *Acacia* (N.O. Leguminosæ). The chief source of the gum is *Acacia senegal*, Willdenow [Bentley and Trimen, 'Medicinal Plants,' vol. 2, plate 94], a tree which grows freely in various parts of Africa. The point is hardly settled yet, but the gum appears to be produced in the cells of the cortex and pericycle, as a result of transformation of the cell-wall. In most cases it exudes spontaneously, but its formation can be promoted by incision. After collection—chiefly in Eastern and Western Africa—the gum is exported by way of the Nile valley and Alexandria (Kordofan gum), or from St. Louis, Senegambia. The gums known in commerce as "Turkey sorts" and "Trieste picked," which are brought from the Soudan by way of Suakin, are as suitable as any for pharmaceutical purposes. Gum acacia is used medicinally as a demulcent and as an emulsifying agent for oils, resins, etc. The official preparations in which it is used are—Mucilago acaciæ, pilula ferri composita, pulvis amygdalæ compositus, pulvis tragacanthæ compositus, and all the trochisci.

CHARACTERS AND TESTS.—The gum occurs in rounded or ovoid, opaque, white or yellowish tears or masses, the largest of which about equal a hazel nut in size. The opacity of the tears is due to numerous minute external fissures. They are also very brittle, and the fragments of broken tears, which are more or less angular and quite transparent, show glistening vitreous surfaces. The gum has a very faint odour, and a bland, mucilaginous taste. It is insoluble, or only slightly soluble, in alcohol and other liquids than water, unless there is a considerable quantity of water present. Thus, it is quite insoluble in 90 per cent. alcohol, and 60 per cent. alcohol only extracts from it certain of its constituents, but weaker alcohols dissolve the gum in proportion to the quantity of water they contain, 100 parts of 22 per cent. alcohol dissolving as much as 57 parts of gum. In water alone, however, gum acacia should dissolve entirely (1 in 1), forming a translucent viscid mucilage, which feebly reddens litmus, owing to the excess of acid present in the gum. If the mucilage is glairy or ropy, or yields a gelatinous deposit after dilution with water, an inferior gum—probably derived from other African or Australian species of *Acacia*, or an Indian gum—has been used to prepare it. By forming a copious gelatinous precipi-

tate with basic lead acetate, but not with the normal acetate, gum acacia is distinguished from many other varieties of gum or mucilage; Ghatti gum, obtained from *Anogeissus, latifolia*, Wall. (N.O. Combretaceæ), yields only a slight precipitate with lead subacetate. Another distinguishing feature of gum acacia is that mucilage prepared from it yields a gelatinous precipitate and forms a translucent white jelly, on the addition of a concentrated solution of borax. An artificial gum has been prepared from commercial dextrin, and powdered gum may be adulterated with starch or flour, both of which can be detected by means of solution of iodine, which colours starch blue in the presence of water. The "dextrin" of commerce is a mixture of uncertain composition. It may contain unaltered starch and be coloured by iodine accordingly, but it also consists largely of erythro-dextrin which gives a reddish-brown colour with iodine, unless the reaction is obscured by the blue colour produced by a considerable proportion of soluble starch. Tannin is present in inferior gums—such as those from Australian species of *Acacia*—and can be detected by the bluish-black coloration produced on adding ferric chloride. Dextrin and certain sugars, which may be found in artificial and powdered gums, reduce Fehling's solution of potassio-cupric tartrate.

NOTES.—The distinctive characters of gum acacia are the numerous minute external fissures, which cause the opaque appearance of the tears, the vitreous appearance of fractured surfaces, the ready solubility of the gum in water, and the adhesiveness of aqueous solutions. The word "acacia" (Gr. *ἀκασία*, from *ἀκμή*, a point or thorn) was probably originally used to designate some thorny shrub, belonging to the N.O. Leguminosæ (L. *legumen*, pulse). The Latin word "gummi" is an indeclinable noun, derived from the Greek *κρόμμυ*. Senegal is a French colony in western tropical Africa, where gum acacia has long been collected for exportation. The specific gravity of gum acacia is about 1.5. The gum consists chiefly of arabic acid, $C_{12}H_{22}O_{11}$, combined with calcium, magnesium, and potassium, and it may be regarded as being essentially an acid calcium salt of arabic acid. It contains from 12 to 17 per cent. of moisture and a trace of sugar, and yields from 2.7 to 4 per cent. of ash. Arabic acid, which is probably not the only acid present in gum acacia, swells in water when pure, but does not dissolve unless an alkali be added; it is converted into sugar—arabinose and galactose—on boiling with dilute mineral acids. Added starch, dextrin, tannin, and sugar should be looked for more particularly in powdered gum. In applying the iodine test, care should be taken that the liquids are cold, as the blue colour with starch and the brown with dextrin are not formed in hot solutions. Sugars used as adulterants can be extracted by alcohol, and tested separately. In using powdered gum acacia for preparing emulsions of fixed oils, a very fine powder is preferable if the oil is to be added direct to the dry gum, but a somewhat coarse powder is better for making fresh mucilage immediately prior to adding the oil.

Aconiti Radix.

ACONITE ROOT should be obtained from plants of *Aconitum napellus*, Linn. (N.O., Ranunculaceæ), which have been cultivated in Britain, the object of that limitation being to insure that the root shall always be grown under uniform conditions. As a further precaution against variation in the strength of the drug, it must be collected in the autumn, preferably in October, when the root attains perfection. After collection, the roots are washed, freed from rootlets, and carefully dried, either entire or sliced longitudinally so as to facilitate driving off moisture. Preparations of aconite relieve acute pain when applied externally, and, administered internally, lessen the frequency and tension of the pulse, produce a steady fall of temperature, and cause moistening of the skin and lowering of the

sensibility to pain. The liniment and tincture are the only official preparations, but the alkaloid aconitine is also official.

ACONITI RADIX.—A. Old root with remains of stem, and B new root with leaf bud, both natural size. C. Transverse section, slightly magnified.

CHARACTERS.—The shape of aconite root is that of an elongated cone, measuring from 5 to 10 Cm. in length, and from 12 to 18 Mm. in diameter at the upper extremity, whence it tapers very gradually downwards. Externally, the root is dark brown in colour, usually wrinkled longitudinally, and marked with the scars and bases of broken-off rootlets; it should also be crowned with the scales of an undeveloped leaf-bud. The root breaks with a short fracture, and appears white or greyish-white internally, as it consists mainly of uniform parenchymatous cells loaded with starch granules. If hollow or spongy, the root has been collected after its reserve material has been exhausted by the development of the flowering stem. The retention of any portions of stem also indicates that the root has not been collected at the proper season, since the old stem must have died down and entirely disappeared by the time the new root attains its maximum development—being then plump and full of starch—and the new stem should not have begun to develop. When the plant is in flower the new root is formed, but only half-grown. If the root be transversely cut and the fresh surface examined with a lens, the stellate pith is seen to consist of a large-celled polyhedral parenchyma, containing an abundance of starch grains; it is divided from the thick parenchymatous cortex by a narrow irregular line—the cambial zone—which gives it the appearance of a star with five to seven rays, and at each angle of the figure thus formed occurs a small vascular bundle. No trace of cuticle is found except at the tips and adjoining parts of the roots; elsewhere it is replaced by brown parenchymatous cells which have formed part of the primary cortex. The fresh root has only a very faint odour, which is neither pungent nor radish-like as has been stated, though there is the faintest possible momentary irritation when the root is first smelled. The taste is at first slight, but a persistent sensation of tingling and numbness soon manifests itself in the mouth, the effect being due to aconitine, the extremely poisonous active principle of the drug.

NOTES.—The distinctive characters of aconite root are its elongated conical shape, starchy interior, stellate cambium, and the persistent tingling produced on tasting it. The name *Aconitum* (Gr. ἀκόνιτον) is probably derived from ἀκων, a dart, or from Acone, a town of Bithynia, in the vicinity of which aconite plants were abundant; *napellus* is the diminutive of the Latin *napus*, a turnip, a fancied resemblance to the shape of that root having been seen in aconite. The natural order Ranunculaceæ derives its name from the Latin *ranula*, the diminutive of *rana*, a frog. The common English name of the aconite plant—monkshood—has reference to the hooded calyx of the flower. The fresh leaves and flowering tops of aconite were formerly used in medicine, but the dried root alone is now official. The quantity of aconitine in the root

is supposed to be greatest in the autumn, but that point has not yet been definitely established by analysis; no satisfactory method of assay is as yet available, and, on account of the extremely poisonous nature of the drug, it is necessary that the potency of its preparations should be regulated as far as possible by growing and collecting the root under uniform conditions. The official description excludes German and Japanese aconite roots, and English roots which are not fully matured, though the supply of aconite root which will meet the official requirements is as yet not sufficiently regular to meet the demand.

Aconitina.

ACONITINE or acetyl-benzaconine is the chief alkaloid found in aconite root, and the only one which has been obtained in crystalline form. The crystals are colourless hexagonal prisms of the rhombic system. Crystals belonging to that system have three axes of unequal length at right angles to each other, as in the case of potassium bicarbonate, chromate and sulphate. The alkaloid has the formula $C_{33}H_{45}NO_{12}$ (eq. 642·53) and is intensely poisonous, its extreme toxic power being attributed to the presence of the acetyl radical in its molecule. Aconitine is chiefly used, in the form of ointment, to relieve acute nervous pain. The only official preparation of aconitine is unguentum aconitinæ.

CHARACTERS AND TESTS.—Pure aconitine should have a melting power of 189° to 190° C.; if heated above that temperature it is decomposed, acetic acid being given off and picroaconitine (benzaconine) left. It is soluble in 35 parts of 90 per cent. alcohol, 1 part of chloroform, or 45 parts of ether, but is almost insoluble in water or in petroleum spirit. An alcoholic solution of the alkaloid turns the plane of a ray of polarised light to the right, whereas the salts of aconitine turn a similar ray to the left. The persistent tingling sensation characteristic of aconite root is perceived when a single drop of a solution containing not more than 0·1 per cent. of aconitine is placed on the tongue. Like the base itself, the salts of aconitine are crystalline: the hydrochloride melts at 149° C., and the hydrobromide at 164° C. An aqueous solution of aconitine, containing as little as 1 part in 4,000, and faintly acidulated with acetic acid, should yield a red or purple crystalline precipitate, consisting of a sparingly soluble permanganate of the alkaloid, on adding a few drops of potassium permanganate solution. The reagent must be in very slight excess. The precipitate is readily distinguished from the similar ones given by cocaine, hydrastine, and papaverine, as cocaine and hydrastine permanganates are very readily dissolved by water, and hydrastine and papaverine permanganates are not crystalline. Again, aconitine permanganate is not changed by the addition of a drop of bromine water to the mixture, whilst the cocaine salt turns a deep orange and that of hydrastine a bright yellow.

NOTES.—The quantity of crystallised aconitine yielded by aconite root is about 0·03 per cent., and the total yield of alkaloids about 0·07 per cent. In addition to aconitine, two other alkaloids—picroaconitine (benzaconine) and aconine—occur in aconite root; they are amorphous, non-poisonous, and have a bitter taste. When hydrolysed aconitine yields acetic acid and picroaconitine, and the latter in turn yields benzoic acid and aconine. Pseudoaconitine is a poisonous crystalline alkaloid (m.p. 201° C.), obtained from *Aconitum ferox*. Like aconitine, it is readily soluble in alcohol and chloroform, less readily in ether, and only slightly soluble in water. It can be distinguished from aconitine by the beautiful purple-red colour produced on adding a solution of potassium hydroxide in absolute alcohol to the yellow residue left on moistening a small quantity of the alkaloid with fuming nitric acid and heating to dryness. Aqueous or alcoholic solutions of aconitine tend to decompose unless slightly acidified with hydrochloric acid, and solutions of the more stable crystallised aconitine nitrate are to be preferred. There is no official dose, but Squire gives the maximum single dose as 0·1 Mgm., or 0·5 Mgm. daily.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

ACTIVE PRINCIPLE OF CAYENNE.

The assertion of K. Micko that the acrid taste of *Capsicum annuum* (paprika) is due to capsaicin, has been disputed by Morbitz, who gave to the crystalline body which he separated the name "capsacutin" and described it as having a vanilla-like odour. Micko has again investigated this body, and reasserts that capsaicin is the active principle both of cayenne and of paprika, and that in the pure condition it is odourless, the vanilla odour being due to decomposition with reagents. He states that cayenne pepper contains twenty times as much capsaicin as paprika. The formula of capsaicin is $C_{18}H_{28}NO_3$.—*Pharm. Centralh.*, **40**, 672; after *Zeits. f. Unters. der Nahr. und Genussmittel*.

A NEW INDICATOR.

Reigler describes a brown diazo-compound which gives, with alkali, a beautiful red colour, and with acids, a yellowish green. The body is prepared in the following manner: Guaiacol, 1 Gm., is dissolved in water, 50 C.c.; 10 per cent. caustic soda solution 30 C.c., and mixed with a solution of diazo-paranitraniline obtained thus: paranitraniline, 1.25 Gm., is dissolved by agitation and heat with 4 C.c. of concentrated hydrochloric acid, and 50 C.c. of water; after cooling a solution of sodium nitrite 0.5 Gm. in water 30 C.c. is added. By mixing this solution with the alkaline guaiacol solution, a red fluid is obtained; on gradually acidulating with concentrated sulphuric acid, the colouring matter is thrown down; this is collected, washed free from acid, and dried. For the indicator 0.2 Gm. are dissolved in 100 C.c. of alcohol.—*Pharm. Centralh.*, **40**, 630, after *Bull. Soc. de Science din Bucuresci*.

SYMBIOSIS AND SAPROPHYTISM.

Professor D. T. MacDougal proposes to limit the term saprophyte to those species of plants which derive their supply of food directly from organic products without the intervention of the activity of chlorophyll, and unaided by other organisms. Thus limited, holosaprophytes include numerous fungi and bacteria, but, as far as is at present known, only a single flowering plant, *Wulfschlagelia aphylla*, belonging to the Orchidæ. All species furnished with mycorrhiza or tubercles, or which enter into direct mechanical or nutritive associations, must be classed as "symbionts" or "symbiotic saprophytes." Two types of endotropic mycorrhiza may be distinguished; one adapted for the fixation of nitrogen, the other for the absorption and modification—perhaps the oxidation—of the products of the soil before liberation in the tissues of the higher plants.—*Bull. Torrey Bot. Club*, p. 511.

CYANOFORM AND NITROFORM.

The cyano- and nitro-compounds corresponding to bromoform, chloroform, and iodoform are highly interesting bodies which have been investigated by Hantzsch, Ostwald, and Rinckenberger. Cyanoforn, $H\cdot C(CN)_3$, prepared from the di-sodium salt of methylene cyanide, by acidification and treatment with ether, is, like nitroform, a very powerful monobasic acid. It is only stable in the pure state, or in a solvent free from water, as it polymerises very readily. In watery solutions, and in salts, this acid exists only as isocyanoforn. Nitroform, $H\cdot C(NO_2)_3$, is obtained through treatment of potassium nitroform with strong sulphuric acid, as a colourless mass, melting at $15^\circ C$. The watery solution of this, as well as its salts, is coloured a deep yellow, owing to the formation of iso-compounds.—*Berichte*, **32**, 628.

VOL. 64. (FOURTH SERIES, VOL. 10.). No. 1542.

MERCUROUS IODIDE.

Dr. P. C. Rây states that when the residue in the flask after the interaction of mercurous nitrite and ethyl iodide is heated in a tube, mercurous iodide sublimes off between 190° and 210° . The compact mass of crystalline tablets thus obtained shows all gradations of tint from lemon and orange-yellow to dark brown.—*Proc. Chem. Soc.*, **15**, 239.

ABSORPTION OF NITROGEN BY THE LEGUMINOSÆ.

J. Lutowslawski has determined that, in the case of peas and lupins, an increase in the amount of nitrogen commences with the beginning of the independent growth of the plant; that is, soon after the close of the period of germination, and in all cases before the commencement of the formation of the inflorescence. The maximum amount of nitrogen occurs after flowering, when the pods are beginning to be formed; after which a gradual decrease takes place. The time, therefore, for using leguminous crops as manure, in order to increase the fertility of the soil, is at the commencement of the development of the pods.—*Beiheft zum Bot. Centralbl.*, **9**, 1899, p. 72.

COLOURS OF FLOWERS.

In *Nature* for November 30, 1899, P. Q. Keegan describes a series of experiments with the object of deciding between the view of Berzelius that the original colour of anthocyan is red, and that of Wiesner that it is blue. His conclusion is, on the whole, favourable to the former hypothesis; but he believes that there are different stages in the development of the floral pigment. In the lower stages the natural colour is red, whatever the chromogen may be; while in the higher stages the natural colour of anthocyan is blue; or rather, at least with some chromogens, it becomes capable of forming blue compounds with alkalies and certain metallic acids. There also exist chromogens which, except under very exceptional conditions, are incapable of producing a blue pigment. These, in all stages, naturally develop into a red, the brilliancy of which unquestionably attests its real, original and proper character.

ACTION OF LIGHT ON THE STEM AND LEAVES.

From a series of experiments made on different plants, E. C. Teodoresco finds that if a plant is grown so that the lower leafy part of the stem is exposed to light, while the terminal bud is in the dark, the results, as regards the development of the vegetative parts, are intermediate between plants grown completely in the light and those grown completely in the dark. In a plant thus partially illuminated, the development of the conducting tissue and the lignification of the walls of the mechanical tissue approach more nearly to those in a plant grown entirely in the dark. In a plant entirely deprived of light, starch is altogether wanting in the tissues of the stem; while in one partially illuminated it is present, though in smaller quantities than in a plant grown entirely in the light. The carbohydrates elaborated in the leaves exposed to light may accumulate in the parts of the plants which are not directly exposed to light.—*Bonnier's Rev. Gén. de Botanique*, 1899, vol. xi.

ABSORPTION OF IODINE BY PLANTS.

As the result of a series of experiments on different plants, M. P. Bourcel states that they vary greatly in their power of absorbing iodine from a soil containing a given quantity of that element, some species refusing it altogether. A difference is even exhibited in this respect between different species of the same genus; but some natural orders appear to possess the property in a greater degree than others. The Liliaceæ and the Chenopodiaceæ display this faculty to a much greater extent than the Solanaceæ and the Umbellifereæ.—*Comptes rendus*, **129**, 1899, p. 768.

**QUANTITATIVE DETERMINATION OF ALKALOIDS
IN LEAVES OF DATURA STRAMONIUM, HYOSCYAMUS
NIGER, AND ATROPA BELLADONNA.**

BY PROFESSOR ERNST SCHMIDT.

In the last number of the *Apotheker Zeitung*, the author publishes details of a method which he recommends as applicable to drugs containing considerable amounts of chlorophyll, and yielding to chloroform deep green coloured extracts. It is a modification of Keller's method, and from the experience gained in making numerous examinations of stramonium, hyoscyamus, and belladonna leaves during recent years, it has been found that results can be obtained as exact and accordant with each other as in the case of drugs free from chlorophyll. Even in the hands of inexperienced operators the method can be relied upon as easily carried out and trustworthy when iodeosin is used as an indicator in the manner described.

The finely-powdered drug (10 grammes) is first dried until constant over caustic lime, mixed in a flask with 90 grammes ether, and 30 grammes chloroform, well shaken together, and 10 C.c. of 10 per cent. caustic soda liquor added, while the shaking is continued. The mixture is then left at rest for three hours, and at the end of that time water is added, 10 C.c., or enough to make the powder aggregate together, when the mixture is well shaken, leaving the ether-chloroform solution separated clear on the surface. After being at rest for an hour, 60 grammes of the clear solution, representing five grammes of leaves, is passed through a filter into a flask, and distilled to one-half to separate ammonia. Further distillation must be avoided, as it would be attended with formation of hydrochloride in consequence of reaction with chloroform.

The dark green coloured liquid is then transferred to a separator, the flask washed three times with 5 C.c. of ether, and the whole well shaken with 10 C.c. of 1/100 normal hydrochloric acid. After complete clarification of the liquid, and, if necessary, addition of enough ether to make the ether solution float, the acid liquor is passed through a small wetted filter into a flask of about 200 C.c. capacity. The ether-chloroform solution is shaken out three times, with about 10 C.c. of water, and each portion, after becoming clear, is passed through the same small filter, which is finally washed with water until the whole quantity of liquid measures about 100 C.c. Ether is then added, sufficient to give a layer of about 1 Cm., with 5 drops of iodeosin solution (1 in 500 alcohol), and 1/100 normal potash solution is gradually run in, with vigorous shaking after each addition, until the aqueous liquor acquires a pale red colour.

In the titrating back of the uncombined 1/100 normal hydrochloric acid, it is advisable to add only one C.c. of 1/100 potash solution at a time, and to shake well after each addition until the aqueous liquor begins to appear faintly but distinctly red when observed on a white background, while the ether layer is, if necessary, covered with a piece of black paper. Then 1 C.c. of 1/100 normal hydrochloric acid should be added, and, after the whole has been well shaken, the colour should entirely disappear, and the operation is to be completed by adding 1/100 normal potash solution in successive quantities of 0.1 C.c. until the aqueous liquor acquires a faint red colour.

Deducting the measure of 1/100 normal potash solution from 11 (the number of C.c. 1/100 normal hydrochloric acid), the remainder represents the quantity of 1/100 normal hydrochloric acid requisite for neutralising the alkaloid of 5 grammes of the leaves operated upon.

To calculate from these data the quantity of atropine or hyoscyamine, 1 C.c. of 1/100 normal hydrochloric acid is taken as equivalent to 0.00289 gramme of alkaloid.

In making such determinations the 1/100 normal hydrochloric acid and potash solutions should be previously adjusted, under the same

conditions, that the determinations are made, *i.e.*, in carrying out the titration there should be 10 C.c. 1/100 normal hydrochloric acid, with 100 C.c. of water in flask of white glass, with a 1 Cm. layer of ether, and 5 drops of the iodeosin solution.

The condition of the iodeosin used as an indicator is another point of importance in regard to the accuracy of the determination. It should be a scarlet crystalline powder dissolving in alcohol with deep red colour, and in ether with a yellowish-red colour. In water, mixed with a trace of hydrochloric acid, it should be absolutely insoluble. To test the suitability of the iodeosin 5 drops of solution should be mixed in a flask with 100 C.c. of water, 1 Cm. layer of ether and one drop 1/100 normal hydrochloric acid solution, and, then, after the whole has been well shaken, the aqueous liquor should remain free from colour. On adding two drops of 1/100 normal potash solution and shaking, the aqueous liquor should have a pale red tint.

In order to save expense in carrying out such determinations, the ether-chloroform and ether solutions should be saved, and purified for further use. For that purpose, it has been the practice to shake with excess of dilute sulphuric acid and distil in a water-bath, drying the distillate with calcium chloride, and again distilling. The product thus obtained is then brought to a specific gravity of 0.850 by addition of ether or chloroform, so as to make the mixture of the proportion (1 to 3) suitable for the operation.

By means of this method the following results have been obtained:—

Belladonna leaves:—	
Whd	0.40 per cent. alkaloid.
Cultivated	0.26 per cent. "
Stramonium leaves grown in the Marburg Botanic Gardens, 0.40 per cent. alkaloid.	
Hyoscyamus leaves (Cæsar and Loretz):—	
Leaves without stalk, I.	0.2762 per cent.
" " II.	0.2861 per cent.
Leaf stalks, I.	0.363 per cent.
" " II.	0.365 per cent.

The amount of alkaloid obtained from henbane leaves and stalks is very high as compared with the results of other observers.

PRACTICAL PHARMACOGRAPHY.

COLCHICI SEMINA.

MACROSCOPIC CHARACTERS.

Syn. Meadow Saffron, Eng.; Colchique, Safran bâtard, Fr.
Herbstzeitlose, Wiesen-safran, Germ.

The seeds of *Colchicum autumnale*, Linn., are of a dark brown colour, globular, about two millimetres in diameter, and are furnished at the base with a fleshy appendage, the remains of a funiculus. The testa is minutely punctate, somewhat glutinous when fresh, but becoming powdery when kept dry for some time. The seed is closely adherent to the seed-coats, and consists of a minute embryo placed nearly opposite to the hilum and near to the circumference in a hard, horny albumen or endosperm. The seeds have no odour, but a bitter and, subsequently, an acrid taste. They are not likely to be mistaken for any other official medicinal seed. The seed of black mustard is smaller, and is much softer, being easily crushed between the teeth. It has also a pungent taste. The seed of *Amomum melagueta*, or "Grains of Paradise," or "Guinea Grains," have a soft, white, endosperm, and a very pungent biting taste, and are larger and of a paler brown colour than colchicum seeds.

MICROSCOPIC CHARACTERS.

Integuments.—Beneath a thin outer layer of narrow, tangentially extended, thin-walled cells are found two rows of large irregular thin-walled parenchyma. The innermost layer consists of two rows of closely compressed small-celled parenchyma with contents of a brown colour. The tissue of the funiculus consists of loose parenchyma and some small vascular bundles; the parenchyma contains numerous starch granules.

COLCHICI SEMEN.—Section, greatly enlarged. A. Embryo; B. Funiculus (after Berg).

Endosperm.—This consists of closely compacted radially arranged parenchyma; the cells near the centre are almost iso-diametric, but those near the periphery are most decidedly extended radially.

COLCHICI SEMEN.—Section: S. Integuments. E. Endosperm (after Vogl).

The cells are separated from each other by a very distinct middle lamella; they have very thick walls pierced by few, but large, circular perforations; they contain small aleuron grains and drops of oil.

COLCHICI SEMEN.—Powder: s. Fragments of integuments in section and in surface view. e. Fragment of endosperm tissue. e'. Fragments of endosperm cells. Between the particles of tissues are scattered globules of oil.

Embryo.—The small embryo is eccentric and in close contiguity to the integuments at the side opposite to the funiculus. It consists of cells decidedly smaller than those of the endosperm.

Distinctive Characters.—The distinct funiculus containing starch. The small eccentric embryo. The radially arranged thick-walled parenchyma of the endosperm; its middle lamella, and the large circular perforations in the cell walls; the cell contents of aleuron and oil.

DOES IT PAY THE PHARMACIST TO MAKE COMPRESSED TABLETS ? *

BY AMBROSE MUELLER, PH.G., WEBSTER GROVES, MO.

This question I shall answer affirmatively, and try to illustrate that it pays in more than one way. First, it pays to cater to the wants of physicians, and if they think that tablets are the best form in which certain remedies should be administered, it is our duty to dispense them as ordered. Again, if your physicians see that you are doing such work they will feel more confident that anything they may order will be attended to properly and promptly, and they will recommend you to their patients as a thorough pharmacist, and it will not be long until you feel the effect of such quiet recommendations.

Secondly, it pays to make them, from the same point of view that it pays to do your other pharmaceutical work, for if you want to be absolutely satisfied "that what you dispense is the article wanted" you must make it yourself, otherwise there might be a mistake, for which you are held responsible. Again, it is by keeping abreast with progress that we prevent degeneration of our calling, and if every pharmacist would make his own fluid extracts, extracts, pills, triturate and compressed tablets, etc., there would be no danger of manufacturing houses depriving us of our daily bread in supplying physicians with ready-made compounds. Stop to think—who is to blame for this state of affairs? Everyone knows it is the pharmacist himself, for if it had not been for his support such plants would not be in existence. Bear in mind, every specialty (proprietary secret remedy), that you buy means to reduce your professional profit, and every pharmaceutical preparation that you buy which you ought to make means to decapitate yourself as a professional man.

Thirdly, it pays from a commercial point of view, with compound interest. Analyse the cost of material, the very best quality, and you can save money by making up the stock that you are called on to dispense. Some few things may make it seem as though it would not justify you to do the work, but when you look deeper into the question you will agree that you are money out in buying your tablets. Again, look at the many tablets that have been put on the market, the true value of which is about ten to twenty-five cents per ounce, and the pharmacist must buy them and pay the fancy price of 1 dol. to 2 dol. per ounce. In short there is everything in favour of the pharmacist making tablets.

In conclusion, I may enumerate a few cardinal points:—

First. Study your machine so that you may become thoroughly familiar with all parts.

Second. Keep it always perfectly clean, well oiled, and the dies bright and free from rust.

Third. Have your material in finely granular form, or when the substances are very finely powdered, prepare a granulation by very slight moistening by spraying with water, alcohol, or ether, and also using such binding agents as necessary according to the nature of the material you wish to compress, and be sure always to pass it through a number twenty sieve before feeding it in the machine.

* Read before the Missouri Pharmaceutical Association. Condensed from a report in the *Western Druggist*.

FACTS AND FANCIES.

BY AN ORDINARY PHARMACIST.

Pharmacists and the Pharmacopœia.

Dr. Tirard was assuredly ill-advised to attack pharmacists as he did at the close of his third lecture on the British Pharmacopœia, but it is impossible for ordinary pharmacists not to sympathise with him to some extent. The mistake he made was, by singling out for notice a particular passage in a leading article which appeared in the *Pharmaceutical Journal*, to associate himself, apparently, with those who oppose the views supported by the article quoted from. I am quite of opinion that pharmacists possessed of any sense of self-respect should decline to assist in the work of pharmacopœia revision, "unless they are to receive full recognition as co-workers on the Pharmacopœia Committee"; on the other hand, I am firmly convinced that it is a fundamental error to permit anyone to have a hand in the work of pharmacopœia revision who is personally interested in the fixing of standards. That is to say, I would exclude all but medical practitioners and pharmacists who are normally engaged in the practice of their respective professions from any share in the actual work of compiling the British Pharmacopœia. All wholesale druggists, whatever their personal qualification, should be regarded as ineligible for the performance of such an important duty, though due consideration might be given to expressions of opinion on their part. Their trade interests, however, are too closely affected to justify the General Medical Council in allowing them to have any voice in the fixing of standards, and, to that extent, Dr. Tirard is justified in directing attention to "the risks of trade competition, of trade influence, and the constant danger of introducing a standard which might create a monopoly." But he ought to discriminate between pharmacists, actually practising as such, and mere dealers in drugs, as the former can have no personal interest in the matter beyond that of desiring the requirements of the Pharmacopœia to be of a practicable nature.

The "British Medical Journal" and Pharmacists.

How utterly mistaken the editor of the *British Medical Journal* is in assuming that the letter addressed by the President of the Pharmaceutical Society to the President of the Board of Trade "marks the final and definite abandonment of the attempt to prohibit *in toto* the practice of pharmacy by limited companies"! Equally mistaken is the conclusion that "as a necessary corollary" there is any idea of abandoning "the intention once entertained of pressing that pharmaceutical chemists should be included in the medical clause which does go this length." Why, to my mind, the "pronouncement," as the oracle of the British Medical Association terms it, is but the first step in the direction of securing recognition of the principle that, in pharmacy as in medicine, it is essential, in the public interest, that duties which require a professional qualification should be restricted absolutely to individuals who possess that qualification. There is good reason for the belief that pharmacy and medicine must hang together in this matter; if one cannot be properly protected the other must remain equally unguarded. Full recognition of that fact would probably result in a successful issue, but the position taken up by that section of the medical profession which would protect itself without the least consideration for pharmacists must be stigmatised as one of unmitigated selfishness. Which is the most just and logical claim—that companies should not be permitted to do what individuals may not, or that companies should be prohibited from doing what individuals may do? The first is what pharmacists say is fair and reasonable; the second is what the Lord Chancellor has proposed in the interests of the medical profession. At present the practice of pharmacy is legislatively protected to some extent; the practice of medicine is not protected at all. Why should pharmacists submit quietly to a process of spoliation whilst acquiescing in a strengthening of the position of those who should be their natural allies, but

who will not lift a little finger to help them in their hour of need?

Division of the Minor Examination.

It is, I think, distinctly to the credit of the *Pharmaceutical Journal* that its columns are freely open to the discussion, by members of the Pharmaceutical Society, of the most important matters in connection with the administration of the Society's affairs. Only rarely, I believe, is that privilege withheld, and then only after the most careful consideration and a proper explanation to the writer of the excluded communication. How near the limits of what is permissible in the way of criticism correspondents may go is well illustrated by Mr. Flemming's letter in last week's issue, for the writer attacked a body of men who, by reason of their position, are unable to defend themselves, and apparently he was allowed a free hand in the choice of expressions. A protest must be entered, however, against his reference to "the unfairness of our qualifying examination" and to his implied suggestion that there cannot be "any moral sense or real personal kindness about our examining board." It is my impression that the manner in which the Minor examination is conducted has always been acknowledged—by those who are in a position to judge—to render it essentially one of the fairest professional examinations conducted at the present day. We have been given to understand—by Dr. Stevenson and other responsible persons—that every allowance is made for the confusion of nervous candidates, and that, unless his knowledge of any of the subjects approaches absolute zero, no one risks a single failure, let alone repeated ones. I, for one, am prepared to accept those assurances without question. So far as the moral sense of examiners is concerned, I fail to see what that should have to do with the question of testing the fitness of candidates to practise pharmacy, whilst real personal kindness is well-known to be more strongly manifested by the Society's examiners than any words of mine can possibly convey. It must be recognised that it is often the truest kindness to reject a candidate, for his own sake quite as much as that of the public whose representatives the examiners really are. And whatever view may be held regarding the desirability of dividing the qualifying examination, nothing but harm can result from imbuing candidates with the idea that examiners are their natural enemies, anxious to reject them at all costs, and filled with a sense of savage satisfaction when they break the record by the number of men they send back to their studies. The true position of affairs is the exact opposite, and a possible defect in the system of examination should not afford ground for abusing those whose duty it is to see that the legal requirements are fulfilled.

Pharmacists as Traders.

The compound rhubarb powder case decided by Mr. Baggallay, at West Ham Police Court, last week, comes as a curious commentary on the leading article published in the *Pharmaceutical Journal* of December 30. In that article it was urged—very properly, in my opinion—that, although the British Pharmacopœia is not legally a standard under the Sale of Food and Drugs Acts, it should be regarded by pharmacists as being morally so; the question was also offered for serious consideration whether, with due regard to the position of a pharmacist as a professional man, he should ever defend a case brought under the Sale of Food and Drugs Acts when—through accident or otherwise—an article supplied by him for medicinal purposes is not in accordance with the British Pharmacopœia. In the case referred to, the defendant pleaded that he had only recently acquired the business, and found the compound rhubarb powder in stock. After his attention had been directed to the matter, he examined the powder and found it contained magnesium carbonate in place of oxide. Those being the facts, it would be unreasonable, under the circumstances, to blame the defendant, but he would have been well-advised not to make the incorrect statement, attributed to him in the newspaper reports, that "most chemists" use the carbonate instead

of the oxide in making compound rhubarb powder. Such is not the case, and I have not the least hesitation in saying that any registered chemist who retails as compound rhubarb powder, or Gregory's powder, a mixture containing magnesium carbonate, is doing what is professionally wrong. Fortunately for the defendant in the case under consideration, the magistrate held that the case must be dismissed because the British Pharmacopœia is not a standard under the Sale of Food and Drugs Acts. That is quite correct, but it is a question whether the book is not a standard in common law for preparations defined therein, if asked for under the B.P. names or synonyms. Again, Mr. Baggallay was wrong in asserting that there is no Act of Parliament which makes the Pharmacopœia the standard for compounded drugs; the Pharmacy Act, 1868, so provides in its fifteenth section, whilst, under the Merchandise Marks Act, 1887, the B.P. would also probably be regarded as a standard for official preparations, the offence in such a case as that referred to being the application of a false trade description to goods. Dealing with the matter, however, under the Sale of Food and Drugs Act, 1875, the magistrate, in his wisdom, decided the case on a question of fact, and so the defendant is clear—fortunately, he will doubtless think, but perhaps unfortunately if the matter be regarded in a proper light. The difficulty of the situation appears to be the lack of a High Court decision as to what extent the British Pharmacopœia is a standard. It is undoubtedly a standard for its own preparations, under the Pharmacy Act, 1868, but the wording of the Section which makes it so has tended to make the law quite inoperative.

Prospects of Company Legislation.

Parliament is expected to be summoned for the Session of 1900 rather earlier than was at first thought probable, and the end of the present month may see the resumption of the two Houses. The prospect of "company" legislation is, naturally enough, being anxiously discussed both in pharmaceutical and commercial centres, whilst the wildest speculations are indulged in as to the probable attitude of the Government in respect to the problem. So far as the indications afforded by the public press may be relied upon, it would seem that the outlook is not particularly favourable to the passage of domestic reforms of the magnitude of the Companies Acts Amendment Bill. Evidence is not wanting that something like a ministerial revolt is in progress, so that if the disruptive elements in the opposite camp could be opportunely eliminated, and advantage taken of the situation, there is no saying what might happen—it might even precipitate a general election. The Government, as a matter of fact, cannot rely upon getting its full working majority during the coming session; for some five-and-twenty of its supporters are either already fighting the Queen's enemies in South Africa, or are on the eve of departing for that purpose. The Opposition does not suffer denudation in a like manner, and may possibly confine its bellicose faculties to fighting the Government at home. Now this state of things has a distinct bearing on the legislative hopes of chemists, for it may be that the chastening effects of present misfortune and the fear of future difficulties will render the Government more amenable to the representations of the Pharmaceutical Society than it has hitherto proved to be. Note will doubtless be taken by the Law and Parliamentary Committee of the Council that at least twenty-five constituencies will be disfranchised by the absence of members abroad, and that it will be useless labour to ask chemists in those constituencies to "bring pressure" to bear on their representatives. I would suggest that disfranchised chemists should notify the fact to the Secretary of the Society, so that the Law and Parliamentary Committee might, if it thought fit, devise a means whereby the views of chemists unrepresented in Parliament could be brought to the notice of the House. Whatever vigour in a parliamentary direction pharmacists are prepared to develop during the approaching Session, I hope it will all be expended on the enemy and not frittered away in mutual recriminations or abuse.

And, let me add, that vituperative references to persons prominently associated with the "limited company" interest are to the last degree puerile, however much they may relieve the mind. Registered chemists have a splendid case, and there is not a shadow of reason why they should utilise the forlorn hope of "abusing defendant's attorney."

PHARMACEUTICAL SOCIETY.

MEETING OF THE COUNCIL.

WEDNESDAY, JANUARY 10, 1900.

Present:—

Mr. WM. MARTINDALE, President.

Messrs. Allen, Atkins, Bateson, Carteighe, Corder, Cross, Glyn-Jones, Harrington, Hills, Park, Savory, Symes, Warren, and Young.

The minutes of the previous Council meeting were read and confirmed.

Report on the Examinations in Scotland.

The report of Dr. G. Balfour Marshall, the Government Visitor in Scotland, on the examinations of the Pharmaceutical Society held in Edinburgh during the past year, was laid upon the table by the Registrar, and is printed in full at page 29.

The Late Mr. Stanford.

The PRESIDENT, in opening the proceedings, said death had been very busy since the last meeting, and more than one prominent member of the pharmaceutical body had been taken from them. He would refer first to Mr. Edward Charles Cortis Stanford. He was a student and prizeman of the School of Pharmacy, and afterwards demonstrator in the laboratory under Professor Redwood. He took great interest in the chemistry of the products obtained from sea-weed, and was the founder of the British Sea-weed Co., which with the aid of the Duke of Argyll at one time was very successful. He was also a member and founder of the Pharmaceutical Conference, and was President at the Edinburgh meeting in 1892, and was connected with various learned societies. He took great interest in educational matters, and was Chairman of the Dalmeir School Board for many years. He was also well known for his genial *bonhomie*, and he (the President) was sure it would be the wish of the Council that he should write a letter of sympathy to the family.

Mr. ATKINS wished to bear testimony to the estimable character of the late Mr. Stanford, whom he had known during the greater part of his life. The President had ably referred to the scientific attainments of the deceased, but he (Mr. Atkins) wished to bear testimony to his extreme geniality. He was a man of exquisite humour. With regard to the sea-weed enterprise to which the President had referred, there was one aspect of his life that was worth noting. During Mr. Stanford's connection with the people in the Western Islands he collected a very large amount of folklore, and deeply interested himself in educational work among the fisherfolk of those islands.

Dr. SYMES said he had known the late Mr. Stanford for a number of years. He had always been a thoroughly loyal member, not only of the Society, but also of the Conference, and had done a great deal of original work.

The late Mr. Andrew Thompson.

The PRESIDENT said he had also to draw attention to the death of the late Andrew Thompson, of Carlisle. He was a pharmaceutical chemist of the old school, who, up to the last, kept himself abreast of what was going on in the science of pharmacy. For several years he was local secretary to the Pharmaceutical Society, and he was an occasional visitor at the Conference meetings. He also took an active part in pharmaceutical politics, and on the occasion of Mr. Carteighe's campaign in the North, Mr.

Thompson took the chair at a meeting which was held in Carlisle. He was well known in that city, where he occupied several civic offices. He was a man of unassuming, genial manners, and might be termed one of nature's gentlemen. Having himself been his pupil for about three years, he might say that he was a most kindly-hearted man, and he felt that he had lost an old friend.

The Late Mr. Richardson.

The PRESIDENT said he had also to report with great regret the death of one of their colleagues, Mr. John G. F. Richardson, of Leicester, at the age of 65. He was a life member of the Society and for sixteen years, viz., between 1879 and 1895—when his health failed—he served the Society as a member of the Council. Most of those present were associated with him as a colleague during some portion, at any rate, of that period, and could personally speak of the interest he took in all matters affecting pharmaceutical education generally, and that portion of it carried on at 17, Bloomsbury Square in particular. That was perhaps to be expected from a pharmacist who was one of the early students of the School of Pharmacy, and who had substantial reasons for entertaining a sense of gratitude for the knowledge acquired there. Mr. Richardson took a very active part in the Volunteer movement, and held the rank of lieutenant-colonel in that organisation, though he was generally known by the familiar title of "the major." He was sure they would all join in passing the resolution "That this Council learns with regret of the death of Mr. J. G. F. Richardson, of Leicester, an old member of the Council, and desires to tender its sympathy with his family in the loss they have sustained."

The resolution was carried unanimously.

New Year's Honours.

The PRESIDENT proposed that the congratulations of the Council should be forwarded to Sir Thomas Lauder Brunton on his attaining the honour of knighthood. Sir T. Lauder Brunton had taken an active part in all matters connected with materia medica. He was a member of the Society's Research Committee, and had also taken an interest in the efforts of the Society to get an amendment of the Companies Bill.

Election of Members.

The following persons having tendered their subscriptions for the current year, were elected "Members" of the Society:—

Allan, Alexander; Glasgow	Leslie, William; Haddington
Bailey, Daniel Jennings; Blackpool	Livesey, Geo. Samuel T.; Leeds
Bambrough, Wilfrid Ernest; London	Lockhart, John; Glasgow
Barnes, Arthur Swaby; Dudley	Lubbock, John William; Spitalfields
Bell, John Rowell; Dunston-on-Tyne	McGregor, Donald; Calcutta
Bell, William James; North Shields	McGregor, James; Calcutta
Bills, Albert James; Stourbridge	Madden, Ronald George; Hackney
Black, William Reynolds; Shipley	Marfitt, George Edward; Leicester
Bower, Frederic Riseley; Cinderford	Martin, John Woolcock; Ashburton
Brice, Frede. Gratton; South Wigston	Massie, John; Brora
Bromfield, John; Hull	Mellor, R. John; Hemel Hempstead
Carter, Charles Edward; Bradford	Mitchell, John; Eastbourne
Carter, William; Oswestry	Newton, Alfred; Walford
Chadwick, Thos. Bentley; Blackburn	Nicolson, Allen Macdonald; Wigtown
Chalmers, James; Kelty	Old, Herbert Ashman; Aldershot
Clegg, Harry Brook; London	Oldroyd, George; Halifax
Cockle, William Henry; King's Lynn	Perrett, Henry John; London
Coltart, John Alexander; Warwick	Pickering, Charles Edward; Hornsey
Count, Sydney; King's Lynn	Prebble, Ernest; Liverpool
Davis, Oliver Chas. Minty; Bristol	Reith, John Reid; Culter
Downar, Frederick William; London	Rickarby, Arthur George; Canterbury
Egginton, John Tertius; Sedgley	Robins, Harry Hollies; Forest Gate
Farr, Minnie; Leamington	Robinson, Bernard C.; Liverpool
Fawthrop, James; Cross Gates	Robinson, C. H.; Market Weighton
Findlay, John; Portobello	Scholefield, William E.; Luton
Ford, Wm. Crossley; Camdeu Town	Shearman, Christopher W.; Cambridge
Foster, Frederick; Birmingham	Smith, Eliza Mary; Fulham
Gilmour, James Pinkerton; Glasgow	Spencer, Rosa Kathleen; Birmingham
Goy, William Henry; Clapham	Spooner, W. Cushing; Lavender Hill
Griffith, Matthew Henry; Rushden	Stedman, C. R.; St. Leonard's-on-Sea
Guthrie, John; Rangoon	Stoneman, John Edey; Kennington
Hadden, Alexander; Ballater	Suttie, Robert; Cambuslang
Hall, Jasper Longsdon; Solihull	Symington, James M.; Inverness
Hall, John; Ashton-under-Lyne	Taylor, Joseph John; Ashford
Handford, Joseph John; Torrington	Tiltman, William John; Highbury
Harding, Christmas; Clerkenwell	Toon, Lionel Edward; Hay
Harries, Frank Reginald N.; Bayswater	Turner, John H. W. R.; Rotherham
Hines, Henry Thomas; Holloway	Turney, Herbert B.; Maidstone
Hogarth, John Tom; Morpeth	Warner, George Oram; Berkeley
Jeanes, Richard; Newport	Warner, Matthew Richard; Warrington
Jenkins, John; Norwood	Watkins, Archibald G.; Brecon
Kelly, Albert Edward; Edinburgh	Weir, Alexander; Belfast
Kirkland, Arthur; Balham	Worth W.; Kingwilliamstown, S.A.

Election of Student-Associates.

The following persons having passed the First examination, and tendered their subscriptions for the current year, were elected "Student-Associates" of the Society:—

Atkinson, Richard Jowett; Bradford	John, John Jenkin; Llanpumpsaint
Avery, Cuthbert Johnson; Birmingham	Jones, Rees Trevclyan; Bridgend
Bourne, C. W. K.; West Bromwich	MacNaught, Archibald H.; Greenock
Buchanan, Lizzie; Kirriemuir	March, Frederick William; Thrapston
Campbell, Duncan; Douglas	Martin, Clarence Win.; Colechester
Chambers, George Henry; Eastwood	Matthaei, Maximilian J.; London
Clark, John Barton; London	Meadows, William Ross; Ilford
Colebrook, Donald; Plumstead	Miller, Alfred Edward; Bath
Collitt, Bernard; Gainsborough	Oddie, Major Sidney; Banbury
Cruickshank, George M.; Turiff	Overend, Frank; Holmfirth
Davies, David Augustus; Whitland	Perry, Wallis Bennett; Basingstoke
Edgar, Allan Herbert; Kennington	Pickup, Ralph; Blackburn
Evans, Arthur Morgan; Colwyn Bay	Prichard, Thomas John; Clynog Fawr
Fellows, Hugh; Dudley	Sidebottom, Walter; Accrington
Futty, Alfred; Scarborough	Smalley, Charles; Halifax
Galbraith, Sarah A.; Wolverhampton	Smith, Harold; Lockwood
Gates, Wilfrid; Rochester	Spencer, John Ernest; South Shields
Gibbins, Richard Ernest; Derby	Steel, Joseph Andrew; Haswell
Gittings, Arthur Henry; Bilston	Stephenson, John Harry; Nuneaton
Gorrie, Peter; Edinboro'	Tasker, Walter Arthur; Goole
Haycock, John; Leicester	Treacher, Allen S. John; Tonbridge
Hedley, Joseph William; Durham	Tucker, Alfred Burnard; Honiton
Herbert, Auberon; Reading	Tugwell, Percival Thomas; Brighton
Higgins, Frederick Samuel; London	Turner, Levi; Mellor Brook
Hinchliffe, Frederick; Lower Weston	Uttley, John Edward; Hull
Hodgson, Harold Fredk.; Streatham	Wain, George Gardner; Boscombe
Iredale, Tom; Workington	Westlake, Ethel Maude; Windsor
Jackson, Ewart Gladstone; Newcastle, Staffs.	Wright, John William A.; Bradford
	Wynn, Alfred; Walworth

Restoration to Register.

The name of the following person, who has made the required declaration and paid a fine of one guinea, was restored to the Register of Chemists and Druggists:—

Walter Atkinson, 323, Penistone Road, Sheffield.

Addition to Register.

The Registrar reported that

Thomas Beutley Chadwick,

having made a declaration that he was in business as a chemist and druggist prior to the passing of the Pharmacy Act, 1868, and these declarations having been duly supported, his name had been placed on the Register.

Restorations to the Society.

Several persons were restored to the Society upon payment of the current year's subscription.

Dispensing by Unqualified Persons.

Mr. GLYN-JONES said that, early last year, the question of dispensing by unqualified persons was deferred until the General Medical Council had reported. Now that the General Medical Council had reported, he wished to ask whether the Council would again take up the question.

The PRESIDENT said he could not answer the question off-hand.

Mr. CARTEIGHE said the question was before the General Purposes Committee, and would come up as a matter of course.

Finance.

The report of this Committee recommending the payment of certain accounts was read.

The PRESIDENT, in moving the adoption of the report and recommendations, said there was a balance in hand of £886 10s., which showed a more satisfactory state of affairs than usual at that time of year. It would not, however, be sufficient to meet the requirements of the current month, but money would be coming in from members and from advertisements, and he hoped they would be able to get on without asking for any advance from the Bank.

The resolution was passed unanimously.

Benevolent Fund.

The report of this Committee recommended the grant of £111 in the following cases:—

The widow (70) of a registered chemist and druggist who died in 1875. Applicant has had fourteen previous grants. (Forest Gate.)

The widow (66) of a chemist and druggist, who has had four previous grants. (London.)

The widow (76) of a chemist and druggist and subscriber, who has had three previous grants. (Worcester.)

The widow (61) of a pharmaceutical chemist, who died in 1897; applicant has had two previous grants. (London.)

A registered chemist and druggist (80), who has had four previous grants, and is bedridden from paralysis. (Cheltenham.)

A registered chemist and druggist (76), who has had six previous grants. (London.)

A former member and subscriber (65), who was in business for thirty-one years, but had to retire from ill-health. (London.)

A registered chemist and druggist (71) and occasional subscriber, who has had several previous grants and was an unsuccessful candidate at the recent election. (Liverpool.)

A pharmaceutical chemist member (74) since 1853, and subscriber for many years; also an unsuccessful candidate at the election. (Seacombe.)

One case was deferred and another was not entertained.

The Secretary had reported the death of two annuitants, viz., Mary Wavell, of Brighton, on December 14, aged 73, and William Copney, Lavender Hill, on December 22, aged 78.

Mr. ATKINS moved the adoption of the report and recommendations. He said there were eleven cases before the Committee, of which nine were relieved and one was deferred. To the two unsuccessful candidates at the recent election the Committee had made grants of £20 each, which was rather more than usual, but the Committee carefully considered the cases with the advantage of the local knowledge of Dr. Symes, and there was reason to believe that with some other assistance those two gentlemen would be able to tide over till next year, when he hoped they would be elected to annuities. Two annuitants had died, viz., Mrs. Wavell, who was elected in 1893, and Mr. Copney, who was elected in 1889. There was something very pathetic about the death of the latter, his wife having predeceased him by one day only, and they were both buried in the same grave. The Committee had a very interesting account from the Secretary of a visit he had paid to Mr. and Mrs. Copney, from which it appeared that the grants made for the last ten or eleven years had been of very great service. Mr. Copney was a man of singular gifts and attainments, and altogether his history was well worth studying. He might add that he had received from Nottingham a cheque for £1,000 from the estate of the late Mr. Waterall, with regard to which a resolution would be moved. He might also say that he had invested the balance of £753 11s. 5d. which was in hand at the end of the year on Benevolent Fund donation account to which he had added £211 18s. 4d. from the current account, in the purchase of £950 Consols.

The report and recommendation of the Committee were unanimously adopted. It was also resolved that the President, Vice-President, Treasurer, Messrs. Carteighe and Hills be appointed a Committee to consider and report on the best method of carrying out the conditions attaching to the Waterall legacy.

Library, Museum, School, and House Committee.

The PRESIDENT moved the adoption of the report of this Committee, which stated that the Librarian had furnished his usual report, including the following particulars:—

Attendance.	Total.	Highest.	Lowest.	Average
November	466	37	7	18
Circulation of Books.	Total.	Town.	Country.	Carriage Paid.
November	147	85	62	11s. 5½d.

Several donations to the Library and Museum had been received (see *P.J.*, December 16 last, p. 586), and the Committee had directed the usual letters of thanks to be sent to the respective donors.

The Committee recommended that the undermentioned books be purchased for the Library in London:—

- Parry, Chemistry of Essential Oils, 1899.
- Letters of Faraday and Schoenbein, 1899.
- Charbot, Dupont, and Pillct, Les huiles essentielles, 1899.
- Bruhl, Chemie der sechsgliedrigen heterocyklischen Systeme, 1899.

The Curator's report had also been received and included the following particulars:—

Attendance.	Total.	Highest.	Lowest.	Average
November	345	33	4	13

Mr. GLYN-JONES said he should feel it necessary to vote against the adoption of the report, for the reason that he had not been able to follow it.

Mr. BATESON, as a member of the Committee, asked if Mr. Glyn-Jones would point to any single item that he did not understand.

Mr. GLYN-JONES said one thing which caught his ear was something which dealt with the closing of the Museum. With reference to the election of members and the Benevolent Fund Committee he had been furnished with information, for which he was grateful, as it enabled him to take an intelligent interest in the report, and he thought the same thing ought to be done with this Committee.

The PRESIDENT said the Committee had ordered that in future and until further notice the Library and Museum in London should be closed at 6 p.m. on every day except Saturday. That had been found to be desirable.

Mr. GLYN-JONES said he did not question that at all, but it was the only thing he had been able to understand while the report was being read.

The motion for the adoption of the report having been put and carried with one dissentient,

Dr. SYMES suggested that Mr. Glyn-Jones should be placed on the Library, etc., Committee.

Mr. CARTEIGHE said that was not the question raised by Mr. Glyn-Jones. The question had been already raised by Mr. Glyn-Jones and discussed, and he thought Mr. Glyn-Jones ought to have waited until the end of the current session before again raising it.

Mr. GLYN-JONES said he merely gave it as his reason for voting against the adoption of the report.

Superintendent and Deputy-Superintendent of Written Examinations.

Mr. STRACHAN, of Aberdeen, was appointed Superintendent, and Mr. John Cruikshank Deputy-Superintendent of Written Examinations for the current year.

Company Trading.

Mr. GLYN-JONES said the agenda for the day contained an item, "Report of the Law and Parliamentary Committee," but he understood there was no report to be presented. He wished to know if he would be in order in moving that the Law and Parliamentary Committee be asked to present a report to the next meeting of the Council.

The PRESIDENT said the agenda was printed before the meeting of the Law and Parliamentary Committee; at the meeting the Committee decided not to report. Mr. Glyn-Jones might make the motion he suggested, and if it were seconded and carried, the Committee could take what steps it liked about it.

Mr. GLYN-JONES then moved that the Committee be asked to present a report at the next meeting of the Council. He did so because he thought the members of the Society and the Council were expecting, and rightly, that the Committee should report. The hands of the members of the Council were tied until the Committee chose to report. There was a very definite reference to the Committee to draft a clause, and he thought the majority of the members would be expecting that the Committee would report to the Council with a clause, or else say they did not think it wise to draft one, or had not been able to do so. He did not think all action should be stayed at the mere pleasure of the Committee. He, for one, should like an opportunity, when that report was presented, of protesting strongly against certain things the Committee had done.

The motion was not seconded.

Carbolic Acid.

Dr. SYMES asked if any reply had been received from the Privy Council with reference to carbolic acid. People were still being poisoned by it.

The PRESIDENT said not yet.

Mr. CARTEIGHE said he had reason to believe that the matter was being attended to.

Correspondence.

The SECRETARY announced that the following resolutions had been communicated to the Federation, and forwarded by Mr. J. Cocks :—

1. Oxford and District Chemists' Association, adopting suggestions 1 and 3 of the Federation Circular, with the addition that the manager's name should be on the facia and labels.

2. Aberdeen Pharmaceutical Association, declaring that titles should be protected, and that practice by companies of unqualified persons should be illegal.

3. Crewe Chemists, stating that opinions are divided, but that the majority favours suggestion No. 1 of the Federation Circular.

4. Exmouth Chemists, supporting suggestion No. 1.

The following resolutions had been forwarded direct to the the Secretary :—

From the Newcastle-on-Tyne and District Chemists' Association, expressing the opinion that carbolic acid, strong mineral acids, butter of antimony, acetate of lead, sulphates of copper and zinc, oxalates and strong solution of ammonia ought to be added to Part II. of the Poison Schedule.

From the Hull Chemists' Association, expressing the opinion that no company should practise pharmacy or use titles unless all the directors and controlling shareholders are qualified.

From the Western Chemists' Association (of London), expressing the opinion that, if it is not feasible to restrain all companies from keeping open shop, legislation should be directed to :—

1. Prohibiting the use of titles by companies.
2. Providing qualified control for all "open shops."

Mr. HILLS asked that the actual resolution passed by the Western Chemists' Association should be read. He objected to an epitome which he thought did not correctly represent the resolution.

The SECRETARY therefore read the resolution as sent to him. It has already been published in the *Pharmaceutical Journal* (see last volume, p. 619).

General Purposes Committee.

The Council went into Committee, as usual, to hear and consider the report of this Committee. On resuming, the report and recommendations were unanimously adopted, and special resolutions passed authorising the Registrar to take proceedings against the persons named.

Death of Mr. Daniel Frazer.

As the Council was rising, a telegram was received announcing the death of Mr. Daniel Frazer, a former member of the Council.

EXAMINATIONS IN EDINBURGH.

January, 1900.

MINOR EXAMINATION.

Candidates examined	97
„ failed	58
„ passed	39

Appleton, John Thompson
Bell, William James
Booth, Fred Soutar
Carr, Hugh Livingstone
Colson, Thomas William
Duncan, Douald
Elder, David
Forsyth, Richard Patterson
Gilchrist, John
Heap, Robert Edwin
Hodgson, Edgar
Hogarth, John Tom
Holmes, Alexander
Hunter, John

Innes, George
Jackson, Robert
Kelly, Albert Edward
Lightbourne, James Ashbourne Archibald
Low, John Grieve
McLean, Alexander Bennett
McLees, John Prentice
Martin, Thomas Stewart
Nimmo, William
Penman, David
Prince, Henry Clifford
Quinn, Gerald
Ritchie, David Wilson

Robb, David Wallace
Ross, Hugh
Scott, Thomas
Selby, William Tordiff
Taggart, Charles John Alexander
Taylor, John Edward Brownlow

Thomson, Robert
Thomson, Thomas
Turner, David
West, Harold
White, Thomas Keachie
Wilson, James Sayburn

FIRST EXAMINATION QUESTIONS.

First Paper.

January 9, 1900, from 11 a.m. to 12.30 p.m.

LATIN.

1. FOR ALL CANDIDATES. Translate into Latin :—

1. The journey was very pleasant.
2. He was fearing the anger of the sailors.
3. The fifth legion had been sent into Britain.
4. He goes away to consult the oracle.
5. It is certain that Cicero will be heard.

2. Translate into English *either* A (Caesar) or B (Virgil).

A.—CAESAR.

1. Flumen est Arar, quod per fines Aeduorum et Sequanorum in Rhodanum infuit, incredibili lenitate, ita ut oculis, in utram partem fluat, judicari non possit. Id Helvetii ratibus ac lintribus junctis transibant. Ubi per exploratores Caesar certior factus est, tres jam partes copiarum Helvetios id flumen transduxisse, quartam vero partem citra flumen Ararim reliquam esse: de tertia vigilia cum legionibus tribus e castris profectus, ad eam partem pervenit, quae nondum flumen transierat. Eos impeditos et inopinantes aggressus, magnam partem eorum concidit: reliqui sese fugae mandarunt atque in proximas silvas abdidierunt.

2. Haec quum animadvertisset, convocato consilio, omniumque ordinum ad id consilium adhibitis centurionibus, vehementer eos incusavit: primum, quod aut quam in partem, aut quo consilio ducerentur, sibi quaerendum aut cogitandum putarent. Ariovistum, se consule, cupidissime populi Romani amicitiam appetisse: cur hunc tam temere quisquam ab officio discessurum judicaret? Sibi quidem persuaderi, cognitio suis postulatis, atque aequitate conditionum perspecta, eum neque suam neque populi Romani gratiam repudiaturum.

GRAMMATICAL QUESTIONS.

(For those only who take Caesar.)

1. Give the genitive singular, Latin and English, and the gender, of the following nouns:—*agmen, bonitas, conatus, domus, jus, latus, manus, salus.*
2. Give the principal parts of all the verbs in passage 2.
3. Account for the moods of *animadvertisset, ducerentur, appetisse.* (Passage 2.)
4. Write in Latin—*twenty-one, thirty-sixth, twenty years old, one thousand soldiers, three thousand soldiers, one-third, four times, 476 B.C.*

B.—VIRGIL.

1. Hinc portum petit, et socios partitur in omnes. Vina, bonus quae deiude cadis onerarat Aestes Littore Trinacrio, dederatque abeuntibus heros, Dividit, et dictis moerentia pectora mulcet: "O socii! neque enim ignari sumus ante malorum; O passi graviora! dabit Deus his quoque finem. Vos et Scyllaeam rabiem, penitusque sonantes Accestis scopulos: vos et Cyclopiæ saxa Experti. Revocate animos, moestumque timorem Mittite: forsan et haec olim meminisse juvabit."

2. Hoc primum in luco nova res oblata timorem Lenit: hic primum Aeneas sperare salutem Ausus, et afflictis melius confidere rebus. Namque, sub ingenti lustrat dum singula templo Reginam opperiens, dum, quae fortuna sit urbi, Artificumque manus inter se, operumque laborem, Miratur, videt Iliacas ex ordine pugnas, Bellaque, jam fama totum vulgata per orbem, Atridas, Priamumque et saevum ambobus Achillem.

GRAMMATICAL QUESTIONS.

(For those only who take Virgil.)

1. Give the genitive singular, Latin and English, and the gender, of the following nouns:—*Achilles, aequor, biremīs, conspectus, famulus, jus, mensis munus.*
2. Give the principal parts of all the verbs in Passage 1.
3. Parse fully—"Hic primum Aeneas sperare salutem ausus." (Passage 2.)
4. Write in Latin—*twenty-one, thirty-sixth, twenty years old, one thousand soldiers, three thousand soldiers, one-third, four times, 476 B.C.*

Second Paper.

January 9, 1900, from 12.30 p.m. to 2 p.m.

ARITHMETIC.

(The working of these questions, as well as the answers, must be written out in full.)

1. From the product of 709 and three hundred and four thousand and sixteen subtract one hundred and eleven thousand two hundred and ninety-four. (Answer in words.)
2. When tea is 2s. 3d. a pound, I buy 5 cwt. 3 qr. How much could I have bought with the same money if tea costs only 1s. 1½d. per lb.?

3. What fraction of one ton must be added to $\frac{9}{17}$ of $\frac{51}{702}$ of 4 cwt. 3 qr. to make $\frac{5}{7}$ of $2\frac{1}{2}$ of $83\frac{5}{17}$ lb.?
4. Write as a vulgar fraction in its lowest terms:—
($7.35 \times .0143 \div 7.5075$)—($152 \times .033 \div 1.045$).
5. If 3 cwt. of hay feeds 14 ponies for $4\frac{1}{2}$ days, how many horses will 9 cwt. feed for three days, if 2 horses eat as much as 3 ponies?
6. A plumber sold 96 cwt. of metal for £109 2s. 6d., and gained at the rate of $12\frac{1}{2}$ per cent. What did it cost him per cwt.?

The following question must be attempted by every candidate:—

7. A man starts along a road and walks 5328 metres, then 74 hectometres, then 2 kilometres, then 943 decametres. Find, approximately, how many yards further he will have to walk to complete 30 kilometres.

Third Paper.

January 9, 1900, from 3 p.m. to 4.30 p.m.

ENGLISH.

1. Analyse:—
"Could Nature's bounty satisfy the breast,
The-sons of Italy were surely bless'd."
 2. Distinguish between a *transitive* verb and an *intransitive* verb. Name two verbs that may be used transitively and intransitively.
 3. Correct the following sentences, giving your reasons:—
(a) He is one of those men who is never satisfied.
(b) Who can this telegram be from?
(c) Neither he or his sister are going.
 4. In the following passage, supply the necessary capital letters, and put in the stops and the inverted commas where necessary:—ship ahoy shouted the officer in charge of the boat as they drew within hailing distance of the vessel hulloa returned the mate who was leaning over the taffrail abaft the mainmast what's the trouble plenty I can assure you the warder said shortly it need hardly be stated that the little humour he possessed before approaching the schooner had speedily evaporated on witnessing the crews demeanour.
- The following question must be attempted by every candidate:—
5. Write a short Composition on one of the following subjects:—
(i.) International Exhibitions.
(ii.) The Civil War in the reign of Charles I.
(iii.) Our Colonies.
(iv.) Your Favourite Occupation.

REPORT ON THE EXAMINATIONS IN SCOTLAND.

The following report on the Examinations of the Pharmaceutical Society, held in Edinburgh during the past year, has been presented to the Privy Council by Dr. G. Balfour Marshall, the Government Visitor for Scotland:

[Copy.]

19, Sandyford Place, Glasgow,
6th December, 1899.

Report on the Examinations of the Pharmaceutical Society held in Edinburgh during the year 1899.

To the Lords of the Council.

My Lords,—I have the honour to report that examinations were held in Edinburgh during the months of January, April, July, and October, 1899, by the Board of Examiners of the Pharmaceutical Society. I was present on fifteen occasions, and beg to submit the results of both the Major and Minor examinations:—

Major Examination.

	Number.	Percentage.
Candidates examined	3	—
Candidate who passed	1	33.3
Candidates who failed	2	66.6

Rejected Candidates.

Failed in practical work.....	1
Failed in botany	1

REMARKS.—It is very regrettable that only three candidates should have presented themselves for this "honours" examination, as it shows that amongst the large number of pharmacists there are very few who aspire to the higher title of "pharmaceutical chemist," with the extra privileges which it confers upon them.

Minor Examination.

	Number.	Percentage.
Candidates examined	484	—
Candidates who passed	175	36.15
Candidates who failed.....	309	63.84
Three candidates entered, but did not present themselves for examination.		
<i>Rejected Candidates.</i>		
(A) Candidates who failed in practical work on the first day, and were not admitted to oral examination ..	175	36.15
Failed in practical chemistry	64	13.22
Failed in practical pharmacy	41	8.47
Failed in both above.....	70	14.46
(B) Candidates who passed in practical work, but failed in the oral examination	134	27.68
Did not appear for oral examination	1	—
Failed in botany	50	—
Failed in oral chemistry and physics	35	—
Failed in materia medica	9	—
Failed in prescription reading.....	8	—
Failed in oral pharmacy.....	21	—
Obtained marks in each subject, but failed in the aggregate.....	17	3.51

The practice of stopping a candidate whenever he fails in any part of the oral examination makes it impossible to give a percentage of the rejections in each subject. Candidates were examined on the basis of the new Pharmacopoeia of 1898, which came into force last January.

REMARKS.—There is again a slight improvement in the percentage of passes. The number of failures is, however, too large, many of the candidates presenting themselves over and over again; and this is only likely to be remedied by students taking more advantage of the existing schools of pharmacy throughout the country, or by the introduction of a compulsory curriculum, which would insure thorough systematic training.

PRACTICAL CHEMISTRY AND DISPENSING.—There is an improvement in practical work, the rejections in these subjects being over five per cent. fewer than last year. It is also evident that more attention is being given to practical training, as students appear more familiar with the apparatus in common laboratory use.

Students frequently show imperfect practice in qualitative analysis, the cause of failure being that the candidate does not properly observe the reactions taking place—e.g., calling a brown precipitate black, or accepting as a precipitate what is merely a colour reaction. This leads to the substance in question being mistaken, and not infrequently tests which would be confirmatory, or show their error, are written down from memory instead of being practically tried.

CHEMISTRY AND PHYSICS.—The only points to which special attention might be drawn are, that candidates should show more experience in the working of chemical sums and more familiarity with the barometer, thermometer, and chemical balance.

BOTANY.—This accounts for over 37 per cent. of the failures in the oral examination. Students appear to give least attention to this subject and many show that they have no practical acquaintance with those plants specially indicated in the syllabus. They should recognise that it is not sufficient to acquire a knowledge of botany from books alone, and that the plants themselves must be handled and studied if a satisfactory appearance is to be made at the examination.

EXAMINERS.—Three new examiners have been appointed this year, vice Mr. Thomas Maben, resigned, and Messrs. Ewing and Nisbet, whose term of office has expired.

I am able to express entire satisfaction with the manner in which the examiners performed their duties.

I have the honour to be,
My Lords,

Your obedient servant,
G. BALFOUR MARSHALL.
Visitor.

LETTERS TO THE EDITOR.

The B.P. Preparations of Ipecacuanha.

Referring to the Annotation in the Journal for December 30 (p. 633), commenting on my notes on the B.P. preparations of ipecacuanha, I beg to state that the figures relating to the liquid extracts were obtained and checked by the official process. Several other determinations were made, using Wilson's and Naylor and Bryant's processes respectively, but I did not publish the results of those, as I was not attempting to enter into the various merits or demerits of the different processes. As there is not an official process for the Wine, those were assayed by Naylor and Bryant's process and the results of each operation checked. In two cases the makers of samples were communicated with, and their results tallied with those published. I have not the slightest hesitation in believing that the results are absolutely as reliable as the processes will allow. They were made in Messrs. Duncan, Flockhart, and Co.'s laboratories by the firm's analyst, who is almost continually making alkaloidal determinations.

Edinburgh, January 4, 1900.

R. GLODE GUYER.

Liquor Bismuthi.

Mr. Dudderidge appears to have entirely overlooked the essential point in our paper on liquor bismuthi. We pointed out that the imperfection in the B.P. formula lies in the fact that it orders less potassium citrate than is necessary for converting the bismuth nitrate into bismuth citrate, as it assumes a degree of purity in the potassium citrate not met with in commerce, and not even expected by the characters and tests for that salt mentioned in the B.P. We also showed that the deficiency in alkali is not of much importance provided the citric acid is in excess.

Mr. Dudderidge refers us to a paper read by himself at the Plymouth Conference, in which he recommends the following three modifications:—(1) Non-dilution until after formation of citrate; (2) Reversing the order of mixing; (3) Increasing the quantity of potassium carbonate. We will discuss the first separately, the other two conjointly, (1) MacEwan, in 1886, pointed out the inadvisability of excessively diluting the solution of bismuth in nitric acid previous to the formation of the citrate. (2 and 3) Mr. Dudderidge cannot lay claim to have first suggested that an increase of potassium carbonate is an advantage. It is easy to see that by increasing the amount of alkaline carbonate there will be less likelihood of forming basic nitrate of bismuth, and less loss of bismuth sometimes than at others, owing to the variability in the quality of commercial potassium citrate; but we are unable to see that the quantity of bismuth citrate can be increased thereby, as Mr. Dudderidge's paper would lead us to believe, if a sufficient quantity of the citric radical is not present to produce the increased quantity, or that loss of bismuth is prevented by reversing the order of mixing, one of the features for which we understand Mr. Dudderidge claims *priority of publication*, and which no one will question.

It would be interesting to know (a) whether Mr. Dudderidge, after having increased the amount of potassium carbonate, tried mixing the liquids as mentioned by the B.P.; (b) whether he determined the amount of bismuth in the finished liquor and in the wash liquid; the little or no loss which he speaks of, after filtering the hot liquid containing the bismuth citrate and washing the latter with hot water, does not accord with our experience. Considering the above we fail to see that Mr. Dudderidge can substantiate his claim to have improved and simplified the process for making liquor bismuthi. We do not lay claim to originality in our work, as any chemist who would seriously take the matter in hand could not avoid coming to the conclusion we did; all we claim to have done is to point out where the B.P. formula is deficient; the remedy of course was obvious, and we suggested a general method for using any alkali together with citric acid, an article

which is of comparatively constant purity. If Mr. Dudderidge considers our formula an unnecessary departure from the B.P. text, it will be easy for him to calculate the required quantity of potassium citrate, and the *correct* amount of potassium carbonate. This may satisfy his conscience. We suppose that chemists who cannot follow the simple process given in our paper would buy the liquor. Finally, our departures from the admittedly imperfect B.P. formula are precisely those improvements necessary for the rapid and economical preparation of a solution which will be in conformity with the B.P. characters and tests.

We really cannot think that Mr. Dudderidge gave serious consideration to our paper before writing the letter published in your last week's issue.

Liverpool, January 8, 1900.

R. C. COWLEY.

J. P. CATFORD.

Petroleum Ether.

I live in a provincial town of about 12,000 population. There is one wholesale drug house for four counties, which cannot supply the above because insurance companies do not allow of their stocking it. London firms cannot supply because railway companies object to carry. Will any pharmacists in a similar position kindly suggest how the difficulty may be overcome?

January 10, 1900.

ON THE SQUARE (16/37).

Chemists and Camwal.

It having been pointed out to me that my letter appearing in *P.J.* of December 30, 1899, might be read as constituting a charge that the Camwal Company has supplied its mineral waters to other persons than registered chemists, I beg to point out that my letter does not state that, nor do I wish that inference to be drawn. The dealers in those goods who are not chemist-members have probably obtained the same from such chemists, and my letter has been written, not for the purpose of causing any inconvenience to the Camwal Company, but with a view to obtaining suggestions from my brother chemists generally as to the best means of dealing with such retailing, which in this part of the West Riding of Yorkshire, at any rate, is doing great injury to chemists like myself who deal with and sell the goods of the Camwal Company. I shall be glad to hear suggestions from chemists as to what steps ought, in their opinion, to be taken.

Halifax, January 10, 1900.

CLEMENT FIELDING.

Division of the Qualifying Examination.

If his opinions upon matters pharmaceutical are to have due weight given to them, I think "An Ordinary Pharmacist" ought to sign his articles with his name. Second, and more particularly, he says in effect, division of the qualifying examination is a subject about which very little interest has been manifested recently. He quotes my letter published in the Journal of December 29 to support his statement. If he re-reads my letter he will find that the complaint as to want of interest refers not to the question of division but to the suggested reform in examination procedure, whereby a candidate might be allowed to have placed to his credit, at a second examination, the subjects in which he satisfied the examiner previously. The interest regarding division, I would suggest in passing, is more widespread and nearer the sphere of practical politics than "An Ordinary Pharmacist" seems willing to believe. And third, whilst prepared to demand a higher standard in the event of division, surely no one can intend seriously to follow the lead of this guide, with his desire to raise the standard so that it will approach, if not equal, that of the present Major examination. Pardon my continued perturbation of mind in the contemplation of such an ideal. The duty of the Pharmaceutical Society, be it known, is primarily to provide chemists and druggists for all classes and grades of business from Land's End to John o'Groats; not, as we might be led to infer, to turn out scientists to suit the better class, or West End, style of business.

Edinburgh, January 10, 1900.

JAMES LENNOX.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

Members of the Pharmaceutical Society must address all communications with reference to the transmission of the Journal, to the Secretary, 17, Bloomsbury Square, London, W.C.

LONDON: SATURDAY, JANUARY 13, 1900.

THE COUNCIL MEETING.

AFTER the minutes of the previous meeting had been confirmed the PRESIDENT drew attention to the absence of the Vice-President and several other members of the Council, who were suffering more or less from the effects of the prevailing epidemic. Reference was also made to several deaths which have occurred since the last Council meeting.

E. C. C. STANFORD, who was in 1857 a student and prizeman in the Society's School, then demonstrator in the Laboratory under Professor ATTFIELD, and subsequently entered into the manufacture of iodine and other products from sea-weed, but continued to keep up his connection with pharmaceutical affairs through the Conference. The PRESIDENT suggested that a letter should be addressed to his family, expressing the sympathy of the Council. This was agreed to and supported by Mr. ATKINS and Dr. SYMES, who spoke with great appreciation of Mr. STANFORD'S many estimable qualities.

ANDREW THOMPSON, of Carlisle, for several years represented the Society as local secretary and occupied a prominent position as the holder of several civic offices. As a former pupil of his, the PRESIDENT spoke of his death as being to him the loss of an old friend.

J. G. F. RICHARDSON, of Leicester, was for sixteen years a member of the Council until his retirement in 1895 owing to ill-health, and on the motion of the PRESIDENT a resolution was passed expressing the sympathy of the Council with his family in the loss they have sustained.

Reference was made to the knighthood of Dr. LAUDER BRUNTON, who, as an honorary member of the Society, has taken an active part in the Society's work, and on the motion of the PRESIDENT it was decided to congratulate him on the honour conferred.

The SECRETARY reported the receipt from the Privy Council Office of the report of Dr. BALFOUR MARSHALL, the Government visitor of the Society's Examinations, held in Scotland last year. See page 29.

The additions to the Society comprised 86 members and 57 student-associates. Several persons were restored to membership, one person was restored to the Register of Chemists and Druggists, and one addition was made.

Mr. GLYN-JONES asked what would now be done by the Council in connection with the subject of dispensing by unqualified persons, the consideration of which had been deferred until the General Medical Council had made its report, and Mr. CARTEIGHE said that as the matter was still before the General Purposes Committee, it would, of course, come up again.

The report and recommendations of the Finance Committee were adopted, the PRESIDENT remarking that the position of affairs was more satisfactory than usual at this time of the year.

On the recommendation of the Benevolent Fund Committee, seven grants were ordered to be paid amounting to seventy-one pounds, as well as two grants of twenty pounds to each of the two candidates who were unsuccessful at the recent election of annuitants. In moving the adoption of the report, the Treasurer mentioned that he had received a cheque for one thousand pounds from the estate of the late Mr. WATERALL, and that he had invested £753 11s. 5d., the Benevolent Fund balance in hand at the end of the year, together with £211 18s. 4d. from the current account, by the purchase of £950 consols.

A resolution was then passed that the PRESIDENT, Vice-President and Treasurer, with Messrs. CARTEIGHE and HILLS should be a committee to consider and report on the carrying out of the conditions attaching to the Waterall legacy.

The report of the Library, etc., Committee dealt as usual with several matters of detail.

Mr. GLYN-JONES expressed his intention of voting against the adoption of the report because he had not been able to follow its details. In reply to Mr. BATESON'S suggestion that he should specify some item of the report which he did not understand, Mr. GLYN-JONES said he thought the same plan should be followed as in the case of the Benevolent Fund Committee and the election of members, so as to enable members of Council to take an intelligent interest in the various proceedings referred to in the report of the Library Committee. After some further conversation the motion was put by the PRESIDENT, and carried with one dissentient.

Mr. STRACHAN, of Aberdeen, was appointed Superintendent, and Mr. JOHN CRUICKSHANK, Deputy-Superintendent, of written examinations for the current year.

Mr. GLYN-JONES, referring to the agenda, said that as he understood there was no report to be presented by the Law and Parliamentary Committee, he wished to know whether he should be in order in moving that the Committee be requested to present a report on the subject of "company pharmacy" at the next meeting of the Council? By permission of the PRESIDENT, Mr. GLYN-JONES moved to that effect, explaining that he did so because members of the Society are expecting to have a report from the Committee and because the hands of members of the Council are tied until the report appears, while for his own part he desired to have an opportunity of protesting against the action of the Committee in certain respects.

The motion was not seconded.

Dr. SYMES inquired whether any reply had been received from the Privy Council Office in reference to carbolic acid. The PRESIDENT said no reply had been

received, and Mr. CARTEIGHE added that he had reason to believe the matter was receiving attention.

Among the correspondence the Secretary announced the receipt from Mr. J. COCKS, the Secretary of the Federation, of several communications relating to company trading, see page 28, and others which had been sent direct to the Society, see page 28.

In connection with a resolution passed by the Western Chemists' (London) Association, Mr. HILLS objected to an epitome of the resolution being read instead of the actual resolution, which was then read as it was reported in the Journal ([4], vol. 9, page 619).

After the consideration of the legal portion of the report of the General Purposes Committee the recommendations made were adopted, and special resolutions were passed authorising the Registrar to take proceedings in certain cases.

As the Council was rising a telegram was received announcing the death of Mr. DANIEL FRAZER, a former member of Council.

BORIC ACID IN FOOD.

IN view of the general interest attaching to the use of preservatives in food, and especially to the employment of borax and boric acid as preservatives for milk, cream, etc., it appears of importance, at the present time, to note that many leading authorities appear to be agreed that the addition of borax or boric acid to food does not render it harmful. Professor OSCAR LIEBREICH points out, in a recently-published monograph on the subject, that boric acid, even in a 5 per cent. solution, exercises no injurious action whatever on the gastrointestinal epithelium. Borax has a more powerful action, but a solution containing at least 2 per cent. is required to cause the disintegration of epithelial cells, *i.e.*, a stronger solution than would be required to produce a similar effect in the case of soda or saltpetre. It is not surprising to learn, therefore, that the "severest criticism of medical observations, and experience won from experimental research justify the conclusion that borax and boric acid are innocuous as preservatives of food." That assertion, of course, is only valid within such limits as apply to all victuals and drugs, for it is known that medicines, food preservatives, and even aliments, though harmless when used properly, may cease to be wholesome and become injurious when taken injudiciously or in excess. It is noteworthy that even common salt, in 5 per cent. solution, exercises an inflammatory action on the intestinal mucous membrane. According to Professor LIEBREICH, experience has proved that 1.2 Gm. of borax or boric acid taken in food daily, even for a considerable time, does not affect health injuriously. "Even quantities twice as large have not been proved injurious, scientific investigations having decisively demonstrated that these doses are far below the limit where deleterious action commences." In conclusion, Professor LIEBREICH expresses the opinion that whoever studies with care the numerous experiments of different investigators will end by adopting the view that borax and boric acid, far from being injurious to the human system, are really wholesome substances. That statement may be commended to the careful consideration of some public analysts.

ANNOTATIONS.

WHAT IS THE PROFIT OVER COST realised by public analysts on the reagents employed by them in the course of their professional duties? The answer may be difficult to give, but the question is one that suggests itself naturally on reading, in the *British Food Journal*, that the profit over the actual cost of the ingredients used by druggists in dispensing prescriptions is seldom less than two hundred per cent., and often more than two thousand per cent. Now, altogether apart from the fact that the profit on the sale of an article cannot exceed one hundred per cent., the writer of the note referred to looks at the matter in a wrong light altogether. The dispensing of medicine from prescriptions is not merely a putting together of medicinal substances, and it is a distinctly mischievous notion, which unfortunately prevails in some quarters, that the dispenser is doing no more than pack up goods sold in the ordinary course of business, and ought not to charge more than the total of the usual retail prices of the ingredients of the medicine dispensed. But that is quite a wrong view of the matter; the question of the commercial value of the ingredients of medicine dispensed from prescriptions does not enter into consideration, except in a very minor degree. The charge is really made for dispensing the medicine ordered, and the price paid represents the value set by the dispenser upon his professional services. That value may be an extremely high one, or it may be absurdly low, but have we not heard of some public analysts undertaking water analyses for five or ten shillings each, prices which their more reputable brethren consider insufficient and unprofessional? Let it be clearly understood, therefore, that inasmuch as the pharmacist's price for dispensing is as purely professional a charge as the analyst's fee for services rendered, it is both incorrect and needlessly offensive to speak of the profits on the ingredients of medicine dispensed from prescriptions as the *British Food Journal* does.

ACCURACY IN DISPENSING is questioned in the *British Food Journal*, in the note previously referred to, the only basis for supposititious lack of accuracy being some misinterpreted evidence given in a case brought some months ago (see *P.J.*, last volume, p. 272) against a registered chemist by the Fulham Vestry. What was accepted as proved in that case by the magistrate was that each dose of the mixture in question contained one-third of a grain of potassium iodide in excess of the forty grains ordered. The writer in the *British Food Journal*, however, represents the action of the magistrate in dismissing the case as being equivalent to permitting a grocer to supply anything between $17\frac{1}{2}$ and $14\frac{1}{4}$ ounces when a pound of tea is asked for. But, surely the conductors of the official organ of the International Commission on Adulteration should possess sufficient common sense to recognise the absurdity of such a comparison of facts which are not at all parallel. Beyond question, it is of the highest importance that prescriptions should be dispensed strictly in accordance with the directions of the prescribers, but it is almost equally important that critics of magisterial decisions should know what they are writing about. The fact that anyone can misinterpret Mr. Rose's plainly worded decision into a statement that, provided the drugs prescribed are contained in the medicine the quantity present does not matter, suffices amply to prove the utter incompetence of such a person to comprehend the report of the case. What Mr. Rose did say was that he doubted whether the Sale of Food and Drugs Act was meant to be applied in a case of the nature of that brought before him; it had no relation, he thought, to a trifling excess of an ingredient in a bottle of medicine, and it could not be supposed that the Act was intended to enforce "absolute exactness" in dispensing medicine from a prescription.

THE "MEDICAL PRESS," by the way, accepts the views of the *British Food Journal*, as representing the facts, and expresses the opinion that the Pharmaceutical Society is the proper body to take the matter in hand. At the same time, that badly-informed organ of medical opinion assumes it may be taken for granted that the Society will do nothing of the kind. That assumption is correct, as it happens, but for a very different reason to that malevolently implied in our contemporary's remarks. In the first place, the Pharmaceutical Society possesses no powers which would enable it to take action in such cases; secondly, if it were possessed of such powers, those responsible for the conduct of its affairs would do what the editor of the *Medical Press* is apt to neglect, *i.e.*, make sure that the facts of the case justified action being taken. For some reason or other the medical organ referred to distinguishes itself almost continually by attacks, which are imperfectly veiled at best, upon the Pharmaceutical Society or upon registered chemists. Readers will recall an objectionable paragraph in its pages, from which we quoted a few weeks ago (see last volume, p. 612), in which it was impudently asserted that compressed tablets afford facilities for the administration in minute doses of the very active alkaloids, "which the practitioner prudently hesitates to order in a prescription." That is to say, the dispensing skill of a factory hand who turns out compressed tablets by the thousand, by the simple operation of turning a crank or setting an engine in motion, is appraised more highly than that of an educated and properly trained pharmacist. The exaggeration, of course, was too palpable for the passage quoted to affect any level-headed reader, even to an infinitesimal degree, but the incident is symptomatic of that strong feeling against pharmacists which, unfortunately is ever-present amongst a large section of the medical profession.

SIR HENRY LITTLEJOHN may have been justified in asserting that chloral is too easily obtained by the public and that boys and girls, amongst others, can get possession of it without let or hindrance (see *ante*, p. 15), but it must be remembered that he was referring to Scotland only, and probably not to sales by registered chemists so much as those effected in establishments where poisons are sold illegally. If the facts be as stated, however, the blame rests with the sheriffs and other public officials in Scotland, who have done all they could to discourage the Pharmaceutical Society in its efforts to carry out the law. It has been asserted that the Pharmacy Act, 1868, is practically a dead letter in Scotland; if that be so, it is the effect of persistent obstruction by those who should have done their utmost to secure the respect for the law. Sheriffs have declined to give judgments, in the face of the evidence, or they have imposed absurdly small penalties; they have also denied the right of the Pharmaceutical Society to proceed under Section 17 of the Pharmacy Act, though the Procurator-Fiscal asserts that the Society is the proper body to take action and declines to do so himself. Hence, so far as pharmacy law in Scotland is concerned, there is, as has been pertinently observed, "stagnation, confusion, and aggravation." Meanwhile, as usual, the public is the chief sufferer, and sooner or later something will have to be done to secure due observance of the law, even in Scotland. If, therefore, Sir Henry Littlejohn's remarks have the effect of directing public attention to what is a very serious difficulty, they will have been well said. For the credit of Scottish pharmacy, however, we had hoped, ere this, to have learned that some steps had been taken to refute, or minimise the effects of, Sir Henry Littlejohn's statements—so far, at least, as they have been supposed to reflect upon registered chemists.

MR. J. G. F. RICHARDSON, whose death is announced this week, was formerly a member of Council of the Pharmaceutical Society, a position he occupied during several years. He was a student at the School of Pharmacy in 1856, passed the Minor and Major examinations in 1857, and shortly afterwards became partner in an old-established drug business in Leicester, which subsequently de-

veloped into the large and well-known manufacturing concern, of which he was so long the head. He was a member of the Leicester Town Council for nine years and also a Justice of the Peace for the borough, whilst for some twenty-five years he was an enthusiastic Volunteer, attaining ultimately to the rank of lieutenant-colonel in the local Volunteer force. For some years past Mr. Richardson has been unable to take any active part in business affairs, and he died in London, at the age of sixty-five years, on Saturday last.

REFERRING TO MR. GUYER'S COMMUNICATION (see p. 30), it can only be said that the official process of determination used by him has been proved to be inaccurate, and it is not sufficient evidence of deterioration in the alkaloidal contents of liquid extract of ipecacuanha to rely on such a method. Moreover, the results obtained by him in other ways are not given, and they could not have agreed with those arrived at by the B.P. process of determination. Mr. Guyer is advised to continue the investigation; but employing throughout, say for example, one of the other two methods he mentions, and ascertaining the alkaloidal value by titration. The loss of 26.5 per cent. of ipecacuanha alkaloids in two months is not confirmed, or even rendered probable, by "believing that the results are absolutely as reliable as the processes will allow."

THE LACK OF A GENERAL INDEX to later volumes of the *Pharmaceutical Journal* has exasperated one reader, who asks, When is "the wealthy Pharmaceutical Society of Great and Greater Britain" going to issue an index to the Journal for the last twenty years? He continues: "It is too bad that searchers after truth should be compelled to wade through the last twenty volumes to find some classic memoir. This is not conservation of energy. Why does the treasurer of the Society keep his breeches' pockets buttoned? The Chemical Society has recently issued an index at a nominal charge of twelvepence."

THE STORY OF A BROKEN PHIAL suggests to a correspondent that the War Office seems to be unrivalled in the art of delay for delay's sake. An Army dispenser, who was some months ago attached to the Belfast Military District, described the difficulties he had in obtaining another phial when one got smashed. "(1) Who broke it? (2) When was it broken. (3) How was it broken? (4) Was it broken by fair wear and tear, through carelessness, or by accident?" These were but few of the searching interrogative minutiae which were formulated regarding sixpenceworth of glass, in the interests of the British Army, and for the preservation of the Empire. The dispenser (like Captain Percy Turner) found it more expeditious and less vexatious to provide the article (and out of his own pocket) than to wait three months! There was also a large-lettered *nota bene*, no doubt in order to emphasise the enormity of the crime particularly impressing upon the dispenser the fact that this money had to be provided at the expense of the Government, which shows that the War Office really has the interests of the country at heart. It appears also that all drugs and surgical appliances are supplied from London, and though there is no necessity to create of this an Irish grievance, contracting chemists in extensive military districts like Belfast are thought to deserve some consideration.

EVENING MEETING IN EDINBURGH.—The third evening meeting of the present Session will take place at 36, York Place, on Wednesday next, the 17th instant, at 8.30 precisely. The proceedings will comprise papers by Mr. George F. Merson, F.C.S., on "Commercial and Powdered Myrrh," and "Tincture of Myrrh." The usual explanatory references to recent additions to the Society's museum in Edinburgh will also be made. The chair will be taken by Mr. P. Boa, punctually at the hour named.

ENGLISH NEWS.

PUBLIC DISPENSERS' ASSOCIATION.—A special general meeting of this Association was held at its new rooms, St. Bride's Institute, Ludgate Circus, on Wednesday, January 3, for the purpose of giving effect to a motion of affiliation passed by the Poor-law Dispensers' Association, Mr. Welford in the chair. It was decided that the name of the Association should be changed to the Public and Poor-law Dispensers' Association, that the Poor-law members of the Council should form a sub-executive, together with a secretary for Poor-law matters, and that in future there should be two secretaries—one for the general duties of the Association and one for Poor-law. The meeting then became the second annual meeting of the Public Dispensers' Association, Mr. Welford again presiding. The Secretary (Mr. Forster) having read the Council's annual report, Mr. Donnan, the Treasurer, then gave his financial statement, which showed, after paying rent up till April, the Association had a balance in hand of £1 6s. 2d. The Executive was then elected as follows:—Mr. F. N. Clark, Chairman; Mr. Welford, Vice-chairman; Mr. Hewitt, Treasurer; Mr. Forster, General Secretary; Mr. M. Smith, Poor-law Secretary. Council:—Messrs. Duff, Miller, Spencer, Totten, Lindsay, and Donnan. A suggestion that all country dispensers should be written to and asked to join having been brought forward, the meeting adjourned.

EXETER SCHOOL OF PHARMACY.—On Wednesday, January 10, Lady Poltimore distributed the prizes and advanced certificates gained by the successful students at the Royal Albert Memorial College, Exeter, to which is attached the Exeter School of Pharmacy, in charge of Mr. Alan H. Ware, Ph., Ch., the Principal of the College being Mr. A. W. Clayden. During the session 1898-1899 there were fewer pharmaceutical students than usual, but most of these obtained successes in chemistry and botany examinations of the Science and Art Department. Several former students of the College have also at recent examinations succeeded in winning their "Minor" qualifications. Three students have presented themselves for the examination at present proceeding, and have been so far successful as to have passed the practical tests of the first day. There are also students working full time for the April or June examinations of the present year. The pharmaceutical prizes were presented as follows:—The prize of one guinea presented by Mr. J. Hinton Lake (local secretary of the Pharmaceutical Society) was divided between W. W. Wilcock and G. H. Kynaston, the former obtaining the same examination success as the winner of Mr. Gadd's prize named below, and the latter doing best in elementary chemistry. Mr. G. Stocker's prize of one guinea was awarded to E. Kingsley Monks, who did best in botany during the session. The prize of one guinea offered by Alderman H. Gadd, J.P., to the senior students in chemistry was divided between W. Samways and H. Pellow.

NORTH-EAST LANCASHIRE CHEMISTS' ASSOCIATION.—At a meeting of the Darwen members of this Association, held on January 2, Mr. R. L. Gifford read a paper on "The Present Pharmaceutical Position," in which he again urged that, so far as concerns keeping open shop as a retail chemist, and selling scheduled poisons, qualified persons should be debarred from taking advantage of limited liability law. He maintained (1) that the views of the majority of the Law and Parliamentary Committee of the Council of the Pharmaceutical Society are right and ought to prevail, (2) that loyalty to the cause demands united action, (3) that it is unreasonable to expect men who stand upon a principle to barter it, and (4) that it is not unreasonable to ask men who acknowledge the justice of that principle to act with others because they are merely actuated by motives of expediency.

DEWSBURY AND DISTRICT CHEMISTS' ASSOCIATION.—At a meeting of this Association, held on Monday, January 8, Mr. A. Foster

(President) in the chair, a letter was read from Mr. H. T. Butler, secretary of Camwal, respecting a discussion at the last meeting of the Association on the proposed reconstruction scheme (see *P.J.* [4], 9, 594). Mr. Butler wrote to the effect that the impression created by the report of that meeting—*i.e.*, that Camwal was bound to supply shareholders with Camwal waters—was not correct, inasmuch as the fact of a person being a shareholder did not qualify him for a supply of the Association's waters.—It was suggested that a mistake had been made in the report, and that what was really said was to the effect that if a chemist ordered waters they would have to be sent where he directed, and in that way they might be sent to grocers or others who were not chemists.—Regret was expressed that any mistake should have occurred in the report, and the matter was then allowed to drop, the Secretary being instructed to write and ask Camwal for a copy of the articles of association.—Mention was made of the Chemists' Defence Fund, and it was announced that nine or ten members of the Association had applied for shares.

THE SALE OF RAT POISON.—An inquiry was held at Norwich on Saturday, January 6, touching the death of Hannah Holsia-Blyth (49), wife of a cattle dealer of Norwich.—Evidence was given to the effect that deceased had been strange in her manner for some time past, and had been carefully watched, because her friends thought she might take her own life. On the previous Wednesday, however, she went out with her grand-daughter. About seven o'clock she went out again, remarking that she was going to a chemist to get the baby some cough mixture, as the child was suffering from cough and cold. About nine o'clock she went to bed, and shortly afterwards told her husband she had taken rat poison. She was very sick during the night. The next morning a doctor was called in. Death, however, occurred on Friday, and in the doctor's opinion was due to poison.—A paper was found in the bedroom bearing the words "Rat Poison," and, according to the evidence of Mr. Orson Boswell Wilson, chemist and druggist, of St. Catherine's Plain, Norwich, it had contained a coloured powder composed of arsenic and a blue pigment, which he had supplied to deceased. He had known her for thirty years and had never noticed any peculiarity about her, so that when she came to his shop on the previous Wednesday for some cough mixture and afterwards asked for some rat poison, as she was troubled with rats, he gave her some wrapped in a paper, marked "Rat Poison." That he put in another paper and sealed it for security. There was about half a teaspoonful of powder. He entered the sale in his poison-book, but did not ask her to sign it.—The Coroner said he thought it would have been better if Mr. Wilson had gone through the usual course. He did not say it would, but it might have caused the woman to alter her mind.—The Foreman said it was absolutely necessary to have a signature, and not under any consideration to act contrary to the Pharmacy Act.—A Juror asked if there was a red label on the packet.—Mr. Wilson said no; he thought it was a white label.—The Coroner briefly summed up the evidence, and said no doubt death was due to poison. There was also no doubt that deceased had been in a bad state of mind, and there was every reason to believe that she had been well looked after. He did not know that there was any cause to complain of anybody's action. But with regard to the chemist, neither Mr. Wilson nor any other chemist should sell a preparation such as had been sold in that case without complying with the Act. No distinction should be made, and he believed that chemists generally were very careful in every respect.—A verdict of "suicide whilst temporarily insane" was returned.

POISONING BY CARBOLIC ACID.—On Thursday, January 4, an inquiry was held at Mansfield into the circumstances attending the death of John T. Spilman, aged twenty, son of a farmer residing at Clexby House, Caistor, Lincolnshire.—From

the evidence it appeared that while deceased was on a visit to Councillor G. A. Fish he was taken ill. A doctor, thinking the case to be one of typhoid fever, prescribed accordingly, and requested that a bottle of carbolic acid should be procured for disinfecting purposes. That was done, but, unfortunately, on the evening of January 3, the bottle containing carbolic acid was placed on the mantel-piece, while the one containing medicine was placed on the wash-stand, the result being that during the night a dose of carbolic acid was administered to the patient by mistake.—The jury returned a verdict of "Death by misadventure," and also recommended that bottles containing poison should be so made as to be quite distinctive from ordinary medicine bottles.

OVERDOSE OF CHLORAL HYDRATE.—An inquiry was held at Buxton on January 2 with respect to the death of William Plant (twenty-nine), until recently landlord of the Waterloo Hotel, Taddington.—Evidence was given to the effect that deceased engaged a bed at the Shakespeare Hotel, Buxton, on Monday, January 1, and retired at about 11.10 p.m. Next morning he was found dead in bed, with his clothes on. Three bottles were found in his pockets, two containing chloral hydrate and one containing potassium bromide.—A medical man having stated that he had treated the deceased man for sleeplessness, and that in his opinion death was due to an overdose of chloral hydrate, the jury recorded a verdict to the effect that death was due to chloral hydrate poisoning, but there was not sufficient evidence to show with what intention it was taken.

MERCURIAL POISONING.—John Jordan (forty-four), a shepherd, of Tettenhall Wood, Wolverhampton, has died as the result of drinking a preparation for foot-rot in sheep. He informed the surgeon who attended him that he had taken a quantity of the medicine, and death was found to be due to mercurial poisoning. An inquest was held on January 2, when a verdict of "Death by misadventure" was returned.

THE SALE OF COMPOUND RHUBARB POWDER.—At West Ham Police Court on January 3, George S. Drayton, chemist and druggist, 80, Woodgrange Road, Forest Gate, E., was summoned for selling compound rhubarb powder not of the nature, substance, and quality demanded, such article not being "genuine compound rhubarb powder according to the formula of the British Pharmacopœia—it contained only 30 per cent. of magnesia, whereas 66.6 per cent. is prescribed by the British Pharmacopœia."—Defendant said he had only recently taken over the business, and the article in question was already made up and marked. After his attention had been drawn to the matter, he examined the article and found that it had been made with carbonate of magnesia instead of oxide of magnesia. Most chemists used the carbonate instead of the oxide (*sic*), as it mixed more freely with water.—Alfred Smith, one of the sanitary officials, stated that he purchased $\frac{1}{2}$ oz. of compound rhubarb powder at defendant's shop on November 14. Defendant served him.—Cross-examined by defendant he said he did not ask for "compound rhubarb powder, B.P.," nor did he present a doctor's prescription. He asked for "compound rhubarb powder."—Thomas W. Crocker, another assistant, spoke to receiving the article, and added in reply to Dr. Sanders (West Ham Medical Officer of Health) that he intended to purchase the British Pharmacopœia article. He understood that to be the only standard.—Mr. Baggallay (the magistrate): When did it become so?—Witness: It is only common knowledge.—In answer to defendant witness said Mr. Smith was not told to purchase the B.P. article. He had his instructions in writing.—Mr. Baggallay: It does not matter what were his instructions; he did not ask for "compound rhubarb pow-

der, B.P."—Defendant: Unless the B.P. is specially asked for the chemist uses his discretion. It makes not the slightest difference. The chief ingredients, ginger and rhubarb, are in the proper proportion.—Mr. Baggallay said he was of opinion that the summons could not be supported, even if it was in itself good. The information stated that the article was not genuine compound rhubarb powder according to the British Pharmacopœia, as it contained only 30 per cent. of magnesia, whereas 66 per cent. was prescribed by the B.P. But it was not necessary that a drug to be genuine should be made according to the B.P. There was no Act of Parliament which made the B.P. the standard of any compound of drugs. The statement that the drug was not according to the B.P. was bad on the face of it, but if that was not bad the certificate of the analyst did not prove the case. He did not say the compound rhubarb powder was not genuine, but that it was not in accordance with the British Pharmacopœia. The case would be dismissed.—Mr. Drayton asked for costs, and was granted 10s.

DEFICIENT SPIRIT OF CAMPHOR.—At the County Petty Sessions, on December 19, Joseph W. Coulston, described as a drug vendor, of Wymondham, was summoned for selling deficient spirit of camphor, and was ordered to pay the costs, £1 0s. 6d., the defence being that he had only recently purchased the business, including the whole stock, and he supposed that the article in question was of proper strength.

SULPHURIC ACID IN VINEGAR.—Samuel Thompson, grocer, 22, Brewer Street, London, W., was summoned at Marlborough Street Police Court on December 29 for selling vinegar adulterated with 0.1556 per cent. of sulphuric acid.—Dr. Edmunds, public analyst to the St. James's Vestry, stated that he found in the vinegar in question the quantity of sulphuric acid mentioned in the summons.—For the defence Dr. J. Atfield gave evidence to the effect that he had examined a sample of the vinegar and had applied every test for sulphuric acid, but could find no trace of it. He did, however, find some phosphoric acid, which was a natural constituent of vinegar.—The prosecution then produced a letter from Somerset House, where a sample of the vinegar had been sent for independent analysis, in which it was stated that the authorities confirmed Dr. Edmunds' certificate.—Mention having been made of the fact that defendant had previously been fined for selling adulterated cocoa, a fine of £5 with six guineas costs was imposed.

IRISH NEWS.

PHARMACEUTICAL SOCIETY OF IRELAND.—The following have passed the preliminary examination:—J. R. D. Holtby, J. Anderson, J. W. Middleton, W. H. McCarthy, A. Haire (F. J. Fitzpatrick and H. C. Smyth—equal), (J. W. Hatch, D. S. Thomson, and W. Walsh—equal), H. Ramage, J. J. Tobin, W. B. Stewart, T. H. Kane, G. L. Lyons, T. V. L. Watson, A. D. McMurray, M. Murphy. Six candidates were rejected.

DUBLIN IMPORTS AND EXPORTS.—According to the trade returns of the port of Dublin for the month of December last, just issued, the exports of chemical goods from Dublin were valued at £38,835, while the imports into Dublin of chemical goods, including dye-stuffs, etc., were valued at £12,718. The quantity of oils imported into Dublin during December were valued at £29,185, while for the whole of the past year they were valued at £1,332,355. The quantity of chemical goods exported at Dublin during 1899 was valued at £466,308, while the quantity imported during 1899 was valued at £284,470.

PHARMACEUTICAL SOCIETY OF IRELAND.

Meeting of the Council.

The monthly meeting of the Council was held on Wednesday, January 3, at 67, Lower Mount Street, Dublin. The members present were Messrs. J. J. Bernard, Wells, Simpson, Dr. Walsh, Grindley, Porter, Michie, and Professor Tichborne.

On the motion of Mr. GRINDLEY, seconded by Mr. SIMPSON,

The chair was taken by Mr. Wells, a letter of resignation of the office of President having been received from Mr. R. J. Downes, and Mr. Beggs (the Vice-President) being absent through illness.

The minutes of the last meeting having been read,

Mr. BERNARD asked if the Society had been able to recommend any members to offer themselves as compounders of medicine in the military hospitals.

Mr. FERRALL, the Registrar, said two names had been sent forward.

Mr. BERNARD: The remuneration offered is so small that the authorities will hardly get pharmaceutical chemists to do the duty.

Mr. GRINDLEY: They have been inviting them to go out to South Africa.

The CHAIRMAN: Ten have been taken from London and ten from Edinburgh, and of the latter ten five were qualified and five were unqualified. The authorities have paid more attention to the chest measurements of the men than to their qualifications as pharmacists. Before proceeding to the business on the agenda paper it is right that a resolution should be passed expressing regret at the death of Dr. Hodges, of Belfast, one of the original members of the Council. He was highly respected in the north of Ireland, and was a man of great scientific attainments.

On the motion of Mr. PORTER, it was ordered that a letter of sympathy should be addressed to the relatives of the late Dr. Hodges.

RESIGNATION OF THE PRESIDENT.

The REGISTRAR then read the following letter from Mr. Downes:—

22nd December, 1899.

To the Vice-President and Council, etc.

Gentlemen,—The time has arrived when I must emphatically relinquish the honourable position in which you have placed me as President. My health suffers increasingly, and I find I have lost that energy and buoyancy which in the coming session are essential for the prosecution of your labours. You will please take this as irrevocable, as there is no use in asking me to reconsider. I take the opportunity of thanking you all for the great kindness I have always received from you, for the high honours you have put on me, and the assistance you have given me in the discharge of my office.

I am, Gentlemen,

Yours truly,

ROBERT J. DOWNES.

The CHAIRMAN said he was sure every member of the Council, as well as of the Society generally, regretted that Mr. Downes' state of health compelled him to resign office. He had held the office of President with very great honour to himself as well as advantage to the Society. It would be unfair to take the usual course of asking him to reconsider his decision.

Dr. WALSH, in moving that the resignation of Mr. Downes be accepted with great regret, said it should be conveyed to him that they all wished that he could retain office.

Mr. GRINDLEY seconded the motion, which was agreed to.

Mr. BERNARD: It is only a resignation of the office of President?

The CHAIRMAN: That is all. I hope that after a little while we shall have him back here again.

Mr. GRINDLEY proposed that the Vice-President, Mr. Beggs, be elected President for the remainder of the year. He knew that he was thoroughly identified with the Society, and was quite sure that he would uphold the dignity of the office in every way in his power.

Mr. MICHIE said he had great pleasure in seconding the motion. Since he became a member of the Council he had had a great deal

to do with Mr. Beggs, and he was quite sure he would make a very competent President.

The CHAIRMAN, in putting the motion, said he was quite sure from what he knew of the energy of Mr. Beggs' character that he would make an excellent President. He (Mr. Wells) had spoken to him that day, and he said he was not at all anxious to take the office, but that if elected he would do his best to merit their confidence.

The motion was unanimously agreed to.

Dr. WALSH said he had great pleasure in moving that Mr. Bernard be elected to the vacant office of Vice-President.

Mr. SIMPSON seconded the motion.

Mr. BERNARD said that if he were to consult his own feelings he would not accept the office, but as he had always endeavoured to do his duty to the Society he did not feel at liberty to refuse it.

The CHAIRMAN, in putting the motion, said he felt perfectly confident that Mr. Bernard's abilities would enable him to discharge the duties of the office with the utmost efficiency.

The motion was passed unanimously, and

Mr. BERNARD, as Vice-President, took the chair, and said he felt deeply grateful for the good opinion they entertained of him, and hoped to show them that it was not misplaced.

Mr. WELLS then moved the following:—

That this Council desires to place on record and to convey to the Ex-President, Mr. Robert J. Downes, its high appreciation of the manner in which he filled the important office of President for the past two-and-a-quarter years, and also to thank him for the very efficient and zealous manner in which he performed the duties of the office; and they regret exceedingly that through ill-health he has been compelled to relinquish it.

He (Mr. Wells) had known Mr. Downes from the time he was himself a boy, and during all the intervening years he had been more or less associated with him. It was matter of history that he had served them well and faithfully. There had been active Presidents in the chair before him, but he did not think any of them had given more thought and attention to the work of the Society than he had done. It had been a mystery to him how Mr. Downes had found time to do the amount of writing he had had to do, especially last year, in connection with the company question; but he knew that when he accepted the office of President he did so simply on account of that work, which he entered upon with the wish to be able to see some definite result from it. Unfortunately, he was not in a position to continue it, and they were the losers; and the best thing they could do under the circumstances was to place on record their feelings in the matter. He would only add that it was the desire and hope of every member of the Council that it might please Providence to restore Mr. Downes to health, and that he might be amongst them again and able to assist them for many years to come.

Mr. GRINDLEY, in seconding the motion, said it was hardly a pleasure to do so, as they were losing one of the best Presidents they had ever had.

The VICE-PRESIDENT said it was a matter of great regret to him that the first duty he had to perform in the chair was to put this resolution. He was sure that it expressed not only their opinion of Mr. Downes as a colleague, but their feeling towards him as a personal friend.

The resolution passed unanimously.

CORRESPONDENCE.

A letter from the Privy Council Office enclosed a copy of the report of Sir George Duffey, the Lord Lieutenant's visitor, on the examinations held by the Council during the year. The report was referred to the School Committee.

A letter from the Attorney-General of the Isle of Man forwarded a copy of the Manx Pharmacy Bill. The Bill was referred to the Law Committee.

PROPOSED ANALYTICAL DEGREE FOR PHARMACISTS.

Professor TICHBORNE then moved his proposition, which stood over from the last meeting of the Council, in favour of the establish-

ment of a degree to meet the requirements of the Local Government Board as regards public analysts. He only asked the Council now to decide the principle involved—that was to say, that it was desirable to create a body of men able to take the position of public analyst.

Mr. SIMPSON asked what it was proposed to call the men who would thus be created?

Professor TICHBORNE said that was a matter of detail which should be left to a committee, but the name of the degree should be one that should not clash with that of pharmaceutical chemist.

Dr. WALSH thought that the matter was outside the scope of the Society. Undoubtedly in theory it was very good; and he believed that the pharmaceutical chemist who was also a practical analyst would be an ideal man for one of those positions under the Local Government Board. If any pharmaceutical chemist, however, wished to go in for one of them the only thing for him to do was to obtain the qualification of "F.I.C."; and as the Society's examination should not be lower than that for "F.I.C." he did not see what the difference would be.

The VICE-PRESIDENT said Dr. Walsh was not quite in order, and asked if anyone seconded the motion.

Mr. SIMPSON then seconded the motion as a matter of form.

Mr. MICHIE and Mr. WELLS having spoken in support of Dr. Walsh's view of the matter, the motion was put and negatived.

Other business having been disposed of, the Council adjourned.

GLASGOW CHEMISTS' AND DRUGGISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.

At the weekly meeting held on the 5th inst. the chair was occupied by the PRESIDENT, Mr. J. P. Gilmour, and a short paper on "Allan Ramsay" was contributed by Mr. M. Meldrum, Ph.C., after which Mr. J. P. Taylor read a paper entitled

For and Against a Curriculum.

He said the advantages of a curriculum were: (1) A more thorough education in the different branches of our profession; (2) more protection from Government for our trade; (3) a better social standing, and, presumably, better remuneration. To take these seriatim, it can hardly be denied that the establishing of a one or two years' curriculum of study in well-equipped, well-taught schools, such as we already have, where students would receive every encouragement to systematic and thorough education, would be an immense improvement on our present system of haphazard learning. It would compel men to attend to their class work, and would entail on them a course of study of sufficient duration to give every man with any brains at all an opportunity of making himself proficient. It would do away with the unavoidable cramming that most of us have to do in the course of a day session of a very few months, or an evening session of, sometimes, even a few years. Then, again, it would be of advantage to both teacher and taught, enabling both sides to do greater credit to themselves and to each other.

The second advantage referred to was increased Government protection. In fairness, if it were required of us that we should go to increased trouble and expense in order to qualify, then we would be entitled to demand some recompense in the assurance that our trade or profession would be secured to us, and to us alone. This, in fact, would be a necessary sequence to an enforced curriculum, or else the game would not be worth the candle.

The third advantage, the improved social standing which chemists would gain, may seem on the face of it to be somewhat paltry and insignificant, but it is really not so. One of the main difficulties which a chemist has to face in his efforts to make money is the impression which the public undoubtedly have, that he is only a shopkeeper, and is only entitled to the limited profit which shopkeepers are generally supposed to content themselves with. But

the chemist is a highly-skilled workman as well as a shopkeeper, and has a considerable amount of the professional element in his training, and he is as much entitled to charge for that skill as is the doctor to charge for his. But the public don't see that.

Turning next to the disadvantages which a curriculum would bring with it, the author said there was only one which he would mention—namely, the increased trouble and expense which would be laid upon students. Undoubtedly, he said, this is a very serious drawback, and until we have some assurance that adequate recompense will accrue, until we know that we are to be treated as worthy of a place in keeping with our skill, we will find few who will support a curriculum, and many in favour of preserving the existing state of things.

MANCHESTER PHARMACEUTICAL ASSOCIATION

The fourth general meeting of the session was held on Wednesday evening, when Mr. W. S. Glyn-Jones, Secretary of the Proprietary Articles Trade Association, delivered an address on

The P.A.T.A. and Its Defence Fund.

Mr. G. S. WOOLLEY, President, occupied the chair, and gave a hearty welcome to Mr. Glyn-Jones for his kindness in coming down to deliver his lecture. He further announced that owing to the War and other causes it had been decided by the Committee not to hold the annual ball.

Mr. GLYN-JONES, in his preliminary remarks, adverted to the usefulness of the Association and the justification shown for its existence. Its usefulness had been shown clearly in connection with the number of new proprietaries which were being added constantly to the protected list of the Association. During the past two years there had been attempts made by large proprietors to meet the trade in some way or other, and there was no doubt that their attempts to do this had been largely due to the organised efforts of the Association. They had been accused of opposing the schemes of certain people, because it had been alleged they had not been members of the Association. But this was not so. The Association had welcomed any scheme, provided it would guarantee a certain profit to the trade. Dealing with the proposal to form a defence section into a limited company, he said this had been done on the advice of their solicitor, who thought it would be better to put the thing on a sound business basis and make the contracts made mutually effective, and that as some sort of guarantee fund would be required they thought the best and simplest way of insuring that guarantee fund was to ask the members to take up one share, on which they would pay 5s., leaving 15s. to call up if necessary. For this they undertook to provide legal advice for members in the business in which they were engaged. This was certainly a desirable thing. There was as much need for an expert solicitor as for an expert medical man. The next object was to provide a legal defence for any members who might be prosecuted under any Acts affecting them in their business. He had no hesitation in saying that eight out of every ten chemists were to-day quite unwittingly committing technical offences under various Acts of Parliament. They would engage an analyst and solicitor to act for them up to a cost of £10, but it would be in the option of the Committee to take a case to a higher court if they considered the case was one which, in the interest of the trade, it was necessary they should get a higher opinion upon. A third object equally important was that of indemnifying members against loss arising from accidents in dispensing and retailing. At present it was considered that the charges of already established insurance societies were unnecessarily high. Information as to changes in Acts of Parliament would also be given so as to prevent members getting into difficulties, and it would be also important under which the whole trade would benefit by watching legislation in their interests. Already some 400 shares had been taken up, and in the course of the next six months it was hoped that the remaining 600 would be subscribed.

The CHAIRMAN said that if chemists could only be induced to take some interest in this matter it might result in something useful being done and protecting the members from vexatious prosecutions.

A discussion followed, and Mr. Glyn-Jones was accorded a cordial vote of thanks for his address.

Obituary.

BELL.—On January 5, at 73, Spring Bank, Hull, Eliza Mary, wife of Charles B. Bell, M.P.S. Aged 64.

KITSON.—On December 30, Edward John Kitson, Chemist and Druggist, Worcester. Aged 66. Mr. Kitson, who had been a member of the Pharmaceutical Society since 1893, was a native of Macclesfield, but had been in business in Worcester for over thirty years. He was for some time a member of the Board of Guardians, and on one occasion sought municipal honours, but with these exceptions the demands of his business precluded his engaging actively in public work. His death was quite unexpected, occurring suddenly in the early hours of Saturday morning, he being apparently in good health the previous evening.

MCALLISTER.—On December 29, Robert Dempster McAllister, Chemist and Druggist, late of Birmingham. Aged 37.

MEE.—On January 4, George Mee, Pharmaceutical Chemist, Enfield. Aged 64. Mr. Mee had been a member of the Pharmaceutical Society since 1869.

MORGAN.—On December 31, Richard Morgan, Chemist and Druggist, Stepney. Aged 39. Mr. Morgan had been connected with the Pharmaceutical Society for some years as an associate, and latterly as a member.

PALMER.—On January 2, Enoch Palmer, Chemist and Druggist, Great Grimsby. Aged 68. Mr. Palmer, who had been a member of the Pharmaceutical Society since 1871, was one of the oldest chemists in the town. He took an active interest in every movement that was for the welfare of the town, and in 1871 was elected to the Town Council. Twenty years later, 1891, he was made an Alderman, and in 1894 and 1895 was unanimously elected Mayor. He was greatly interested in educational matters, being Chairman of the Technical Instruction Committee, under the joint authority of the Town Council and the School Board. He was vice-chairman of the Watch Committee and a member of the Caistor Board of Guardians. He was on the Commission of the Peace for the borough of Grimsby and also for the Hundred of Bradley Haverstoe, in the parts of Lindsey.

RACKHAM.—The death occurred last week of George Rackham, formerly a Chemist and Druggist, of Borough High Street, S.E. Mr. Rackham had been for many years a member of St. Saviour's Board of Guardians and St. George the Martyr Vestry. His early life was spent in Canada, and for some time after he came to England he edited a local paper in Essex.

RICHARDSON.—On January 6, John George Frederick Richardson, Pharmaceutical Chemist, late of Leicester. Aged 65. Mr. Richardson, who had been a member of the Pharmaceutical Society since 1859, was at one time a member of the Council.

SHAPLEY.—On January 10, Charles Shapley, Pharmaceutical Chemist, Torquay. Aged 46. Mr. Shapley, who had been a member of the Pharmaceutical Society since 1875, was a member of a very old Torquay family, and was for many years secretary of the local Science and Art Schools. For a short time he was a member of the Town Council. He was a partner of the firm of Messrs. Shapley and Dwyer, carrying on business in the Strand, Torquay.

VAWSER.—On January 7, Jesse Vawser, Chemist and Druggist March, Cambs. Aged 60. Mr. Vawser had been a member of the Pharmaceutical Society since 1869.

ANSWERS TO QUERIES.

Special Notice.—Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured. Not more than six plants should be sent for recognition at one time.

Aubepine (C. J. M.—37/16).—It is anisic aldehyde.

Hyacinthin (C. J. M.—37/16).—It is not a simple body but a mixture, probably containing benzyl cinnamate or other benzyl esters, with cinnamyl alcohol.

Heliotropine (C. J. M.—37/16).—Yes. Heliotropine is made on the commercial scale from safrol; the method for so producing it is patented.

Medical Preliminary (H. F. W.—37/19).—No. You must pass an examination in the list approved by the General Medical Council.

Optical Examinations (G. A. M.—37/20).—You will find full particulars at page 251 of the Students' Number of the *Pharmaceutical Journal*, published September 9, 1899.

Hamamelin (J. A.—37/8).—Many of the eclectic resinoids and extractives, such as hamamelin, euonymin and others, are prepared both green and brown. R. H. Parker (*P. J.* [3], 12, 41, 62) has shown how those bodies are liable to variation. As probably the bark is richest in the astringent matter, we should prefer to use the brown form for suppositories, which are presumably for hæmorrhoids.

Employment of Shop Boy (J. F. N.—37/21).—The only law which appears to affect you in the matter is the Shop Hours Act, 1892, which provides that no young person (*i.e.*, under the age of eighteen), shall be employed in or about a shop for more than seventy-four hours, including meal times, in any one week; in addition, a notice referring to the provisions of the Act must be exhibited in a conspicuous place, in every shop where a young person is employed.

Non-Publication of Report (W. H. G.—16/14).—The author did not supply a copy of his paper, nor was any proper report of the meeting referred to received. Under the circumstances, the lack of novelty in the matter and in its manner of treatment was such that it was not thought desirable to incur unjustifiable expense by publishing anything beyond a bare summary such as appears in this week's issue. Doubtless the author would not be unwilling to read the paper again, in your town, for the benefit of such of his friends as have not yet heard it, especially if they express a desire to discuss it.

Stylographic Ink (S. H.—37/17).—Take any good writing ink and evaporate every ten fluid parts down to nine. Then make up to the original volume with mucilage of acacia and syrup, equal parts, and filter. Another formula is:—Tannin, 200 grains; gallic acid, 50 grains; indigo carmine, 320 grains; ferrous sulphate, 1 oz.; distilled water, 16 fluid ozs.; mucilage of acacia, 2 fluid ozs.; carbolic acid, 5 drops. Dissolve the tannin and gallic acid in part of the water, and the sulphate of iron separately in another part. Mix, add the indigo carmine, and when dissolved filter. Then add the mucilage and the phenol. Stylo inks should always be allowed to stand for some time to deposit, and then be carefully decanted, or filtered through a little moist absorbent cotton. They should be quite free from suspended matter.

THE STUDENTS' COLUMNS.

THE MATERIA MEDICA OF THE PHARMACOPŒIA.

Adeps.

LARD is the purified abdominal fat of the hog, *Sus scrofa*, Linn. (Order Ungulata). The flat leafy masses known as "flare" are well washed with water to free them from any salt that may have been used as a preservative; the external membranes are then removed as far as possible, and the fat is freed from moisture by exposure to the air for some hours, the effect of so drying it being to render it less liable to become rancid and mouldy. The fat is next cut into small pieces and beaten in a mortar, or otherwise suitably treated, until the membranous vesicles are completely broken and the fat is entirely released. The resulting mass is then heated in a vessel surrounded by warm water, at a temperature not exceeding 57°·2 C., and when the fat is completely melted it is separated from the membranous matter by straining through muslin. If the fat be heated to a higher temperature than that specified it will acquire an unpleasant odour and taste. After straining, the lard is stirred gently till cool to prevent granulation from the crystallisation of stearin and palmitin, but in such a way as to prevent the introduction of air into the melted fat, as that would tend to promote rancidity. Lard possesses emollient properties and is used to prevent poultices drying and sticking to the skin, as well as for making ointments. The official preparations of lard are adeps benzoatus, and the ointments of aconitine, atropine, cocain, iodine, mercury, mercuric nitrate, resin, and veratrine. It also enters into the composition of emplastrum cantharidis and pilula phosphori. Benzoated lard is prepared by melting lard, 500, on a water-bath, adding powdered benzoin (from carefully selected pieces), 15, and heating for 2 hours, frequently stirring meanwhile. The residue of the benzoin is then removed by straining, and granulation prevented by stirring the lard until cold. Benzoated lard is used in the preparation of the ointments of belladonna, cantharides, chrysarobin, galls, mercuric iodide, mercuric oleate, mercurous chloride, potassium iodide, stavesacre, sulphur, sulphur iodide, and zinc. Indurated lard (adepts induratus) is prepared by depriving lard of a portion of its oil by pressure. It may be employed in India and the Colonies when prevailing high temperatures render ordinary lard too soft for use in ointments.

CHARACTERS AND TESTS.—Pure lard should be soft, white, and of a uniform consistence, fusing at about 37°·8 C. and forming a clear liquid at a somewhat higher temperature. It should have only a slight fatty odour (indicating freedom from rancidity), be neutral to litmus (test for free fatty acids), and dissolve entirely in ether. The presence of common salt may be detected by boiling the lard with water, filtering when cool, acidifying the filtrate with nitric acid, and adding a few drops of silver nitrate solution, which gives the white curdy precipitate characteristic of chlorides. A clean platinum wire dipped into the liquid will indicate the presence of sodium by imparting a strong yellow coloration to the blue flame of a spirit lamp or a Bunsen burner. If starch has been added to whiten the lard, the cooled filtrate will be coloured blue on adding a little iodine solution. Cotton-seed oil is frequently present in American lard, and may be detected by Becchi's test: Heat 5 C.c. of the melted fat on a water-bath with a solution of 0·05 Gm. of silver nitrate in 5 C.c. of 90 per cent. alcohol, to which one drop of nitric acid has been added. After heating for five minutes, shake vigorously. The silver salt is reduced by cotton-seed oil, and the fatty layer which separates on standing is then of a dark colour. The limit of acidity is indicated by a per-

manent red colour being produced on dissolving 10 Gm. of lard in a mixture of equal volumes of chloroform and 90 per cent. alcohol, adding two drops of phenol-phthalein solution, and then 0·2 C.c. of volumetric solution of sodium hydroxide.

NOTES.—Lard consists approximately of 40 per cent. of stearin and palmitin, mixed with 60 per cent. of olein. It should dissolve in 22 parts of ether and 16 of oil of turpentine, and combine with 20 per cent. of potassium hydroxide. Its specific gravity at 15° C. is about 0·934 to 0·938 when fresh, but varies more widely according to age. American lard usually begins to melt below 36° C., and is therefore excluded by the official requirements. Rancidity in lard occurs chiefly when the fat is exposed to light; it is due partly to hydrolysis and partly perhaps to oxidation. If any water be present in lard it will not form a clear solution when dissolved in chloroform. Becchi's test alone does not afford conclusive evidence of the presence of cotton-seed oil in lard, as pure lard which has been exposed to the air will give the same reaction, and cotton-seed oil which has previously been heated fails to give it. A better test is that of Bevan, who finds that a decided pink coloration is given when 3 Gm. of lard containing as little as 1 p.c. of cotton-seed oil is heated in a salt bath for about half an hour, with 1 C.c. of amylic alcohol and 1 C.c. of a solution of sulphur (1 p.c.) in carbon disulphide.

Adeps Lanæ.

WOOL FAT, described as the purified cholesterin-fat of sheep's wool, is a mixture of uncertain composition, containing fatty alcohols—cholesterin, iso-cholesterin, etc., together with esters of those alcohols. Cholesterin, the most prominent constituent of the fat, is a monatomic alcohol, $C_{25}H_{43}OH$, of unknown constitution, which exists partly free and partly in the form of stearate and palmitate. The fat also contains a small quantity of ordinary glycerides; if it be saponified with alcoholic potash, and the alcohol be removed by evaporation, the resulting soap may be dissolved in water. The cholesterin can be extracted from the soap solution by agitation with ether and subsequent separation and evaporation of the ethereal layer; characteristic scaly crystals of cholesterin being left. Wool fat possesses emollient properties, and is very readily absorbed by the skin, thus promoting the action of remedies combined with it. Sheep's wool may contain as much as 30 per cent. of fat, but usually it contains 10 to 15 per cent. This is readily extracted by simply kneading the wool with water; the fat forms an emulsion with water, and, on heating, it separates as a distinct layer on top. It may be purified by repeated treatment with water in a centrifugal machine, or by other suitable processes, and can be freed entirely from water by heating until its weight is constant. The anhydrous fat is used for the preparation of hydrous wool fat. It is capable of incorporating more than its own weight of water—Squire states 25 per cent. more. Its saponification equivalent is equal to about 9 to 10 per cent. of potassium hydroxide.

CHARACTERS AND TESTS.—Wool fat is a yellowish, tenacious, unctuous substance, with a slight but peculiar odour, and its melting point varies from 40° to 44°·4 C. The fat dissolves readily in ether or in chloroform, but is less soluble in alcohol; 1 gramme requires 75 C.c. of boiling 90 per cent. alcohol to dissolve it "almost completely," and the greater part of the fat separates in flocks on cooling. When incinerated with free access of air, wool fat should not leave more than 0·3 per cent. of ash, and that should not be alkaline to litmus (indicating freedom from added alkali). The limit of acidity is indicated by a permanent red colour being produced on dissolving 10 Gm. of wool fat in 25 C.c. of ether, adding 2 drops of phenol-phthalein solution and then 0·1 C.c. of volumetric solution of sodium hydroxide. A solution of the fat in chloroform acquires a purple-red colour when poured gently over the surface of strong sulphuric acid; this reaction is characteristic of cholesterin.

Absence of particles of wool and other nitrogenous animal matter is indicated, according to the B.P., by the absence of ammoniacal odour when the fat is heated with sodium hydroxide solution, but it must be very indifferent wool fat which would give such an indication.

ADEPS LANÆ HYDROSUS.—Hydrous wool fat is prepared by placing wool fat, 7, in a warm mortar and adding—gradually and with constant trituration—distilled water, 3. It should be of a yellowish-white colour and free from rancid odour. When heated on a water-bath, it should separate into an upper oily layer and a lower aqueous layer, 10 Gm., so treated and stirred until the weight is constant, yielding not less than 7 Gm. of anhydrous wool fat. Hydrous wool fat is used in the preparation of unguentum conii and unguentum hamamelidis. It is capable of incorporating about half its weight of water and makes an excellent ointment basis when mixed with an equal weight of soft paraffin. The water present in the hydrous fat can be approximately determined by dissolving 10 Gm. in 10 C.c. of chloroform and measuring the water which separates.

Aloe Barbadosis.

BARBADOS OR CURAÇAO ALOES is the product of various species of *Aloe* (N. O. Liliaceæ), including *Aloe vera*, Linn., and *A. chinensis*, Baker. The leaves of the plants contain a yellow juice in the cells of the pericycle, which escapes when the leaves are cut transversely. The juice is concentrated by boiling, and when evaporation of moisture is complete the residue is poured into boxes or gourds and allowed to solidify. This variety of aloes is produced in the Dutch islands of Aruba, Bonaire, and Curaçao, chiefly from *A. chinensis*. Very little, if any, is now produced in Barbados. Aloes is chiefly remarkable for its slow purgative action, but it is also used as a bitter tonic in small doses. The B.P. dose is from 2 to 5 grains. The official preparations of Barbados aloes are aloin, decoctum aloes compositum, extractum aloes barbadensis, extractum colocynthis compositum, pilula aloes barbadensis, pilula aloes et ferri, pilula colocynthis composita, pilula colocynthis et hyoscyami, and tinctura aloes.

CHARACTERS AND TESTS.—The hard masses in which Barbados aloes occurs may vary in colour from yellowish or reddish-brown to chocolate-brown or almost black. The fracture may be dull and waxy or smooth and transparent, the differences in appearance being due to variations in the method of evaporating the juice. Small splinters of the opaque variety, when examined under the microscope, exhibit numerous minute crystals of aloin (barbaloin), imbedded in a transparent mass, but similar splinters from the glassy variety are quite transparent. The odour of Barbados aloes is disagreeable, and the taste is nauseous and bitter. The powder imparts a crimson colour to nitric acid, and yields a slight bluish-green colour when mixed with sulphuric acid and the vapour of nitric acid blown over. The first reaction serves as a distinction from Socotrine and Zanzibar aloes, which impart to nitric acid a reddish or yellowish-brown colour; the second distinguishes Barbados or Curaçao aloes from Natal aloes, which yields a bright blue colour under similar treatment. Barbados aloes is almost entirely soluble in 90 per cent. alcohol diluted with half its volume of water, and it should yield 70 per cent. to cold water.

NOTES.—The distinctive characters of Barbados or Curaçao aloes are the evanescent crimson colour imparted to nitric acid and the slight bluish-green colour produced with sulphuric acid and the vapour of nitric acid. The name *Aloe* is derived from the Greek *ἀλόη*, the aloë. *Aloe vera* (also known as *A. vulgaris*, Lam.; and *A. barbadensis*, Miller) is the common aloes of Spain and Northern Africa. *A. chinensis* is a native of China, now cultivated in the West Indies. Opaque (hepatic or livery) aloes appears to owe its peculiar appearance to the fact that evaporation is allowed to take place more slowly than in the case of the glassy or vitreous aloes, and the conditions

are therefore more favourable to the crystallisation of aloin. Rapid concentration of the juice to the extreme limit, succeeded by a quick cooling process, results in homogeneous transparent masses, which show no trace of crystals. Such masses, however, may become more or less opaque on keeping, owing to the slow crystallisation of the aloin. The only other variety commonly met with in the vitreous form is Cape aloes, which occurs in dark masses, often with a greenish tinge. It is easily distinguished by its marked sour odour, pale yellow powder, and the permanent green colour it imparts to nitric acid after standing a few minutes. Squire gives the solubility in water of Barbados aloes as 75 per cent., and states that it dissolves entirely in 60 per cent. alcohol. The solubility tests insure the use of a carefully-prepared drug.

Aloe Socotrina.

SOCOTRINE AND ZANZIBAR ALOES are obtained from *Aloe perryi*, Baker, and other species of *Aloe*. The juice that flows from the transversely cut leaves is collected in the island of Socotra and on the east coast of Africa, whence it is exported to Europe by way of Bombay. The juice is allowed to evaporate spontaneously, and arrives in this country in a semi-liquid or pasty condition; if the kegs or tins containing Socotrine aloes are allowed to remain undisturbed for awhile, the brownish-yellow, viscid, opaque contents tend to separate into a clear, dark-brown liquid and a dark yellow deposit of aloin in crystals. Socotrine aloes are less purgative than the Barbados variety, two grains of the latter being equal in that respect to three grains of Socotrine aloes. The B.P. dose of the latter is from 2 to 4 grains. The official preparations of Socotrine aloes are aloin, pilula aloes et asafetida, pilula aloes et myrrhæ, pilula aloes socotrinæ, pilula rhei composita, and tinctura benzoini composita.

CHARACTERS AND TESTS.—The odour of the fresh aloes is unpleasant, but an agreeable fragrance is developed on keeping. When dried at a gentle heat, Socotrine aloes forms hard dark-brown or nearly black masses, which break with a dull, waxy, uneven fracture, and are characterised by a strong but not disagreeable odour and an extremely bitter, nauseous taste. Zanzibar aloes may be regarded as a variety of Socotrine aloes. It is usually imported in liver-brown masses, which break with a dull, waxy fracture, differing from that of Socotrine aloes by being nearly smooth and even. The odour of Zanzibar aloes is strong and characteristic, and its taste is nauseous and bitter. Both Socotrine and Zanzibar aloes are usually of the opaque, hepatic variety, though they also occur in the vitreous variety. Examined under the microscope they exhibit numerous minute crystals of aloin (socaloin) imbedded in a transparent mass. Both kinds impart to nitric acid a reddish or yellowish-brown colour (distinction from Barbados and Curaçao aloes), and when the vapour of nitric acid is blown over the powder mixed with sulphuric acid no blue coloration is produced (distinction from Natal aloes). Both Socotrine and Zanzibar aloes dissolve almost entirely in 90 per cent. alcohol diluted with half its volume of water, or in 60 per cent. alcohol, and they should yield about 50 per cent. to water, leaving a practically inert residue.

NOTES.—The distinctive characters of Socotrine and Zanzibar aloes are the reddish or yellowish-brown colour imparted to nitric acid and the absence of colour when the powder is treated with sulphuric acid and the vapour of nitric acid. The specific name of *Aloe perryi* is derived from the name of the individual—Lieut. Perry—who first brought specimens of the plant to Kew. Garnet-coloured, translucent socotrine aloes from *A. perryi* may be seen in museums, but is not now found in commerce. Samples which are nearly black are unfit for pharmaceutical purposes. Fine qualities of Zanzibar aloes are sometimes slightly translucent. The nitric acid test is very important; no true Socotrine or Zanzibar aloes imparts a crimson colour to the acid. The solubility test suffices to exclude inferior samples of the true drugs.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

FAT- DESTROYING FUNGUS.

R. H. Biffen describes a fungus belonging to the Hypocreaceæ found on germinating coconuts, which has the property of breaking up the oil contained in the endosperm. The reproductive bodies observed were megaconids, microconids, pycnidiospores, and peritheces; but no ascospore could be discovered in the latter. The author attributes the property of splitting up oil to an enzyme, which can be obtained in a flocculent precipitate by the addition of an excess of absolute alcohol.—*Annals of Botany*, 1899, p. 363.

According to A. Gautier, arsenic is constantly present in the thyroid gland, apparently, like phosphorus and iodine, combined in the nucleins. When thyroid glands are submitted to peptic digestion, the peptones are absolutely free from arsenic, but the residual nucleins are relatively rich in that metalloid. Arsenic is also found in minute quantities in the spleen and in the skin, but no other organ gives even the faintest trace. This precise limitation of its occurrence has important toxicological significance, since its presence, even in minute trace, in any but the organs specified, is regarded as abnormal.—*Comp. rend.*, 129, 929.

ANIMAL FERMENTS.

The researches of B. Abelous and E. Gérard point to the probable co-existence of an oxidising and a reducing ferment in the tissues of the organs of animals. They find that when a maceration of horse kidney is allowed to act on a solution of potassium nitrate, that a certain amount of nitrite is formed, which after twenty-four hours in the incubator at 42° C., begins to diminish in quantity. If a trace of sodium nitrite be similarly treated, the greater part disappears; but if the kidney maceration be first boiled, no oxidation of the nitrite ensues. Similar but even more pronounced results of the same nature are obtained with the ferment precipitated from the aqueous kidney maceration by means of alcohol. Further, the reducing ferment may be almost wholly removed by submitting the renal pulp to the digestive reaction of papain or of trypsin, while the oxydase becomes even more energetic than before. On the other hand, the last-named ferment may be rendered inactive by removing the air from the aqueous maceration and exposing the experimental mixture to an atmosphere of inert gas, such as hydrogen.—*Comp. rend.*, 129, 1023.

STRONTIUM AND BARIUM PHOSPHIDES.

By reducing the phosphates of strontium or of barium by means of lampblack in the electric furnace, A. Jaboin has succeeded in obtaining the respective phosphides in a crystalline state. *Strontium phosphide*, Sr_3P_2 , which is a very stable body in dry air, occurs as a blackish mass of microscopic crystals, showing a bright, crystalline, reddish-brown fracture. Its density is 2.68; it rapidly decomposes in moist air. Hydrogen is without action on it below the fusing point of glass; it burns in chlorine at about 30° C. Bromine combines with it at 170-175° C., and iodine at a red heat. At very high temperature carbon replaces the phosphorus, so that during the preparation, exposure in the electric furnace must not be prolonged. Water causes its decomposition with the formation of strontium hydrate and phosphoretted hydrogen. It is not attacked by strong acids; with oxidising agents, violent reaction takes place. *Barium phosphide*, Ba_2P_3 , is analogous in all respects to the strontium compound, occurring in dark masses of minute crystals, with a brilliant fracture.—*Comp. rend.*, 129, 762.

VOL. 64. (FOURTH SERIES, VOL. 10.). No. 1543.

INFLUENCE OF SOLAR RAYS ON PLANTS.

E. C. Teodoresco has made a series of experiments on this subject, employing the spectroscope and different coloured screens. With regard to the leaf, he finds the various coloured rays to be less favourable to the development of their tissues than total light. The palisade and air tissues have a minimum development in the green, more in the red, most in the blue. The chloroleucites are smallest and least numerous in the green, the stomates are more numerous in the green than in the red, and in the red than in the blue. The results obtained in the root and in the stem confirmed the general conclusion that green light is least favourable to the development of the plant, the maximum development of all the tissues being, on the other hand, most promoted by the most refrangible rays of the spectrum, viz., the blue and the indigo.—*Ann. Sci. Nat. (Bot.)*, 10, 1899, p. 141.

EXPLOSION OF POTASSIUM CHLORATE.

Although potassium chlorate is not generally considered to be a detonating explosive, Berthelot finds that when suddenly introduced into surroundings previously heated to a temperature above that at which decomposition commences, it will detonate under ordinary pressure in an open vessel, even when enveloped in an inert gas. In that respect it resembles picric acid. This may be shown experimentally in the following manner. A glass tube 25 to 35 Mm. in diameter closed at one end, and fixed almost vertically, is heated in a gas flame to a red heat for about 25 to 30 Mm. of its length; in the meanwhile, a glass rod, drawn out to a thread, is dipped several times into a melted mass of $KClO_3$, each coat of the melted salt being allowed to cool before a fresh immersion is made. In this way a bead of the salt is formed at the end of the thread. This is then plunged into the red hot tube to about 10 Mm. from the bottom, taking care not to touch the sides. As the chlorate liquefies under the influence of heat radiating from the sides of the tube, it slowly drips on the bottom, and as each drop falls, a sharp detonation, accompanied by white fumes, will be obtained. The detonation, however, does not affect the melted salt which remains adherent to the glass thread. The chlorate detonates more markedly when heated directly in a hydrocarbon flame. The conditions cited above may easily be reproduced in the case of a great fire, where the walls of a warehouse may become heated as described; this probably explains the recent fatal explosion at the chlorate works of the United Alkali Company at St. Helens.—*Comp. rend.*, 129, 926.

ACTION OF HEAT ON SEEDS.

Doyère has shown that grains of wheat may be heated to 100° C. without affecting their powers of germination, if they have previously been dried *in vacuo*. V. Jodin finds that the same results may be obtained with certain seeds, without employing a vacuum, if the temperature be regulated so that they are thoroughly deprived of moisture before being exposed to a greater heat. Thus the seeds of *Lepidium latifolium* and peas, heated at once to 98° C. for ten hours were all killed; but if first exposed for twenty-five hours to a temperature of 60° C., then for ten hours to 98° C., 30 per cent. of the peas and 60 per cent. of the *Lepidium* seeds germinated. In fact, a temperature of 60° C. appears to be quite harmless to these particular seeds. This is only the case, however, if the seeds are exposed in an open vessel, so as to permit the rapid elimination of hygrometric moisture. If this be checked, the vitality of the seeds is at once impaired. If they are heated in sealed tubes, or even in tubes with an open capillary aperture, they are killed even at 40° C. But if a hygroscopic body, such as quicklime, be previously introduced into the same tubes, so as rapidly to absorb the moisture given off, the seeds remain as resistant to the effects of heat as those treated in an open vessel.—*Comp. rend.*, 129, 893.

CHEMISTRY OF JASMIN OIL.*

Some years ago the examination of jasmin oil was undertaken in the laboratory of Messrs. Heine, of Leipzig, and it was found to contain a considerable amount of benzyl acetate, $C_7H_7 \cdot C_2H_3O_2$. Subsequently Verley (*Compt. rend.*, 128-314), by heating a fraction of the oil with oxalic acid, obtained a crystalline product which he took to be phenyl-glycol, $C_6H_5 \cdot CH(OH)CH_2 \cdot OH$, and thence he inferred that the odour of the oil was due to the presence of phenyl-glycol-methylene acetal. $C_6H_5 \cdot CH-CH_2 \cdot O \cdot CH_2 \cdot O$

As it appeared unaccountable that a body of such marked characters should have been overlooked, the investigation of the oil was resumed by A. Hesse and F. Muller, and the behaviour of phenyl-glycol-methylene acetal with alkalies and acids was also studied. It was found to be readily volatisable with steam, unaltered when boiled with alcoholic potash, but readily convertible into phenyl-glycol when boiled with a 1 per cent. solution of oxalic. In the examination of jasmin oil it was first separated into fractions by distillation with steam, and the portion distilling between 96° and 101° was subjected to the action of oxalic acid, without yielding the least trace of phenyl-glycol. By saponification of the oil it yielded benzyl alcohol, with a small quantity of linalol and acetic acid, showing that the ester portion of the oil consists chiefly of benzyl acetate, with a small proportion of linalyl acetate.

But, though the results obtained sufficiently proved that the odour of jasmin oil is not due to phenyl-glycol-methylene acetal, it was evidently influenced by the presence of other bodies in small proportion, for the detection of which large quantities of the oil required to be operated upon. Then, in the second paper on the subject, Hesse and Muller state that the average composition of jasmin oil is benzyl acetate 65 per cent., linalyl acetate 7.5 per cent., including, perhaps, esters of other terpene alcohols, benzyl alcohol 6 per cent., linalol 16 per cent. (?), and other constituents amounting to about 5.5 per cent.

From the further investigation of the oil of jasmin flowers, Albert Hesse concludes that the most important constituents are indole, the methyl-ester of anthranilic acid, and a ketone of the formula $C_{11}H_{16}O$, to which he gives the name of jasmone.

INDOLE was determined by conversion into the picrate and the amount found to be 2.5 per cent. Indole reacts with sodium disulphite like aldehyde, forming a crystalline compound very sparingly soluble in methyl alcohol and again yielding indole when heated with alkalis.

ANTHRANILIC METHYL-ESTER was determined by several methods:—When it amounts to more than one per cent. of the oil, on mixing 1 C.c. of the oil with an equal volume of a cooled mixture of 1 C.c. concentrated sulphuric acid and 5 or 6 C.c. of ether, a crystalline sulphate of the ester is deposited: on washing the crystals with alcohol and ether and then decomposing with soda solution the methyl-ester is recovered. Crude jasmin flower oil does not react sharply with this reagent as neroli oil does, and hence Hesse infers that the amount of anthranilic methyl-ester in jasmin oil cannot be more than 0.5 per cent.

JASMONE, $C_{11}H_{16}O$, is a pale yellow oil, becomes darker when kept, it has an intense jasmin odour; specific gravity, 0.945 at 15° ; boils at 257° — 258° under a pressure of 755 Mm. The oxime, $C_{11}H_{17}ON$, crystallises in fine needles melting at 45° and volatilises with water vapour. The semi-carbazone melts between 201° and 204° . This ketone constituent of jasmin oil is contained in the fraction distilling in vacuum (4 Mm.) above 100° , or under normal pressure above 230° , and it can be separated by conversion into the oxime or the semi-carbazone. The crude oxime can be separated from oily admixtures by distillation with water, the oxime passing over last—or by shaking with dilute sulphuric acid, in which the oxime is very soluble, extracting the acid solution with ether, and then on neutralising the solution with ammonia, the oxime is deposited

in crystals. The amount obtained was 3.5 per cent. The semi-carbazone can be purified by distillation with water and from the non-volatile residue the ketone can be separated by treatment with the equivalent quantity of sulphuric acid and straining

COMMERCIAL MYRRH AND POWDERED MYRRH.*

BY GEORGE F. MERSON.

Pharmaceutical Chemist.

In examining a series of samples of myrrh obtained in the ordinary course of business from brokers and others, and variously described as "Sorts," "Sorts Elect.," "Sorts Parv.," etc., but all included in the generic title myrrh, I was struck by the widely dissimilar character of the samples, yet was unable, from official data, to say that they were other than what the Pharmacopœia directed to be used in the preparation of the tincture. One sample yielded, on ignition, as much as 15.7 per cent. of ash, over 8 per cent. of which was insoluble in acid; earthy impurities.

The Pharmacopœia gives in the case of similar gum-resins, asafetida and gamboge, an ash limit and a spirit solubility; yet in the case of myrrh, galbanum, and ammoniacum there is neither ash limit stated nor percentage which should be soluble in 90 per cent. alcohol given. It may be urged that myrrh is not of very great pharmaceutical importance, and that no special harm would accrue through the presence, more or less, of sand and other extraneous matter.

The same would apply equally to gamboge and asafetida, yet these substances are safeguarded from adulteration. The following notes make no pretence to absolute accuracy, but are intended for general guidance to pharmacists, the manipulations necessary being such as can be readily carried out at the dispensing counter.

* Read at an Evening Meeting of the Pharmaceutical Society in Edinburgh, January 17, 1900.

* *Berichte*, 32, 565, 765, 2611.

Tables I. and II. represent the approximate composition of twenty-five samples examined during the course of last year—eleven of lump and fourteen of powder—and obtained from all parts of the country. I am indebted to Mr. Rutherford Hill for nearly half of them, and which represent pharmacy north of the Tweed.

The figures given in the second column show the percentage soluble in 90 per cent. alcohol. This would include resin, essential oil, and moisture, and was arrived at by treating 1 Gm. in fine powder with successive small quantities of rectified spirit, filtering through two counterpoised filter papers, washing the insoluble portion till perfectly exhausted, drying at water oven temperature, and weighing. The weight of the insoluble residue expressed as per cent. is given in column three. Its composition would be gum, woody fibre, and extraneous mineral matter.

The ash was determined by igniting 1 Gm. of the drug, cooling and weighing. This treated with hydrochloric acid, washed with water, drying the insoluble portion and again weighing, gave respectively total ash, insoluble mineral matter (silica), and, by difference, soluble ash, as shown in columns four, six and five.

It will be noticed that there is a certain relationship between the percentage soluble in alcohol and the quantity of total ash present.

The higher the yield of spirit soluble matter the lower the percentage of ash. It is noteworthy also that, with the exception of the first four samples, the total ash is practically entirely soluble in dilute hydrochloric acid.

In other words, the normal ash of myrrh is entirely soluble. The small percentage of insoluble matter found in the ash of Nos. 5 to 11 was proved to be adherent sandy particles embedded in the surface layers of the pieces of myrrh. The soluble character of normal ash being thus proved it will aid us presently in fixing a standard of ash limit for the powder. No. 1 on the table was a very sandy sample. Fragments of granite or quartz, of considerable size, could be distinguished with the naked eye, hence the high yield of ash. When sifted and again ignited, the ash content fell very considerably.

It was "Small Sorts," and certainly not such as anyone would be likely to buy for tincture making.

Yet it, with Nos. 2 and 4, are closely reproduced in some of the powdered samples in Table II. The assumption that much of the siftings find their way into the commoner grades of powder is borne out by the amount of sand present in the powdered article of commerce. The soluble portion of the ash was found to be chiefly carbonates (as would be expected) of lime and magnesia, with traces of iron, but no attempt at a complete chemical analysis was made.

The insoluble portion was, to all intents and purposes, "silver sand," with, in the worst samples, a good deal of dust. Two only of the samples yielded over 5 per cent. of soluble ash, and these not to any extent in excessive quantity. Even *total* ash in good commercial myrrh does not reach 5 per cent., although K. Dieterich ('Year-Book,' 1899, p. 167) gives 10 per cent. as the limit of ash allowable. This, in my opinion, is much too high, even for powdered myrrh. Excluding No. 1 in Table I. as being not a fair type, but including Nos. 2, 3 and 4, which are undoubtedly of low grade, the mean total ash of ten samples is 4.75 per cent.

Dieterich also states that not more than 70 per cent. should be insoluble in alcohol. This, again, is, in my opinion, to allow too wide a margin.

I would incline to 65 per cent. of insoluble matter as the maximum, and that, according to column three in the tables, is a liberal allowance. The mean of ten samples, again, is 60.3 per cent., while if the first three are omitted we obtain 59.5 per cent. as the figure. The powders in Table II. show over all a mean of practically the same percentage, and I am tempted to suggest 60 per cent. insoluble in spirit as the correct figure.

Turning now to the powders, we find uniformity conspicuous by

its absence. Although the spirit soluble percentage is approximately the same as in the lump, the yield of ash is much more varied, as well as being altogether higher and containing a larger proportion of silica.

Table II. is interesting from the fact that it indicates what chemists' ideas of powdered myrrh are. The yields of ash shown by the table certainly indicate a wide range of quality.

Only in the very finest grades of powder does the total ash fall so low as 5 per cent. It would appear from the table that three only, Nos. 22, 23, and 25, are absolutely pure, although 16, 21, and 24 are by no means bad. Where the total ash rises above 6 per cent., and the insoluble portion exceeds 2 per cent., it is evident that carelessness, or intent, exists in the preparation of material for grinding.

As commercial myrrh contains an average of from 5 per cent. to 7½ per cent. of moisture, which is driven off before grinding, we must allow for a higher normal ash in the powder than we would pass in the crude state. As the crude drug can be valued fairly accurately by the eye and nose, so the powder, in which the resin value is fairly constant, can be assayed roughly, yet sufficiently accurately, for general purposes by the elutriation of a weighed quantity (say 1 Gm.) with warm spirit.

Two or three successive treatments in a small flask, using a tared-filter paper upon which to decant the liquid, and allowing a few moments for the denser particles to subside, will separate the powder as follows:—

Sand (chiefly) in flask,
Gum (insoluble) on filter paper,
Resin (in solution) in filtrate.

The flask, being tared before commencing the operation, is placed in a water oven to dry, likewise the filter paper with gum, this latter being washed with a little more alcohol if necessary. The net weight of sand and gum combined deducted from 1 Gm. will be the weight of resin. Even elutriation itself will show at a glance the presence or otherwise of an undue proportion of sand. This, of course, applies only to foreign mineral matter, not ash proper.

In addition to the above, for shop purposes, a rough assay may be made by igniting 1 Gm. in a porcelain crucible, treating the ash successively with dilute HCl and water in the crucible and pouring off the clear liquids. There should be practically no sandy or crystalline residue.

Colour is a useful guide to purity in powdered myrrh. The samples examined ranged in colour from rich lemon or straw for the finest varieties to dull greyish and brown for the common grades.

In the inferior sorts an ordinary hand lens, and even the naked eye, revealed distinctly crystalline particles in considerable quantity.

One Gm. of medium quality lump was powdered coarsely and dried on a watch glass in water oven for an hour, cooled in a desiccator, and weighed. Result: 0.911 Gm., equal to a loss of 8.9 per cent. The essential oil exuded freely and collected in globules on the watch glass. Even at this temperature the oil was seen to be volatilising, so that the loss did not accurately represent the moisture present. On again placing in water oven for a further period of twelve hours, cooling and weighing, the myrrh was found to have gained in weight to the extent of 0.011 Gm., whilst the globules of oil, which were quite fluid in the first instance, had become resinified. A similar quantity in coarse powder dried for forty-eight hours over sulphuric acid gave results equal to 7.42 per cent. of moisture, and practically the same was obtained (7.32 per cent.) with double the quantity in twelve hours.

The dried residues when finely powdered were of a beautiful lemon colour, and this shows that the darker grades of powdered myrrh on the market are the product of a much inferior gum resin.

Invariably a dull or dark-coloured powder is associated with a high ash yield and much insoluble mineral matter.

To summarise:—

(1) Myrrh is easily obtainable of good quality, and is not adulterated to any great extent, except by the inclusion of earthy matter which can readily be removed by sifting.

(2) The normal ash in good "sorts" does not exceed 5 per cent., which should be almost entirely soluble in dilute hydrochloric acid.

(3) One Gm. when exhausted by 90 per cent. alcohol should leave a residuc which, when dried at 100° C., should not weigh more than 0.60 Gm.

These data I would respectfully submit upon which to base a supplementary paragraph to be included in the British Pharmacopœia under "Characters and Tests."

TINCTURE OF MYRRH.*

BY GEORGE F. MERSON.
Pharmaceutical Chemist.

In the present Pharmacopœia, percolation as a means of exhaustion for drugs is much more largely employed than in the previous one, and I thought it might be interesting to see whether any special reason existed as to why tincture of myrrh, which was made by maceration and percolation in the 1885 edition, should, so to speak, take a backward step, and revert to maceration only. On the score of economy, which, efficiency being always kept in view, is an important feature in the manufacture of spirituous preparations, percolation gives a smaller loss of menstruum through evaporation, and a more perfect exhaustion, than does maceration.

The increased proportion of gum resin ordered in the present formula (4 oz. per pint, as against 2½ oz. previously) cannot be held as a reason for the change, as it is well known that, weight for weight, percolation will more thoroughly exhaust a drug than will maceration, provided always the substance is suitable for percolation—this, myrrh is. The Pharmacopœia orders myrrh in *coarse powder* and maceration for seven days in three-fourths of the final volume of 90 per cent. alcohol; filtering and washing the marc with more alcohol to produce the required volume of the tincture. The question here arises, what is a coarse powder? I would have said without hesitation No. 20, and several *confrères*, on being asked the question, at once gave No. 20 as being their reading. Some even said 16 to 18 in the case of myrrh. On glancing over the Pharmacopœia, however, we find that three common numbers, "degrees of coarseness or fineness," are employed—viz., 20, 30, and 40. Higher than these we have "fine powder" and "finest powder" specified, the degree of comminution being left to the common sense of the pharmacist. Conversely we have certain substances ordered in "coarse powder," which we are justified in taking to mean of a degree or degrees coarser than No. 20, but certainly not so fine as No. 20. Had No. 20 powder been meant in *Tinctura Myrrhæ*, why not say so? The assumption is that it is coarser than No. 20 that is indicated. However suitable such a powder might be in the case of woody or fibrous drugs, it is manifestly unsuited to a compact resinous body like myrrh. I made no attempt to experiment with anything in a coarser state than No. 20, thinking that no useful end would be served by doing so. I have prepared six quarter-pint lots of tincture from, respectively, 20, 30, and 40 powder, using maceration in one set and percolation in the other. The figures in Table III. give comparable results:—

TABLE III.

No. of Powder.	Maceration.		Percolation.	
	S.G. at 60° F.	Resin undissolved.	S.G. at 60° F.	Resin undissolved.
20	0.85044	8.2 p.c.	0.85120	3.4 p.c.
30	0.85090	3.7 p.c.	0.85182	1.5 p.c.
40	0.85192	1.3 p.c.	0.85250	0.0 p.c.

* Read at an Evening Meeting of the Pharmaceutical Society in Edinburgh, January 17, 1900.

It will be seen that percolation gives distinctly the better tincture. Not only is the specific gravity higher than that of the tincture made by maceration, but the percentage of undissolved resin in the exhausted marc is considerably lower. The time taken to finish the tincture is inside of twenty-four hours, as against seven days—an obvious advantage. No. 20 powder macerated with frequent agitation daily and finished off according to official directions left 8.2 per cent. of resin undissolved. No. 30 powder under similar treatment gives a specific gravity and percentage of undissolved resin which closely approximate the results obtained by *percolating* No. 20 powder, the latter, however, having slightly the advantage—the gravity being a trifle higher and the proportion of undissolved resin somewhat smaller. No. 30 powder percolated bears practically a similar relation to No. 40 macerated, while No. 40 powder percolated is to all intents and purposes completely exhausted.

The only drawback to using 40 powder is the difficulty experienced in getting the myrrh to pass so fine a sieve, owing to its oily nature.

Then, again, for percolation it is too moist and cohesive when freshly powdered to get introduced uniformly into a percolator without packing too hard. If, however, the powder be allowed to stand over-night in a closed vessel after sifting, it will cake somewhat, and can then be re-sifted in a "free" condition, oxidation of the oil, which is fairly rapid, bringing this about. The powder now run into a conical percolator, slowly rotating this the while and tapping the sides gently all round afterwards, will allow the menstruum to pass rapidly, and by the time half the spirit has passed the percolate will be practically colourless. A small pad of cotton is put in the bottom of the percolator before filling. When most of the colour has been discharged it is advisable to close the tap of the percolator, say over-night, for maceration, and draw off the remainder of the spirit in the morning. The marc may be pressed off, or the spirit recovered by distillation, although it is preferable to use about seven-eighths of the total volume of alcohol, drain, press off, adding pressings to the tincture and making up, if necessary, with more alcohol.

As the drug is exhausted before all the menstruum has passed through, there can be no objection to making up to bulk with spirit. It is no use attempting to displace with water, as can be done in *Tinct. Zingiberis*.

Consequent upon a paper read in November, 1894, by Mr. H. W. Jones, before the Midland Pharmaceutical Association, an exchange of ideas regarding the percolation of tincture of myrrh took place in the correspondence columns of the *Pharmaceutical Journal* between that gentleman and Mr. A. McKellar, of Glasgow. Mr. Jones advocated maceration and percolation, referring to the difficulty in getting uniform packing and freedom from air bubbles unless the drug was previously mixed with a considerable quantity of spirit and then transferred to the percolator. The air bubbles I do not think are of any moment, and if the creamy mixture is poured into the percolator the coarser particles settle at the bottom, leaving the fine powder in the upper layers—exactly the opposite condition to that which should prevail to secure thorough exhaustion. Solution of the resinous principle of myrrh is so rapid that a percolator should be chosen, relatively large, compared with the bulk of powder to be operated on, so that the tendency to clog, which is troublesome when using No. 40 powder in a long column of marc, may be obviated. The depth of powder in the percolator should not be more than twice the diameter of the lower part of the percolator. If 30 powder is used, there is no trouble with clogging if care is taken in filling the percolator.

Specific gravity varies considerably in samples of tincture which I have examined.

Colour gives no indication of the gravity of the tincture, or, if any, then in inverse ratio.

High-coloured tinctures are made from inferior grades of myrrh, and those having a high ash content will give a low spirit solubility. The specific gravity of one dark sample I found to be 0.8474, while the figure for a standard tincture should not fall below 0.851.

Specific gravity, however, is not of very much importance, as the percentage of moisture present in the crude drug, which is variable, will affect it to a greater or less extent, and it would be very easy to adjust a tincture to any given figure.

I have here two specimens each of tincture, powder, ash, and exhausted gum residue for comparison.

They are respectively examples of fine and common products.

STRYCHNINE HYDROCHLORIDE AND SODIUM ARSENATE.*

BY J. RUTHERFORD HILL.

In his paper at our last meeting Mr. Dunlop suggested, but did not profess to prove, that the precipitation of strychnine in his mixture (*Ph. J.*, page 604) was due to sodium oxide as a contamination in the sodium arsenate. Other explanations were suggested in the discussion. In view of the process for making sodium arsenate, sodium oxide as an impurity is improbable. Drying at 300 F. would not produce it. Moreover, I have found that the crystallised salt $\text{Na}_2\text{HAsO}_4 \cdot 12\text{H}_2\text{O}$ causes precipitation exactly in the same way as the dried salt, and there could be no sodium oxide in the crystals. The official liquor sodii arsenatis is only faintly alkaline at ordinary temperatures. Mr. Dunlop found at least 0.5 grain of strychnine precipitated from half an ounce of the solution. The sodium arsenate would have required to be contaminated with hydroxide to the extent of 2.75 per cent. to cause such a precipitation, and this would give a very distinct alkaline reaction. The hydroxide would have been detected in the alcohol with which the salt was washed, but I could find none. The evidence therefore seems to be that sodium oxide did not cause the precipitation. The varying reaction with mercuric chloride is referred to later.

It was suggested that the salt contained some sodium carbonate, and that this explained the precipitation. In view of the process of manufacture such a contamination is not at all improbable, but a salt so contaminated would not conform to the pharmacopœial tests. The salt I used in my experiments, and which acted in the same way as Mr. Dunlop reports, gave not the slightest indication of effervescence on adding strong sulphuric acid to the dry salt. I found that one part of Na_2CO_3 in 1000 of dried Na_2HAsO_4 could be quite distinctly detected by effervescence when treated in the foregoing way. The salt therefore contains no Na_2CO_3 or less than 0.1 per cent. But in order to precipitate 0.5 grain of strychnine you must have 0.08 grain Na_2CO_3 which is equal to 3.7 per cent. of a contamination, and that would be very readily detected by adding strong sulphuric acid. This leads to the conclusion that sodium carbonate is not the cause of the precipitation.

The third suggestion quoted by Mr. Dunlop, and supported in the discussion, was that sodium arsenate undergoes partial hydrolysis in aqueous solution, and that the faint alkalinity and precipitation of strychnine are due to the NaOH thus produced, the equation being,

Reference to authorities gave little useful information, but much was learned by reference to the isomorphous salt sodium phosphate Na_2HPO_4 , in regard to which Ostwald and others support the view as to hydrolysis of the salt in aqueous solution. On repeating experiments with both phosphate and arsenate of sodium, it was found that both acted in precisely the same way under similar conditions. When Na_2HAsO_4 is added to a solution of NH_4Cl there is no immediate evidence of free ammonia. But

if the solution is allowed to stand, free ammonia is plainly perceptible in a few hours both to test-papers and by smell. When the solution is heated free ammonia is immediately and very perceptibly evolved. This would indicate, and accords with theory, that hydrolysis takes time to develop at ordinary temperatures, and is hastened and probably increased at higher temperatures. This phenomenon may be easily demonstrated by adding a few drops of solution of phenolphthalein to a suitable quantity of liquor sodii arsenatis. Fill two test-tubes with the faintly-pink liquid. Heat one, and the tint will be observed to deepen gradually up to the boiling point. Place the hot tube alongside the cold tube and the contrast will be very distinctly seen. As the hot liquid cools the depth of colour gradually diminishes until after a few hours both tubes have again the same tint, showing that the salt has resumed the same molecular condition. The experiment may be repeated at will by again applying heat. The varying evidences of sodium oxide which Mr. Dunlop says he got with HgCl_2 may be due to differences in concentration of the solution, in the time it has stood, and in the temperature, all of which will affect the degree of hydrolysis and the percentage of free NaOH.

It was proved by Rose that a solution of Na_2HPO_4 decomposes NH_4Cl with liberation of NH_3 . Thomas has shown (*Journal of the Chemical Society*, vol. 33, p. 76), that Na_2HPO_4 absorbs HCl, giving up half its Na to form NaCl and NaH_2PO_4 . He found that when HCl is added to a saturated aqueous solution of Na_2HPO_4 at the boiling temperature, the whole of the acid combines with the Na of the phosphate and forms NaCl, provided there be two equivalents of Na to one of HCl in the solution. When tribasic sodium phosphate was dissolved in water, and HCl added equal to $\frac{3}{2}$ of the equivalent of the base, and the solution subjected to distillation in a vacuum, the distillate was neutral. If more than the above proportion of HCl was present, the distillate was acid. The reaction is made clear by the following equation:—

This result was confirmed by Stolba, who applies the method to the volumetric determination of phosphoric acid in minerals and manures by titration of ammonio-magnesian phosphate thus:—

Pagenstecher has also shown that solutions of Na_2HPO_4 absorb CO_2 . As already stated, sodium arsenate was found on experiment to behave in all cases precisely as sodium phosphate does.

All these observations favour the theory that sodium phosphate and arsenate in aqueous solution do undergo hydrolysis, and that the tendency is to separate into the dihydrogen phosphate or arsenate and sodium hydroxide. They tend also to suggest that the precipitation of strychnine is not due either to sodium carbonate or sodium oxide present as an impurity in the original salt, but to free NaOH, resulting from hydrolysis. Mr. Dunlop manifestly did not attempt to determine quite accurately the amount of strychnine precipitated, and the method of collecting with so small a quantity would probably be attended by considerable loss. He says he got about 0.5 grain, or twenty-eight per cent. That quantity would theoretically require for precipitation 0.06 grain of NaOH, and would indicate that little more than an eighth part of the sodium arsenate undergoes dissociation in the solution. This further seemed to favour the view of hydrolysis as the cause, for it is alleged, and confirmed by my experiments, that at ordinary temperatures the hydrolysis of the Na_2HAsO_4 is only partial and very slightly apparent by reagents. I was disposed to rest satisfied with this explanation, and the prescription in question seemed to furnish a very interesting proof of the fact of hydrolysis as well as a means of determining its extent by precipitation of a relatively definite quantity of strychnine.

But it occurred to me to test the actual amount of strychnine liberated with some accuracy, and in doing so the method of washing out the precipitated alkaloid with chloroform in the usual way

* Read at an Evening Meeting of the Pharmaceutical Society in Edinburgh, January 17, 1900.

was adopted in preference to the less convenient plan of collecting, as Mr. Dunlop did.

It may be noted that on mixing the two solutions, shaking the mixture, and allowing to stand, crystals were seen beginning to form in about five minutes. Using an aqueous solution of trychnine hydrochloride in place of the official liquor, which contains 25 per cent of 90 per cent. alcohol, crystals began to form almost at once, the precipitation was much more rapid, and the crystals showed less tendency to adhere to the sides of the bottle. The spirit, therefore, appears to slightly retard precipitation. The solutions were allowed to stand for twenty-four hours. The precipitated alkaloid was thoroughly washed out with four quantities of chloroform, collected in a tared beaker and weighed. Half an ounce of liquor strychninæ hydrochloridi contains 1.797 grain strychnine. Two determinations gave as a mean 1.780, or 0.017 less than theory requires. This result was a surprise. Observing that Mr. Dunlop only allowed his mixture to stand one hour, it occurred to me that the reaction had not concluded in that time. On repeating the determination, allowing the mixture to stand only one hour and then washing out the yield was 1.760 (one determination), or 0.037 less than theory. It therefore appears that even in an hour the whole of the alkaloid is set free, though probably only gradually deposited from solution. That the deficiencies above noted were due to experimental error was proved by adding faint excess of HCl to the solution from which the alkaloid had been washed out and then a little potassio-bismuthic iodide solution. The absence of any precipitate showed that the alkaloid had been entirely removed. An aqueous solution of strychnine containing about one in 8,000 gives a perfectly distinct precipitate under these conditions. It seemed therefore clear that the hydrolysis theory was not an adequate explanation of the facts.

A consideration of Thomas's researches with Na_2HPO_4 suggested what seems the true solution of the problem. In his critical experiment the reaction evidently is as follows:—

It seems probable, too, that free NH_3 is given off when solutions of Na_2HAsO_4 and NH_4Cl are boiled together thus:—

It does not, then, seem necessary to assume that there is any prior hydrolysis in aqueous solution. Doubtless there does seem to be some, but it is unimportant. It is well-known that mineral acids in combination with alkaloids behave like free acids towards the fixed alkalies. The instability of the Na_2HAsO_4 in solution and the loose attachment of the HCl in the strychnine hydrochloride result in a double decomposition, explained by the following equation:—

An analogous experiment with a one per cent. solution of quinine hydrochloride and sodium arsenate solution gave an immediate precipitate, almost making the liquid solid, of the bulky quinine hydrate which dissolved readily in ether. In the course of these experiments, many interesting points of a physico-chemical nature relating to theories of solution emerged, which neither time nor ability made it possible for me to follow up.

SODIUM METAVANADATE IN MEDICINE.—Pécourt points out that from the ease with which vanadic acid and its salts part with their oxygen in the presence of organic matter, and from the difficulty in obtaining sodium metavanadate in a pure state, the therapeutic results obtained with those compounds are not likely to be satisfactory, unless care be taken to ensure that the preparations are fully active. This is the more needful, since the erroneous opinion prevails that the vanadates are as stable as the phosphates (See *P.J.* [4], 493).

FACTS AND FANCIES.

BY AN ORDINARY PHARMACIST.

The Red Rag of Anonymity.

It is rather a curious comment on the boasted level-headedness of the average Briton that he can rarely avoid introducing personalities into any argument in which he may be engaged—he must, in fact, have something concrete to belabour. I notice that a correspondent in last week's Journal chafes at my incognito, and even goes to the flattering length of suggesting that in order to have "due weight" my views should bear my signature. Now, that seems a very neat compliment to pay one, but it hardly appeals to me. My name is not one to conjure with, and it certainly has nothing whatever to do with the soundness or otherwise of the views I have advanced on pharmaceutical matters. It has ever been a profound mystery to me why a truth should be deemed unworthy of credence unless coupled with the name of its herald; or why disputants eager to arrive at the right or wrong of a debatable matter should think rather less of crushing fallacies than of damaging the reputation or feelings of their opponents! A little reflection should show that whatever weight attaches to the observations published in this column would not in the least be enhanced by the announcement that the writer's name was Brown or Smith. On the other hand, I can foresee that a great deal of force might be lost—such is our peculiar mental constitution—if the author disclosed his ordinary name and his very ordinary position in pharmacy. For it must be said that the feeling which prompted the disparaging inquiry of old, "Can any good come out of Nazareth?" has its counterpart to-day in the innermost recesses of the national heart; and every man of average intelligence knows perfectly well that any shortcomings in social or official position, or any physical or moral blemish inherited or acquired, will invariably draw punishment down upon one's utterances, to the more or less utter asphyxiation of the truth that may be in them. I propose, therefore, still to skulk behind the mask of anonymity, as a prominent pharmacist pleasantly puts it, but if I can induce those who enter into the arena of pharmaceutical politics to cultivate a thinking habit, instead of emulating the "Stanislaus" methods of discussion, with their unparliamentary use of English and "old red sandstone," I shall have largely accomplished the object with which I have delivered myself into the hands of the printers.

Division of the Qualifying Examination.

Mr. James Lennox states, in his letter published last week (*ante*, p. 30), that he did not complain of lack of interest in the proposal to divide the qualifying examination, but in a suggested reform of examination procedure. I find it difficult to perceive, however, how placing to a candidate's credit at his second attempt to pass an examination the marks awarded to him in the subjects in which he has previously satisfied the examiners differs from division of that examination. As a matter of fact, the two suggested changes would be the same in effect, though in one case it would be definitely understood that certain subjects must be taken in each part of the divided examination, whereas in the other the candidate would only be required to satisfy the examiners in the subjects in which he had previously failed. Of the two plans the first appears to me preferable, and I would assure Mr. Lennox of my cordial approval of it, though I must still contend that it is not yet within the sphere of practical politics. I can only express my regret that he declines to recognise the necessity of further raising the standard in the event of the proposed division becoming, as I sincerely hope it may, an accomplished fact. If the supply of mere retailers of drugs and sundry articles were to be the primary duty of the Pharmaceutical Society, it might be a moot point whether much in the way of examination is required at all. My own view, however, has always been that the maintenance of a definite pharmaceutical qualification is a matter of much greater importance, and that would seem to necessitate a continual advance rather than such a retrograde step as Mr. Lennox advocates.

The Woes of Army Medical Compounders.

The reports that have come to hand respecting the manner in which the newly-enlisted army medical compounders are being treated appear to me to be likely to act as a serious deterrent to others who might have been inclined to take a holiday and see a bit of life in South Africa at the public expense. Those whose applications were accepted seem to have expected—and not unreasonably—that they would rank as non-commissioned officers, at least; in reality, they are being treated as private soldiers, and there is a prospect of their having to undertake many other duties than those which strictly appertain to a medical compounder's province. So far as concerns individuals who are qualified under the Pharmacy Acts, many pharmacists are disposed to say, "Serve them right," the feeling being very strong that no registered chemist should have offered his services under the conditions stipulated. But various motives have doubtless actuated those who thought the conditions good enough for them, and loyalty to his fellow-workers is not yet too conspicuous in the average registered person's character. The lack of that loyalty, indeed, is one of the most painful features of modern pharmacy, but those in whom it is manifested are frequently more to be pitied than blamed. Let us, then, hope for amendment and sympathise somewhat with our brother pharmacists who have had the gilt so roughly removed from the army medical corps gingerbread. Personally, I wish them all well through their troubles and a safe return to their native country after a not altogether unpleasant sojourn in South Africa.

Pharmacy Act Administration.

The extreme difficulty sometimes experienced by the Pharmaceutical Society in securing favourable judgments in cases brought under the Pharmacy Act, 1868, is well illustrated by the result of the Worcester weed-killer case, as reported in the daily press this week. The defendant—a seedsman and florist, and not registered as a chemist and druggist—admitted having accepted payment for weed-killer containing arsenic, but claimed immunity on the ground that he acted as agent for the makers of the preparation. He did not keep any stock of the weed-killer, but booked orders for it, took the money in payment, and gave receipts on bill-heads bearing the name of the makers, to whom he sent the orders for execution direct. He accounted quarterly for the business done, deducting 25 per cent. from the selling price as his commission, and had absolutely nothing to do with the handing over of the poison to the seller. The Pharmaceutical Society, nevertheless, contended that he both kept open shop for the sale of poison and actually sold it. But the County Court judge decided adversely to the Society (see *P.J.*, last volume, p. 167), and an appeal was therefore entered. Again, however, the Society has been defeated, Justices Grantham and Channell having found, without troubling the respondent, that the County Court judge was right. Mr. Justice Grantham thought the respondent was undoubtedly an agent only—"the conduit pipe to introduce the one person to the other"—and Mr. Justice Channell said it seemed to him the evidence proved that the florist had not the control and management of the sale. The appeal was, accordingly, dismissed, but leave to appeal further has been granted, and more may yet be heard of the matter. Meanwhile, I may point out that, in the event of the Queen's Bench decision being upheld, the Society would still have had a remedy against the makers of the weed-killer, but for the fact that they are registered as a limited company. Otherwise, in the event of a case being brought against them, they might have pleaded that the transaction was a wholesale one. But the supply of an article by a wholesale dealer to a consumer is not a sale "in the ordinary course of wholesale dealing." Any sale to a consumer must necessarily be a retail transaction, a point which wholesale dealers who sell scheduled poisons would do well to note.

PROCEEDINGS UNDER THE PHARMACY ACT.

THE SALE OF WEED-KILLER.

Pharmaceutical Society of Great Britain v. White.

In the High Court of Justice, Queen's Bench Division, before Justices Grantham and Channell, on January 16, 1900, an appeal was heard from a decision of the County Court judge at Worcester, in August last (see *P.J.* [3] 9, 167), dismissing a claim by the plaintiffs to a penalty under Section 15 of the Pharmacy Act, 1868, for the sale of a weed-killer containing arsenic by the defendant, a seedsman and florist, on the ground that the defendant had not actually sold the article, but had simply taken the order for it, which he sent on to the Boundary Chemical Company to execute. Mr. Crump, Q.C., and Mr. Grey appeared for the appellants, Mr. Cavanagh for the respondent.

Mr. Crump, in opening the case, stated the facts shortly. The defendant admitted that he sold the weed-killer containing arsenic, but he said he acted as agent for the Boundary Chemical Company, Liverpool. He stated that he did not keep the weed-killer in stock, but sold it, took the money, and sent on the order to the Chemical Company, to whom he accounted quarterly, deducting 25 per cent. from the selling price as his commission. The learned County Court judge, in deciding the case, said he found, as a fact, that the defendant did not sell the article in question, but acted as the agent of the Chemical Company. He submitted that this was not a question of fact, but of law. In reply to Mr. Justice Grantham, he admitted that the defendant did not retail, dispense, or compound the article in question; but he contended that he was a seller. He kept an open shop in which he sold poisons. He cited the case of *Templeman v. Trafford*, 8, Queen's Bench Division, a case under the 17th Section, in which Mr. Justice Grove said: "I am of opinion that in cases under Section 17 the seller is the person who actually conducts the business of selling," etc. He then referred to the case of the *Pharmaceutical Society v. Wheeldon*, 24, Queen's Bench Division, and read the judgment of Mr. Justice Hawkins.

Mr. Justice Channell pointed out that in the case cited the sale was the actual handing over of the poison; the question really was what was intended by selling.

Mr. Crump, continuing his argument, referred to the case of the *Pharmaceutical Society v. London and Provincial Supply Association, Limited*, in which it was laid down that the actual seller must be a qualified person. He quoted several passages from the judgments in the House of Lords, one of which stated that "he who sells, whether he be master or servant, principal or person to whom the conduct and management of the sale is delegated, is struck at by the 15th Section, because otherwise a very wide door would be opened to the evil which the Act was intended to guard against." There was no question of delivery, or the handling of the poison, in any of the judgments he had referred to.

Mr. Justice Channell thought it might make a difference when the poison was not kept on the premises.

Mr. Crump submitted that it did not. He proceeded to read a passage from the judgment of Lord Blackburn in the House of Lords, who pointed out that an unqualified person was forbidden not only to sell, but to keep open a shop for the sale of poisons. He concluded by reading the judgment of the County Court judge, in the course of which he said that the case would have been wholly different if Mr. White had kept the weed-killer in stock, and had handed it across the counter, or had sent it out in his cart. He held, however, that it was not the sale of Mr. White, but of the Boundary Chemical Company; the acceptance of an order did not make the person who took the order responsible for the sale. On the whole, he submitted that that decision was contrary to the judgments to which he had referred. In reply to the Bench, he

said that the receipt for the money was given on a billhead bearing the name of the Boundary Chemical Company. The document was handed up to the Bench.

Mr. Justice Grantham said they need not trouble the respondent. He had no doubt that in this case the County Court judge was right. He had found, as a fact, and he had evidence before him to justify the finding, that the defendant did not sell this article. Practically the evidence was uncontradicted as to the position of the defendant. He was a florist, and, knowing what was useful for killing weeds, he was ready to advise people where to get it; and he thought also he might assist his own business and make a little money, and so he arranged with the people who were the sellers—who, as it were, kept the shop for it—to tell the people who wanted to buy weed-killer to go to them. He said, in his evidence, if anybody came to him for it, he told them they could either send the order direct to the Company at Liverpool, or, if they liked, he would take the order and send it on; and he was provided with billheads by the Liverpool firm for the purpose of giving receipts for the money which was paid him on their account. For that recommendation he was entitled to a commission of 25 per cent. That being so, it seemed to him that he was not the person who was managing the sale; he was merely the conduit-pipe to introduce the one person to the other. He could not give a better example than the case of a shop in which the whole transaction took place—a chemist's shop. A person went into that shop to buy some poison. In the shop was a boy or a girl, or any unqualified person to whom the request was made for some rat-poison or weed-killer. The boy said, "There is my master, at the other counter; if you go to him, you can get it." Thereupon the master, being a qualified person, hears what the person wants, and supplies it. Could it be said that the boy who first saw the person who came into the shop and told him where to go was the person who sold? Certainly not; and if that was so in a shop, where the poison was kept, how could it be said that the person who did not keep it on his premises at all, did not make it, and did not deliver it, was the seller, or the person who managed the sale? He quite accepted, as he was bound to do, the judgment of Lord Selborne in the House of Lords, and though it did not apply to this case directly, he thought the learned County Court judge had been guided by it. He also accepted the judgment which had been cited, of Mr. Justice Hawkins, of which he entirely approved, but it did not touch this case at all. He did not think the County Court judge could have come to any other conclusion.

Mr. Justice Channell was of the same opinion. He thought the County Court judge must be taken to have found as a fact that the defendant had not the control and management of the sale. The cases clearly established that a person acting in the control and management of the sale was liable as seller, although he was not the principal; but here, it seemed to him, there was ample evidence upon which to find that the defendant had not the control and management of the sale. The only question of law in the case was as to the meaning of having the control and management of the sale. As far as he gathered from the cases, the person having control or management of the sale was the one who might do, or not do, the things which the Act required to be done with reference to the sale. This man was merely a messenger or something of the sort, though he received 25 per cent. commission. He might be supposed to get that because as a florist he recommended this substance as an effective weed-killer, and it was obviously for that reason that he was employed.

Mr. Cavanagh asked that the appeal should be dismissed with costs, and said it was arranged when leave was given to appeal that the defendant's costs should be as between solicitor and client.

Mr. Crump asked leave to appeal, as it was an important question of principle, and after some discussion the Court gave leave to appeal, on condition that the defendant's costs of any unsuccessful appeal should be as between solicitor and client.

ALLEGED ILLEGAL SALE OF LAUDANUM.

Pharmaceutical Society of Great Britain v. Freeman.

At the Birmingham County Court on Monday, January 15, before His Honour Judge Whitehorne, the Pharmaceutical Society of Great Britain brought an action to recover, under the provisions of the Pharmacy Act, a penalty of £5 from Ernest Freeman, described as a chemist's assistant, of High Street, King's Heath, near Birmingham.

Mr. Arthur Smith appeared to support the action, and Mr. Cochrane was for the defence.

Mr. Smith, in opening, said the proceedings were taken under the Pharmacy Act of 1868. Section 1 declared it to be unlawful for any person to sell or keep open shop for the sale of poisons unless he were registered under the Act, and Section 15 enacted that any person contravening the Act in this respect should be liable to the penalty claimed in the present instance. A certain number of poisons were scheduled in the Act, and opium was among them. As regarded the present case, the facts were that on September 29 a lady acting under the directions of the Society visited the shop of a gentleman who traded under the name of "Freeman's," at High Street, King's Heath. The lady purchased from an assistant (the present defendant) twopennyworth of laudanum.

His Honour: The lady was, so to speak, a detective?

Mr. Smith said this was so. The lady marked the bottle, handed it to her husband, who was formerly a member of the Birmingham detective force, and who was waiting outside. The husband then entered the shop and had a conversation with the young man, who stated that his name was Ernest Freeman. Subsequently the bottle was handed over to a representative of the Registrar of the Pharmaceutical Society, and in due course its contents were analysed and found to come within the schedule of the Act.

Annie Painter gave evidence as to the purchase of the laudanum and as to the marking the bottle.—In cross-examination she said she did not tell the assistant that she wanted the article for the purposes of analysis. She had not seen the assistant between September 29 and last Friday, when she again visited the shop ostensibly to purchase a tablet of soap.—The witness was asked to look round the court, and when both Ernest Freeman and his brother William stood up, she said she believed it was the former who had made the sale.—Mr. Cochrane: Are you sure?—Witness: To the best of my belief it was.—Mr. Cochrane: Will you say you are sure?—Witness: I won't say I'm sure, but to the best of my belief it was.

William Painter, husband of the last witness, said that after seeing the sale effected, he entered the shop and saw the young gentleman just identified by his wife. He entered into conversation, in the course of which the assistant said his name was Ernest, and that his brother William had a shop in the City Road.—In cross-examination, witness said he was not aware of the fact that defendants and even judges were constantly complaining of the fact that the prosecution in such cases kept it secret that the article had been purchased for analysis.—Mr. Cochrane: Do you think it fair to let a month go by between the sale and the making of the accusation?—Witness: I have nothing at all to do with that. I act under instructions.—Continuing, the witness said that he sealed the bottle received from his wife, and kept it locked up in a drawer, until it was handed to Mr. H. Moon, an official of the Pharmaceutical Society.

Mr. H. Moon proved the receipt of the bottle, and said he forthwith handed it over to Mr. Eastes for analysis.—Cross-examined, he said there was nothing in the Act requiring that notice should be given to the shopkeeper that the article purchased was for analysis.—Mr. Cochrane: Can't you see that it's hard upon a shopkeeper to trace out who made a sale which took place months before?—Witness: We are not proceeding against the shopkeeper.—Mr. Cochrane: You are complaining that Ernest Freeman sold poison, and it is not until a month afterwards that you give him notice of it?—Witness: That is so.

Mr. E. J. Eastes, Fellow of the Institute of Chemistry, deposed that the bottle contained three fluid drachms of laudanum.—His Honour: Is that a poisonous dose?—Witness: More than enough to poison an adult person.—Mr. Cochrane: Do you mean to say that what you found in the bottle would have killed any ordinary person?—Witness: Yes; there is more than enough to kill any ordinary person.—His Honour: Will you try, Mr. Cochrane?

Mr. Cochrane, in defence, asked His Honour to insist upon the strictest proof in such a case.

His Honour: Not a bit stricter than in any ordinary case. I must be satisfied honestly upon the evidence.

Mr. Cochrane: That there has been an infringement of the Act of Parliament?

His Honour: Yes.

Mr. Cochrane said that in any case he did wish to make one strong complaint, and he hoped that the Pharmaceutical Society, which appeared to be strongly represented in court, would take it to heart for the future.

His Honour: Societies have no hearts.

Mr. Cochrane said he appeared not only on behalf of the defendant, but on behalf of his father and brother, both of whom were members of the Pharmaceutical Society, and properly registered chemists. They complained that the Society, instead of taking up arms against people who were adverse to its interests, adopted a system which he called "sniping," picking out cases where possibly a mistake had been made, but cases which were never for a moment aimed at by the Act of Parliament. The Act was express in what it was designed to put a stop to. Its very preamble showed that it was passed for the protection of the public—to protect the public against the indiscriminate sale to them of poisons by unregistered chemists. The proprietor of the shop about which the present complaint was made was Mr. John Freeman, a registered chemist. His eldest son, who was his assistant at this and other shops, was also a registered chemist and a member of the Pharmaceutical Society. The defendant, Ernest Freeman, was unregistered.

His Honour: He hopes to be registered?

Mr. Cochrane said such was no doubt the case. To begin with, the sale of poisons as enumerated in the Act was but an infinitesimal part of the practice. Far and away the largest business done at the shop was the sale of drugs which were not included in the Act. It was perfectly obvious that in a shop of the kind it was impossible to keep a properly qualified chemist behind the counter every minute it was opened. At any rate, such a thing was commercially impossible, and it was not reasonably necessary. What Mr. Freeman did was to instruct his unregistered assistants not to sell poisons. The defendant in the present case had been strictly forbidden to do so. He did not think the Society could raise the smallest objection to such a course.

His Honour: Supposing the father and the eldest son leave the shop, isn't it your duty to lock up the poisons? I tell you candidly I am asking the question upon Wheeldon's case.

Mr. Smith: The very point is discussed by Mr. Justice Hawkins in his judgment.

Mr. Cochrane said instructions were given to the unregistered assistants that they were not to sell poisons. They did all they were legally called upon to do when they arranged that poisons should not be sold by an unqualified assistant. The next point he wished to make was that they were brought there months after the event. The purchase was made on September 29, and they got no intimation that anything was wrong until November 9. He protested that this was not a fair way for a Society entrusted with the administration of an Act of Parliament to conduct its business. It was not fair to allow such a length of time to elapse before the defendant was asked to give his explanation.

His Honour: That would be a proper argument to address to a fellow-citizen, but for this particular term I happen to be not a fellow-citizen, but an administrator of the law. My private opinion, even if it should be with you, is neither here nor there.

Mr. Cochrane said it was very hard for a man to be called upon to pay £5 and to find that any explanation he might have been able to give was out of his reach. All he could say was they had done their best to prevent any breach of the Act.

His Honour: Now you are speaking for the father and brother, with whom I have nothing to do. What I have to consider is whether it is proved against Ernest Freeman that he has committed an offence.

Ernest Freeman then deposed that he was not at the King's Heath shop on September 29 at any time of the day. He produced his order books, and said by the entries they contained he would be able to recollect exactly how he spent the day. He had never seen the witness Painter.—In cross-examination, witness admitted that he had sat twice for the Preliminary Examination and had failed on each occasion.

Wm. Freeman, who said he was a member of the Pharmaceutical Society, said he was at the shop the whole of the day, and his brother was not there at all. He recollected Mr. Painter, and the conversation detailed by the latter very probably took place. It was quite possible that he gave his name as Ernest Freeman, as he should regard Mr. Painter's question as to his name an impertinent one. Ernest was occasionally left in charge of the shop, but he had strict instructions not to sell poisons, which were locked in a cupboard. The key, however, was always accessible.

Mr. Smith, in addressing His Honour, said the case resolved itself into a question of identity.

His Honour remarked that the person who stated the case against the defendant was Mrs. Painter, and she was uncertain.

Mr. Smith said that Mr. Painter, an experienced detective, was able to identify the defendant, whom he saw immediately after the sale was made. As against this, what was the probability of the truth of the evidence on the other side? William Freeman, according to his own showing, was willing to forswear his own name and adopt the name of another person. On the one side the evidence was absolutely clear, whereas on the other there was the evidence of an interested defendant, one whom the Act sought to reach, and that of a man who on his own admission had lied.

His Honour said he had to consider whether the plaintiffs had made out their case; whether they had produced evidence which forced him to the conclusion that it was Ernest Freeman who sold the laudanum. On the one side the only evidence he had to act upon was the evidence of the detectives. He was not saying that the evidence of the detectives was damaged because they were detectives, but, after all, it was their business to prove their cases, and to a certain extent they were not absolutely independent. On the other side there was the evidence of the two brothers, and what had struck him most of all—he hoped for their own sakes that they had been speaking the truth—that their accounts coincided entirely. It was true that the elder brother admitted having told a deliberate falsehood to the detective and assumed his brother's name. That he did not forget, but on the balance of testimony he could not come to the conclusion that the Society, which had acted simply in its public capacity, had proved its case. Therefore, he gave judgment for the defendant, but, in the circumstances, without costs.

ILLEGAL SALE OF LAUDANUM.

Pharmaceutical Society of Great Britain v. Mottram.

Similar proceedings were instituted at the Birmingham County Court, on the same day as the foregoing case, against Charles Mottram, in respect of the sale of laudanum in a shop belonging to Mr. Freeman at Six Ways, Birmingham.

Mr. Cochrane pointed out that the defendant in this case was an infant, and under the County Court rules a solicitor could not act for him without the instructions of a guardian.

His Honour overcame the difficulty by appointing Mr. Registrar Whitelock as the guardian.

Evidence similar to that given in the previous case was produced, and Mr. Painter stated that when addressed as Freeman in the

shop, the defendant said, "I'm not Freeman; I'm Mottram. I married the daughter."

No evidence was offered in defence, and His Honour, in giving judgment for the amount claimed, asked whether Mr. Smith pressed for costs?

Mr. Smith said he must, having regard to the conflict of testimony in the other case, but whether the Society would insist upon enforcing the order or not was another matter. These were prosecutions in the public interest.

Mr. Cochrane submitted that in this case there was no reason why the Society should have costs.

Mr. Smith remarked that whilst the Society sued for penalties of £5, it cost a lot more than that to get them. It was only because the Treasury helped in the matter that they were able to bring these prosecutions at all. He would take care that any order made was not unduly enforced. He would undertake, for instance, that the Registrar was not troubled.

His Honour: Then I cannot refuse it, but I must record for the Registrar's safety that the plaintiffs' solicitor undertakes not to enforce the order against the guardian.

Mr. Smith: As a matter of fact, I believe these costs are at the end of a very long vista.

A TEXT-BOOK OF PHARMACEUTICAL CHEMISTRY.

LEHRBUCH DER CHEMIE FÜR PHARMACEUTEN. Von Dr. BERNHARD FISCHER. Verlag von Ferdinand Enke, Stuttgart, 1900.

Dr. Fischer's book contains an exposition of the principles and facts of chemistry intended chiefly for the use of students preparing for the German Gehilfen-Examen—*i.e.*, the examination which confers upon successful candidates the right of acting as assistant in a German pharmacy. It includes a fairly complete account of the science, but what renders the book so valuable is the attention which has been devoted to the practical and technical details which are not to be found in text-books, or at least in English text-books. These details, moreover, impress one as having been written by a chemist thoroughly familiar with industrial chemistry as practised at the present day. Manufacturing processes for obtaining chemicals from natural products are described in clear and convincing language, and methods of preparation for substances made in the laboratory are given with sufficient detail and exactness to enable the student to prepare for himself the substances dealt with. Under each of the more important medicinal chemicals a special paragraph is given dealing with the tests for their purity and detection of adulterations. These are also extremely practical and valuable for the pharmaceutical student because they are framed with a view of indicating the standards which are requisite for substances used for the particular purpose in which he is interested. While developing his work in this manner, the author has not failed to retain a systematic and scientific method of treatment. From this it is apparent that he has produced a book which has no counterpart in this country. Those who maintain that such a thing as "pharmaceutical chemistry" really exists will derive support for their opinion by a perusal of Dr. Fischer's manual, where, side by side with the principles of the science, will be found those facts which, as a worker in a technical branch of chemistry, it behoves the pharmacist to know.

After an introductory portion, the author devotes 250 pages to descriptive inorganic chemistry, where all the more important compounds of the non-metals and metals are dealt with in the manner already broadly indicated. In addition to the details having specially pharmaceutical interest, many other important technical applications are also described, and at the end of each of the sections dealing with the metals their analytical reactions are given. The descriptions and tests naturally refer more particularly to the requirements of the German Pharmacopœia.

Organic chemistry occupies nearly 200 pages. The ordinary scheme of classification is adopted, those sections containing sub-

stances of medicinal importance being amplified. All the modern synthetic remedies having any claim to recognition are dealt with in their proper position in the scheme of classification, so that the student may realise their relative position and importance among the carbon compounds.

The sections dealing with glycerin, the carbohydrates, oils, fats, and soaps are all excellent so far as they go. The practical and technical details provide very interesting reading far in advance of anything usually found in books of the same scope, for one must assume that the author intends his book to cover only elementary ground. Dr. Fischer appears to employ constitutional formulæ and diagrammatic methods in explaining chemical equations more freely than is usual in books written by English chemists. This, however, may be generally observed in comparing German and English books on chemistry, and may perhaps indicate a greater reliance upon the mental vigour of the German student. Some of the modern diagrammatic methods are undoubtedly useful in explaining reactions provided the student understands the limitations which must be imposed upon the diagrams as a material representation of what actually occurs.

Following the part dealing with organic chemistry there is an excellent, although somewhat compressed, part treating of qualitative analysis. The use of flame reactions, the blowpipe, heating on charcoal, and other methods of preliminary testing are very clearly explained, and a very useful table for the detection of acids is given.

Volumetric analysis claims only a comparatively small share of attention, the standard solutions described being only five in number—*viz.*, hydrochloric acid, potassium hydroxide, iodine, sodium thiosulphate, and silver nitrate. The general methods and the use of apparatus in volumetric determinations are, however, described succinctly.

Next follows a chapter on chemical calculations, containing a set of examples worked out and explained in simple and clear language and by methods which commend themselves by their simplicity and directness.

An appendix dealing in a somewhat fragmentary manner with physics completes the volume. It is devoted for the most part to a description of instruments used in physico-chemical observations—*e.g.*, the thermometer, barometer, balance, microscope, and polariscope. The descriptions are chiefly supplementary to those found in elementary books on physics where detailed description of apparatus is subordinated to general principles. It will afford the student the means of enlarging his acquaintance with those instruments of cardinal importance, and is probably intended by the author to be useful to students having already a knowledge of the elementary principles of physics.

We may regret that no work of similar scope is available in English; but those British students possessing a knowledge of German will find in Dr. Fischer's book a store of information on technical points well worth their attention. There is an agreeable freshness and originality about the arrangement of the matter due perhaps to the way in which the author has succeeded in introducing, side by side with the purely chemical, the information having direct pharmaceutical importance.

PERUVIAN BALSAM IN TUBERCULOSIS.—By dissolving 50 Gm. of balsam Peru in a litre of cognac, Schmey (*Deutsche med. Zeit.*) obtains what he terms "Cognac de Perou," with which he claims to have cured cases of even advanced tuberculosis. It is administered in teaspoonful doses every two hours, either alone or in milk. A little food such as egg or milk should be taken immediately before the dose. It is stated that the cinnamic acid contained in the balsam acts as well when given in this way as when injected hypodermically. The favourable influence of cognac alone (in medicinal doses) in cases of tuberculosis has been previously pointed out by Dettweiler and others.—*L'Union Pharm.*, 40, 448.

PHARMACEUTICAL SOCIETY.

EXAMINATIONS IN LONDON.

January, 1900.

MAJOR EXAMINATION.

Candidates examined	19
" failed	13

Wood, John Frederick; Wolverhampton	

Donations to the Library and Museum.

At a meeting of the Library, Museum, School and House Committee, on Wednesday, January 17, the Librarian and Curator presented the following reports of donations :—

TO THE MUSEUM (LONDON).

Dr. Geo. Watt, C.I.E., Government Reporter on Economic Products, Calcutta :—Six specimens of varieties of *Aconitum ferox*.

Mr. D. Hooper, Indian Museum, Calcutta :—Specimens of *Aconitum ferox*, var. *atrox*, and of the wood of *Aquilaria agallocha* from Assam.

Messrs. Potter and Clarke, London :—Specimen of the stem and root bark of *Daphne mezereum*.

Messrs. Hearon, Squire and Francis, London :—Fresh specimen of the Bergamot orange; specimen of aloes containing stony matter.

Messrs. Dalton and Young, London :—Specimen of so-called "ginger" from Porto Rico.

Messrs. Hale and Son :—Specimen of asafetida in the tear, and of *Strophanthus Kombe* seed, and *Strophanthus* seed in pod.

Messrs. Wright, Layman and Umney :—Specimen of *Sagapenum* in the tear,

TO THE HERBARIUM (LONDON).

Dr. Geo. Watt, C.I.E., Calcutta :—Six specimens of varieties of *Aconitum ferox*, corresponding to the roots sent.

TO THE MUSEUM (EDINBURGH).

Mr. Donald McEwan, Edinburgh :—Specimen of Mescal Buttons (*Anhalonium lewinii*).

Messrs. Finsler and Wheeler, London :—Specimen of "Iguana Stone," a calculus from the stomach of the iguana lizard, *Iguana tuberculatus*, of Nicaragua.

Messrs. Evans, Lescher, and Webb, London :—Fine specimens of asafetida in the tear.

Mr. F. M. Moir, the East African Lakes Co., Glasgow :—Specimen of *Strophanthus* stem, leaf, flower, and fruit.

TO THE LIBRARY (LONDON).

Ecole supérieure de Pharmacie de Paris :—Thèses par MM. Bondouy-Lépinos, Maronneau, Cordier et Tarible.

Thé Leigh-Browne Trust :—Biological Experimentation, by B. W. Richardson, 1896.

University of Durham :—Calendar, 1899-1900.

American Pharmaceutical Association :—Proceedings, 1899, v. 47.

TO THE LIBRARY (EDINBURGH).

American Pharmaceutical Association :—Proceedings, 1899, v. 47.

EVENING MEETING IN EDINBURGH.

The third evening meeting of the session was held in the Society's House, 36, York Place, Edinburgh, on Wednesday, January 17, Mr. PETER BOA, Chairman of the Executive, in the chair. The minutes of the last meeting were read and approved. Apologies were intimated from Messrs. Ewing, Guyer, Lunan, Dunlop, Gil-mour, Currie, Davidson, and Dey.

The CHAIRMAN said he had received from Mrs. Stanford an acknowledgment of the letter of sympathy sent by the last meeting. He regretted to say he had now to call attention to another loss sustained by the Society in Scotland, in the death of Mr. Daniel Frazer, of Glasgow. Having referred to his association with the Society in various capacities for many years, he said Mr. Frazer was very popular and generally liked by those who came in contact with him. He (the Chairman) had been a member of his staff, and could testify that he never lost touch with those who had been in his employment. It might be said that Mr. Kinninmont represented in Glasgow the scientific side of pharmacy, and Mr. Frazer the political. The meeting agreed to send a letter of sympathy to Mr. Frazer's family.

Mr. G. F. MERSON then read his papers on

COMMERCIAL MYRRH AND POWDERED MYRRH AND TINCTURE OF MYRRH,

which are printed in full at pages 42 and 44 respectively.

Mr. DOTT said they were indebted to Mr. Merson for a true contribution to pharmaceutical knowledge, such as was very appropriate for such meetings. More tests of the kind indicated would be an advantage. The percentage of extractive, and especially of ash, were valuable tests for gum resins, and easily determined. As to maceration and percolation, much depended on what was meant

by maceration. If well stirred, the result would be different than if the ingredients were merely shaken up. But he agreed that percolation where practicable was preferable to maceration.

Mr. FRASER thought that No. 40 powder was too fine. Coarse powder, he thought, meant anything between 16 and 20. He found no difficulty in obtaining myrrh of good quality at a fair price.

Dr. G. COULL said he had seen myrrh only coarsely bruised exhausted very thoroughly by percolation. He thought they should not depart from the official method.

Mr. HENRY said that the results submitted showed that little confidence could be placed in such trade names as "opt" or "elect."

Mr. GLASS said the main point as to the tincture seemed to be the fineness of the powder. It seemed that a finer powder than No. 40 might be entirely exhausted by maceration.

Mr. BARRIE asked if the percentage of undissolved resin in the maceration marcs was calculated on the original weight of drug used or on the residual marc.

Mr. J. RUTHERFORD HILL said a member had sent a note objecting to the vague description "coarse powder." Why should myrrh be in "coarse powder," kino in "powder," and asafetida "bruised"? The United States Pharmacopœia defined "coarse powder" as No. 20. Some grinders adopted No. 10 sieve as their standard for coarse powder, while others called it bruised when passed through a No. 10 sieve. There was no uniformity. Mr. Leman sent a note suggesting that a 1 in 10 tincture would be better. It was strong enough and much less liable to clot in gargles, and the drug was more thoroughly exhausted by the menstruum. The public did not appreciate the difference of strength in the new tincture, and expressed surprise at the increased price. Mr. Dunlop wrote that he preferred percolation to maceration in making the tincture. In making tincture of asafetida he found 3 per cent. of resin in the marc after completing the official process. In percolating myrrh he found it was practically exhausted when four-fifths of the menstruum had passed through.

The CHAIRMAN said many people tried to use up the lower grades of myrrh. In that connection the fineness of the powder was of importance. If a good fat myrrh were used, the resin was soft and easily dissolved, and the powder did not require to be so fine as when a cheaper and more compact sample of the "sorts" variety was used. Possibly that led the Pharmacopœia compilers to leave the point indefinite so that the operator in his discretion might adjust the fineness of the powder to the quality of the myrrh. Mr. Merson's figures should cause authors of books on materia medica to revise their figures. His own experience was that percolation was preferable to maceration for the tincture. But, like Dr. Coull, he felt bound by the official regulations. To make a percolation tincture of myrrh required some skill in the process, and possibly the fear that different operators might vary in such skill led the authorities to adopt maceration as on the whole less likely to give varying results.

Mr. MERSON, in replying, said in regard to Mr. Barrie's inquiry that the undissolved resin was calculated on the weight of the marc.

Mr. J. RUTHERFORD HILL then read a paper on

STRYCHNINE HYDROCHLORIDE, AND SODIUM ARSENATE, which is printed in full at page 45.

Mr. DOTT said he concurred in the conclusion come to by the author as to the cause of the separation of strychnine. It was not due to any slight hydrolysis of the arsenate in solution. They were apt to regard strychnine and alkaloids generally as stronger bases than they really were. The analogous dibasic phosphate of strychnine was very unstable, decomposing and depositing strychnine on warming. He did not think a tribasic alkaloidal phosphate had ever been formed. The point as to four washings with chloroform was important, and indicated the weak point in the official process for the determination of nux vomica. Where the quantity of chloroform was deficient the various mixtures shown by Mr. Hill emphasised what he (Mr. Dott) said at the last meeting, as to the

danger of doctors trying rash experiments in prescribing pharmacopœial salts.

Mr. DUNCAN said he was still in favour of the view that hydrolysis had much to do with the liberation of the strychnine, but he congratulated the author on the way he had worked out his results.

Dr. COULL said, assuming the accuracy of the results submitted, he was satisfied that his suggestion at the last meeting as to carbonate being the cause had been disproved.

Mr. COWIE said he could confirm most of the author's results. He had made a solution of strychnine hydrochloride by Cockburn's method, and on mixing it with liquor sodii arsenatis there was no precipitation, but on examination he found the strychnine solution distinctly acid. Mr. Dunlop's mixture, in his experience, took a few hours to precipitate, and the crystals were long and silky. With aqueous solution of strychnine hydrochloride, silky but much shorter crystals formed immediately. After a day a second crop of crystals similar to those in Mr. Hill's mixtures appeared. He thought there might be excess of acid in the strychnine salt, but on washing with ammonia the whole of the strychnine came out. He got similar results with sodium phosphate. He questioned the second equation, in which free ammonia was said to be liberated when ammonium chloride was added to sodium arsenate solution. That was how microcosmic salt was formed, and he would not have expected free ammonia unless the solution was warmed. As to the basic properties of strychnine, he had dissolved some strychnine arsenate in cold water and washed out with chloroform, and got a considerable quantity of free alkaloid, as if the salt had been split up. But he had not completed the experiment.

Mr. HILL having replied, he next directed attention to recent donations and additions to the library, including a specimen of the mescal button, the fruit of *Anhalonium lewinii*, presented by Mr. Donald McEwan, and seeds of *Oroxylum indicum*, from London.

On the motion of the CHAIRMAN, votes of thanks were awarded to authors of papers and donors of books and specimens. The meeting then closed.

LETTERS TO THE EDITOR.

The Pharmacopœia as a Standard.

The question suggested in the Journal of December 30 concerning the defence of cases under the sale of Foods and Drugs Acts being of such importance to every chemist and druggist, I hope you will permit me to point out, as others have done on other occasions, that the Pharmacy Act of 1852 recognised or established a distinction between qualified and unqualified persons. Likewise, the Medical Act, which created the British Pharmacopœia, also distinguished the unqualified from the qualified, and added in Section 55:—

Nothing in this Act contained shall extend or be construed to extend to prejudice or in any way to affect the lawful occupation, trade, or business of chemists and druggists.

Anyone moderately acquainted with the history of medicine and pharmacy in this country must know that for something like 250 years medical authorities did their best to keep the Pharmacopœia, with its mass of information—dangerous to the public when in the hands of the ignorant and vicious—out of the hands of the public. The Orders in Council did not refer to or interfere with domestic medicines, but only to those prescribed by medical men. There is nothing to show that the Legislature, or any Order in Council, ever required unskilled and unqualified people to be served with the same sort of remedies as those that would be proper for the Queen's physicians to handle. On the contrary, Parliament, while recognising the existence of unqualified persons, has consistently avoided giving countenance or encouragement to the practice of ignorant people, dabbling with drugs, and there is no room for doubting that unskilled or unqualified persons have no legally recognised right to have in their possession any medicine of the Pharmacopœia except by prescription of some physician in their

behalf. Nevertheless, it is well known that it has for a long time been the practice for legally qualified retailers of drugs and medicines to supply the public with some medicines of the Pharmacopœia, with more or less modifications of the official formula, such as in their trained discretion and as a result of their practical local experience have appeared advisable; excepting only those cases where very potent medicines, as laudanum, are asked for, when something near to practical uniformity of strength has been generally considered desirable. For whose benefit then is the policy followed for more than 250 years now to be changed? For what good reason is Bill, the bricklayer, or Sarah Gamp to be put on the same level with trained physicians? Would it conduce to the safety of the public? Have not the abuse and criminal use of drugs ever formed one of the great dangers that have dogged the advance of both ancient and modern civilisation? Would it be to the advantage of the public that public functionaries should declare the equal right of the unskilled and vicious to be supplied with any of the same agents for good or evil, such as are the medicines of the Pharmacopœia, which have been designed by skilled physicians for their own particular use? The sale of tincture of opium for laudanum seems perfectly justifiable, but the selling of spirit of nitrous ether 0.842 B.P. when sweet spirit of nitre is asked for at the retail counter looks very like a mischievous fraud without a shadow of legislative sanction. Moreover, if a chemist and druggist chooses to use either mineral or vegetable oil for preparing his camphorated oil for retail sale he is acting only within his rights as recognised by several Statutes. It is in the lawful exercise of his trained discretion whether he make this oil according to the Pharmacopœia or according to his own formula. It is a question of procedure which the special training of the pharmacist qualifies him alone to answer. Lawyers are trained to exercise their discretion as regards the best mode of conducting their legal processes. Medical men are likewise trained to exercise their discretion as regards the treatment of their patients. The law does not attempt to interfere with them in the exercise of their discretion. Chemists and druggists likewise are trained to exercise their discretion in the conduct of their business, and the Legislature has repeatedly expressed in very clear terms its recognition of their right to act according to their discretion. Not only is it the object of their training, but it is their duty to exercise discretion regarding the kind of preparation to be sold on demand of the ordinary unskilled retail customer.

London, N., January 10.

J. EAGLE.

Reclamation.

[The only excuse the Editor can offer for occupying space in the Journal by the publication of the following letters is consideration for Mr. Gifford's plea that his reputation is at stake: he cannot, however, extend that consideration so far as to comply with Mr. Gifford's further request that he should alter his decision as to the desirability of publishing the paper to which Mr. Gifford refers.—ED. P.J.]

Enclosed you will find copies of a letter I addressed to the Council and the Secretary's reply. Kindly publish these in *Pharmaceutical Journal*.

I exercise my privilege as a member in protesting against the practice—for such it has become—of occupying the best space of the Journal with lectures (presumably paid for) by an anonymous contributor. I refer to "An Ordinary Pharmacist." Is it not patent that these lucubrations have all value taken from them by the fact that we cannot appraise them and therefore they may be misleading, but it is altogether intolerable that perversions of the truth shall be allowed under a *nom de plume*. I will further draw your attention to a few facts.

1. On December 16, 1899, you printed a paper by one John Humphrey (a name not on the register) occupying two pages and a half-column (was this paid for?) of premises, reasonings, and conclusions I altogether object to.

2. On December 23, 1899, you print in leader type, by the way, was this report paid for? a speech by Mr. Harrington, a paper by Mr. Hills and speeches by Messrs. Parker and Glyn-Jones—with most of the arguments advanced I disagree.

Permit me to point out to you that you have effectively recognised my position in pharmaceutical politics over and over again during the last eighteen months. The Council has also officially recognised that position, therefore there is not a shadow of doubt that not only have I the right but it is an obligation on my part as the mouthpiece of *ordinary pharmacists* to combat these views.

It is my duty to tell Mr. Hills—for whom it should not need to be said that I have, for him, the very highest regard and esteem—that we need no lines of defence at all, as we have nothing to defend. It is my duty to tell Mr. Glyn-Jones and the president that it is most likely by combination, immediate action and agitation, that the intention of the Act of 1868 can be established viz. the text of my Darwen paper, so well put by yourself page 589. That this position (ours for the time being in the hands of the enemy) can only be taken by attacking movements, that we do not want to have considered how much we are prepared to accept to relinquish claim to the position. What we do need to be prepared with is a proper and common-sense Pharmacy Bill, based on the public needs and consistent with the privileges of qualification. This ought to have been before the world long ago but it is now a most urgent necessity.

It is my duty to tell Mr. Harrington that we ought to have had our flag (if we can find one) "nailed to the mast" long ago, in order that the world may know how just our claim is. It is further my duty to say that the traditional policy of the Council of strategical movements to the rear must end, and a manly open forward policy substituted. The Pharmaceutical Council has duties, public duties first, duties to members of the Society, in the second, and duties to all qualified persons in the third place, ordinary pharmacists say these duties have been neglected. It is my duty to take the responsibility of saying that I believe them to be right, that the Council has neglected its duties, and that it is doing so still in not facing the situation, also that the president's action in taking up a position which you allow may mean anything, is undignified and damaging to our interests.

Let me say that my reputation is involved, and I ask that my paper unsatisfactorily summarised this week, be printed in full and with as much prominence as the Western Chemists' report, or "An Ordinary Pharmacist" or "John Humphrey."—Yours faithfully,

Blackburn, January 15, 1900.

R. LORD GIFFORD.

[COPY.]

January 8, 1900.

The President and Council of the Pharmaceutical Society of Great Britain.

Gentlemen,—I claim your protection of my rights and privileges as a member of the Society. It is beyond argument that I represent the opinions of a large section of the members of the Pharmaceutical Society, and I claim that my views shall have as full exposition in our official organ as those which I endeavour to combat. May I crave the Council's serious consideration of my complaint.

On January 2, 1900, I read a paper, the preparation of which cost me the whole of three weeks' leisure, intended to oppose arguments advanced week by week, and which most certainly are not representative of the opinions of the great body of chemists. These opinions—as I think, fallacies and sophistries—I oppose with facts and arguments based upon known data: not by a mere *ipse dixi*. My paper is entirely suppressed in your issue of January 6, being dismissed with a sentence, which is untrue (*vide* page 3 of the market report supplement).

I further complain that persons skulking under *nom-de-plumes*

are allowed full liberty, and all the importance of leader-type and prominent position to misrepresent and abuse my views.

I ask you if it is honest or decent to allow such a person to attack the views of a vast majority of chemists in the way done in the Journal, page 3, where it is made to appear that we are acquiescing in proposals which I absolutely despise and abhor, whilst the management of the official organ have my reply in its possession and refuses publication. I may here say that the contemptible reference to myself lower down on page 3 is untrue, and even, as I am advised, libellous.

I beg the Council to understand I do not wish to become controversial, or even to correct misrepresentation—that is beneath me—but I do claim the right of stating my own case, and that my arguments shall be given in the official organ.

Gentlemen, I ask from you what I wish you to ask from the Legislature—viz., simple justice. I beg you to direct that my paper shall be printed in the official organ.—Believe me, yours respectfully,

(Signed) R. LORD GIFFORD.

[COPY.]

January 12, 1900.

R. Lord Gifford, Esq., Blackburn.

Dear Sir,—I have to inform you that your letter of the 8th inst. was submitted to the Council at its meeting on Wednesday, and, in reply, I am instructed to say that the Council does not propose to interfere with the discretionary power given to the Editor of the Journal with reference to the publication of reports of meetings.

With regard to the other matter referred to in your letter, it will on reflection, probably become obvious to you that as a public man you can hardly hope to escape from criticism and even attack.—I am, yours faithfully,

(Signed) RICHARD BREMRIDGE, Secretary.

Assistants' Testimonials—A Warning.

We wish to warn chemists against accepting any testimonial bearing our signature in favour of David Fettes, Montrose. This warning is necessary, as we find he is making use of a variety of testimonials with our name attached, which he did not earn, and which we did not write. He was dismissed by us after six months' service, in November last.

Dundee, January 13, 1900.

CUMMINGS BROTHERS.

PRACTICAL NOTES AND FORMULÆ.

Rubus ammobius (Focke) in Wales.

Last summer I went to explore the Lonely Llyn an Afon situated about 1,200 feet above Aber, in Carnarvonshire, in order to obtain a rooting specimen of *Potamogeton griffithii*, which a member of our craft—Mr. J. Griffith, of Bangor, the author of the 'Flora of Anglesey and Carnarvon'—discovered some years ago, and has not been found up to the present time in any other locality. In the recent excellent 'Monograph of the British Pond Weeds,' by Mr. A. Fryer, the author has given it full specific rank. The pond weed grows near the middle of the lake, and it went much against the grain to endure the coldness of the icy water and the sharp stones which formed the bottom of the lake in quest of it; however, specimens were obtained, which Mr. Fryer has in cultivation. Between Aber and the lake I gathered a bramble of the suberect group which was unfamiliar to me. Recently I have submitted it to my friend, the eminent Rubologist, Dr. Focke, of Bremen, who identifies it with his *R. ammobius*, which he described in the 'Synopsis Ruborum Germaniæ' of 1877, as follows:—

R. plicato similis; differt turionibus teretiusculis superne obsolete angulatis, foliis haud raro septenatis, foliolis latioribus supra obscure viridibus, adultis planis, junioribus plicatis subtus cano vel albo-tomentosis, foliolo terminali lato cordato-ovato acuto vel acuminato, floribus majoribus, petalis obovatis concavis, staminibus

stylis paullulum super antibus, sepalis in fructu reflexis, germinibus apice hirsutis, fructibus nigro-purpurascensibus.

Habitus R. plicati, sed folia majora supra obscura minus plicata floresque majores aspectum diversum praebent. Foliola juniora semper subtus cana vel albida, adulta in umbrosis viridia, in apricis discolora. Petioli basin versus canaliculati foliolis infimis longiores. Aculei paullo minores quam in R. plicato.

Differt a R. opaco aculeis minoribus, foliis septenatis haud raris, foliolis latioribus, terminali breviter acuminato, fructibus perfectis, sepalis in fructu reflexis.

R. ammobius occurs in the north-eastern part of Germany in sandy soil. In the 'Index Kewensis' it is given full specific rank, but Nyman in his 'Conspectus Floræ Europææ' puts it as a hybrid species under *R. plicatus*. This is the first time it has been authentically recorded for Great Britain, and the Welsh locality is a great extension of its known geographical range.—G. CLARIDGE DRUCE, Oxford.

The Official Tests for Copaiba.

Among the characters and tests for Copaiba in the Pharmacopœia occurs the following:—"The volatile oil should . . . rotate the plane of a ray of polarised light from 28° to 34° to the left (absence of African Copaiba)." These figures appear to have been taken from a paper on African Copaiba by J. C. Umney (*P.J.* [3], 24, p. 215), in which he gives -28° 55' and -34° 18' as the rotatory powers of two samples, Para and Maracaibo respectively. Mr. Umney, however, does not state that these figures represent the highest and lowest of a series, but conveys the impression that they are only two isolated samples; moreover, although not so stated in the table given, it is mentioned in the text of the paper that they refer to the rotation in a 20-centimetre tube. If, therefore, as seems to be the case, the compilers of the Pharmacopœia took their figures from the above source, the latter should at any rate be halved. Even then they will probably be too narrow; the figures given by Gildemeister and Hoffmann range from -7° to -35°.—F. W. SHORT, Hampstead.

Ext. Ipecac. Liq. B.P.

I have been a little astonished as to the statements made regarding the stability of this preparation. Having worked up large quantities of root, principally converting it into ext. ipecac. liquid, permit me to give one or two facts which I think go to corroborate your own remarks. A laboratory sample of a 12-gallon lot made six months ago shows no sign of deterioration. On examination it indicates the same alkaloidal value to-day as when made—viz., 2.1 per cent. Samples of more recent make bear out the same stability. Further, seven months ago I made some liquor containing 1.4 per cent. total alkaloids, using a 25 per cent. alcoholic menstruum, and its strength to-day is unimpaired; it still contains 1.4 per cent. From the above examples I do not find this preparation deteriorate so very readily, whether made with the B.P. menstruum or a weaker one.—J. W. THOMSON, Edinburgh.

To Gild and Silver Copper.

For gilding, dissolve potassium cyanide, 30, in a little water and add gold and sodium chloride, 10; potassium carbonate, 6; and calcium carbonate, 15. Then add enough water to make a soft paste; apply this to the surface to be gilded, wash off thoroughly with water and dry in sawdust. For silvering, take silver nitrate, 3; sodium chloride, 2; cream of tartar, 210; mix. Apply by rubbing with a damp rag. For surfaces subjected to rubbing, from which the silver has worn off, the following paste should be applied, and allowed to dry on:—Silver chloride, 1; cream of tartar, 2; sodium chloride, 3; water sufficient to make a soft paste. After remaining on the article for some hours, this is washed off with acidulated water, the article dipped in cyanide solution, and again washed.—*Union Pharm.*, 40, 509.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

Members of the Pharmaceutical Society must address all communications with reference to the transmission of the Journal, to the Secretary, 17, Bloomsbury Square, London, W.C.

LONDON: SATURDAY, JANUARY 20, 1900.

DANIEL FRAZER.

ONE of the few remaining Scotch pharmacists of the older generation and the head of the well-known firm of FRAZER AND GREEN, Glasgow, died at his residence Bowmore House, Garelochhead, on Wednesday, 10th instant, in his eightieth year. At the early age of ten years he was apprenticed to his elder brother Mr. N. B. FRAZER, who had opened a druggist's shop in Buchanan Street, Glasgow, in 1830. His brother died six years later and his widow ten years afterwards. She had assumed Mr. GEORGE GREEN, a Londoner, as a partner in the business, and the firm's name thus came to be FRAZER AND GREEN. At her death in 1847, Mr. DANIEL FRAZER became a partner. In 1849, Mr. GREEN died, and Mr. FRAZER became sole proprietor. He threw himself with great energy into everything he took up, and under his skilful guidance the business rapidly extended, the establishment becoming one of the best known in Scotland. In 1853 Mr. Frazer became a member of the Pharmaceutical Society. For eighteen years, from 1874 till 1892, he was a member of the Executive of the North British Branch, and for nine years, from 1872 till 1881, he occupied a seat on the Council. He held somewhat strong views, not quite in accordance with his colleagues, on legislation affecting pharmacy and on pharmaceutical policy generally. But his honesty and sincerity won for him universal respect. He was very keen in his loyalty to the Pharmaceutical Society and for a time resolutely refused to countenance the British Pharmaceutical Conference, imagining that it involved some antagonism to the Society. Afterwards he was entirely satisfied, and when the Conference visited Glasgow, in 1876, he was most liberal and princely in his entertainment of the Conference officials and leaders. He again showed his interest at the last visit of the Conference, in 1897, when a select party visited him at his home on the Gareloch. He was President of the Glasgow Pharmaceutical Association in 1876 and an honorary President at the time of his death.

He continued to take an active part in the management of the business until about seven years ago, when he had a stroke of paralysis. Since that time he has been wholly laid aside, though enjoying a fair measure of

health. He was a Justice of the Peace, as well as one of the best known and most highly respected citizens of Glasgow, always keenly interested in all that pertained to the prosperity of his native city. In politics he was an enthusiastic Liberal, taking great interest in the passing of the second Reform Bill, and in promoting the cause of Liberalism in the city. He was an elder of Free St. Stephen's Church, Glasgow, in which he took a very deep interest. He was proud of the fact that he "came out" in the famous Disruption of the Scottish Kirk in 1843. Few laymen were better known or more highly respected in the Church Courts or Committees. He possessed a strong literary taste, and has left an extensive library. He beguiled the leisure of his later years by writing a book entitled "A History of Buchanan Street," in which he gives a graphic account of the marvellous progress which the city had made during his lifetime. He was able to be about the house as usual until about three weeks ago. Two sons and two daughters survive. One son, Dr. JAMES G. FRAZER is a distinguished fellow of Trinity College, Cambridge, and one of his daughters is married to Professor STEGALL, of University College, Dundee. His death makes no change in the business. In 1897 it was formed into a private limited company, all the shares being held by members of his family, and by Mr. J. W. SUTHERLAND, pharmaceutical chemist, who has sole control and is assisted by qualified managers. The firm has four places of business in Glasgow, and it was Mr. FRAZER's care to follow up the rapidly extending boundaries of the city. This enabled him to retain and extend his connection with the business centre in Buchanan Street, as well as with the residential neighbourhoods of Charing Cross and Hillhead.

THE QUALIFYING EXAMINATION.

THE results of the qualifying examination just concluded in London afford powerful evidence of the necessity for insisting upon a compulsory curriculum in the case of candidates for registration as chemists and druggists. Of the three hundred and fourteen candidates examined, no less than two hundred and thirty-eight failed to satisfy the examiners, the percentage of passes being thus only slightly above twenty-four per cent. The proportion of failures, if not absolutely the lowest on record, closely approaches that point, and it would be difficult to advance a more saddening proof of the insufficiency of the methods of education usually resorted to by candidates for registration. Presumably, most of those who have been rejected—many not for the first time—have been engaged for at least three years in pharmacies, where they were supposed to be acquiring a practical knowledge of the business of a chemist and druggist; in addition, it may also be taken for granted that they have devoted a not inconsiderable period of time to the special work of preparing for examination, as that operation is usually understood. But in the case of more than seventy-five per cent. of the candidates, the training they have received has proved utterly insufficient for the attainment of their desired object. The remedy is not far to seek. It consists, as already indicated, in nothing short of the enforcement of a definite course of study.

ANNOTATIONS.

THE "MEDICAL PRESS" adheres to its assertion that compressed tablets afford facilities for the administration, in minute doses, of the very active alkaloids "which the practitioner prudently hesitates to order in a prescription," but the writer fails to adduce any evidence in support of that statement, and contents itself with calling the general practitioner (*sic*) as its witness. To avoid any misconception as to the position taken up, our contemporary goes more into detail, contending that strychnine, phosphorus, strophanthin, cocaine and atropine "cannot be compounded, even by the most capable and conscientious chemist, without the risk that the entire dose will be concentrated in one or two pills." Such a misstatement can only proceed from a person who is utterly ignorant of the subject he is writing about, or has deliberately determined to assert the superiority of certain manufactured articles at all costs. To maintain that "tableid makers" can effect in the way of sub-division of potent remedies what the individual dispenser cannot do, is palpably absurd, while the suggestion that pharmacists are setting up a "trades-union opposition to the public buying of tableids and other conveniently concentrated medicaments" is malicious and equally untrue. In conclusion, it is quite unnecessary for any medical journal to recommend pharmacists to adapt themselves to inevitable change in the public taste; it would be more to the point to advise medical practitioners to prescribe the medicines recognised in the authority provided for their convenience, and to cease to be dependent upon the makers of proprietary medicines for instruction in what should be their own especial art.

ANOTHER MEDICAL JOURNAL, the *Medical Times and Hospital Gazette*, has taken alarm at the decision of Mr. Baggallay in the compound rhubarb powder case recently reported in the Journal (see *ante*, p. 35), and remarks that it would be interesting to know how far a chemist may be permitted to exercise his discretion in such matters. The special reason for the alarm evinced is that the difference between selling a compound which is not in accordance with the B.P., but constituted according to the chemist's own fancy, and prescribing across the counter, is thought to be scarcely perceptible. The connection between the two things is not obvious, and we quite fail to see why Mr. Baggallay's decision should lead the *Medical Times* to ask "what earthly use is the British Pharmacopœia, and what possible certainty can any practitioner feel that any prescription of his will be properly dispensed?" But it is still more difficult to understand why, almost in the same breath, it should be asserted that the law relating to chemists requires revision, as it would be beneficial to all if its provisions were more stringent. The selling of "patent" medicines is alleged to be a great hindrance to proper legislation, but, since the benefit derived by Government through the duty upon patent medicines is very considerable, it is feared that nothing will ever be done to remove that obstacle. The following passage is especially unhappy. "Counter prescribing, too, requires putting down with a strong hand. The chemist says that as long as the doctor dispenses his own medicines so long will he continue to prescribe. The fallacy is so obvious as to be almost grotesque. The doctor is acquainted not only with the constitution but also with the effects of the drugs. The chemist knows little of the latter and nothing of medicine. The doctor by law is entitled to dispense." But what is to be gained by raking up these old grievances? The *Medical Times* expresses a great respect for pharmaceutical chemists, many of whom are hought to be admirably qualified for their special work. But at

the same time it is asserted that in trespassing on the doctor's province they have aroused a feeling of antagonism against themselves which has done their calling harm, so that signs are not wanting that in many districts "practitioners are uniting to fight the prescribing chemist on his own ground, by starting opposition drug stores which, supported by the profession and by adequate capital can undersell the retail chemist, and thus either reduce his profits to the vanishing point or compel him to seek another field for his energies." What useful purpose can be served by such idle threats?

THE AUTOMATIC ANALYST appears to a correspondent as great a bungler as the automatic dispenser would be, for though the latter has been much praised it is lacking in many respects, and as to the automatic analyst the scientific sophistication of sweet milk, according to the Master of the Belfast Workhouse, is carried out with such skill as to defy detection by the lactometer. One of the samples containing 10 per cent. of added water showed a normal specific gravity. He therefore concludes that a scientific analysis is the only accurate and reliable test. Another case has occurred where a farmer was repeatedly fined because of the lactometer's adverse decision, although he affirmed the fact of non-adulteration. He finally threw up the contract and, the local farmers refusing to tender, the District Board found it necessary to bring milk from great distances at a high price, also to purchase thousands of tins of condensed milk, and ultimately, with the sanction of the Local Government Board, bought an extensive farm and stocked it with cattle, prepared to produce milk as far above suspicion as Cæsar's spouse!

THE FOREGOING PARAGRAPH may direct attention to the inefficiency of many other mechanical methods so much in favour in the present age, for at the present rate of advance, unless there is a modified reversion to a saner method of medication, the automatic doctor may soon be at our door or upon our sidewalks. One wonders whether the Government will think it worth while to protect the legal status of the physician when every disease can be cured by dropping a shilling in the slot and the medical alumni of our universities shall have hired themselves as agents to the vendors to point out to the patient which particular slot to patronise; what with the gradual cessation of prescription-writing and the facile style of medical practice in prescribing proprietaries, the horoscope of the doctor for the new century is not greatly hopeful. For just as the "patent medicine" vendor has captured the pharmacy for the distribution of his wares, so also is the prescribing of proprietary medicines preparing the ground upon which Bachelors of Medicine will be called upon to surrender, bag and baggage, the practice of their profession.

A NEW ELECTRIC LAMP DANGER is pointed out by Mr. George C. T. Bartley, who has written to the *Times*, stating that, whilst turning on the electric light on his study table, the bulb exploded with a report like a pistol; the socket of the lamp was blown out, and the glass, in myriads of atoms, sent in all directions. Fortunately, a tilted shade saved his face, but he must have got some of the dust in one eye, for he is still confined to his room and cannot even read. The lamps had been supplied by the Westminster Company a week or so before Christmas, when all the lamps were changed on doubling the voltage of the current. The Company denies that doubling the voltage can have had anything to do with the accident, but cannot explain it, and Mr. Bartley rightly thinks that users of the electric light should be warned, as this danger exists, to put some protection on the lamps which they use close to their faces.

THE DRUG SALES IN JANUARY generally present a large quantity of material and not unfrequently contain items of unusual interest. Thus no less than 635 packages and cases of asafetida were offered this week, much of which is of very inferior quality. Two cases of the drug in tear, of fair quality, were noted, a dock sample of which afforded half its weight of good tear, yielding 10 per cent. of ash, and half of rather more earthy tear yielding 15 per cent. of ash, when examined by Mr. Moor. Messrs. Hale and Son, from whom the sample was obtained, were good enough to state that there was no difficulty in obtaining a supply of similar asafetida at anything from 80s. to 140s. per cwt. The same firm had 10 bags of *Strophanthus kombe* of recent importation, similar to that used by Professor Fraser, containing a mixture (as all previous importations have) of seeds, some of which give a red and others a green colour with sulphuric acid. Of the seed imported in pods a sample gave the red reaction only, and appeared to be of uniform character, affording an excellent opportunity for a chemical examination of seed of uniform character. Croton seeds of good colour, which have not been plentiful of late, were noticed. About 200 small gourds of Curaçao aloes were offered, 18 cases of Zanzibar, and 68 kegs of Socotrine aloes, some of which were of excellent quality, that in kegs being mostly firm, and that in tin-lined boxes was chiefly in the form of pasty liquid, loose or in skins. Dried orange-flower buds and pistachio kernels, the genuine *Pareira brava* root, four cases of sagapenum in fine tears, Korarima cardamoms, and reddish kino from Natal, were noticeable as drugs not seen at every sale. Of false drugs there were offered, Japanese aconite, Japanese star anise, woolly strophanthus seed, and a bark called "cuprea" bark, the presence of quinine in which is doubtful. We understand that about 70 bags of so-called ginger root, in the living state, have been thrown on the London market from Porto Rico. It differs from ginger in having a bitter taste, and is probably the rhizome of *Renalmia sylvestris*, which in Jamaica is known as "great wild ginger." The root is aromatic; the juice is said to stain a brown colour, and to have been used as ink.

THE MANX PHARMACY BILL was under consideration by a Committee of the House of Keys, on January 11. The Manx Society of Chemists was represented during the proceedings by counsel, who asked for the insertion in the Bill of a provision prohibiting companies from acting as chemists and druggists, or, failing that, of a provision prohibiting such companies from describing themselves as chemists and druggists. It was pointed out that such legislation would be in advance of British law, but counsel replied that it was only owing to an oversight in drafting the British Act of 1868 that companies had been allowed to act as chemists in Great Britain, and that the Lord Chancellor and others had strongly recommended an amendment of the law affecting companies. Counsel also asked that certain articles not already included in the scheduled list of poisons should be included, notably carbolic acid and rat poisons containing phosphorus. Mr. J. C. Radcliffe, chemist and druggist, gave evidence before the Committee. He stated that chemists have to serve an apprenticeship of four or five years, and undergo a system of special training. He, in common with others, had a strong objection to companies using the titles of chemists, giving the assumption that they were qualified. In the majority of cases, he said, the boards of directors are totally unacquainted with the profession, and oftentimes the managers of a shop have no voice in the matter of purchasing the drugs, and have to sell what is supplied to them. If the drugs were bad they would be injurious to the public. He thought there should be a clause put in the Bill to restrict the use of titles to qualified persons only, and he would prohibit company trading, except in the case of a qualified company. He also suggested that the name of a properly qualified person should be over each shop. The Committee promised to consider the suggestions carefully and to deal with them in the report on the Bill.

NEW REMEDIES.

ASPARAGUS AS A DIURETIC.—The well known fact that asparagus tops, when eaten, produce free diuresis, has caused H. A. Hare, of Philadelphia, to experiment with the fluid extract of the root stalks. This he has found to exert a powerful influence on the urinary organs, doses of one drachm of the preparation, three times a day, causing marked diuresis, even in one case where other remedies had been inactive. The drug appears to be quite free from any bad effects on the heart.—*Therap. Gaz.*, **23**, 589.

ALCOHOL DRESSINGS IN PSORIASIS.—H. Lau finds that an application of compresses of absorbent cotton soaked in rectified spirit, containing 2 per cent. of salicylic acid, to the œdematous and congested surfaces of the parts affected with psoriasis, exerts a very beneficial effect. He claims that the results obtained are at least as good as those with tar, pyrogallol, ehrysarobin, etc; the spirit dressing has the advantage of being cleanly and easy of application. The compresses are applied at night, covered with a protective layer, and removed the next morning, when the patches are cleaned with soap and a sterilised nail-brush. Should excoriations appear, the treatment is intermitted for a day, and lanoline ointment applied.—*Med. Press*, **58**, 329.

TANNIGEN IN DYSENTERY.—With doses of tannigen of 5 to 10 Gm., combined with 25 centigrammes of ealomel, the patient being carefully dieted, Cronkhite has cured twenty-one out of twenty-three cases of dysentery. Croja has also employed the same remedy in combination with milk somatose with very satisfactory results, feeding the patient with milk somatose immediately the excretion blood of and mucus ceased.—*Wien Klin. Rund.*, **13**, 466, after *Med. Review*.

UROSIN IN THE TREATMENT OF URIC ACID DIATHESIS.—Under the name of urosin a combination of quinic acid, 0.5 Gm., lithium citrate, 0.15 Gm., and sugar, 0.3 Gm., in tablet form, has been put on the market. It is stated that this combination brings about the rapid decomposition of uric acid, and thus eliminates the excess of that body from the system. It is given in doses of six to ten tablets daily.—*Pharm. Post*, **32**, 480.

EMOLLIENT PASTE FOR ECZEMATIC INDURATIONS.—To remove the hardened layers in chronic cases of eczema and psoriasis, P. Unna employs the following ointment:—Zinc oxide paste and resorcin, of each, 4; ichthyol and vaseline, of each, 1; mix. When the indurations are extensive, a less energetic application is employed, composed of zinc oxide paste, 3; resorcin and vaseline, of each, 1. A little of the paste is applied every morning until the epidermis begins to peel off. The application is then stopped, and if necessary, a soothing ointment is applied.—*Bull. Gen. de Therap.*, **138**, 636.

RUSSIAN METHOD OF TREATING ANTHRAX.—According to the *Deutsch. Med. Zeit.*, the following popular Russian treatment was successful in twenty cases of anthrax, in some of which both the local and general infection was very severe. Clean washed raisins a few drops of distilled water, and sal ammoniac are triturated together to the consistence of honey; the ammonium chloride forming about one-fifth of the whole mass. This is spread thickly on clean linen, dusted with powdered sal ammoniac and placed over the abscess, care being taken that the whole inflamed surface is covered with the poultice; the whole is covered with lint and a bandage, and the dressing renewed twice daily.—*Med. Press*, **68**, 300.

ENGLISH NEWS.

THE CHEMISTS' BALL.—The thirty-fourth annual chemists' ball—the last in the century—was held at the Portman Rooms, Baker Street, London, W., on Wednesday, January 17, and in spite of influenza and the war, which had doubtless fought against it, the ball was a complete success. Mr. Dan Godfrey's celebrated quadrille band provided music for an excellent programme of dances, which was thoroughly enjoyed. The stewards of the ball were Messrs. J. J. Arrow, John Attfield, A. R. Arrowsmith, W. A. Baiss, I. Bourdas, J. W. Bowen, E. N. Butt, M. Carteighe, R. L. Cassie, F. Clarke, A. Cooper, E. H. Farr, C. W. Langley Flux, W. H. Francis, T. H. Francis, F. M. Fisk, Thos. Farries, W. F. Gulliver, E. W. Hill, Walter Hills, A. G. Howard, D. Lloyd Howard, C. Hodgkinson, J. T. Humphrey, E. M. Holmes, E. A. Holloway, R. K. Harvey, C. A. Hill, E. A. Hugill, J. H. Hugill, J. C. Hyslop, Leonard Horner, Edward Horner, W. L. Howie, J. F. Harrington, T. H. W. Idris, W. Adpar Jones, Fred N. Layman, J. Lorimer, G. A. Lansdowne, S. Lynn, W. Martindale, C. W. Martin, Chas. Maw, Peter McEwan, Chas. Morley, Jno. H. Mathews, A. R. Morson, G. Matthey, E. R. Marsh, G. T. W. Newsholme, Henry A. Potter, B. H. Paul, A. J. Phillips, W. J. Ignatius Philp, R. Pain, Clifford Probyn, A. C. Preston, H. W. Kilby Pears, C. Rundle, J. Morgan Richards, Alfred Rose, A. L. Savory, A. H. Solomon, Charles Sanger, H. Silverlock, J. Thompson, A. E. Tanner, J. C. Umney, Ernest Umney, J. A. Wink, F. W. Warrick, H. Walker, W. P. Want, W. Warren, H. Wiggins, Harold Wilson, H. C. Wright.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.—The fifth meeting of the session was held in the Lecture Theatre, at 17, Bloomsbury Square, on Friday, the 12th inst., Mr. W. Garsed in the chair. The minutes of the previous meeting were read and confirmed. The Chairman, there being no business to bring before the meeting, then asked Mr. Pollard to read a paper on "Evolution." Mr. Pollard dealt with his subject in a most interesting and instructive manner, drawing numerous diagrams on the blackboard in order to illustrate the mode of development of the primary cells of the animal body. At the close of the paper, the Chairman invited members present to put questions; Messrs. Harris and Heslop responded, Mr. Harris contesting some of the views put forward in the paper. Mr. Finne-more, in a short speech, expressed the general appreciation of the paper felt by the meeting. Mr. Pollard having answered the questions put to him, the Chairman thanked him for the excellence of his paper, and the interest which he had imparted to the subject.

CHEMISTS' ASSISTANTS' ASSOCIATION.—On Thursday, January 11, the President, Mr. F. W. Gamble, took the chair at a social and musical evening, held in the Association's Rooms, 73, Newman Street, W. There was not a large attendance, but the excellence of the programme made up for the poorness of numbers. Mr. Ellis efficiently performed the duties of accompanist, songs being rendered by Messrs. Victor Blin, A. Latreille, C. J. Strother, and Marcus, the latter gentleman appearing in the uniform of the Honourable Artillery Company, being one of the candidates for active service in South Africa. A duet, "Excelsior," by Messrs. Blin and Ellis was perhaps the best item in the programme, but all the songs were highly appreciated. Mr. T. Morley Taylor recited in his well-known style "Dodd's Flat." Refreshments were provided, and a very enjoyable evening's entertainment terminated about eleven o'clock.

A CORONER ON COUNTER PRESCRIBING.—Mr. C. Luxmore Drew conducted an inquiry at the Hammersmith Coroner's Court on January 5 into the circumstances attending the death of Mrs. Laura E. A. Bartels (71), wife of a schoolmaster residing at 52, Devonport Road, Shepherd's Bush, W., on the previous Tuesday.—Evidence was given to the effect that deceased had suffered from

bronchitis, and the day before her death, as her breathing was very bad, deceased's son, Mr. H. H. Bartels, went to Messrs. Barnett, Newth, and Co., chemists, of Uxbridge Road, and asked for something to relieve bronchitis. The person who served him was stated to have said, "I think this will give almost immediate relief," and handed to him a bottle of "Stars and Stripes" mixture. Two doses of the mixture were administered. Next morning a change was noticed in the condition of the patient, and a doctor was sent for, but she died directly after his arrival. Mr. Bartels thought that the assistant who served him was Mr. Edgar Smith, who told the Coroner that he was an assistant to Messrs. Barnett, Newth, and Co., but was not a registered chemist and druggist. He remembered selling a bottle of "Stars and Stripes" mixture on the day in question. He was not aware at the time that it contained laudanum. It was a "patent" medicine, and was not labelled poison.—The Coroner said it was a very slack way of doing things for an unqualified assistant to prescribe—contrary to the Apothecaries Act—and at the same time to supply a mixture containing poison, although he did not know it.—Mr. John Arthur Barnett, pharmaceutical chemist, one of the partners of the firm of Barnett, Newth, and Co., in the course of evidence, said he believed he sold the particular bottle of medicine in question, although he could not swear to it. The assistants always, however, brought medicine to him before selling, and asked if it were the right thing to give. "Stars and Stripes" mixture was a "patent" medicine, and contained a weak preparation of opium or laudanum. It was an innocent mixture and was not labelled "poison," but in future—rather than there should be any doubt in the matter—he intended to so label it.—In reply to a question by the Coroner as to whether he did not know that it was contrary to the Apothecaries Act to prescribe, Mr. Barnett said he really could not say where prescribing begins or ends, and he asked "Are we to sell at all?"—The Coroner said chemists could sell, certainly. It was laid down by decisions in the High Court that if a person asks for a definite article they may sell; but if a chemist himself selects the medicine for the treatment of internal disease it is prescribing.—Medical evidence having been given to the effect that death was due to syncope from bronchitis, and that death was not affected by the medicine, Mr. Bartels was recalled, and said it was certainly not Mr. Barnett who served him. The assistant, to the best of his knowledge, served him direct off the counter and did not consult anyone.—The Coroner, addressing the jury, said it was a clear case of prescribing. The chemist's assistant had selected the medicine and, being unqualified, had no right to sell the poison, which he did. It was also sold without the necessary poison label. It was the duty of the person selling to know what he was really selling. In the present case, however, it had been sold blindly. After hearing the statement of Mr. Bartels, he could not think the assistant went to consult his principal. Mr. Barnett said it was his duty to have done so, and if he failed it was the fault of the assistant.—The jury returned a verdict that death was due to "natural causes." A rider was added to the effect that more care should have been exercised in the sale of such "patent" medicines.

THE ANGLO-COLONIAL CHEMICAL COMPANY, LIMITED.—A petition presented by a shareholder for the compulsory winding-up of this company was heard before Mr. Justice Wright, on Thursday, January 11. The company was formed to take over the benefit of certain inventions for the manufacture of artificial musk and other specialties in chemical or pharmaceutical products, together with certain letters patent already granted, and to manufacture, sell and deal in the said product of artificial musk. It was alleged that one patent was useless, and that the other could not be used owing to the Court having granted an injunction. Under these circumstances petitioner alleged that the substratum had gone, and the company ought to be wound up. On the other hand, it was contended that the company had power to buy musk if they did not choose to

manufacture it, and that an agreement had been entered into for the supply of musk, which would result in a profit of £40,000 a year to the shareholders. His lordship came to the conclusion that the substratum of the company was not gone, and dismissed the petition with costs.

PURCHASE OF A BUSINESS.—At Marylebone County Court on Monday, January 15, before Deputy Judge Fitzroy Cowper, and a jury, Mr. John Llewellyn Rowland, chemist and druggist, 17, Sussex Place, Queen's Gate, Kensington, London, W., sought to recover £48 15s. 1d. from Mr. Arthur John Sarson, also a chemist and druggist, 33, High Road, Willesden Green, N.W., the amount claimed said to be due under an agreement by which the plaintiff sold to the defendant a business at 9, Station Parade, Willesden Green. The defendant counter-claimed for £49 19s. for return of money said to have been over-paid by him for plaintiff's book debts, owing, it was said, to misrepresentation as to the amount of those debts.—Mr. W. H. Moresby was counsel for the plaintiff, and Mr. Stuart Sankey, counsel, defended.—Counsel for the defendant, at the outset, admitted the amount of the claim, and proceeded to deal with the counter-claim. The action, he said, had been remitted from the High Court. About June last the defendant, hearing the plaintiff's business was to be sold, wrote, and afterwards saw the plaintiff with a view to purchase. Subsequently an agreement was entered into by the parties by which the defendant purchased the goodwill, stock-in-trade, furniture, fittings, etc., of the business for £900, together with the book debts. The stock-in-trade was put down at £150, and if, on the valuation, it proved less, defendant was to receive the difference, and, if more, the surplus was to be handed to the plaintiff. There was no dispute as to entering into the agreement nor as to the amount of the stock-in-trade, which was valued at £198 15s. 1d. To the surplus above £150—namely, £48 15s. 1d.—the plaintiff was clearly entitled, and the only reason this amount had not been paid, as the rest of the purchase money had been, was that the book debts were represented as amounting to £170 or £180, whereas they really proved to be only £92 11s. Prior to the completion of the purchase defendant had asked to see the plaintiff's books, but owing to their not being made up, it was impossible to ascertain the amount of the book debts. A Mr. Green, accountant, had the disposal of the business, and it was he who represented the amount of the book debts as being £170 or £180.—Evidence having been given for both parties the jury found that there had been misrepresentation by Green as to the amount of the book debts; that this representation was made recklessly; that the defendant bought the book debts relying upon Green's representations, and they assessed the damages in favour of the defendant on his counter-claim at £33 16s. 4d., being the difference between £142 10s., the amount paid by defendant for the book debts, and £108 13s. 8d., their actual amount, excluding the £16 2s. 6d. said to have been paid to the plaintiff.—His Honour gave judgment for the plaintiff on his claim with costs, and for defendant on the counter-claim according to the jury's finding, with costs, and referred the question of the £16 2s. 6d. to an arbitrator, unless the parties could agree, the question of costs being reserved.

SALE OF SPIRIT OF NITRE.—At the County Police Court, Huddersfield, on Tuesday, January 9, the adjourned case against Dennison Priestley, grocer, Golcar, for selling sweet spirit of nitre not of the nature, substance, and quality demanded, came on for hearing (see last volume, p. 610c).—The case for the defence at the last hearing was that the wrong person had been summoned, inasmuch as the sale was made by the defendant's wife, and that she was the person to be proceeded against. Also that the analyst's certificate was bad.—Mr. F. A. Reed defended, and now stated that after closely studying the law on the subject he now withdrew the first objection. With regard to the analyst's certificate, it contained certain

observations respecting adulteration which ought not to have been there, and that fact invalidated it, as there was no charge of adulteration in the summons.—Mr. Wardle, for the prosecution, contended that the certificate was in good form.—The Bench accepted that contention, and imposed a fine of 12s. 6d., including costs. It was agreed, however, to state a case upon the following points:—(1) That the analyst's certificate was bad; (2) if the certificate was good there was no evidence as to adulteration.—At Boston Borough Police Court, on Friday, January 12, Thomas Bar Joans Booker, chemist and druggist, Main Ridge, was fined 10s. and costs for selling sweet spirit of nitre, 50 per cent. below the standard of the B.P., 1898.—At North London Police Court, this week, William P. Swift, pharmaceutical chemist, was fined £1 12s. 6d. including costs, for selling sweet spirit of nitre deficient in ethyl nitrite to the extent of 33 per cent. The defence was that the deficiency was due to evaporation, and the magistrate remarked that there were evident difficulties in the case, one remedy being a smaller bottle.

THE SALE OF CAMPHORATED OIL.—John Thomas Griffin was fined 15s., including costs, at Market Harborough Police Court on Tuesday, January 9, for selling camphorated oil containing only 15 per cent. of camphor instead of 21 per cent., as required by the B.P., and adulterated with 20 per cent. of cottonseed oil. The defence was that there was no guilty knowledge on the part of the defendant, as the oil in question was part of the stock taken over by him on coming into possession of the business.

SALE OF LIMEWATER.—At Stratford Petty Sessions, on Saturday, January 6, Henry W. Denny, of Katherine Road, East Ham, was fined 20s. 6d., including costs, for selling limewater which was not of the nature, substance, and quality demanded.

BELLADONNA LINIMENT TAKEN INTERNALLY.—An inquest was held on Tuesday, January 9, at the Islington Coroner's Court, concerning the death of Helen Lee (44), wife of Henry Walter Lee, a french-polisher, of 13, Bracey Street, Hornsey Road, N.—It appeared from the evidence that the deceased had received some liniment from University Hospital in a small blue bottle, but, having given some of it away, she had changed the rest into a bottle similar to that containing medicine, which she had also obtained from the hospital. On Saturday, January 7, she swallowed some of the liniment in mistake for the medicine, with a fatal result.—Dr. Foster, of the Great Northern Hospital, said the deceased had drunk belladonna liniment. Death was really due to pneumonia, but it had been accelerated by the overdose of liniment.—The jury returned a verdict of "Death from misadventure."

POISONING BY SODIUM SALICYLATE.—An inquest was held at St. Pancras, on Thursday, January 4, with respect to the death of Wm. Dugan (50), a Blackpool artist, who was said to have come to London to paint a large picture on the war. He lodged in Camden Town, and as he was suffering from a cold Dr. Malcolm Wheeler was called in to see him, and prescribed an 8-ounce mixture containing sufficient sodium salicylate for eight doses. Dugan, however, drank the whole at a draught, and died next day.—The jury returned a verdict of "Death from misadventure."

OVERDOSE OF LAUDANUM.—The Coroner for the City of Leeds held an inquest at Hunslet on January 15, on the body of Abraham Link (57), a core maker, of Hunslet.—The evidence was to the effect that deceased suffered from rheumatism, and was in the habit of taking laudanum to relieve the pain. On the previous Saturday he took two doses of the opiate and died early on Sunday morning.—A verdict of "Death from misadventure" was returned.

IRISH NEWS.

PHARMACEUTICAL SOCIETY OF IRELAND.—At the Pharmaceutical Assistant Examination, recently held, Messrs. J. S. Strange and J. Patton passed. One candidate was rejected. At the Registered Druggist Examination Messrs. J. Bell, E. J. Clancy, J. P. McEvoy, and D. Manson passed. At the Pharmaceutical License Examination Messrs. J. McGrotty, C. J. B. Dunlop; W. B. Conyngham, J. P. Myles (equal); F. C. Warren, and R. Kingston passed. Ten candidates were rejected.

NORTH OF IRELAND CHEMISTS' AND DRUGGISTS' SOCIETY.—At the general meeting of the Northern Branch of the Chemists' and Druggists' Society of Ireland, held recently at Belfast, the following resolution, proposed by Mr. Carse and seconded by Mr. Acheson, was unanimously adopted:—"Believing that the Pharmaceutical Council is agreeable to accept increased representation for chemists and druggists, we recommend the latter body in the north of Ireland to qualify as associates, with the view of securing further and adequate representation, as the members of this Society are strongly convinced such a course would tend to advance the best interests of both sections of the trade."

AN IRISH DISPENSARY SEIZED FOR POOR RATES.—At the last meeting of the Ennistymon, Co. Clare, Board of Guardians, the Clerk read a letter received from Dr. Peter O'Dwyer, Medical Officer, stating that the rate collector, Mr. Hynes, had seized on the Ennistymon dispensary for poor rates due. The dispensary could not be reopened for public use for some days in consequence, and he, in the meantime, had to procure medicines and drugs for patients from the local Medical Hall. Mr. Hagrave, a Guardian, said that the attention of the Local Government Board should be called to that letter. Mr. O'Dwyer, J.P., said that the bill for the medicines and drugs which had to be procured from the Medical Hall would be more than the amount of rates due. The Clerk of the Union, Mr. Griffy, explained that the rate collector had asked him for the rates due, and he (the Clerk) communicated with the Local Government Board as to whether it would be legal for him to pay the amount owing. To that communication he had received no reply. The Guardians made an order that the Medical Officer's letter should be inserted on the minutes for the observation of the Local Government Board.

CORK MEDICINE CONTRACT.—At the meeting of the trustees of the North Charitable Infirmary, Cork, held last week, the tender of the Cork Chemical and Drug Company was accepted for supplying the institution with medicines, drugs, oils, etc., for a period of twelve months. The contract is one of the most important of the kind in Cork.

INSPECTORS OF EXPLOSIVES IN IRELAND.—A largely-attended meeting of the Wexford County Council was held last week, at which Sir Thomas H. Grattan Esmonde, Bart., M.P., presided. An application of considerable interest to Inspectors of Explosives in Ireland came up for consideration. It was made by Messrs. M. J. O'Connor and Company, solicitors, Wexford, on behalf of the Petty Sessions Clerks of Wexford, New Ross, Gorey, Enniscorthy, and Aulart, for £50 compensation each for the abolition of their offices as Inspectors of Explosives under the Local Government (Ireland) Act. The work will henceforth be done by the Royal Irish Constabulary, and the present application for compensation has been the first of the kind made in Ireland. At the County Council meeting a long discussion took place as to whether the superseded Inspectors of Explosives who have been superseded all over the country

relieved of their offices by the Local Government Act. A letter was read from the Local Government Board deciding in the affirmative. The question then arose as to whether half the amount of the compensation to be allowed should not be contributed by the Government. This the Local Government Board also said they were not empowered to do under the Act. The County Council therefore decided to fight the matter out in Court, Mr. O'Connor, solicitor, having served processes for the amount of compensation claimed by each of the Inspectors of Explosives. The subject is of much public interest in Ireland, affecting, as it does, the Inspectors of Explosives who have been superseded all over the country by the Local Government Act.

FOREIGN NEWS.

WANTED! A NEW RAT POISON.—The anxiety caused by the enormous increase of rats in Paris during the last few years led recently to Dr. Henry Thiéry, of the City Hygiene Service, being commissioned by the authorities to look into the matter. Dr. Thiéry's report shows the urgent necessity of measures to destroy the vermin, and contains many interesting facts. The sewers are it appears, a refuge where the rats fear nothing but an inundation. When, however, their ordinary resorts were disturbed by the work connected with the 1900 Exhibition along the banks of the Seine they took refuge in the neighbouring houses, preferably the new ones. There are now, it appears, streets near the river where the inhabitants are afraid to allow their children to cross the garden or the courtyard after dark. The central markets are infested to such an extent that rat-hunting has been abandoned in despair. As soon as dark sets in armies of rats attack the reserve provisions, to which they have burrowed their way beneath the masonry. A singular detail is that the cats, which are very numerous at the central markets, live on the best of terms with the rats. They can be seen trotting about together. The city cat has lost its reputation in Paris. It still enjoys killing a mouse, but with other food at hand a rat has become rather large game from the feline point of view. For this reason the Budget Commission suppressed this year the credits for the cats kept in the storehouses of the Ministry of War. The cat as an official is now only to be found at the Ministry of Finance and the Council of State. No decision has yet been come to by the authorities as to how the plague is to be got rid of, though poisons with instantaneous effects, which have the additional advantage of mummifying the body, are favourably regarded. The system, however, has the disadvantage of making poison too readily obtainable, the results of which, in the hands of the unscrupulous, cannot be over-estimated. Dr. Thiéry mentions four terriers belonging to Monsieur Girard, chief of the Municipal Laboratory, which are excellent rat-catchers. They have cleared the cellars of the Prefecture of Police from the vermin, and are so ardent in the chase that they have strayed two miles from home, along the sewers, as far as Bercy, killing large numbers of rats on the way. Monsieur Girard's favourite English terrier can break instantaneously the back of a rat weighing a pound and a half. Paris could hardly, however, be freed from the plague by dogs. On Achèves Plain rats, estimated to be 10,000 in number, have been seen at one time on two acres of ground planted with beetroot. There is, therefore, fame in store for the chemist who can meet the wishes of the authorities and rid Paris of rats without endangering human life.

GERMAN MEDICAL CONGRESS.—The Committee of the Society of German Naturalists and Doctors met on January 13 to settle the date of the Congress to be held in Aix-la-Chapelle this year. It was proposed to hold the congress in August, so as to allow of a deputation being sent to the various congresses to be held in

Paris during the Exhibition. It was, however, seen that the Paris congresses are spread over such a space of time that such a deputation would be impossible. It was therefore resolved that the congress be held at the date originally fixed—September 17 to 21 next.

PROPOSED NEW THERMOMETER SCALE.—Monsieur C. Mocuery, President of the Académie des Sciences, Paris, and of other learned bodies, has proposed that we should abandon the conventional scales of our thermometers and adopt one starting from the absolute zero of temperature, which was so nearly attained by Professor Dewar in his solidification of hydrogen. This would be a rational and truly scientific scale. The absolute zéro corresponds to the cessation of molecular vibration, and is calculated as 273° below zero of the centigrade thermometer. With such a scale the troublesome negative degrees (or "below zero") would be avoided, and existing thermometers could serve by altering their gradation.

ARSENIC IN THE HUMAN BODY.—In a paper communicated to the Académie des Sciences, Monsieur Armand Gauthier showed that arsenic plays a part in the organism as important as that of iron. The Asiatics, as well as the Greeks and Romans, prescribed it as a medicine. Nevertheless, it is only now that the part played by arsenic, which is not found in the blood, has been made out. Last time, Monsieur Gauthier introduced an organic arsenic, under the form of cacodylic acid, for the treatment of phthisis, and with so much success that large quantities of it have been made. Knowing that the thyroid gland contains iodine, he suspected that it also produces arsenic, and investigation of these glands in cattle and in man proved that his idea was correct. The thyroid gland of man is the richest in arsenic, but the thymus gland also contains it. Arsenic plays the part of organic phosphorus in the organism, he says, and it occurs in the thyroid gland in the state of nucleine. Arsenic ought, therefore, to be present in the organism in sufficient quantity, or else myxœdemic troubles arise. A very little arsenic is also found in the brain and in the skin.

STARTLING SHELL EXPLOSION IN A CHEMICAL LABORATORY.—At the time of the Anarchist outrages in Paris in 1893, the Prefecture of Police had four shelters made in the walls of the fortifications at Montrouge, Aubervilliers, Bercy, and Point du Jour, where infernal machines or unexploded shells could be opened without danger. Since the shelters were made, 251 infernal machines and 113 shells have been opened under the direction of M. Girard, Director of the Municipal Laboratory. When it is found impossible to open the suspected machines by chemical means, the chemists proceed to crush it by hydraulic pressure in a well specially constructed in the hut, the operators seeking shelter in a casemate protected by a wall of earth three metres thick. On Tuesday morning last, at mid-day, M. Truchon, Chief Chemist of the Municipal Laboratory in the Point du Jour shelter, proceeded to crush a shell 22 centimetres in diameter and 53 centimetres high, which was found during the excavations for a house at the angle of the Boulevard Murat and the Rue d'Auteuil. M. Tramus, driver of the special waggon used to pick up the infernal machines, was with M. Truchon in the laboratory, working the hydraulic press, when suddenly there was a violent explosion in the well. A spark, produced by friction of the metal, had exploded the ten kilos of powder or guncotton with which the shell was loaded. The roof covering the well was blown to atoms, and the shock broke several panes of glass in the windows of a house over on the other side of the Boulevard Sachet, but, thanks to the precautions taken, the operators escaped with a slight shock. Great alarm prevailed

in the neighbourhood for some time, the residents fearing that a terrible disaster had happened.

COLONIAL NEWS.

A PHARMACIST ON THE WAR.—The following extract is from a letter received from an old student in the Pharmaceutical Society's School of Pharmacy, who is now in Durban:—"I suppose you are wondering how I came to be here, and no doubt anxious to learn my news, so I shall begin by telling you how I left the Transvaal. My partner and myself both decided to stay in Johannesburg if possible. So when the war broke out on October 11, and when all British subjects were given eight days wherein to leave the country, we both applied for permits to stay. Very few permits were given, and so it happened that my partner obtained one and I did not. I therefore had to leave. To have stayed and defied the Transvaal authorities would have been the height of folly. So I packed up a few things—just what I could carry—and went. I could not go *via* Natal route, as the war had started and the Boers were already in possession of the northern Natal towns, so I came out *via* Delagoa Bay, and now here I am, stranded in Durban. If I am lucky, after the war is over, I shall go back to my property in Johannesburg, for, of course, I had just to leave everything as it was. But if I am unlucky, I stand to lose every penny, with a very doubtful chance of getting compensation, and shall have to begin life over again. Meanwhile, I am stranded here with nothing to do, in consequence of every vacancy which occurs being instantly snapped up by other refugees. I tried to get work, not caring to remain idle, and I offered my services as dispenser to the military; but up to date I have not been accepted anywhere, and so am having an enforced holiday. I need not say that this is very unpleasant. I have not volunteered as a "scout," because I cannot shoot, but I do not despair of yet getting accepted as a dispenser later on. The war is a terrible war, as you will know from the home papers. I have spoken to many of the eye-witnesses of the various fights, and all agree as to the horror of modern warfare. Yet the war was absolutely necessary, and I am glad it has come about, for, not until we give the Boers a thorough beating, will this country be fit for Englishmen to live in, and no prosperity is possible till then. Yet it is sad to see how everybody here is affected by the war. Many are utterly ruined and rendered destitute. One old lady, staying at the same place as I am, has nine grandchildren at the front fighting, five are Free State burghers, fighting for the Dutch, and four are Natal Colonists fighting for the English. Owing to intermarriage many years ago, this war becomes often akin to civil war. Another man staying here has two sons at the front fighting. He also is a Johannesburg refugee, and stands to lose all he possesses, while his daughter had her lover killed at the front. But I suppose similar things happen in all wars—it is so always—but personal contact with war makes one realise it so much better. Well, enough about the war. Let me talk of other things. I met Mr. Wood, the botanist of the Natal Botanical Gardens, and I took the opportunity to ask him about the Natal aloes. Mr. Wood tells me that no one has been able to discover where the aloes grow which produce the variety hitherto called 'Natal Aloes.' This agrees with my own results. You will remember that when I was in Ladysmith I tried to obtain aloes from local plants. The aloes I obtained answered to the tests of Cape aloes, and I never succeeded in getting an aloes to answer to the test for Natal aloes. Mr. Wood tells me he has tried the Mooi River districts with the same result. I cannot, therefore, explain how it is that the Natal aloes used formerly to have different characteristics to the present kinds. Travelling in Natal here away from the railway line is very costly, and also just now impossible, because of the war, and so I have not been able myself to pay the Mooi River district a visit."

NOTICES OF BOOKS AND OTHER PUBLICATIONS.

'THE OFFICIAL CALENDAR OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN FOR 1900' is now obtainable from the Secretary, price 2s. Members of the Society and student associates are given the privilege of having the Calendar they purchase sent to them post free, but other purchasers are required to add 4½d. to their remittances to defray postage. It is difficult within the limits of this notice to enumerate the many claims of the book to be regarded as a valuable adjunct to the pharmacist's reference library, but it may be said without much risk of incurring a charge of "puffing" that if more chemists and druggists were to consult this official publication there would be fewer misconceptions among the general body as to the constitution, aims, work, and limitations of the Society, and a more widespread knowledge of the statutes intimately affecting the calling of pharmacy. In the present edition several noteworthy additions and amendments have been made. The old recommendations for the keeping, dispensing, and selling of poisons have been removed from their hiding-place, and are now prominently printed in all the glory of heavy type as poison regulations. The new conditions to be fulfilled after August next by persons desirous of registering as "Apprentices or Students" are also clearly set forth, side by side with the regulations which expire in July. With regard to that portion of the Calendar dealing with legal information, considerable care appears to have been given to revision, and the matter may be safely relied upon as being accurate. The new medical scales under the Merchant Shipping Acts are published in full, and though it may be a moot point whether the space they occupy might not have been better utilised, they afford a good example of the desire of the Council to give the fullest information possible to every section of the calling. It may be stated in passing that those scales were brought into conformity with the latest edition of the Pharmacopœia by a committee of the Board of Trade on which pharmacists were represented by Mr. A. J. Phillips, of Kensington. Other important additions are the London County Council order respecting the use of petroleum spirit by chemists, and the new Sale of Food and Drugs Act—both of which merit close attention. For a summary of the principal contents of the Calendar readers are referred to our advertisement pages.

'INTRODUCTION TO THE OUTLINES OF THE PRINCIPLES OF DIFFERENTIAL DIAGNOSIS, WITH CLINICAL MEMORANDA.' By Fred. J. Smith, M.A., M.D. (Oxon.), F.R.C.P. (Lond.). (London: Macmillan and Co., 1899. Pp. 253. Price, 7s. 6d.)—In this work Dr. Smith does not lay claim to much that is new except some original ideas which are the outcome of long study and research. The book has been written more with the object of arranging the old phenomena of disease in such a manner as to show more clearly their fundamental meaning and relationship, the author drawing his inferences from the data of physiology and facts of pathological anatomy which constitute a critical analysis of clinical symptoms and so lead up in a scientific and systematic manner to the underlying principles which govern disease and health. No one reading this work can fail to appreciate the able manner in which the varying signs and symptoms of pathological conditions are classified, and the author has built up from fundamental and scientific principles a system which proves the relative dependence of the various conditions upon one another. Isolated, or apparently isolated facts, thus lose their isolation, becoming members of a related community, and so fall naturally into their places as deductions from a universal law. The book deserves the most careful reading, and this is rendered the more easy and entertaining by the lucid and logical style of the author. The latest results of bacteriological investigation are fully considered, and the whole work is written in accordance with the latest discoveries of medical research.

Obituary.

ARROWSMITH.—On January 6, at Rensburg, South Africa, Sergeant Henry Raymond Saddler Arrowsmith, son of Mr. G. Arrowsmith, Chemist and Druggist, Whitstable. Aged 24.

BARRETT.—On January 9, James Barrett, Pharmaceutical Chemist, late of Bayswater. Aged 57. Mr. Barrett had been a member of the Pharmaceutical Society since 1866, and was a subscriber to the Benevolent Fund. He had been in business at Chichester only a few weeks before his death.

COOPER.—On January 8, Mrs. Cooper, widow of the late Benjamin Cooper, Chemist, of 93, Kingston Road, Wimbledon. Aged 69.

FENNINGS.—On January 7, Alfred Fennings, Chemist and Druggist, West Cowes, I.W. Aged 85. Mr. Fennings, who was well known as the proprietor of various preparations for children's ailments, contributed regularly and generously to the Pharmaceutical Society's Benevolent Fund.

FRAZER.—On January 10, at Rowmore House, Garelochhead, Daniel Frazer, J.P., Pharmaceutical Chemist, in his 80th year. Mr. Daniel Frazer was head of the well-known firm of Frazer and Green, Glasgow, but had for some years past been laid aside from work consequent on a shock of paralysis, and had ceased to take any active interest in pharmacy, imperial politics, or ecclesiastical affairs, to all of which he had for some many years given great attention. His remains were interred on Saturday last at Row Churchyard, in the presence of his relatives, a few personal friends, and some of the heads of departments of Frazer and Green. Mr. Frazer was born in 1820, and served his apprenticeship with his brother in a shop at 105, Buchanan Street. On the death of Mr. N. B. Frazer, his widow took Mr. Green into partnership, an arrangement which subsisted for ten years. At the close of that period Mrs. Frazer retired, and on January 1, 1847, Mr. Daniel Frazer was assumed as a partner, so that for more than half a century he has been associated with the great concern that he built up by his unaided and untiring energy, Mr. Green having died in 1849, leaving him sole proprietor. In an account of the early days of his brother's business, Mr. Frazer mentions that for the first six months the takings were less than £20 a month, there had been only two days in the half year when the drawings were over £2, and it was as low one day as 3s. 6d. To Mr. Frazer alone is due the credit of having reared and carried on with success the splendid business of Frazer and Green, which says much for his industry, caution and ability. Mr. Frazer took an active part in pharmaceutical politics, and was from 1871 to 1881 a member of the Council of the Society, in which position he was distinguished by an outspoken frankness which was sometimes unpleasantly candid, but so kindly was his nature that no one ever took offence at his criticism, and when he resigned his post on account of the illness of his wife, his colleagues were unanimous in deploring his loss. He was a Liberal in politics, and an active member and office-bearer of the Free Church of Scotland.

HUME.—On January 13, Nathaniel Hume, Chemist and Druggist, Torriano Avenue, London, N.W. Aged 77.

LINES.—On January 10, George Lines, Pharmaceutical Chemist, Hertford. Aged 85. By the death of Mr. Lines the Society loses one of its most steadfast supporters. The deceased gentleman was a Founder of the Society, and had he lived a few months longer might have celebrated his diamond jubilee of membership. For very many years he acted as local secretary for his district, and was always ready to speak a word in good season in furtherance of the best interests of pharmacy. The little band of surviving founders is now reduced to half-a-dozen—five of whom still figure on the list of members published in the 1900 Calendar.

MUIR.—On January 8, George McCartney Muir, Chemist and Druggist, Newcastle-on-Tyne. Aged 34.

BLACKPOOL PHARMACEUTICAL ASSOCIATION.

Business and pleasure were united in an eminently successful dinner on Wednesday evening, January 10, by the chemists of Blackpool and district, at the Palatine Hotel. The chair was occupied by Mr. T. CARTER, of S. Shore, and Mr. Councillor J. Laurie the vice-chair.

Letters were read by the local secretary from Messrs. Billington, Weidham, Henderson, and Councillor Lofthouse (Fleetwood), expressing sympathy with the objects of the meeting and regret at being unable to be present.

After the usual loyal toast had been ably dealt with by the CHAIRMAN, the VICE-CHAIRMAN, and Mr. H. WITHERS, Councillor J. LAURIE, who has acted as local secretary for a number of years, proposed the toast of:—

THE PHARMACEUTICAL SOCIETY.

Mr. Laurie, in dealing with the toast, spoke of the necessity for an association of chemists for the Fylde. Nothing could be done except by union; if anything was wanted from Parliament one of the first things asked was, "Who are you and what are you?" and a Society that represented only a fraction of the trade could not expect to carry the weight that it otherwise ought to. Mr. Laurie spoke of the difficulty there would be in preventing limited liability companies carrying on the business of chemists and druggists, but maintained that they ought only to be allowed to do so when putting the name and qualification of the person responsible on the label. He thought it would be better to form an association under the auspices of the Blackpool Tradesmen's Association. Local chemists had taken an important part in its formation and support; there were four local chemists on its executive council and two were hon. officials.

Mr. TAYLOR, of St. Anne's, supported the toast. He often heard it asked, "What is the Society doing for us?" Before he answered this question he would ask, "Are you a member? because, if not, you have no right to ask it"; if you are a member, "What do you want the Society to do?" His experience was that in many cases the Pharmaceutical Society had no means of knowing what pharmacists do want. The business of the evening was the formation of a local association, and it was by means of such associations as it was proposed to form that they could get their wishes expressed, and also be able to exert a greater influence on public opinion in the country. As a watering-place he believed Blackpool to be without a rival in the world, and it was high time that some means were adopted of obtaining the collective opinions of the pharmacists there and in the district. The company question was the question of the hour, and the position of pharmacists was a very peculiar one. The pharmacist, he contended, is a professional man, for the fact that he has graduated as a scientific man and has to go before the Examination Board of the Pharmaceutical Society, and the titles Ph.C. or M.P.S. are as much degrees as an M.D., and as much a personal degree, too. No company could pass those examinations, no company could be an M.A. or Mus. Doc., no more could a company be a chemist and druggist; and pharmacists had a right to ask that that degree shall be confined to qualified men only. But they were also tradesmen, and as tradesmen must meet competition, and if their predecessors of thirty years ago had taken the steps they now found necessary, they would not have been in the position they are in to-day. He had a theory—he believed advancement may be in a personal direction, and they must start with the apprentice and the preliminary examination. There should be an entrance fee that would raise the social standard of the candidates, as is done in other professions. He believed the Council of the Pharmaceutical Society saw this—perhaps it was afraid of interfering with other legislation. Mr. Taylor concluded by predicting a better future for pharmacists, and asking them to be more particular as to the stamp of young men they admitted as appren-

tices; it would entail some inconvenience now which would be well worth enduring for the future benefit to be derived.

Mr. W. C. RICHARDSON supported the proposal. At present the facilities for a high-class technical training for the youths committed to their charge was not what it might be. The Technical Instruction Committee provided classes in pure science, but classes in pharmacy were also required, and an association would provide the necessary machinery.

Mr. ASHTON also supported the scheme. In company with the local secretary, he had called on a number of chemists in Blackpool, South Shore, St. Anne's, and Lytham, and they had been most cordially received, especially at the three former places. Opinion was strongly in favour of forming an association. He believed the committee who had assisted in getting up the dinner had stated the same thing.

Mr. BUCKLEY said he had been associated with a very large association of chemists in the South of England, which had done a very good work, especially in the matter of classes for young men.

Several others spoke in favour, and a resolution was then submitted by Mr. W. WITHERS, seconded by Mr. SEDGWICK, that steps be taken to form such an Association.

It was also resolved, on the motion of the CHAIRMAN, seconded by the VICE-CHAIRMAN, that Mr. C. H. Turver be appointed Secretary *pro tem.* and call a further meeting at some convenient date.

The LOCAL SECRETARY, Mr. C. H. Turver, on behalf of the Pharmaceutical Society, suitably responded, thanking those present for the hearty manner in which the toast had been received. Thanks to the exertions of the late local secretary, Mr. Councillor Laurie, the Society was well represented in Blackpool, and nearly every member of the craft in the town were subscribers to the P.A.T.A., and he hoped to have those yet. An association was a *sine qua non*. If bricklayers and engineers could combine, and had combined, to raise their social status, and everyone knew what the engineers had done, then it was a reflection on the intelligence of chemists that they were not a closely-united body. When that came to pass they might do anything.

Among those present were Messrs. Ashton, Buckley, Carter, Bailey, Keeley, Councillor Laurie, Johnson, Greenwood, Richardson, Sankey, Sexton, Sedgwick, Turver, Withers, Turnbull (Blackpool), Kershaw (Paulton), Taylor and Evans (St. Anne's).

NORTH-EAST LANCASHIRE CHEMISTS' ASSOCIATION.

At a meeting of this Association, held on Thursday, January 11, Councillor CRITCHLEY presided, and Mr. W. S. GLYN-JONES addressed the members upon the advantages of

THE CHEMISTS' DEFENCE ASSOCIATION, LIMITED.

At the outset he remarked that if every town of the size of Blackburn could show meetings of the size and character of that one, then pharmacy, on both its professional and trade sides, would be in a very much better position than it was. He did not think the Council of the Pharmaceutical Society had so far recognised the power for good or evil which local associations might exercise. Proceeding to explain the merits of the Defence Association, Mr. Glyn-Jones remarked that it was notorious it was the minority who joined trade organisations and worked and paid to secure benefits of which the whole body of chemists reaped the advantage. The P.A.T.A. therefore welcomed the opportunity of giving to their members, in this Defence Association, something to which only members would be entitled.

The CHAIRMAN spoke strongly in favour of the Association, giving instances which had occurred within his own knowledge of proceedings against chemists in which expert knowledge on the part of the chemists' solicitor would be most valuable.

Councillor SHORROCK (Darwen) also expressed decided approval of the Association. A most vexatious methylated spirit prosecution, in which he had been involved, might have been avoided had he had at command the services of a lawyer who understood the Acts bearing upon the matter.

MESSRS. HOWARTH, BEAN, and YATES having also expressed approval of the objects of the Association,

Mr. HOLT said he thought the defence scheme an admirable one; but he wished to ask Mr. Glyn-Jones why, as a member of the Pharmaceutical Council, he gave away the position as to the practice of pharmacy as he did.

Mr. R. LORD GIFFORD said that meeting would disabuse Mr. Glyn-Jones of the idea that Blackburn concerned itself solely with ideals. The North-East Lancashire Chemists' Association had insisted, perhaps at the cost of some misunderstanding, that the profession of pharmacy must be absolutely dissociated from the ordinary drug trade. He appreciated the remarks of Mr. Glyn-Jones as to the minority having to work for the whole body. If the majority, who took advantage of the work of the minority, would be a little more liberal in their views, and a little more tolerant of other workers, it would be a good thing.

Mr. GLYN-JONES, in reply, explained at length how the Defence Association would act in cases quoted by the different speakers. Mr. Howarth had expressed the opinion that the taking up of prosecutions should be the work of the Pharmaceutical Society. He quite agreed that it was the proper work of the Pharmaceutical Society, and he was certain that that Society had not in the past done enough of such work. But it would be useful for chemists to have an Association able to force the hands of the Pharmaceutical Society in such matters, while there were prosecutions which it would not be to their interests that the Pharmaceutical Society should take up, but which an independent association might take up with advantage. As to

THE QUESTION OF COMPANY PHARMACY,

upon which his opinion had been asked, they must not for a moment think that he was sacrificing the position. He was accused of relinquishing a position which had never yet been occupied, owing to the supineness and apparent indifference or incompetency of the men who had constituted the Pharmaceutical Council for the last twenty years. The position which they imagined those who were now trying to do something had abandoned was never occupied by them. Twenty years ago, when certain decisions were given against them, those members of the Pharmaceutical Council who waited for the members of the Society to lead them instead of leading the trade let an opportunity pass and were guilty of a breach of trust which it was unfair to suggest those who came to the Council twenty years too late were responsible for. He was not the man to abandon any position he had the slightest chance of maintaining, and he was quite prepared to be a party to a deputation from the Society which should take up the position of the Law and Parliamentary Committee, and ask the Government for everything he believed they had a right to claim. But he did contend that in the event of their getting a straight "No," a definite refusal, from the Government, they should be prepared to fall back on the next best thing for them, rather than let their opponents, Mr. Jesse Boot and his kind, in conjunction with the Lord Chancellor and the Government, make arrangements to suit themselves and not the trade. They as a trade would never secure any legislation apart from the Government. For twenty years, he was told, the Pharmaceutical Society had been trying to get Bills introduced which would remedy that, but apart from the Government he was convinced that no private Bill would stand the ghost of a chance. It was getting more difficult every year to get private Bills through the House, and their only chance was to get the Government to see their position. If the Government refused, let them not neglect the opportunity to

get a good step in advance because they could not have everything they had a right to get. They were in a rather helpless position, but he refused to take the responsibility of giving away something which, through the supineness of the Pharmaceutical Council, they had never possessed. As to Mr. Gifford's remarks about minorities, some members of the Pharmaceutical Council, as well as persons in other walks of life, would be very glad if some of the minorities would not be quite so much in evidence. He himself had great sympathy with the minority, and unfortunately he found himself in that position almost every month. His experience was that unless the minority was particularly noisy it stood not a shadow of a chance against the majority. It was always a satisfaction to him when in a minority to remember that Carlyle once said that the majority of the population of this kingdom were not wise men.

Mr. GRIMSHAW, in moving a vote of thanks to Mr. Glyn-Jones, expressed a hope that other members of the Council would come amongst the members and let them know how matters stood.

Mr. PICKWELL seconded the motion, which was supported by Mr. JEPSON, and carried with applause.

Mr. GLYN-JONES said he certainly endorsed the statement that it would be well if the members of the Pharmaceutical Council and the officers of the Society got into closer touch with local associations, and attended their meetings, prepared to answer questions which they, as members of the Pharmaceutical Society, were entitled to ask. He hoped they would give him credit for having his own welfare and that of his brother chemists at heart, and if he had the time to discuss the question, they would find that between the position he held and that of the North-East Lancashire Association there was not the difference of a sheet of paper. If the Association did him the honour to ask him to come down and discuss the matter in public or in private he should be very glad to avail himself of the opportunity.

IRISH PHARMACISTS' ASSISTANTS' ASSOCIATION.

On Friday, January 12, Dr. J. A. WALSH, M.C.P.S.I., delivered before the above Association a lecture entitled

Nerves,

In the course of his remarks, Dr. Walsh stated that, in advocating the study of the action of drugs upon the body, and more particularly upon the nervous system, and the necessity for the pharmacist having some knowledge of the arrangement and structure of the nerves, he did not intend that such knowledge should be applied to the development of the much-discussed sin of counter-prescribing. As to the usefulness of a knowledge of therapeutics to the pharmacist there could be no question. They could call to mind many occasions on which they had been handed a bundle of prescriptions by a customer with the statement that one was for his liver and another for, perhaps, influenza or asthma, and he would be a very sorry pharmacist who could not solve the difficulty. Materia medica and therapeutics were closely connected, and should be studied together. In some of the older works upon materia medica the various articles were grouped according to their therapeutical action. For instance, all the astringents were considered together, and in the same manner the tonics, carminatives, antacids, etc. He thought the arrangement a good one. In studying therapeutics they would constantly meet statements as to the action of drugs upon different nerves and nerve endings. For instance, the endings of the third nerve are paralysed by atropine, the sensory nerves by opium, in their action on the pupil, he would endeavour to explain some of these items in the hope that it would be of some help to them studying the materia medica. The lecturer then proceeded to describe the appearance of a nerve. Before commencing his medical studies he

imagined that a nerve was a kind of vague ethereal substance, not a tangible body, but upon commencing to dissect and having removed the outer layer of skin and fat he came upon a number of slender thread-like strings somewhat like fine twine, these were nerves containing an internal nerve fibre and an outer protective sheath.

The lecture was illustrated by lantern slides, the first slide showing a piece of the Atlantic cable, also a transverse section contrasted with a nerve. The internal copper wire which conveys the current might be considered the axis cylinder of the nerve, and the outer layer of insulating material the medullary sheath. The next slide illustrated the arrangement of the nerves in the body, the spinal cord arising in the brain and terminating in the base of the spine. Several excellent photos of the brain were shown and described by the lecturer, and finally the cranial nerves were fully described.

Dr. McWALTER, in proposing a vote of thanks, stated that after hearing a lecture containing such an immense amount of information, delivered extempore, they might well place Dr. Walsh in the front rank of intellectual pharmacists.

Dr. WALSH, in replying, stated that he wished to express his thanks to Professor Birmingham, who had kindly lent him the slides to illustrate his lecture.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.

At a meeting held on Wednesday, January 10, Mr. FRASER McDIARMID, President, in the chair, Mr. A. P. Grainger read an interesting historical *résumé* on "Cinchona: Its introduction into Medicine," for which he was cordially thanked; after which Mr. J. G. MURDOCK read a paper on—

AN APPRENTICE'S IDEA OF THE RETAIL TRADE.

He said: The large number of prizes offered by this Association and the relatively small number of competitors has suggested to me the general inquiry why apprentices in the drug trade show such lack of studious habits? The conclusion that has been arrived at is that the occupation and not the worker is the source of this regrettable condition. The prominent reasons observed were long hours and the amount of work. Time to enable the pharmaceutical student to take a real interest in his occupation should fall to his lot, but never comes his way. The hours of work in a retail shop are long, and the weekly or fortnightly half-holiday comes as a boon to the apprentice. But when the half-holiday has to be given up for the time required off for classes, then these classes become a bore, and the reading needed for them in truth a "weariness to the flesh." This, however, is no real excuse for the fault I am dealing with. One who is determined to work will overcome such difficulties. Even if allowed it can only hold good for such subjects as botany and physics. But the prize schemes, such as the Ewing and the McLaren, call for a knowledge of practical pharmacy, materia medica, and prescription reading. The student is required to recognise the various galenical preparations of the Pharmacopœia. To do this he must have had a thoroughly practical knowledge of them, and this can only be gained by the making and keeping in constant touch with them. How many of these preparations is it the good fortune of the small-shop apprentice to make, and how many are the instances in which he does not even have a chance of handling such articles. The preparations of the Pharmacopœia are not so generally known to doctors as they should be, and when such galenicals are not prescribed the chemist has no call to make them, and the knowledge gained by the apprentice is nil. Even in establishments where the greater number of the preparations of the Pharmacopœia are stocked, how many of them are made on the premises. When economy, standardisation, and

other considerations are taken into account the products of the wholesale house are found to be most suitable. The retailer cannot be blamed for this. The apparatus required for the manufacture and standardisation of certain drugs is too expensive, and the processes too protracted to make the manufacture of small quantities a financial success. Still, the fact remains that it is the apprentice who suffers. Illustrating this want of practice, I quote my own experience. Confident of my nearly five years' apprenticeship in two shops, I entered for the Ewing Pharmacy Competition. In the practical part of the examination, out of four galenicals for recognition two I had never come across. The third I knew in its old B.P. form, but had never had a chance of making it according to its new formula. The fourth, a powder, was, in at least one of its ingredients, powdered by hand, what I had been accustomed to handle being powdered by machinery. The appearance of the two was entirely different, and but for the smell I would not have recognised even it. Of course, the remedy is for the apprentice to go over the Pharmacopœia and make up small quantities of all the preparations that he is able to make. Such a remedy, however, depends on the generosity of the employer, and even when permission is granted it has to be done in spare time, which is very little, or after hours, and thus in still another way the few leisure hours are encroached upon. The advice given to the student of an enquiring disposition is not conducive to his perseverance in study. Questions about the apparatus which he reads about, but has small chance of seeing, elicit the answer that he will see enough of them when he starts his Minor classes at one or other of the schools. This time for preparation for the great examination looms up before him as something awful to be faced, and if at the end of it he is successful in getting his certificate he has the prospect of going back to the handling of wholesale houses' goods, and forgetting what little he at one time knew concerning the manufacture of all but the simplest galenicals. These are not the observations of one who was unwillingly forced into the wholesale drug trade. The glamour of the hand-bottles attracted me in my school-days, making me pass the preliminary examination some three months before I started my apprenticeship, and the reading about the processes seems to point out that there is still something of interest in the occupation. But more than mere reading is required, and while the retail business remains as I have found it, while concentrated preparations and liquors hold sway, and all the apprentice does is to dilute them in their proper proportions, so long will there be a lack of those studious habits and interest in all that relates to the real practice of pharmacy, which it is the desire of this Association to promote by our prize schemes.

The reading of the papers was followed by a discussion taken part in by Messrs. Gorrie, Grainger, Harley, Hill, Kidd, Lennox, McDiarmid, Murdoch, Reid, and Selator. The meeting closed with a vote of thanks to the authors and Mr. Harley.

XEROFORM IN MILITARY SURGERY.—Noguera, from experience with xeroform, gained on the field during the recent war in Cuba, considers it to be the antiseptic *par excellence* for use in the treatment on the spot of gunshot and sword wounds. The wound, after being cleansed, should be freely dusted over with xeroform, and then covered with a protective layer of sublimate gauze and carbolised cotton. A single treatment with xeroform will render wounds aseptic for forty-eight hours, thus allowing the more serious cases, which cannot be treated on the spot, to be set aside without risk, until means for treatment are available. Simpler wounds under its influence heal at once by primary intention. Where there is loss of substance, xeroform favours the formation of small healthy granulations, without the production of soft and fungoid proliferations, often observed in cases treated with iodoform and other antiseptics.—*Bull. Gen. de Therap.*, 138, 634.

EXTRACTS FROM CONSULAR REPORTS.

OIL AS A DUST PREVENTIVE.—According to a recent report, experiments have been made on the line of the Baltimore and Potomac Railroad between Baltimore and Washington, to keep down the dust by spraying the track with oil of a high fire test and of high gravity. Those experiments are said to have been most satisfactory, and to have proved excellent for the purpose, especially where the tracks are ballasted with gravel. The non-existence of dust reduces the wear and tear on the rolling stock, and preserves the upholstery of the carriages, besides making travel much more comfortable and enjoyable. The oil is said to sink into the ballast to a depth of four inches on first application, destroying vegetation and remaining effective for about a year. A second or third application penetrates below the cross-ties and subsequent treatment is unnecessary unless fresh ballasting is used. A specially constructed car is used for sprinkling the oil, and is connected by rubber hose with an ordinary tank car. The cost of oil per mile of single track for the first application is from £6 to £9, depending on point of delivery, and the quantity used is about 2,000 gallons. Subsequently an expenditure of £1 to £1 10s. per mile annually is sufficient. About 1,000 miles of track in the United States is said to have been treated with oil.

THE WHOLESALE DRUG TRADE of Baltimore is reported to have been better in 1898 than it has been for the past ten years, while the manufacture and sale of chemicals has increased about 25 per cent. Baltimore is the second city in the United States for the manufacture of drugs and chemicals, Philadelphia being the first in importance. The retail sale of drugs, however, is said to have been most unsatisfactory, the cause being attributed to the existence of too many retailers. It is also stated that the sale of "patent" medicines fell off nearly 25 per cent., on account of the cutting of prices leaving no profit to the retailer.

ALTHOUGH THE EXPORT OF VANILLA from Mexico in 1898 was over 9,000 lbs. in excess of 1897, the value decreased from £83,240 to £65,011. The average price of vanilla in the London market during 1898 was a little over 15s. per lb. In New York it ranged from 8 dols. 25c. to 14 dols. gold per lb., according to quality. Owing to the frosts which prevailed during last winter, affecting the warmer climates where coffee, sugar, and vanilla are cultivated, it is expected that this year's crop of vanilla will be very small.

THE MEXICAN EXPORTS OF CHICLE GUM—the produce of the white zapote tree, which grows wild in the warmer parts of the country, especially in the States of Vera Cruz, Tabasco, and Oaxaca—fell off both in weight and value in 1898. The exports for 1897 amounted to 3,840,874 lb., value £118,796, as against 2,113,962, value £59,904 last year.

THE EXPORTS OF QUICKSILVER by sea from California during 1898 show a fair increase upon those of 1897, but the quantity sent overland is considered to have been even larger. The total yield was 31,092 flasks, value 1,188,626 dollars, or an increase on the preceding year by 16 per cent. Owing to a fear of the production and shipment of Spanish quicksilver being affected by the war, prices improved from 38 dol. 50c. to 42dol. 50c., and closed at 40dol. per flask.

ONE OF THE RUBBER-GIVING VINES of the Upper Congo is stated to give a delicious fruit, in size about as big as a tennis ball. The rind is hard, streaked with red and yellow, and full of a sticky paste much liked by the natives as a palatable thirst-quencher.

THE STUDENTS' COLUMNS.

THE MATERIA MEDICA OF THE PHARMACOPŒIA.

Aloinum.

ALOIN is the generic term applied to the bitter, crystalline, purgative principles found in all varieties of aloes, but only those obtained from Barbados and Socotrine aloes are official. The aloins are anthracene derivatives, varying in composition according to their source, and to them are due the colour reactions of aloes. Barbados (Curaçao) aloes yields barbaloin, $C_{16}H_{16}O_7, 3H_2O$ (eq. 371·36); Socotrine and Zanzibar aloes yield socaloin, which seems to have the same composition. The aloes are made into a thin paste with alcohol, the aloin allowed to crystallise out, then purified by recrystallisation from alcohol and, subsequently, from water. The medicinal properties of aloin are similar to those of aloes. The dose is from 0·5 to 2 grains.

CHARACTERS.—The needle-shaped yellow crystals, which occur in tufts, are inodorous, but possess the characteristic taste of aloes. They are sparingly soluble in cold water (1 in 400), more soluble in 90 per cent. alcohol (1 in 18), freely soluble in hot water or alcohol, but nearly insoluble in ether. Aloin is not readily altered in acidulated or neutral solutions, but it is rapidly altered in alkaline liquids.

NOTES.—Aloin is anhydrous and has the formula $C_{16}H_{16}O_7$ when crystallised from absolute alcohol, but on recrystallisation from water it takes up three molecules of that liquid. Barbaloin exists in two varieties, α -barbaloin, which imparts a crimson colour to cold nitric acid (s.g. 1·42), and β -barbaloin, which requires fuming nitric acid or hot acid of s.g. 1·42 to give the coloration. Both varieties, when oxidised, yield oxalic, chrysammic, and picric acids. Socaloin is a rarity in the market, the commercial aloin being α -barbaloin. Nataloin, from Natal aloes, yields picric acid when oxidised, but not chrysammic acid. It has less effect on man than any other aloin, whereas capaloin is the most powerful. The amount of aloin contained in aloes varies considerably, and is believed to increase with age. Barbados aloes yields from 10 to 18 per cent. of aloin, besides which it contains a very minute quantity of essential oil to which the odour is due, the so-called resin of aloes, and a small quantity of emodin, which appears to be easily formed from aloin by oxidation. The resin, which is a compound of aloresinotannol with cinnamic acid, appears to vary somewhat in composition—the one constant constituent of it being the alcohol—aloresinotannol.

Ammoniacum.

AMMONIACUM is a gum-resin which exudes from the flowering and fruiting stem of *Dorema ammoniacum*, D. Don (N.O. Umbelliferae), and probably other species, the plants that yield it being widely distributed throughout Persia and extending into Southern Siberia, though the drug is chiefly collected in Central Persia. It possesses antispasmodic, stimulant and expectorant properties, and enters into the composition of emplastrum ammoniaci cum hydrargyro, mistura ammoniaci, pilula ipecacuanhæ cum scilla, and pilula scillæ composita. The dose of ammoniacum is from 5 to 15 grains. The stem of *D. ammoniacum*, and especially the bark, abounds in a milky secretion, contained in large schizogenous ducts. During the fruiting season large numbers of boring beetles are attracted to the plant and puncture the stem, so causing the secretion to exude in the form of milky drops, some of which harden into tear-shaped masses on the stem, while others fall to the ground and there become mixed with stones, dirt, stalks of the plant, mericarps of the fruit, and other impurities, so forming the masses known in com-

merce as lump ammoniacum. Towards the end of July the ammoniacum is collected by peasants and shipped in a crude state from ports in the Gulf of Persia to Bombay; there the drug is sorted and exported to Europe.

CHARACTERS AND TESTS.—The tear ammoniacum alone is official, but that includes nodular or irregular rounded masses, varying from 6 to 26 Mm. in diameter, in addition to the small tears. Both are hard and brittle when cold, soften when warmed, and are of a dull pale yellow colour externally when fresh, though the colour darkens to brown on keeping. Internally the tears are opaque, and the colour varies from milky white to pale brownish-yellow, the freshly fractured surface having an opaque waxy appearance and being coloured yellow by solution of potassium hydroxide, or dark red or orange by solution of chlorinated soda. The drug possesses a faint, non-alliaceous, but thoroughly characteristic odour, and a bitter acrid taste. It forms a white emulsion when crushed and triturated with water; the emulsion is coloured yellow by solution of potassium hydroxide, deep orange-red by solution of chlorinated lime (distinction from African ammoniacum), and a transient violet colour, due to the presence of free salicylic acid, is imparted on adding solution of ferric chloride. The gum-resin does not contain umbelliferone, as proved by strongly heating a small fragment in a dry test-tube and, after cooling, treating the contents of the tube with boiling water; on largely diluting the solution thus obtained, with cold water, and making it alkaline with solution of ammonia, no blue fluorescence is exhibited as in the case of African ammoniacum, asafetida, or galbanum.

NOTES.—The distinctive characters of ammoniacum are its occurrence in clean, hard pieces, which do not crumble between the fingers, the characteristic odour, presence of salicylic acid, and absence of umbelliferone. The name *Dorema* is derived from the Greek δῶρημα, a gift, being indicative of the high esteem in which the gum-resin was formerly held; the specific name *ammoniacum* has been alleged to be derived from Jupiter Ammon, in the vicinity of whose temple the plant yielding the gum-resin originally known as ammoniacum is somewhat improbably supposed to have been discovered. That gum-resin was probably the non-official African ammoniacum, the product of *Ferula tingitana*, Linn., which contains umbelliferone and does not yield the orange-red colour with solution of chlorinated lime. Ammoniacum is only sparingly soluble in water, but yields 80 per cent. when digested with about seventeen times its volume of 90 per cent. alcohol, and 60 per cent. to the same volume of 60 per cent. alcohol. Umbelliferone or oxy-coumarin, C₉H₆O₃, is an anhydride corresponding to coumarin. It occurs in African ammoniacum, asafetida and galbanum. Dieterich's test for umbelliferone is more delicate than that of the Pharmacopœia. He boils 5 Gm. of the suspected substance, for fifteen minutes, with 15 C.c. of strong hydrochloric acid, dilutes with 15 C.c. of water, and filters the liquid. Any umbelliferone present is split off from its natural ester and causes an intense blue fluorescence in the clear filtrate when that is supersaturated with ammonia. Ammoniacum of good quality contains 1 to 2 per cent. of volatile oil, 65 to 70 per cent. of resin, about 20 per cent. of gum, 2 to 12 per cent. of moisture, 1 per cent. of ash, and 3.5 per cent. of insoluble residue. Luz has found that the resin is a mixture of two resin-alcohols—galbaresinotannol (also found in galbanum) which is combined with salicylic acid, and ammosinotannol, which is peculiar to ammoniacum. The gum is said to be allied to gum acacia. According to Dieterich, ammoniacum should not yield more than 15 per cent. of ash.

Amygdala Amara.

BITTER ALMONDS are the ripe seeds of *Prunus amygdalus*, Stokes, var. *amara*, Baillon (N. O. Rosaceæ), a native of Persia, Asia Minor, and Syria, naturalised in the Mediterranean basin and Central Europe, and maturing its fruit in some parts of England. The fruit of the almond tree is a green velvety drupe, from which

the fleshy mesocarp and thin epicarp separate as ripening proceeds, leaving the seed enclosed in the shell-like endocarp. The seed is exalbuminous, free from starch, contains two large plano-convex oily cotyledons, and is covered with a thin, rough, cinnamon-brown testa or seed-coat. There are several varieties of the bitter almond, the best being imported from the South of France, and others from Sicily and Northern Africa (Barbary). They possess sedative properties, and an emulsion of bitter almonds is sometimes prescribed as a lotion, but they are chiefly used for flavouring.

CHARACTERS.—Bitter almonds agree in general appearance with sweet almonds, resembling more particularly the Valencia variety, but generally speaking they are shorter, proportionately broader, and usually smaller and less regular. The bitter taste is characteristic, as is also the odour of hydrocyanic acid and benzaldehyde given off by the white emulsion formed when the seeds are triturated with water. Bitter almonds contain amygdalin, C₂₀H₂₇NO₁₁, to which their bitter taste is due. It is a colourless crystalline glucoside, soluble in alcohol and water, and is decomposed in the presence of water by emulsin, an enzyme found in both sweet and bitter almonds. Dextrose, benzaldehyde (essential oil), and hydrocyanic acid are the products of the reaction, thus:—

Being localised in the parenchyma of the cotyledons, the amygdalin is unable to come in contact with the enzyme (which resides in the axile parts of the embryo and the vascular bundles of the cotyledons) until the seeds are crushed and water is added, as in preparing the emulsion; under those conditions the reaction can take place. Bitter almonds contain various proteids and from 42 to 44 per cent. of a bland fixed oil, which can be separated by heavy pressure. They also yield nearly 0.9 per cent. of volatile oil and 0.25 per cent. of hydrocyanic acid, which can be extracted together from the cake left after expression of the fixed oil. Water is added and the mixture left for some hours, after which it is distilled. The hydrocyanic acid in the distillate is partly free and partly combined as benzaldehyde-cyanhydrin. It can be separated by shaking the oil with milk of lime, with which the acid combines to form calcium cyanide; the addition of ferrous sulphate converts that into Prussian blue, and, on redistillation in a current of steam, the volatile oil is obtained pure.

NOTES.—The distinctive characters of bitter almonds are their small size, broadly ovoid shape, bitter taste, and the characteristic odour of the emulsion formed on triturating them with cold water. The name *Prunus* means a plum tree; *amygdalus* is from the Latin *amygdalum* (Gr. ἀμυγδάλη), an almond. Bitter almonds are only official as a source of the fixed oil, and they yield the bulk of the commercial product, the fact that the essential oil can subsequently be obtained from the residual cake rendering their use more profitable to the oil pressers than would be the case if sweet almonds were used. Amygdalin occurs in the seeds, young-shoots, or flower-buds of many other rosaceous plants; it is closely allied to, if not identical with, laurocerasin, which is found in cherry-laurel leaves, and to a similar glucoside found in the bark of *Prunus serotina*, Ehrh.

Amygdala Dulcis.

SWEET ALMONDS are the ripe seeds of *Prunus amygdalus*, Stokes, var. *dulcis*, Baillon [Bentley and Trimen, 'Medicinal Plants,' vol. 2, plate 99], which is not distinguished from the bitter almond tree by any permanent character, but grows in the same districts and is cultivated more largely. The seeds known in commerce as Jordan almonds are alone official. Other varieties of the sweet almond, distinguished in the order of value, are the Valencia, Sicily, and Barbary. Jordan almonds are imported from Malaga, free from the endocarps, and are distinguished from all others by their large size and long, narrow shape. They are demulcent and nutrient, and are used for making pulvis amygdalæ compositus and mistura amygdalæ.

CHARACTERS.—In general appearance sweet almonds resemble the bitter ones, the Valencia variety resembling them closely, but Jordan almonds are 2.5 Cm. or more in length, nearly oblong in outline, more or less compressed, pointed at one extremity and rounded at the other; the thin rough testa or seed-coat is cinnamon-brown, the seed exalbuminous, free from starch, and containing two large plano-convex oily cotyledons. Sweet almonds have a bland taste, and the white emulsion formed when they are triturated with water is distinguished by no marked odour. Like bitter almonds, they contain various proteids (about 20 per cent.), including the enzyme emulsin, together with 50 to 55 per cent. of the same fixed oil that is found in bitter almonds. They do not contain amygdalin and, consequently, yield no volatile oil or hydrocyanic acid when crushed and triturated with water.

NOTES.—The distinctive characters of Jordan almonds are their elongated shape, bland taste, and the freedom from marked odour of the emulsion formed on triturating the seeds with cold water. The seeds are readily freed from their coats or skins (blanched) by steeping in cold water; they must be thoroughly dried subsequently if they are to be used for preparing pulvis amygdalæ compositus, as they can then be rubbed to a smoother consistence and the resulting powder keeps better.

ANSWERS TO QUERIES.

Special Notice.—Scientific, technical, legal, and general information required by readers of the *Pharmaceutical Journal* will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured. Not more than six plants should be sent for recognition at one time.

Incompatibility (J. S. W.—16/40).—No further instalment has appeared since the date you mention.

Chemists' Assistants' Union (J. P.—37/30).—The present address of the Union is 67, Shaftesbury Avenue, W.

Solder for Aluminium (F. J. C.—37/23).—The formula you refer to was: Aluminium, 1; phosphor-tin (10 p.c.), 1; zinc, 11; tin, 29.

Blueing Gun-Metal (R. D.—36/27).—See Spon's 'Workshop Receipts,' second series, page 246. The details of the process are too lengthy to be given here.

Names for Proprietary Medicines (R. P.—38/3).—The names seem equally trivial, and we should advise you not to use any of them. Why not describe the articles in plain English?

Cement for Glass (A. W. W.—37/29).—Marine glue is the only thoroughly satisfactory cement for the purpose. It is applied by the aid of heat, and requires a considerable amount of skill to use it properly.

Stove Polish (J. S.—37/2).—You will probably find the addition of a little common brown glycerin prevent the drying of the cake and, if not used in excess, without effect on the polishing properties.

Patenting a Medicine (E. P.—38/1).—Apply to the Comptroller, Patent Office, Chancery Lane, London, E.C., for information respecting the method of securing Letters Patent or registering a title.

Sale of Poisons (F. S. H.—38/2).—(1) The sale of any preparation of strychnine must be entered in the poison-book.

(2) There is no restriction of the kind you suggest, and the matter is entirely one for the exercise of your own discretion.

Massage Training (J. A. H.—37/27).—We do not know of any classes in your district, but you should be able to get the information you require and the necessary instruction at any institution where hospital nurses are trained. Have you seen Miss Ellison's 'Manual for Students of Massage,' published by Bailliere and Co., at 3s. 6d. net?

Chemists in South Africa (C. E. F.—37/36).—If any gold mines be left after the war is over, you will find that the best qualification for the post of assayer is a thorough knowledge of analytical work, particularly in connection with the assay of metals. But you would also doubtless find it an advantage to be a Fellow of the Institute of Chemistry.

Divison of the Minor (R. B. G.—17/13).—"The beginning of another century" has not yet "dawned," except in Germany, and even if it had, we fail to see why the fact that certain hypothetical burdens afflicting "Minor students" are "unredressed" should justify us in publishing unsupported charges against the Society's examiners, especially when advanced in an anonymous letter.

Oil of Juniper (F. W. J.—37/24).—There is no good reason for assuming that the sale of oil of juniper, other than the B.P. oil, would be regarded as an offence, so long as what was sold was a pure article. Oil of juniper may be none the less oil of juniper because it departs to some extent from the B.P. standard. At the same time, the use of the suggested label would put the matter on a more satisfactory footing.

Panbotano (B. A. M.—37/31).—It is the root or root-bark of *Calliandra houstoni*, Benth., or *C. grandiflora*, Benth., anti-periodics from which a tincture is prepared of such strength that each dose represents half an ounce of the drug. Four doses are administered during twenty-four hours. Messrs. Potter and Clarke, Artillery Lane, E., or Messrs. Parke, Davis, and Co., North Audley Street, W., could doubtless supply the drug.

Starch Gloss (J. S.—37/22).—The following, from a German source, is said to give very good results:—Boric acid, 5; borax, 3; stearin, 1; white wax, 1; are mixed with sufficient caustic soda solution, s.g. 1.16, to produce a uniform mass, which is then evaporated to dryness. The product thus obtained is next mixed with the finest rice starch in the proportion of 1 to 10 to form a starch, and that is said to produce an excellent gloss and a very stiff surface.

Koumyss (T. L.—37/28).—Mix new milk with an equal volume of water, and to each quart of the mixture add 15 grains of pure compressed yeast, previously rubbed down gently with a little of the diluted milk. Bottle off into champagne bottles, and to each bottle add 1½ ounce of powdered white sugar. Leave the bottles uncorked for twenty-four hours, at 63° F., then cork and wire down, and keep in a cool cellar for five days. On the sixth day the koumyss is ready for use.

Tinct. Camph. Co. (F. W. J.—37/24).—Such an addition is not justifiable, but it is doubtful if the local authorities would take any action in regard to so comparatively trifling a matter. It should be borne in mind that any standards of colour, etc., for official galenicals must be based on the characteristics of preparations made in the quantities and by the methods presented in the British Pharmacopœia. Preparations made on a very large scale frequently differ more or less in appearance, and sometimes in other ways, from the same preparations made in the quantities that are usual in pharmacies. You should give preference to galenicals made by yourself, strictly in accordance with the B.P.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

LEMON ESSENCES.

A. S. Mitchell has examined a number of lemon-flavouring extracts, and reports the presence of some curious sophistications. The "spiritus limonis" of the U.S.P. should be prepared from 1 part of oil of lemon, 1 part of fresh-grated lemon peel, and 20 parts of 95 per cent. deodorised alcohol, the oil being dissolved in 18 parts of the alcohol, the lemon peel macerated in the mixture for 24 hours, and, after filtration, sufficient alcohol added to make up to 20 fluid parts. But a preliminary examination of preparations supplied by grocers showed them to contain alcohol in amounts varying from 14 to 94 per cent., and oil of lemon from none to 8 per cent. The extracts low in alcohol had in many cases a fine aroma, derived from agitation with new oil of lemon in some cases, but more frequently produced by citral and so-called "soluble oil of lemon," or by lemon-grass or citronella aldehyde, and frequently with the addition of tincture of mace, nutmeg, or capsicum. The cheaper grades contained so little oil in solution that the addition of water frequently failed to produce turbidity. Among the colouring matters found to have been used in preparing the extracts were naphthol-yellow, tropæolin, and dinitrocresol.—*Journ. Am. Chem. Soc.*, **21**, 1,132.

ACETIC EXTRACT OF BELLADONNA.

Dr. E. R. Squibb has now experimented with acetic acid in preparing some sixty drugs and spices; the results tend to support two generalisations. In the first place, a menstruum of ten per cent. acetic acid is about the weakest that will surely extract, protect, and preserve the active principles of many drugs, and such a menstruum leaves not less than six nor more than eight per cent. of free acid in the finished fluid extract, being about equivalent to alcohol of forty-one per cent. Secondly, it is found that from one-fourth to one-third of the fluid extracts made with acetic acid give a small deposit within three months, but the proportion is not greater than that from preparations made with alcoholic menstrua, and the two deposits are equally inert. In the case of belladonna root, the acetic and alcoholic (U. S. P.) extracts appear to be of equal value, the total alkaloid present being 0.688 and 0.683 per cent. respectively. The acid preparation, however, is of much lighter colour, yields no deposit on standing for three months, and does not precipitate on being added to water, whereas the alcoholic preparation is very dark, yields within three months a slight precipitate containing traces of alkaloids, and precipitates on being added to water.—*Ann. Journ. Pharm.*, **72**, 1.

MERCURY IN URINE.

Drs. Schumacher and Jung describe in the *Lancet* for January 13, p. 92, what they term a simple and thoroughly trustworthy method for the determination of mercury in urine.

It depends upon the fact that stannous chloride, when added to solutions of mercury salts, reduces them to metallic mercury, and the finely divided metallic particles thus obtained in suspension can be combined with gold to form an amalgam. The gold must be in an extremely fine state of sub-division, obtained by soaking fine asbestos fibres in a concentrated solution of gold chloride, and reducing the gold salt by heating the fibres in a current of dry hydrogen gas. The resulting "gold asbest" is cleaned with diluted hydrochloric acid, then dried and used as a filter for the liquid containing the mercury in suspension. A thick pad of asbestos is first placed in the narrowest part of the filter tube, a layer of "gold asbest" is placed next, then a layer of granular spongy gold, and, finally, a second layer of

"gold asbest." The dilute mercury solution, after being heated to about 70° C., is mixed with about 50 C.c. of clear, freshly prepared stannous chloride solution. After cooling a little, the mixture is aspirated through the filter amalgam tube, which is afterwards washed with moderately warm diluted hydrochloric acid, followed by three or four lots of warm water, then with alcohol and, lastly, with ether. The tube is next warmed at about 40° C., dried by drawing a stream of dry air through it, and weighed; the asbestos is then ignited and the loss equals the amount of mercury in the liquid examined. The editor of the *Lancet* is of opinion that the method, though ingenious, is unnecessarily complicated, inasmuch as the whole of the mercury in urine, even when the quantity is very small, can be readily separated in a short time by merely using the electric current.

COLOURING MATTER OF DIGITALIS LUTEA.

From the residue obtained in the preparation of crystalline digitalin from the Hungarian *D. lutea*, Adrian and Trillat have isolated a yellow colouring body which they consider to be distinct from the digitoflavone of Fleischer, and to which they attribute the formula $C_{16}H_{12}O_4$. It is remarkably resistant to the action of chemical reagents, boiling hydrochloric acid does not decompose it, nor is it affected by acetic acid nor by phenylhydrazine. It is insoluble in water, in dilute acids and in petroleum ether, but dissolves in alcohol, in chloroform, and in amylic alcohol. It gives a bright red colour with alkali. It is not a decomposition product of chlorophyll and differs from carotin. It forms fine yellow silky felted needles, which melt at 217–218° C.—*Comp. rend.*, **129**, 889.

CONSTITUENTS OF TOBACCO SMOKE.

H. Thoms has detected in tobacco smoke a very poisonous oily substance which produces violent headache, trembling, and giddiness. The chief part of this oil boils between 220°–230° C. By treatment with 2 per cent. potash solution, a phenol-like body may be separated which has an odour resembling creosote and which boils at 190°–200° C. To the presence of this oil, the observed toxic effects of tobacco may be attributed, since it is known that those are not altogether dependent on the proportion of nicotine in the tobacco.—*Pharm. Centralh.*, **40**, 706; after *Zeitsch. d. Nahr. u. Genussm.*

PHOSPHORUS IN ORGANIC COMPOUNDS.

The following method is employed by C. Marie to destroy organic matter in the determination of the phosphorus combined with it:—The substance is first dissolved in a considerable excess of nitric acid, the solution is heated on the water bath, and a small quantity of finely powdered potassium permanganate is added. This addition is repeated several times, as the red colour disappears, until, finally, the red tint persists for five or six minutes. The amount of permanganate requisite will be generally five or six times that of the organic matter. The mixture is then cooled, and a ten per cent. solution of sodium or potassium nitrite is added, drop by drop, until the precipitated manganese oxide is dissolved, and a perfectly clear liquid is obtained. The solution is then heated to drive off nitrous fumes, and excess of nitric acid, and the phosphorus precipitated in the usual way, as phosphomolybdate. Care must be taken to wash the phosphomolybdate perfectly free from manganese, otherwise the results will be vitiated, and the magnesium ammonio-phosphate finally obtained will contain manganese. The washings must, therefore, be tested with lead dioxide, and filtration continued until no reaction for manganese is obtained. This method of analysis is much more convenient than the ordinary one of oxidising in a sealed tube. It has given good results in the analysis of glycerophosphates.—*Comp. rend.*, **129**, 766.

THE MATERIA MEDICA OF THE SOCIETY'S MUSEUM.*

BY E. M. HOLMES, F.L.S.,
Curator of the Pharmaceutical Society's Museum.

BUCHU LEAVES.

Barosma betulina, Bart. and Wendl.—This species, which yields the official buchu, is represented in the Materia Medica Museum by the leaves only. Of the other species official in the previous British Pharmacopœia, viz., *B. crenulata*, Linn., and *B. serratifolia*, Willd., specimens of the plants occur in the Herbarium, and in the Materia Medica Museum there are specimens of the twigs, leaves, flowers and fruits of *B. crenulata*, and of leaves and fruit of *B. serratifolia*. Of the constituents of the leaves, the essential oil, and the stearoptene, diosphenol, and an eclectic preparation, called barosmin, are exhibited. The diosphenol occurs most abundantly in the leaves of *B. betulina*, from the oil of which it is usually deposited on cooling. This is filtered off by some wholesale dealers and distillers, and the oil sold in the clear state. The oil of the other species is said not to deposit the stearoptene on cooling. The properties of the drug are due to the volatile oil. Not feeling sure how far these properties might not be lessened by the removal of the stearoptene, which is present to the extent of about 30 per cent., I sent a specimen to Professor Cash, of Aberdeen University, who kindly undertook to report upon it. He found that diosphenol was distinctly antiseptic and prevented decomposition of the urine. The *B. betulina* appears to be the richest in oil and other constituents (*P. J.* [3], 21, 940; *Proc. Amer. Ph. Assoc.*, 1863, 211). Nevertheless, the leaves of *B. crenulata* are preferred by some, and at the present time are worth 25 to 30 per cent. more in the drug market. The peppermint odour of the diosphenol appears to be due to traces of a hydrocarbon with a peppermint odour that occurs in the oil (*Journ. Chem. Soc.*, 72, p. 227).

A number of species of this and allied genera are used in South Africa for the same purpose as buchu. These are: (1) *Adenandra fragrans*, Roem. and Schult. (2) *Agathosma Cerefolium*, G. Don.; (3) *A. microphylla*, Mey., which has an anise odour; (4) *A. chortopila*, Eckl. and Zeyh., which has a cummin odour; (5) *Diosma ericoides*, Linn.; (6) *D. oppositifolia*, Linn.; (7) *D. succulenta*, Thunb.; (8) *Barosma eckloniana*, Bartl.; (9) *Empleurum serrulatum*, Sol. Of these No. 1 occurred in the London drug market in 1882; the leaves are about the length of those of *D. crenulata*, but entire, oblong, obtuse, and more leathery in texture, and have a slight caraway odour. No. 8 occurred in 1873, and is represented in the Hanbury collection of materia medica, and again in 1898. The leaves are like those of *B. crenulata*, but rather broader and more distantly crenate-serrate. No. 5 has small heath-like leaves. It has occurred several times in the drug market during the last twenty-five years, and is said to be preferred by the natives to the ordinary buchu. Another species (10) *Barosma venusta*, Eckl. and Zeyh., was offered in 1884. It has small obovate or oblanceolate serrate leaves, from 2—4 lines long and about 2 lines broad.

Empleurum serrulatum is the substitute which most frequently comes into the market and is designated as a "Fine long buchu." It is distinguished by its acute apex, in which no oil gland is present, the apex of the leaves of the three species formerly official having a gland in the slightly obtuse apex. The fruits of *Empleurum* are sometimes present with the leaves and are then easily distinguished by having only one follicle, while those of *Barosma* have five. The leaves have not the same odour as those of buchu, but yield about 0.74 per cent. of an essential oil, described by Mr. J. C. Umney (*Pharm. Journ.* [3], 25, 796).

Nos. 1, 8, 9 and 10 are represented in the Cape Colony collection in the Reference Museum.

* NOTE.—The object of the series of notes of which this communication forms part was explained in an introductory article which appeared in the *Pharmaceutical Journal* for September 9, 1899, page 237, and the first notes in the series appeared in the issue for November 25 last, page 495 *et seq.*

THE CHEMIST AND SOME OF THE LAWS THAT PARTICULARLY AFFECT HIM.*

BY W. S. GLYN-JONES.

The subject of my paper is such a wide one that I fear, even if I were capable of doing so, it would be impossible to deal with it exhaustively in one paper. I have thought, however, that it might be interesting and perhaps instructive, if I called attention to a few of the more important features of some of the Acts of Parliament which we are called upon as retail chemists to comply with. The consideration which I have been able to devote to this paper has been sufficient to strengthen my opinion that if ever a curriculum for the Minor Examination is enforced it should include a course of lectures upon the various legal enactments which the chemist is required to fulfil. There are, I think, few chemists' shops in which offences, more or less technical, are not being unwittingly committed almost daily.

Apothecaries Act, 1815.

Apart altogether from its importance, our journals might use their space to very much less advantage than printing in full the Apothecaries Act, 1815. It is full of interest. The preamble, which commences as follows, is an indication of this:—

Whereas His Majesty King James the First, by Letters Patent, under the Great Seal of Great Britain, bearing Date the Sixth Day of December, in the Fifteenth Year of His Reign, did for Himself, His Heirs, and Successors, grant unto William Besse and divers other Persons therein named, and to all and singular other Persons whomsoever, brought up and skilful in the Art, Mystery, or Faculty, of Apothecaries, and exercising the same Art, Mystery or Faculty, then being Freemen of the Mystery of Grocers of the City of London, or being Freemen of any other Art, Mystery, or Faculty in the said City of London (so as they had been brought up and were expert in the Art or Mystery of Apothecaries), that they, and all such men of the said Art or Mystery of Apothecaries of and in the said City of London and Suburbs of the same, and within Seven Miles of the said City, might and should be one Body Corporate and Politic, in Substance, Deed, and Name.

POWERS TO SEARCH SHOPS FOR UNFIT DRUGS.

The charter referred to gave the Apothecaries Society the right to go into any shop or shops, house or houses, cellar or cellars, of any person whomsoever using or exercising the Art or Mystery of Apothecaries within Seven Miles of the City of London, and to search, survey, and prove if the same Medicines, simple or compound, Wares, Drugs, Receipts, Distilled Waters, Chemical Oils, Syrups, Conserve, Lohocks, Electuaries, Pills, Powders, Lozenges, Oils, Ointments, Plaisters, or any Thing or Things whatsoever belonging to the Art or Mystery of Apothecaries aforesaid, be and shall be wholesome, medicinable, meet and fit for the Cure, Health, and Ease of His Majesty's Subjects.

POWERS TO GO AND EXAMINE APOTHECARIES.

The charter also gave the Society full Power and Authority to examine and try all and singular Persons professing, using, or exercising, or which hereafter shall profess, use, or exercise the Art or Mystery of Apothecaries, or any Part thereof, within the aforesaid City of London, the Liberties or Suburbs thereof, or within Seven Miles of the same City, as well within Liberties as without, touching or concerning their, and every of their Knowledge, Skill, and Science, in the aforesaid Art or Mystery of Apothecaries, and to remove and prohibit all those from the Exercise, Use, or Practice of the said Art or Mystery, whom hereafter they shall find either unskilful, ignorant, or insufficient, or obstinate, or refusing to be examined by virtue of these Presents, in the Art or Mystery aforesaid;

and also to remove all the articles above enumerated which they shall find unlawful, deceitful, stale, out of use, unwholesome, corrupt, unmedicinable, pernicious, or hurtful, to burn before the Offender's Doors.

The 1815 Act repealed those powers, and in lieu of them gave the Society the right to enter into any shop or shops of such persons in any part of England or Wales, and to burn or otherwise destroy the deceitful drugs, etc., though they are not enjoined to make the bonfire in front of the offender's doors. This power, contained in Section 3 of the Act, is still in force, though I have never heard of its having been exercised. Section 5 of the Act is also of interest:—

* Read at a meeting of the Chemists' Assistants' Association, Thursday, January 18, 1900.

APOTHECARIES BOUND TO DISPENSE PHYSICIANS' PRESCRIPTIONS.

And whereas it is the Duty of every Person using or exercising the Art and Mystery of an Apothecary, to prepare with Exactness, and to dispense such Medicines as may be directed for the Sick by any Physician lawfully licensed to practise Physic. And it also enjoins that if an Apothecary shall knowingly wilfully, refuse to compound, to mix, prepare, give, supply, or administer, or in any way to sell, set on sale, put forth, or put to Sale to any Person or Persons whatever, any Medicines, Compound Medicines, or Medicinable Compositions, or shall deliberately or negligently, falsely, unfaithfully, fraudulently, or unduly, make, mix, compound, prepare, give, apply or administer, or in any way sell, set on Sale, put forth, or put to Sale to any Person or Persons whatever, any Medicines, Compound Medicines, or Medicinable Compositions as directed by any Prescription, Order, or Receipt, signed with the Initials, in his own Handwriting, of any Physician so lawfully licensed to practise physie,

he shall be liable to a fine of £5 for the first offence, £10 for the second, and for the third forfeit his certificate.

THE SECTION IN FORCE BUT NOT ENFORCED.

I have yet to learn that the Society is in the habit of enforcing this section, and I know a number of L.S.A.'s who would certainly refuse, perhaps contumaciously, to dispense a Harley Street prescription. I doubt whether many of them would be in a position to faithfully mix, compound, and prepare some of the prescriptions which many of us have to deal with almost daily. Section 14 provides that for persons who do not hold a certificate from the Apothecaries' Society to practise as an apothecary is illegal. Mr. Justice Creswell held that an apothecary is a person "who professes to judge internal disease by its symptoms and to cure the disease by medicine." Clearly such practice is not to-day confined to Licentiates of the Society. I should contend that such a definition would equally apply to the medical practitioner, whether holding the L.S.A. certificate or not. It is clear from the Medical Act of 1858 that all medical practitioners are entitled to demand reasonable charges for professional aid, advice, cost of medicine, and other surgical or medical appliances supplied by them to their patients, and this, I take it, gives them the right not only to diagnose and prescribe, but also to supply the medicine. It will sooner or later be important to get the present-day legal definition of an apothecary. In my opinion the answer is, a Licentiate of the Societies of Apothecaries. A decision on this matter will have an important bearing upon the question of dispensing in doctors' surgeries. If it be held that every general practitioner is an apothecary, then under Section 17 of the Act no person could act as an assistant to a medical man "in compounding or dispensing medicines without undergoing an examination by the said Court of Examiners, or the major part of them, or by five apothecaries, so to be appointed as hereinafter is mentioned, and obtaining a certificate of his or their qualification to act as such assistant from the said Court of Examiners, or the major part of them, or from the said five apothecaries who are hereby authorised and empowered to examine all persons applying to them for that purpose, and to grant a certificate of such fitness and qualification."

A "MINOR" MAN CANNOT LEGALLY ACT AS A DISPENSER TO AN L.S.A.

It is quite evident that any chemist holding either the Minor or Major qualification who acts as a dispenser to an L.S.A. is as much breaking the law as the doctor's coachman would be if he so acted. This is the only Act of Parliament which in any way restricts the practice of medicine. It is under this Act that chemists are liable to be prosecuted for prescribing. I have before given a legal definition of what constitutes acting as an apothecary, and judges in the High Courts have held that a chemist who systematically sets himself to diagnose by questioning his customers as to their symptoms and uses his judgment in supplying them with medicines for the treatment of such symptoms is contravening this Act.

CHEMISTS AND PRESCRIBING.

At the same time it was pointed out by the courts that if a chemist supplied something to a customer in answer to a request

for "something for a headache," though there might be a technical offence, no one would think of instituting proceedings. It is difficult to draw a line as to what a chemist can legally do in the direction of prescribing, and I for one would welcome a House of Lords' decision on the matter. I am confident that if the Act was strained so as to prohibit the supplying by chemists, across the counter, of remedies for simple ailments, its repeal would be certain.

EXAMINERS TO BE IN ACTUAL PRACTICE.

This Act contains a principle I would like to see adopted by the Pharmaceutical Society. Section 4 stipulates that an examiner shall have been engaged in actual practice as an apothecary for at least ten years previously to his being appointed. I have every respect for university professors, but I think we should have less than 60 per cent. of rejections if the examiners were all actual chemists. I think no candidate should be expected to pass an examination in any subject of such a character that our own pharmaceutical chemists are not qualified to examine in. I have dealt with this Act at this length because of its important bearing upon the question of the relation between the medical man and the pharmacist, a question which, I think, is bound to come to the fore in the immediate future.

Dentists Act, 1878.

The Dentists Act of 1878 prohibits the use of the title dentist, or of any name, title, addition, or description implying that they are registered under the Act or are specially qualified to practise dentistry. It does not prohibit the practice of dentistry by unqualified individuals, though the law will not assist such persons to recover any fee or charge in connection with such work. The dentists have attempted to interfere with the use by chemists of such a phrase as "Teeth skilfully extracted." Their contention apparently is that it is not an offence for an unqualified person to say he extracts teeth, but that he must not say he does it skilfully, on the ground that such language implies special qualification. The *Chemist and Druggist* some two or three years ago took up this question and organised a fund to contest the next suitable case. The dental authorities have not since provided such a suitable case.

Veterinary Surgeons Act, 1881.

The Veterinary Surgeons Act of 1881 does practically neither more nor less for veterinary surgeons than the law does for the dentist.

Adulteration Laws.

The Sale of Food and Drugs Acts.—These Acts alone would require a volume if they were to be in any way satisfactorily dealt with, and I will therefore confine my observations to the more important features, especially the effect of the recent addition to the law on this subject, the Act which came into force on the 1st of this month. In reading up this subject I have found a pamphlet—"The Adulteration Acts"—issued by the Federation of Grocers' Associations, published at 6d., of the utmost value. It has been written by Mr. Frederick W. Beck, solicitor to the Federation, and also the solicitor of the recently-formed Chemists' Defence Association. I have no hesitation in saying that every chemist in business should procure a copy of this pamphlet. It is a serious drawback that the law upon adulteration, etc., is not comprised or consolidated in one measure. The chemist at present who wishes to know where he stands has to consider three separate Foods and Drugs Acts—namely, those of 1875, 1879, and 1899, because, as amended, they are all of them still in force.

CUSTOMS CAN EXAMINE FOODS, BUT NOT DRUGS, AT THE PORT OF ENTRY.

The first section of the 1899 Act bears evidence of class legislation. It makes it illegal to import any adulterated or impoverished *article of food* to which her Majesty may by Order in Council direct that this section shall be applied, unless the same be imported in packages or receptacles conspicuously marked with a name or

description indicating that the article has been so treated, and the Commissioners of Customs shall, in accordance with directions given by the Treasury, *after consultation with the Board of Agriculture*, take samples. This section shows a greater desire on the part of the authorities to protect agricultural interests rather than the general interests of the consumer, otherwise drugs would not have been specially excluded from this arrangement. The drug trade has as much right to expect the Government to deal with adulterated or impoverished drugs at the port of entry as have the grocers and agriculturists in regard to articles of food. If such was the law, and it was enforced, nothing would do more to prevent adulteration in the drug trade.

Section 2 is of the greatest importance. In effect it gives the Local Government Board control over the local authorities in the matter of enforcing the Food and Drugs Act.

LOCAL GOVERNMENT BOARD CAN ENFORCE THE ACT.

Hitherto, there can be no question, some local authorities have neglected their duty in taking samples and enforcing the Act, so much so that it has in those districts practically been a dead letter. Under this new Act the Local Government Board are empowered to take samples, and to compel the authorities to take action where necessary; or, failing that, to take proceedings themselves, and charge the local authorities with the expenses incurred. It is well that chemists should recognise this important change in the enforcement of the Act.

WANTED A STANDARD.

Section 4 gives the Board of Agriculture power to determine the standard for milk, cream, butter, or cheese. This suggests the need for an authoritative standard, not only for the articles mentioned, but for all foods and drugs.

In reference to drugs, it is sometimes argued that the B.P. is the standard under the Food and Drugs Act. There is not a sentence in any of the Food and Drugs Acts which warrants the assertion, and no magistrate could rightly convict a defendant on the ground that the analyst's certificate says the article in question is not of B.P. strength. He must have oral evidence to prove to him that the B.P. is the commercial standard for that particular article.

THE B.P. NOT THE LEGAL STANDARD.

At Plymouth, Dr. Attfield, surely an authority as to what the Pharmacopœia is or is not, stated that it was not the legal standard, that it was not prepared with that object in view, and in answer to certain criticisms on the Pharmacopœia, where it was pointed out that articles made according to the Pharmacopœia would not answer the tests there given for that article, the reply was that the money at the disposal of the compilers was not sufficient to enable all the processes and tests to be adequately checked and verified. Surely it is the duty of the Government to provide an efficient standard for foods and drugs under the Act, and I think that the proper authorities to produce that standard would be a combined committee of the Medical and Pharmaceutical Councils. I quite agree with the suggestion thrown out by Mr. Tyrer at Plymouth that the Society's research laboratories should be used for the purpose of investigating these processes and tests, and that the Government should properly subsidise the work.

POWERS TO SAMPLE FOODS BUT NOT DRUGS IN PROCESS OF DELIVERY.

Section 14 confers fresh powers upon the authorities; here again, unfortunately for chemists, the powers are confined to articles of food. The 1879 Act gave inspectors the power to take samples of milk, in course of delivery, and to proceed where the milk was adulterated. Under this section samples of milk have been taken at railway stations on its way from the farmer to the retailer, and great protection afforded to the retail dairymen in consequence. The new Act gives the authorities similar powers in relation to all

articles of food. I quote from Mr. Beck's pamphlet the following extract from his notes on this section:—

The retail customer, suspecting that a shopkeeper is dealing dishonestly, and supplying adulterated articles, may order goods to be delivered, and may arrange with the local inspector to meet the goods on delivery and take samples of them with a view to prosecution. Remembering this new power, the vendor should be careful that ordered goods are properly labelled and correctly described in the invoice.

2. The retailer who has been supplied with a sophisticated article can first assure himself by getting a sample analysed, and, finding his suspicions confirmed, can order a fresh delivery of the same goods and arrange with the inspector to sample them at the railway station or at the moment of delivery, and the inspector will thus be enabled to proceed against the wholesaler or manufacturer—a proceeding which he otherwise could not adopt, as no power exists to take samples in warehouses and factories.

By careful usage this section may be made the means of putting a healthy check upon firms who are known to be adulterators, and who have in the past exposed the retail trade to prosecutions and to serious injury.

Samples may also be taken by inspectors without the request, but with the consent, of the purchaser, and if any inspector sees goods being delivered from a van there is nothing to prevent his introducing himself and obtaining the consent of the purchaser to his taking samples of the goods.

It is obvious that a similar protection for retail chemists would have been of the utmost value.

TINS OR PACKETS NEED NOT BE OPENED.

The 1875 Act makes it illegal to refuse to sell articles for analysis on the demand of an inspector, and before now inspectors on being offered, say, a labelled tin of mustard, have asked for loose mustard. The chemist has served this from the tin, and, unwittingly neglecting to use a wrapper stating perhaps that the article is a mixture, has been convicted of an offence.

Section 18 of the new Act states that no person shall be required to sell articles exposed for sale in unopened tins or packets, duly labelled, except in such tins or packets.

PROCEEDINGS TO BE TAKEN WITHIN TWENTY-EIGHT DAYS.

The 1879 Act stated that proceedings should be taken within a given time where perishable articles are concerned.

Section 19 of the new Act provides that all proceedings under these Acts should be commenced within twenty-eight days from the purchase. It also contains a most important and beneficial alteration from the defence point of view, in that the summons must now be accompanied with a copy of the analyst's certificate obtained by the authorities. The defendant will now know exactly what he is being charged with. Section 22 of the new Act is also an amendment in the interest of the trader.

DEFENCE CAN USE A PUBLIC ANALYST'S CERTIFICATE.

In the old Act the authorities were not bound to call their analyst unless the defendant demanded it. His certificate was evidence; but if the defendant wished to put in analytical evidence he had to call his analyst in person. His certificate was not sufficient. What is sauce for the goose is now to be sauce for the gander. The public analyst's certificate produced by the defence will be accepted as evidence unless the authorities give notice that they require his attendance, but it should be remembered that a copy of such certificate must be sent to the prosecutor at least three days before the summons is returnable.

WHAT IS A WARRANTY?

The vexed question as to what constitutes a warranty is still somewhat an undecided one; but Mr. Beck advises us, as an Association, that each invoice must be accompanied with a written statement that the article invoiced is guaranteed pure, etc. A rubber stamp impression, provided the statement was signed, would be sufficient. I know of a number of cases in which retail chemists have required wholesale houses to warrant their goods, and letters have been sent by the wholesalers in question stating that they thereby give a general guarantee and undertaking that all B.P. articles sold by them as such are warranted to be B.P. It is well that the retail trade should remember that such a letter does

not constitute a legal warranty except for the particular consignment of goods which it might accompany. Each consignment of goods must be separately and specifically warranted.

Section 26 gives a new definition of a food.

BAKING POWDER NOW A FOOD.

It is important to chemists, in that such articles as baking powder, egg powder, etc., will now be within this definition. The new Act provides enhanced penalties, and for a third offence under the same sentence the defendant may in future be sent to gaol.

Two other amendments of importance suggest themselves—namely, that now the magistrate is bound to refer the third sample to the Government laboratory if either party ask him to do so. He had previously the option.

PUBLIC ANALYST TO BE QUALIFIED.

Section 2 of the new Act says:—

Any public analyst appointed under the Sale of Food and Drugs Act shall furnish such proof of competency as may from time to time be required by regulation framed by the Local Government Board.

NEED FOR ORGANISATION TO WATCH TRADE LEGISLATION.

This new Act is a striking example of the need that exists for some organisation which would put before the authorities the views of chemists and druggists in regard to such Acts of Parliament by which they are to be so particularly affected. The interests of the grocery trade were splendidly watched by the Grocers' Federation, and Mr. Long, the Minister in charge of the Bill, received repeated deputations from that body. The Act, as now passed, bears evidence to the benefits resulting to the grocery trade from such deliberations between the Government and their representatives.

Merchandise Marks Act.

Under this Act it is illegal to forge any trade mark, to use any colourable imitation of a trade mark, to make any die, block, machine, or other instrument for the purposes of forging a trade mark or apply any false trade description to goods. It is also an offence to sell or expose for sale anything with a forged trade mark or false trade description unless the accused can show that, having taken all reasonable precautions against committing an offence, he had no reason to suspect the genuineness of the mark or trade description, that he is ready to give all information in his power as to where he obtained the goods, and that he had otherwise acted innocently. Penalties are severe, more so than under the Foods and Drugs Act, the offender being liable to imprisonment on the first offence. The authorities have recently used this Act in order to get at the manufacturing and wholesale houses who supply foods or drugs—any goods, in fact—under a false description, and heavy penalties have recently been imposed upon wholesalers of camphorated oil not of B.P. quality.

Weights and Measures Acts, 1878, 1889, 1897.

The 1878 Act lays down that every contract, bargain, sale or dealing shall be deemed to be made or had according to one of the imperial weights and measures ascertained by the Act, or to some multiple or part thereof; and if not so made or had, shall be void. It also prohibits the use of local or customary measures. The use of the avoirdupois weight is enforced for all articles except gold, silver, platinum, diamonds, precious metals or stones, which may be sold by troy weight; and drugs, which, when sold by retail, may be sold by apothecaries weight. By the 24th Section it is illegal not only to use, but to have in possession for use in trade, a weight or measure which is not of the denomination of some Board of Trade standard. It is also an offence to wilfully use, knowingly make, or cause to be made or sold, any false or unjust weight, measure, scale, balance, steelyard, or weighing machine. Every weight, unless it is too small, must have the denomination on the top or side in legible figures or letters, and measures must be similarly stamped on the outside. In addition to being correct, every measure or weight whatsoever used for trade must be verified and

stamped by an inspector with a stamp of verification. Lead or pewter weights must be substantially cased with brass, copper or iron before being stamped. It is the duty of local authorities to appoint a sufficient number of inspectors for the enforcing of the Act in their district. Section 45 states that if a weight or measure is stamped by an inspector under this Act it may be legally used throughout the United Kingdom unless found to be false or unjust, and it does not need restamping by the local authority where it is for the time being in use. The inspectors have authority in writing from the magistrate at all reasonable times to inspect weights, measures, scales, etc., used within his jurisdiction. The same power is given to every Justice of the Peace, and any person who neglects to produce such weights, measures, and scales, etc., is liable to be fined. Under the 1889 Act if a person is convicted of a second or subsequent offence, and if the Court is of opinion that the offence was committed with intent to defraud, he may be sent to prison. The Court can also, if it thinks fit, order the publication of any conviction. Equivalents of metric and imperial weights and measures have been issued from the Standards Office of the Board of Trade, but the 1897 Act legalises the use of metric weights and measures, and these should be verified and stamped by the inspector.

Petroleum Acts, 1871, 1879.

Section 3 defines the term "Petroleum" as follows:—

For the purposes of this Act the term "Petroleum" includes any rock oil, Rangoon oil, Burmah oil, oil made from petroleum, coal schist, shale, peat, or other bituminous substance, and any products of petroleum or any of the above-mentioned oils; and the term "petroleum to which this Act applies" means such of the petroleum so defined as, when tested in manner set forth in Schedule 1 to this Act, gives off an inflammable vapour at a temperature of less than one hundred degrees of Fahrenheit's thermometer.

Section 14 states that by an Order in Council this Act or any part thereof may be made to apply to any substance, and shall be construed as if such substances had been included in the definition of petroleum above referred to. Where any petroleum is kept for seven days after it is imported, or is sent or conveyed by land or water between any two places in the United Kingdom, the vessel containing it must have attached thereto a label in conspicuous characters stating the description of the petroleum, with the addition of the words "highly inflammable," and also in the case of a vessel kept, the name and address of the consignee or owner; in the case of a vessel sent or conveyed, the name and address of the sender; and in the case of a vessel sold or for sale, the name and address of the vendor. Section 7 prohibits petroleum being kept except by persons licensed by the local authority. Petroleum kept in contravention of the Section shall, together with the vessel containing it, be forfeited, and the owner of the place shall be liable to a penalty not exceeding £20 per day during which he keeps the petroleum; but the Section does not apply to petroleum kept for private use or sold if it is kept in special glass, earthenware, or metal vessels, each of which does not contain more than a pint, and is securely stopped, and that the aggregate amount kept does not exceed three gallons. The local authorities have power to endorse the licence with conditions as to the mode of storage, etc. The test for petroleum was altered in the subsequent Act of 1879, reducing the flash point to 73 degrees—"the deadly low flash."

The Pharmaceutical Society last year induced the London County Council to issue instructions in reference to persons keeping petroleum spirits, and they will not be required to obtain a licence provided—

That the total quantity kept does not exceed three gallons (*i.e.*, of everything coming under the designation "Petroleum").

That the spirit is kept in securely-stopped vessels, each of which contains not more than one pint.

That not more than one of such vessels is opened upon the premises at one time, whether for use or for rebottling for sale.

In the absence of such instructions chemists cannot legally keep benzine, etc., in open bottles in their premises for serving small

quantities. By Orders in Council issued in 1897 carbide of calcium comes under the definition of petroleum, thus necessitating a licence before it can be stored or sold. Five lbs., however, may be kept in 1-lb. sealed packets without a licence. Such packets, if sold or exposed for sale, must contain the label:—"Carbide of Calcium. Dangerous if not kept dry," with the addition of the following notice:—"The contents of this package are liable, if brought into contact with moisture, to give off a highly inflammable gas."

Explosive Acts.

By the Explosive Act, 1875, the term "explosive" included every substance used or manufactured with a view to producing a particular effect by explosion or a pyrotechnic effect. Such substances cannot be manufactured except by licensed persons at registered premises.

Shop Hours Acts.

The important thing to remember under this Act is that no person under eighteen can be employed for longer than seventy-four hours a week, including meal times, and that a notice concerning this Act must be exhibited in every shop where such young persons are employed. Under the Shops Seats Act, which came into force on the 1st of January, in all rooms of a shop where goods are retailed and female assistants employed for the retailing of goods to the public, the employer shall provide seats in suitable positions in the proportion of one seat for each three female assistants. I trust I am not ungallant in hoping that this Act will never have much bearing upon the business of a chemist and druggist.

Criminal Laws.

I want to refer to two Criminal Laws which I am convinced chemists and their assistants are in danger of breaking. I would have preferred not to have had to deal with them, but I feel I should be lacking in my duty if I did not use the occasion to solemnly warn a number of my fellow chemists and their assistants from what I know to be a danger which many almost daily run of standing in a criminal dock. I refer first to Offences against the Persons Act, 1861. I quote from the Act Clauses 58 and 59, which are as follow:—

58. Every woman being with child who, with intent to procure her own miscarriage, shall unlawfully administer to herself any poison or other noxious thing, or shall unlawfully use any instrument or other means whatsoever with the like intent, and whosoever, with intent to procure the miscarriage of any woman, whether she be or be not with child, shall unlawfully administer to her or cause to be taken by her any poison or other noxious thing, or shall unlawfully use any instrument or other means whatsoever with the like intent, shall be guilty of felony, and being convicted thereof shall be liable at the discretion of the Court to be kept in penal servitude for life, or for any term not less than three years, or to be imprisoned for any term not exceeding two years, with or without hard labour, and with or without solitary confinement.

59. Whosoever shall unlawfully supply or procure any poison or other noxious thing, or any instrument or thing whatsoever, knowing that the same is intended to be unlawfully used or employed with intent to procure the miscarriage of any woman, whether she be or be not with child, shall be guilty of a misdemeanour, and being convicted thereof shall be liable at the discretion of the Court to be kept in penal servitude for the term of three years, or to be imprisoned for any term not exceeding two years, with or without hard labour.

I say nothing as to the immorality of the practices aimed at here, but I urge every chemist and assistant to carefully study the plain English of those sections. I know that many chemists, actuated by motives of pity or gain, are constantly sailing far too near the wind if they desire to avoid being convicted felons.

The other Act is that to Suppress Indecent Advertisements, 1889. Section 5 of that Act says:—

5. Any advertisement relating to syphilis, gonorrhœa, nervous debility, or other complaint or infirmity arising from or relating to sexual intercourse, shall be deemed to be printed or written matter of an indecent nature within the meaning of Section 3 of this Act, if such advertisement is affixed to or inscribed on any house, building, wall, hoarding, gate, fence, pillar, post, board, tree, or other thing whatsoever, so as to be visible to a person being in or passing along any street, public highway, or footpath, or is affixed to or inscribed on any public urinal, or is delivered or attempted to be delivered to any person being in or passing along any street, public highway, or footpath.

This needs little comment from me except to say that there are many chemists within a radius of two miles of this spot who, while priding themselves on their professional standing, are exhibiting articles with labels attached which contravene this Act. They are liable to a penalty of forty shillings or a month with or without hard labour.

Pharmacy Acts.

I have left myself little time to deal with the law which above all others affects us as chemists most particularly. I refer to the Pharmacy Acts of 1852 and 1868. The chief provisions of these Acts are surely known to every chemist. They ought to be known to every chemist's apprentice, but there are various points in the 1868 Act as to the force or meaning of which it would be rather difficult to make an authoritative statement. Under the 15th Section it is an offence for any person to compound any medicines of the British Pharmacopœia except according to the formularies of the said Pharmacopœia. This particular feature of the 15th Section is practically a dead letter. The only body who can take action is the Pharmaceutical Society, and, so far as I have been able to gather, the Society has never taken any proceedings in that connection. It would be useful to have a legal decision as to what constitutes such compounding, and I am personally of opinion that the Pharmaceutical Council owes it as a duty to the public, and would enhance its value from the public point of view, if it would enforce this portion of the 15th Section. There can be no doubt that cheap and nasty medicines are being sold, and that the practice constitutes the worst form of competition which we as chemists have to put up with. Anything that the Society can do in putting down such practices would be of use to the public. There are a number of unsettled points in the 17th Section and, for the present, I should prefer having nothing to say about them except to point out the important duty devolving upon the chemists and their assistants to see that the provisions of this Section are effectually carried out. I have reason to believe that there is a great deal of neglect in omitting to label poisons, especially proprietaries containing poisons, with the name and address of the seller.

I must apologise for the length of my paper and the dryness of my subject. I have not pretended to speak with any authority, or to assume the technical knowledge of the lawyer in dealing with it. I hope the paper will show chemists the importance of making themselves thoroughly conversant with not only the various laws I have been able to touch upon, but the others (quite as many again) which they are liable to contravene. I should personally be a strong supporter of the establishment at our School in Bloomsbury Square of a Professorship of Pharmaceutical Jurisprudence. I hope also that one result of the paper will be to show the need there was for some such organisation as that which has already been provided by the Association of which I am the secretary—namely, the Chemists' Defence Association. It will be part of the duty of that organisation to keep its members in touch with those laws and any alterations which may be made in them. It will be its duty to keep in touch with the proper authorities, with the view to securing legislation which is at least just to us as a body. If the Defence Association does no other work than this, and does it well, I claim that its existence will be amply justified.

OXAPHOR IN DYSPNŒA.—R. Jacobson finds that oxaphor has not the same injurious effect on the heart as camphor. He prescribes it as follows:—Solution of oxaphor (50 per cent.), 10; rectified spirit, 20; extract of liquorice, 10; distilled water, to 150. A tablespoonful three times daily. In eighteen cases of heart and lung disease, and chronic nephritis, it gave very good results. Senator has also obtained good results in cases of chronic nephritis with asthma, angina pectoris, and emphysema.—*Wien Klin. Rund.*, 13, 626.

FACTS AND FANCIES.

BY AN ORDINARY PHARMACIST.

The Pharmacopœia as a Standard.

I have read with great interest Mr. Eagle's letter (*ante*, p. 52), in which he contends that pharmacists have a right to exercise their discretion as to what preparations they should supply in the ordinary course of retail trade. His point appears to be that, when dispensing medical prescriptions, B.P. preparations should be used exclusively unless the contrary is indicated, but that the special training of the pharmacist legally entitles him to exercise his discretion whether he sells B.P. preparations or not. The argument I am disposed to urge is that, undoubtedly, he is entitled to exercise such discretion, and practically does so in many instances—*i.e.*, when he knows definitely that his customer does not require the B.P. article, milk of sulphur. But, I fear, it is much too late in the day—or, is it too early?—to maintain such a position in its entirety. To determine the point we require to have a test case carried up to the House of Lords, for the purpose of deciding if, and to what extent, the Pharmacopœia is a legal trade standard for the sale of drugs and preparations thereof. Until that is done, pharmacists would do well to continue loyal to the official standards and exercise their discretion very discreetly indeed. After all, it is well to support the intention of the British Pharmacopœia in regard to medical practice, and with that view to maintain one and the same standard for the medicinal preparations used throughout the length and breadth of the land, whilst—in trade and so far as local or special requirements are concerned—there is nothing to prevent the pharmacist supplying what he knows his customers require.

B.P. Standards for Drugs.

I notice that, in his paper on myrrh, published in last week's Journal, Mr. Merson suggests—including in the British Pharmacopœia monograph of that gum-resin—standards for ash and alcohol-insoluble residue. Judging from the results of his experiments, the suggestion appears thoroughly justified, but the question arises whether—in the event of such standards being fixed—the official article would be readily obtainable. To take an analogous case, the B.P. already fixes standards for ash and alcohol-insoluble matter in asafetida, but a member of one leading firm of wholesale druggists asserts that B.P. asafetida is not a commercial article, and I observe that his firm does not quote B.P. asafetida in its latest price-list, nor do other firms to whose price-lists I have referred specifically quote the B.P. article. The prices quoted for the non-official gum-resin range from 1s. to 2s. per pound; apparently no firm cares to quote anything much higher in price than its competitors. But, according to last week's Annotations (see p. 57), asafetida which would appear to contain half its weight of gum-resin up to the B.P. standard can be obtained without difficulty, in the open market, at 1s. per pound or less. Surely, therefore, it ought to be possible for wholesale druggists to supply a B.P. article to retailers at or about 2s. or 2s. 6d. per pound. But no; they say the B.P. gum-resin is not a commercial article, and if the pharmacist requires something which will answer the B.P. tests he must buy purified strained asafetida—an imperfect substitute which has lost a considerable proportion of its volatile constituents—at a cost ranging from 2s. 3d. to 3s. 6d. per pound, according as it has been treated with methylated or rectified spirit.

Wanted, a New Apothecaries' Hall.

Why does not some enterprising firm of wholesale druggists, whilst prepared to supply lower grade goods at the same prices as their competitors, make a point of quoting drugs up to the B.P. standards, however high the price may need to be fixed? It has long been known that the pareira root usually supplied by wholesale houses is not the B.P. drug, which should be the dried root of *Chondrodendron tomentosum*, but a Menispermaceous root of unknown

botanical origin. To such an extent has the custom developed that wholesale druggists now ignore the falsification and boldly offer the substitute as Rad. Pareiræ. But they quote an absurdly impossible price for the root, and therein lies the clue to the mystery of an official drug being practically unobtainable in the ordinary course. For genuine pareira root can be produced in sufficient quantity if a fair price be paid for it; but, apparently, no wholesale house cares to be the first to raise its price. Why not, however, continue to offer the lower grade article at the lower price and quote the B.P. drug at its proper price? Consider, again, the case of aconite root. The B.P. article, grown in Britain, can readily be obtained by wholesale druggists, if they are prepared to pay a reasonable price to growers for producing it. But they are averse to paying more than 6d. or 8d. per pound, a price at which the B.P. drug cannot be produced. As a consequence, the supply fails, and we are coolly told that—because of that failure!—recourse must be had to Continental aconite root to fill the gap. But, again I ask, would it not be wiser and better for wholesale druggists to help pharmacists to maintain the official standards, by securing and offering B.P. drugs at appropriate prices, whilst also stocking goods of lower grade for those who require them. There would almost appear to be a good opening for an establishment—say, run on similar lines to the Apothecaries' Hall—which should supply B.P. drugs and preparations, and no others. In any case, it seems to me that pharmacists who want the best articles, and are prepared to pay for them, should be able to get them, so long as it is not physically impossible to produce them.

The Weed-Killer Case.

The chief thing that struck me on reading the detailed report of the weed-killer appeal, which appears in the *P.J.*, was the off-hand way in which the judges decided the matter. They seem to have considered the letter of the law only, without the least consideration for public policy. What the judgment amounts to is virtually that the defendant was an agent only, and, therefore, not liable, so that, if the principals cannot be got at because of a defect in the law, no one can be made liable, and the public must suffer until the law is amended. What a contrast this affords with the House of Lords' decision in the case of the London and Provincial Supply Association. If memory serves me correctly, the judges then declared that, though companies were not specifically mentioned in the Pharmacy Act, they would have felt bound, in the public interest, to give a decision in favour of the Pharmaceutical Society if they had not felt that—in the particular case under consideration—sufficient protection was afforded by the qualification of the actual seller, who had not long before been the proprietor of the business afterwards carried on by him as the servant of the London and Provincial Supply Company, Limited. Whilst, therefore, Justices Grantham and Channell may have decided the case rightly on the strict point of law, I think it is far from improbable that the Court of Appeal and the House of Lords may reverse that decision on grounds of public policy. At any rate, I am strongly of opinion that the higher courts should be afforded the opportunity of dealing with the question and, if the original decision should then be upheld, the need for serious amendment of the Pharmacy Acts will be more manifest than ever.

The Next Pharmacy Bill.

Whilst referring to the possibility of a new Pharmacy Bill being called for before long, I may point out that the difficulty created by the decision just referred to, like that created by the House of Lords' decision thirty years ago, takes its rise in the dual character of the Pharmacy Act, 1868. The 1852 Act constituted an ideal basis for the establishment of a real pharmaceutical qualification, but its successor was spoiled by grafting upon it Sections regulating the sale of poisons. I fear the two objects can hardly be separated now; an amending Act, therefore, should complete the scheme of the 1852 Act, whilst also doing what is necessary

to protect the public against the indiscriminate distribution of poisons. The professional qualification in pharmacy should be fully protected, no unqualified individual or corporate body being permitted to usurp the privileges rightly attaching to that qualification, or to do what the possession of that qualification alone fits an individual to do. It must be recognised that the pharmacist cannot perform his professional duties by proxy or delegate to unqualified persons the functions which he is required to show himself specially fitted to perform; on the other hand, the public safety requires that the dispensing of medicines shall be restricted to individuals who are duly qualified to deal with those matters, and in like manner that the sale of poisons shall be subject to similar control; and that, in brief, represents the ground which, in my opinion, the next Pharmacy Acts Amendment Bill should cover; the details may safely be left to the consideration of those whose special duty it must be to draft and legalise the measure.

POLITICAL GOSSIP.

THE ELEVATION OF SIR JOHN LUBBOCK to the peerage has involved the University of London in both a Parliamentary and an academic contest—a struggle within a struggle. It is not only the question of choosing a political representative that is placed before the graduates, but also the wider consideration of whether that representative should be selected for the orthodoxy of his politics, or on the higher recommendation of intellectual endowment or academic distinction. There are at present three names mentioned in connection with the vacancy—two of them belong to politicians, who are popularly supposed to put party above every other earthly consideration, but the third name is that of Sir Michael Foster, who has consented to go to the poll in what may be termed the intellectual interest; and a very proper interest it seems for safeguarding in the House of Commons. Dickens used to maintain, in one of his delightful occasional pieces, that "Verbosity" was the best represented place in Great Britain; similarly one might say that Intelligence has the worst parliamentary representation in the world. Not that political candidates have no intellectual side. To say so would be to speak slightly of the brilliant career of Dr. W. J. Collins, the Radical candidate, and of Mr. E. H. Busk, who appeals to Liberal Unionist graduates. Dr. Collins was a scholar and Gold Medallist of the University, has occupied a high position in the profession of medicine, and is a past-Chairman of the London County Council; whilst Mr. Busk graduated with high honours, is a Fellow of the University, as well as Chairman of Convocation, and is one of the Commissioners under the University Commission Act. Both gentlemen are, however, said to be of opinion that while the University sends a member to Parliament the election should be on political lines. There is reason to believe that this opinion is not generally shared by the electorate, and that a large body of influential graduates welcome the advent of the personality of Sir Michael Foster, and will express their sense of his non-political attitude in a practical manner. Pharmacists, as a body, will not be slow in congratulating Sir Michael in the event of his adding M.P. to the long procession of honourable affixes attached to his name, and they will not be displeased, on their own account, to have in Parliament an additional member who has heard of the Pharmaceutical Society and is not disposed to sneer at its work, or snub its members.

SHOP ASSISTANTS have been urged by Mr. Yoxall, M.P., to rise in their thousands and form a Union, with a view to putting an end to the underpaid and overworked career which is too generally their lot in life. Mr. Yoxall maintained that shop assistants are about the worst paid body of workers in England, but he did not specify the particular class of business in which the offence is most rife. Can someone have brought to his notice the remuneration offered to qualified chemists for twelve hours a day skilled work of a professional nature? Naturally, the assistants addressed by the member for West Nottingham were eager to adopt any suggestion for improving their position, and therefore passed a resolution protesting against the "living in" system with its accompanying social and political isolation, and further, they resolved to support the Shops Bill brought in last Session by Sir Charles Dilke. The remedies appear to be rather heroic to say the least.

NEW REMEDIES.

IODOPYRINE.—Junkers considers iodopyrine to be superior to antipyrine and other antipyretics, since it is tasteless, not nauseating, never causes collapse, and, at the same time, has marked antiseptic properties. It occurs in acicular crystals melting at 160° C. It is insoluble in cold water, but gradually dissolves in cold alcohol or ether. Chemically iodopyrine is antipyrine, in which one atom of H is replaced by iodine. The doses are, for adults, 1 Gm. every 3-4 hours daily; for young children, 10 to 50 centigrammes; for those above ten years, 50 to 75 centigrammes, three times daily, are without any ill effect. It provokes profuse diaphoresis, followed by decrease of temperature, the pulse becoming regular. Albumin is not found in the urine after its administration.—*Therap. Monats.* 13, 604.

ANTIPHLOGISTON AND ANTITHERMALIN.—Under these names a mixture of kaolin and glycerin has been introduced in the United States as a substitute for poultices for local application. As the mass requires no heating or preparation, and need not be renewed for twelve to forty-eight hours, while at the same time it gives almost instantaneous relief in most cases of inflammation or congestion, the advantages are considerable. The application is, moreover, easily washed off with cold water. Any medication may be added to the basis. According to J. Wilbert it is prepared as follows:—Kaolin, 1,000; glycerin, 1,000; boric acid, 1,000; peppermint oil, 1; Wintergreen oil, 1; eucalyptus oil, 2. The kaolin is put through a 60 sieve, and heated to 100° C. for one hour to sterilise it, the glycerin is then added, and heated again for 30-40 minutes, and then rubbed up till it forms a homogeneous mixture; after cooling the acid and oils are added and the preparation filled into well closed tins or bottles to prevent action of air. A trace of iron in the kaolin sometimes causes a little colouring, but in no way affects the value of the preparation.—*Pharm. Post*, 32, 630.

CLINICAL USES OF LIQUID AIR.—Pearce states that liquid air has been satisfactory as a local anæsthetic, minor operations being done with no pain at all, and no injury to surrounding tissues. In neuralgias and pain of herpes zoster it has given prompt relief. It was used in a case of erythematous lupus without producing the deep searing attending other forms of treatment. A case of epithelioma of the face yielded easily. In cases of small tumours of the face, nævi, etc., it can be used, and leaves a scar which is hardly perceptible. Cases of boils, carbuncles, and bubos showed marked modification in their course. A case of facial erysipelas was subjected to the spray until the infected surface felt very cold, and when the patient returned three days later, having had no other treatment, the inflammation was found to have subsided completely. Sluggish ulcers seem to take on a new growth when they have been subjected to a spray of liquid air, which appears to have all the effects of a caustic without its attendant inflammation.—*Inter. Med. Mag* 8, 775.

SULPHOSOTE.—This is, according to Gehe and Co., a syrup containing 5 per cent. potassium guaiacol-sulphonate and 5 per cent. potassium creosol-sulphonate.—*Pharm. Centralh.*, 40, 576.

LETTERS TO THE EDITOR.

The Society's Examinations.

I wish to endeavour to remove the somewhat unjust as well as unkind suggestion of "An Ordinary Pharmacist" that my letter on the above subject in a previous issue of the Journal was a personal attack on the examiners. Lest others should have gained the same impression, allow me to say that such was far from my intention. What I endeavoured to do was to plead the cause of the student from the student's standpoint. Naturally, in an examination which gives such absolute power to examiners, they were necessarily involved in my remarks, but it was more against a system which gave such power than against the use made of it that my words were directed.

I am sorry "An Ordinary Pharmacist" did not criticise or discuss the real question at issue, as put forth in my letter, rather than single out two phrases for comment. I can only understand the exception he takes to these expressions after reading his words:—"So far as the moral sense of examiners is concerned, I fail to see what that should have to do with the question of testing the fitness of candidates to practise pharmacy." Now, surely my choice of expression was not incorrect in an examination where so much is left to the examiner's sense of what is right or wrong. Even the most rigidly legal matters have sometimes to be tempered by this moral guidance. If, however, "An Ordinary Pharmacist" thinks I suggested that examiners are without this quality or without kindness of feeling, he is quite mistaken. Such would be opposed to my own experience of them. But if, as I have, he has come in contact with hundreds of students, and listened to accounts of their examination (supposing only a fraction of what they recount to be actual fact), I should be surprised if he has not sometimes felt, as I felt, that a little more consideration might have been shown in a matter which is a very serious drag, both pecuniarily and otherwise, on many students. In the light of my own experience it would require more than even the word of eminent authorities to cause me to accept the Minor as a fair examination. It has not been my experience that the knowledge of students on any subject needs to be approaching absolute zero for them to risk chance of failure, and I venture to think that if a census of student opinion could be taken throughout the country, even "An Ordinary Pharmacist" would be compelled to slightly alter his views.

Finally, let me say that I entirely agree with "An Ordinary Pharmacist" when he says that nothing could be more harmful than to cause candidates to feel that examiners are their natural enemies. If such a feeling exists it has not been drawn from any outside source, but is the result of the present system, and due largely to examiners themselves. I feel most strongly that our Society cannot afford to ignore the feelings of students on a subject of such vital importance. How many a student waves a good-bye to the Society when he grasps his Minor certificate, who could be won as a strength to that Society but for the bitter feelings born of a system which his own experience tells him is unjust. I believe this is the greatest reason why, as a Society, we are so numerically weak, and I call upon those who have had better opportunities than myself of mixing with our students to express an unbiassed opinion on the subject.

Newcastle-on-Tyne, Jan. 15, 1900. THOS. HY. FLEMMING.

Liquor Bismuthi.

Messrs. Cowley and Catford seem to have misunderstood the point of my previous letter. My Conference paper did not attempt to remedy the slight deficiency of potassium citrate in the B.P. formula, but to ensure the entire formation of soluble bismuth citrate and not a variable and partly insoluble mixture of citrate and oxynitrate, and this aim it effects with a minimum of trouble to the pharmacist and deviation from the present formula. The

chief cause of deficient strength in commercial potass. citrate is absorption of moisture owing to its hygroscopic nature, and the B.P. requires a minimum purity of 98.33 per cent. If a damp salt be used, of course there will be a greater deficiency of citrate. With regard to their criticisms on my paper:—(1) Having reference to the 1898 formula, it could not have been affected by a criticism made in 1886 of the 1885 process. (2) Mr. J. C. Unmey in 1898 pointed out the deficiency of citrate, but I have not a copy of his original paper, and am unaware if he also noticed the inadequate amount of potass. carbonate. If he did not, I am not aware of anyone else who has done so. I fail to see anything in my paper which would lead anyone to believe that an increased quantity of carbonate will remedy a deficiency of citrate. It will, however, prevent loss of citrate through solution in excess of unneutralised acid. The reversal of order of mixing will prevent formation of an insoluble basic salt in the precipitate. I have yet to learn that the order of mixing is an unimportant consideration in pharmacy. In reply to query (a) I tried mixing the liquids in the B.P. manner after increasing the quantity of potass. carbonate—with unsatisfactory results; (b) I did not quantitatively determine the actual amounts of bismuth in the finished liquor and in the washings, but made relative and comparative tests with H₂S water on the washings from samples containing respectively the B.P. and increased quantity of carbonate, resulting greatly in favour of the larger quantity. Lastly, I would again recognise the complete and careful manner in which Messrs. Cowley and Catford have dealt with the subject. The correct amount of potassium carbonate per litre, using 100 per cent. citrate, is almost 27.1 grammes. The quantity I suggested was 27 grammes.

Newcastle-on-Tyne, Jan. 16, 1900. FRANK R. DUDDERIDGE.

Science and Agriculture.

The last issue of the *Journal of the Royal Agricultural Society* contains matter that should be of interest to chemists residing in agricultural centres. The apathy which seems to have existed amongst chemists regarding poisonous substances used in agriculture in letting the sale of poisons of any kind used as weed-killers slip through their hands, when they are the most competent to devise means and to impart knowledge to protect the public from the dangers arising from such preparations, is extraordinary. A study of the work that is being done on the scientific side of agriculture deserves careful perusal by country chemists, and the *Journal of the Royal Agricultural Society* affords them the means of keeping pace with the progress made in that direction. Thus, it is stated (*l.c.*, p. 659), that sulphate of copper is being sold in various degrees of purity, often containing a large amount of sulphate of iron, a substance that any chemist could easily detect and estimate, but which farmers are not always competent to do. The chemist should be able to determine the value of feeding-stuffs, such as linseed and cotton-cake, and of manures, basic slag, superphosphates, etc., and his special training and knowledge should enable him to examine and report upon them better than others less well equipped. There is plenty of room for enterprising chemists to devise remedies for attacks of botworms in horses, grass ticks in sheep, and for killing the various insects that cause serious injury to the fruit crops, fungoid diseases in plants, etc. The consulting chemist to the Royal Agricultural Society reports that a sample of lawn sand for killing weeds in lawns consisted of sulphate of ammonia and sand. The sulphate shrivels or burns up the plants upon which it immediately falls, and when the excess is washed away it exerts a forcing effect upon the grass around. Useful information as to the time of year when such remedies can be effectually used can be gathered from the pages of this valuable publication. The report of the consulting botanist indicates that during the past year *Ranunculus acris* has proved poisonous to sheep in Yorkshire, and *R. flcaria* was suspected of being injurious to cattle. A

much more frequent cause of mischief, *R. flammula*, is, however, not noticed. The statement that the laurel (*Laurus nobilis*, Linn.) and the cherry laurel (*Prunus laurocerasus*, Linn.), both contain an essential oil rich in prussic acid is new to me, and the suggestion that the action of the poison has been arrested by artificial respiration, accompanied by the injection of atropine, seems rather an unwise one to make in a journal whose readers are scarcely likely, as a rule, to know how atropine should be administered.

London, January 24, 1900.

E. M. HOLMES.

The Company Pharmacy Problem.

Although I strongly disagree with Mr. Lord Gifford's mode of attacking "An Ordinary Pharmacist" concerning his anonymity, I consider that any person writing articles for a journal should follow the fashion adopted by all writers on the Continent of publishing the contributor's name therewith. "An Ordinary Pharmacist's" excuse regarding his obscurity is somewhat lame. If he has anything worth saying, I should imagine that his brethren of the pestle are sufficiently enlightened not to depreciate his efforts on that account. The overwhelming genius of a Junius might think it necessary to let his name stand under a shade, but for one who is so modest in his description of himself, viz., "An Ordinary Pharmacist," it can hardly be so important to conceal his identity. On the company pharmacy question I think I am on all fours with Mr. Lord Gifford. I trust the great majority of chemists will insist upon their rights and titles being defended tooth and nail. To my mind, it is not only egregiously absurd, but also the symptom of a despicable, craven, abject, cowardly spirit, to entertain for a single moment the idea of according the slightest recognition to, or of making any compromise with, a class of persons who are stealing our clothes—either by way of company legislation or any other way. Let persons who wish to be on the same platform with us undergo the same ordeals; the remedy is simple enough, and in their own hands. Let our policy be one of no surrender, and let us quit ourselves like men.

Hitchin, Herts, January 23, 1900.

E. A. MORGAN.

What has the Society Done?

The Pharmaceutical Society has been in existence for over fifty years, and what has it accomplished in that time? If the retail trade is any better off it is due mainly to the business capacity and shrewdness of the individuals engaged in it. True, the Society has been a little more active the last few years, but in a very half-hearted way. But what has it done for that hard-working and long-suffering class of men, the public dispensers? As your correspondent, Mr. A. C. Stark, points out, they are about the only men who make pharmacy, pure and simple, their sole occupation. Most of them, I think, are members of the Society, yet how much sympathy or help have they received from the Society in their particular difficulties?

First, as to pay: The maximum allowed by the regulations of the Local Government Board is £140 per annum (a little more in the metropolis), while a relieving officer, who needs no special qualification, can receive considerably more. Has the Pharmaceutical Society ever used its influence to remedy this? Did it make any protest when the standard for these posts was lowered a few years ago? Again, look at the terms offered by the War Office for compounders in the Transvaal war. What protest does the Society offer to this scandalous insult to the whole of our profession?

In fact, the pay and status of union and hospital dispensers is lower than it was twenty or thirty years ago. It is absurd to argue that the Society is not a trades union. Whether it is one or not, it is its duty to protect, as far as it has power, the interests of its licentiates, and hitherto, it cannot be denied, it has signally failed in that duty. What more powerful trades unions exist than the General Medical Council, which, after all, is composed of representatives of the different medical societies and colleges,

and the Incorporated Law Society? Look, again, what power the National Union of Teachers has.

I have subscribed to the Pharmaceutical Society for many years now, but, unless its leaders show more spirit in furthering the interests of those they are supposed to represent, I shall soon cease to subscribe to its funds.

Stoke-on-Trent, Jan. 16, 1900. A HOSPITAL DISPENSER (17/36).

The Storage of Poisons.

As pharmacists who have the welfare of the public at heart, I think we ought not to rest until medical men who do their own dispensing are placed under the same restrictions in the storage of poisons as we are. It certainly ought to be impossible to keep liquor strychninae side by side with aqua chloroformi, for every dispenser knows how easy it is to pick up the wrong bottle.

January 22, 1900.

CORPUS (18/15).

The Public and Poor Law Dispensers' Association.

I wish to ask any past or present Public or Poor Law dispenser who has not received a copy of the rules, etc., of the Public and Poor Law Dispensers' Association, to communicate with me at the Shuttleworth Club, Fye Foot Lane, Queen Victoria Street, London, E.C., or to attend our next meeting at St. Bride's Institute, Ludgate Circus, on January 31, at 8 p.m.

G. F. FORSTER,

Shuttleworth Club, January 22, 1900.

Hon. Gen. Sec.

The Pharmacopœia as a Standard.

I trust that the letter signed "J. Eagle," in the *Pharmaceutical Journal* for January 20 (see p. 52), will not be allowed to pass unchallenged. That the authority of the Pharmacopœia as a standard should be disputed is not surprising, in view of the conflicting views of different authorities, but that it should be seriously maintained that we need no standards at all would be amusing if it were not sad. The too ready access of the public to potent medicines should be remedied by an extension of the Poisons Schedule, certainly not by adjusting the strength to the supposed needs of the purchaser. If any pharmacist prefers his own formula for camphorated oil to that of the Pharmacopœia he is perfectly justified in using it, but he should not call the product by the official name, without qualification. "Substitutes," as the *Lancet* remarks this week, "may be even better than the original article, but that does not justify deception." "In any case the purchaser has a right to get exactly the article in nature, in substance and in quality that he demands." The course advocated by your correspondent would be a suicidal one for pharmacists to adopt, and could only result in the present confusion being worse confounded.

Exeter, January 23, 1900.

Members of the Pharmaceutical Society must address all communications with reference to the transmission of the Journal, to the Secretary, 17, Bloomsbury Square, London, W.C.

LONDON: SATURDAY, JANUARY 27, 1900.

CHEMICAL CONSTITUTION AND PHYSIOLOGICAL ACTION.

THE connection existing between the almost infinite diversity in the constitution of carbon compounds and the physiological action of particular bodies on the animal organism, is one of the most interesting revelations of modern research, and though the knowledge of the conditions of chemical constitution, capable of producing various kinds of physiological effect, is but slender and fragmentary at present, the field of inquiry to which it points is a specially fascinating one. A very interesting illustration of the manner in which the presence of a particular organic group in a carbon compound appears to be connected with the power of producing physiological effects, as well as the manner in which a particular group appears to be capable of determining different physiological effects of the compounds in which it exists, according to the way in which it is chemically associated with other organic groups, has recently been pointed out by Mr. WATSON SMITH in a paper read by him at a meeting of the Society of Chemical Industry. The difference between the bodies referred to is manifested in the effects produced upon the senses of smell, taste and sight, while the character common to all of these bodies is the presence in them of a nitrogenous group related to the radicle of benzoic acid, but containing NH in the place of one atom of hydrogen in the ortho position. Anthranilic acid, or ortho-amido-benzoic acid $C_7H_7NO_2$ —which has been long known as a product of the oxidation of indigotin—is a body of this kind, its constitution being $C_6H_4 \begin{matrix} \langle CO \cdot OH \\ NH \cdot H \end{matrix}$ and that of the corresponding methyl ester—which has recently attracted attention on account of its odour being like that of orange blossom oil, and of its being found as a constituent of other essential oils — by the formula $C_6H_4 \begin{matrix} \langle CO \cdot OCH_3 \\ NH \cdot H \end{matrix}$ Methyl anthranilate is described as forming colourless crystals having an intense odour of orange blossom and exhibiting a blue fluorescence. The crystals melt at $23 \cdot 5^\circ C.$ and distil in a partial vacuum at $127^\circ C.$ The ester dissolves readily in mineral acids, alcohol or ether, and the solutions exhibit a beautiful blue fluorescence.

Indigotin, $C_{16}H_{10}N_2O_2$, is the substance to which the

colour of indigo is due, and its constitution—as represented by the annexed formula—presents a close relation to that of anthranilic acid, inasmuch as the same ortho-benzoyl-imido group is present in that body as well as in anthranilic acid and its methyl ester. The close relationship of these bodies is also shown by the circumstance that just as the indigotin structure is broken down by oxidation, with removal of the $=C=C=$ group in the state of formic acid, while the two ortho-benzoyl-imido groups unite with the elements of water and form anthranilic acid, so by the reaction of ortho-nitro-benzaldehyde $C_6H_4 \begin{matrix} \langle COH \\ NO_2 \end{matrix}$ —a body related to anthranilic acid—with acetone, the indigotin structure can be built up, by a reverse process, and a body produced which is characterised by its action on the sense of sight through its intense blue colour.

Another compound in which a variation of the group above referred to, is present and the body itself is marked by an intense sweet taste, is saccharin, the constitution of which is represented by the formula— $C_6H_4 \begin{matrix} \langle CO \\ SO_2 \end{matrix} NH$ the NH group being in close juxtaposition with the CO group, though its place, relatively to the CO group, is taken by the sulphonic group SO_2 . In these three bodies anthranilic methyl ester, indigotin and saccharin, the presence of the remarkable ortho-benzoyl-imido group, is a common feature, and the marked difference of their effects upon the senses is coincident with differences of arrangement in the molecules of the respective compounds. A fourth body, indole C_8H_7NO —the constitution of which is still more closely related to that of indigotin than anthranilic acid, anthranilic methyl ester or saccharin— $C_6H_4 \begin{matrix} \langle CO \\ NH \end{matrix} CH_2$ may be mentioned in this connection, since it has lately been discovered as a constituent of the essential oil of jasmin flowers associated with anthranilic methyl ester (see *ante*, p. 42). The known characters of indole are not such as would suggest its being contributory to the perfume of jasmin oil; but Hesse states that when highly purified and in very small proportion it has the effect of very considerably enhancing the perfume of mixtures of essential oils. As indole is a possible condensation product of methyl anthranilate, the source of it in essential oils containing that ester may be accounted for in that way as shown below—

In the course of the discussion of Mr. SMITH'S paper, Dr. POWER mentioned that anthranilic methyl ester was discovered by Messrs. SCHIMMEL to be a constituent of neroli oil, and the artificially prepared ester was introduced into commerce by them in 1895. According to the specification of a patent recently taken out by the firm of MEISTER, LUCIUS AND BRÜNING, anthranilic methyl ester can be made a source of indigotin by reducing a mixture of it and ethyl acetyl anthranilate with sodium, so as to produce indoxyl-methyl-ketone, a pale yellow substance melting at $153^\circ C.$, and readily soluble in ether, alcohol or benzene. When this body is heated with caustic alkalies it forms a yellow mass which yields indigotin when the water solution is exposed to the air, or when a solution of the yellow mass in concentrated sulphuric acid is heated.

LONDON WATER.

THE Royal Commissioners—appointed to inquire into and report upon the water supply of London as it is at present and as it may require to be adapted to the wants of an increased population at a future time—have now completed their task, and their final report on the subject has just been published. One of the most important features of this lengthy report, in regard to the desirability of the water supply of such a population as that of London being in the hands of a public authority, is the expression of an opinion that the circumstances of the case take the duties to be performed out of the category of purely municipal or local functions and make them a matter of national as well as local concern. That view, while tacitly condemning the system of leaving water supply to the enterprise of joint-stock companies, does not by any means indicate approval of the proposal to transfer the water supply of the metropolis to the control of the London County Council. On the contrary a definite recommendation is made that this important function should be entrusted to a special permanent authority, or Water Board, of a representative, as well as executive character and so constituted as not to give preponderance to any of the conflicting interests concerned.

The Commissioners suggest that the Water Board should consist of not more than thirty members to be appointed by the London County Council and other interested bodies. They also suggest that the Water Board should include delegates of the Local Government Board, in order that the influence of the executive government might be continuously felt, as it is considered necessary that the proceedings of such a Water Board should be brought periodically and automatically under the influence of Parliament. A further suggestion is that the Local Government Board should appoint the chairman and vice-chairman, who are to receive adequate salaries, while a sum would be allotted annually for division among the other members of the Board according to their attendances, as in the case of the Conservators of the River Thames. This Water Board is to have power to acquire the undertakings of all the eight metropolitan water companies, either by agreement or arbitration, and to assume all their existing powers and obligations.

In regard to provision for prospective requirements, the Commissioners express their opinion that, from the present sources, a supply may be obtained to suffice for the needs of London up to 1941. While admitting the attractiveness of the scheme for bringing water from the Welsh mountains, they consider that extra expense to be unnecessary now; but that, if the population of London continued to increase at the rate adopted for the purpose of calculation, the resources of the Thames would be more sorely tried after 1941 and the finding of some other source of supply would assume a different degree of importance. On that point the Commissioners consider that nothing but experience can show whether twelve or thirteen million inhabitants would be accumulated within the area in question, and the conclusion arrived at by the Commissioners appears to point to the desirability of posterity being left to provide for themselves as their necessities may require.

ANNOTATIONS.

THE COUNCIL OF THE PHARMACEUTICAL SOCIETY is alleged to be "hopelessly out of sympathy with its constituents," and that in spite of the fact that several policies have been asserted by members of the Council to represent the views of different sections of their colleagues. Moreover, each of those policies is warmly supported by a greater or less proportion of the members of the Society. Inasmuch, therefore, as each member of the Council may fairly claim to represent the views of part of the electorate, it is hardly correct to assert that the Council is out of sympathy with its constituents. Indeed, whether regarded as parts or wholes, the two bodies appear to be in very close sympathy, and if the Council hesitates before entering upon what is certain to be a very serious struggle, its apparent timidity is fully justified by the irresolution and lack of agreement manifested by registered chemists, whether members of the Society or not. Instead of referring to an assumed lack of sympathy between the Council and its constituents, it would, perhaps, be more correct to say that the Council is not disposed to commit itself to what is absurd and impracticable at the bidding of irresponsible critics. And even if the alleged "deadlock" in pharmaceutical affairs should continue a few months longer, it reveals a strange lack of originality to suggest that the electors must either get Mr. Glyn-Jones off the Council "as an ineffectual member," or return "seven others like him." The extravagance of the supposition that seven such could be found is only equalled by the implied reproach that the latest addition to the Council—who, by the way, cannot be turned off for two years—has not done his duty.

THE PRACTICAL ANTI-CUTTER naturally prides himself upon his superiority to the "arm-chair strategist" and "amateur theorist," even though the latter individual be capable of dissociating himself from all mundane conditions and, while in a state of mental ecstasy, can deliver himself of "pharmaceutical beatitudes," whatever they may be. But it may be questioned whether the writer who has been good enough to direct special attention in the *Anti-Cutting Record* to the article on pharmacists as traders, which recently appeared in the *Pharmaceutical Journal*, has the least conception of what the position of the pharmacist as a professional man is or might be. Indeed, it is too much to expect that he should. As a mere trader, imbued with an aggressive fighting spirit, he is doubtless well fitted to be a leader among those of his own particular type. Unfortunately, while endeavouring to be a little too smart, he fails to realise how exaggeration, even when playful, may spoil an apparently good case. His main point, it may be stated, is that chemists should defend themselves to the uttermost when attacked, but he overlooks the fact that some methods of defence are vastly superior to others. The position taken up in the *Pharmaceutical Journal* was that when a chemist finds himself at fault, it would appear better on the whole, from the professional standpoint, for him to own himself in the wrong and have as little as possible said about the matter. It must be remembered that carelessness or neglect is no excuse under the Sale of Food and Drugs Acts, and in the case of those who claim a professional position it is not safe to assert that carelessness or neglect is a more excusable offence than a wilful infringement of the law. That may, naturally, seem a mere empty platitude to Mr. Glyn-Jones's tame humorist, but it nevertheless represents what he would probably recognise as sound common sense if he were concerned in matters where the conduct of a medical man or a lawyer was in question.

CARELESSNESS IS THE UNPARDONABLE SIN for professional men, and though it may appear sheer idealism to the *A.C.R.* hard and fast commentator, the assertion may be repeated that no pharmacist with any respect for professional reputation can afford to plead

in open court, in extenuation of an offence under the Sale of Food and Drugs Acts, that a medicinal preparation supplied by him has been allowed to deteriorate before he sold it, and that he was unaware of the fact. Such a stupid admission of neglect would be a reflection upon pharmacists generally, for some of the mud with which the offender wilfully daubs himself must of necessity attach and cling to the class of which he is a more or less unworthy member. That drugs, chemicals, and galenic preparations can deteriorate is well known, but that affords no sufficient reason why the pharmacist should sell deteriorated articles. It is his special duty to prevent deterioration, to recognise its existence before anyone else can do so, and to decline to dispense or sell anything that is not exactly what it ought to be. The anti-ideal commentator of Stonecutter-street apparently thinks otherwise. Doubtless he is a firm believer in turning everything to account—even his deteriorated stock. He has no time to test the articles he sells, and would seemingly prefer to trust to luck, hoping that inspectors may not ask for drugs or galenicals liable to go wrong, or that he may be able to escape the penalty of his neglect by some legal quibble. In fact, he takes things as he finds them. He is content to know that his stock is only "occasionally deficient in quality, either through being improperly made or through deterioration," and consoles himself with the reflection that, when prosecuted, he need not "forego the inalienable right of even the meanest criminal to defend himself," nor "betray that instinct of self-preservation inherent in man from time immemorial." That very unambitious doctrine may be consoling to the *A.C.R.* critic; but what if he has no case to defend, or if a successful defence should carry in its train worse disaster than could be brought about otherwise?

AS A CONTRAST to the utilitarian comments in the *Anti-Cutting Record*, we have something approaching unadulterated idealism in the remarks of Mr. Glyn-Jones on some of the laws that particularly affect the chemist (see p. 70). He refers to important features of the Apothecaries Act, Sale of Food and Drugs Acts, and other measures concerning which chemists should know much more than they do—not with the object of showing how the provisions of the Acts may be evaded, but rather that it may be brought home to chemists what they can legally do in certain directions and what is prohibited. Presumably Mr. Glyn-Jones would be one of the first to acknowledge that chemists frequently get into difficulties through ignorance of the law; they do not offend wilfully, but, through neglect or carelessness, offences are proved against them from time to time. In such cases a plea of ignorance may prove effective in reducing the penalties imposed; but the more serious consequence is the slur cast upon the reputation of the chemist—as a professional man—willing to own in public that he has neglected to make himself conversant with matters about which he ought to have been fully informed? Here again, ignorance is itself a crime, and especially so in the case of one who aspires to be regarded as a professional man. Merc traders may save themselves trouble by remaining ignorant through choice; but in that event they are neglecting what should be a cardinal principle with shrewd business men. In the end, therefore, ignorance is a mistake anyhow.

THE CHEMISTS' BALL went with more than its usual spirit last week, for, although influenza had kept many away, the ball room was comfortably filled, and the dancing never flagged till the last strains of Mr. Dan Godfrey's band ceased, at about 4.15 a.m. Mr. J. W. Bowen and Mr. J. F. Harrington officiated as M.C.'s, and under their care everything went smoothly. It was particularly noticeable that all the ladies present appeared to be well supplied with partners. About two hundred and twenty persons sat down to supper, and—perhaps because it was the last senior ball supper of the century—a greater spirit of revelry and fun pervaded that function than is usually found. It was difficult

therefore, to catch all the President of the Pharmaceutical Society said, when—as Chairman—he inflicted upon the hon. sec. the usual chaff about his bachelor condition. Mr. Warren, in responding, said, as this was his last year of office, he could not help saying what a pleasure it had been to him to be secretary of the ball. His thanks were due to the committee and stewards for their kind and loyal support; as for the ladies, in spite of all the banter, they had not refused to accept him as their spokesman. It was because he knew them so well that he was proud to respond for them. If in the new century ladies responded for themselves, they could not find amongst their own numbers one who had more affection for them than he had.

THE MANX PHARMACY BILL, having emerged from the Committee stage, has been further considered by the House of Keys and passed after the inclusion of a clause recognising the right of companies of unqualified persons to carry on the business of a chemist and druggist. The clause is reminiscent of the Lord Chancellor's attempt to legalise a similar illogicality, as it provides that

No company may carry on the business and use the description of chemist and druggist unless such business and each branch thereof is *bona-fide* conducted by a manager or assistant being a duly registered pharmaceutical chemist, or chemist and druggist, as the case may require, and unless the name of the person so qualified is conspicuously posted in the shop or other place in which the business is carried on, but, subject to this provision: Anything which would be an offence under Section 6 of this Act, if committed by an individual, shall be an offence if committed by a company.

The House of Keys has also agreed to place on the poison schedule carbolic acid and its poisonous preparations; phosphorus and vermin-killers containing phosphorus; hydrochloric acid, sulphuric acid, sulphate of copper, chlorine and its poisonous preparations, and preparations of red and white precipitate. The member of the House who explained the intention of the added clause said it would have the effect of putting companies on the same footing as individuals, besides causing all chemists' shops to be under the charge of properly-qualified persons. But to put companies really on the same footing as individuals is neither more nor less than to prevent them from carrying on the business of a chemist and druggist, for they cannot be registered under the British or Irish Acts as required in the case of individuals. That, however, will not be the effect of the amended Bill.

THE INSTITUTE OF CHEMISTRY now conducts an examination—written, practical, and oral—in therapeutics, pharmacology, and microscopy. The printed paper set at the latest examination included four tests. First, the candidate was asked to prepare slides of arrowroot and wheat flour, to examine the specimens under the microscope, and report as to their purity. Second, a prepared slide was submitted for examination and description. Third, the candidate was asked what are the chief effects of silver nitrate, phosphorus, crude oil of bitter almonds, and nicotine when taken in dangerous quantities. Fourth, he was asked to state the maximum safe doses, and the fatal doses when known, of corrosive sublimate, arsenious oxide, phenol, morphine hydrochloride, and atropine sulphate. Subsequently, he was "examined practically as to the recognition of drugs and interrogated orally."

TARDY TIDINGS reach us from the Japanese capital of the death of Dr. Rgokishi Yatabe, of Tokyo University, which took place on July 7 last. The Doctor was enjoying a morning swim in the sea at Kamakusa, when he was overpowered by the current and carried out of the reach of immediate assistance. He was still alive when eventually brought to shore, but never recovered consciousness and died the same day. Dr. Yatabe had been for the past seven years a corresponding member of the Pharmaceutical Society, and followed with much interest the progress of pharmaceutical events in Great Britain.

THE EVIDENCE GIVEN before the Departmental Committee inquiring into the use of preservatives and colouring matters in food affords many indications of the prevalence of opinions based upon crochets and fads, as might have been expected; but it is more remarkable to find one of the learned members of the Committee reported as betraying such want of acquaintance with the subject matter of his questions in regard to the preservation of the green colours of peas, as to state, as a leading question, that "the object of the copper is, of course, to restore the colour of a faded pea?" That was too much even for the witness—by the way, the President of the Society of Public Analysts—who discreetly replied, "No doubt it is to make it a good colour." But this answer was not sufficient for the examiner, who again asked "But is it not a fact that the use of copper in peas allows the substitution of a pea which has gone "off colour" and which competes with a pea that has been preserved by a somewhat better process and which has retained its colour?" To which the witness, perhaps, with less discretion than before, replied, "I think it very probable; but I really do not know!"

"AROMATIC SPIRIT OF AMMONIA" is the title of the paper to be read at the next evening meeting in London, and Mr. Edmund White, now pharmacist to St. Thomas's Hospital, and sometime member of the Board of Examiners for England and Wales, is the pharmacist who has been good enough to promise that paper. The meeting will take place at 8 p.m. on Tuesday, February 13, and this ample notice is given in order that members and student-associates may make arrangements to be present on that occasion. There should be no difficulty in securing a good gathering of the craft to listen to a pharmacist on an official preparation. The President will occupy the chair precisely at the hour named.

IN MR. FLEMMING'S LETTER, which appears at page 77, he takes objection to the inference drawn by "An Ordinary Pharmacist," after perusal of his first communication, that he was attacking the Pharmaceutical Society's examiners. As the same idea has occurred to other readers of the Journal, it is satisfactory to learn from Mr. Flemming that nothing of the kind was intended. It may be suggested, however, that he was a little careless in his method of expression; even now he declines to accept the statement that the Minor is a fair examination. With regard to that point, it may be observed that, before it can be settled satisfactorily, a definition of the word "fair" must be agreed upon. Presumably, the worst that Mr. Flemming means is that the conditions under which the examination is conducted are not absolutely the best. But that is more the fault of the system of training undergone by the candidates than of the conditions which prevail in the examination room. So long as registration under the Pharmacy Acts is based upon the results of examination only, conditions must prevail which may at times appear to press with undue severity upon candidates, and particularly upon those who are ill-prepared.

THE PRESS COMMENTS on the Queen's Bench decision in the Worcester Weed-killer case vary in their tendency, as might be expected. That in the London *Evening Standard* may be selected as the most violently opposed to the action taken by the Pharmaceutical Society, and that in the *Northern Whig* as a fair and reasonable statement of what is requisite in the public interest. The first-named newspaper advises the Society to beware of meddling, a sin which is thought to be "specially attractive for that body"—and describes it as "monstrous" that a "poor man should be brought up to London to defend himself at great expense, when the charge was obviously ill-grounded." But the assertion contained in the concluding words of the quotation remains to be proved. The defendant claimed to have acted simply as an agent; the Pharmaceutical Society

held a contrary opinion, and—the more especially as a very important principle is involved—the decision must rest with her Majesty's judges rather than with the editor of the *Evening Standard*, wise and learned in the law though he may be. In the Belfast organ no attempt is made to prejudice the decision which may ultimately be arrived at, but it is pointed out that "on the bare ground of common sense" there is a good deal to be said for the view that the practice which the Pharmaceutical Society seeks to stop affords a new means of selling poisons without incurring liability. The general principle of "irresponsible agency" involved is stated to appear to suggest an easy way for any unregistered person to distribute any kind of poison without incurring a legal risk, and that, it is suggested, "would surely be to defeat the purpose of the law in regard to the sale of such dangerous commodities."

THE PUBLIC AND POOR LAW DISPENSERS' ASSOCIATION is an amalgamation of two bodies which were originally constituted with similar aims. Its objects, as defined in the printed rules are (a) to protect and further the interests of Public and Poor Law Dispensers, and generally improve their position; (b) to provide basis for consultation and united action in all cases of difficulty arising out of the nature and in the discharge of their duties; (c) to secure adequate remuneration for dispensers, and generally raise their status; (d) to hold meetings, institute lectures and demonstrations, promote discussions, and increase practical and theoretical knowledge of subjects pertaining to the calling; (e) to promote occasional social and pleasant evenings for members and their friends. Those objects are all commendable ones and—if the Association should attain the position of being thoroughly representative of the two classes of dispensers—will probably be accomplished much more satisfactorily than if the individuals constituting the body were to content themselves with doing nothing except look to the Council of the Pharmaceutical Society to help them. Much more than "A Hospital Dispenser" suggests (see p. 78) should be done has been done by the Council in the interests of dispensers in the public services, though the facts have not always been announced with a flourish of trumpets. For the rest, the individuals most directly concerned are advised to keep pegging away, whilst not neglecting to support the organisations which can most effectually assist them—if they continue to help themselves.

PROFESSOR D. E. HUGHES, F.R.S., the distinguished electrician, died on Monday last, aged sixty-nine years. Though his early life was spent in America, he was born in London, and he returned to England in 1857 to advocate the claims of the type-printing telegraph instrument known by his name, now in use throughout the world. He also invented the microphone, the instrument which made the use of the telephone practicable. His induction balance, though less known, has found several interesting applications—in testing the sensitiveness of hearing, discovering the position of bullets in wounded men, and locating ores in the ground. It has been suggested that if Professor Hughes had published at the time the results of investigations conducted by him more than twenty years ago, he would probably now be regarded as the actual inventor of "wireless telegraphy." He noticed the phenomenon of "cohesion," whereby a substance which is normally a poor electrical conductor becomes a good one under the influence of electricity, and he used that property for the detection of electric waves, to which he correctly attributed the effects produced when he succeeded in transmitting signals, without connecting wires, to a distance of more than five hundred yards. He was a Chevalier of the Legion of Honour, was elected a member of the Royal Society in 1880, and awarded a Royal gold medal by that body in 1885. The following year he occupied the position of President of the Institution of Electrical Engineers, and in 1897 he was awarded the Albert Medal of the Society of Arts. Prior to that he was the recipient of numerous foreign decorations.

THE LAW ABOUT GIVING NOTICE has been interpreted by Judge French, at the Bow County Court, in a somewhat unusual way. A Covent Garden salesman sued a former employé for a week's wages in lieu of notice, but Judge French said the meaning of the law about giving notice was that, supposing a man was summarily dismissed by his employer, he was entitled to wages in lieu of notice. If, however, the man found other employment during the period he should have been engaged, he could not expect to be paid by both employers. Again, in the labour market, if a man left his employment without a word, and the employer could easily get another man, there was not the slightest reason why he should sue his workman. The present claim would therefore be dismissed.

CARBOLIC ACID is estimated to have been the cause of death in at least sixty per cent. of the suicides recorded in the State of New York during the past year. With the object of preventing the poison being obtained so readily as at present, the New York State Medical Society has prepared a Bill which proposes that carbolic acid shall not be sold to anyone except when ordered in a physician's prescription. In spite of the drastic nature of the proposal, it is commented upon in a Washington newspaper as though it were not regarded as being at all unreasonable. Curiosity is expressed, however, as to what will be the effect on the statistics respecting suicide if the Bill becomes law and—as though he were dealing with the solution of a conundrum or a picture puzzle—the editor of the paper in question wonders what will be done to stop the next “gap between life and death,” when a new means—which he appears to regard as inevitable—comes to be generally employed by would-be suicides in place of carbolic acid.

ARMY DISPENSERS, the editor of *Truth* remarks this week, have been recruited for service in South Africa at the magnificent pay of four shillings a day, with uniform, and free board and lodging, though the latter are not likely to be such that they can be regarded as inducements to intending recruits. A young chemist has written to *Truth* to complain of the meagreness of the terms offered for skilled labour, but so far as the chemist is concerned, he can, it is pointed out, please himself as to whether he will go or not. What impresses our contemporary far more in the matter is that the labour which is likely to be obtained on such terms may possibly be far from skilled. He concludes: “Our soldiers have surely enough perils to encounter in the field without exposing them to the tender mercies of youths like the chemist's boy in ‘Pickwick,’ who thought that Epsom salts was oxalic acid.”

CARL FRIEDRICH RAMMELSBURG, the eminent mineralogist, who died quite recently at the age of eighty-nine, commenced his career as a student of pharmacy but, before qualifying, took up, by preference, the study of chemistry and mineralogy. In 1840 he was appointed private tutor at the University of Berlin, and eventually Professor in 1874, and in 1883 director of the Chemical Laboratory. He was one of the founders of the German Chemical Society, and was its President from 1870 to 1874. He resigned his professorial position in 1891, and until his death last December lived in retirement at Gross Lichterfelde. Rammelsberg's scientific works related entirely to inorganic chemistry, the analysis and composition of minerals, on which subjects he was a leading authority, having published a large number of important researches, and many systematic works on chemistry, mineralogy, crystallography, and analysis.

THE DEATH IS REPORTED of Jan Willem Gunning, Professor of Chemistry at the University of Amsterdam; also that of the mineralogist, Peter Waage, Professor of Chemistry at the University of Christiania.

ENGLISH NEWS.

INSTITUTE OF CHEMISTRY EXAMINATIONS.—The following are the Pass Lists for January, 1900:—Intermediate Examination: F. W. Aston, Mason Univ. Coll., Birmingham; J. H. Austin, Mason Univ. College, Birmingham; H. J. Bailey, Univ. Coll., Sheffield; H. G. Bayly, King's Coll., London; G. Clarke, jun., Univ. Coll., Nottingham; M. W. Danks, Mason Univ. Coll., Birmingham; R. E. Blake Smith, B.Sc. (Lond.), Univ. Coll., London; Thomas Taylor, Glasgow and West of Scotland Tech. Coll.; John Webster, Mason Univ. Coll., Birmingham; W. E. Woodman, King's Coll., London. A.I.C. Examination (Old Regulations): J. R. Brooke, Pharmaceutical Society's Laboratories and King's Coll., London; M. Priest, Finsbury Tech. Coll.; T. Tickle, Pharmaceutical Society's Laboratories, King's Coll. and Univ. Coll., London. Final A.I.C. Examination:—Branch “A” (Mineral Chemistry: W. A. Fyffe, Univ. Coll., Dundee; L. V. Wright, B.A., Sidney Coll., Cambridge. Branch “B” (Metallurgical Chemistry): H. J. Winch, A.C.G.I., City and Guilds of London Central Institution and Finsbury Tech. Coll. Branch “C” (Physical Chemistry): T. S. Price, B.Sc. (Lond.), Ph.D. (Leipzig), Mason Univ. Coll., Birmingham; and the Universities of Leipzig and Stockholm. Branch “D” (Organic Chemistry): F. G. Edmed, Assoc.R.C.Sc. (Lond.), B.Sc. (Lond.), Royal College of Science, London; L. Eynon, Finsbury Tech. Coll.; H. Hall, Univ. Coll., Nottingham; F. Shedden, B.Sc. (Lond.), Mason Univ. Coll., Birmingham. Branch “E” (the Analysis of Food and Drugs, including an Examination in Therapeutics, Pharmacology, and Microscopy): L. W. Stansell, Maidstone, and W. Thorp, B.Sc. (Lond.), Limerick, both for the Fellowship. The Examiners in Chemistry were Dr. Bernard Dyer, D.Sc. (Lond.), F.I.C., and Professor Percy F. Frankland, F.R.S., F.I.C., and the Examiner in Therapeutics, Pharmacology, and Microscopy was Dr. Thomas Stevenson, M.D., F.R.C.P.

LONDON COLLEGE OF PHARMACY.—The first dinner and distribution of prizes took place in the Venetian Chamber, Holborn Restaurant, on Monday evening, January 22, Mr. T. Skewes-Cox, M.P., J.P., presiding. The guests included about 150 present and former pupils of the Principal. The Chairman, in proposing “The London College,” said it gave him much pleasure to be present and assist in giving his old friend, their host, a good send-off in his new undertaking. He had been over the College, and could testify to the care and completeness with which everything had been thought out and provided that was essential and necessary, not only for the convenience of study, but also for the comfort of the students. He congratulated the students in being connected with such an institution, as he considered that Mr. Wootton was not only a teacher, but also had the capacity of being able to teach. Touching upon the legal position of the chemist, Mr. Skewes-Cox remarked that it did not seem right to him that unqualified men under the guise of limited liability companies should have the handling of poisons, the distribution of such should be in the hands of duly qualified and responsible men. Replying to the toast of “The College,” Mr. H. Wootton stated that both during the present and previous terms, all the benches in the chemical laboratories were occupied, and that the number of students attending the various lectures and classes far exceeded his expectations, and considering that the College was only opened on August 2 last, the fact that thirty-two London College students had passed the pharmaceutical examinations must be considered highly satisfactory. He also remarked that the botanic garden had been much appreciated by the students during the season, and that it had provided flowers and specimens for daily demonstrations in botany. The other toasts were “The Staff” and “The Students.” All the toasts were very heartily received, and much enthusiasm prevailed throughout the evening. The presentation of medals and certificates was made by

the Chairman. Four silver and five bronze medals were awarded, the recipients being Messrs. B. Abelson, A. R. Bateman, A. S. Kent, O. E. Bennett, J. Farquhar, and E. A. Barton. The excellent musical entertainment provided by the host was much appreciated, and a very enjoyable evening was brought to a close by a hearty vote of thanks to the Chairman.

WESTERN CHEMISTS' ASSOCIATION (OF LONDON).—A successful social and musical evening was held by this Association, at the Westbourne Restaurant, Craven Terrace, W., on Wednesday, January 24. The chair was taken by the President, Mr. J. F. Harrington, and there was an interesting musical programme, arranged by Mr. Andrews.

UNIVERSITY OF LONDON.—At a meeting of Convocation held at Burlington House on January 15, Mr. E. H. Busk presiding, the report of the Standing Committee, embodying the scheme of election of members of the Senate under the new draft statutes, was presented by Mr. Blake Odgers, Q.C., who, in moving its adoption, referred to the arrangements made for the establishment of the University in its new home at the Imperial Institute. The report was adopted, and a resolution was afterwards carried requesting the Senate's favourable consideration of the recommendations of the Standing Committee with respect to the accommodation at the Imperial Institute. A vote of thanks was unanimously accorded to Mr. Busk for his services during the past eight years as Chairman of Convocation.

LIVERPOOL PHARMACEUTICAL STUDENTS' SOCIETY.—There was a good attendance on Thursday evening, January 18, at the Star and Garter, on the occasion of a supper and smoking concert to celebrate the beginning of the latter half of this Society's session. The President, Mr. Prosper H. Marsden, took the chair, and with the assistance of Mr. Percy Jenner and the other officers of the Society kept the proceedings going merrily until midnight. After the supper had been duly disposed of, and the toast of "The Queen" loyally drunk, a long and well-executed series of songs, instrumental pieces, and recitations was rendered by the following gentlemen: Messrs. Sydney Lee, Harrison, Bob Smith, Stevenson, Nicholson, Irving, Sutton, Kempson, Bottomley, and Dr. Gill. In the course of the evening several toasts were proposed, that of "The L.P. Students' Society," by Mr. Edward Davies, F.C.S., "The President," by Mr. Frank Walker, and "The Principal of the Liverpool School of Pharmacy, Mr. Cowley," by Mr. Marsden, all of which toasts were drunk with zeal and acclamation. The proceedings, which had been very jovial and enjoyable throughout, came to a conclusion shortly before midnight with the singing of "God Save the Queen."

PROPOSED PHARMACEUTICAL DRILL CLASS.—A general meeting of the staff and students of the School of Pharmacy was held on Monday, January 15, to discuss Mr. Upsher Smith's proposal to form a drill class. The Dean of the School (Dr. Collie) was in the chair, and there was a large attendance. The Chairman said he considered the proposal a most excellent one, and then called on Mr. Upsher Smith to bring forward his resolution as follows:—"That a committee be formed to make inquiries about forming a drill class, which shall report at an adjourned meeting." Mr. Smith gave a *résumé* of the history of the suggestion, and said that inquiries had shown that nothing had been done with regard to Lord Mount Edgecombe's scheme, and that it would be impossible to become attached to a Volunteer battalion. Mr. Allen then gave an account of his inquiries at the headquarters of the 1st Middlesex V.R.C. Professor Greenish heartily supported the proposal. Mr. Finmore, in a vigorous speech, opposed it and said the proposed class would be useless, and that anyone wishing for exercise could do it better at football than in playing at drilling. Mr. Spurge traversed the last speaker's ideas, and strongly dissented from his views.

Mr. Lawson and others continued the debate, and the resolution was then carried with only one dissentient. A committee consisting of Messrs. Upsher Smith, Gompertz, Chapman, Bignell, Metcalfe, Newton, Heslop, S. Ambrook, Allen and Deane was then formed. A meeting of the committee was afterwards held, with Mr. Upsher Smith in the chair. Messrs. Allen and Deane were appointed joint honorary secretaries. Mr. Chapman suggested that an ambulance class should be held at the same time as the drill class. He also moved the following resolution:—"That the movement to form a drill and ambulance class be for the present restricted to past and present students of the School of Pharmacy of the Pharmaceutical Society of Great Britain," which was carried, the committee considering that it would be too great a task for them to organise such a class for outsiders, but that if anyone would get one up among London pharmacists they would consider joining it. It was then decided that 5.30 p.m. would be the most suitable time for the class, and Wednesday the most suitable day. The secretaries were instructed to make inquiries about ambulance lectures and the cost of obtaining a drill instructor, and whether it would be possible to obtain the use of the Pharmaceutical Society's Examination Room for drilling.

A SCHOOL OF MALTING AND BREWING.—As the project of establishing a School of Pharmacy in connection with Mason University College, Birmingham, has been discussed, it is interesting to note what has been done by the brewers, who have already instituted a School of Malting and Brewing. The brewers of the country contributed £28,000 towards the University funds, on the understanding that some such provision should be made, and the Birmingham and Midland Counties Wholesale Brewers' Association have guaranteed the cost of the erection and equipment of the brewing laboratories as well as the expenses of maintenance for five years. Mr. A. J. Brown, formerly consulting expert to Messrs. W. Salt and Sons, of Burton-on-Trent, has been appointed professor of brewing, and director of the school. It is intended to provide a complete course of scientific and technical training in all subjects connected with brewing and malting. Research works in subjects connected with the fermentation industries will also be encouraged.

THE ANALYSIS OF DRUGS.—At a meeting of the Exeter City Council on Wednesday last, January 24, Mr. C. J. Moor, F.I.C., public analyst of the City of Exeter, presented his annual report on the work done by him during the year under the Food and Drugs Act, in which he stated that 100 samples of food and drugs have been examined in all, of which ninety-two were foods and eight drugs, the latter being *asafetida* one, *tinct. asafetida* two, *cloves* two, and *saffron* three. Three samples were adulterated among the drugs—namely, the gum *asafetida*, which contained a large quantity of mineral matter, and the two tinctures which, being made from adulterated gum *asafetida*, were deficient in extractive matter. He was of opinion that the system of giving public notice of the standards to which foods and drugs should conform might be extended with advantage, and if it was the desire of the Council, he was prepared to draw up a list of such articles of common use in the case of which standards for composition were known. The publication of a circular on this matter would assist traders who desired to be certain that the goods they offered for sale were strictly genuine within the meaning of the Acts. Such a circular might also include extracts from the new Sale of Food and Drugs Act. The British Pharmacopœia, 1898, has greatly extended the tests for the purity of drugs, and he was strongly of opinion that while no diminution should be made in the number of foods examined, it was important that drugs should receive attention. As there were some 400 different foods and drugs which were all more or less liable to adulterations or deficiencies, it would be plain

that while several samples must be taken of the more important articles of everyday use, such as milk, butter, flour, bread, etc., many articles were very rarely or never examined under the Acts, and indeed never would be, unless an increase were made in the total number of samples purchased during the year.

WHOLESALE THEFT OF DRUGS.—At the County of London Sessions on Friday, January 19, John Jones (30), labourer, Henry Parker (27), dealer, Jethro Lardent (36), herbalist, and William Edward Royou (39), foreman, were indicted for conspiring and agreeing together to steal three casks of cod-liver oil and a quantity of iodoform, camphor, and quicksilver, value £27 12s., the property of Messrs. Davy, Hill, and Co., wholesale druggists, Park Street, Southwark (see last volume, pp. 562b, 610a). Jones and Parker were further indicted for stealing the goods, and Lardent and Royou for receiving them. Jones pleaded guilty to the felony, and Royou to receiving. The others pleaded not guilty. —Mr. Muir and Mr. Leycester were for the prosecution, and Mr. Purcell defended Lardent.—The jury found Lardent guilty, and Parker not guilty.—The Chairman said it was evident that Lardent tempted Jones, and used Royou as a tool.—Lardent was sentenced to eleven months' hard labour, Royou to five months' and Jones to six weeks' imprisonment in the second division. Parker was discharged.

MR. CHAMBERLAIN, presiding on January 18 at the annual meeting of the governors of the Mason University College, Birmingham, referred to the development of the teaching equipment, and expressed the hope that before long they would be able to give specialised instruction to qualify students for every large trade in the town. He stated that the charter for the new University was prepared, and about to be laid on the table of both Houses of Parliament, so that about six weeks after the meeting of Parliament the University might become a reality. The subscriptions to the endowment fund amounted altogether to about £225,000, but he was convinced that a much larger sum would be required to meet the necessarily large expenditure on buildings and equipment.

MR. WILLIAM HENRY POWER, F.R.S.—the assistant medical officer and medical inspector for general sanitary purposes of the Local Government Board—has been appointed to the office of medical officer of the Board, in the room of the late Sir Richard Thorne Thorne, K.C.B. Dr. H. Franklin Parsons has been appointed assistant medical officer and medical inspector for general sanitary purposes, and Dr. R. Bruce Low has been appointed an assistant medical officer of the Board.

ROYAL PHOTOGRAPHIC SOCIETY.—On Wednesday, January 31, Mr. J. Craig Annan will provide the first of a series of "One Man" shows, to be held at the Society's house, 66, Russell Square, W.C., by the exhibition of a selection of his work. The exhibition will be opened at 8 p.m., when Mr. Craig Annan will make a few introductory remarks, and it will remain open during the month of February, from 10 to 4. Admission on presentation of card.

SCOTTISH NEWS.

GLASGOW CHEMISTS AND DRUGGISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.—At the weekly meeting held on Friday, January 19, Dr. DEVON, Surgeon to H.M. Prison, Glasgow, gave an address on "The Habitual Offender," of which the following is an abstract:—In the legal sense an offender is a person who breaks police law, while a felon is one who violates the criminal law of the land. According to "The Habitual Offenders Act," which came into force in 1898, an habitual offender is defined to be a person who is brought before

a magistrate on a similar offence three times in the course of twelve months. That Act was designed to create machinery for dealing with the inveterate offender, on sound punitive and reformatory lines. It provides that any person who has been convicted three times during the same twelve months is to be taken before the Sheriff or County Court Judge, and warned that if he is convicted again, he will be sent, on the expiry of his sentence, to an adult reformatory for three years. This is an excellent provision, but, unfortunately, it cannot be made effective, because the erection and maintenance of the reformatory institutions is merely permissive to municipalities or private charitable enterprises, and as such an undertaking is really too formidable for any public body lower than the State, the Act is practically a dead letter. There may not seem to be much hope of reclaiming habitual offenders, but there are always a few who are amenable to moral influence, and, in any event, prolonged detention, even of incorrigible cases, would be a public sanitary benefit.—In answer to a question from the Chairman, Mr. J. G. Gilmour, Dr. DEVON expressed a qualified approval of the American system of sentences of indefinite duration, but he deprecated the coddling of prisoners, as practised at Elmira. On the motion of Mr. G. C. ADAMS, the meeting awarded Dr. Devon a hearty vote of thanks for his lecture.

SCHOOL OF PHARMACY, GORDON'S COLLEGE, ABERDEEN.—The second annual supper in connection with the above took place on Friday evening, the 19th inst., at the Royal Hotel, Mr. Hugh E. Ellis, the Head Teacher, being in the chair. There was a good attendance of students and their friends. The Aberdeen Pharmaceutical Association was represented by Mr. Simpson (President), Mr. Clark (ex-President), and Mr. Cruickshank (Secretary), who were present as guests. After the usual loyal toasts, Mr. Morris (Demonstrator) very ably proposed that of "The Pharmaceutical Society." Mr. Cruickshank, in reply, spoke of the work done by the Society, and said that if the students present did not think that the Society was doing what was best for their interests, they had the remedy in their own hands, for by passing the "Minor," they could become members, and so have a voice in the administration of its affairs. The toast of "The Aberdeen Pharmaceutical Association" was proposed by the Chairman, who pointed out that it was the oldest body of its kind in the kingdom, and had always done its best for furthering the cause of pharmaceutical education. Mr. Simpson, with whose name the toast was coupled, said that it was not the custom of the Association to publish its doings from the housetops, but he contended that the Association was taking an intelligent interest in all matters concerning pharmacy. Mr. Clark, in proposing what he considered to be the toast of the evening, viz., "The School of Pharmacy," said that the School had already proved to be a great success. In point of equipment and the excellence of its teachers, it was second to none in the kingdom. Mr. Ellis suitably responded. "The Present and Past Students" was proposed by Mr. Cruickshank in fitting terms. Mr. Murray replied on behalf of the past students, and Mr. Anderson, in an extremely humorous speech, replied on behalf of the present students. "The Guests and Visitors" was given by the Chairman, who remarked that he felt sure he echoed the sentiments of all present, when he said that he was very pleased to see them there, and that he hoped they would be there again on many similar occasions. Mr. Simpson, in a few well-chosen words, replied for the guests, Mr. Watt responding for the visitors. Mr. Adam, B.Sc., in proposing "The Teachers," said that he was associated with them on the staff of Gordon's College, and was glad to be able to congratulate them on the results which had attended their efforts. Messrs. Ellis and Morris briefly responded. Songs were rendered during the evening by Messrs. Jones, Anderson, Douglass, Sharp, Ellis, and Morris. A most enjoyable evening was brought to a close by the singing of "Auld Lang Syne."

IRISH NEWS.

STRYCHNINE POISONING AT WATERFORD.—An inquest was held by Coroner Power at Waterford on January 18 in connection with the death of a young lad named John Dunphy, who died recently, shortly after admission into Waterford Infirmary. The report by Dr. Edwin Lapper, F.R.C.P., F.I.C., R.C.S.I., Chemical Laboratory, Royal College of Surgeons, Dublin, on the results of his analysis of the viscera of the deceased, showed that Dr. Lapper had found two-fifths of a grain of strychnine in the stomach. The total amount of strychnine obtained from the viscera was between half and three-quarters of a grain. Dr. Kelleher deposed that when deceased was admitted to the Infirmary the boy was in great agony and distress. He died half an hour after admission. His opinion was that the boy died from strychnine poisoning. After the Coroner summed up, the jury returned a verdict that the deceased died from strychnine poisoning.

CHEMISTS' ASSISTANTS' UNION.

A general meeting was held at the Horse Shoe Hotel on January 23, when Mr. E. WHINERAY took the chair, and in a few words reviewed

THE WORK OF THE UNION

since its commencement, remarking that many young men from the country had found situations in London by means of the Union; also that there was a small balance to the credit of the Union. He impressed on those present the necessity of direct representation on the Pharmaceutical Council, and trusted they would do all in their power to get one of their number elected.

Mr. C. E. PICKERING spoke at some length on the desirability of charging a small registration fee for assistants requiring situations. He asked the members of the C.A.U. to assist as much as possible in the work, and not leave it all in the hands of the Council. He also referred to the long hours assistants have to work, and suggested that steps should be taken to shorten them.

Mr. GREATREX (Liverpool) drew attention to the apathy of some of the local secretaries of the C.A.U., who had never held a meeting or even a smoking concert to call assistants together. He felt sure numbers of young men would join the Union if the right man were found in each large centre to act as local secretary.

Mr. ANDERSON (Dublin) said this was the first meeting of the C.A.U. he had attended, but assured them that in future, as an active member, he would do his share.

Mr. R. E. WRIGHT, in the course of a few remarks, said that it was the duty of everyone to protect the interests of his craft, and flagrant infringements of the Pharmacy Act should therefore be reported to the Registrar of the Pharmaceutical Society at once. Whilst defending the members of the C.A.U. against the charge of apathy, he was well aware that it was the apathy complained of that had, in the past, allowed seven unqualified individuals to usurp the title and conduct the business of a chemist.

Mr. GLYN-JONES, who was received with applause, said that he considered the fee suggested by Mr. Pickering too small to cover initial expenses, and if the chemist's assistant of to-day could not rise to 5s. a year, it was as well to leave him out. He suggested that

A REGISTER OF ASSISTANTS

be kept at the office of the C.A.U. with copies of testimonials attached to each name, so that employers could see at a glance whether a man was suitable or not, and if in a hurry could engage by wire. He refused to be drawn on the subject of company pharmacy at such a late hour, but assured those present that the Pharmacy Act of 1868, with a very slight amendment, was all that was required to put an end to company pharmacy, and it rested

with the members of the Society to elect on their Council men calculated to carry the work through. He wished the Union every success, and hoped to see the scheme of registration at work soon.

CHEMICAL SOCIETY.

At a meeting held on Thursday, January 18, the PRESIDENT, Professor Thorpe, LL.D., F.R.S., in the chair, a paper by Messrs. Julius Stieglitz and E. E. Slosson, on

NITROGEN HALOGEN COMPOUNDS,

was read by the Secretary. The authors point out that in a recent paper on the same subject Messrs. Chattaway and Orton overlooked work done by them in Chicago on somewhat similar lines.

Dr. CHATTAWAY then rose and remarked that the two investigations had not much in common. Whilst he and his colleague had tried to explain the mechanism of certain reactions, the American workers seem to have approached the subject with a different object in view. He regretted, however, that reference had not been made to the paper.

There was a small attendance of Fellows, and for a few minutes the proceedings were at a standstill, pending the arrival of others who were to bring forward communications.

Dr. SCOTT read a paper by E. C. Szaroasy, Ph.D., on the ELECTROLYSIS OF NITROGEN HYDRIDES AND OF HYDROXYLAMINE.

The investigation was taken up in order to determine the conditions under which ammonia, hydrazine, and certain other bodies may be electrolysed, giving nitrogen and hydrogen at the two electrodes in the same proportion as they are present in the molecule.

Experiments were tried on the free bases and on the salts. Twenty per cent. ammonia was used, also 10 per cent. with the addition of 20 per cent. of common salt. In the case of hydrazine the three strengths employed were 50, 25, and 12 per cent. In each case the nitrogen and hydrogen given off were in the proportion of 1:2. The salts of hydrazine showed the same agreement with the currents that were tried. Full particulars of the experiments were given in the paper. An attempt has been made to get a condensed form of nitrogen, but so far without success.

In the discussion that followed the paper Professor RAMSAY said that he too had attempted to get a condensed form of nitrogen of the formula N_6 . To a solution of silver hydrazoid in ether or chloroform he added iodine in solution in sufficient quantity to combine with most of the silver. The precipitate of silver iodide was separated by filtration, and the solution was expected to contain N_6 . He was, however, unable to experimentally demonstrate its presence, though there are good reasons for believing that the substance may exist. He tried distillation, concentration, and finally titration with silver nitrate, but at length gave up the quest. It is probable that N_6 does exist, but at present the means of ascertaining its existence by experiment are wanting.

Then followed a long paper by J. T. HEWITT, M.A., D.Sc., dealing with

THE RELATIONSHIP BETWEEN THE CONSTITUTION OF SOME SUBSTANCES AND THE FLUORESCENCE WHICH THEY EXHIBIT.

Attempts have been made in the past to connect the colour of compounds with their constitution, but little has been done to ascertain how far fluorescence and constitution are interdependent. There is a marked difference between coloured and fluorescent bodies. In the case of fluorescent bodies the molecules absorb radiant energy of one wave length and emit that of a different wave length. As a consequence, fluorescence might be expected in the case of a substance having molecules of different forms. Again, unstable compounds that are constantly breaking up into simple compounds might be expected to exhibit this property.

Where a substance exists in tautomeric forms—*i.e.*, the molecules constituted in two different ways—a molecule at the moment of

passing from one form to another may absorb energy of one wave-length, while the body into which it passes may absorb energy of a different wave-length. Thus energy would be absorbed of one wave-length and energy of a different wave-length given out. As a matter of fact, such tautomeric bodies often give fluorescent solutions. At the same time, some tautomeric bodies are not fluorescent, while many fluorescent bodies are not tautomeric.

The CHAIRMAN congratulated the author on his speculations, but thought that his hypothesis scarcely covered the field. He admitted that there might be a relation between fluorescence and change in molecular condition.

Professor RAMSAY mentioned that some years ago a medical student of his in Glasgow was colour-blind, but was able to detect a fluorescence in acid solution of quinine sulphate by artificial light. He humorously proposed to the author to submit to his former student—who is now in practice—some of the bodies in which the author himself was unable to detect fluorescence.

Professor CLOWES recalled the fact that, as shown by Professor Dewar, cellulose, paper, and wood are strongly fluorescent in liquid air.

In reply, Dr. HEWITT declined to be drawn on the subject of a substance like cellulose, whose constitution is so ill-defined. He had confined his investigations to substances of well-known constitution.

The papers that were taken as read included:—"The Action of Fuming Nitric Acid on α -dibromocamphor," by A. Lapworth and E. M. Chapman; "A Note on Volhard's Method for the Assay of Silver Bullion," by T. K. Rose, D.Sc.; and "*c*-Substituted Hydroxytriazoles," by Geo. Young, Ph.D.

ROYAL INSTITUTION.

A lecture was given on Friday, January 19, by Lord RAYLEIGH, M.A., F.R.S., on

FLIGHT.

The problem of aerial flight has long furnished material for speculation to the layman and the philosopher. The natural flight of birds has been imitated with more or less success by the inventive genius of Langley of Washington, Hiram Maxim, and others. The flying of kites is a natural introduction to the subject of aerial navigation, and here it may be mentioned that the best kites have no tail. In flying a kite its surface should be convex to the wind in order to gain a maximum of stability. Kites have frequently been put to scientific use. Thus, Archibald used them for meteorological purposes by fastening thermometers to them, Faraday made electrical researches by this means, Marvin and Roche also sent up self-recording meteorological instruments, while Baden Powell—of Mafeking fame—has utilised them for the purpose of lifting a man above the ground in scouting. In the case of kites, as with aerial machines, we have to deal with the problem of the aeroplane, *i.e.*, the incidence of wind on an inclined surface. But the kite differs in being anchored to the ground.

Observations have been made and recorded on the soaring of sailing flight of birds, by which is meant the flight of a bird which to all appearances makes no effort, and does not flap its wings. This phenomenon is explained by the fact that a bird in such a position has taken advantage of air currents. In the first place, the wind is not moving uniformly and horizontally; a bird could no more maintain itself in such a wind without flapping its wings than in air at rest. Again, the question of relative velocity comes in. The bird gains relative velocity by passing from a lower to an upper stratum. The albatross is believed to make its way by so taking advantage of air currents. According to Langley the gustiness of the wind materially assists birds to so turn the internal work of the wind to their own account. It can be shown that there is suction at work as well as pressure underneath the bird's wings.

The question has been raised, can a man raise his own weight

by turning a screw by his own muscular effort? When a body is freely suspended in air, it is necessary for something to fall; either the body must drop, or air must fall in place of it. Now, it is found that by means of a screw a man cannot send down enough air to maintain himself in air. His weight is against him. Supposing that a man could do ten times as much as an ordinary man can perform, the size of the wings that he would require to effect the downward pressure of air would be altogether out of proportion to his own size. A bird does not use a screw, or a revolving mechanism, but Langley and Hiram Maxim have succeeded in attaining a certain measure of success by means of a revolving apparatus. It is difficult to see how alighting from a flying machine is to be rendered a perfectly safe process, because gusts of wind are so often found near the ground, and frequently cause birds to lose their balance. As Mr. Maxim once remarked, the first use for flying machines will be in war, and war itself has not yet been made safe.

CHEMISTS' ASSISTANTS' ASSOCIATION.

On Thursday, January 18, a meeting of this Association was held at 73, Newman Street, W., the President, Mr. F. W. GAMBLE, in the chair. There was a fair attendance. Two new members were proposed, and the President then called upon Mr. W. S. GLYN-JONES, to read a paper, entitled:—

THE CHEMIST AND SOME OF THE LAWS THAT PARTICULARLY AFFECT HIM,

which is printed at page 70 *et seq.*

The PRESIDENT, at the conclusion of the paper, expressed the pleasure with which those present had listened to what was practically an exhaustive *résumé* of the laws affecting pharmacists. As Mr. Glyn-Jones had said, it would be impossible in the course of a single paper to deal with them in detail, but he thought the author had touched upon all the most important points. Pharmacists seemed to be beset by so many Acts that it was a wonder they kept out of the clutches of the law as they did. It was not that no offences were committed, but because in many cases the laws were not enforced. With regard to Mr. Glyn-Jones' remarks concerning the qualifying examination, he must join issue with him when he said that no candidate should be examined by anyone holding a higher qualification than a pharmaceutical chemist. He thought that in such subjects as scientific botany and chemistry, it was better to have as examiners men who were specialists in those subjects. He had expected Mr. Glyn-Jones to speak on the new phase of the law which involved the defeat of the Pharmaceutical Society that week in the High Court of Justice. There seemed to be a loop-hole in that a person could employ an agent to sell scheduled poisons provided he sent on the order to a wholesale house for delivery. He thought their best thanks were due to Mr. Glyn-Jones for the arduous labour involved in compiling a paper such as he had read that night.

Mr. C. J. STROTHER, speaking with regard to the decision in the High Court of Justice, said that whatever it might be legally, logically he thought the decision was as it should be. The case was somewhat similar to the representative of a wholesale house, and it would be hard if the representative was to be summoned instead of the house he represented.

Mr. PETER MACÉWAN, who rose after a prolonged pause, said he thought the silence was an indication that a paper such as had been read that night was very much wanted. It was a subject with which they ought to be well acquainted. He could quite understand Mr. Glyn-Jones' silence about the case decided in the High Court. With regard to Mr. Strother's objection that the defendants were simply acting as agents, it was for the Society to contend that selling poisons, although not kept on the premises, was an infringement of the Pharmacy Act. But if the Higher Courts upheld the decision, it would afford very good

grounds upon which qualified persons could claim further protection (*sic*). He thought that the subject of the laws affecting the chemist should be more carefully studied, and that it should be one of the subjects taken at the schools of pharmacy. He, however, had no doubt that a few shillings would purchase all the Acts referred to by Mr. Glyn-Jones for chemists' own perusal. He knew from personal observation that chemists break the law almost every day through ignorance of the Acts affecting them. He admired Mr. Glyn-Jones' courage in speaking of the two Acts dealing with sexual matters. Mr. Justice Darling's remarks in the Madame Frain case were a splendid commentary on that subject, and should be studied by chemists. (See last volume, p. 534*c*.) He believed they very frequently committed offences unwittingly against those Acts. He was inclined to agree with Mr. Glyn-Jones' suggestion as to the founding of a chair of Pharmaceutical Jurisprudence, but wondered who would be the first professor. Mr. MACEWAN then expressed his pleasure at the formation of the Chemists' Defence Association, and hoped that it would be for chemists what the Grocers' Federation has been for the grocers.

Mr. T. MORLEY TAYLOR said amongst the many interesting points brought out by Mr. Glyn-Jones in his paper, the most interesting matter from his point of view was the reference to the old Apothecaries Act. It was interesting to note the power invested in the Apothecaries' Society with respect to drugs, and to compare it with the power delegated to the Pharmaceutical Society in the 15th section of the Pharmacy Act, 1868. That part of the section, however, he believed to be practically a dead letter. With regard to the term "apothecary," he thought an apothecary must be a L.S.A., and no one else. It seemed to him that the medical profession was dependent upon the Apothecaries' Society for its protection, and in that connection it was curious to know that the British public is only safeguarded as regards medical dispensing by going to the man that holds the lowest qualification.

Mr. GLYN-JONES having replied to the various points raised, a hearty vote of thanks was accorded to him on the motion of the PRESIDENT.

The meeting then adjourned.

SOCIETY OF PUBLIC ANALYSTS.

The annual dinner was held on January 24 at the Criterion Restaurant, London. Mr. W. W. Fisher, President of the Society, occupied the chair, and among those present were Mr. R. T. Prowse, Secretary of Her Majesty's Customs; Dr. T. E. Thorpe, President of the Chemical Society; Dr. Thomas Stevenson, President of the Institute of Chemistry; Mr. F. M. Mercer, Master of the Wheelwrights' Company; Mr. William Martindale, President of the Pharmaceutical Society; Dr. Stocker, Master of the Society of Apothecaries; Professor F. Clowes, Dr. H. E. Armstrong, Dr. F. D. Chattaway, and Dr. B. Dyer. Mr. Otto Hehner proposed the toast of "The Institute of Chemistry," which was acknowledged by Dr. Thomas Stevenson, President of the Institute, who said that the Institute had been in existence for a quarter of a century, and had fulfilled a very useful function. The Institute, by its examinations, maintained a very high standard of professional knowledge.—Professor H. E. Armstrong proposed "Kindred Societies," and Professor T. E. Thorpe, in reply, referred to the aid given to chemistry by the Royal Society, and pointed out that the Chemical Society had done an enormous amount of good in raising the general status of chemical manufacturers in this country.—Professor Clowes proposed "The Society of Public Analysts," and the President, in the course of his reply, said that the Society was now in a healthy and flourishing condition. During the past ten years it had largely increased its membership and had doubled the responsibility of the work which its members had to undertake. During 1898 fifty thousand samples of food and drugs had been submitted to the public analysts for their verdict, and of that number less than 10 per cent. had been reported as adulterated.

NOTICES OF BOOKS AND OTHER PUBLICATIONS.

'PROCEEDINGS OF THE AMERICAN PHARMACEUTICAL ASSOCIATION FOR 1899.' (American Pharmaceutical Association, Baltimore, and co. Pp. 148. Price 3s. 6d. 1899.)—Originally published to the pharmacist's library includes the papers read at the forty-seventh annual meeting of the Association, held at Put-in-Bay, O., during September last, and a full account of the proceedings on that occasion. But the most important feature of the volume is the annual report on the progress of pharmacy; that, with the exhaustive index, covers nearly four hundred and forty pages, and constitutes the best summary in the English language of the year's work in pharmacy and the allied sciences.

'LESSONS ON PRESCRIPTIONS AND THE ART OF PRESCRIBING.' By W. Handsel Griffiths, Ph.D., L.R.C.P.E. (London: Macmillan and Co. Pp. 148. Price 3s. 6d. 1899.)—Originally published, twenty-five years ago, with the object of teaching the art of writing prescriptions, this little book has passed through numerous editions, the latest of which has been adapted to the British Pharmacopœia of 1898. The first eight lessons deal with (1) the grammatical construction of a prescription, (2) parts of a prescription, (3) signs and symbols, (4) the words and phrases most frequently employed, with their abbreviations and contractions, (5) the principles of medicinal combination, (6) incompatibility, (7) posology, and (8) varieties of magistral formulæ. It is instructive to note that, at the beginning of the eighth lesson, readers are told there are no better models in the construction of extemporaneous formulæ than the official preparations; they are further assured that a careful study of the principles which have guided the compilers of the British Pharmacopœia cannot fail to render them the greatest assistance. The remaining lessons, which occupy the greater part of the book, are devoted to examples and exercises, the different remedies being classified and the classes arranged in alphabetical order. There is no index, unfortunately, but in all other respects the book continues to be well adapted to its purpose.

'AIDS TO MATERIA MEDICA, PART III.' By William Murrell, M.D., F.R.C.P. (London: Baillière, Tindall and Cox. Pp. 94. Price 2s. 6d. 1900.)—In this, the concluding part of Dr. Murrell's work, attention is directed to synthetic products used in medicine, drugs of animal origin, and glandular and serum therapeutics. With so wide a field to cover, the monographs are necessarily very brief, but they are sufficiently comprehensive for all practical purposes. Though more suited for medical than pharmaceutical students, the latter will find the book useful for reference, particularly when its handy size is taken into consideration.

'AN INTRODUCTION TO ANALYTICAL CHEMISTRY.' By G. G. Henderson, D.Sc., M.A., F.I.C., and M. A. Parker, B.Sc. (London: Blackie and Son. Pp. 228. Price 5s. 1899.)—The authors of this latest addition to the seemingly endless list of introductions to analytical chemistry do not claim that it fills a long-felt want, neither do they apologise in the most remote degree for its appearance. But the fact that it is almost devoid of tables impresses one favourably, and the statement in the preface—that the book has been written for the use of students working under the direction of a demonstrator—effectually abolishes any notion that it is intended to show private students, working with the proverbial test-tubes on a tea-tray, how to become public analysts in twelve months or less. In the laboratory, which is under the control of Professor Henderson—that of the Glasgow and West of Scotland Technical College—the students, before beginning qualitative analysis, work through a course of exercises in practical chemistry illustrative of chemical theory, including "the preparation of the common gases, the determination of the density and of the qualitative composition of gases, the determination of the equivalents, specific heats, and

valencies of a number of the elements, and other experiments." They are then, presumably, set to work on the lines laid down in the text-book under consideration. At the beginning of the volume there are exercises on dry reactions, on common mineral acids and caustic bases, on carbonates, and on the properties and applications of sulphuretted hydrogen. Then, follow analytical classifications of the metals and acid radicals, explanatory remarks on the separations, a general scheme for the analysis of inorganic substances, notes on the ultimate analysis of organic compounds, determination of melting points, etc., etc. Some errors in equations have been overlooked in reading the proofs, but generally the information is clearly conveyed and well arranged for school purposes.

'REVUE DES MEDICAMENTS NOUVEAUX ET DE QUELQUES MEDICATIONS NOUVELLES.' Par C. Crinon. (Paris: Rueff et Cie., 106, Boulevard Saint-Germain. Pp. 424. Price 4 francs. 1900.)—The seventh edition of this book includes particulars concerning aspirine, dionine, dormiol, nirvanine, tannocol, urosine, and other new remedies. The monographs on formol, tuberculin and other substances have been revised and brought up to date. The brief descriptions of the origin of the medicaments are followed, in each case, by notes on their properties, therapeutics, posology, etc.

'PHILADELPHIA HOSPITAL FORMULARY.' (Philadelphia, U.S.A.: Department of Charities and Corrections, Bureau of Charities. Pp. 42.)—The authorities of the Philadelphia Hospital have been well-advised to adopt the term "Formulary" in place of the more ambitious "Pharmacopœia" in the title of the fourth edition of this work. The preparations for which formulæ are given number one hundred and eight, and the quantities are given in terms of the metric system, side by side with those of the apothecaries' weights and measures. The text of the formulæ, again, is expressed in a new system of English abbreviations, and not in the older mixture of neither Latin nor English. The Latin symbols used in prescription-writing to express weights and volumes have also been replaced by abbreviations of English terms. Both changes represent progress in the right direction—that of simplicity.

'EFFECTS OF BORAX AND BORACIC ACID ON THE HUMAN SYSTEM,' by Dr. Oscar Liebreich. (London: J. and A. Churchill. Pp. 44. Price 2s. 1899.)—This is a translation from the German of a most important contribution to the subject of which it treats. The author shows how borax and boric acid were at one time considered drastic remedies, and how the prejudice against their use has since been confuted, no idiosyncrasy having ever been specially noticeable in cases treated with them. Boric acid causes no change in the blood, acts as a preservative on fresh material only, and is non-poisonous, proving innocuous even after prolonged use. Borax has a more powerful action, though much milder than that of soda or saltpetre; moreover, it is easily excreted from the system, no accumulation taking place. Taking all the facts into consideration, it would appear that neither borax nor boric acid is injurious to the human system (see *P.J.*, ante, p. 32). In appendixes to Professor Liebreich's monograph, the results are given of feeding experiments with boric acid, borax, sodium bicarbonate, saltpetre, etc., on dogs, rabbits, and guinea-pigs. The influence of the same substances on the salival ferment, pepsin, pancreatin, and emulsin, is also shown in a series of tables, whilst the letterpress is illustrated by coloured plates.

Obituary.

BUNKER.—On January 19, James Bunker, Chemist and Druggist, Da'ston. Aged 65.

GIBBS.—On January 14, Joseph Gibbs, Chemist and Druggist, Eastbourne. Aged 75.

HOBSON.—On January 12, Charles Hobson, Chemist and Druggist, Beverley. Aged 77.

THE STUDENTS' COLUMNS.

Percentage Solutions in Prescriptions.

The following prescriptions, concerning which a question has been submitted by a correspondent, who asks how they should have been dispensed, afford a suitable opportunity for explaining the source of a difficulty which is not unfrequently experienced:—

- (1) Make ℥i. of a 3·5 per cent. solution of menthol in paraffinum liquidum.
- (2) Make ℥i. of a 5·0 per cent. solution of menthol in almond oil.

One view taken in reference to the first prescription assumed that 3·5 per cent. equals 3·5 grains in 110 minims, and that the solution should be made accordingly; the other view assumed that 5·0 per cent. equals 5 grains in 110 minims, but the dispenser who took that view was informed that he was decidedly wrong.

The prescriptions illustrate the unsatisfactory nature of the weights and measures used in British pharmacy. The pharmacist is often called upon to decide between what is actually written in a prescription and what he knows from experience is really intended by the writer. Thus to interpret exactly the two prescriptions sent it is necessary to remember that the sign ℥ really stands for the apothecary ounce weight of 480 grains. Then a percentage solution should be a solution containing the number of parts indicated, in one hundred similar parts; *i.e.*, the parts being of the same denomination for the dissolved substance, and the solvent. On this basis prescription (1) should have contained 16·8 grains of menthol and 463·2 grains of liquid paraffin, and prescription (2) 24 grains of menthol and 456 grains of almond oil. The preparations would be most accurately made by placing the menthol in a tared bottle, and then adding the oil until the contents weighed 480 grains in each case. The solutions would then contain respectively 3·5 and 5 grains of menthol in each 100 grains, *i.e.*, they would be truly 3·5 and 5 per cent. solutions.

There are, however, two or three considerations which render it improbable that this strictly accurate interpretation would represent the intentions of the prescriber. First, in applying the terms ounce and drachm to various substances the conventional rule is adopted of taking solids by weights, and liquids by measures, unless, in the case of liquids, the reverse is expressly indicated. For this reason ℥i. of a solution of menthol in oil is probably intended to represent, not 480 grains, but one fluid ounce; *i.e.*, the volume of one ounce avoirdupois (437·5 grains) of water. Secondly, liquid medicines are compounded and administered almost universally in this country by measure, so that the percentage solution is often intended to be one containing parts by weight in corresponding parts by measure; *i.e.*, ounces of solid in fluid ounces of the solution, or grains in fluid grains. Finally, the use of the minim, in measuring and compounding small quantities of fluids, has led to a supposition that a percentage solution is one containing so many grains in 100 minims, and while the minim exists as the unit of volume for prescribers, a solution of this character, *i.e.*, grains in 100 minims, offers certain obvious advantages from a practical point of view, although doubly wrong from a mathematical and physical standpoint.

To give a specific example, consider the three following cases:—

- (a) Solution of strychnine containing 1 grain in 100 minims.
- (b) " " " " 1 grain in 100 fl. grains.
- (c) " " " " 1 grain in 100 grains (by weight).

If a prescriber wishes to order, say $\frac{1}{50}$, $\frac{1}{25}$, $\frac{1}{10}$, or $\frac{1}{5}$ grain of strychnine he would have merely to write 2, 4, 5, 10, or 12½ minims of solution, and the exact fractional parts of a grain of strychnine are administered if solution (a) be dispensed. With solution (b) the prescriber would have to order to 2, 4, 5, 10 or 12½ fluid grains in order to attain the same accuracy of dosage. But since the fluid grain is practically unused and no measure glasses would be found in the pharmacy graduated in that denomination, the

prescriber would be compelled to write 2·2, 4·4, 5·5, 11, or 14·1 minims, or, in order to avoid fractions, accept the approximately equivalent quantity of strychnine represented by 2, 4, 5, 11 and 14 minims of solution. With solution (c) accuracy could only be obtained by ordering grains by weight of solution, for in this case the density of the solution would differ from that of water owing to the influence exerted by the dissolved substance on the specific gravity of the solvent. In this country, however, prescribing and dispensing of fluids are always carried out by measure and not by weight, and hence this form of solution is seldom employed. While this confusion exists concerning weights and measures, or in other words, while the existing weights and measures (with various conventional ideas attached) are employed in medicine, it will sometimes happen that prescriptions are of an ambiguous character so far as their exact dispensing is concerned.

Since the variation involved by the alternative interpretations indicated above is usually not more than 10 per cent. from the actual quantity which may be intended, and since the ordinary doses of drugs permit this variation to occur without any obvious difference to the patient, the question of pharmaceutical weights and measures does not receive the attention which it deserves from an academic point of view. With regard to the opinions expressed it may be said that both were correct; the first because it probably interpreted the intentions of the prescriber (3·5 parts of menthol in 100 fluid parts of solution), and the second because it indicated the desire for an exact rendering of the prescription as written (*i.e.*, a true percentage solution). All one can do, as a practical pharmacist, is to be quite familiar with the various views that are held, and to use the judgment which a competent dispenser is supposed to possess, to decide specific difficulties that may occur.

ANSWERS TO QUERIES.

Special Notice.—Scientific, technical, legal, and general information required by readers of the *Pharmaceutical Journal* will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured. Not more than six plants should be sent for recognition at one time.

Botanical (G. W. B.—38/7).—It is *Petasites fragrans*.

Preliminary Examination (E. B.—17/49).—You will find the particulars in the Students' Number of the *P.J.*, published September 9, 1899.

Writing on Parchment (A. H. H.—38/6).—The parchment must be prepared by sprinkling it with pounce—precipitated chalk, or very finely powdered sandarac, pumice stone, or cuttle-fish bone.

Botanical (F. G.—38/13).—(1) *Tremella mesenterica*; (2) *Stereum purpureum*; (3) *Mniium ligulatum*; (4) *Lecidia canescens*, in the sorediate state; (5) *Physcia parietina*; (6) *Lecidea canescens*.

German Book (E. A. G.—38/10).—Messrs. Dulau and Co., Soho Square, W., or Messrs. Williams and Norgate, Henrietta Street, Covent Garden, W.C., can probably supply you with the particulars you require.

Mineral (W. H. M.—38/12).—It looks like lapis lazuli, but we are unable to say with certainty, nor can we suggest the probable source of the mineral. Apply to some dealer in geological and mineralogical specimens, or to some local geologist.

Dionine (G. M. C.—38/4).—It is the hydrochloride of morphine mono-ethyl-ester, a white, bitter, crystalline powder, said to be of especial service in quieting cough. One-sixth to one-fourth of a grain is administered every four or five hours, or a single dose of half a grain at bedtime.

Analytical (H. E. E.—37/32).—Please read the special notice at the head of this column. (1) It is only necessary to cut the filter paper so that it can be inserted in the tube readily. (2) Bell's 'Analysis and Adulteration of Foods,' in two volumes, published by Chapman and Hall, London, at 2s. 6d. each.

Limited Companies (W. B. W.—18/15).—The fact is as stated by "An Ordinary Pharmacist." There is no obligation on the part of limited companies to employ registered chemists as managers or assistants; the risk is incurred by unqualified persons who actually sell the poisons, not by the companies.

Paper on Atomic Theory (A. J. F.—38/9).—Williamson's Paper on the Atomic Theory appeared in the *Journal of the Chemical Society* for September, 1869. We do not think you can purchase a copy; but perhaps you can see it in a public library. If not, we would suggest that you should address the Librarian of the Chemical Society, Burlington House, London, W.

Book on Pharmacy (B. L. B.—38/5).—The best work on pharmacy for general use is Squire's 'Companion to the British Pharmacopœia.' A much larger and more comprehensive work of reference, of which every British pharmacist would do well to secure a copy, is 'The Dispensatory of the United States of America,' published by the J. P. Lippincott Company, 36, Southampton Street, Covent Garden, W.C., at thirty-six shillings.

Cacodylic Acid and Cacodylates (D. O. D.—38/8).—The acid can be prepared by distilling potassium acetate with an equal weight of arsenious acid and treating the resulting cacodyl oxide and cacodyl with mercuric oxide, in the presence of water. You should be able to convert the acid into sodium cacodylate by dissolving it in water, neutralising with sodium carbonate, and evaporating the solution to dryness. We do not know of any book giving the information you ask for, but Crinon's 'Revue des Médicaments Nouveaux' for 1900 (Paris: Reuff et Cie. Price 4 francs) gives particulars regarding the pharmacy and therapeutics of the compounds.

Addresses of Examinees (W. B.—18/8).—The lists are printed as supplied to us by the Registrar. You will see that, even in the case of the First Examination, addresses are not given, but merely the names of towns. We understand that the addresses given by candidates when they come up for examination are for the purposes of the Registrar only, and not for publication; moreover they are usually of a temporary nature only, and communications sent to those addresses after the examinations are over would, probably, not reach the persons for whom they were intended.

CORRECTION.

Pharmaceutical Society.—In connection with the donations to the Library and Museum reported last week, at page 51, the specimens presented by Messrs. Evans, Lescher, and Webb, and Mr. M. F. Moir, credited to the museum in Edinburgh, should have been credited to the museum in London.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

ALKALIMETRY OF AMINES. A. Astruc points out that the amines of the fatty series, such as methylamine, ethylamine, and propylamine react monobasically both with phenolphthalein and with helianthin; while the primary aromatic amines such as aniline, the toluidines, and the naphthyl-amines, are neutral towards phenolphthalein, but are monobasic to methyl-orange. These facts agree with the thermo-chemical results, the fatty amines acting as powerful bases, while in those of the aromatic series the basicity is diminished. This diminution is produced by the substitution of an atom of H in the NH₂ molecule by a hydroxyl group. On the other hand, the substitution of two fatty radicles for two of ammoniacal hydrogen, as in dimethyl-aniline, does not affect the basicity. When the ammoniacal nitrogen forms part of the aromatic nucleus, as in pyridine and quinoline, the basicity is lessened. Helianthin therefore serves to indicate a marked acid action with a corresponding weak basicity, while phenolphthalein on the contrary will indicate a weak acidity with a strong basic reaction.—*Comp. rend.*, **129**, 1021.

MANNOCELLULOSE IN GYMNASPERMS. Gymnosperms differ from Angiosperms in the chemical constitution of their tissues, as well as in their morphological features. G. Bertrand finds that mannocellulose is present in the wood of all the Cycadaceous and Coniferous plants examined by him; but it is noteworthy that of three Gnetaceous plants examined, *Ephedra distachya* gave only a relatively small amount, while *Gnetum thoa* and *Wetwitschia mirabilis* contained none. It would appear, therefore, that the Gnetaceæ are not true Gymnosperms, but constitute a connecting link between that group and the Angiosperms. The amount of mannocellulose present in the other conifers is so considerable as to suggest the wood of these plants as a favourable source of mannose. Thus, on hydrolysis of the mannocellulose with 5 per cent. HCl solution, the outer wood of the yew gave 10 per cent. of mannose, the branches of *Abies pectinata* 8.4 per cent., and the stems of *Cupressus torulosa* 3.4 per cent. The wood of all the gymnosperms examined gave but little xylane when treated with caustic soda, after removing the portions soluble in alcohol and in water. This body would appear to be peculiar in the wood of Angiosperms.—*Comp. rend.*, **129**, 1025.

OIL EXTRACTION FLASK. F. A. Anderson describes a special extraction flask, devised by him with the object of overcoming the difficulty experienced in endeavouring to weigh accurately the comparatively large flasks generally used in oil extractions. An ordinary flask of about 150 C.c. capacity is provided with a short side tube, fused on slightly above the middle of the globular part. A weighing flask of about 15 C.c. capacity is ground on to the side tube like the cap of a glass spirit lamp, so that the side tube projects a little way into the weighing flask when the latter is in position. In use, the small flask is cleaned, heated in a water-oven, cooled, and weighed; it is then placed in position and the large flask connected to an extractor, as usual. At the close of the extraction the solvent is evaporated off until only enough remains to hold the oil in solution; the large flask is then disconnected from the extractor and slowly tilted until the residue runs into the little flask. If the latter be then warmed, the large flask may be rinsed out by the condensed vapour of the solvent. When the oil has been completely transferred the weighing flask is disconnected, heated in the water-oven, and weighed.—*Chem. News*, **81**, 45.

VOL. 64. (FOURTH SERIES, VOL. 10.) No. 1544.

ORIGIN OF THE BASIDIOMYCETES.

G. Masee has read a paper, before the Linnean Society, on the origin of the Basidiomycetes. He remarked that Juel, a Danish mycologist, had recently demonstrated that *Stilbum vulgare*, hitherto regarded as a typical Hyphomycete, is a true Protobasidiomycete. Following up that hint, the majority of the species of *Stilbum*, some of which are the known conidial phase of species of *Sphaerostilbe*, and others existing without any known higher form, were examined, with the result that the conidial condition of *Sphaerostilbe microspora* and *S. gracilipes* proved to be identical in structure with *Stilbum vulgare*, in other words, true Protobasidiomycetes. This discovery reveals the fact that the conidial condition of an ascigerous fungus may be a true Protobasidiomycete. Similar discoveries have been made with forms of *Tubercularia* and *Isaria* known to be the conidial stages of ascigerous fungi.

MEXICAN DRUGS.

Among the Mexican drugs recently described by Duyk, are "Simonillo," a Composite (*Conga flaginoides*, D.C., and *C. parvifolia*, D.C.), which was known to ancient Mexicans by the name "Zaca-chichic" and "Zacate-chichic" and was used as a cholagogue and antidyspeptic. It gives a very bitter decoction, which froths when shaken. The bitter taste is due to a glucoside, lennesin, isolated by Altamirano. The drug is said to be useful in the treatment of catarrh, and is prescribed as an infusion 1:40. "Tolocopetale" is a poisonous plant belonging to the genus *Coriaria*; it contains coriarin and coriamyrtin, and may be used to replace digitalis or caffeine. "Yerba del Tabardillo," from *Piqueria trinervia*, Cav., which is used as a sudorific and febrifuge by the Indians, contains an alkaloid, piquerine, which crystallises in white prismatic needles, has no odour, and faint bitter taste. "Yerba del Pollo," *Commelina pallida*, Weld. The action of this drug is analogous to that of hamamelis. It is used as a hæmostatic and for leucorrhœa. The most active preparations are the fresh juice of the leaves for external application, and the decoction and extract for internal use. Exposure to high temperature during the preparation of the extract reduces the activity of the drug. The dose for internal use is 5 to 20 Gms. of the dried plant, or 10 to 20 centigrammes of the extract, in pills.—*Bull. Soc. Pharm. Brux.*, **43**, 306.

FERMENTS OF SEEDS.

Extending their researches in the light of the interesting results already obtained by them in their investigations on the ferments of the seeds of the locust bean, E. Bourquelot and H. Hérissey find that these seeds may be considered typical of all those which possess a horny albumin. Among these, the seeds of fenugreek and of lucerne, selected from the rapidity with which they germinate, are also found to secrete soluble ferments during germination, which are capable of hydrolysing and rendering assimilable the carbohydrate reserve material of the horny albumin. The action of these ferments is comparable to that of warm dilute sulphuric acid, finally producing mannose and galactose; while the insoluble residue which they leave is but feebly attacked by the same dilute acid.—*Compt. rend.*, **130**, 42.

TEA SUBSTITUTES.

In Russia the leaves of *Epilobium angustifolium* are largely used as a substitute for Chinese tea under the name of "Kaporie tea," the manufacture of which gives rise to a considerable industry in certain localities. The leaves of *Epilobium hirsutum* are also employed for the same purpose. The leaves of *Vaccinium arctostaphylos*, and sometimes of *A. myrtillus*, are similarly employed in the production of "Caucasus tea" or "Thé du Kutais." Both these fictitious teas and the genuine article are the subject of an exhaustive histological note by E. Collin in the *Journ. de Pharm.* [6], **11**, 15-52.

COMPANY TRADING AND THE PRACTICE OF PHARMACY.

A LETTER TO THE PRESIDENT OF THE PHARMACEUTICAL SOCIETY FROM A LAYMAN.*

DEAR MARTINDALE,—One or two points struck me since the conversation I had with you the other day *re* the pharmaceutical clause in the coming Companies Bill.

You will understand that I come to the matter as a layman, knowing, for the nonce, little or nothing of the professional interests in the matter—or rather, that having no stake in the practice of pharmacy, I am solely interested from the point of view of the public.

The pharmaceutical chemist, then, for me is simply a person that I must be able to trust implicitly in regard to the preparation of medicine in all branches of that art—as implicitly as I trust my doctor, my solicitor, my banker, or my spiritual director if I have one. That point I wish to emphasize—I must be able to regard him as a person endowed first with knowledge and skill; secondly (and quite as essentially) with that kind of *esprit de corps* that makes for conscientiousness in all professions. I gather from you and, to some extent, from personal deductions, that although, in regard to some individuals, there is little danger of the skill of the pharmaceutical chemist suffering from the prevailing conditions of the drug trade, there is a considerable danger that the average qualification of those engaged in that trade may deteriorate at no distant period. This, if it were to be the case (a point to which I will return later on) would lay me, as a member of the public, open to two very considerable dangers. You, on the contrary, in speaking of the matter, lay most stress on the matter of the sale and dispensing of *poisons* by persons legally unqualified. That, however, appears to me as the less important branch of the pharmaceutical chemist's business, and, were I seeking to convince a member of the public—or the public at large—that limited companies ought to be absolutely prohibited by law from carrying on the general business of a chemist and druggist, I should take another and a bolder course, for the following reasons.

The pharmaceutical chemist, for me, is primarily a man who dispenses prescriptions that my doctor gives me—that is his justification for existence. The medicines ordered by those prescriptions may or may not contain poisons—but that I know nothing about. I only know that I get from my doctor a direction that tells the chemist to supply me with certain drugs mixed in a certain way, to have a certain effect, and I want to get that prescription carried out to the minutest point.

If, then, I wished to convince the public at large that limited companies carrying on the business of chemists are a danger to the community at large, I should try to prove to them that their legal ability to *dispense at all* should be abolished. The sale of poisons—as far as I, being a layman, can tell, doesn't much concern me. It is very unlikely that I shall either commit a murder or be murdered; nearly as unlikely that I shall be poisoned by accident. I may, of course, become subject to some "habit" or other, and in that case it might be desirable that it should be difficult for me or for those in whom I am interested, to obtain a supply of whatever drug I or they may become a slave to. That is very desirable, but it is not the main point for me—a normal person. As a normal person I am *very* likely to be ill in the course of my life—to be ill many times and seriously—and what I want is to be certain that when I get a prescription made up that I get everything that is ordered in that prescription.

I labour this point because I have noticed that in the course of two or three conversations, you have never once mentioned it, but have always gone on what I will call the "poison

line," which is, or appears to be, entirely a trade matter, and to suggest the idea of seeking for trade monopoly. Of course the "dispensing idea" is not new to you, but it seems to me very probable that it is one of those ideas that from long familiarity have become platitudes and dropped out of sight. That, however, is not the case with the public; if you wish to convince the public, and the body of the public that makes its laws, I feel convinced as to which is your best line to take. It seems to me that you (to use a cant phrase) should "rub this idea in" as hard as you possibly can—that you should try to thoroughly impress the public with the idea that its liver and lungs and its brain may be in considerable danger. That I am right on this point I feel certain, because as soon as you proved it to me I became interested in your case. It doesn't much matter to me whether you are ruined by competition or not—but it does matter to me very much that your place should not be taken by incompetent or dishonest practitioners. For that reason I put my pen (a pen which has had some practice in convincing the public about other things) temporarily at your service. I want to obviate danger to my health and the health of my wife, or children, and connections. For the same reason I continue to indicate to you the lines on which my conversion ran, so that you may convince others by laying stress on these points.

You must understand that I, as a member of the public, was at first entirely against you. I want to get my drugs, like everything else, as cheaply as possible. I want competition in the drug trade just as I want the home farmer, perhaps, to be ruined that I may have a cheap loaf. But when I come to think about the matter, I want my medicines pure and truly dispensed even more than I want them cheap.

I am impressed by the consideration that my butter may be margarine and my bread made of potatoes without doing me much harm; but if my medicine is not just right it won't act properly, and my cure, at best, may be delayed until it is too late. I may even have been taking chemicals so badly mixed or so noxious that I am seriously harmed.

And inasmuch as I am quite in the dark as to what I am taking, and have no particular means of testing it, I want particularly to be able to rely on the chemists—on all chemists, and every chemist. I may be taken ill anywhere, and may have to go to the nearest shop without knowing anything about its proprietor. For that reason I want the type of man who is a pharmaceutical chemist to be of the highest possible order. This is the essential point of the matter *to me*. Then, although I dislike paying high prices, I am a sufficiently sensible person to know that if I want to be well served by anyone above the position of a mere chap-man, I must pay high prices. I pay my judges well, all my public officials well, my lawyer, my doctor, and so on. I do that in order that I may be served not only skilfully but honestly. I know that in countries where the judges are not well paid the type of man attracted by the judicial career is so low that justice is frequently endangered, and you have convinced me that there is danger that the pharmaceutical profession may get into the same state—that a type of man may dominate it who, for the sake of trade competition, would be capable of substituting for a costly drug, or one difficult to obtain, in a prescription, a drug that would not have the like curative power, and might be positively dangerous.

I don't know much about the technical side of your profession, but I know personally (and I suppose most people know) that doctors give prescriptions consisting, let us say, of one drug that has certain good effects, but which, at the same time, has certain dangerous effects, and of another whose object is to mitigate the dangerous effects of the first drug without interfering with the good. Now, if for one reason or another, the dispenser omits the second drug, the first may do me serious injury. You instanced, I think, a case in which paregoric, which ought to contain opium, had been supplied without opium, chiefly in order that the seller might not infringe the law against the sale of poisons, and perhaps also to allow of

* The above letter is printed at the request of the President of the Pharmaceutical Society, as being of especial interest at the present time.

greater cheapness. This is a pretty strong instance, but it would be still stronger if you could instance a case in which a chemist had made up a prescription without the palliative because he had not got it in stock and did not wish to lose a customer: because a chemist's position ought to be so assured that he would prefer losing a customer to injuring him. This brings us again directly to the matter of *esprit de corps*. I understand that it is the custom of your craft to instruct your assistants that, when a seemingly incompetent (or, possibly, suspicious) person applies for a dangerous article, they should refuse to supply it without making inquiries or applying for directions to their employer or superior. That is obviously highly proper and desirable, but here, again, the matter of losing a customer steps in. A chemist may lose a customer without much feeling it, but suppose the chemist to be in the employ of a man who sells everything, from butter to knitting-needles. He applies to his employer for direction, and the employer, fearing to offend a person who may buy not only drugs but every other kind of requisite, directs his assistant, against that assistant's better judgment, to supply the customer in question. This same case becomes even stronger if in the argument one substitutes for the dangerous drug a costly one, for which the employer (being a person of no particular knowledge and without any incentive of the *esprit de corps*) directs his assistant to supply something cheaper but less effectual. To do this the employer need not be a particularly dishonest man—he might simply do so in order to avoid frightening his customer by a high price, which would be necessary if he supplied the costly drug.

This is distinctly, in my opinion, the line you ought to take in applying to the public for further powers. You must give comparatively homely and quite untechnical instances. It is not very much good giving even M.P.'s historical details that prove the justice of your claim. The M.P. doesn't care about you; he cares about his constituents getting their things cheaply, and, in consequence, giving him their suffrages.

But if you tell him that his liver, heart, lungs, or brain will suffer, and if you prove that to him, you will secure more certain attention, and he will have a good set of facts to oppose to any objections of his constituents.

For this reason, if you elect to oppose companies altogether you should take the line of opposing their ability to dispense altogether. This would include the sale, dispensing, etc., of poisons, because they could not employ a qualified person at all.

I don't think that if you merely go on the "poisons line" you will have much chance of stamping out the limited companies, because, however important that matter may actually be, the public does not think it is so, and it naturally suggests the idea of trade monopoly. I am aware that the percentage of prescriptions that do not contain poisons is small, but most people do not know this, and, in consequence, will not give you much moral support out of consideration for that circumstance alone; whilst the limited liability chemist and druggist, being aware of it, will oppose your attempt to restrict his sale of poison just as much as if you attempt to suppress him pharmaceutically altogether. The fact is, that you must keep the public interest altogether in the foreground of your agitation, making your own position subordinate as far as you can, except in so far as you can prove convincingly, and by definite, homely examples, that the public will suffer if your professional position does.

If on that ground you can get a good body of public opinion on your side, you will have won more than half the battle; without it your chances are rather small now that competition in trade is recognised as the ruling principle under which the advantages of unlimited free trade are most fully secured. As traders you are nowhere—only in so far as you can convince the public that their interest requires professional qualification on your part, is there any chance of your maintaining a position different from that of traders.

BALSAM OF TOLU.*

BY J. SPILSBURY AND T. G. JOYCE.

It has occurred to the authors that whilst the quantitative process quoted in the last edition of the B.P. distinguished between a spurious and a genuine sample, still it was inadequate for determining an exhausted or a mixture of an exhausted and a genuine one. Hence, the present investigation was initiated, with a view also, if possible, of eventually fixing a standard of quality. A brief review of some of the previous work was given, including that of Busse, Oberleander, Bentley and Redwood, Thoms, Davis and Braithwaite, and the conclusions accepted as to the composition of balsam as quoted by the various authorities were:—Cinnamic and benzoic acids, the esters benzyl cinnamate and benzoate, toluene and resins. References were also made to the numerous tests for detecting adulterants, as also the quantitative processes employed; comparisons being made with the results obtained from the valuable work undertaken by Mr. J. O. Braithwaite. In his paper published in the 'Transactions of the Pharmaceutical Conference for the Year 1895,' Mr. Braithwaite prefers to express the amount of potassium hydrate consumed by the residue soluble in carbon bisulphide as parts per thousand of the residue. The authors of the present paper suggested that it would be better to calculate the amount of potassium hydrate consumed into its equivalent of cinnamic acid and record it in parts per hundred of the balsam. Five samples of balsam were submitted to analysis, employing the Pharmacopœia process, with the precautions to evaporate the carbon bisulphide as far as possible by exposure to the air, and finally in an oven not exceeding 100° F. till the weight of the residue was constant. In the present investigation the drying was carried out for the purpose of comparison with the figures of Mr. Braithwaite's residues; otherwise, if the author's suggestion be adopted absolute drying would be unnecessary, which would prove a further precaution against loss by volatilisation. No. 1 sample was balsam from which syrup had been manufactured, and for convenience called "exhausted," the remaining four were represented to them as genuine balsams. The following were the results obtained:—

	Percentage of Cinnamic Acid in the Balsam.	Percentage of Balsam Soluble in CS ₂ .	Character of Residue Soluble in CS ₂ .	Saponification Number of CS ₂ Residue.	Percentage Ash from Balsam.
1	11.5	12.28	Crystalline	357.2	0.27
2	20.2	26.95	"	282.5	0.33
3	20.8	27.32	"	286.9	0.32
4	20.2	23.88	"	318.8	0.30
5	..	47.12	{ Transparent and Resinous	266.2	0.57

The saponification number here represents the parts of potassium hydrate consumed by 1,000 parts of the residue soluble in carbon bisulphide. In the case of No. 5 the character of the residue soluble in carbon bisulphide indicated a spurious balsam, the amount of resin present rendering the saponification number useless for calculating the equivalent of total acid calculated as cinnamic acid.

Nos. 2, 3 and 4, were considered to be genuine specimens, each possessing good aroma and characteristic taste, and Nos. 2 and 3 having proved of excellent quality, judging by the preparations manufactured from them.

Mr. Braithwaite considers that the saponification number in the case of a balsam of good quality should not fall below 300.

The equivalent percentage amount of cinnamic acid calculated from the saponification numbers of his genuine samples range from

* Report of a paper read before the Midland Pharmaceutical Association (see page 110).

16.5, 18.0, 18.3, 26.0, 26.0, to 29.0 per cent., whilst the authors show that although the saponification numbers of two of their genuine samples are below 300, yet the three samples yield respectively 20.2, 20.2, and 20.8 per cent. of cinnamic acid.

Again, the saponification number of their No. 1 sample of exhausted balsam (357.2) compares very closely with No. 10 of Mr. Braithwaite's genuine samples, the saponification number of which is 352.7. No. 1 sample, therefore, according to the requirement of the Pharmacopœia, would pass muster, thus showing the saponification number alone to be inadequate for the purpose of determining its true value. It is essential, however, that the residue soluble in carbon bisulphide should be only slightly coloured and distinctly crystalline; otherwise, if more than mere traces of resin be present, it would render the saponification number unreliable for calculating the equivalent of cinnamic acid. The percentages of ash were deemed of comparatively little importance. As expected, that from No. 1 sample was the lowest, whilst those from the three genuine specimens were uniform in amount. The microscopic examination of the samples gave the following classification:—No. 4 exhibited the largest number of crystals, then followed No. 2, 3, 5, and No. 1 the lowest number. The authors referred to another process they had under consideration, which, however, was not sufficiently perfected to enable them to compare results with those obtained by the official one; they were, however, of opinion that up to the present carbon bisulphide had proved the most efficient solvent with which to extract the balsam, but that the interpretation of the results should be expressed in percentages of total acid (calculated as cinnamic) rather than the proportion of potassium hydrate to the residue soluble in carbon bisulphide. At the conclusion of the paper Mr. Spilsbury expressed an opinion that the data so far at their disposal were hardly sufficient to enable them to definitely suggest a standard yield of cinnamic acid, but so far the results pointed to 18 per cent. as being the lowest requirement for a balsam of satisfactory quality.

DISPENSING NOTES.*

BY D. B. KIDD.

AN INCOMPATIBLE MIXTURE CONTAINING STRONTIUM BROMIDE.

The following prescription was recently presented to be dispensed:—

R Strontii bromidi	ʒii.
Sodii bicarb.....	ʒii.
Aquam	ad ʒvi.

When the two salts are placed together in water reaction takes place with evolution of carbon dioxide and precipitation of a white powder, and if placed in a bottle and the bottle corked there is every chance that it will be smashed. The following equation explains what happens:—

The best plan is to agitate the mixture well till nearly all the carbon dioxide has passed off, and dispense with a "Shake the bottle" label.

HYDROCHLORIC SOLUTION OF ARSENIC AND TINCTURE OF NUX VOMICA.

When the following mixture is dispensed there is an immediate precipitate, which on examination proved to be apparently inert resinous matter from the nux vomica seeds. The 1885 tincture gives a perfectly clear mixture:—

R Liq. Arsenici Hydrochlor,	ʒii.
Tinct. Nucis Vom.	ʒiii.
Aquam	ad ʒiii.

A clear elegant mixture may be made by mixing the solution and tincture with two ounces of water, filtering, and washing the filter

with the remaining ounce of water, but three filtrations were found necessary before the mixture passed clear. A simpler and perhaps more satisfactory plan would be to suggest to the prescriber the use of an equivalent quantity of liquor strychninæ hydrochloridi. The relative strength of the liquor and the tincture in strychnine is very nearly as 1 to 3, and the prescription would read—

R Liquor. Arsenici hydrochlor.....	ʒii.
Liquor Strych. Hydrochl.	ʒi.
Aquam	ad ʒiii.

This prescription illustrates incidentally the many side issues that arise when any change is made in the strength or character of any pharmacopœial preparation without any change in its name. It is very apt to differ in its behaviour towards preparations with which doctors have been accustomed to prescribe it. It would be well for dispensers to bring such points to the notice of the prescriber.

PHENAZONE AND SODIUM NITRITE.

The incompatibility of phenazone with spiritus ætheris nitrosi is well known. The following prescription is an instance of incompatibility due to a similar cause:—

R. Phenazoni,	
Caffeinæ citras	aa gr. v.
Sodii nitris	gr. iss.
Ft. pulv. Mitte tales vi.	

Caffeine citrate is an unstable salt, and, in presence of water, readily dissociates into caffeine and free citric acid. In the above powders the moisture present is sufficient to set citric acid free, which reacts with the sodium nitrite, forming sodium citrate and free nitrous acid. The latter oxidises the phenazone, and the powder becomes green, gradually passing on to red from formation of isonitrosophenazone. This substance is said to be non-poisonous, but its formation leads to loss of nitrous acid, an important constituent, and is otherwise to be avoided as possible. In a solution it has been found that an excess of sodium carbonate prevents decomposition in mixtures of phenazone and spiritus ætheris nitrosi. It also does so for a considerable time, but not completely when the above powders are made into a solution. But it does not prevent the reaction taking place when the substances are in powder. The powders keep perfectly if an equivalent quantity of caffeine alkaloid (2½ grains) be used in place of the citrate of caffeine. It was incidentally discovered that the powders must not be dispensed in parchment paper, as is not infrequently done in the case of substances like sodium nitrite, which are apt to attract moisture. It was found that powders made with free alkaloid in place of citrate, nevertheless, speedily become coloured green and then red, or rather the paper became stained green and then red when parchment paper was used, whereas if dispensed in ordinary powder paper they remained white and the paper was not stained. On examination this was found to be due to a small percentage of free sulphuric acid in the parchment paper, resulting doubtless from the process of manufacture. This is a point worth noting by dispensers.

QUININE SOLUTIONS AND AMMONIUM ACETATE.

The following is an example of mixtures which frequently cause trouble to dispensers:—

R Quin. Sulph.	40 grs.
Acid. Hydrobrom. Dil	ʒii.
Liq. Ammon. Acetat.	ad ʒiv. M.

When the dilute acid is added to the sulphate of quinine the soluble acid sulphate and hydrobromine are produced thus—

There is still excess (about 8 grains) of HBr, and the quinine salts do not entirely dissolve in this acid medium. A few drops of water make a clear solution,

* Paper read before the Edinburgh Chemists', Assistants', and Apprentices Association (see p. 112).

When the ammonium acetate solution is added the solution is at first clear; but double decomposition almost immediately takes place thus:—

The acid hydrobromide is also decomposed thus:—

That is to say the acid quinine salts are reduced to the neutral salts with liberation of free acetic acid. That is why the precipitate which first begins to form is in acicular crystals and insoluble in ether. But in a few minutes a very bulky, white, amorphous precipitate begins to form, and the mixture becomes solid in a very short time. This precipitate is very like quinine hydrate in appearance, and it dissolves in ether when shaken up with it. It seems to be due to the further reaction—

and also

The free acetic acid is too feeble to prevent precipitation of quinine hydrate when there is a large excess of ammonium acetate or any alkaline acetate in the solution. The ammonium ions, as it were, dilute the acetic ions, so as to render their acidic properties ineffective. When there is a sufficient excess of acetic acid, a perfectly clear mixture may be easily made. In this instance a clear mixture was obtained by adding ʒii. of glacial acetic acid. The dose of the mixture is one teaspoonful, and that would be equivalent to 98 minims of official dilute acetic acid. That is within the official dose (ʒiii.), but might be considered too much by the prescriber. The only other alternative is to prescribe the quinine and ammonium acetate in separate mixtures, and order a teaspoonful of each to be taken. Though the mixture is chemically incompatible there is no reason to suppose that it is therapeutically so. I know it may be said that it is acetate and not hydrate of quinine that is separated in this case. If so I do not see why the precipitate is so bulky, nor why it is soluble in ether, and I shall adhere to my explanation till the contrary has been proved.

NEW REMEDIES.

SODIUM SULPHOCARBOLATE IN CHOREA.—T. Stacey Wilson in the *Birmingham Med. Review* records a case of very severe chorea in a female patient, aged twenty-two, which was successfully treated with sodium sulphocarbolate; 20-grain doses of the salt and 1 grain of quinine were given alternately every two hours. As the sulphocarbolate is somewhat depressant in action, nutrition must be kept up by full and stimulating feeding with such food as raw or partially pancreatised meat juice, in addition to milk.—*Quart. Med. Journ.*, 8, 81.

MERCUROL IN GONORRHEA.—F. Fraley reports on a series of cases of gonorrhœa treated with an injection of mercuriol, a compound of mercury with nuclein, containing about 10 per cent. of the metal. As a rule, a half per cent. solution in normal salt solution was employed, but in a few obstinate cases a 2 per cent. solution was injected. Patients were instructed to inject every two hours, retaining the injection for two minutes. Of fourteen cases so treated, six were cured in less than three weeks, three were practically cured in three weeks, only two were not permanently benefitted, although in these the original conditions were relieved, but relapses occurred. The best results were obtained in cases of simple anterior urethritis. The author considers mercuriol to be of great value for injection; but for irrigation he finds permanganate to be superior.—*Therap. Gaz.*, 22, 732.

FACTS AND FANCIES.

BY AN ORDINARY PHARMACIST.

Pharmacy Law for Manxland.

So duly-trained pharmacists in the Isle of Man appear to be in a fair way to secure legal recognition, whilst having their status as professional men definitely fixed. The Bill which has just passed the House of Keys does not go so far as we in Great Britain could wish, but it provides for much more than our own Pharmacy Acts. Thus, it restricts the compounding of medical prescriptions, as well as the retailing of scheduled poisons, to duly registered persons, and the schedule of poisons is much more extensive in its scope than that which has force in Great Britain—carbolic acid, phosphorus, hydrochloric and sulphuric acids, and copper sulphate being amongst the articles not recognised by the law as poisons in this enlightened land of ours. Nevertheless, there appear to me to be three weak points in the Manx Bill, two of which might certainly have been guarded against, though the third has been permitted to remain after prolonged and careful consideration. In the first place, I think experience teaches us that there should be a penalty for "selling" as well as "compounding" medicines of the British Pharmacopœia otherwise than in accordance with the official formularies. Then, the "widow's clause" should not have been adopted without modification from the British Act, as appears to have been the case. As regards the company trading question, that, as I have already stated, seems to have been fully considered, but the House of Keys has not seen its way clear to prohibit company trading in pharmacy entirely. The clause regulating company trading (see *ante*, p. 81) may be regarded as representing a compromise, and, short of actually prohibiting the practice of pharmacy by companies, it will probably prove as effective and satisfactory in regulating that practice as any such clause could do. But it is extremely disheartening to find that the use of pharmaceutical titles is to be permitted to companies and, if no other modification of the clause can be effected by the local pharmacists, I think they should at least attempt to secure the omission of the words granting such permission.

The Position Elsewhere.

So far as the rest of the United Kingdom is concerned, the signal for battle is given by a few words in the Queen's Speech, "My Lords and Gentlemen" having been informed that "the time is not propitious for any domestic reforms which involve a large expenditure," but that "amendments are required in the laws which govern limited liability companies." The two sentences I have quoted have a peculiar significance when taken together, as the non-appearance of contentious measures involving the outlay of large sums of public money may enable the Government, in the event of the war difficulty becoming less acute, to press forward a Companies Bill with a greater appearance of vigour and earnestness than was manifested last Session. Undoubtedly, the omens are bad and, in my opinion, the sooner the real or apparent deadlock in pharmaceutical politics is replaced by a serious effort to secure unanimity and to press upon the Government the just claims of registered chemists, the less will be the risk of our projects of reform miscarriage. We may—probably shall—have to concede something on the trading side, *i.e.*, in regard to the sale of poisons; but that after all is a public and not a pharmaceutical question. The legitimate distribution of poisons should not be restricted more than is absolutely necessary in the interests of the public safety, and pharmacists can advance no satisfactory arguments against that view. But with regard to the pharmaceutical qualification, a totally different state of affairs exists. It appears to me that the pharmacist's only claim for special treatment is in respect of his primary function—that of a dispenser of medicines. In the public interest it is every whit as necessary that none but duly qualified individuals should be permitted to dispense medicines ordered by medical prac-

tioners for their patients, or to use titles indicating qualification to do so, as that none but legally qualified medical practitioners should be allowed to hold themselves out as such. The attempt must be made, therefore, in connection with the promised Companies Bill, to prevent companies using our titles and, for the rest, the best possible bargain must be made with the Government, as little stress as possible being placed upon the exclusive right to sell certain poisons.

The Standardisation of Drugs.

The question of fixing standards of purity for drugs, brought prominently forward at the Plymouth Conference by Mr. U. G. Moor, is persistently kept to the front by that energetic individual, as witness a report in last week's *P.J.* (see p. 84). In presenting his annual report as public analyst for the City of Exeter, Mr. Moor has expressed the opinion that wider publicity should be given to known standards for the composition of certain articles in common use, including certain drugs. It is not clear whether Mr. Moor would include in the list he proposes to publish other standards for drugs and galenicals than those given in the British Pharmacopœia, but judging from published articles on the subject, of which he is joint author, I think it is not unreasonable to assume that he does. As Mr. Moor's case presents itself to me, he is anxious to have a general agreement arrived at, by the parties chiefly interested, regarding the average composition of genuine articles. In some cases that would result in the adoption of a lower standard than that of the B.P., and in others it would probably be higher, the object being the not unreasonable one of fixing standards of purity which could readily be conformed to by traders prepared to pay a fair price for a satisfactory article. To put the matter somewhat differently, it is distinctly unfair to penalise retailers of drugs and galenicals for selling articles which are below standards that are unattainable in the ordinary course; at the same time, standards should not be fixed so low that the buyer of second-rate articles can offer them under the same designations as the higher-priced goods purchased by more conscientious and high-spirited dealers. If Mr. Moor can secure general acceptance for such views he will have done good service to the public and to pharmacists. But, I fear, he or others must first clear the way by getting a legal decision of sufficient weight to make standards of purity essential in the case of drugs and galenicals sold in the ordinary course of retail business. Pharmacists, as a class, are loyal to the British Pharmacopœia and require no threats of legal penalties to compel them to maintain standards of purity as high as are reasonably attainable. But they would prefer to have the position better defined and, if standards of purity are to be enforced by legal means, they may be expected to demand that other dealers in medicinal articles should be compelled to toe the same line as themselves. As things are, however, they are fairly content to be recognised as being "the" acknowledged dealers in drugs of the highest character.

We Want Live Men.

The faculty of communicating enthusiasm is a most precious one, and the man who possesses the gift is of distinct value to his fellows, even though he may not always exercise his talent in the direction considered by Orthodoxy to lead to salvation. Those who have been privileged to listen to the public utterances of Mr. Glyn-Jones will recognise the force of this, for they cannot but have been impressed by the convincing manner in which that gentleman presents his arguments. One may not concur in his deductions and may even be opposed to the course of action they indicate, but all are forced to yield homage to the evident sincerity of the speaker. This was impressed upon me anew in connection with the Chemists' Assistants' meeting on January 18, when a dry subject was invested with unwonted interest by the personality of the lecturer. It must have been the inherent vigour and earnestness of the

speaker, for I have heard much better matter fall flat and insipid and appeal to no person's intelligence. Now, I hold no brief for any particular pharmaceutical champion, but I must frankly say that Mr. Glyn-Jones has done good service to pharmacy in persuading pharmacists to think about the legal and moral obligations devolving upon them in the ordinary course of their calling. Whether, after thinking upon the dangers that environ them in this respect, they will rush for shares in the Chemists' Defence Association, Limited, or, having obtained them, will grow in wisdom, as well as in wealth, and finally die in the odour of official sanctity, is a point upon which the engineer of the new pancea and I may have somewhat divergent views. To remove apathy and to galvanise lethargy is, to my mind, a noble mission, and a hard one to boot, for it involves persistent labour and a vast amount of personal confidence and sincerity. The latter quality is an essential, for, as Lytton has said, "enthusiasm is the genius of sincerity, and truth accomplishes no victories without it"; when, therefore, one voluntarily faces those arduous conditions and consigns himself to restless days and laborious nights, who wants to question motives or launch conjectures as to the probable shallowness of disinterestedness? We want live men in pharmacy, and, whether they think with me or against me, I am always prepared to take off my hat when I meet one of them.

Where is the Professor?

The suggestion that a legal course might with advantage be added to the pharmaceutical curriculum possesses some curious features. One is the extreme poverty of the craft in regard to competent teachers of the subject. Let any chemist run over the names of the prominent registered men he knows and say which of them could efficiently and judiciously give instruction in the laws affecting chemists and druggists; he would soon admit the difficulty of finding proper instructors. I only know of one man on the Register who could properly fill a Chair of Pharmaceutical Jurisprudence, but he is a past President of the Society, and, I suppose, on that account barred by etiquette. Nearly all the jurisprudence requisite for the ordinary pharmacist has been uttered at one time or another during the past fifteen years by Mr. Michael Carteighe, and published in the *P.J.*, and I should not be surprised if he gave a further course of gratuitous lessons on the same subject in the near future, perhaps during the ensuing Parliamentary Session! Another point is that the endowment of a legal faculty in the School of Pharmacy would be a two-edged sort of weapon—it would certainly be instrumental in showing retail chemists the pitfalls in their path, but it would help the unscrupulous quite as much as the conscientious. I have small doubt, for example, that some of the proprietors of limited liability drug stores would be prepared to pay tolerably liberal fees for a course of instruction that, incidentally, must show the weaknesses and limitations of the Pharmacy Acts! And, however sad it may be to reflect upon, human nature is such that a competent knowledge of statutory obligations is apt to glide insensibly into the recognition of how they may safely be avoided—in fact, a school of legal ethics would always be in danger of drifting into a mere string of lectures on close-sailing tactics, and would thus bestow more blessings upon the enemy than upon anyone else. It would not seem wise, therefore, to push the idea about pharmaceutical jurisprudence too far—the better the idea the more it suffers by being forced beyond its natural level. At present the Society's Council encourages the study of the laws relating to what may be called official pharmacy—*i.e.*, the sale of poisons—by requiring candidates for the qualifying examination to know the salient features of the Pharmacy Acts and the Arsenic Act; and very little development on those lines might prove sufficient—the object in view being, as I take it, not to convert chemists into bad lawyers but to make them better chemists and better guardians of the public safety.

POLITICAL GOSSIP.

THE SEVENTH SESSION of the thirty-sixth Parliament was inaugurated on Tuesday last with all the time-honoured formalities of manner and speech. The Speech from the Throne, a little more leaden than usual, has been delivered, and one-half the Kingdom is wondering how much of the official programme will be realised, whilst the other half is deploring the absence of items untabulated and unrecognised in the Government tale of work. The amendment of company law is placed in the forefront of the programme, and the departure from the official form of words in which reference to Bills is usually made in the Speech is significant of an honest intention to make progress with this very difficult problem. Proof additional was forthcoming later on in the sitting on Tuesday, for Mr. Ritchie gave notice that on Monday next he will introduce, as President of the Board of Trade, a Bill to amend the Companies Acts.

IN A FEW DAYS, therefore, we ought to know how far the Government is prepared to go in the direction of regulating companies trading as chemists and druggists. Rumour is exceedingly busy with every one of her hundred tongues on the subject of Mr. Ritchie's intentions and his inclinations in relation to the pharmaceutical aspect of the case. There seems to be a general feeling amongst those best able to judge the course of Ministerial action, that the Bill to be introduced will be last year's Bill minus the pharmacy clause. If this prove accurate, pharmaceutical leaders will have to make up their minds to act with vigour and judgment or for ever lose the confidence of the rank and file. It is understood that up to the present Mr. Ritchie has not found it necessary to avail himself of the offer of assistance which the President of the Society conveyed in his letter of December 14. It would thus seem that he has decided in his own mind how to deal with the case for the pharmacists. Next week will show whether history will repeat itself, and whether the Martindale statement is to meet the same sad fate as the famous "Suggestions" of a bygone Session.

MR. SWIFT MACNEILL proposes to move an amendment to the Address in order to call attention to the frightful condition of public life as exemplified by the fact that twenty-five of the forty-four Ministers of the Crown hold among them no fewer than forty-one directorships in public companies. This wholesale reformer will invite the House to declare that the position of a company director is incompatible with the position of a Minister of the Crown, and that the combination is not consistent with the dignity of Parliamentary—or, at any rate, official life. The invitation will, in all probability, not be responded to, but it will give Mr. MacNeill an opportunity of driving a few stout nails into the coffin of Corruption with limited liability.

SEVERAL CHANGES in the *personnel* of the House have to be noted. On Tuesday, four new members took the oath and their seats, viz., W. M. Guthrie (C.), for Bow and Bromley, in the room of the Hon. Lionel Holland, resigned; Sir Edgar Vincent (C.), for Exeter, in place of Sir Stafford Northcote, promoted to an Indian Governorship; R. E. Dickinson (C.), for the Wells division of Somerset, in succession to Mr. Hylton Joliffe, who has been created a peer; and E. Wason (L.), who follows Lord Balfour in the representation of the combined counties of Clackmanan and Kinross. Vacancies exist in London University, York, and Mid. Armagh through promotions, and Mr. J. H. Maden (L.), who has represented the Rossendale Division of Lancashire since 1892, has, like Mr. Gwilym Evans, found himself unable to bear the continual strain and worry of the persistent local and Imperial attacks upon his pockets. He has, therefore, had recourse to the refuge afforded by the Chiltern Stewardship.

PROCEEDINGS UNDER THE PHARMACY ACTS.

THE SALE OF BELLADONNA PLASTER.
Pharmaceutical Society of Great Britain v. Walker.

At the Sheriff Court House, Linlithgow, on Tuesday, January 30, 1900, the case of *The Pharmaceutical Society v. James Walker*, wholesale provision merchant, 35, Hopetoun Street, Bathgate, came before Sheriff Macleod. The accused was charged with keeping open shop for the sale of poisons on December 16 last, when his assistant, Matthew Gilmour, sold a quantity of belladonna in a plaster to an agent of the Society. Mr. P. Morison, junr., of P. Morison and Son, S.S.C., Edinburgh, appeared for the prosecutor.

The defender pleaded guilty, and asked to explain that he had only recently added patent medicines to his stock. When he did so he consulted the nearest chemist to him, Mr. Freeland, Bathgate, and asked him to look over his price list, as he did not want to sell any that came under the restriction of the law. Mr. Freeland struck out a number of things, and he was quite ignorant of the fact that belladonna plaster came within the Act. That was how, quite unwittingly, one of his men had sold this plaster. But the price of it was only fourpence, and he thought it was a very trifling matter. He was extremely sorry for what had happened. It was not like a medicine that was to be swallowed, and there was nothing to show that it was a poison. He thought the Act only dealt with things that were sold as medicines to be taken, and not things that were only to be applied externally.

The Sheriff: You do not claim that belladonna plaster is a patent medicine. What is belladonna plaster?

Defender: No, I do not claim that. It is used as a strengthening plaster.

Mr. Morison: I am told it is applied externally as an anodyne, to relieve pain, much in the same way as opium is used.

The Sheriff: Can you say anything, Mr. Morison, as to the *bonâ fides* of the explanation that defender consulted Mr. Freeland. Do you know if he did so? I suppose if it is not marked poison that points to another offence?

Mr. Morison: I have never heard of it till now, and can say nothing about it. I don't know, however, that it matters much. I am surprised to hear a trader doing so large a business as the defender saying he did not know that belladonna was a poison. We have had several similar cases in Scotland. The last was in March, 1897, in this same sheriffdom, when the defender was fined £2 and expenses. As your Lordship says, the omission of the poison label is an offence under Section 17 of the Act, but we have not charged that here. It is not a patent medicine, but even if it was in the ordinary sense of that term it would be no more exempt than, say, Powell's Balsam of Aniseed. As to its being for external use, that is no answer, for the Statute makes no distinction between poisons for internal and external use. As to the price, it is sufficient to say that the plaster contains sufficient belladonna to poison a considerable number of people, and even the external application of such plasters has frequently been followed by marked symptoms of belladonna poisoning. I have here the price list issued by defender, and I find in it no less than eight articles which come within the Poison Schedule. There are, for instance, Bow's Liniment, a powerful preparation of opium, labelled poison, and known to everybody as a poison; and Fellow's Syrup of Hypophosphites, which bears on the label that it contains strychnine. I cannot understand how any qualified chemist could have said these did not come within the Act.

The Sheriff (to Defender): Of course, your statement about consulting Mr. Freeland does not affect your plea of guilty; it will only affect the sentence.

Defender: I can only say that I submitted the whole list to Mr. Freeland. With regard to Williams' Pink Pills, it does not say they are poison. I did learn that Bow's Liniment was poison, and it has been withdrawn from sale. I have examined the list of other

general merchants like myself who sell patent medicines, and I find these articles that are objected to on most of these traders' lists. I give my word of honour that I overlooked this on my list, and throw myself on the mercy of the Court. The young man who sold it is sick and could not come to-day, but he says he so seldom sold these plasters that he could hardly find them when asked for, and it took him some time to get it. This plaster was not to be used, but was evidently a bait laid to get me into a trap.

The Sheriff: I must tell you, Mr. Walker, that the Legislature has said you must not sell belladonna plasters. It is not for me to say why, and I do not see much danger in your doing so, for no one would be poisoned by eating a plaster; they would not eat it. At the same time, the law has been made so, and your plain duty is to obey it, and my duty is to impose a suitable penalty when it is infringed. The penalty will be £2 and £1 2s. 6d. for expenses, or eighteen days' imprisonment if the fine is not paid.

Mr. Morison: I think, my Lord, the Statute does not allow of imprisonment. The remedy in case of non-payment is by pointing.

The Sheriff: How is that? We are under the 1864 Procedure Act, which gives the Sheriff discretion. That is a curiously-worded section as to pointing in the 1852 Act. It is not so worded in any other Statute I know of, but it only says it shall be lawful. It does not say it must be imposed, as it says sentence must be imposed. The Sheriff might think pointing inexpedient, and in some cases it might be unjust. In a case where the Sheriff thought it inexpedient to insert pointing in his interlocutor, and if he cannot insert imprisonment, how could the decree be made effective if the fine is not paid?

Mr. Morison: When the particular Statute specifies any mode of recovery that is the only one that can be adopted, and it must be adopted if the fine is not paid. Of course, if the fine is paid at the bar there would be no need to insert any pointing order in the judgment. There are no decisions on the point, but it is our experience that the constant practice is in accordance with the view that the insertion of pointing in the 1852 Act precludes the discretion given by the 1864 Procedure Act in cases where the particular Act contains no such provision.

The Sheriff: I am quite willing to put in "imprisonment," but if you prefer not to run that risk I will leave it out. You might look into that point if you should have any cases before me again.

Mr. Morison: I shall do so, my Lord.

ILLEGAL SALE OF CHLORODYNE.

Pharmaceutical Society of Great Britain v. Lewis's.

At the Liverpool City Police Court on Wednesday, January 31, an information at the instance of the Pharmaceutical Society against "Lewis's," of Liverpool and Manchester, for selling a bottle of poison, to wit, a bottle of chlorodyne, which did not bear their name, came on for hearing before Mr. W. J. Stewart, the stipendiary. Mr. Nield appeared for the prosecution, and Mr. Cornett (North, Kirk, and Cornett) for the defendants.

Mr. Cornett intimated that defendants admitted the offence.

Mr. Nield called Arthur Foulds, who proved the purchase of a bottle of Dr. Collis Browne's chlorodyne at the defendant's establishment in Liverpool, and stated that the name of Lewis's did not appear on any part of the wrapper.

Mr. Cornett said his clients knew nothing about it. Everything was carefully done in their establishment, and there was no intention to defraud.

The Stipendiary said an offence had been committed, but there was no deliberate attempt to do wrong, and there would be a fine of 3s. 6d. and 2s. 6d. costs.

Mr. Nield argued that the case had cost the Society a considerable amount, and that the costs should be higher. Defendants were quite prepared to pay the costs before.

The Stipendiary: Then you should have settled with them. I cannot allow more costs on so small a fine.

ROYAL INSTITUTION.

The discourse on Friday evening, January 26, was given by the Hon. C. A. PARSONS on the subject of:—

MOTIVE POWER, HIGH SPEED, AND STEAM TURBINES.

The first traces of steam engines have been found in Alexandria, where Hero devised a novel steam turbine. For many centuries little progress was made in the matter of steam turbines until, in 1884, the dynamo-electric machine gave promise of greater speed in rotary engines. At that time the laws which govern the flow of steam, unknown to Hero, were pretty well understood by the experimenters who sought to construct an ideal rotary engine.

The first experiments were unsatisfactory. A 10-horse power turbine, making 18,000 revolutions a minute, showed a loss of efficiency by reason of a tendency to whip in the spindle. It was thought that this defect would be minimised by increasing the size of the engine, so bigger engines were constructed. In 1888 several turbo-alternators were made, making from nine to ten revolutions a minute, and in 1892 turbines of the radial flow type, fitted with condensers, effected a further economy in steam power.

The new forms of turbine have many uses, being employed for electrical purposes generally, centrifugal machines, ventilation, pumping and lighting stations, and notably for the propulsion of ships. The turbine, on account of its lightness and economy of steam, is especially suitable for the last-named purpose. In 1894 a syndicate was formed for conducting the necessary experiments. The "Turbinia" was built, of 44 tons displacement and 2,000 horse power. The result of the trials was disappointing, inasmuch as the propeller gave trouble through an insufficiency of blade-area. The revolution of the screw caused the formation of cavities or vortices in the water behind the blades, the cavities being filled with water-vapour. This effect has been named "cavitation," and is noticed when the speed of revolution is 1,200 per minute, reaching a maximum at 1,500 revolutions. As a result the propeller is pulled backwards, and much power is absorbed, with a corresponding decrease in efficiency.

The "Turbinia" was refitted with improved turbines, alterations were made in the screw and blade, and in trials made at the measured mile at a Naval Review a speed of 34½ knots per hour was registered. This excessive speed was accomplished with but little vibration, and with an economy of steam.

Larger works were then erected at Wallsend-on-Tyne, and a contract was made with the Admiralty for building a torpedo-boat destroyer, which should have a displacement of 350 tons and a speed of 31 knots per hour. The engines resembled those of the "Turbinia"; they were in two duplicate sets, working four screw-shafts, each of which was provided with two propellers. The engines were so constructed that they could be reversed almost immediately. This destroyer, which was named the "Viper," was soon recognised as the fastest vessel afloat when, on her second trials, she attained a mean speed of 34·8 knots, while her fastest speed was 35 knots, equivalent to 41 statute miles (nearly) per hour, the indicated horse-power being 11,000.

These steam turbines possess advantages, besides that of speed, which should render them specially suited for other types of vessels, including ocean liners, battleships, and cruisers. The reduction in weight and economy in the consumption of coal and the absence of vibration not only conduce to the comfort of passengers, but they also render possible a far greater accuracy in sighting when firing off naval guns. Thus, a cross-Channel boat, 270 ft. long, 53 ft. beam, could carry 600 passengers with a speed of 30 knots, against the present speed of 19-22 knots.

It is possible to construct an unarmoured cruiser, twice as long as the "Viper," with a displacement of 2,800 tons, capable of maintaining a speed of 44 knots per hour during eight hours. Similarly, vessels of other types might be built, ocean liners, large

cruisers, etc., in all of which reduction in weight, a minimum of vibration, economy of coal, and increased speed are of primary importance. It has been said that in engineering simplicity and economy are the main objects to aim at. In these respects the steam turbine is without an equal, and promises to achieve a wide popularity.

LETTERS TO THE EDITOR.

The Pharmaceutical Position.

Parliament is about to meet. It has now met, and the Pharmaceutical Council is said to be at a deadlock. Admittedly it is, Micawber-like, walking round, talking wisely, and waiting for something to turn up. Something will turn up, and it is merely a truism to say that the chances, practically amounting to a certainty, are that the unexpected will happen. So far the statement cannot be questioned; then what do the elementary principles which govern everyday occurrences dictate? Do not reason and prudence say this is the time for action, for forethought, for being prepared for any eventuality? Let me briefly state the case, and see if we can ascertain what and where the issue is. If I am wrong in my statement it is best I should be put right. Thirty-two years ago compulsory examinations were instituted, and it was expected that a period of progression, of enhanced status, and greater public utility, was inaugurated; but some dozen years later we have a decision nullifying the Act of Parliament, inasmuch as it confiscated the privileges acquired according to law. Indeed, it did more, this illogical and unjust decision placed penalties upon the qualification; for the acquirement of a qualification involved neglect of business training and, to that extent, incapacity for the free competition. This, then, came to be the state of affairs, and we neglected to insist upon our rights and principle—in all probability we thought our principle was “such a little thing” that it was not worth fussing about; anyway, it is a fact that we heeded not the prophet, Dr. Atfield, who warned us what was coming, and to-day the whole position of the qualification and the practice of pharmacy has become so absurd and preposterous as to force even the Government to step in and say that so far as the practice of pharmacy by companies goes it must be made regular. That is the position at the present moment—viz., it is intended by the Lord Chancellor to define the nature of our qualification. He says, in illustration of his meaning, “Personal qualification and responsibility do not cohere with company practice of pharmacy,” so that, clearly, if we allow company pharmacy at all we also allow that the personal responsibility and qualification essential to a profession is not necessary in pharmacy, and therefore a profession of pharmacy is unnecessary. This is the position which it is said we must not face; but it is there nevertheless. The beginning and ending of all idea of limited liability law is limited responsibility, and, further, no servant is responsible in the same way as a proprietor. Take a qualified assistant to a qualified proprietor, you have the proprietor's responsibility; but take a qualified servant of a company—any sort of company, either qualified or unqualified—and what is the result? Destruction of the principle of personal responsibility. And that would be a fact to be reckoned with for ever! For there is no questioning it, pharmacists would have to become “hewers of wood and drawers of water.”

We have another section of chemists, almost as small, numerically, as upholders of the qualified managership idea, who possess themselves with the idea they have found a remedy in qualified directorates; and this “ignus fatuus” seems to cast such a glamour over otherwise clear-thinking minds and attracts them to coquette and trifle with it. In this connection it must before all things be remembered what is possible to us on this companies question, and it will be found that the nature and character of the qualification is the only matter to be considered. I say that the Lord Chancellor

focuses the issue in such a way as to give us one grand, possibly final, opportunity of settling the chemist's status.

It is clear as noonday we need to compel the withdrawal of the companies clause which relates to pharmacy. It cannot be amended, and we need to prosecute our claim by every resource in our power for exemption from the operations of the Companies Act along with the other professions. As a mere matter of expediency this is the soundest course to adopt. Well, but these authors of qualified directorates say we shall gain more by skirmishing than by attacking movements. I do not appreciate their reasoning. There is a position which is ours by right, which is always allowed to be ours. And we have to go out skirmishing! What for, pray? Is it to harass the enemy, whom we affect to despise, in order to induce him to permit us to use our own position in some way not inimical to him? I call that selling your soul and, though it may not be in good taste, I beg to say that I am not prepared to do that *at any price*. Now, why cannot Mr. Glyn-Jones, *e.g.*, face this argument? It is fair!—His “wonderful panacea,” I take from Mr. Carteighe's description at the Council, is something which, whilst recognising companies on the one hand, would make it very awkward for them to practise—in other words, while proposing to formally recognise them in the matter—only so far, mind you, as the Pharmacy Act extends, viz., some twenty poisons—he would make their recognition ineffective. To go to the Lord Chancellor or the Government with such proposals is as if you wished to defeat your own ends. Allow company pharmacy—the Government will take care it is not ineffective. This is an argument I have used many times in different ways, and I once more dare supporters of this phantasy to face what they would do. No! In the delightful phraseology of Mr. Rymer Young, the “thing is unclean.”

The country is not satisfied with this policy of shelving our problem because it is perhaps difficult, which seems to be going on. Good heavens! to read the everlasting apologies for existing, one would imagine we were a body of grocers—rather hard on the grocers, though—instead of a body having, at a cost of the educative period of their lives, complied with requirements which the State by deliberate enactment demanded.

By implication I am posing as a practical man; and it is fair to ask for at least a general indication of a plan of campaign I would favour. I assert that I am familiar with the inner feelings of that great body in the trade which is necessarily inarticulate—that I am familiar with it, and the feelings are the same all through the country; and I further say that it would be comparatively easy to organise the drug trade into a united and compact body in defence of their professional position.

Blackburn, January 27, 1900.

R. LORD GIFFORD, Ph. C.

[*] At the moment of going to press the Editor learns with regret that a sudden domestic bereavement has prevented Mr. Gifford from completing his communication as he had intended.—Ed. P. J.]

The Pharmaceutical Examinations.

I have read with much interest the many views expressed through the medium of your pages on the Minor examination, the advisability of enforcing a definite period of study, the sectionising of the examination, the crediting to the student of subjects once passed and the fairness of the examiners. Now—all these points have been so thrashed out to leave the subject almost threadbare; but one point has been left without comment—the uncultivated, non-receptive state of the brain of the Minor student when he begins to study for the Minor. On entering the ranks of pharmacy the pupil may have secured an equivalent to the first examination; if not, he immediately proceeds to take this now fast dying examination, generally passing in the first or second year of his apprenticeship. On the demise of this first examination it will be more often than not usual for the pupil to take an accepted examination previous to entering pharmacy. Then comes the retrograde movement; for five, perhaps more, years the tutored state of his brain gradually slips away, and when the day of his manhood and

the Minor comes round we find, no doubt, a practical man, but from the theory point of view a sad condition of mental uncultivation, with the cobwebs of inertia all too strongly holding a decided habitation and a place. Again, the compulsory cultivation of the student to a state of mental receptiveness, a state to be only slowly acquired. I am here referring to the average Minor candidate—the average man who may have for a little while after passing his first examination waded through a series of science lectures and even have his name inscribed in the annals at South Kensington—the average man who sickens and sadly murmurs, “Years yet.”

Now it is this gap of years that requires filling, the interest of the student that wants coaxing to the way that leads to the Minor; to this end an intermediate examination should be enforced. An examination of an elementary nature, the boundaries of which should be clearly defined; an examination the pupil of three years' acquaintance with pharmacy should be able to pass. Let not the syllabus be constructed on the plan of that for the Minor, in whose labyrinth of ambiguity both examiners and candidates lose themselves. When he has taken this step the student will have climatised himself to a pharmacy examination, the idiosyncrasies of which are unique, he will then approach his final with less temerity and doubtless better result. It has always been most patent to me that the candidate at the Minor is at a greater disadvantage than the candidate at the qualifying examination of any other chartered body.

The Minor syllabus reads: “An elementary knowledge is required, etc.,” in botany; this is practically incorrect, and the student, grown wise in his and others' disappointments, lays himself out to read, mark, and learn the latest theory on the alternation of generations, the special functions of chromatophores, centrospheres, and the just discovered eccentric conduct of protoplasm; for this he knows the examiner, not himself, considers elementary, and, fully charged with the fact that the protoxylem being turned towards the periphery is characteristic of the structure of a root, and other “elementary” knowledge, collapses ignominiously when the examiner in the kindness of his heart asks him to describe the humble carrot placed before him; thus he calls again. Six years ago this student could have discoursed on the carrot *ad infinitum*, and the examiner murmurs under his breath, “Dear me, the simplest of questions—every possible chance.” Let us then have this qualifying more gradual, more thorough, and less indigestible. A moderate intermediate, with a moderate fee, and in the accrediting to the student of the first day when passed, a good standard being required ensuring a thorough knowledge of the practical part of the business, for it should not be forgotten that the chemist is qualified for the dispensing of physicians' prescriptions. No doubt there is a chance given to the weak on the first day of the examination to pull through by theoretical merit; on the second this should be done away with, as the lost ground to be made up is so great that the student is generally vainly kicking against the pricks, and so the farther the student has gone, the downfall when it comes—too frequently when all subjects have been passed—is the more bitter and disheartening.

London, January 29, 1900.

H. BROOK CLEGG.

Liquor Bismuthi.

As we have satisfactorily demonstrated where the shortcomings of the B.P. formula for the above lie, and Mr. Dudderidge has failed to do this, it is difficult to understand his reason for occupying your valuable space with, and giving us the trouble to reply to, remarks which he cannot mean to be serious. Fully confident in the stability and utility of our work, we would recommend to Mr. Dudderidge a careful perusal of our paper, and especially that portion which deals with the amount of alkali required. As our paper and previous letter entirely state our case, this correspondence is closed as far as we are concerned.

6, Sandon Terrace, Liverpool,

J. P. CATFORD.

What Has the Society Done for Public and Poor-law Dispensers?

In your Annotations last week you refer to the Public and Poor-law Dispensers' Association, and state that much more has been done in the interests of that body by the Society than is generally known. I am not going to deny that, yet I should like to see the result of what it has done take a more practical turn in the interests of dispensing chemists than is at present manifest. In this parish we have two members of the Society on the Board, we have four dispensers, two registered and two not; a few years ago they were all registered—why not now? The President of the Society I believe is a Governor of one of the large London hospitals where they have recently appointed an unregistered assistant dispenser, where previously the post was held by a registered one. Why?

There are many other instances which could be given of a similar state of things. The Pharmacy Act has been in force now thirty-two years. Poor-law dispensaries have been established twenty-eight years, and there are fewer registered dispensers employed in them now than ever. What the Society has done to prevent this I fail to see, and should be glad to be enlightened on the subject. In a short period the British Medical Association has ousted every unregistered assistant from the medical profession. The Public Analysts have made it most difficult for a person of doubtful qualification to hold a post in that capacity. The Sanitary Institute has made it imperative for a sanitary inspector to hold its certificate of qualification. The Medical Officers of Health have made the D.P.H. a *sine qua non* for all aspirants to that office. The Board of Trade has made it impossible for any person to hold the post of inspector of weights and measures unless he passes an examination and obtains a certificate. The Local Government Board has made it possible for an unregistered person to dole out strychnine and other deadly poisons to sick paupers, and the Pharmaceutical Society has been unable to prevent it up to the present. Whether or not the Council is troubled about it I don't know; I only say it ought to be able to prevent it, if it tried with a determination to succeed.

The local secretaries might do a great deal to prevent unregistered persons from obtaining public appointments in their districts by pointing out to the authorities concerned the importance of having a person duly registered under the Pharmacy Act to dispense the poisons supplied to the patients. So also might the Federation of Chemists' Associations if it were on the alert when these appointments are going. There are about 120 dispensers employed in the Poor-law Service, with salaries from £100 to £180 per annum. There is a much larger number employed in general hospitals and dispensaries, and it is my opinion that these appointments should be jealously guarded in the interests of those pharmacists who prefer dispensing and pharmacy to selling hair oil, tooth brushes, and soap.

St. Pancras, January 31, 1900.

W. E. MILLER

B.P. Standards for Drugs.

An “ordinary” pharmacist would hardly make such an unwarrantable attack on the wholesale houses generally as appears on page 75 of your last issue. The writer must be an extraordinary pharmacist, not in regular practice, whose knowledge of the subject on which he dilates so freely is of the armchair order, largely based upon hearsay. There is little or no difficulty in obtaining from any of the recognised wholesale houses the finest qualities of any particular drug or chemical. Speaking for ourselves, our top prices refer to such, and it is our invariable rule to send those out, unless lower qualities are indicated, either by price or name. We have Rad. Patiera Brav. in stock, which has been approved by the Curator of the Society's Museum, and which we list in the ordinary way at a “fair,” and not at any “absurd price.” We hold stock of English aconite root (Bedfordshire grown), and the same appears in our price list. We can also supply from stock good drop gum asafetida when

it is required. The existing houses, most of which have been established nearer two centuries than one, are quite capable and willing to supply all the needs of the trade, either for B.P. articles, or lower grades when required, without the introduction of further competition.

London, January 31, 1900. HEARON, SQUIRE, AND FRANCIS, LTD.

In last week's notes by "An Ordinary Pharmacist," in discussing the question of B.P. standards, your correspondent does me the honour to refer to my notes on an ash standard and spirit solubility for myrrh, and raises the question as to whether, such standard being adopted, it would be possible readily to obtain a commercial article which would respond to the tests imposed. He quotes asa-fetida as on all fours with myrrh. This I do not hold with. The samples I examined were all commercial varieties and listed by wholesale houses. The powders especially show what a wide range exists under the title "Pulv. Myrrhæ." The standards which I suggested are, in my opinion, reasonable, and as it is simply a question of sifting out or otherwise removing extraneous mineral matter—no injurious treatment of the gum resin being necessitated—there is no valid reason why some limit should not be imposed as to the amount of insoluble ash which is permissible. Any good clean "sorts" will come well within the limit stated by me, whilst the higher commercial grades do not yield much more than half the ash content mentioned.

Newcastle-on-Tyne, January 30, 1900.

GEO. F. MERSON.

ANSWERS TO QUERIES.

Special Notice.—Scientific, technical, legal, and general information required by readers of the *Pharmaceutical Journal* will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured. Not more than six plants should be sent for recognition at one time.

Medical Student (A. G. Y.—38/20).—You should register at once. It is not necessary to begin your professional studies immediately.

Laxative Syrup for Children (W. H. M.—38/12).—Fluid extract of senna pods, 25 fl. oz.; fluid extract of liquorice, 5 fl. oz.; oil of cinnamon bark, 6 minims; oil of coriander, 2 minims; oil of pimento, 2 minims; syrup to make 50 fl. oz.

Zinc White Cement (C. W. R.—38/22).—(1) Rub 60 grains of the finest zinc oxide to a paste with a little turpentine and add gradually, stirring continually, 1 ounce of a thick syrupy solution of dammar resin in turpentine. (2) Pay your subscription to the local secretary if he is prepared to take it.

Prescription for Ointment (C. W. C.—38/14).—Unless anything to the contrary appears, or is known to the dispenser, the prescription you quote— \mathcal{R} Ung. bismuth. oleat., 15 per cent., ζ iss.—should be understood to order 1½ oz. (Troy) of an ointment containing 15 per cent. of bismuth oleate, made up with benzoated lard or soft paraffin.

Morphine Salts (G. B.—38/18).—The coloration is probably due to impurities in the materials employed. You must not expect to obtain products equal in appearance to the commercial salts by the crude method you describe. Moreover, when studying the B.P., there is no occasion to trouble about the details of processes which are not mentioned in that work.

Pharmacy Act Cases (C. E. P.—18/37).—The view you take is quite a mistaken one, as both cases were essential in the public interest and, therefore, undertaken with the worthiest possible object. Even if such results as you suggest were probable, that would not afford a satisfactory reason for refusing to take action when properly authenticated cases of infringement were reported.

Percentage Solutions in Prescriptions (A. Y.—38/19).—In the article dealing with the matter in last week's issue (see p. 89), a slight confusion was introduced by the omission of a few words in the paragraph immediately following the prescriptions. Both dispensers, of course, took the same view of the prescriber's intentions, but the one who dispensed the first prescription was informed that he was right, and the other that he was wrong. The reference in the concluding paragraph of the article was to the opinions expressed by those persons—not by the Editor—who criticised what the dispensers had done.

Limited Companies (38/21).—There was no assistant of the company concerned in the case. The order for the preparation was accepted by an unqualified person, in business as a seedsman on his own account, who has, so far, been held to be simply an agent for the company, and, therefore, not the actual seller. The preparation was sent by the company direct to the purchaser, and it is obviously impossible to secure evidence as to whether or not it was actually despatched by an unqualified person. If you are referring to the possibility of a penalty being recovered under Section 17 of the Pharmacy Act, you will find that the company itself can be, and has been, proceeded against in such a case. See *Pharmaceutical Journal*, July 1, 1899, page 11.

PRACTICAL NOTES AND FORMULÆ.

Starch Gloss.

Boric acid, 5; borax, 3; stearin, 1; white wax, 1. These ingredients are heated with sufficient solution of caustic soda, sp. gr. 1.38, to form a clear fluid, which is then evaporated to dryness. The powder is then mixed with fine starch in the proportion of 1 to 10. —*Pharm. Centralh.*, 40, 539.

Corks Impregnated with Caoutchouc.

According to a recent patent, corks are immersed in a solution of caoutchouc, 1; in benzol, 19; and then dried in a vacuum and freed from odour by exposure to air.—*Pharm. Centralh.*, 40, 406, after *Neueste Erfind und Erfahr.*

Gold Toning Bath.

F. Bühler recommends the following toning bath for matt gelatin paper:—(1) Gold chloride, 5 Gms., is dissolved in water 150 C.c., at 36° C. (2) Strontium chloride, 50 Gms., is dissolved by boiling in water 100 C.c. and added to 1. (3) Potassium sulphocyanide, 25 to 50 Gms., is dissolved in boiling water 250 C.c.; allowed to cool to 97°·5 C. Solutions (1) and (2) are now added to (3), in 4 to 5 portions, with constant stirring; after cooling, the mixture is filtered, any precipitate which forms being redissolved by heating to 100° C.—*Pharm. Centralh.*, 40, 566, after *Chem. Industrie.*

Cleaning Marble Slabs.

(1) The slab is rubbed with a mixture of sodium chloride, 2; powdered lime, 1; pumice stone powder, 1. Afterwards wash with soap and water. (2) The slab is covered with a mixture of sodium bicarbonate, 2; chlorinated lime, 1; and enough water to form a paste, and then washed with water. (3) Grease stains are removed by covering with a paste consisting of kaolin and benzene, and then rubbing off with a towel. Old grease stains can only be removed by rubbing down.—*Pharm Centralh.*, 40, 449, after *Neueste Erfind und Erfahr.*

Betulin as a Colouring Agent,

By heating the bark of *Betula alba* with alkaline solutions and adding hydrochloric acid to the filtrate, a precipitate is obtained, which, after washing and drying, forms a reddish brown powder, having an odour resembling leather and a faint bitter taste. By dissolving it in alcohol or hot glycerin, a concentrated dye solution is obtained, suitable for colouring cosmetics and pharmaceutical preparations. The colour obtained is between a rose tint and a deep red brown, say between that of rhatany and cochineal. A gradual addition of alkali deepens the colour, while organic acids in weak aqueous solutions precipitate the colouring matter. Organic acids are without influence upon it. Solution of lead acetate and quinine sulphate also precipitate the colouring matter. For practical use a solution is made by rubbing down 0.05 Gm. of the colouring matter with 5 Gm. of glycerin containing a little 90 per cent. alcohol until completely dissolved, and then making up to 20 Gm. with distilled water.—*Pharm. Centralh.*, 40, 588.

Imitation of Old Silver.

The metal should be blackened before silvering by immersing in a solution of copper sulphate or lead acetate, 100 Gm., and sodium thiosulphate, 300 Gm., in 10 litres of distilled water. The solution should be heated to 60° C.; after drying, the article should be polished with fine pumice stone. It is now silvered by immersing in a silver bath or by rubbing. For the latter method, silver nitrate, 20 Gm., and potassium cyanide, 50 Gm., are dissolved in distilled water, 150 Gm.; and made into a paste with a mixture of cream of tartar, 1, and chalk, 10. This paste is laid on the metal with a soft brush, and washed off when dry.—*Pharm. Centralh.*, 40, 406.

Unna's Domestic Ointment.

As pointed out at page 637 of last volume, this ointment is composed of yolk of egg, 2; almond oil, 3. The yolk of egg is first rubbed down and the oil is then added drop by drop. The ointment, when rubbed on the skin, produces a smooth soft surface on drying. As a preservative, 1 per cent. of Peruvian balsam is added. The following proportions of medicaments may be incorporated with this basis:—Mercuric chloride 0.5 per cent., lead subacetate, ichthyol, lime water, lianthral, Peru balsam, steatite, starch, styrax and tar, 10 per cent.; vinegar, 33.3 per cent. Goulard water, 50 per cent.; but not vaseline, which prevents drying, nor bodies of the phenol group (carbolic and salicylic acids, etc.), nor most metallic salts, nor oxides, nor chrysarobin, pyraloxin, kieselguhr, nor magnesium carbonate. The addition of sulphur may cause an unpleasant odour, due to the formation of volatile sulphuryl compounds but that may be prevented by the addition of camphor.—*Pharm. Centralh.*, 40, 688.

INTERNATIONAL PHARMACEUTICAL CONGRESS IN PARIS.

Provisional Programme of Subjects to be Discussed at the Meetings.

SECTION I.—GENERAL PHARMACY AND PHARMACEUTICAL CHEMISTRY.—1. Analytical methods suitable for determination of alkaloids glucosides, or other active principles of drugs or their galenic preparations. Problem remitted by the Brussels Congress in 1897, to the Paris Congress of 1900. 2. Posology and antidotes of toxic-substances. 3. International pharmacopœia.

SECTION II.—BIOLOGICAL CHEMISTRY—BACTERIOLOGY—HYGIENE. 1. Unification of methods of analysing urine and pathological products. 2. Unification of methods of bacteriological culture.

SECTION III.—PROFESSIONAL INTERESTS.—1. What preliminary studies are required of pharmaceutical candidates in different countries? 2. System of pharmaceutical study in different

countries. 3. Limitation of pharmacies: Results of the practice. 4. How is inspection of pharmacies carried out in different countries, and how should it be arranged?

Organising Committee.

PRESIDENT.

M. Planchon, Director of the Ecole supérieure de Pharmacie de l'Université de Paris.

VICE-PRESIDENTS.

M. Petit (a), President d'honneur of the Association générale des Pharmaciens de France.	M. Dupuy, Professor at the Faculté de Médecine et de Pharmacie de Toulouse.
--	---

GENERAL SECRETARY.

M. Crinon, General Secretary of the Association générale des Pharmaciens de France,

SECRETARIES.

M. Desvignes, Assistant Secretary of the Société de prévoyance des Pharmaciens de la Seine.	M. Viaud, Vice-President of the Association générale des Pharmaciens de France.
M. Langrand, General Secretary of the Syndicat générale des Pharmaciens de France.	M. Voiry, Secretary of the Société de Pharmacie de Paris.

TREASURER.

M. Labélonye, Treasurer of the Société de prévoyance des Pharmaciens de la Seine.	M. Leroy, Treasurer of the Société de Pharmacie de Paris.
---	---

MEMBERS.

M. Antheaume, Vice-President of the Association générale des Pharmaciens de France.	M. Jungfleisch, Professor at the Ecole supérieure de Pharmacie de l'Université de Paris.
M. Bavay, Pharmacien en Chef de la Marine, Membre du Conseil supérieur de santé de la Marine.	M. Klobb, Professor at the Ecole supérieure de Pharmacie de Nancy.
M. Béhal, agrégé à l'Ecole supérieure de Pharmacie de l'Université de Paris.	M. Léger, Pharmacien en Chef de l'hôpital Beaujon à Paris.
M. Boulay, Secrétaire général de la Société de prévoyance des Pharmaciens de la Seine.	M. Leidié, President of the Société de Pharmacie de Paris, Professor at the Ecole supérieure de Pharmacie de l'Université de Paris.
M. Boulicaud, représentative of the Sociétés Pharmaceutiques des Départements.	M. Loisy, Représentative of the Sociétés Pharmaceutiques des Départements.
M. Bourquelot, Professor at the Ecole supérieure de Pharmacie de l'Université de Paris.	M. Marty, Pharmacien Inspecteur honoraire de l'Armée.
M. Burcker, Pharmacien - Inspecteur de l'Armée.	M. Mazières (de), Vice-President of the Association générale des Pharmaciens de France.
M. Cappez, President of the Société de prévoyance des Pharmaciens de la Seine.	M. Moissan, Professor at the Ecole supérieure de Pharmacie de l'Université de Paris.
M. Gamel, Representative of the Sociétés pharmaceutiques des Départements.	M. Poirée, President of the Syndicat général des Pharmaciens de France.
M. Grimbert, agrégé à l'Ecole supérieure de la Pharmacie de l'Université de Paris.	M. Prunier, Professor at the Ecole supérieure de Pharmacie de l'Université de Paris.
M. Guignard, Professor at the Ecole supérieure de Pharmacie de l'Université de Paris.	M. Rêthe, Président of the Association générale des Pharmaciens de France.
M. Jadin, Professor at the Ecole supérieure de Pharmacie de Montpellier.	

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

Members of the Pharmaceutical Society must address all communications with reference to the transmission of the Journal, to the Secretary, 17, Bloomsbury Square, London, W.C.

LONDON: SATURDAY, FEBRUARY 3, 1900.

THE NINTH INTERNATIONAL PHARMACEUTICAL CONGRESS.

THE prospective attractions of the International Exhibition to be held in Paris this year did not leave much room for consideration of the claims of any other city as being a suitable locality for the holding of the Ninth Pharmaceutical Congress, when the decision of that question was before the members and delegates of the Congress held in Brussels three years ago. The coincidence of the meeting falling in the same year as the Exhibition was a further determining condition, and though the matter was not definitely decided at the time, little doubt remained that the proposition then made by M. PETIT would be adopted. A communication just received from Paris bearing the impress of the Ministry of Commerce and Industry enables us to state that, in connection with the International Congress, an Organising Committee, authorised to make the necessary arrangements for the purpose, has been formed, with Professor PLANCHON as President, M. PETIT, Vice-President, and M. CRINON, General Secretary, supported by many other eminent pharmacists holding official positions in France (see p. 102).

Applications are now in course of being addressed to pharmacists in other countries requesting them to join the Congress at once as members by forwarding their names, together with a postal order for the amount of the member's subscription of twenty francs to be enrolled as *membres effective* or of one hundred francs as *membres donateurs*. This circular also states that in view of the Pharmaceutical Congress being held in Paris this year all the pharmaceutical associations of France have combined to give their assistance in making the preparations requisite for receiving visitors on that occasion. That is the case not only with societies which are purely scientific, like the Société de Pharmacie of Paris, but also with those which are concerned more especially with general pharmaceutical affairs like the Association générale des Pharmaciens de France, the Société de prévoyance des Pharmaciens de la Seine, and the Syndicats pharmaceutiques Français.

The time fixed for the meeting is August 2, so

that ample opportunity will be offered for being present without interference with the arrangements of British and Irish pharmacists who may attend the Pharmaceutical Conference to be held in London at the end of July. The meetings of the International Congress will continue until August 8. They are to be held at the Ecole supérieure de Pharmacie de l'Université de Paris, No. 4 Avenue de l'Observatoire. The members of the Organising Committee express their intention of making the occasion as interesting as possible to all who attend the Congress, and they also request that those who do so may likewise help in that respect by contributing to that great professional assemblage the first publication of some result of their researches. In accordance with the regulations adopted by the Committee the proceedings of the Congress will be arranged in four sections, viz. :—

1. General Pharmacy and Pharmaceutical Chemistry.
2. Materia Medica or Pharmacognosy.
3. Biological Chemistry, Bacteriology, and Hygiene.
4. Professional Interests.

Under these several heads the Organising Committee has already selected several subjects to serve as an indication of the kind of questions to be discussed at the Congress (see page 102), but these are to be regarded only as constituting a provisional programme that is to be completed by the subjects subsequently recommended by the Sectional Committees and also by the papers contributed by members of the Congress.

In order to render the discussions profitable and to make the Congress of 1900 of influence upon the future, the Organising Committee desires most strongly to impress upon members of the Congress the desirability of their bringing forward only subjects which have a general international interest and an importance that cannot be disputed. Such communications as are sent in complete three months before the opening of the Congress will, if suitable, be made the subject of reports, that can be discussed in the sections or in general assembly: those which are not presented until a month before the opening can only be discussed at the sectional meetings; but the Organising Committee in any case reserves to itself power to withhold from the proceedings of the Congress any contribution that may not receive its approval. In addition to the meetings devoted to the discussion of scientific and professional subjects the Committee proposes to arrange various excursions that may be likely to offer attractions to visitors. As among events of this kind that will take place during the Congress mention is made of the inauguration of the monument to be erected in memory of MM. PELLETIER and CAVENTOU, to whom the world is indebted for the discovery of quinine. As for any information desired in reference to the Congress, application should be made to M. CRINON, the General Secretary of the Organising Committee, whose address in Paris is No. 45, Rue Turenne.

The circulars of invitation to join the Congress referred to above are being issued by the President and General Secretary, on behalf of the Organising Committee, to pharmacists whose addresses are known to them, and they request that the terms of the invitation should be published in this Journal in order to secure more general cognisance of their desire that the Congress should be largely attended.

THE STRENGTH OF THE SOCIETY.

At the close of 1899 the Pharmaceutical Society was stronger numerically than it has been at any former period of its existence, as shown by the following table, in which the figures are given for corresponding periods during the past three years:—

Subscribers.	1897.	1898.	1899.
Registered Chemists	4,775	4,840	5,820
Students	873	866	884
Total	5,648	5,706	6,704

The registered chemists connected with the Society at the end of 1899 were nearly a thousand in excess of the total twelve months earlier, and there was also an increase in the number of subscribing students. At the January meeting of the Council further additions were made to both lists and, to follow the precedent of last year, the real strength of the Society at the present time, as compared with similar periods in former years, is shown in the following table:—

Subscribers.	1898.	1899.	1900.
Registered Chemists	4,864	5,166	5,906
Students	974	1,007	941
Total	5,838	6,173	6,847

That is to say, the total strength of the Society has increased by more than a thousand during the past two years, whilst the number of registered chemists subscribing to the representative body—a much more important matter—has been increased during the same period to a still greater extent.

THE SOCIETY AND "THE TRADE."

TWELVE months ago it was pointed out in these columns that the extent to which the registered chemists of Great Britain were directly represented by the Pharmaceutical Society was then of exceptional interest, in view of the necessity for a very decided increase in the membership of the Society if the Council was to attempt seriously to secure further parliamentary powers to regulate the practice of pharmacy. At that time the number of registered chemists connected with the Society barely attained to one-third of the total number of persons whose names were entitled to appear upon the Register of Chemists and Druggists; but the number has since steadily increased, and at the end of the year 1899 the position was as follows:—

Registered Chemists.	1897.	1898.	1899.
Members	4,775	4,840	5,820
Non-Members	10,440	10,633	9,775
Total	15,215	15,473	15,595

The foregoing table shows that the number of members had been largely augmented during 1899, so that the relative proportion of members to non-members had been increased to considerably more than one-third instead of being well under that proportion. But considerable additions have been made both to the Register and to the strength of the Society during January of this year, and the actual position a fortnight ago was as shown in the following table:—

Registered Chemists.	1898.	1899.	1900.
Members	4,864	5,166	5,906
Non-Members	10,481	10,412	9,804
Total	15,345	15,578	15,710

The table includes the figures for the corresponding period—mid-January—in 1898 and 1899 respectively, and it will be seen that whilst the net additions to the Register during the past two years number 365 only, the membership of the Society has increased by 1,042, *i.e.*, nearly three times the number. At the same time this result is far from what it ought to be, and the Council of the Society cannot yet be congratulated upon having behind it such largely increased forces as would alone justify such a vigorous policy as has been advocated in certain quarters.

SUBSCRIPTIONS TO THE SOCIETY.

At this period of the year, it is desirable that members of the Pharmaceutical Society, particularly if they have any intention of giving up their membership, should have a clear idea regarding their liabilities in connection with the body to which they belong. The bye-law which regulates the payment of subscriptions provides that "all annual subscriptions shall become due on the first day of January in every year, and if any person shall not have paid his annual subscription before the first day of May in any year, his name shall be omitted from the Register of Members or of Student-Associates." But it must not be supposed that this automatic omission of his name relieves the individual from all further responsibility in the matter. In reality, if he has omitted the formality of sending in his resignation, he can be sued for arrears of subscriptions. Moreover, it is quite competent for the Council to decline to recognise even a formal notice of resignation as terminating the contract entered into by the individual, unless it has been received before the end of the year for which the latest subscription has been paid. Accordingly, members who may at any time feel disposed to retire from the Society should bear in mind that if they do not give formal notice of their resignation during the term covered by the latest subscription they have paid, they will be—legally as well as morally—liable to contribute further to the Society's funds, unless the Council, as an act of grace, consents to forego its undoubted claim upon them.

ANNOTATIONS.

THE BRITISH PHARMACEUTICAL CONFERENCE is, we are informed by the president of that body, in need of more members, more funds, and greater support generally, and he is anxious that, during his year of office, considerable improvement should be manifested in that direction. But how the improvement is to be effected is not altogether obvious. Of course, if every existing member were to nominate at least one other person as a member, the problem would be solved so far as present needs are concerned, but even then the position would not be an ideal one for such an association. At present there appear to be some eleven hundred subscribing members of the B.P.C.; doubling that we get more than two thousand; but there are nearly sixteen thousand registered chemists in Great Britain, to say nothing of those in Ireland and of the fact that membership is not limited to registered persons. Nevertheless, the accession of a considerable number of new members is imperative if the Conference is to continue its course on present lines, and it must devolve chiefly upon existing members to find the lacking material. At the outset, however, the most enthusiastic canvasser has been confronted with the difficulty that he does not know who, in his particular district, is a member and who is not. The only way in which he could obtain the desired information was the tedious method of going carefully through the alphabetical list in the latest 'Year-Book,' and that would naturally deter many from proceeding further. To get over the difficulty, the president of the Conference, Mr. E. M. Holmes, has had a fresh list compiled, in which the names of all the members are arranged alphabetically under the names of towns, so that it is possible to see at a glance whether any particular individual residing in a given town is connected with the Conference or not. If a copy of this list could be sent to every member, with a notification to the effect that any assistance he could give would be beneficial to himself and the whole body, the result ought to prove distinctly encouraging, and it is to be hoped that means will be found of providing for a wide distribution of the list.

A CURIOUS FACT brought out by Mr. Holmes' list is that a certain amount of lip-loyalty to the Conference sometimes takes the place of the real thing in the centres visited on the occasions of the annual meetings, and that those meetings do not always result in a large and permanent addition to the membership. Thus, to take the last eight centres—Edinburgh is represented by forty-four members, Nottingham by seven only, Oxford by six, Bournemouth by nine, Liverpool by fifty-one, Glasgow by forty-three, Belfast by twenty-two, and the Plymouth district by fourteen. In view of the fact that the town visited in any given year is usually regarded as the chief recruiting ground for that year, the state of affairs disclosed by some of the figures is not satisfactory. At the same time, it must be borne in mind that many residents in a district join the Conference during the year that district is visited, and subsequently cease to subscribe, feeling no further interest in the association afterwards. But if there is any substantial reason for the existence of the Conference as a separate organisation, it would seem as if the body ought to be more largely and continuously supported by registered chemists in some of the towns and districts where the annual meetings have been held during recent years. London, by the way, is credited with three hundred and one members; if all those attend the meeting in July next and bring their sisters, cousins, and aunts, the occasion will probably be a record one, without reckoning the numerous contingents from outside. Each London member, too, may reasonably be expected to induce at least one other person to join the Conference, and in the event of that being done, the funds of the wandering association should be in an exceptionally flourishing condition six months hence.

THE PRELIMINARY EXAMINATION, which has been conducted by the Pharmaceutical Society for so many years past, will be held

for the last time on July 10 next, and its place will subsequently be taken by scholastic examinations conducted by universities and other examining bodies in the United Kingdom. It is important to note the latter fact, for, though the "First" examination of the Society is to be abolished, the necessity of passing an approved preliminary examination prior to entering for the Minor examination will exist as heretofore. June 26 next is the last day upon which candidates can give notice to the Registrar of their intention to present themselves for the final "First" examination; after that date persons desirous of obtaining registration as "apprentices or students," and of thus becoming eligible to enter for the Minor examination, must deliver to the Registrar, on behalf of the Boards of Examiners, a certificate of having passed an examination—in English grammar and composition, Latin, a modern foreign language, arithmetic, algebra, and Euclid—conducted by one of the recognised examining bodies. It may be pointed out that, in accordance with the Society's bye-laws, a candidate who has attended and failed to pass the "First" examination is entitled to attend an examination "on any future occasion" on payment of a reduced fee of one guinea, but after July next there will be no "future occasions" upon which previously unsuccessful candidates can attend the "First" examination. A registration fee of two guineas must, subsequently, "in every case" accompany the certificate submitted by a candidate for acceptance.

THE NINETEENTH JUNIOR PHARMACY BALL will be held at the Portman Rooms, Baker Street, W., on Wednesday next, February 7, the time announced for the first dance being 9 p.m. precisely. Mr. Mortlake Mann's Orchestral Band has been engaged. Among the prominent pharmacists who have promised their support on the occasion are the President of the Pharmaceutical Society, Mr. William Martindale; two past-Presidents, Messrs. Walter Hills and Michael Carteighe; and Mr. Arthur L. Savory, a member of the Pharmaceutical Council. As in the case of the Chemists' Ball, any surplus remaining after payment of expenses is usually handed over for the benefit of the Pharmaceutical Society's Benevolent Fund. Tickets (7s. 6d., each, including supper and light refreshments) should be promptly applied for by those who propose to attend and have not already secured them. They can be obtained from the Hon. Secretary, Mr. Ralph L. Cassie, 49, Newgate Street, E.C.

A CHEMISTS' CLUB has been established in New York, and the *Pharmaceutical Era* publishes an interesting account of the institution, which has no counterpart in London, much as a place of the kind seems to be required. The objects of the Club are the promotion of good fellowship among the members and the advancement of the science and application of chemistry. There are two classes of members—resident and non-resident. Any person who is interested in the science or practice of chemistry is eligible for membership, and, although the club has only been in existence for about a year, there are already more than a hundred and thirty resident members. The club-house contains a general reading-room, a library, smaller reading-rooms, etc., and is comfortably furnished. It is intended to establish a great chemical library in the house and to inaugurate a system by which members living at a distance can receive abstracts, copies, or translations of chemical papers. A directory of all chemists living in the United States and Canada is also being prepared for reference purposes. What the club at present offers to non-resident members is the use of a large and rapidly-growing chemical library, including files of all the leading chemical journals, together with the surroundings and advantages of a private study. The results of the first year's working have proved successful, and the president—Professor C. F. Chandler, of Columbia University—has now issued a circular, in which he appeals to the chemists of the United States and Canada to rally to the support of the club. The annual subscriptions are twenty-five dollars for "resident" members, living within a radius of twenty-

five miles of the New York City Hall, and five dollars for "non-resident" members, living beyond that radius.

THE USE OF SPECIAL BOTTLES FOR POISON is attended by one drawback which no expenditure of ingenuity can be expected to overcome, for it is difficult to see how any practical means can be devised to prevent such bottles being used for liquids which are not poisonous. On the whole there is no doubt that the use of special bottles for poisons affords a certain measure of safety, but it is quite conceivable that the safeguard so afforded may be weakened by their indiscriminate use. Pharmacists, as a rule, decline to put ordinary medicaments in poison bottles brought for the purpose by customers, but many tradesmen are less particular. The result is that the effect of the warning conveyed by bottles of unusual shape and colour tends to become minimised amongst people who are content to use any kind of bottle for liquid preparations they are in need of. A bad case of the kind referred to has been brought under notice by a correspondent who expresses the hope that it is unique. A one-ounce blue, ribbed, octagon bottle, with the words "Not to be taken" on one side, has been sent out from the surgery of a medical man containing medicine for internal use. The label on the bottle shows the printed words "A tablespoonful to be taken every three hours," but those words are scored out, and below appears the written statement, "The draught, as directed." The chemist who sends the bottle states that it was handed to him, in the condition described, to be filled with sal volatile. The facts may be left to speak for themselves, but the lack of discretion betrayed by the medical practitioner whose name appears on the label is certainly worthy of attention.

THE SALE OF INSECTICIDES is the subject of a leading article in the *Garden*, which commences with the statement that the Pharmaceutical Society was "professedly" incorporated for the public benefit, more particularly to secure that the sale of poisons and the dispensing of drugs should only be undertaken by persons properly trained and qualified for the work. Everyone, it is stated, will admit that it is to the advantage of the community that physicians' prescriptions should be compounded by skilled hands, and that it would not be for the good of the community if certain dangerous preparations could be dispersed broadcast by anyone who chose to deal in them for purposes of mere profit. "It conduces to the public weal that supervision should be exercised by a recognised authority over the retail vendors of poisons, and that in the case of certain special preparations a register of retail sales must be kept, in which must be entered the date of the sale and the name and address of the purchaser, together with the purpose for which he stated the material was intended to be used. Such regulations are for the good of the public, and should be properly enforced." But, the writer of the article continues, after accomplishing much good work in taking action against unqualified persons for selling proprietary medicines containing poisons—"a legitimate sphere for its operations"—the Society seems of late to have taken quite a new view of the reason for its existence. It is almost needless to say that the proceedings taken against seedsmen and florists for the illegal sale of scheduled poisons constitute the Society's offence inveighed against in the rest of the article under consideration. In putting down such illegal sales the Society is declared to be simply acting as a trade protection society, though under the pretence that what is done is in the public interest.

AN INEVITABLE RESULT of that action, it is alleged, will be to raise the price of poisonous weed-killers to the consumer, but how that effect is to be produced is not explained. In conclusion, much comfort is derived by the writer from the recent Queen's Bench decision, and it is asserted that there is little cause to fear that the decision will be reversed. But if that be so, why should the gardening papers be so excited about the matter? Why, also, should they quote with such unction certain alleged remarks of

"the distinguished lawyer who now fills the position of Lord Advocate?" The opinion of the individual referred to may be worth something, though it is doubtful how much, and in any case it is not always advisable to put too much trust in statements given utterance to amid the excitement of large public meetings. Being asked if he would support a Bill in Parliament making it legal for "seedsmen and other agents" to sell poisonous preparations, such as sheep-dips, insecticides, weed-killers, etc., the Lord Advocate is reported to have replied that where poisonous substances were dealt with in the way of being dispensed, it was only right that it should be done by qualified persons only. But, in his view, where those substances did not need to be dispensed, but were supplied by the manufacturer in the final form in which they were to be applied, "he saw no reason why any trade or profession should have a monopoly of selling them, provided proper regulations were made and precautions taken that they would not be supplied or used for any other purposes than those for which they were meant." It is evidently intended to work the "monopoly" fiction for all it is worth, both in and out of Parliament; but, in all seriousness, it is high time that public officials and the conductors of important periodicals should learn to use the English language with a proper sense of its meaning.

A REFORM MOST URGENTLY NEEDED, according to the outspoken editor of the *Practitioner*, is that would-be reformers should reform their manners. "Whether they are denouncing the General Medical Council for not excommunicating club doctors, or shrieking against the British Medical Association because it does not transform itself into a trade union, or calling on the State to protect them against midwives, they can only be described as literary Hooligans. With a very few exceptions, they are men of no professional or social standing, who find an easy means of notoriety in medical politics." It would almost appear, Mr. Malcolm Morris remarks, as if some of the individuals referred to must get their living by "reform" work, for they seem to do nothing else, and the serious point in the business is that the profession is, through mere inertia, allowing itself to be represented before the eyes of the public by "a mere handful of fussy nobodies, ill-bred, ill-educated, and ill-conditioned both in intelligence and in temper. To see them and hear them speak is enough to make one ashamed of one's profession." Though exaggeration is manifest in the passages quoted, there is doubtless much truth underlying Mr. Morris's complaint, and with slight modification his remarks might be applied with a fair degree of appropriateness to certain chronic grumblers in pharmaceutical circles.

THE SALE OF FOOD AND DRUGS ACT, 1899, requires, for its efficient working, the drafting and adoption of regulations dealing with various matters, and the Right Hon. W. H. Long, M.P., President of the Board of Agriculture, has now appointed a departmental committee to inquire and report as to what regulations, if any, may with advantage be made by the Board of Agriculture—under Section 4 of the Sale of Food and Drugs Act, 1899—for determining what deficiency in any of the normal constituents of genuine milk or cream, or what addition of extraneous matter or proportion of water in any sample of milk (including condensed milk) or cream shall, for the purposes of the Sale of Food and Drugs Acts, 1875 to 1899, raise a presumption, until the contrary is proved, that the milk or cream is not genuine. The committee will consist of the following gentlemen, viz.:—Lord Wenlock, G.C.S.I., G.C.I.E. (chairman), Mr. George Barham, Mr. George Cowan, Major Patrick George Craigie (an assistant-secretary of the Board of Agriculture), Mr. S. W. Farmer, Mr. Shirley F. Murphy, M.D., Professor Thorpe, F.R.S. (Principal Chemist of the Government Laboratories), and Mr. J. Augustus Voelcker, Ph.D. Mr. Robert Henry Rew, of the Board of Agriculture, will act as secretary to the committee.

ENGLISH NEWS.

ANNUAL DINNER OF THE SCHOOL OF PHARMACY.—All past students, and all those who are interested in the welfare of the School of Pharmacy, are reminded that the above dinner will take place at 7 p.m. on Wednesday, February 21, at the Holborn Restaurant, in the Caledonian Salon. Tickets (to be returned if not required) have been sent to those whose addresses are known to the secretaries, and any who have not received one by this time, and are desirous of being present, should communicate with the Hon. Secretaries, Messrs. Edgar M. Chapman and John Lawson, 17, Bloomsbury Square, W.C. Tickets, price five shillings each. The dinner this year bids fair to be a great success. The Dean of the School, Prof. J. Norman Collie, will be in the chair, supported by the President of the Society, Wm. Martindale; two past-Presidents, Messrs. Walter Hills and Michael Carraighe; Prof. J. R. Green, Dr. Atfield, and many other prominent pharmacists, who have intimated their intention of being present. The musical arrangements for the evening have been undertaken by Mr. A. Newton, who will act as pianist, and who has got together a strong programme, given entirely by present students and their friends.

PHARMACEUTICAL DRILL CLASS.—A second meeting of the staff and students of the School of Pharmacy was held on Monday, January 29, to receive the report of the Committee which had been appointed at the last meeting. Professor Collie took the chair, and called upon Mr. Upsher Smith, Chairman of the Committee, to present the report. He said that permission had been provisionally obtained from the President, until the Council meeting, for the use of the Examination Hall, providing gymnasium shoes were worn. The cost would probably not exceed half-a-crown a head. A drill instructor could easily be obtained. Full particulars had not yet been obtained with regard to the cost of an ambulance class, but the local district secretary was coming to interview the Committee on Wednesday. About twenty students had intimated their intention of joining if it would not take more than an hour a week and the cost was not more than five shillings. The Committee, therefore, recommended "That a School of Pharmacy drill class be formed," and he begged to move it as a resolution. Mr. Garsed seconding, it was carried unanimously. Mr. Chapman then proposed, and Mr. C. T. Allen seconded, "That this general meeting of the students of the School of Pharmacy requests the Council of the Pharmaceutical Society to favour them with the use of the Examination Hall for the purpose of drilling," which was also carried. Mr. Deane having given further information about ambulance classes, the matter was left for report to another general meeting. A vote of thanks to the Chairman, moved by Mr. Chapman, and carried by acclamation terminated the proceedings. The Secretaries afterwards went to the Wellington Barracks and obtained the services of a sergeant from the 2nd Battalion of the Grenadier Guards, and the first drill was held on Wednesday, January 31. If any old Square students wish to join they are requested to communicate with the secretaries.

IMPERIAL COLLEGE OF CHEMISTRY.—On Thursday, January 25, Dr. W. Hampson lectured to the students of this college on "Liquid Air." After a few preliminary remarks upon the effects of cold and pressure, and other physical phenomena, Dr. Hampson, by means of apparatus, obtained a temperature of -192°C ., and prepared about half a pint of liquid air, subsequently performing a series of most interesting experiments. Chloroform, ether, absolute alcohol, whisky, were frozen in the fluid, and passed to the students in the solid state, for handling and inspection. Metallic mercury was immersed in the liquid air, becoming solid and malleable, being bent, forming a hook from which a pound weight was suspended; whilst liquid air placed upon ice boiled away so

vigorously on account of the comparative great heat of the ice that the students perceived that the term cold is an expression not fully appreciated. It was noticed that as a portion of the liquid air boiled away from the inner tube of the vacuum jacket the remainder assumed a blue colour. This, Dr. Hampson explained, was due to the nitrogen passing off more rapidly than the oxygen, so that the fluid remaining consisted of nearly pure liquid oxygen, which was proved by further experiment. The carbon dioxide and moisture were removed from the air employed for the experiments prior to liquefaction. In the course of his remarks Dr. Hampson stated he had supplied the liquid air in which Professor Ramsay discovered neon, crypton, xena, etc.

NEWCASTLE CHEMISTS' ASSOCIATION.—The third annual dinner of this Association was held on January 24 at the Hotel Metropole, Newcastle-on-Tyne. There was a large and representative attendance. Mr. Charles Ridley (Newcastle), the President of the Association, occupied the chair, and others present included Dr. Drummond, Dr. Limont, Dr. Slater, Mr. T. M. Clague, Mr. G. F. Merson, Lieutenant John Gibson (Hexham), Mr. T. D. Ridley, Mr. G. Weddell, Mr. Rose (Jarrow), and Mr. Wm. Kerse (Treasurer). The Secretary (Mr. F. Gilderdale) was unfortunately prevented from attending owing to indisposition. After the toast of "The Queen," proposed by the Chairman, and that of "The Army, Navy, and Auxiliary Forces," proposed by Mr. Kerse, Mr. T. Maltby Clague proposed "The Medical Profession." That was responded to by Dr. Drummond. Mr. G. Weddell proposed "The Pharmaceutical Society," to which Mr. J. D. Rose responded, and "The Newcastle and District Chemists' and Kindred Associations" was proposed by Mr. F. R. Dudderidge, and responded to by Mr. G. F. Merson. The toasts were agreeably enlivened with harmony.

WOLVERHAMPTON AND DISTRICT CHEMISTS' ASSOCIATION.—The chemists of Wolverhampton and district met on Monday, Jan. 29, and elected the following officers:—President, Mr. F. J. Gibson; Vice-President, Mr. S. Philips; Hon. Treasurer, Mr. Cullwick; Hon. Secretary, Mr. J. H. Coleman; Members of Committee, Messrs. Hall, Towler, and Walker.

LIEBIG'S EXTRACT OF MEAT.—On January 27 the action of Liebig's Extract of Meat Company, Limited, *v.* Stacey and Co., was tried before Mr. Justice Buckley in the Chancery Division of the High Court of Justice. The plaintiff company, which has carried on the business since 1865 as a manufacturer of extract of meat made according to the instructions of the inventor, the late Baron Justus von Liebig, sought to restrain the defendants (who carry on business as grocers at Yarmouth) from selling extract of meat not made or manufactured by the plaintiff company as and for the company's extract. Evidence was given to the effect that the plaintiff's extract was known by the names of "Liebig Company's Extract of Meat," "Liebig Company's Extract of Beef," "Liebig Company's Extract," and the "Company's Extract," and that defendant's assistant, in response to an order for "Liebig Company's Extract," supplied an extract made by the South American Meat Company. Defendants denied that there had been any misrepresentation, but after hearing the witnesses his Lordship granted an injunction and ordered defendants to pay the costs of the action.

SALE OF CAMPHORATED OIL.—A decision of some importance was given at the recent Luton Divisional Sessions, when an adjourned case against Ellen S. Cowdery, grocer, of Leagrave, charged with selling camphorated oil deficient in camphor to the extent of 16 per cent., came on for hearing. The facts of the case were that Inspector Mason purchased six twopenny bottles of camphorated

oil from the defendant, with whom he left two bottles. Two other bottles were submitted to analysis, and the oil was said to contain 17.5 per cent. of camphor. It was contended for the defence that the Inspector had not properly divided the samples taken, the suggestion being made that the bulk purchased must be mixed up and then divided.—It was now contended for the prosecution that the suggestion referred to was little short of an absurdity, and that the Inspector had carried out all the requirements of the Food and Drugs Act.—Mr. A. Ekins, M.P.S., of St. Albans, having given evidence as to the component parts of camphorated oil, the Chairman said the magistrates were of opinion that the Act had not been complied with, and they therefore dismissed the case.—Inspector Mason is stated to have entered into recognisances to prosecute an appeal in the High Court.

INLAND REVENUE PROSECUTION.—William H. Hewett, chemist and druggist, West Cowes, was summoned at the Isle of Wight County Bench on Saturday, January 20, for selling methylated spirits on November 27 without a licence.—The Supervisor of Inland Revenue said that the defendant had taken out a licence for twenty years, and the usual notice was sent him on October 27, and on November 20 he was reminded that the tax was still unpaid. On December 6 Mr. Hewett renewed his licence, but in the meantime an assistant Excise officer had purchased some methylated spirits at defendant's shop.—Mr. Hewett, who pleaded guilty, said it was an oversight.—The magistrates inflicted a fine of 6d. and costs 16s.

CHEMISTS' DEFENCE ASSOCIATION CASE.—On Monday, January 29, Mr. W. R. Barnes, pharmaceutical chemist, Upton Manor, was summoned before Mr. Baggallay at the West Ham Police-court, for having, on December 23 last, employed a lad under the age of eighteen for a longer period, during the week ending that date, than is allowed by the Shop Hours Act.—Dr. Sanders, Medical Officer of Health, prosecuted, and Mr. Barnes was represented by Mr. F. W. Beck, solicitor to the Chemists' Defence Association.—The first witness for the prosecution was the lad, who stated that his name was Charles Pack, and that he was employed by Mr. Barnes as an errand boy. His age was eighteen on December 21, 1899.—Dr. Sanders said that if that were so he would, of course, have to withdraw, but his information was that the lad was under eighteen.—Mr. Beck then handed to the magistrate a certificate of birth, showing that the boy was eighteen on December 21 last. He asked that the case should be dismissed, and that the defendant be allowed costs. It was due to Mr. Barnes to point out that if the case had been gone into the most the prosecution had alleged was that Mr. Barnes had employed the lad seventy-six instead of seventy-four hours per week. He also pointed out that Mr. Barnes had allowed the lad two hours each day for dinner and tea, whereas if he had allowed him only half-an-hour for each of these two meals, he would have been able to employ him for four hours a week longer.—The magistrate dismissed the case, but said that he would not allow costs, as the lad was only two days over age.

BRADFORD AND DISTRICT CHEMISTS' ASSOCIATION.—A meeting of this Association was held on Tuesday, January 30, when Mr. Waddington read a paper on "Proprietary Articles: How far is Substitution Justifiable?" He said the subject was so important to every individual in the business that no apology was needed for introducing it. After tracing the origin of the trade in proprietary articles, he summarised his conclusions as follows:—(1) Sell proprietaries at store prices, but not below cost; (2) keep them in the background; (3) let your customer know you have them; (4) then try substitution; (5) maintain your standing as chemists and not store-keepers; (6) discard all gratuitous bills and stationery and P.A. show cards; (7) use your own; (8) influence the medical men as much as you possibly can.—A discussion ensued, and Mr. Waddington was thanked for his paper.

LIVERPOOL CHEMISTS' ASSOCIATION.

The annual meeting took place at the Royal Institution, Liverpool, on Thursday evening, January 25, the President, Mr. ANTHONY S. BUCK, in the chair.

After the minutes of the previous meeting had been read and confirmed, and various donations of periodicals announced, Mr. F. D. Fossett was elected a member.

Mr. R. C. COWLEY then asked if

FERROUS ARSENIATE

was used to any considerable extent in dispensing, and, if so, what were its special recommendations to favour in the eyes of medical men. In the light of recent researches he had undertaken it would be of interest to him to know if its value was based upon its arsenic content or upon that and the ferrous iron it was supposed to represent.

Several members agreed that it was not of general use, and Mr. MARSDEN suggested that Mr. Cowley embody his results in a paper for the edification of the Association—a suggestion which was well received by the meeting and emphasised by the PRESIDENT. Mr. COWLEY said he would consider the matter.

PRESENTATION OF REPORTS.

A very satisfactory annual report was then read by Mr. DUTTON, showing a well-sustained numerical roll and alluding to the various business and scientific topics broached in the course of the year. Following that Mr. WILLINGS read the Treasurer's report, by which it was seen that the financial affairs of the Association were in a very prosperous condition.

The usual votes of thanks were then accorded to the retiring President, Mr. Edward Evans, and the other officers of the Association. Special mention was made of the ability with which Mr. Prosper Marsden had conducted and was conducting the duties of Secretary in the absence abroad of Mr. Theo H. Wardleworth. The donors of books, periodicals, and pamphlets to the library and of materia medica specimens to the museum also came in for appreciative recognition of their generosity.

ELECTION OF COUNCIL.

The election of seven members of the Council then took place, and resulted in the following gentlemen being re-elected:—Messrs. Bain, Buck, Cowley, Marsden, Wardleworth, and Wokes, the new member being Mr. Hudson.

Presidential Address.

The PRESIDENT proceeded then to deliver his inaugural address, in which he first referred to the subject of:—

MEDICAL DISPENSING.

He held that medical practitioners frequently take up dispensing from actual necessity. Patients have not yet been educated to paying for advice only, and do not see the force of paying a fee unless they have something for it. They do not recognise the advice as that something; but when a bottle is handed over the case is quite altered. Then, again, in some districts the stock in chemists' shops is not of a nature to fill the position or requirements of a dispensing pharmacy. A nurse has been known to take a prescription for liquor atropinæ sulphatis to six shops without being able to get it dispensed. Naturally if a doctor cannot obtain locally what he requires for his patients the tendency must be for him to obtain it from one of those wholesale firms who are so ready to supply doctors, especially those just commencing practice, with drugs and sundries for setting up a dispensary.

In a recent issue of a medical paper a firm of wholesale chemists advertised that as it did not employ travellers it was enabled to supply the best drugs, chemicals, and pharmaceutical preparations at the lowest possible prices. The advertisement also said: "Medical practitioners cannot fail to observe that there is nothing in their business relations with wholesale chemists that cannot be done by writing, thus saving time and the frequent intrusions upon

their privacy which the visits of travellers occasion. The profession, moreover, must be aware that the expense of employing travellers is paid by themselves in increased prices." Others offer drugs, and one firm of high standing offers corks, of which few would be used unless for dispensing. That was quite sufficient to show that much encouragement is given to doctors to do their own dispensing, and frequently similar help is given by registered chemists. One medical man who strongly objects to dispensing is obliged to do it because in his district there is no shop in which he can place reliance, or at which he could even get his wants supplied. If that defect were remedied, he would at once give up the work. It was not a question of club dispensing, in which prices were so low that if the dispensing were done by chemists and minimum prices charged nothing would be left for advice.

The medical profession, therefore, are not entirely their own masters in this matter, and instead of chemists saying and writing so much about the evils of medical dispensing, it should be their duty to meet the doctors in every possible way, and do all in their power to induce them to hand over the work to chemists where possible. At the same time, chemists should guard against anything of the nature of direct profit to the physician from their work. The indirect advantage would be saving of time and a better feeling on the part of chemists towards the medical profession in those places where dispensing was discontinued. Such an arrangement, of course, would be open to abuse, but it offered the lesser of two evils. Worked on those lines, the speaker had found no cause to regret it. In some cases dispensing had been discontinued, and in other cases much had been given up which could as easily have been accomplished as that which was still conducted for club work. It was certainly advisable to prevent people who were able to pay a small fee from attending hospitals which are already suffering from overwork, and by aiding the profession in the way suggested chemists would really be helping the charitable institutions to act as they were originally intended to—for the benefit of the very poor only.

On the other hand, as the pharmaceutical training does not include those subjects which enable the medical profession to diagnose and prescribe for ailments, chemists should, wherever possible, refuse to treat cases, and send the applicant to a man who has studied those subjects. That was at times difficult to accomplish, as the patient would frequently suggest what should be given him, and, in case of refusal, simply pass on to the next place, where he would obtain what he thought he required. Perhaps that case would not come under the heading of advice gratis, but certainly in all other matters chemists should use their best persuasive powers with the view to inducing the patient to take proper advice.

With reference to qualified dispensers for doctors' dispensaries, that state of things could not be insisted upon all at once. No doubt it would be very advisable, but at the present time there was not a sufficient supply of qualified men for chemists' own requirements, and they would simply produce a block which would recoil upon themselves, and possibly prevent any legislation in their interest for many years. With open surgeries the case was different, as outside work was frequently attended to for other doctors than the man who owned the place, as in Scotland, and those should be under the same rules and regulations as pharmacies. In the case of a dispenser for a doctor's own work, the Apothecaries' Hall Assistants' Certificate might meet the needs of the case.

Turning next to the subject of

COMPANY PHARMACY,

Mr. Buck said the subject had been discussed and written upon for so many years that there was great difficulty in saying anything really new about it. Chemists were all agreed that the compilers of the Pharmacy Act of 1868 could not have anticipated that what one man could not do alone should be allowed on his taking six members of his own family, or outsiders, into partnership without

any of the seven being qualified. The trouble had always been to find a remedy, and it did not seem possible to put matters straight until there was an entirely new Pharmacy Act. The amount of education which would be required for that work would undoubtedly be a matter of many years' hard work. The Pharmacy Acts of 1852 and 1868 were both based on the fact that they were expedient for the public safety, and it was difficult to see how a union formed for the sole purpose of evading those Acts could make for the safety of people who possibly, in these days of a little knowledge, require more looking after than they did thirty or forty years ago.

A noteworthy point was the number of eminent men who took part in the debates in both Houses of Parliament on the 1868 Act, and it might be taken for granted that in any attempts made in the matter of further legislation, in the interests of pharmacy, the goodwill and help of the medical faculty would be an absolute essential.

From the passing of the Pharmacy Act, 1868, and the short amending Act in 1869, there had been no legislation bearing directly upon pharmacy until the amendment of 1898, but in the meantime there had been many judicial readings which for the time being have shaken the Pharmacy Act of 1868 to the very root. The most noted case was that of the London and Provincial Supply Association, Limited. It had been suggested recently that a test case should be tried again on those lines, and that a fund should be started for that purpose; but it would be well if those who advised that action and others would bear in mind the wording of some of the judicial remarks in the case mentioned. It was well-known that the judges are bound to interpret Acts of Parliament according to their intent and meaning, and the intention of Parliament is only to be found in the words of the Pharmacy Act itself. From all the expressions of judicial opinion it was clear that the Act was thoroughly bad, and that if the advice were taken of those who are anxious for the Pharmaceutical Society to try another case on the same lines as the 1880 test case, there would be very little chance of success. The previous authorities on the Act would naturally be examined, and certainly he would be a brave judge who would give a decision in direct opposition to those learned men who have made history and law on the Pharmacy Act, and whose readings of the measure were so uniform.

One thing which had undoubtedly given an impetus to the selling of medicine by general dealers was the readiness with which registered chemists, on the least encouragement, immediately proceeded to plant branch pharmacies in every new district. If branch shops had not been introduced, companies would not have flourished. Whatever difference chemists might see between a branch managed by a qualified man and owned by a pharmacist, and one under a qualified manager owned by a body of shareholders, the Legislature and the general public would not see it in the same light. Both managers were entitled to open and conduct pharmacies on their own account, and possibly the actual difference between the two bodies of pharmacy managers and store managers is that in one case the individuals have capital, or possibly friends or relations who will advance capital to help them into business for themselves, whereas in the other case the managers have not been born with the proverbial silver spoon, and find that by working for companies they will the sooner be able to gain the funds which should enable them to commence business for themselves. Companies carrying on business as chemists and druggists have been allowed to flourish for twenty-five years, the people of this country have had time to become educated to their presence, and chemists must put their own position straight before they could even ask for what is so dear to the hearts of so many—the suppression of company pharmacy. An endeavour should be made to get rid of that portion of Section 16 of the Pharmacy Act which refers to business being continued by executors. That clause seemed to be the base upon which all company pharmacy had been founded. Get that clause removed, and

there would be an improved position for the present, and certainly a much improved outlook for the benefit of any pharmaceutical enactment in the future.

The Government Companies Bill which passed the House of Lords during the last session of Parliament will no doubt be brought forward at an early date, but Clause 2 of that Bill did not seem to go far enough. It should compel registration of all managers under the Act and the registered name to be the only one used for the purpose of the business. The object to be aimed at should be the protection of pharmaceutical titles and of what is left to chemists under the Pharmacy Acts. A slight alteration in Clause 2 of the Companies Bill would probably be all that was necessary. The wording suggested for adoption was:—

“No company can carry on the business of a pharmaceutical chemist or chemist and druggist unless such business is *bonâ-fide* conducted by a manager being a duly registered pharmaceutical chemist or chemist and druggist, who shall be also registered under this Act, and unless the name of the person so qualified is conspicuously posted in the shop or other place in which the business is carried on and also used for trading purposes, but subject to this provision anything which would be an offence under Section 15 of the Pharmacy Act, 1868, if committed by an individual, shall be an offence if committed by a company.”

A qualified directorate would not suffice, as the directors could easily be obtained from the managers in the larger companies, the fees being a valuable addition to the salaries previously received, and rewards being thus created for long and faithful service, or for exceptional ability. There was no law which prevented the director of one company from being on the board of several other companies, and in that way the smaller companies, by uniting, could override the Act. The simple alteration suggested only required the omission of three words, but the effect would be to allow the chemists of this country to reserve to themselves the titles which have been conferred upon them after examination and years of patience and industry devoted to the cause of pharmacy, and in qualifying themselves to ensure the public safety. It was hopeless to expect the practice of pharmacy by limited companies to be put an end to, and the best way for the chemists of this generation to help those who shall come after will be, as it were, to entrench themselves, reserving all they have a reasonable chance of retaining and, remembering that although tea, tobacco, and alcohol have a place in the *materia medica*, they should have no place in retail pharmacy. They should also remember that “God helps those who help themselves.”

Referring next to the

PROPRIETARY ARTICLES TRADE ASSOCIATION,

Mr. Buck said he looked upon that organisation as a very valuable union of chemists formed with a view of accomplishing work and fulfilling certain duties in connection with their calling which did not fall within the programme of the Pharmaceutical Society, the Conference, or yet of the Federation. The duties were connected with the financial side of their work, and were very necessary in the interests of those who have a large part of their business made up of the sale of so-called “patent medicines,” as well as to others who have much demand for the proprietary liquids, salts, tablets, etc., which now form such an ever increasing feature in the prescriptions of the present-day physicians, as well as in the demands of those members of the general public who dose themselves and their friends. Chemists are all more or less interested in the supply of those articles, as also of the various foods and meat preparations which unfortunately cannot be disconnected from pharmacy. Evidently it was advisable that those goods should at least carry their proportion of working expenses, even if they did not leave anything over for the more necessary needs of a living wage.

With regard to

SECRET COMMISSIONS,

they had formed a topic of much interest during the last twelve months. On that abuse the Lord Chief Justice seemed to have been

the most active worker with a view to stopping the practice. In a speech before the London Chamber of Commerce the Lord Chief Justice was reported to have asked “if it were not intolerable and disgusting that a general practitioner should have an understanding with chemists and an arrangement with them to receive a share of their profits.” But chemists would be agreed that the profits were scarcely worth dividing, and during an experience of twenty-five years the speaker had never known a case in which a commission was asked for or expected.

The next matter touched upon was the

STAMPING OF PRESCRIPTIONS.

Some prescriptions when brought to be dispensed were found to be disfigured by having stamps placed all over the face of the prescription, and in some cases those are apt to interfere with the correct reading of the intentions of the prescriber. Doctors were scarcely likely to value those “decorations.” Some physicians had a note on their prescription paper asking dispensers to stamp on the back, and it would be an act of courtesy towards the medical profession if a few of the chemists of Liverpool were to work together to get that form of marking prescriptions generally adopted.

In conclusion, reference was made to the proceedings of the Association for the coming session, and it was suggested that there should be additional meetings of a less formal character than those now held, to talk over business matters.

At the close of the address, which was listened to with undoubted interest, a vote of thanks was proposed by Mr. BAIN, who facilitated the President on the choice of topics he had made and on the light and facile manner in which he had treated several undoubtedly controversial subjects. The motion was ably seconded by Mr. J. SMITH (local Secretary of the Pharmaceutical Society), who, whilst agreeing with the President on most points, emphatically protested against any other certificates of a man's ability as a dispenser being accepted or recognised, than those bestowed by the Pharmaceutical Society in Great Britain and those by the Irish Pharmaceutical Society in Ireland, even when the dispensing was done in a doctor's employ.

The vote was then put to the meeting, and passed with acclamation.

MIDLAND PHARMACEUTICAL ASSOCIATION.

A well-attended meeting of this Association was held on January 25 at Mason University College, Birmingham, the President, Mr. JEFFREY POOLE, in the chair. A paper was communicated by Messrs. J. Spilbury and T. G. Joyce on:—

BALSAM OF TOLU,

and a report of it appears at page 93.

In the discussion which followed, Mr. BRYANT inquired whether the authors had found benzoic acid in the carbon bisulphide, and whether they had determined the volatility of cinnamic acid, as in experiments conducted in accordance with the official requirements, some of the cinnamic acid would be lost owing to its volatility. Some authorities calculated the amount of acid obtained in terms of cinnamein, and one authority stated that it contained from 50 per cent. to 70 per cent. when thus calculated.

Mr. H. S. SHORTHOUSE put questions as to the origin of the samples shown and their age. He had found that no samples in recent times came up to the standard of a sample which he had had in his possession for twenty years. Samples varied so considerably as to suggest that their origin could not be the same plant. In one case which had come under his notice the bisulphide method yielded a non-crystalline product, but after standing a long time it became a mass of crystals, and possibly some of the resinous residues shown by the authors might have kept long enough, even in the crystalline form.

Mr. F. H. ALCOCK said the ordinary pharmacist would no doubt first apply the physical tests, to which no reference had been made in the paper. A test which was sometimes of great value was examination by taste and smell, warming a little in the test tube with water. He showed a sample recently obtained which, while it had a feeble odour of tolu, when warmed with water in the test tube emitted a decided terebinthinous odour, and when the aqueous solution was allowed to cool it scarcely yielded any crystals of cinnamic acid. The figures given by Squire seemed to show that the physical test might be applied in differentiating certain resins, seeing that they differed in gravity so much. Apparently the authors thought that the carbon bisulphide contained cinnamic acid, but he personally was of opinion that there might be other substances in addition which would affect the saponification equivalent and render that test of doubtful value.

Mr. SPILSBURY, summing up the discussion, gave it as his opinion that the percentage of benzoic acid in balsam of tolu was not more than from 1 to 1½, and it was a matter of great difficulty to separate benzoic and cinnamic acid for quantitative purposes. A question had been put with reference to the sources of the specimens, but being a natural product the plant would be affected to some extent by its environment, and they were largely in the hands of the collectors. His specimens were from two to three years old, and had been purchased from good houses and brokers. He was not able to say what the diluent was in the specimens that he had examined, and no author, so far as he could find, had fixed upon what it was. It would be a matter of great difficulty to differentiate by chemical tests the various resins that might be put in balsam of tolu, but there was no doubt that balsam was exhausted, and subsequently mixed with genuine material and put on the market again, and that in London.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The ordinary members of the C.A.A. were not present in great numbers at 73, Newman Street, W., on Thursday, January 25, when the President, Mr. F. W. GAMBLE, took the chair. Whether they had taken to heart the advice tendered at the previous meeting and had stayed away in order to study the laws which affect chemists, or were elsewhere discussing the latest war news, was not apparent, but they were evidently not very anxious to take part in the

Impromptu Discussion

which was down on the programme for that evening. However, most of the members of the Council were present, and discussed a few interesting points. The first dealt with

THE VEIL OF ANONYMITY

said to be covering the pharmaceutical Press, a question being put to Mr. C. J. STROTHER asking if he thought it advisable that it should be raised, and that "An Ordinary Pharmacist" and "Xrayser" should disclose their patronymics. He was of opinion that circumstances alter cases, and that although as a rule it was best for writers to append their names to articles, if the matter written was worth reading and they preferred to withhold it he saw no reason why they should reveal their identity.

The PRESIDENT said he had noticed in the *Pharmaceutical Journal* of the previous week an expression of opinion made by Mr. R. Lord Gifford that writers should say who they are. Personally, he did not think much of his arguments. There was a great deal to be said in favour of writing under an anonymer, because a good sound argument then stands at its own valuation, and is not influenced by the position or personality of the writer.

Mr. HYMANS was much of the same opinion. Writers were somewhat like artists; if they had already "made a name" the public would accept their work whatever its quality on the strength of that name, whereas the work of an unknown writer or artist had to stand on its merits.

The second query had reference to the war and the dispatch of Volunteers to South Africa. The questioner had evidently been asked by relatives of departing Volunteers to fit up small cases of medicine, and had left the choice of the most suitable remedies to him. Hence the query as to what would be the best six

REMEDIES FOR A SOUTH AFRICAN WARRIOR

to take to the front Mr. C. MORLEY, to whom the question was put, said he really did not know what to say, because pharmacists most religiously refrained from encroaching upon the domains of physicians, and therefore knew nothing about remedies. However, he had heard that the Boers were not very cleanly, so that perhaps a little potassium permanganate would be a good thing; such drugs as quinine, opium, and a good old-fashioned aperient might also be useful. Dover's powder, chlorodyne, antiseptic ointment, whisky, and a preparation of antipyrine or phenacetine for neuralgia were also recommended by other members. It was, of course, necessary that the drugs should be in the most portable form.

SPECIAL DISPENSING CHARGE FOR NIGHT CALLS.

Mr. T. MORLEY TAYLOR was asked to say whether a special dispensing charge should be made for night calls. He said it was a matter of opinion. His opinion was that in the case of regular customers it would be unwise to make an extra charge, but in the case of casual customers the chemist must use his discretion, although he would be quite justified in making a special charge.

Several members supported Mr. Taylor's view of the matter.

MR. GLYN-JONES AND COMPANY PHARMACY.

Mr. DEWHIRST said the question he was asked to answer was: "Is Mr. Glyn-Jones' company pharmacy proposal acceptable to chemists?" He must admit that he had not the slightest idea what that proposal was.

Mr. FOTHERGILL said he was not the writer of the question, but he thought that all present ought to know something about Mr. Glyn-Jones' proposal, and should be able to discuss it.

Mr. C. MORLEY confessed that he was in the same position as Mr. Dewhirst, and had not the most remote idea what the proposal in question was.

The PRESIDENT said it was possible to know a great deal about the company pharmacy problem and yet have difficulty in picking out any particular man's ideas. He believed that Mr. Glyn-Jones' proposal was to allow no limited company to carry on the business of a chemist and druggist unless the directors were qualified persons. It was rather amusing that they, as rising pharmacists, should have to confess to so little knowledge of a subject which was supposed to touch the trade to its very vitals, that they could not formulate the views of so prominent a man as Mr. Glyn-Jones.

Mr. JAMES said he had read so much upon the subject that it had become almost *ad nauseam*. He did not agree with a qualified directorate idea, because he thought it would be quite easy to get qualified persons to act in that position. Such directors could easily be turned off the board. He thought the state of apathy that had been shown that night was due to the fact that they did not think anything would come of the present agitation, and that pharmaceutical legislation is as far off as ever. He had recently had a conversation with a member of Parliament, who said he had received a letter from the president of the Pharmaceutical Society which put the case very clearly. "But," said he, "the House of Commons will never grant what you want. They sympathise with you, but look upon the question in a far broader light."

Mr. T. MORLEY TAYLOR thought the company pharmacy question had resolved itself into a waiting game. It was not a bit of use worrying about the matter; they must patiently wait and see what they can get. The whole subject had been so much overdone that he must confess it was only on rare occasions that he read anything about it.

Mr. DEWHIRST was of opinion that it was *infra dig.* for chemists to be backed up by legislation. The safety of the public was quite protected by the existence of qualified persons for dispensing. If chemists could not live by their trade they must simply go under.

IMPROVEMENT OF THE C.A.A.

Mr. HYMANS was asked to make some suggestions for the improvement of the C.A.A. He thought the question should have been: "Is some suggestion necessary?" then the answer would have been "No!" so far as management was concerned; what the C.A.A. lacked most was the support of its members.

Others present thought likewise, and Mr. DEWHIRST mentioned as an instance of the benefits derived from connection with the Association that he had recently received a letter from a friend in India, and in the letter he stated that, on the sole recommendation of having once been secretary of the C.A.A., he had obtained the secretaryship of a good club out there at a salary of about £50 per year, the work requiring the expenditure of but a few hours per week. He added at the end of the letter, "Good old C.A.A."

UNIVERSITY PROFESSORS AS EXAMINERS.

Mr. A. LATREILLE, in answer to a question as to whether university professors should be allowed to examine candidates for the Minor, said, personally he did not think that because a man has had a university training he should be debarred from examining candidates for either the Minor or Major. Candidates generally knew something about the subjects in which they were to be examined, and he thought that professors, whether they were from a university or not, should be quite justified in examining them.

Messrs. FOTHERGILL, HYMANS, MORLEY TAYLOR, and the PRESIDENT all expressed the opinion that although candidates for the Minor are only expected to have a good sound elementary knowledge of scientific subjects, specialists in those subjects were the persons best qualified to examine them, because they had a greater capacity for judging the capabilities of the candidates and, as Mr. Taylor put it, were far less likely to press particular little views of their own.

The terms offered by the military authorities to

ARMY COMPOUNDERS

was the next subject discussed, the general consensus of opinion being that while the chemists who had enlisted had only themselves to thank for rushing blindly for the berths without first finding out what was expected of them and the position they were to occupy in the ranks, there was not the slightest doubt that the War Office had made a mess of the whole business, and had practically insulted pharmacists by the terms offered.

DIVISION OF THE MINOR EXAMINATION.

The PRESIDENT was asked if he was in favour of a division of the Minor examination. He said he had not sufficient originality to advance arguments as to why he was in favour of a division of the Minor, but he thought no one present would object to it. A curriculum was, however, first necessary.

Mr. DEWHIRST said he objected most strongly, as he considered it would be a fatal mistake to make the examination easier, because it would enable persons of less capacity to join their ranks; what was wanted was to make it more difficult for them to get in. He also did not agree with a curriculum, as it was possible for a person to pass an examination without the knowledge acquired doing much good.

Mr. T. MORLEY TAYLOR thought it would not be possible to divide the Minor until they had a curriculum. Then the theoretical and scientific part could be taken first and the practical work later, thus enabling a candidate to do more credit to himself.

The PRESIDENT supported this view, and the meeting then adjourned.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.

At a meeting held in the Pharmaceutical Society's House, 36, York Place, Edinburgh, on Wednesday, January 24, Mr. FRASER McDIARMID, President, took the chair. The Pottage Herbarium prize, £2 2s. 0d., was presented by the Chairman to Mr. R. H. Martin, 21, Duke Street, who had sent in an extensive and beautifully mounted collection of plants, which were exhibited at the meeting. On the motion of Mr. HARLEY, Vice-President, seconded by Mr. SCLATER, Treasurer, a very cordial vote of thanks was awarded to Mr. Pottage.

Mr. D. B. KIDD had communicated a series of

Dispensing Notes,

which are printed at page 94. After they had been read,

Mr. HILL said that, assuming that the equations were correct, the last mixture seemed analogous to a case instanced by Professor Crum Brown, in which sulphuretted hydrogen, when passed through a solution of ferrous acetate acidified with acetic acid, gave no precipitate. On adding a solution of potassium acetate, even distinctly acid from free acetic acid, and then passing sulphuretted hydrogen, there was an immediate precipitation of ferrous sulphide. This was explained on a similar theory that the potassium ions diluted the acetic ions in the solution and rendered their acidic properties non-effective.

Mr. COWIE was inclined to think the precipitate was acetate of quinine. He had examined a similar precipitate in a mixture of quinine sulphate and liquor ferri acetatis, and the precipitate contained a considerable quantity of acetic acid. Acetate of quinine was very insoluble, insoluble in water about 1 in 600. It was almost as insoluble as the hydrate, which dissolved 1 in 650. The solubility of the precipitate in ether was not conclusive, because acetic acid was a weak acid, and the salt might be easily split up. The same happened with some strychnine salts.

Mr. HARLEY said the addition of glycerin to the nux vomica mixture might prevent the separation of the fatty or resinous matter. He had frequently observed in making the new tincture from fluid extract that it differed very much in clearness even when made, and sometimes on standing it became cloudy.

Mr. McBAIN said he had just dispensed a powder containing phenazone, caffeine citrate, and sodium bromide, and he observed that they became yellow, probably from a decomposition due to the citric acid, as in Mr. Kidd's case.

Mr. HILL then gave a practical demonstration on

Botany in January.

He said there were three ways in which they could study botany practically in Edinburgh at this season of the year. They might pay a visit to one of the many nursery gardens within the city, where they would see many things, and for a few pence could take home much useful material for practical study; they might visit the florists' shops, which almost always furnished at a moderate cost an ample variety of living plants; or they could do as he did, take a run out to one of the many spots in the near vicinity, like Colinton Dell, and have a look round. His excursion occupied only about two and a-half hours, and he returned with nearly forty plants, and could have easily had more in the time. Though the day was wet, and the Dell a veritable mud-puddle, he found the outing very interesting and enjoyable. The season had been unusually mild, and with a heavy rainfall. The consequence was that winter wheat was unusually advanced, and the fields were green with an abundance of new grass. There was a tendency to develop vegetable tissue highly charged with water, and the danger was that if sharp frosts came there would be much greater damage to vegetation than if the tissues had been drier and more compact.

On the motion of the PRESIDENT votes of thanks were awarded to Messrs. Kidd and Hill, and the meeting closed.

THE STUDENTS' COLUMNS.

THE MATERIA MEDICA OF THE PHARMACOPŒIA.

Amylum.

STARCH for pharmaceutical purposes must be procured from the grains or fruits of common wheat, *Triticum sativum*¹, Lam.; from maize or cornflour, *Zea mays*², Linn.; or from rice, *Oryza sativa*³, Linn., all three plants belonging to the N.O. Gramineæ. The cells containing the starch must be ruptured by crushing the grains, and the gluten and other soluble and insoluble matters can then be separated from the starch by adding water to form a dough, from which the starch grains can be washed by kneading the mass in a stream of water, the gluten, etc., being left behind. The gluten may also be removed from the crushed grains by dissolving it in dilute sodium hydroxide solution, or by allowing a mixture of crushed grains and water to undergo putrefactive decomposition, the gluten being destroyed in the latter process and acetic, lactic, and other acids formed. In any case the starch must subsequently be purified by washing repeatedly with cold water to remove any traces of cell debris, alkali, or acid. Starch possesses protective and absorbent properties, and is used to prepare glycerinum amyli and pulvis tragacanthæ compositus.

WHEAT STARCH (x 200).—After Tschirch and Oesterle.

CHARACTERS AND TESTS.—Purified starch is white and inodorous, and occurs either as a fine powder or in irregular angular or columnar masses which are readily reduced to powder. It is quite insoluble in cold water and leaves only a trace of ash when incinerated. Freedom from traces of acid or alkali, remaining as the result of imperfect washing during the process of purification, should be indicated by the colour of blue or red litmus paper remaining unaffected when immersed in cold water with which the starch has been lightly rubbed in a mortar. As a rule, however, starch is faintly alkaline. On boiling with water the starch grains are ruptured and a gelatinous mixture results; on cooling that and adding solution of iodine a deep blue addition compound of starch and iodine is formed.

MICROSCOPIC CHARACTERS.—The grains of wheat starch vary considerably in size, the larger usually measuring from 30μ to 38μ in diameter and the smaller from 6μ to 7μ , though both larger and smaller ones may be met with. The large granules show a central hilum surrounded by faint concentric striæ, and are either flattened or lens-shaped, appearing round or somewhat kidney-shaped when lying flat; when standing on edge they appear spindle-shaped. The hilum and striæ are less conspicuous in the smaller granules; those are round or oval, and occasionally two or

¹ *Triticum*, L., wheat, from *tritus*, beaten, and *tero*, to rub, bruise, or thrash; *sativus*, L., sown or cultivated.

² *Zea*, Gr., ζεία, a kind of grain; *mays*, a native American term for Indian corn.

³ *Oryza*, Gr., ὄρυζα, from the Arabic *êruz*, rice; *Sativa*, L., cultivated.

three may be found combined in a compound grain. Maize starch, the kind mostly used, consists of granules which are more uniform in size, measuring from 10μ to 25μ in diameter; they are round, or polygonal with rounded angles, and have a very distinct hilum, usually with one or more small clefts radiating from it,

MAIZE STARCH (x 200).—After Tschirch and Oesterle.

but there are no striæ. Rice starch consists of still smaller granules, also very uniform in size, measuring from 4μ to 6μ in diameter; they are polygonal, with sharp angles, being in reality the fragments of large oval compound grains, and are usually without evident hilum, cleft, or striæ.

RICE STARCH (x 200).—After Tschirch and Oesterle.

NOTES.—The distinctive characters of starch are its shape and markings when examined under the microscope, and the formation of the blue addition compound with iodine. Starch is a member of the cellulose group, its formula being a multiple of $C_6H_{10}O_5$. When air-dried it contains from 12 to 16 per cent. of moisture. It is present in all assimilating plants, being built up in the chlorophyll granules from the carbon dioxide absorbed. The granules are enveloped in an insoluble coating which probably consists of cellulose, and they contain granulose, the substance which forms a jelly when starch is heated with water. To examine the granules under the microscope they should be mounted in water; the addition of strong chloral hydrate or potassium hydroxide solution (near the edge of the cover glass) makes the hilum and striæ more plainly visible, but in either case the starch grains swell and gradually lose their distinctive shape, so that no time should be lost in examining them.

Anethi Fructus.

DILL FRUIT is the dried ripe fruit (cremocarp) of *Peucedanum graveolens*, Benth. and Hook. f. (N.O. Umbelliferæ), an annual herb indigenous to the Mediterranean districts and Southern Russia, but cultivated in England and certain parts of the Continent of

⁴ *Peucedanum*, Gr., πευκέδανος, an unknown umbelliferous plant; *graveolens*, L., heavy-smelling,

Europe. The fruits met with in commerce are usually of British, German, or Indian origin; preference should be given to the first two, which alone meet the official requirements. Dill fruits are stimulant, aromatic and carminative, and are used for preparing aqua anethi and oleum anethi.

ANETHI FRUCTUS.—A, British fruit (nat. size); A1, convex side of mericarp (magnified); A2, flat side of mericarp (magnified); B, Indian fruit (nat. size); B1, convex side of mericarp (magnified); B2, flat side of mericarp (magnified); C, transverse section through mericarp (magnified).

CHARACTERS.—The two smooth, brown, oval mericarps of which dill fruit consists are usually separate and freed from the pedicel (distinctions from Indian dill fruits), each one being about 4 Mm. long and 2 to 3 Mm. broad, having five equidistant filiform ridges, and being so strongly compressed dorsally as to be almost flat. In transverse section each mericarp exhibits six vittæ or elongated oil-glands, four on the dorsal and two on the commissural surface. Three of the ridges are prominent—though described in the B.P. as inconspicuous—at the back, and the other two are merged in the broad thin margin or wings. The agreeably aromatic odour and taste of the fruits are due to the volatile oil they contain.

ANETHI FRUCTUS.—Transverse section of mericarp. V, vitta; VB, vascular bundle; E, endocarp; End, endosperm. (x Abt. 60.) After Berg.

NOTES.—The distinctive characters of dill fruits are the very flat, usually separate, mericarps, with three dorsal ridges and two-winged lateral ones. They contain from 3 to 4 per cent. of volatile oil, nearly half of which consists of carvol. Indian dill, imported from Bombay, is more elliptical in form than British, more convex at the dorsal surface, and paler in colour; the mericarps of the fruits are frequently united and attached to the pedicels, they are also narrower and less prominently winged than those of the British fruits.

Anisi Fructus.

ANISE FRUIT is the dried ripe fruit of *Pimpinella anisum*⁵, Linn. (N.O. Umbelliferae), an annual plant indigenous to Greece, Egypt, and Asia Minor, but cultivated largely in Southern Russia, Germany, Spain, Italy, South America, etc. The different commercial varieties—Russian, German (Thüringian), Greek, Maltese, Spanish (Alicante), Italian, and Chilian—differ from each other in size, colour, flavour, and relative freedom from impurity. When fresh, the Russian and German fruits are greyish-green in colour, and the Levant and Spanish, both of which are larger than other varieties, are brownish-green and yellowish-green respectively, but the greenish tints tend to become grey with age. Chilian fruits are so mixed with foreign matter that their colour is not readily discernible, and their mericarps are usually separated more

⁵ *Pimpinella*, said to be derived from *bipennula*, twice pinnate; *anisum*, L., the classical name for the plant.

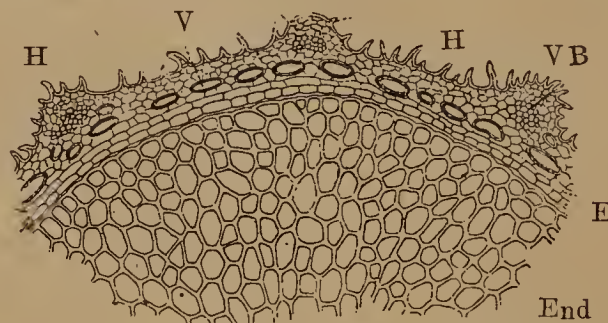

or less. The larger varieties alone are admitted by the official description. Anise fruits are stimulant, aromatic, and carminative; they are used for preparing aqua anisi and oleum anisi.

ANISI FRUCTUS.—A, Russian; B, Maltese (nat. size); C, magnified; D, do. longitudinal section.

ANISI FRUCTUS.—Transverse section (magnified). (x Abt. 50.) After Tschirch and Oesterle.

CHARACTERS.—The cremocarp is usually entire in the case of anise fruit, the mericarps remaining united and attached to the pedicel. The fruit is ovoid in form, greenish-brown or greyish-brown in colour, somewhat compressed laterally, and rough owing to the presence of numerous short cone-shaped bristly hairs; it measures about 5 Mm. in length and 2 Mm. broad. Each mericarp is marked by five pale, slender, and entire ridges, two of which are lateral. In transverse section each mericarp of anise fruit exhibits from thirty to forty vittæ, the largest occurring in the commissure. The agreeably aromatic odour of the fruit and its aromatic sweet taste are due to the volatile oil.

ANISI FRUCTUS.—Transverse section of mericarp. V, vitta; VB, vascular bundle; E, endocarp; End, endosperm. (x Abt. 50.) After Tschirch and Oesterle.

NOTES.—The distinctive characters of anise fruits are the short, stout, bristly hairs, the entire fruits, the characteristic odour and taste, the absence of any deep groove in the endosperm and of prominent crenations on the somewhat inconspicuous primary ridges. In hemlock fruit, which has been found mixed with German and Italian anise, the ridges exhibit prominent crenations; there are no hairs or vittæ, and the endosperm exhibits a deep groove on its commissural surface. Hemlock fruit is also virtually devoid of odour or taste, though on crushing it and adding some potassium hydroxide solution, a strong mouse-like odour is developed. Anise fruits yield about 2 per cent. of volatile oil, consisting almost entirely of anethol.

Obituary.

ELLIS.—On January 21, Ernest Frederick Ellis, Chemist and Druggist, Topsham, Devon. Aged 32. Mr. Ellis was the only son of Mr. Frederick Ellis, M.P.S., and was in business with his father. He was greatly respected in the district, and much sympathy is felt for the parents in their bereavement.

A REVIEW OF CURRENT WORK.

EXTRACTION OF RICININE.

T. Evans, in a preliminary communication upon ricinine, states that he has found it advantageous to modify Tuson's method of extracting (*Journ. Chem. Soc.*, **17**, 195) that substance from the seeds of *Ricinus communis*, by using boiling toluene instead of alcohol to extract the residue from the evaporation of the aqueous extract. Upon sudden cooling of the toluene solution, ricinine deposits on the sides and bottom of the containing vessel, in small, almost colourless prismatic crystals; those are frequently crossed and sometimes whetstone-shaped, and adhere closely to the vessel. On purification by recrystallisation from alcohol, from which it was deposited in small plates frequently united to form rosettes, the ricinine was found to have a melting point of 193° C., and analysis gave results which agreed very well with Schulze's figures, $C_{12}H_{13}N_3O_{31}$, though that formula does not suit the bromine derivative as well as others suggested. The bromine derivative of ricinine was obtained in long, colourless crystals, the melting point of which was 230°-232° C., and indications were afforded of the probability that ricinine is an acid amide or perhaps a diureide. Ricinine dibromide is soluble in about 200 parts of 93 per cent. alcohol, and in practically the same amount of water. It crystallises in long needles from dilute solutions, and in short, silky, white needles from more concentrated solutions. The aqueous solution appears to be neutral. The compound is also soluble in hot, dilute or concentrated, hydrochloric acid, but separates out unchanged on cooling. Upon treating an alkaline solution of ricinine with potassium permanganate, and subsequently acidifying with hydrochloric acid, white silky crystals were obtained which melted at 279°-280° C., becoming black several degrees below the melting point. An aqueous solution of the oxidation product was acid to litmus paper, and crystalline salts were formed on adding alkalis or silver nitrate. The acid was found to contain nitrogen and, on evaporation with nitric acid and moistening with ammonia, gave the reddish purple colour characteristic of ricinine, but in a lesser degree.—*Journ. Am. Chem. Soc.*, **22**, 39.

PHARMACY OF HEROINE.

The following formulæ are given in *Nouveaux Remèdes*, **16**, 3, for the various preparations of heroine:—*Cough Drops*.—Heroine hydrochloride, 10 centigrammes; bitter almond water, 20 Gms. Dissolve, 15 to 20 drops to be taken in sweetened water. *Cough Pills*.—Heroine hydrochloride, 15 centigrammes; excipient *q.s.* Mass and divide into 30 pills. One pill to be taken three or four times daily. *Sedative Syrup*.—Heroine hydrochloride, 15 centigrammes; simple syrup, 100 Gms. A teaspoonful at bedtime. *Sleeping Powder*.—Trional, 1 Gm.; heroine, 5 milligrammes. To be taken at bedtime in a cup of warm milk. *Sleeping Draught*.—Heroine, 2 centigrammes; alcohol, *q.s.* to dissolve; syrup of tolu, 100 Gms. One half to be taken at bedtime, and the dose repeated, if required, during the night. *Heroine Mixture*.—Heroine, 5 centigrammes; alcohol (90 per cent.), *q.s.* to dissolve; syrup of orange flowers, syrup of tolu, glycerin, of each 50 Gms. Dose one tablespoonful. *Heroine Pills for Constipation*.—Heroine, 5 milligrammes; marsh mallow powder, 3 centigrammes; extract of rhubarb, 3 centigrammes. For one pill. *Heroine Cachets*.—Heroine, 5 milligrammes; powdered sugar, 25 centigrammes; magnesia, 10 centigrammes. For one cachet.

VOL. 64. (FOURTH SERIES, VOL. 10.) No. 1544.

DEPILATION BY RÖNTGEN RAYS.

Dr. Neville Wood records a case in which a considerable overgrowth of hair on a woman's face was removed by applying Röntgen rays. There were six sittings per week, of ten minutes each, the face and neck being protected with a lead-foil mask, except where the rays were intended to act. The distance between the anticathode and the skin was between six and seven inches. The current through the primary coil was maintained at about five amperes, and the number of interruptions varied between two hundred and fifty and three hundred per second. After fourteen exposures it was noticed that the darker hairs had lost some of their lustre, and a week later there was an obvious lessening in their number. The shed hairs were brittle and pale in colour, with atrophic bulbs, while microscopically the normal striation was indistinct, and the medullary substance appeared to be collected into separate nodes with clear intervening spaces. During this period occasional slight reddening of the skin was noticed. After forty-five exposures the whole of a very thick downy and hairy growth had disappeared, except nine hairs which remained at least a week after the total removal of the others. They were found, however, to be really separated at the bulbs, being retained in position by a more superficial part of the root-sheath. Only a few thick hairs had returned within three months of cessation of treatment, and those it is proposed to remove by electrolysis. In conclusion, Dr. Wood states that the treatment neither pains nor disfigures, and expresses the opinion that ten short exposures will be found useless, that about twenty will clear the ground for electrolysis or simple traction, if for any reason the ray treatment has to be suspended, and that between thirty and forty exposures will probably result in permanent alopecia.—*Lancet* No. 3987, 231.

FIXED OIL OF TROPÆOLUM.

In the course of the preparation of the volatile oil of *Tropæolum majus*, J. Gadamer has isolated, by extraction with ether, a fatty oil which solidifies on the evaporation of the solvent, but readily melts again with the warmth of the hand. This property is due to the presence of tri-erucin, which melts at 30°·5 C. By treatment with potassium nitrite and nitric acid, erucin is transformed into tri-brassicidin, which, when crystallised from alcohol, melts at 54°·55 C. On saponification of this body erucic and brassidic acids are obtained, which are isomers. It is noteworthy that although tri-erucin so readily crystallises from tropæolum oil, it does not separate, at ordinary temperatures, from the fixed oils of white or black mustard, or from that of colza, in which it is present in equally large quantities.—*Archiv*, **237**, 471.

VOLUMETRIC DETERMINATION OF MAGNESIA.

J. O. Handy determines magnesia volumetrically by adding strong solution of ammonia equivalent in bulk to one-tenth of the solution, cooling to 20°-25° C., then precipitating with saturated sodium ammonium phosphate solution. When the reaction is complete the precipitate is collected, washed, and dried in an air oven, at a temperature of 50°-60° C.; it is then dissolved in excess of decinormal sulphuric acid and, after the addition of two drops of alcoholic solution of methyl orange (0·1 per cent.), the solution is titrated with decinormal sodium hydroxide. The method is said to be both simple and accurate.—*Journ. Am. Chem. Soc.*, **22**, 31.

PIGMENTS OF AMANTIA MUSCARIA.

A. B. Griffiths reports on the presence of a green amorphous colouring matter in *Amantia muscaria*, which has the composition $C_{29}H_{20}O_{10}$, and affords characteristic spectroscopic absorption bands. It is extracted with chloroform-ether, and purified after the evaporation of the solvent, by several successive solutions in chloroform. The red pigment, in the same fungus, has the composition $C_{19}H_{15}O_6$.—*Compt. rend.*, **130**, 42.

NOTES RELATING TO THE SOLANACEOUS BASES.¹

BY DR. O. HESSE.

In a previous communication to Liebig's *Annalen*² I gave an account of the results of my investigation of these bases, and they now require to be supplemented in regard to several details.

ATROPINE.—The observation recorded in my previous paper that this base has a feeble optical activity was in accord with the experience of Ladenburg³, E. Schmidt⁴, Will, and Bredig⁵ and others. At the same time Ladenburg considered atropine to be really inactive, though he was unable to prepare the base in such a condition that it had no action upon polarised light. Subsequently Ladenburg obtained atropine⁶, in two instances, that was perfectly inactive; but since the influence of the solvent used may have some effect in that respect, the question still remains whether the base examined in those instances was really inactive. The same remark applies also to the statement made by Bender⁷.

I have already observed that atropine sulphate has a rather strong action upon polarised light, and a similar behaviour may be assumed in the case of other neutral salts of atropine, for instance, the hydrobromide.

I was, therefore, surprised, in examining the roots of *Scopolia atropoides*, at obtaining atropine which, in the state of well crystallised hydrobromide, polarised very slightly, and after two recrystallisations of the salt from absolute alcohol it became perfectly inactive.

The base separated from that salt crystallised from ether in long needles of silky lustre, melting in Roth's apparatus at 115°·5—116° C. With $p=5$ and $t=15^\circ$ C. in absolute alcohol a 220 Mm. column did not show the slightest deviation of polarised light, nor did a water solution containing two molecules of oxalic acid. Analysis of this base gave results agreeing with the formula $C_{17}H_{23}NO_3$.

The *hydrobromide* crystallised from alcohol in fine colourless brilliant needles containing no water of crystallisation; it melted at 162° C., and with $p=6$ and $t=15^\circ$ C. in water solution the salt had no action upon polarised light. Analytical results were in accordance with the formula $C_{17}H_{23}NO_3 \cdot HBr$.

The *hydrochloride* was prepared by treating the water solution of the last-named salt with silver chloride; it crystallised from the concentrated solution in long colourless needles, was anhydrous, optically inactive, and melted at 165° C.

The *gold salt*, prepared by precipitation from a warm water solution with gold chloride, was a yellow flocculent precipitate; it crystallised from a hot water solution, after becoming slightly turbid, in small yellow laminae, melting at 136° C. After repeated recrystallisation the melting point remained constant. Analysis gave 31·34 per cent. gold, against 31·31 per cent., calculated according to the formula $C_{17}H_{23}NO_3 \cdot AuCl_4H$.

The *neutral oxalate* $(C_{17}H_{23}NO_3)_2 \cdot C_2O_4H_2$ was prepared by saturating an alcoholic solution of the base with oxalic acid; the salt crystallised from the concentrated solution in white prisms, melting at 190°—191° C.; it was very readily soluble in water, and the solution was optically inactive.

The data above stated were recorded in a paper read at the meeting of the Wurtemberg branch of the German Chemists' Association at Stuttgart in March, 1896, and an abstract of them was published in the *Zeitschrift für angewandte Chemie* the same year. Some time after that Gadamer published a paper on atropine, in which he stated that absolutely pure atropine is inactive, and that the optical activity hitherto observed in commercial atropine was due to the

presence of a certain amount of hyoscyamine. However, Gadamer⁸, did not state that any attempt had been made by him to ascertain the presence of hyoscyamine in the samples of atropine referred to. Moreover, the yield of really inactive atropine obtained was very small; so that the question arose whether it might not have been merely an admixture forming part of the atropine examined. I have therefore made a further examination of several samples of commercial atropine having special reference to these two points.

The atropine hydrobromide of E. Merck, already mentioned by Ladenburg⁹, was taken first. It was a white crystalline powder, but the crystal form could not be recognised. At 100° C. it lost 0·75 per cent. water, and melted at 159° C.: with $p=6$ and $t=15^\circ$ C. in water solution $[\alpha]_D = -7^\circ 88$. After repeated recrystallisation from absolute alcohol the salt was obtained in delicate concentrically grouped needles without any essential alteration of the optical activity, for after three recrystallisations it was $[\alpha]_D = -7^\circ 60$.

The hydrobromide was then converted into hydrochloride by treatment with silver chloride, and that salt was fractionally precipitated with gold chloride. The first fraction of gold salt melted at 142° C., and after three times recrystallising from hot water it gave a pure hyoscyamine gold salt melting at 158° C. From the last fractions of gold salt atropine could be obtained, but it was not quite inactive.

Operating upon a commercial sample of atropine purissimum melting at 114°—115° C., giving with $p=6$ and $t=15^\circ$ C. in absolute alcohol solution $[\alpha]_D = -6^\circ 44$, the results obtained were no better. After this base had been kept for two years the optical activity was sensibly reduced to $[\alpha]_D = -2^\circ 38$.

A portion of this base had been converted into gold salt, which melted at 142° C., but after two years the melting point of the gold salt was 148° C., and by once recrystallising from hot water a gold salt was obtained in yellow laminae, which melted at 156°—158° C., and was for the most part hyoscyamine salt. The quantity thus obtained was almost equal to that operated upon, and consequently it may be inferred that the atropine originally present in this sample had been almost completely converted into hyoscyamine. Such a conversion may be assumed to take place only in consequence of the presence of some hyoscyamine originally, for a gold salt of perfectly inactive atropine, free from hyoscyamine, was not found to present any alteration of the melting point when recrystallised from hot water, even after having been kept for two years.

Two other samples of atropine sulphate A and B, bearing on the label "Ph.G. III.," were also examined. A contained 4·24 per cent. crystal water, and in alcohol solution, with $p=4$ (anhydrous) $t=15^\circ$ C. $[\alpha]_D = -1^\circ 25$ C.; in water solution $[\alpha]_D = -1^\circ 07$. The base separated from this salt crystallised in white silky needles, melting at 115°—115°·5 C., and in alcohol solution with $p=5\cdot956$ gave $[\alpha]_D = -1^\circ 25$. After evaporating off the alcohol and dissolving the residue with water and two molecules oxalic acid, it gave $[\alpha]_D = -4^\circ 66$. The presence of hyoscyamine in this sample could not be ascertained with certainty by means of fractional precipitation with gold chloride. After being kept for two years this sulphate gave the same rotatory action; but a portion of the base which had been separated two years previously gave, in alcohol solution and in oxalic water solution, not the slightest deviation of polarised light, having within that time become perfectly inactive.

The sample of sulphate B was anhydrous; with $p=4$ and $t=15^\circ$ C. it gave $[\alpha]_D = -10^\circ 8$ and the base separated from it melted at 114°—115° C. The warm water solution was fractionally precipitated with gold chloride, and on cooling the first deposit of small dull laminae melted at about 148° C. After due recrystallisation from hot water, brilliant gold coloured laminae were obtained, melting at 158°—159° C., which agreed in all respects with the gold salt of hyoscyamine. By further fractionating, precipitates were obtained

⁹ *Berichte*, 21, 3067.

which melted as low as 137° C., and were mixtures of the gold salts of hyoscyamine and atropine in which the relative proportion of atropine was larger, the later, the precipitate was thrown down:

From these results it is evident that even the atropine sulphate of the German Pharmacopœia is not absolutely inactive, but contains more or less hyoscyamine corresponding to its power of rotation. The following conclusions may also be drawn:—

1. That absolutely pure atropine is optically inactive.
2. That commercial atropine in a free state, if originally capable of slight polarisation, may become, when long kept, optically inactive, and in any case suffer diminution of rotatory power.
3. That the optical activity of commercial atropine is due to the presence of some hyoscyamine.
4. That commercial atropine sulphate does not suffer alteration of its rotatory power when kept.
5. That owing to the presence of hyoscyamine in a gold salt of atropine, this base is more or less converted back again into hyoscyamine when the salt is kept.

HYOSCYAMINE.—The base and its sulphate previously used in my examination were obtained from Trommsdorff and described as being absolutely pure, as was found to be the case.

Though hyoscyamine sulphate when kept for several years does not undergo any alteration in rotatory power, the free base does show signs of alteration after two years, amounting to nearly 2°, so that to that extent the value of $[\alpha]_D$ in alcoholic solution will be less than before.

The hyoscyamine sulphate examined by me had a somewhat higher rotatory power than the sample prepared by Gadamer from material in the Pharmaceutical Museum at Marburg, and from that circumstance the inference may be drawn that the free alkaloid had already undergone some alteration. That inference is supported by Gadamer's observation¹⁰ with the corresponding oxalate, which should rather have polarised more strongly than the sulphate if the hyoscyamine had not been a mixture. In view of that probability I do not think it is necessary to refer more in detail to Gadamer's remarks as to the quality of my hyoscyamine.

The rotatory power of pure hyoscyamine sulphate with $p = 4$ and $t = 15^\circ$ was found to be $-28^\circ.2$: with $p = 2$ it was $-28^\circ.6$, and from those data the amount of hyoscyamine sulphate in the above-mentioned atropine sulphate (Ph. G. III.) can be calculated as follows:—

Sample A	=	$\frac{1^\circ.07 \ 100}{28^\circ.2}$	=	3.8 per cent.
Sample B	=	$\frac{10^\circ.8 \ 100}{28^\circ.2}$	=	38.3 per cent.

From these results the difference that is experienced by oculists as to the action of "atropine sulphate" will be sufficiently intelligible.

HYOSCINE.—My former investigation of this base has demonstrated that its composition is not that assigned to it by Ladenburg,¹¹ when it was discovered by him, viz., $C_{17}H_{23}NO_3$, but $C_{12}H_{21}NO_4$. Since then I have shown¹² that the base is amorphous and not the same as the crystalline scopolamine of E. Schmidt,¹³ which he obtained from Bender, and is said to constitute the chief part of commercial hyoscyamine.

I find that hyoscyamine exists, together with hyoscyamine and small quantities of atropine, in henbane as well as in *Datura alba* especially in the flowers of the latter plant; also together with considerable proportions of hyoscyamine, some atropine and atrosine in the roots of *Scopol a atropoides*.

When hyoscyamine is separated from its salts by a water solution of potassium mono- or bicarbonate and shaken out with chloroform it is obtained without alteration. Instead of the potassium salts above named the corresponding sodium salts may be used and the behaviour of hyoscyamine in that respect is mentioned in reference to the following base.

ATROSCINE.—The base to which I have given this name was first obtained by me from commercial scopolamine hydrobromide,¹⁴ then from the roots of *Scopol a atropoides*, the material from which the above-mentioned salt is generally prepared.

In preparing this base the roots are finely divided, moistened with a solution of potassium carbonate, and then exhausted with ether under a reflux condenser. The ether liquor is then shaken out with dilute hydrochloric acid, the acid liquor separated and supersaturated with potassium carbonate and then shaken out with chloroform. This chloroform solution is distilled and the residue recrystallised from ether. Hyoscyamine then separates, for the most part in a crystalline state, while hyoscyamine and atrosine remain in solution in the mother liquor, which is drawn off and neutralised with hydrobromic acid, the solution then treated with animal charcoal, gradually evaporated to a small bulk, and left to crystallise in a cold place. The crystals are washed with strong alcohol and again recrystallised from water at a low temperature repeatedly, until no more hyoscyamine remains in the mother liquor. The hydrobromide, thus partially purified, is to be dissolved in water, the solution mixed with excess of potassium monocarbonate, and the base shaken out into chloroform. The residue left on distilling off the chloroform is run out into a shallow dish, and, after complete removal of the chloroform, mixed with enough warm water to dissolve it. This solution, when exposed to a very low temperature, soon begins to deposit crystals of atrosine, which can be rendered pure by once recrystallising from water. Hyoscyamine then remains in the mother liquid.

Atrosine may be prepared in the same way from the commercial scopolamine hydrobromide.

Thus obtained, atrosine contains water of crystallisation, part of which can be separated in the exsiccator, and the remainder between 50° and 60° C. The base forms two hydrates—a monohydrate and a dihydrate.

Mono-hydrate, obtained from hydrobromide $C_{17}H_{21}NO_4 \cdot HBr + H_2O$, as above described, has the form of large crystals of glassy lustre, melting at 56°—57° C. in Roth's apparatus.

The *dihydrate* is prepared in the same manner, except that the highly concentrated solution is to be exposed to a temperature of one or two degrees below the freezing point until crystallisation takes place, and then kept a little higher until it is completed. In one instance a few crystals of monohydrate were first formed, but they soon changed into the dihydrate. The salt melts at 36°—37° C.

Anhydrous atrosine is readily obtainable in crystals when the monohydrate is exposed in a shallow dish to a temperature of 54°—55° C. While losing water the crystals of monohydrate swell up and sometimes a portion melts, but it soon changes into a mass of colourless glassy prisms. The dihydrate is less suited for the preparation of the anhydrous base, since it melts far below the temperature at which the molecular change takes place; but if the dehydrated base is exposed for some length of time to a temperature of 54°—55° C. it swells up and becomes crystalline.

The crystallised anhydrous atrosine melts at 82°—83° C., so that the difference between the melting point of the monohydrate and the dihydrate corresponds exactly with the difference in the percentage of crystal water.

Atrosine, $C_{17}H_{21}NO_4$, dissolves in 38 parts of water at 18° C., very readily in ether, chloroform, acetone, benzene or alcohol. The alcohol solution as well as the water solution has a strong alkaline reaction, and both of them are quite optically inactive.

¹¹ *Annalen*, 206, 299.

¹² *Ibid.*, 303, 159.

¹³ *Archiv d. Pharm.*, 230, 689.

¹⁴ *Apotheker Zeitung*, 10, 187.

The composition of atrosine hydrochloride is represented by the formula $C_{17}H_{21}NO_4 \cdot HCl$, the gold salt by the formula $C_{17}H_{21}NO_4 \cdot AuCl_4H$: the hydriodide and hydrobromide contain one molecule of water.¹⁵ The gold salt melts at 201° - 202° in Roth's apparatus without first frothing, and only when the temperature rises one or two degrees above that point or the heating is longer continued does frothing occur.

The gold salt is obtainable from a water solution, slightly acidulated with hydrochloric acid, in extended laminae and from a pure water solution in granular crystals which dissolve at 50° C. in 690 parts of water, containing in the litre 10 C.c. of hydrochloric acid (1.19 sp. gr.). The gold salt of atrosine is therefore the most sparingly soluble in slightly acidulated water of any solanaceous bases having a mydriatic action.

The hydrobromide obtained by neutralising an alcoholic or water solution of the base crystallises according to the prevailing conditions in different forms and of a different composition. When the water solution of the salt is evaporated low down, large rhombic tables are sometimes formed, $2C_{17}H_{21}NO_4 \cdot HBr + H_2O$. On recrystallisation, this salt, or the dehydrated salt from alcohol (97 per cent.), warty aggregates, consisting of short prisms, are formed, together with granular shiny crystals, which become dull at 100° C., both of which have the same composition.

When a solution of hydrobromide in two parts of water is exposed to a freezing temperature, the salt crystallises in colourless needles that are often several centimetres long, and when it is dried have the composition represented by the formula $C_{17}H_{21}NO_4 \cdot HBr + 3H_2O$. To prevent this salt from efflorescence it must be dried at a low temperature.

When the salt is dissolved in four parts of water fine large glassy rhombic crystals are often formed at a low temperature after some hours or days, but they lose all their water when broken up and exposed in the exsiccator. The measurement of these crystals by Professor Groth and his assistant, Herr Zirngiebl,¹⁶ showed that they were crystallographically identical with Ladenburg's hyoscyne hydrobromide.

In the anhydrous condition atrosine hydrobromide melts at 181° C. and in alcoholic or water solution it has no optical activity.

For the splitting up of atrosine dilute caustic potash was used, warming for a short time on the sand bath. The final products were found to be oscine and atropic acid, the formation of which is preceded by that of tropic acid, which is resolved under the influence of caustic potash into water and atropic acid—

In connection with the foregoing details some remarks are to be made bearing on the history of atrosine and its occurrence in various commercial articles.

In the first place mention must be made of the circumstance that E. Schmidt was of opinion that he had found hyoscyne together with hyoscyamine in the roots of *Scopolia atropoides*.¹⁷ For the last ten years these roots have been used as a source of atropine into which the hyoscyamine is readily convertible, and in the working of this material a bye-product was obtained which has been brought into commerce partly under the designation of "hyoscyne," partly also as scopolamine. It differs from true hyoscyne however in its low rotatory power. Unaware of that fact E. Schmidt contended that Merck's hyoscyne hydrobromide consisted essentially of scopolamine salt,¹⁸ although the results of my investigation showed that the salt in question was nothing else than true hyoscyne hydrobromide.¹⁹

In a later communication E. Schmidt made a distinction between this scopolamine hyoscyne, the hydrobromide of which he

described as "ordinary scopolamine hydrobromide," and the i-scopolamine, which was slightly levorotatory, and the hydrobromide of which was said to be nearly inactive optically.²⁰

My investigation of that "ordinary scopolamine hydrobromide," and also of the hyoscyne hydrobromide obtained from *scopola*, which are in fact the same thing, showed that this salt is really a mixture of true hyoscyne salt with the hydrobromide of a base to which I gave the name of atrosine, and that to the presence of this salt was attributable the difference in optical behaviour shown by this salt as compared with that of true hyoscyne hydrobromide. Still later the i-scopolamine prepared by E. Schmidt from "ordinary scopolamine hydrobromide" was ascertained to be nothing else than impure atrosine.²¹ This base is optically inactive, as was long since stated by me, and since acknowledged by E. Schmidt,²² both in a free state as well as in combination with hydrobromic acid. So much could not be said in regard to i-scopolamine at first, because E. Schmidt stated that it was slightly levorotatory, and that character appeared to be essential to i-scopolamine, since E. Schmidt expressly stated that on dissolving this slightly levorotatory scopolamine in alcohol, to which a minute quantity of caustic potash had been added, a further reduction of its rotatory power was not effected, even after long standing.²³ Since atrosine had then always been obtained with two molecules of crystal water, while i-scopolamine was described as containing only one molecule, I was of opinion that the difference was merely owing to the impurity of Schmidt's preparation, which was in the first instance evident. But, meanwhile, when E. Schmidt succeeded in obtaining his i-scopolamine in a state of purity the base still had the same melting point and the same amount of crystal water as the previous preparation. Although that circumstance was suggestive of the probability that atrosine and pure i-scopolamine must be one and the same base, with a different proportion of crystal water in the two cases, that still remained to be proved. Now, however, the proof has been furnished, since I have converted the dihydrate into the salt $C_{17}H_{21}NO_4 \cdot HBr + 3H_2O$, and from that have prepared the monohydrate as above described almost in quantitative proportions, while Gadamer has also under other conditions succeeded in converting the dihydrate into the monohydrate.²⁴

Quite recently the publication of Luboldt's investigation of scopolamine²⁵ has shown that he finds crystallised scopolamine has a composition represented by the formula $C_{17}H_{20}NO_4 + H_2O$, and that its melting point is 56° C.: he does not give the optical behaviour of this crystalline base; but he has made a supplementary observation of scopolamine hydrobromide supplied by his firm (Gehe and Co.), and found that it gives for $[\alpha]_D = -14^\circ 58'$, while the base separated from that salt by potash gave for $[\alpha]_D = -4^\circ 30'$ in a water solution and in an alcoholic solution $[\alpha]_D = -1^\circ 37'$. E. Schmidt prepared from that base the hydrobromide, and found, to his astonishment, that it gave for $[\alpha]_D = -50'$. If both chemists had also ascertained what, in both instances, remained in the mother liquor, the circumstance which excited their astonishment would have been cleared up; but instead of that, E. Schmidt makes the assertion that the rotatory power of scopolamine has experienced very considerable reduction under the influence of potassium carbonate.²⁶

As I have already stated, hyoscyne or normal scopolamine, as E. Schmidt now pleases to call the base in question, does not undergo any reduction of its rotatory power when it is separated from the hydrobromide by means of potassium carbonate. That is also the

case with the commercial scopolamine hydrobromide. A sample of it gave with $p = 4$ (anhydrous) and $t = 15^\circ \text{C}$. $[\alpha]_D = -7^\circ 5$. The anhydrous salt (4.405 Gm.) treated with potash solution and shaken out into chloroform yielded 2.813 atrosine $\text{C}_{17}\text{H}_{21}\text{NO}_4 + 2\text{HO}$, while the calculated quantity was 2.811 Gm. Since atrosine is not quite insoluble in the mother liquor, containing hyoscyne, the results obtained in other experiments of the same kind would probably be somewhat less than calculation indicated. The same result was observed when freshly precipitated silver oxide was used for separating the base from the hydrobromide, or when, as E. Schmidt directs,²⁷ a minute quantity of caustic soda was added to the solution, though, according to the statements of E. Schmidt, the quantity of atrosine might have been expected to be larger than calculation would indicate. In all these experiments the separation of the atrosine present was effected, but there was no indication of a conversion of hyoscyne into atrosine.

The amount of atrosine hydrobromide in the commercial scopolamine salt was found in one instance to be 15 per cent., in other instances it was from 44.8 to 83.7 per cent. The first sample had probably been obtained chiefly from *hyoscyamus*, the hydrobromide obtainable from that material being, as was formerly the custom, mixed with that obtained from *scopolia*. The other samples were undoubtedly derived from *scopolia*, and one of them was described as "hyoscyne hydrobromide." That came from Schering's factory, and it is on that account of special interest as being identical with the hyoscyne hydrobromide that E. Schmidt obtained from Bender.²⁸ It contained a considerable amount of atrosine salt and readily allowed of the preparation of "crystalline hyoscyne," which when crystallised from water proved to be perfectly pure atrosine. Hence it follows that the crystalline base which E. Schmidt found in Bender's crystallised hyoscyne, and was supposed to be really crystalline hyoscyne, was not what was supposed, but atrosine, though it was not quite pure, since its gold salt frothed in melting.

I was interested to ascertain some further information concerning the crystallised scopolamine obtained by Luboldt from Gehe's material, the identity of which with E. Schmidt's scopolamine is not disputed by him, but is fully admitted. Through a friend I obtained a sample of it described as "pure scopolamine" in an original package. It was in the form of colourless crystals, the size of a pea, melting in Roth's apparatus at 56°C ., and when rapidly heated in a sulphuric acid bath at 58°C . Analysis gave results agreeing with the formula $\text{C}_{17}\text{H}_{21}\text{NO}_4 + \text{H}_2\text{O}$. When heated for some hours to 54° — 55°C . in an air bath, it was converted into anhydrous crystals, which then melted at 82° — 83°C ., and required for solution 37 parts of water at 18°C . A 220 C.c. column of this solution caused no deviation of polarised light. A gold salt prepared with this base had all the characters of the atrosine gold salt, melting at 201° — 202°C . without frothing. This base was therefore nothing else than atrosine.

From all these details it follows that the crystals obtainable from commercial scopolamine hydrobromide, or from the hyoscyne hydrobromide prepared from *scopolia* are really atrosine, and further that the crystallised scopolamine, either with or without the prefix i, normal or not normal, are in the pure state atrosine. The natural occurrence of that base extends apparently only to the different kinds of *scopolia*, and the designation scopolamine chosen for it by E. Schmidt would be an appropriate one. But Schmidt in his first investigation of the subject confused this base with the hyoscyne of Merck and Ladenburg,²⁹ and since then the confusion of two different things has continued, extending even to the German Pharmacopœia Commission, with corresponding disadvantages to

German apothecaries, who are compelled to use labels accordingly. But since the commercial scopolamine hydrobromide—now official—is, according to my previous observations, a mixed substance, an end should be put to the mystification that has prevailed. In the place of this mixture the pure hydrobromides of the two bases should be substituted, since their preparation does not involve any particular difficulty.

While under the name of scopolamine two entirely different bases have been understood, the designation atrosine is applicable to only one, and on that account I recommend the adoption of this name. That name closely resembles the one chosen by Ladenburg for the isomeric base obtainable from hyoscyamine, and both of those names correspond to that of the pair of bases hyoscyamine-atropine, as shown below:—

Just as atropine differs from hyoscyamine in its action upon the eye, so does atrosine differ from hyoscyne, and thus the better action of scopolamine, as compared with hyoscyne, is explicable as being due to the atrosine it contains.

THE MEDICINAL PLANTS OF THE CLYDESDALE FLORA.*

BY W. BOWIE.

John Ruskin, the great art critic who has just passed away, never was wider of the mark than when he said that Glasgow has now no nature left within thirty miles of it. In fact, the very opposite is the case, for no city in the world is surrounded by a country district so rich in the beauty and variety of nature. Turn where we please, we have evidence of the fact. The river Clyde, a few miles up, flows sweeping on through woods of stately trees 'tween banks which on a summer's day are decked with flowers of blue and gold. On the one side of the great basin on which our town is built we have the Cathkin Hills replete with interest for the student of natural science, and furnishing vantage ground from which the lover of beautiful scenery may look and be satisfied. On the other side we have the Campsie Fells, o'er which the botanist and geologist may roam at will, and collect a bountiful supply of specimens; or, gazing from any of the eminences, there stretches northward a noble prospect of lake and forest, mountain and valley, streamlet and meadow. Even within range of an afternoon's walk we have places of striking interest for the student of nature, such as Cadder Wilderness, Kenmuir Woods, Possil Marsh, the upper reaches of the Kelvin, Hogganfield and Bishop's Lochs, and many other stations which the plant-lover may visit, with profit to body and mind. It will be seen, therefore, that it is no wonder there have been so many men, some of whom moving in the humblest walks of life, who have taken a great interest in the field botany of the district, and spent the greater part of their spare time in following the subject.

I remember the late Dr. Keddie telling me that in his younger days he knew men who not only watched over the preservation of rare plants in their favourite haunts, but actually transplanted specimens to a safer locality when they threatened to become obsolete, and Hugh McDonald confirms this statement in one of his "Rambles Round Glasgow." And now, as a result of the continuous and intelligent work of several generations of local botanists, there has just been published a catalogue of the native and established plants of the district as complete as it can possibly be. But there can be no doubt that, to a very large extent, the interest and enthusiasm expended on the subject has been based on utilitarian rather than æsthetic grounds. With the masses of

* Read before the Glasgow Chemists' and Druggists' Assistants' and Apprentices' Association (see p. 135).

the people it is a treasured tradition that there are plants growing in the field which provide a certain cure for every disease to which our human flesh is heir, if we only knew where to get and how to use them. And so, in the early days to which I have referred, our predecessors were, on a small scale, amateur herbal physicians, who collected their own medicinal plants, and either in the dry form sold them or gave them away gratuitously to those suffering from disease, or in the form of an infusion or decoction, to which whiskey was added for preservation; they were distributed with directions for use. The word "official," which is attached to so many plants in our Flora as a distinguishing mark, proves this fact. Thus we have *Valeriana officinalis*, *Pulmonaria officinalis*, *Symphytum officinale*, *Cochlearia officinalis*, and many others. The word "official," derived from the Latin *officina*, a shop, and meaning, in the broad sense, as sold in shops for medicinal use. Again, in the tribal names we find tussilago, for coughs; taraxacum, meaning to disturb; scrophularia, for scrofula, and many others. The common nomenclature of a great number of plants also indicates the medicinal use to which they have been and are still applied, as gout weed, scurvy grass, dog-mercury, fever few, eyebright, purging flax, pilewort, birthwort, woundwort, liverwort, kidney wort, balsam, self-heal, etc. Throughout our city there are a few shops having signs such as "Herbalist, Botanic Medical Hall," and others of like significance, where a comfortable trade is done in the sale of medicinal herbs, or ointments and extracts made from them, with what benefit to the patient I do not presume to say, but am of opinion that, if they do no good, they certainly do no ill. Regarding the literature of the subject, there are several books in circulation containing much chaff and little wheat, many of the remedies being recommended on purely empirical grounds, and the fulsome praise in which they are referred to excites suspicion. One herb is lauded so highly as a panacea for rheumatism that the most obstinate case may be cured by simply carrying about a piece of the plant in the pocket.

There are, however, many plants in the Clydesdale flora possessing the Pharmacopœia stamp of authority, or, though not official, the beneficial action of which has been proved by long and general use, and it shall be the province of this brief paper of mine to point out and describe a few of the plants which fall under these two heads.

Let us for a beginning take the spotted hemlock, *Conium maculatum*; order, Umbelliferae. This is a common plant in the district, and in some places I have seen it grow to a height of five feet, and last year I was surprised to find it in wild profusion on a recently-acquired piece of ground now within the city boundary. Its umbelliferous inflorescence, tripinnate leaves, and purple spotted stem make its recognition easy. The plant, on being pressed, gives forth a mice-like odour. The fresh leaves, young branches, and unripe fruit are official, and the preparations are the succus and ointment made from the leaves, and the tincture from the fruit. Internally the use of this plant is valuable as a sedative and antispasmodic, while the ointment eases the pain of hæmorrhoids. None of the preparations are popular in the West of Scotland.

Hyoscyamus niger, Solanaceae.—The henbane is extremely rare in the district, but is still found; the lower leaves are stalked, upper ones sessile, sinuate, clasping the stem. The flowers are pale dingy yellow, with purplish veins. The fresh leaves, flowers, with the branches, also the dried leaves and flowering tops, are official. These must be gathered from the flowering biennial plants. The preparations are the green extract, succus, and tincture. Its action is diuretic and narcotic, and it is largely prescribed.

Digitalis purpurea, Scrophulariaceae.—The foxglove is a common plant in the Clydesdale Flora, sometimes growing to a height of four feet. Its purple, finger-shaped flowers in a unilateral raceme, with long-stalked ovate lanceolate rough of leaves, are so characteristic that it is easily known. The dried leaves collected from

plants beginning to flower are official. The infusion and tincture are extensively used for cardiac affections.

Aconitum napellus, Ranunculaceae (common name, monkshood), is still catalogued as found in the district, and I have a specimen on the table, but it is almost obsolete. The much-divided leaves and dark-blue flowers with hood-like sepals are very striking. The root collected in autumn is official, and the preparations are the liniment used for rheumatism and neuralgia and the tincture prescribed to reduce inflammation.

Humulus lupulus, Urticaceae.—The hop plant is not common, but I have found it growing in hedges near Glasgow. It has long twining stems that climb over hedgerows and thickets. The leaves, heart-shaped at the base, and the greenish-yellow flowers are characteristic. The dried strobiles of cultivated plants are official, and the preparations infusion and tincture. The medicinal properties are tonic and soporific. In some villages near here the miners collect the plant and prepare a decoction for their own use.

Taraxacum officinale, Compositae.—The dandelion is so common that I need not describe it. The fresh and dried root are official, and the preparations are succus, extract and liquid extracts. It is an invaluable medicine for stomachic and liver complaints, and much prized by the people, who gather the roots and prepare a decoction for themselves.

Valeriana officinale, Valerianaceae.—This plant is frequently met with growing on the banks of streams and ditches near the city. It is a tall, coarse, herbaceous plant with large pinnate leaves and pale purple flowers in broad corymbs. The dried rhizome and roots collected in autumn are official, and there is now only one preparation—the ammoniated tincture. When fresh, strange to say, the plant has no odour, but on drying a volatile oil is developed of characteristic disagreeable smell. The medicinal properties are nerve stimulant and antispasmodic.

Arctostaphylos uva ursi, Ericaceae.—The bear berry has rarely been found in the Clydesdale flora, save on heaths in the islands of Cumbrae and Arran. The leaves are official, and there is one preparation, the infusion. Its medicinal properties are tonic and astringent, but is not in demand in the West of Scotland.

Sambucus nigra, Caprifoliaceae.—The elder, or boortree, is common all round the city. It is a small tree, with spreading branches and pinnate leaflets. The inflorescence is cymose, with cream-coloured flowers. The flowers are official, with one preparation, the aqua. Its medicinal properties are to reduce inflammation, applied in the form of a lotion. An ointment made from the dried flowers is much valued by those who believe in domestic medicines.

Cytisus scoparius, Leguminosae.—The broom grows in bush-like form, wherever we turn, and is known by everybody. The fresh and dried tops are official, and the preparations succus and infusion. Its action is diuretic, and used largely in dropsical complaints. When walking in the country I have often met people collecting the plant for medicinal use.

Aspidium filix-mas, Filices.—This is the only official fern, and is very common in our district. The stripes are very scaly, and the fronds grow in tufts. The liquid extract is the official preparation, and is used to expel tapeworm.

Solanum dulcamara, Solanaceae.—I have found the bittersweet frequently in the hedgerows a few miles from the city. Its climbing habit, hastate upper leaves, corymbose flowers, purple corolla, and yellow anthers make it easy of recognition. It is not official, but an infusion of the young twigs is used in skin diseases.

Tormentilla potentilla, Rosaceae.—The tormentil is a very common plant growing on heaths and pastures in the vicinity, and is easily known by its beautiful little yellow rosaceous flowers. It is not official, but a decoction of the rhizome is popularly used as a remedy for dysentery. I have occasionally seen Glasgow physicians prescribe it boiled in milk for the same complaint.

Menyanthes trifoliata, Gentianaceae.—The bogbean is frequently found in marshy places, its delicately-fringed corolla making it an

object of great beauty. It has a place in several foreign Pharmacopœias, and in our own locality is gathered for medicinal purposes, the rhizome and seeds being used as a substitute for gentian. The powdered leaves have proved beneficial in ague.

Galium aparine, Rubiaceæ.—The goose grass or cleavers is a common plant in hedges, its scrambling habit and reflex prickles marking it readily. A decoction of this plant has long been used for obesity, scurvy, etc. Squire says that the most suitable preparation of it is a fluid extract.

Linum catharticum, Linaceæ.—Purging flax grows in many places in the vicinity, and has a beautiful inflorescence of white cymose flowers. Among country people a decoction of the leaves is often used as a safe purgative.

Geum urbanum, Rosaceæ.—The wood avens is a common yet beautiful plant growing in woods and by the banks of streams. The root is much prized for its tonic and astringent properties. In the neighbourhood of the city I have frequently met women gathering it for medicinal purposes.

Symphytum officinale, Boraginaceæ.—The comfrey is one of our commonest plants, and grows everywhere in our district. Squire says that after removing the rind the mucilaginous root is most valuable as a casing for fractured limbs.

Tussilago farfara, Compositæ.—The coltsfoot is our earliest wild flower, and in a few weeks may be found in flower on all waste places on the fringe of our city. It is said to be a good remedy for coughs, and itinerant quacks make candy from it, which finds a ready sale.

Agrimonia eupatoria, Rosaceæ.—Agrimony is frequently found in the district, growing on the borders of fields, sometimes to the height of two feet. Medicinally it is much valued, and used in the form of an infusion for hæmorrhage of the lungs.

Scrophularia nodosa, Scrophulariaceæ.—The figwort, or, as it is sometimes called, rose-noble, is the typical plant of its order, and, as its name indicates, was famous as a remedy for scrofula. Now it is chiefly used on account of its tonic properties and in combination with bogbean. It is a common local herb.

Cochlearia officinalis, Cruciferae.—The scurvy grass may be found growing on the banks of the Clyde, and, like most cruciferous plants, is of great value as a blood purifier.

But what need I say more? For although I have only touched the fringe of the subject, I am afraid I have wearied you with so much detail. And now, it may be asked, what is the good of all this information I have compiled and laid before you? Well, I can answer that a druggist nowadays is expected to be able, like Solomon, to discourse on everything, from the Cedar of Lebanon to the hyssop that grows on the wall. From a trade point of view, one of the most serious blunders a shopman can make is to have to answer "I don't know." That response weakens the inquirer's confidence alike in the seller and his wares. In acquiring a language, the larger your vocabulary the abler you are to speak. So, the wider the knowledge which we possess on all that bears on our trade, the greater the likelihood of our success. We hear in these days a great deal about the store *versus* private trading. In my opinion, the great antidote to the store opposition is strong personality in the private trader, and one of the factors to make personality is knowledge. Many of the obscure remedies I have mentioned are occasionally asked for in drug shops, and although you may not have the herb your customer wants, still if you can tell him anything about its nature, habitat, use, etc., make sure he will come back another day and purchase something you have got. Knowledge is power, and it is often the knowledge of little out-of-the-way matters connected with pharmacy that gives the shopkeeper a name, and through time a good business in the district. Again, let us not despise the ministry of some of these simple herbal remedies I have mentioned. Remember that the curative power of such valuable barks as cinchona and cascara sagrada was known to barbarous tribes long before the civilised

world knew their worth, and in the same way it is quite likely that the humble villager may discover among the plants growing round his home some safe and effectual remedy for the physical troubles against which he has to contend. The element of faith, doubtless, contributes to the benefit derived from simples. But the same may be said of the most scientific treatment, for if a patient have faith in a remedy it is half the cure. I have yet another reason for bringing before your notice "The Medicinal Plants of the Clydesdale Flora," and it is this: Although the subject has a direct bearing on our trade, it will also bring you into touch with the broader study of botanical science; and there is no science the pursuit of which asks so little of you and gives you so much in return. It will take you out of the crowded city to the open, breezy country, by stream and lake, on moor and meadow, o'er hill and glen, in fen and forest, ever discovering something new to charm and interest you, a discipline alike to eye and brain. And although you may never be able to discover any herb which will help to lessen the sum of human suffering, nor even be able to add anything to the catalogued flora of your district, yet you shall be repaid for the interest and energy expended and of the infinite secret of nature. You shall at least know a little.

NEW REMEDIES.

CIMICIFUGA RACEMOSA IN AURAL TINNITUS.—A. Robin and Mendel have found that fluid extract of cimicifuga gives good results in the treatment of aural tinnitus, which is notoriously difficult to treat; the remedy has only failed in old-established cases, or where previous disease existed. It is given in doses of ten drops three times daily. It is prescribed thus: Extr. cimicifugæ fluid, 25 Gm.; menthol, 10 centigrammes. Take ten drops three times daily. Cimicifugin, a resinoid from the drug, the dried extract, or an alcoholic tincture are also employed. The doses of these preparations are: Cimicifugin, 6 to 40 centigrammes daily; of the dry extract, 20 to 60 centigrammes per diem; and of the tincture (1:10), five drops given hourly.—*Merck's Report*, 1899, 68.

ARSENIC CASEINATE.—A patent has been taken out for the preparation of a combination of arsenic and casein by heating casein in aqueous or alcoholic solution with an arsenic haloid. The arsenic caseinate obtained dissolves easily in water, and in weak alkaline solutions, from which it is reprecipitated by acids.—*Pharm. Cent.* 40, 575.

PARNASSIA PALUSTRIS IN EPILEPSY.—Peters ascribes to this plant remedial powers in epilepsy. He employs a tincture of the whole plant (1:5), and gives an adult a dose of half a teaspoonful after meals. If the tincture produces congestion, an infusion may be used, made by allowing two teaspoonfuls of the fine-cut dried herb to infuse for fifteen minutes with 500 C.c. of boiling water, half of which infusion is to be taken morning and evening.—*Pharm. Cent.*, 40, 611.

THYROID IN FRACTURES.—In the *Echo Medical du Nord*, Lambret suggests that thyroid medication may materially hasten the process of union in cases of fracture. He points out that in 1895 Hanau and Steinlein drew attention to the tardiness with which the union of broken bones takes place in animals which have been deprived of the thyroid gland, and that they suggested, as a corollary, that medication with thyroid would promote the formation of callus. Gauthier, Quénu, and Folet have all found this to be borne out in practice. In support of this, the author brings forward a case of fractured tibia, in which solid union resulted on the seventeenth day, the patient having been treated with nine grains of thyroid gland per diem. This case, although not conclusive, is suggestive.—*Therap. Gaz.*, 22, 750.

FACTS AND FANCIES.

BY AN ORDINARY PHARMACIST.

Pharmaceutical Festivities.

Dances, dinners, and smoking concerts are the three recognised social functions amongst pharmacists; and of those we appear—in London, at least—to have quite enough to prove that the British pharmacist does not take his pleasures sadly. The oldest established pharmaceutical dance dates back to just over a third of a century—this “so-called nineteenth century,” of the approaching end of which the genial honorary secretary to the Chemists’ Ball has been so persistently reminding us. He does not appear to have been so fortunate as to establish a record by the last ball of the century, which is also, as rumour has it, the last under his secretaryship; but I doubt if a more generally satisfactory meeting of the kind was ever held. The rooms were far from crowded, but everyone present seemed to be taking a fair share in the entertainment of the rest of the company, and the common or garden wallflower was entirely masked, if present, by other and even sweeter blossoms. The supper was good, and the speeches subsequently delivered were—perhaps fortunately—none too audible. I say fortunately because, after supper, no one wishes to hear speeches; of wise sayings we can have enough at any time, and witty ones we all overflow with for the time being. The most noticeable feature of the ball was the diminution in the number of elderly persons who have been wont to dissipate on that one night in the year at least; the younger element does not yet attend in sufficient force to fill the gap, and to that fact, rather than to the war or the prevalence of influenza, must be attributed the smaller attendance than usual. But, really, there were quite enough present for comfort; those of us who like a crowd were able to indulge freely in that respect at the Junior Pharmacy Ball this week. To many that was a more enjoyable affair than the Chemists’ Ball; but each fills a distinct place, and they do not clash in the least.

Wanted—A Chemists’ Club.

The brief description in last week’s *P.J.* of the Chemists’ Club established in New York serves to accentuate the fact that London pharmacists are so badly served as regards club accommodation. A chemists’ club, of a sort, existed near Ludgate Circus some time ago; but it was altogether out of the way, and failed utterly to satisfy an undoubted want. The Pharmacy Club, again, is by its very nature insufficient for the purpose. It is nothing but a social dining club, at the meetings of which persons connected officially with the Pharmaceutical Society, together with a limited number of elected members, are brought together on a footing of equality and friendship. The meetings are but few in number, and the absence of proper accommodation makes the Club one in name only. Moreover, many of the individuals constituting the select circle referred to are understood to appreciate their exclusive privilege so little that they are but rarely seen or heard of at the meetings, and the main object of the club is therefore not attained. What is required is a house, or a set of rooms, adjoining the Pharmaceutical Society’s house if possible, where all the accommodation and comforts of a club—properly so called—should be available. Club premises containing a reading-room, writing-room, tea-room, billiard-room, etc., etc., with the privileges of membership limited to persons connected with the Pharmaceutical Society, should prove a sufficient attraction for a real pharmacy club to be managed at a profit. It might be run as a joint-stock affair, say with ten-pound shares, and I believe there would not be much difficulty in securing the necessary hundred or more subscribers to provide the capital required to commence operations. Apart from the actual subscribers, the hospitality of the club might be freely offered to other members of the Pharmaceutical Society, on presentation of their

eards; but in time membership of the club would probably come to be regarded as being as much a matter of course as membership of the Society.

The Conference Membership.

I take it that the present year may be regarded as a critical one in the history of the British Pharmaceutical Conference. According to the figures in the last financial statement, the members’ subscriptions do little more at the present time than cover the cost of the ‘Year-Book’! That being so, a very large addition to the membership roll is absolutely necessary if the work of the organisation is to be continued on existing lines. At one time, I understand, there were more than three thousand subscribing members; now there are not many more than one-third of that number, and three hundred of those hail from the London district. London, therefore, supplies the backbone of the Conference, and unless London can furnish material for reconstructing the sadly-diminished body, I fear that the B.P.C. as a separate organisation is within measurable distance of the time when it will cease to exist. Lack of enthusiasm may be survived for awhile, but a diminishing list of members and accompanying scarcity of funds must speedily prove fatal, unless checked. Any remedy, to prove effectual, must be less tentative than the addition of a number of members from the district where the annual meeting is held in any given year. Usually, I believe, that addition hardly makes good the continual waste due to resignations and deaths, and though Londoners may come to the support of the Conference in such numbers as to cover the losses of several years to come, the inevitable end will only be postponed for a few years. To be really effective, every part of the kingdom must take its share each year in maintaining the membership strength of the B.P.C. at a proper limit, and it seems to me that the list recently compiled by the president, Mr. E. M. Holmes, should prove extremely useful in enabling that to be done. It would be well, by the way, if similar lists were submitted to the Secretary of the Pharmaceutical Society with a request that he would be good enough to help the Conference authorities in determining what pharmacists in a given district are or are not members of the Society.

B.P. Standards for Drugs.

The only wholesale firm which appears to have taken notice of my remarks about the difficulty of obtaining certain drugs up to the B.P. standards is one with which I have done business for many years, and for which I have the highest respect, as I have always found that I could order drugs, galenicals, etc., from that firm in the full assurance of getting exactly what I require. But in the letter, published last week (see p. 100), a totally wrong view is taken with regard to the purport of my note, and a little too much is taken for granted. Thus, it is stated that there is “little or no difficulty in obtaining from any of the recognised wholesale houses the finest qualities of any particular drug.” It is a somewhat indiscreet thing for any wholesale house, however ancient or prominent, to venture to speak thus on behalf of other firms, the more especially as one presumably “recognised” wholesale house has recently published statements to the contrary. Moreover, the absurdly low prices quoted in some “prices current” for the “best” qualities of certain drugs preclude the idea that the articles quoted can meet the requirements of the British Pharmacopœia. For example, to refer only to articles which I have previously mentioned, it may be possible to supply aconite root, B.P., in the regular course of trade, at 8d. per lb.; asafetida, B.P., at 1s. 4d.; and pareira root, B.P., at 1s.; but I have serious doubts on the subject. Nevertheless, such prices are the highest quoted in lists issued by “recognised wholesale houses,” to which I have lately had occasion to refer. This is not as it ought to be, and I hope before long to have the satisfaction of seeing B.P. drugs quoted, as such, in the price lists of the leading wholesale houses.

PHARMACEUTICAL SOCIETY.

MEETING OF THE COUNCIL.

WEDNESDAY, FEBRUARY 7, 1900.

Present:—

Mr. WM. MARTINDALE, President.

Mr. G. T. W. NEWSHOLME, Vice-President.

Messrs. Allen, Atkins, Bateson, Carteighe, Corder, Glyn-Jones, Grose, Harrington, Hills, Park, Savory, Symes, Warren, and Young.

The minutes of the last meeting were read and confirmed.

Death of a Corresponding Member.

The PRESIDENT said he regretted to announce the death of a noted Japanese pharmacologist, Dr. Yataba, who was elected a corresponding member of the Society in 1892. He was well known by his work in the medical faculty of the University of Tokio, and was a man of great promise. He was unfortunately drowned while bathing.

The Late Mr. Daniel Frazer.

The PRESIDENT then proposed that a letter of condolence be sent to the family of the late Mr. Daniel Frazer, whose death was announced at the close of the last Council meeting. Mr. Frazer, who was an active member of the Council fifteen years ago, was well known in the western parts of Scotland. He was a man of sterling worth and genial character.

Retiring Members of Council.

On a ballot being taken, the lot fell upon the following members, who will retire from the Council at the next election:—Messrs. Bateson, Cross, Grose, Hills, Storrar, Symes, and Warren.

Election of Members.

The following persons having tendered their subscriptions for the current year, were elected "Members" of the Society:—

Allen, Archibald Clive; Birmingham	Laverack, Ernest Wilson; Malton
Amiss, Albert Edward; Shipdham	McLean, Alexander Bennett; Glasgow
Annesley, Sara; Camden Town	Manley, Henry; Aston
Appleton, John Thompson; Sheffield	Martin, Henry Arthur; London
Archer, Joseph Sykes; Guiseley	Melling, Alfred E.; Ashton-in-Makerfield
Bailey, John Herbert; Nottingham	Mercer, Alfred; Bakewell
Bayes, James Austin; Stechford	Moate, Benjamin; Birmingham
Benzie, Robert; Ceylon	Morris, Robert Leitch; Aberdeen
Bowie, George Duncan; London	Muscott, Rowland W.; Birmingham.
Breese, John Soley; Manchester	Newcombe, Thomas; Liscard
Campbell, Andrew T.; Alexandria	Oldfield, Frederick Charles; Woodford
Coney, Joyce Muriel; Highbury	Oldham, Thomas, Towcaster
Davis, Richard Llewellyn; Southsea	Owen, Philip Nicholas, Whitland
Deane, Annie, M.; Cradley Heath	Pilgrim, Horace Greenville; Luton
Drabble, Frederick P.; Kensington	Poad, John Edward; Looe
Dutson, Robert Thomas; Chepstow	Pritchard, Elias Roberts; Ebenezer
Eakin, James; Bombay	Robertson, David Smart; Birmingham
Eastland, Thomas Nix; Wisbech	Sampson, John Wm.; Helpringham
Evans, Roger Jones; Liverpool	Samways, Wm. Edgar; Gillingham
Finnemore, Horace; London	Scattergood, William J.; Nottingham
Flowerdew, Frederick P.; Birmingham	Sharp, Ernest T.; Hayward's Heath
Foster, George; Burnley	Sleigh, Frederick Bentley; Walsall
Freeman, Andrew John; Newbury	Smalley, Charles; Bolton
French, Frederick, A.; London	Smith, Frederick A.; Birmingham
Greaves, Sydney Chater; Chesterfield	Smith, Harry; Edinburgh
Haddock, John; Birmingham	Smith, Richard Henry; Leeds
Halstead, Harold B.; Rawtenstall	Smith, Thos, William; Fallowfield
Hartley, Albert Edward; Burnley	Spear, Frederick A.; Birmingham
Heap, Thomas Henry; Sowerby Bridge	Stewart, Fergus Ferguson; Lasswade
Hodgson, Edgar; Manchester	Sturt, Clifford Henry; Seacombe
Hopps, William Thomas; Leamington	Sweetman, Robert; Ludlow
Hunter, John; Glasgow	Taylor, Emma Bennett; Hungerford
Jamieson, Martin; Edinburgh	Theakston, Thos. Walburn; Masham
Jeffrey, Alexander Hill; Craigton	Tonge, Chas. Bursall; Gravesend
Johnson, Frank Horace; Lewisham	Turner, Robert Michael; Oundle
Johnston, John William; Kennington	Uppill, William Thos.; Walworth
Jones, David Richard; Cardiff	Warneford, Frederick; Brighton
Kaberry, William Todd; Southport	Whitworth, Arthur Upsall; Battersea

Young, James; Torquay

Election of Student-Associates.

The following persons having passed the First examination, and

tendered their subscriptions for the current year, were elected "Student-Associates" of the Society:—

Arthur, James William; Peterborough	Jones, Thomas Ernest; Pontypridd
Barton, Ernest Alfred; London	Jones, Walter John; London
Battershill, Frank Easton; Truro	Keen, Florence Edith; Cheltenham
Bayley, Arthur Wesley; Brighton	Lasham, Harold Frank; Guildford
Bell, James Douglas; Cardiff	Lewis, Alfred Pearson; Birkenhead.
Brackenbury, Alice; Stroud Green	Male, Charles Edgar; Cottenham
Bullen, Frederic Edward; Streatham	Maw, Arthur Trentham; Nutfield
Cartwright, Alfred Harry; Silverdale	Michelmores, Philip John; Paignton
Cox, Horace Nelson; Edinburgh	North, Henry Howard; Grantham
Dale, Isabel Marian; London	Palmer, Ralph; Bedford
Davis, John David; Braintree	Paterson, Alex. G. C.; Scarborough
Ennals, William Selby; Clapham	Prevell, William; Newcastle-on-Tyne.
Field, William James; Witney	Richards, Shelley; Shaftesbury
Goble, Joseph Harold; St. Leonards	Riley, Walter; Derby
Harbordt, Paul Harold; London	Rogers, Edward Parsons; Cheltenham.
Hyslop, David Scott; Lockerbie	Swinn, Robert Fred; Manchester
Jensen, Harold R.; New Brighton	Thompson, Thomas W.F.; Edinburgh
Thorne, William Henry; Swindon	

The Registrar's Report.

The Registrar's Report (see page 124) was laid on the table and ordered to be published.

The PRESIDENT remarked that it was satisfactory to see that the Society was about one thousand stronger than it was last year. It was very unsatisfactory to find such a number of failures in all classes of the examinations, more especially in the Minor, the percentage in England and Wales being 71.6 and in Scotland 63.91. It was satisfactory to notice that the number of men on the Register was 15,595, which, notwithstanding the number of deaths and erasures, was 100 more than last year.

Mr. YOUNG suggested that in view of the enormous number of failures some investigation should take place as to the cause. Was it entirely due to the inefficiency of the candidates, or did it arise from over-zeal on the part of the examiners?

The PRESIDENT did not think there was any unfairness in the conduct of the examiners.

Mr. YOUNG did not suggest unfairness, but it was a singular fact that the enormous increase in the number of failures was contemporaneous with the change in the mode of conducting the examinations.

Mr. CARTEIGHE said it was not correct to say that it was contemporaneous, as there was a complete change in the examinations long before. At the next examination, no doubt, there would be a still greater number of failures, in view of the ten-guinea fee that was looming in the distance. It would be found that the failures were not necessarily in the subjects that were examined in by the teachers.

Dr. SYMES said there was always a little danger of a professor in any one subject expecting a candidate to be proficient in that one subject, though he did not suggest that that was the cause of the failures on the present occasion. A chemist was inclined to think that the candidate before him should be a thorough chemist whether he knew anything else or not.

Mr. CARTEIGHE said he was surprised to hear Dr. Symes say that. His experience of the Board of Examiners, both north and south of the Tweed, was that the most exacting examiners in science were pharmacists, and their object in appointing teaching examiners was that they had constantly before them the amount of elementary knowledge of the science that could be acquired in a definite time, and in that way the students would have greater consideration extended to them. Experience was worth more than any theory, and experience showed that if a pharmacist were put to examine in any of the subjects he would prove to be a stiffer examiner than one who was teaching day by day.

The PRESIDENT said there was a rush of candidates during the last year, which would no doubt continue at the next two examinations. It was a curious fact that there were a great number of failures in practical dispensing, which was not taught with that efficiency that it used to be in the old days. Ready-made remedies had perhaps decreased the amount of practical dispensing.

Mr. HILLS said he could entirely corroborate from his experience as President what had been said by Mr. Carteighe. He would only

REGISTRAR'S REPORT.

SUBSCRIBERS TO THE SOCIETY FOR THE YEAR 1899.

ANALYSIS OF EXAMINATIONS FOR THE YEAR 1899.

FIRST EXAMINATION.

Number of Candidates during the Year.	Number of successful Candidates during the Year.	Number of Rejections during the Year.	Number of Examinations during the Year.	Average number of Candidates at each Examination.	Average number of Rejections at each Examination.	Percentage of Rejections.
1530	723	807	4	382.50	201.75	52.74

Number of Certificates received in lieu of the First Examination, 167.

MAJOR, MINOR, AND MODIFIED EXAMINATIONS.

ENGLAND AND WALES.

Examinations.	Number of Candidates during the Year.	Number of Successful Candidates during the Year.	Number of Rejections during the Year.	Number of Examinations during the Year.	Average Number of Candidates at each Meeting.	Average Number of Rejections at each Meeting.	Percentage of Rejections.
Major	100	49	51	4	25.00	12.75	51.00
Minor	1,331	377	954	4	332.75	238.50	71.67
Modified.....	One	Candidate presented himself and passed.					

SCOTLAND.

Examinations.	Number of Candidates during the Year.	Number of Successful Candidates during the Year.	Number of Rejections during the Year.	Number of Examinations during the Year.	Average Number of Candidates at each Meeting.	Average Number of Rejections at each Meeting.	Percentage of Rejections.
Major	3	1	2	3	1.00	0.66	66.66
Minor	485	175	310	4	121.25	77.50	63.91

THE REGISTERS OF PHARMACEUTICAL CHEMISTS AND CHEMISTS AND DRUGGISTS, 1899.

Additions during the year:—

Number of persons who have passed the—	
Minor	552
Major	50†
Modified	1
Number of persons restored to the Register on payment of a fine	15
Number of persons registered on payment of the registration fee; having been in business before Aug. 1, 1868	1
	569

Erasures during the year:—

Deaths	282
Erased at the request of registered persons themselves ..	8
Erased by the Registrar in pursuance of the provision set forth in Section 10 of the Pharmacy Act, 1868, after sending two registered letters, to which no answer has been received	157
Increase of numbers on the Register	122
	569

† These, having already been included in the number who passed the Minor, do not increase the numbers on the Register.

Number of Pharmaceutical Chemists on the Register, December 31st, 1899 ..	2,248
„ Chemists and Druggists	13,347
	15,595

add that he hoped, with the improved preliminary testing in general knowledge, this sad condition of things would be altered.

Dr. SYMES said it was very gratifying to hear what had been said, and he thought such an authoritative statement would be satisfactory to those who were disposed to sympathise with rejected candidates and to fancy that the examiners were rather too exacting.

Restoration to Register.

The name of the following person, who has made the required declaration and paid a fine of one guinea, was restored to the Register of Chemists and Druggists :—

Thomas Newcombe, 134, Seabank Road, Liscard.

Restorations to Membership.

Several persons were restored to their former status in the Society.

Examiners for the Council Prizes Examination.

The PRESIDENT said this examination had not recently been conducted by any members of the Scotch Board, and it was thought desirable this year to ask their co-operation. He therefore moved that Prof. Balfour, Dr. Dobbin, and Mr. Boa be invited to conduct the examinations for the Pereira Medal and the Council Prizes competition in April next.

The resolution was at once agreed to.

Finance Committee.

The report of this Committee was read, recommending the payment of various accounts.

The PRESIDENT, in moving the adoption of the report and recommendations of the Committee, said it was satisfactory to find that the finances of the Society were in a sound condition. There was nothing in the report calling for special comment.

The report and recommendations were unanimously adopted.

Beneyolent Fund Committee.

The report of this Committee recommended the grant of £63 in the following cases :—

The widow (70) of a registered chemist and druggist and subscriber to Fund Has had one previous grant. (Bradford, near Manchester.)

A pharmaceutical chemist, life member (81), and subscriber to Fund. Was in business in Manchester, and afterwards for thirty years in Richmond.

A registered chemist and druggist (56), who passed the Mod. Exam. in 1868. A former associate and subscriber to Fund. (Seedley, near Manchester.)

The widow (74) of a pharmaceutical chemist member. Has had three previous grants.

One case was deferred, and another was not entertained.

The death of Mrs. Naftel, aged 82, who had been an annuitant since 1877, was reported.

Mr. ATKINS moved the adoption of the report and recommendations. He said the list was not so long as usual, and it was remarkable in two respects; first, that the average age of the applicants was seventy-three, and, secondly, that the majority of them had been subscribers to the Society and the Fund. He regretted to say that was not always the case.

The report and recommendations were unanimously adopted.

Diplomas.

The undermentioned being duly registered as pharmaceutical chemists, were respectively granted a diploma stamped with the seal of the Society :—

- Britton, Alfred Brook.
- Edwards, John Griffith.
- Normansell, John William.
- Paterson, George Derwent.
- Sykes, Henry Vincent.
- Taylor, Samuel.

Library, Museum, School, and House Committee.

The report of this Committee stated that the Librarian had furnished his usual report, including the following particulars :—

Attendance.	Total.	Highest.	Lowest.	Average
December	259	25	1	11
Year 1899	4,117	37	0	14
Circulation of Books. Total.	Town.	Country.	Carriage Paid.	
December	119	59	60	9s. 10d.
Year 1899	1,776	950	826	£8 12s. 7½d.

Several donations to the Library and Museum had been received (see P.J., January 20 last, p. 51), and the Committee had directed the usual letters of thanks to be sent to the respective donors.

The Committee recommended that the undermentioned works be purchased for the Library in London :—

Braemer and Suis, Atlas de Photomicrographie des Plantes Médicinales 1900.

D'Aygalliers, L'Olivier et l'Huile Olive, 1900.

The Committee also recommended that a copy of the United States Dispensatory, 18th Ed., be sent to the Library in Edinburgh.

The Curator's report had been received and included the following particulars :—

Attendance.	Total.	Highest.	Lowest.	Average.
December	416	44	1	17
Year 1899	6,107	65	1	20

The PRESIDENT moved the adoption of the report which, he said, did not call for any comment, and it was carried with one dissentient.

Company Trading.

Mr. GLYN-JONES asked whether the company question was now out of the hands of the Council and in the hands of the Law and Parliamentary Committee.

The PRESIDENT said that was so.

Mr. GLYN-JONES said that being the case, and seeing that there was no report from the Law and Parliamentary Committee, and that they had since the last Council meeting acknowledged that the Government was introducing a Companies Bill, and that there was a probability, which amounted to a certainty, that that Bill would include a pharmacy clause similar to the clause in the last Bill, he would ask if the President had any statement to make as to what the Committee or the Council was doing in the matter.

The PRESIDENT said the Bill had not yet been introduced into the House of Commons. They had had no definite information on that head.

Report on the Examinations.

The report on the examinations was then read, and is printed at page 127.

Mr. GLYN-JONES said he forbore to say anything when the question of the failures at the examinations was mentioned earlier, because he thought it would be more appropriate to put his question on this report; but he knew that a large number of students and also members who wanted qualified assistants felt that the percentage of rejections was very serious, and also that the best remedy would be a division of the examination. He would ask, therefore, if there was any reason why the Minor examination should not be divided, provided, of course, that no sort of qualification was given to a man who passed any particular portion of it.

The PRESIDENT said the question had been considered, and it was a matter for consideration both for the Council and the Boards of Examiners whether any such division should take place until there was a curriculum in force. He could not say at present what the opinion of the Boards of Examiners was.

Mr. CARTEIGHE said he had always been of opinion that such an examination as the Minor ought not to be conducted at a two-days' sitting, and that in fact such a course was inimical to true education; but unfortunately they were told by the authorities that they could not interpose any interval between the various parts of the examination. Whether a bye-law interposing a three-months' interval between two parts of it would be accepted now by the Privy Council he did not know, but some years ago it was not entertained, and that had been the difficulty. It might be possible to give a man an option if that were thought desirable, as a matter of administration, but according to the opinion of the legal advisers of the Privy Council when a man was twenty-one he was entitled to come up and pass within a reasonable period a qualifying examination. The suggestion was to interpose a period of three or six

months, and whether a bye-law to that effect would be sanctioned now he did not know.

Mr. GLYN-JONES said if in the view of the Council some division would be wise under certain conditions, surely it would be well to consider it. He understood Mr. Carteighe to say that under the present bye-laws it could not be done.

Mr. CARTEIGHE said it was not merely the bye-law, it was the law, which accounted for many awkward things in connection with the examinations.

Mr. GLYN-JONES thought it would be worth while for the Council to again approach the authorities with the view of getting some division of the examination. Their own members were feeling it very keenly. He could give an instance where it had caused great dissatisfaction, and if the Council would at an early date go in for a division of the Minor their members would be well pleased.

Dr. SYMES said the question was discussed before the Council some years ago, when he strongly advocated the division of the Minor examination. Perhaps he was wrong, but he believed that under the law they could divide the examination; the bye-laws might require to be altered, but he believed the law allowed it. They had not the power to say that a man, when he attained twenty-one, might not complete the examination and obtain his certificate; but he always felt that if they could hold some portion of the examination—for instance, the written portion—before he was twenty-one, and was allowed to complete it afterwards, that that would be perfectly within the law. It possessed immense advantages. A youth who passed the preliminary examination soon after he entered on his apprenticeship or before that time had no examination before him for some four or five years, and he believed that that was at the root of many of the failures. The boy became unaccustomed to study, and it was all the more difficult for him to again enter on his studies when the time came. He thought it was worth while to consider whether something could not be done if they should have again to alter their bye-laws. The examination was already divided to a certain extent—that is to say, there might be a week between the first and second part—and he did not see that there would be any difference in making an interval of three months or so.

The PRESIDENT said before he came on the Council the matter was well considered, and it was then found that the Privy Council would not allow them to divide the examination so as to let the candidate come in before he was twenty-one and pass a part of the examination, and then, when he was of age, complete his examination. He was in favour of the examination being divided, because it was a great strain for a candidate to go through all the subjects in a satisfactory way in a limited time. It was hard pressure to get the mind filled with the amount of knowledge required all at one time to pass a qualifying examination.

Mr. YOUNG said there was a general impression that this question should only be discussed together with the question of an enforced curriculum. He agreed with that up to a certain point; but in view of the fact that the attainment of a compulsory curriculum was Utopian or remote, he thought it might be worth while for the Council to give this matter some consideration, especially as it did in some way or other rest with the Council to divide the examination into two parts. He took it that the Council had power to do this. He did not quite see that it should hold out in favour of what was distinctly an inconvenience, and he might almost say an obstruction to the examinations.

Mr. CARTEIGHE said he had had to fight this battle single-handed in former times, and knew all about it. There would have been no battle if the Council and the members of the Society had been agreed, and if other interests besides the welfare of pharmacy had not intervened. There were vested interests in teaching which were all set to work, and statements were made that the Society wanted to enrich itself through its School, and so on. The decision

of the Privy Council, speaking from memory, was that—in the opinion of their advisers—under the Act of 1868 there were no powers to impose a curriculum or interpose periods of time between the respective parts of the qualifying examination. It was] no use to say that the Preliminary was part of the Minor, and they had separated that, the bye-law to that effect had been authorised. The only way would be to approach the Privy Council again on general educational grounds, and see if there would be any probability of bye-laws in a certain direction not being refused.

Mr. GLYN-JONES asked if the Council had power to refer a man back in one part of the examination without referring him back entirely.

The PRESIDENT said each man must pass the whole examination at one time.

Mr. YOUNG said at one time a man could come up and pass one portion of the examination.

Mr. CARTEIGHE said that was so, and he was one who did so, but that was in the days when the examination was voluntary, and the Society could make what regulations it liked. After the passing of the Act of 1868, matters were altered.

Mr. HILLS said if at present a member failed in one subject he had to come up again and pass in every subject. What was desired, he understood, was that if a man passed in one subject, although receiving no certificate, he should not be called upon in that subject when he came up again. That was a question well worth discussing, and he would willingly go to Parliament, if necessary, for power to improve the method of education and examination, but he should prefer it being done in connection with a curriculum. He did not think it advisable that examination in so many subjects should be crowded into a few hours, and if by altering the bye-laws or by going to Parliament they could obtain power to divide the examination he should be glad. But he still thought it would be wise to try at the same time to improve the whole system of education.

The PRESIDENT said the matter had been under the consideration of the Boards of Examiners, but they had not come to any definite conclusion. Anything like a piecemeal examination—unless in connection with an authorised curriculum of study—would, he thought, be injurious.

Mr. HILLS said a man always had a chance of getting through if he were generally competent, and weak only in one subject. He was not rejected unless he was hopelessly ignorant in one or more subjects.

The PRESIDENT said, when he passed his examination, it was possible to take the subjects seriatim, and it was found decidedly disadvantageous. In some examining bodies, he believed in Scotland, credit was given to a candidate at a subsequent examination if he had passed in certain subjects before, but it was not a satisfactory mode. It was much better to have the examination divided, and a certain course of study should be distinctly laid down.

Correspondence.

The SECRETARY announced that a communication had been received from the Privy Council, enclosing regulations current in Austria with reference to the sale of drugs. That letter had already been acknowledged.

The SECRETARY announced that communications had been received from the French Ministry of Commerce with reference to the International Congress.

The PRESIDENT said the International Congress would be held in Paris, from the 2nd to the 8th of August; the subscription for attendance being twenty francs. He suggested that the question of whether any steps should be taken for the Society to be represented on the Congress should be referred to the Library Committee.

That was unanimously agreed to.

The PRESIDENT then announced that the following resolution had been received from the Hon. Secretaries of the School of Pharmacy

Drill Class:—"That this meeting of the Students of the School of Pharmacy requests the Council of the Pharmaceutical Society of Great Britain to favour them with the use of the Examination Hall for the purpose of drill." That permission had been verbally granted to the students, and he proposed that the Council should confirm it.

The proposition was unanimously agreed to.

General Purposes Committee.

The Council then went into committee to consider the report of this Committee. On resuming, the report and recommendations were adopted, and a special resolution was passed authorising the Registrar to take proceedings against the persons named therein.

Report on Examinations.

January, 1900.

The REGISTRAR reports the following statistics of the January Examinations:—

England and Wales:—

	Candidates.	Pass.	Fail.
Major	19	6	13
Minor	314	76	238*
	333	82	251

Scotland:—

Major	—	—	—
Minor	97	39	58
	430	121	309

First Examination.	Candidates.	Pass.	Fail.
January 9, 1900	391	168	223

Certificates of approved Examining bodies were accepted in lieu of the "First" examination in 44 instances.

The REGISTRAR further reports that:—(a) The Board in London, to whom the matter had been remitted by the Council, recommended that it be empowered to accept in lieu of the "First" Examination the "Certificat de Grammaire," submitted by Mr. L. W. J. B. Verdrier. In several other cases which were also submitted, the Board made no recommendation.

"FIRST" EXAMINATION RESULTS.

A meeting of the Board of Examiners for England and Wales was held on Tuesday, February 6.

Certificates from approved examining bodies were received from the undermentioned in lieu of the Society's First Examination:—

Butcher, Charles W.; Kennington	Pine, George; Bristol
Cardell, Harry Parminter; Bodmin	Spiers, Charles S.; Melton Mowbray
Davies, David Lewis; Clapham	Strange, Harold G.; Shaftesbury
Hornsey, John Frederick; Oxford	Edwards, Percy W.; Devizes
Jackson, James Eustace; Barnsbury	Edwards, Rowland F.; Devizes.
King, Herbert Henry; London	

The report of the College of Preceptors on the examination held on January 9 was received. 391 candidates had presented themselves for examination, of whom 223 had failed.

The following 168 passed, and the Registrar was authorised to place their names upon the Register of Apprentices or Students:—

Adams, Thomas Wilfrid; Coleford	Bullions, John; Glasgow
Alexander, William John; Aberdeen	Cargill, Daisy; Arbroath
Allan, David Souter; Aberdeen	Carter, Harold Lovelace; Exmouth
Anderson, William Purvis; Edinburgh	Cartmell, Edmund; Lazonby
Appleyard, Frederick W.; Bradford	Clark, Herbert Holmes; Leeds
Ashworth, Arthur; Lancaster	Cleaver, Gilbert Duncan; Poole
Austin, John; Burton-on-Trent	Conway, John; Conway
Baillie, J. D. Martin; Edinburgh	Cordwell, Walter Raleigh; Harleston
Baird, Douglas Graham; Margate	Coutts, Charles; Aberdeen
Barker, Jesse; Heanor	Craine, Thos. Howard; Douglas, I.M.
Barlow, Ernest Cranston; Werneth	Creasey, William Rufus; Heckington
Baxter, William; Lanark	Cross, William Henry; Preston
Beattie, James; Thornhill	Dallman, Arthur A.; Ashton-on-Ribble
Blair, William King; Girvan	Dell, George; Northchurch
Bolton, Joseph Hook P.; Southgate	Douglas, Albert; Egham
Bradbury, John H.; Market Drayton	Douglas, Alexander; Dunblane
Brown, Howard I. F.; Cockermonth	Dundas, Harold Hewson; Arbroath
Brown, Joseph W.; Galashiels	Dunningham, Albert Geo.; Colchester

* MEMO.—One of the candidates in London was detected in the use of unfair means, and was failed accordingly.

Elias, Evan; Ferndale
 Emslie, Francis Henry; Aberdeen
 Esam, Richard Middleton; Leicester
 Evans, David George; Tenby
 Evans, William Morse; St. Clears
 Farrow, George Clarkson; Scarcroft
 Ferguson, Peter; Glasgow

LETTERS TO THE EDITOR.

Company Trading and the Practice of Pharmacy.

The letter from "A Layman" to the President compels our admiration by the clear, strong common sense which it displays, and by the force with which the argument is clinched and driven home. Too seldom by far is the duty of the community towards proved ability employed in its service set forth with such surpassing skill and lucidity. The weak point in its contention is the assumption that the public demand from the average chemist a high moral standard and considerable technical knowledge. A large proportion both of the medical profession and their patients require only a man competent to take down from his shelves some factory-made medicament and to hand it across the counter. That ignorant contempt of science which has sent out soldiers to South Africa armed with inferior cannon and wrongly-sighted rifles shows itself towards our craft in a refusal to believe that a qualified pharmaceutical chemist can practise pharmacy. If science has been hooted at in the army, it has no less been derided behind the counter. Any assertion of a confidential position between prescriber and patient is fiercely resented. Not long since a lady demanded that I should translate her husband's prescription for her, with an asperity of tone which would have been unbecoming if she had told her footman to put some more coals on the fire.

Tabloids will be accepted as an equivalent for a dose of Easton's syrup, but no one will believe that a chemist can make a pill to do the like, even under the guidance of the President's invaluable book. Last week a doctor from a neighbouring fashionable resort came to me. Did I keep Corbyn's Mist, Bismuthi Co., or Gale's or Hewlett's? No; I had none but my own. It was produced; he dipped a finger into it and tasted it, remarking, affably, "I don't know how you find this answer, but nothing else seems to take hold of a patient like theirs." Then he wrote a prescription for something else. Seeing that he had mentioned three different makers, "theirs" was not as definite as could be wished. I silently summed up the situation that—like many of the public—he was willing to accept anything but the handiwork of the individual chemist he was addressing. And that is the crux of our position—the Tugela which we fail to cross—that the labours of a generation to educate and qualify ourselves result in an obstinate incredulity as to our capability to *do* anything. The confidence of the public is reserved for the advertising quack, and he has so industriously heaped calumny upon our heads that the most unswerving integrity and the highest craftsmanship cannot dispel the cloud of suspicion and mistrust.

Dover, February 4, 1900.

J. F. BROWN.

Company Legislation.

I do not think that Parliament will have much time to devote to home legislation this session, but there is evidently an intention to proceed with a new Limited Companies Act, and it is quite possible that the intention will be carried out. If so, it is more than likely that there will be a clause in it relating to pharmacy, and we have no good grounds for supposing that this clause will be very different from the one framed last year by the Lord Chancellor. It may be said, therefore, that the fate of pharmacy in this country hangs in the balance just now. I have never at any time been other than a friendly critic of the Pharmaceutical Council, and I have no wish whatever to indulge in criticism just now. I know the difficulties with which the Council has had to contend quite well, and I am not of those who think that all difficulties will be brought to an end by adopting any special line of policy. I think, however, that considering the importance of the Bill which may be brought before Parliament soon, we ought to know whether the Council of the Pharmaceutical Society has made up its mind to any definite line of policy, and, if possible, what that line of policy is. If it is

to play into the hands of the enemy, it may be wise not to divulge the tactics about to be adopted, but the world of pharmacy needs to be assured at the present time that the watchmen are not asleep, and that they have a reasonable prospect—if not of routing the enemy, at least of preventing him from routing us. The matter is, in my opinion, urgent. It is probable that this Bill will be taken early in the Session, and it is almost sure to be forced through without adequate discussion, simply because of the pressure of business in the House. It is quite plain that chemists throughout the country cannot give the Council a policy "cut and dry" ready to take into the House of Commons; but, after all, I don't think it is the duty of a body like the Council to expect this. The Council cannot shirk its responsibility by telling the chemists that they cannot agree. It is the duty of the Council to take the lead, to strike the keynote, and set the tune for chemists throughout the country. Chemists have agreed as far as agreement can be expected from so numerous a body of men, especially as they have so far got no strong lead. I believe that if the Council would produce a strong, well-considered, wise plan of campaign men of all shades of opinion, and men who have no opinions at all, would fall into step and follow the leaders. That the Council should do this is nothing more than chemists have a right to expect. It is the duty of leaders to lead, else why have they come forward as leaders? I do not know what we would think of officers in the Army who refused to go forward because the rank and file had not said how, or where they were to go. It seems to be supposed that I am an out and out supporter of the qualified directors' policy, but the most I have ever said is, that this appears to me the policy most likely to meet with success. I have repeatedly said that if any man will produce a better policy which has a fair chance of success I believe the supporters of this policy will give in at once. This is the feeling in pharmaceutical circles everywhere, I think. There is no appearance anywhere of stubborn adherence to opinions in the face of a large majority who think otherwise. Chemists have their opinions, but they are ready to fall in in support of any likely policy which will lead to a fair settlement of their claims. The world of pharmacy needs strong leaders with a strong definite policy. That is all.

Dumfries, February 5, 1900.

JAMES REID.

ANSWERS TO QUERIES.

Special Notice.—Scientific, technical, legal, and general information required by readers of the *Pharmaceutical Journal* will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured. Not more than six plants should be sent for recognition at one time.

Apprenticeship (J. D. D.—38/26).—The phrase "effluxion of time" means completion of the period of the contract. The indenture can be cancelled by mutual agreement at any time.

Removing Superfluous Hairs (J. A.—38/25).—Any maker or dealer in surgical instruments could supply you with an electrical apparatus for the purpose. You may be interested in a case of depilation by Röntgen rays recently recorded in the *Lancet*. See page 115 of this week's Journal.

Bell Scholarship Examination (I. N. I.—38/27).—(2) Refer to the article on the subject which appeared in the *P. J.* for September 9 last. With regard to your other queries, (1) you will find it advisable not to supply the substance under such circumstances. (3) We have no such recipe. Try the effect of fresh air, exercise, and mild tonics.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

Members of the Pharmaceutical Society must address all communications with reference to the transmission of the Journal, to the Secretary, 17, Bloomsbury Square, London, W.C.

LONDON: SATURDAY, FEBRUARY 10, 1900.

THE COUNCIL MEETING.

At the opening of the proceedings last Wednesday the PRESIDENT mentioned that he had received apologies for absence from several members of Council, and after the minutes of the previous Meeting had been read and confirmed, proceeded to read letters of acknowledgment that he had received from the relatives of the late Mr. J. G. F. RICHARDSON, and from Sir THOMAS LAUDER BRUNTON. Reference was made to the death of Dr. R. YATABE, the Japanese pharmacologist, who was a corresponding member of the Pharmaceutical Society, and also to the death of Mr. DANIEL FRAZER, a resolution being passed that the PRESIDENT should write to his relatives a letter expressing the regret and sympathy of the Council.

On the ballot being taken to determine which members of the Council should retire from office, the lot fell upon Messrs. BATESON, CROSS, GROSE, HILLS, STORRAR, SYMES, and WARREN. After this year the retirement of members of Council will take place according to the greater length of time that they have been in office.

The additions to the ranks of the Society comprised 77 members and 35 student-associates.

The annual report of the Registrar, showing the number of members of the Society, the state of the Registers of Pharmaceutical Chemists and Chemists and Druggists at the end of 1899, and giving an analysis of the examinations for the past year, was presented and ordered to be published.

The PRESIDENT commented upon the satisfactory addition that has been made to the strength of the Society in consequence of membership being thrown open to all registered chemists. He expressed regret that the number of failures should be so large in all classes of examinations, and pointed out that the number of persons on the Register of Chemists and Druggists is, nevertheless, 122 in excess of last year.

In reply to a question put by Mr. RYMER YOUNG, whether the present enormous number of failures in the examinations were due to inefficiency of the candidates or a consequence of over-zeal on the part of the examiners, the PRESIDENT said he did not think it was due to any unfairness, and, in response to a further suggestion by Mr. RYMER

YOUNG, that an increase of failures was contemporaneous with the altered mode of conducting the examinations, Mr. CARTEIGHE said that was not correct, as there had been a complete change long before. He thought there might be a still greater number of failures at the next examination, as the time for the ten-guinea fee would be approaching. Moreover the failures would not necessarily be found to take place in subjects that are undertaken by teachers. Dr. SYMES suggested that there might be some little danger of a professor unduly expecting a candidate to be proficient in his own subject, and Mr. CARTEIGHE expressed surprise at hearing that remark, as his own experience was exactly the reverse that the most exacting examiners in scientific subjects were pharmacists, and the object of appointing teaching examiners was that candidates might have the advantage of that greater consideration which teachers might be expected to extend to them from having the peculiar difficulties of the case constantly before them.

The PRESIDENT remarked that the rush of candidates which has taken place during the past year would probably continue at the next two examinations, and he mentioned as a curious fact that a great number of the failures had been in practical dispensing, which is now taught with much less efficiency than in the days when ready-made medicines were not so much in use.

Mr. HILLS added that he could entirely corroborate Mr. CARTEIGHE's remarks, and he hoped that the improved preliminary examination would have the effect of altering the present sad condition of things.

Dr. SYMES expressed gratification that such an authoritative statement had been made, and hoped it would be satisfactory to those disposed to sympathise with rejected candidates as having been hardly dealt with.

In reference to the appointment of examiners in connection with the Council prizes, the PRESIDENT suggested that members of the Scottish Board should, on this occasion, be invited to conduct these examinations, and on his motion it was resolved to invite Professor BALFOUR, Dr. DOBBIN and Mr. BOA.

The report and recommendation of the Finance Committee were adopted without comment.

On the recommendation of the Benevolent Fund Committee, four grants, amounting to sixty-three pounds, were ordered to be paid. The SECRETARY reported the death of an annuitant who was elected in 1877.

The TREASURER, in moving the adoption of the report, mentioned that the average age of the applicants on this occasion was seventy-three, and that most of them had been subscribers to the Fund, which he regretted to say was not always the case.

The report of the Library, etc., Committee contained the usual statement of particulars as to the attendances at the Library and Museum, donations, etc., and when put to the vote was carried with one dissentient.

In answer to an inquiry by Mr. GLYN-JONES whether the company question was now out of the hands of the Council and in the hands of the Law and Parliamentary Committee, the PRESIDENT said that was the case. Mr. GLYN-JONES then said that as there was no report from that Committee he would ask if the PRESIDENT had any statement to make as to what was being done in the matter by the Committee or by the Council, since the Companies Bill would probably include a clause affect-

ing pharmacy similar to that in the last Bill? The PRESIDENT replied that the Bill had not yet been introduced into the House of Commons and the Council had no definite information on that head.

The SECRETARY having read the Report on the Examinations, Mr. GLYN-JONES—referring to the circumstance that a large number of students as well as members who wanted qualified assistants felt that the large percentage of rejections was a very serious matter and that almost the best remedy would be a division of the examination—asked if there was any reason why the Minor examination should not be divided? The PRESIDENT replied that the subject had long been considered by the Council and by the Board of Examiners, and the question was whether any division of the examination should take place until a curriculum was in force.

Mr. CARTEIGHE said he had always been of opinion that the Minor examination ought not to be conducted in two days' sitting; but the Council had been told by the authorities that it could not be divided by interposing an interval between parts of it. Whether a bye-law for that purpose would now be accepted by the Privy Council he did not know; but some years ago that was not entertained. The opinion of the Privy Council's legal advisers was that a candidate when twenty-one years of age was entitled to come up for examination and have an opportunity of passing a qualifying examination within a reasonable time. After some conversational explanation between Mr. CARTEIGHE and Mr. GLYN-JONES that the division of the examination is not merely a matter of bye-law, Dr. SYMES suggested that further consideration of the matter is desirable in view of the advantage that might be secured; the PRESIDENT also agreed that the examination as now conducted is a great strain upon candidates, and Mr. RYMER YOUNG added that whether the question of an enforced curriculum was necessarily connected with the division of the examination or not, he thought there should be no holding out in favour of what appeared to be distinctly an inconvenience, and he might say an obstruction to examinations.

Mr. CARTEIGHE, referring to former contests in connection with this subject, said there would have been no contest if the Council and the members of the Society had been agreed; but other interests had also intervened, representing that the Society wanted to enrich itself through its School. The only course now would be to approach the Privy Council on general educational grounds to see if there were any probability of suitable bye-laws being sanctioned. Mr. HILLS also expressed his opinion that it is not advisable to crowd so many subjects into a few hours of examination and that, if the whole system of education could be improved, it would be desirable to obtain power to divide the examination. Some conversation then followed, chiefly in reference to the practice followed while the examinations were voluntary.

The SECRETARY announced that a communication relating to the International Pharmaceutical Congress had been received from the French Minister of Commerce, and the PRESIDENT stated the nature of the conditions for becoming members, proposing also that the communication should be referred to the Library, etc., Committee.

The PRESIDENT drew attention to a resolution passed at a meeting of students of the School of Pharmacy remarked that he was glad to see that all the men were not gone requesting the Council to grant them the use of the Examination Hall for the purpose of drill: he had provisionally given permission, and proposed that the Council should confirm it, which was agreed to.

After the report of the General Purposes Committee had been considered, it was adopted, and special resolutions were passed authorising the Registrar to take proceedings in various cases of alleged infringements of the Pharmacy Acts.

DIVISION OF THE QUALIFYING EXAMINATION.

As will be gathered from the report of the discussion at the Council meeting on Wednesday (see p. 125), the question of dividing the qualifying examination appears likely before long to come within that sphere of practical politics, which—as a contributor recently pointed out—it can hardly be said to have entered yet. So far as the discussion goes, the members of Council appear to be at one regarding the desirability of dividing the examination into two parts, but the report of Wednesday's proceedings also reveals the fact that there are many points to be considered, and several difficulties to be overcome, before the proposed division can become an accomplished fact.

In the first place it must be ascertained whether the alteration can be effected by means of a modification in the bye-laws, or whether the necessary powers can only be procured by means of an Act of Parliament. The Privy Council alone can decide that point, and if, as Mr. CARTEIGHE seems to fear, fresh legislation should be required, it may be some time before the matter can be settled, the more especially as any Pharmacy Bill that may be promoted by the Pharmaceutical Society at the present time must obviously deal with other matters besides an alteration in the examination arrangements, so that the consummation of the wide-spread desire to lighten the candidates' burden may be deferred indefinitely.

One of the best arguments in favour of dividing the examination was that advanced by Dr. SYMES, who urged the desirability of endeavouring to keep apprentices interested in the necessary subjects of study during the long interval which may elapse between passing the preliminary and entering for the qualifying examination. But other good arguments are plentiful, and of serious opposition there would now, probably, be none. Most pharmacists will doubtless agree that division of the examination is desirable, but whether that division be made to coincide with the enforcement of a curriculum, or dealt with as a separate matter, will probably depend upon the manner in which powers to divide the examination are secured. If such powers can be obtained by a mere alteration of the Society's bye-laws the probability is that division of the qualifying examination will come long before a curriculum can be enforced, but if fresh parliamentary powers should be needed it may be anticipated that the two great changes will be effected together.

ANNOTATIONS

THE COMPANIES ACTS AMENDMENT BILL, which passed the House of Lords last Session, is being introduced into the House of Commons by Mr. Ritchie, the President of the Board of Trade, as a new measure, but it is understood that the Bill will be practically identical with its immediate predecessor. Assuming that to be the case, the Bill will contain the following clause, applying the provisions of the Pharmacy Act, 1868, to limited companies:—“No company may carry on the business and use the description of a pharmaceutical chemist or chemist and druggist unless such business is *bonâ fide* conducted by a manager or assistant being a duly registered pharmaceutical chemist or chemist and druggist, as the case may require, and unless the name of the person so qualified is conspicuously posted in the shop or other place in which the business is carried on, but, subject to this provision, anything which would be an offence under section fifteen of the Pharmacy Act, 1868, if committed by an individual, shall be an offence if committed by a company.” In addition, the Bill will contain the clause providing that it shall be unlawful for a company to carry on the profession or business of a physician, surgeon, dentist, or midwife.

THE NOTTINGHAM AND NOTTS. CHEMISTS' ASSOCIATION may have to effect some rearrangement in the course of instruction provided at University College, Nottingham, for pharmaceutical students, as support is being given in the City Council to the attempt that is being made to secure the benefits of the course for others than those on whose behalf it was especially arranged. Reference has already been made to the matter in the *Pharmaceutical Journal* for December 23 and 30 respectively, where it was explained how the managing director of a limited company carrying on the business of a chemist and druggist had complained in the local newspapers because persons employed by the company were excluded from classes specially organised and conducted for the benefit of chemists' assistants and apprentices. It now appears that a member of the City Council has been induced to ask, at a meeting of that body, whether it was true that the Nottingham Chemists' Association had arranged with the University College Committee that certain classes for pharmaceutical study should be provided at the College, the Association guaranteeing a minimum sum for each subject taught, and—if it were true—whether the Association, which was in no sense responsible to the Council, had the power to exclude from those classes anyone they chose, considering the fact that the University College was established for the benefit of the ratepayers? In reply, the Councillor who had so suddenly developed an anxious desire to know what has been matter of common knowledge for several years past, was informed that, in the early history of the College, an arrangement was made with the Nottingham and Notts. Chemists' Association by which certain classes were held in addition to the ordinary College classes.

THE BASIS OF THE ARRANGEMENT is that the Nottingham Chemists' Association should bear the cost of such additional classes, but that in return the classes should be limited to the young men in the employ of members of the Association. The object of the classes is to prepare those young men for the pharmaceutical examinations, and the ordinary College classes, which are open to all at a fee less than that charged for the classes arranged for the Association, give an adequate preparation for those examinations in botany and inorganic chemistry. In materia medica and dispensing, however, the committee did not arrange classes, but allowed the use of a room at the College for classes to be held under the auspices of the Association by teachers appointed by that body. The Association is so determined that the classes shall be confined to chemists' assistants that the Committee has been given to understand that, in the event of the classes being thrown

open, the Association will arrange for their own men outside the College. If that were done, it was pointed out, there would probably not be sufficient demand for pharmaceutical classes to justify the College Committee in arranging such classes. For the information of the Council it was also stated that the practice of having limited or closed classes was receiving the attention of a committee. At the next meeting of the Council the matter is again to come under consideration, and it is thought probable that some modification in the existing arrangements may be made.

THE BRITISH PHARMACEUTICAL CONFERENCE, the affairs of which were briefly alluded to last week, is held to represent the progressive element in pharmacy, including, as it does, every member of the Council of the Pharmaceutical Society and, with few exceptions, all the Scottish Executive and the examiners of the Society, besides having had during nearly forty years some of the most loyal and scientific members of that body as its presidents. It would seem, therefore, that the B.P.C. should be better supported by the local secretaries of the Pharmaceutical Society, for only eighty-eight out of three hundred and two local secretaries belong to it. The proportion of Welsh and Scottish local secretaries is greater than that of English ones. A map showing the distribution of members of the Conference would reveal some singular blanks and curious anomalies. Thus, large towns like Portsmouth, Blackpool, and Darlington are not represented at all, and others such as Perth, Canterbury, Winchester, Middlesborough, and Weymouth have only one member each on the list. It is also interesting to note that in many towns where a local secretary of the Pharmaceutical Society exists, but does not belong to the Conference, there are often other chemists who do, being apparently more fully awake to the business advantages that accrue to the man who moves about the world, exchanging views with others who may have wider opportunities of acquiring useful information, and seeing and hearing of the newest and best things in science and commerce.

THE CONFERENCE MEETINGS are regarded by many as mere occasions for unnecessarily expensive holidays, the opportunities they afford of coming in contact socially with business people, seldom met otherwise, and of learning much that is useful, not being sufficiently recognised. Mr. Holmes, the President of the Conference — who asks us to state that copies of the classified list of members referred to last week can be obtained by any pharmacist who is inclined to make use of it, in furthering the aims of the B.P.C.—would like to direct the attention of local secretaries of the Pharmaceutical Society and other pharmacists to the fact that the Conference is to pharmacy very much what the British Association is to the scientific societies of Great Britain, and should accordingly be more widely supported. It is obvious that the work it is capable of accomplishing must be in direct proportion to the numbers who belong to the body, and perhaps, with a more thorough organisation than exists at present, it may become a useful factor in combination with other bodies that are working for the good of pharmacy.

ETHER AND ATOMS provided Professor Fleming with interesting subject-matter when lecturing recently at the London Institution. He began by pointing out that among the achievements of philosophic thought in the nineteenth century a high place must be given to speculations on the existence of an ether filling space. He then gave a brief sketch of the rise of the undulatory theory of light, and, as a second stage in the development of the ether theory, of the conception of an electro-magnetic medium. The existence of electric waves was deduced as a consequence of the system set forth by Clerk Maxwell in 1864, Maxwell prophesying that they would be found to have the same speed as light waves. Hertz discovered an experimental way of verifying those predictions in 1879. Hertz's method of detecting the existence of the waves was described, as well as that afforded by the “coherence” of metallic filings, discovered by

Hughes in 1879, afterwards rediscovered by Branly and applied by Marconi to the purposes of wireless telegraphy. The chief thing known about the all-pervading ether is its power of taking up enormous quantities of energy, though what becomes of the energy thus sunk in it remains to be discovered. The ether possesses elasticity which, however, probably differs from the bulk elasticity of a compressed gas or the elasticity of a steel spring. With regard to atoms, Lord Kelvin and others have of late years approached some conception of their dimensions. But even if it were possible to improve the microscope so as to render visible things of the size of atoms, they could not be seen, for to be seen they must be still, whereas they are in very rapid motion, a hydrogen atom, for example, going a mile a second, while the velocity of the atoms in solid bodies is probably not of a very different order. In conclusion, reference was made to the recent work of Professor J. J. Thomson, which seems to show that chemical atoms are not the smallest objects with which we can be acquainted, and that each one can be split up into about a thousand parts—a condition in which they form, in Sir William Crookes's phrase, "a fourth state of matter."

THE SUBJECT OF BOTANY IN SCHOOLS was discussed by Professor Miall at a recent Conference of Science Teachers. He pointed out that while chemistry and physics have lately come to the front in education, botany has stood still, though it is admirably suited for school work, as being the best initiation into the group of sciences formerly known as natural history. It also has a practical value, since exact scientific knowledge has become more and more necessary for success in farming. But at present botany is often not taught in the right way. In classes consisting of children ranging from about eight to twelve years of age Professor Miall thinks the lessons should be based on natural objects, not on pictures or photographs, and the introduction of books into the class or the use of technical terms of Greek or Latin origin should not be permitted. Where the ages of the students range from thirteen to sixteen, Professor Miall thinks that chemistry, mathematics, and physics should take the lead; but students from about seventeen to nineteen should return to the natural history sciences, and the great practical value of botany would make it a favourite subject. Since, as urged by a writer in the *Standard*, the main aim of a scientific training is to inculcate accurate observation and inductive reasoning, the students should be told nothing that they can find out for themselves, but they should be shown how to set about doing that. With regard to the use of technical terms, for fairly advanced pupils their employment is often useful, and sometimes necessary, but they should be employed cautiously, as many young people delight in using fine words to conceal hazy ideas.

FOR TEACHING BOTANY—the science on the natural history side, which is best suited for school work—the materials for object-lessons and for more mature study are alike easily obtained. They afford great variety and subjects progressing in difficulty, and do not involve the pain or death of sentient creatures, while the beauties and the marvels of plant structure cannot fail to attract and awaken an intelligent curiosity. But the study of botany, as Professor Miall regretfully admitted, is at present very far from having realised his ideal—at any rate, in this country. It has to contend with various difficulties, such as expense, lack of time, etc. Professor Miall, however, would teach fewer things at a time, rubbing in one subject well before going on to another, so that the knowledge is likely to stick. The multiplication of subjects is one cause why so many students quickly forget what they have learned. It is also possible to set too high a value on examinations. Though useful in their way, they have become almost a fetish in this country, and too often at the present day preparing for examinations is superseding genuine education.

BACTERIOLOGICAL EXAMINATIONS have been conducted on a satisfactory basis, in the Lambeth district, during the past year, judging from the report presented to the Lambeth Vestry by its medical officer, Dr. J. Priestley. The report shows the result of the first year's working of the bacteriological laboratory established by the Vestry. Bacteriological outfits were supplied to medical practitioners in the parish, and examinations made free of charge. A total of 388 examinations were made during the year, and out of 214 suspected cases of diphtheria, the true diphtheria germs were found in 99 (*i.e.*, 46.2 per cent.); whilst in 81 cases of suspected typhoid, 43 (*i.e.*, 53.1 per cent.) gave the Widal or typhoid reaction. There was thus a saving in notification fees sufficient to justify the provision of the bacteriological laboratory, not to mention the great advantages from more exact diagnoses.

ACETYLENE MAY CAUSE SERIOUS ACCIDENTS when mixed with air or oxygen, such mixtures being peculiarly liable to explode. It is not surprising, therefore, to find the *London Gazette* giving notice this week that it is proposed to submit to her Majesty in Council the draft of an Order in Council providing that acetylene, when in admixture with atmospheric air or with oxygen, shall be deemed to be an explosive within the meaning of the Explosives Act, 1875, and that it shall not be manufactured, imported, kept, conveyed, or sold. Notice is also given that, in accordance with the provisions of the Rules Publication Act, 1893, copies of the proposed draft Order in Council can be obtained by any public body at the Privy Council Office, Whitehall.

THE 'MEDICAL PRESS' has at last expressed regret for giving needless offence to pharmacists by its untrue statement that the very active alkaloids "cannot be compounded even by the most capable and conscientious chemist without the risk that the entire dose will be concentrated in one or two pills." It is suggested that the remarks published on the subject have been misinterpreted, but the words quoted above do not lend themselves to obvious misinterpretation. In the circumstances, the *Medical Press* does not abase itself unduly by stating that it does not doubt there are "many skilled and punctiliously careful compounders" who could properly subdivide a quantity of strychnine into a given number of pills. There is, of course, no doubt about the accuracy of our contemporary's original assertion that, while makers of compressed tablets "can grind a drachm or an ounce" of strychnine into a multitude of tablets, an individual dispenser "cannot be certain of effecting the same subdivision for half-a-dozen pills." Apart from the fact that no manufacturer is ever likely to attempt to "grind" strychnine into tablets, it is a physical impossibility to get a drachm, let alone an ounce, of the alkaloid into six pills of any ordinary size. But perhaps the words quoted cover a hidden joke, and failure to appreciate that constitutes the misinterpretation of which the *Medical Press* now complains.

THE NINETEENTH JUNIOR PHARMACY BALL was held on Wednesday, February 7, at the Portman Rooms, Baker Street, W. The arrangements were admirably carried out under the direction of Mr. R. Cassie, who held office as secretary for the first time. The company numbered about 320, and amongst those present were the President of the Pharmaceutical Society and Mrs. Martindale, Mr. W. Warren, Mr. and Mrs. Francis, Mr. and Mrs. J. C. Umney, Mr. and Mrs. A. J. Phillips, Mr. and Mrs. E. W. Lucas, Mr. J. H. Mathews, Mr. F. W. Gamble, etc. Mr. W. Martindale took the chair at supper and, in proposing the double toast of "Success to the Junior Pharmacy Ball" and "The Ladies," coupled the name of Mr. Cassie with the first part of his toast, and that of Mr. R. A. Robinson, jun., with the latter. Both gentlemen briefly replied, and a very successful ball terminated at about 3.30 a.m. Messrs T. C. W. Martin and C. W. Martin acted as M.C.'s.

PROCEEDINGS UNDER THE PHARMACY ACTS.

THE LABELLING OF POISONS.

Pharmaceutical Society of Great Britain v. Lewis's, Limited.

At the Manchester City Police-court on Friday, February 2, before Mr. Headlam, Stipendiary, Lewis's, Limited, who have large stores in Market Street in that city, were summoned by Mr. Harry Moon, acting on behalf of the Pharmaceutical Society of Great Britain, for contravening the Act regarding the labelling of poisons.

Mr. Robson, solicitor, Manchester, appeared on behalf of the prosecutor, and Mr. Orford, solicitor, conducted the defence.

Mr. Robson said the summons was taken out under Section 17 of the Pharmacy Act of 1868, and he might remind his worship that this Act was one under which the Pharmaceutical Society acted the part of police, and that in taking out the summons they were just doing their duty under the Act. The summons charged Lewis's, Limited, with selling certain poison—to wit, chloroform and morphine, forming part of Dr. J. Collis Browne's chlorodyne, on January 3, 1900, without labelling the bottle with the name and address of the seller, and under the Section they were liable to a fine not exceeding £5. He might say his friend, Mr. Orford, had admitted, and was willing now to admit, the presence of the poison, so that he had no need to call witnesses to prove that part, but he should call a witness who bought poison, and that would form his case.

Arthur Foulds stated that on January 3 last he went to the drug department of Lewis's shop and bought the bottle of Dr. J. Collis Browne's chlorodyne, which he produced. He paid 2s. 2d. for it. There was no label showing the name and address of the seller. He bought the bottle of castor oil produced at the same time. The young man who served him was about twenty-five years of age, and he thought he should know him again if he saw him.

By Mr. Orford: It was five or six years since he bought anything at Lewis's, or attempted to do so.

Mr. Orford: You mean to say that during the last six years you have not made a single purchase at Lewis's of this kind, or with this object in view?

Witness: No.

Mr. Orford: I have nothing further to ask him. I have not seen the bottle, your worship. (Bottle handed in.)

Mr. Robson: The Section says it shall have the name and address of the seller.

Mr. Headlam: Quite right. It ought to have had Lewis's label on in addition to Dr. Collis Browne's.

Mr. Robson: My friend has just asked a question which I should like to make one remark upon, and that is as to the witness having bought anything at Lewis's before. It is only fair to assume on that, that this being only one purchase, there are other cases in which labels have been omitted.

Mr. Orford: I think my friend must confine himself to the case in point, although I do not think he has dealt very harshly with me. Proceeding, Mr. Orford said he thought the briefest way to put it was that it was an accident—an accident it was impossible to provide against where the employees were so numerous and the establishment so extensive. He would put the chemist, who was a competent man, into the box, and he would explain how, in all probability, the accident had arisen. He thought it was a case which could be dealt with by the smallest punishment which could be meted out.

Wm. Hartley Nichols stated that he was the chief of Lewis's, Limited, drug department, in Market Street, and they kept the poisons in a particular place. Dr. Collis Browne's chlorodyne was kept upstairs in the stock-room, and brought down each morning as required. The practice was simply to send it down the hoist, and an assistant put the bottles on the counter, and stamped them with a rubber stamp, as time is valuable. This had been inadver-

tently omitted. Since he got the summons he looked, and there was only one unstamped. There must have been two unstamped.

Mr. Orford: The sale is very extensive?

Witness: Very extensive indeed, and we do our best to see that the law is carried out. It is a matter of inadvertence. To do away with this I have since insisted upon the assistants putting adhesive labels on. You cannot do more than that. You cannot be behind every assistant's back. I give them the order to do that, and they ought to do it.

Mr. Robson: I should like to ask if there are many qualified assistants, and, if so, how many, at your drug counter?

Witness: Simply myself.

Mr. Orford: And he has issued instructions that these bottles are to be labelled.

Mr. Headlam: And this bottle has got none. It is very remarkable.

Mr. Orford: It is useless for me to waste your time. We have made a blunder, and must abide by it.

Mr. Headlam: We shall fine you 40s. and costs.

ENGLISH NEWS.

THE PHARMACOPŒIA AS A STANDARD.—The following comments on Mr. Baggallay's recent decision appear in *Food and Sanitation* for February 3:—"Mr. Baggallay is, it would appear, right in his statement that there is no Act of Parliament which makes the B.P. the standard for any compound of drugs, but there is a high court decision in *White v. Bywater*, 19 Q.B., D. 582; 36 W.R., 280; 51 J.P., 821, which recognises the British Pharmacopœia as the standard, and is nearly on all-fours with the case dismissed by Mr. Baggallay. A chemist sold some tincture of opium deficient in strength as compared with that prepared according to the standard of the British Pharmacopœia. It was held by Lord Coleridge, C.J., and A. L. Smith, justice, that the chemist was rightly convicted, although the purchaser had not asked for tincture of opium prepared according to the standard of the British Pharmacopœia. Mr. Justice A. L. Smith said, 'Tincture of opium must mean the article known in commerce as tincture of opium. The thing supplied was not tincture of opium, but an inferior article.' (*Vide* Bell and Scrivener, 'Sale of Food and Drugs Act,' 2nd edition, pp. 19 and 20; Hedderwick, 'Sale of Food and Drugs Act,' page 10; Cribb and Robinson, 'Food and Drugs,' page 48; Macaulay, 'Law on Adulteration of Food,' page 5.) Amongst others Mr. Glyn-Jones states: 'In reference to drugs, it is sometimes argued that the B.P. is the standard under the Food and Drugs Act. There is not a sentence in any of the Food and Drugs Acts which warrants the assertion, and no magistrate could rightly convict a defendant on the ground that the analyst's certificate says the article in question is not of B.P. strength. He must have oral evidence to prove to him that the B.P. is the commercial standard for that particular article. At Plymouth, Dr. Attfield, surely an authority as to what the Pharmacopœia is or is not, stated that it was not the legal standard, that it was not prepared with that object in view.' Mr. H. Wippell Gadd, of Exeter, says:—"That the authority of the Pharmacopœia as a standard should be disputed is not surprising, in view of the conflicting views of different authorities.' The legal position of the question appears, however, not to disclose any serious conflict by authorities. We believe that had the case been taken to the court of Queen's Bench Mr. Baggallay's decision would have been reversed. In any case, it is not worth taking as a serious precedent because it is clearly overridden by the case of *White v. Bywater*, in the Queen's Bench appeal."

"TRUTH" ON ARMY MEDICAL COMPOUNDERS.—In last week's *Truth* the editor says:—"It appears that I overrated the generosity of the War Office last week when I said that 4s. a day was being offered to dispensers for service with the Army in South Africa."

The pay is really only 3s. 6d. a day. There is not the slightest possibility that chemists holding the diplomas of the Pharmaceutical Society will be recruited on these miserable inadequate terms, and, in default, the War Office will have to accept the services of men supposed to have had more or less—generally less—practical experience of dispensing. In this respect, however, the War Office is only following in the footsteps of the Local Government Board, which admits men to Poor-law dispenserships with qualifications of much less value than those required for similar appointments in her Majesty's prisons. Soldiers and paupers are apparently both considered of less account than criminals."

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.—The sixth meeting of the session was held in the Lecture Theatre, at 17, Bloomsbury Square, on Friday, 26th ult., Mr. E. M. Chapman in the chair. There were thirty-eight members present. The minutes of the previous meeting were read and confirmed, and the Chairman then asked if any member had business to bring before the meeting. Mr. Garsed asked what had been done in regard to printing a fresh supply of pamphlets of the Rules of the Association. He was informed by Mr. Heslop, one of the secretaries, that no decision to print a further quantity had been come to. Some discussion ensued as to the advisability of revising the existing Rules and appointing a committee for the work. It was finally decided to revise the Rules, and the following are the names of those elected as a committee to undertake the revision:—Messrs. Garsed, Upsher Smith, Gray, Pollard, Finmore, Allen, Woolcock, and Heslop. The Chairman then called on Mr. Lenton to read his paper, "Digestion, with a Short Note on Digestive Ferments." Mr. Lenton first described, in a simple and interesting manner, and with frequent reference to explanatory diagrams, the mechanism by which the process of digestion is carried out in the human body. He then proceeded to explain the various actions to which our food is subjected before it can be absorbed by the tissues of the body, and concluded with some remarks on those ferments which play an important part in digestive operations. Mr. Lenton was thanked by the Chairman for his paper, which was greatly appreciated by all present. Several members had questions to ask, and those having been answered by the writer of the paper, the meeting terminated.

BURNLEY AND DISTRICT CHEMISTS' ASSOCIATION.—At a general meeting held on Tuesday, January 30, Mr. J. A. Heaton, President, in the chair, several questions of importance came up for consideration, and amongst other things it was decided shortly to hold a dinner. Mr. U. A. Coates read a paper entitled "Test Your Drugs," in which he pointed out that the greatest mistake a chemist could possibly make was to endeavour to supply an article as cheaply as possible without consideration as to quality. He mentioned a number of the different adulterations and impurities in drugs he had met with during recent years. A good many chemists, he said, were content to leave the responsibility for the purity of their drugs to the wholesale houses who supplied them, or, if made by themselves, they trusted to the perfect accuracy in manufacturing them. But, however pure and up to the standard they might be at first, time eventually worked wonders, and when a prosecution ensued the only plea that could be put in was that it had been a long time in stock. It was really astonishing when a man accustomed himself to continually examine his stock how easy it was to detect deterioration or adulteration. On the motion of the Chairman, seconded by Mr. Dodsley, a vote of thanks was accorded to Mr. Coates for his paper, which was greatly appreciated by all present.

A MEDICAL "PICK-ME-UP" containing strychnine appears to have caused the death of Dr. Harvey (34), a single man, and a well-known practitioner in the Ecclesall Road district of Sheffield.

According to newspaper reports, on Saturday evening, February 3, Dr. Harvey and a Mr. Barraclough played a friendly billiard match at the Conservative Club in Ecclesall Road. The game was followed by supper and an impromptu concert, during which Dr. Harvey delivered a short speech. He arrived at his home about 3 a.m., and Mr. Barraclough went into the house with him, leaving about 3.30 a.m. A short time afterwards the housekeeper and her husband were aroused by Dr. Harvey, who came to their bedroom door and said, "Do you want to see me die? If so, come now, because I shall be dead in ten minutes." His prediction was practically verified, for before Dr. Furness, who was immediately summoned, arrived, he died, apparently in great agony. It is surmised that after Mr. Barraclough left him, Dr. Harvey consumed a large quantity of whisky out of a bottle, which had been nearly emptied, and subsequently mixed himself a "pick-me-up," such as he was known to be in the habit of taking, and one of the ingredients of which was strychnine. A beaker, which Dr. Furness stated had contained a strychnine solution, was found on the surgery table. Dr. Harvey was a Sheffield man, and at one time was employed as a chemist's assistant by Messrs. Cubley and Preston.

THE SALE OF CAMPHORATED OIL.—At Cwmbran Police-court, George Frederick Thorne, grocer, of Newport, Caerleon and Cwmbran, was summoned for selling camphorated oil said to be deficient in camphor to the extent of 50 per cent.—It was contended for the defence that the county analyst's certificate was bad, on the ground that it did not specify the ingredients, consequently the Bench could not form an opinion upon it, the case of *Fortune v. Hanson*, Queen's Bench Division, being quoted in support of the argument.—The Magistrate's Clerk, after reading the certificate, said the analyst did not certify that he was analysing camphorated oil, merely stating that he had analysed oil from a bottle marked "Camphorated Oil."—The Bench retired to consider the point, subsequently giving judgment to the effect that the case must be dismissed, and ordered the prosecution (the County Council) to pay the Court costs and two guineas towards the solicitor's fees. The magistrates did not wish to discourage such prosecutions, but proceedings must be taken in the proper form. In the event of the County Council appealing, the Bench was prepared to state a case for the High Court.

SCOTTISH NEWS.

GLASGOW CHEMISTS' AND DRUGGISTS' ASSISTANTS', AND APPRENTICES ASSOCIATION.—At the weekly meeting, on the 2nd inst., Mr. J. P. Gilmour, President, occupied the chair, and Mr. W. Bowie read a paper on "The Medicinal Plants of the Clydesdale Flora," which is printed at page 119. The Chairman, in conveying the thanks of the meeting to the essayist, remarked that the mediæval Doctrine of Signatures, which asserted that Providence or Nature had "signed" or distinguished certain plants with the appearance of the organ whose diseases they had intended to cure, had led to the inclusion of many inert vegetable substances in the popular materia medica, e.g., Solomon's seal, pilewort, eyebright, etc. At the same time, as Mr. Bowie had reminded them, it was as unwise as it was pedantic to despise domestic simples just because they were vulgar, since it was always from empirical sources that science took its rise. Mr. Mayo had long ago shown even the most grotesque popular superstitions had often some substratum or suggestion of scientific truth in them.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.—During the practical demonstration on "Botany in January," referred to last week (see page 112), Mr. J. Rutherford Hill said among the plants gathered were *Geranium robertianum* growing luxuriantly in a sheltered corner, *Lamium album* in flower under the shelter of a railway bridge, *Stellaria media* and *Senecio vulgaris* in flower and fruit on open ground; *Epilobium montanum*, bearing last

year's stems, and opened empty capsules, and the young shoots with compact four-ranked leaves; *Taraxacum officinale* with root containing much thick latex; *Geum urbanum*, an excellent illustration of a rhizome; and *G. rivale*, with large lyrate leaves: *Lychnis dioica*, *Mercurialis perennis*, young shoots with panicles of unopened flowers; *Valeriana pyreniaca*, *Sanicula europæa*, *Scrophularia nodosa*; large tuberous root showing stems of two years and the young shoots of a third, and bearing the two-celled opened capsules of the Scrophulariaceæ. *Urtica dioica*, *Cratægus oxyacantha*, a branch loaded with ripe fruit. There was a Scotch maxim, "Many haws many snaws," but this proverb had been belied so far as the present winter had gone. *Ulmus campestris* with flower buds almost ready to open, *Fraxinus excelsior* bearing last season's two-celled winged capsules, *Hedera helix* in flower and fruit, and showing that the ivy does not flower till it gets free of supports on which it is climbing, *Bellis perennis*, lateral rooting offsets showing how the common daisy spreads rapidly and damages fine lawns; *Ranunculus ficaria* gathered at an earthslip, where the tubercular roots had been freely exposed; *Heracleum sphondylium*, showing the very large perennial roots of this common umbellifer, *Prunus padus*, with well-developed clusters of flower buds; *Cytisus scoparius* in fruit; *Rubus fruticosus* in bud and flowers and also with rain-washed, dried fruits from which the fleshy parts had disappeared; *Taxus baccata fastigiata* bearing flower buds; *Acer pseudoplatanus*, the ground in some places was littered with green leaf buds of this. Was it birds, or wind, or frost that detached them? Dead branches of this tree were showing bearing a rich crop of the pretty red beadlike fungus, *Tubercularia vulgaris*; *Buxus sempervirens* with flower buds almost open; *Galanthus nivalis*. The pretty musci *Funaria hygrometrica* and *Mnium cuspidatum* from a stone and lime dyke, *Hypericum perforatum* and *H. quadrangulare* bearing the open three-celled capsules of last season and the young shoots of the present and *Ulex europæa* in flower.

POLITICAL GOSSIP.

JUDGE SNUBBING is a form of amusement in which few mortals can indulge, for it is too apt to be attended by unpleasant consequences to ever become generally popular. Even privileged folk like members of the House of Commons are somewhat chary of selecting the Bench as the subject for their admonitions, homilies, or exhortations. Mr. D. A. Thomas (Merthyr Burghs), however, is not one of the timid members of St. Stephen's, and he has secured Tuesday, March 6, for the purpose of inflicting the following classic snub on a High Court judge:—"That an Address be sent praying her Majesty to express her disapproval of the many foolish and extra judicial utterances made from the Bench by Mr. Justice Grantham, one of her Majesty's Judges of the High Court, and previously a member of this House." Mr. Thomas is a J.P. and a D.L. for Glamorganshire, and appears to have merited his appointment to these high honours if the judgment displayed in his notice of motion be taken as a criterion, for he has devised a form of punishment calculated to "fit the crime." Judges must not be garrulous, and if inclined that way must have gentle aid to self-restraint, thinks this Welsh mentor of judicial morals. But the subtlety of it, too; the House will not, of course, adopt Mr. Thomas's motion—but what of that? The honourable gentleman has obviously calculated on Mr. Justice Grantham perusing the Votes and Proceedings of the House, and thus receiving a psychological castigation through the medium of an accusing conscience. The motion may fail, but "rescripta manet," and no man, however judicial his mind, cares to be written down an ass, even by implication.

BILLS, BILLS, BILLS, but no Companies Bill! Nearly 400 members took part, or intended to take part, in the ballot for private members' Bills, and sixty-seven measures were let loose on Friday

night—but Mr. Ritchie did not produce *the* Bill pharmacists were expecting on Monday evening with so much anxiety. As a matter of fact, there may possibly be an intention to make some short general statement in introducing the Bill under what is known as the "ten minutes" rule, and this would account for the postponement of the first reading until February 8. If the debate on the Address be still in the way a further postponement may then be necessary. It must be remembered, too, that all Parliamentary business must be subordinated to the exigencies of the military situation. Meantime patience and hope, together with a little further trust in the constituted leaders, must be enjoined upon the pharmaceutical calling. There is good reason to believe that the Minister in charge of the Bill is quite disposed to give pharmacists an opportunity of stating their case; but he is not disposed, nor are any of his colleagues in the House, to consider the matter in any other aspect than as affecting the interest, safety, and convenience of the public.

A COMPANIES ACT AMENDMENT BILL was announced as having been introduced on Friday, 2nd inst., and quite a flutter of excitement was experienced in some pharmaceutical circles until it was discovered that the announcement referred to Mr. Faithfull Begg's measure, which has now become an annual one. With Mr. Begg are associated Messrs. L. Walton (S. Leeds), J. E. Gordon (Elgin and Nairn), Hedderwick (Wick), and H. H. Marks (St. George's, E.), a combination highly representative of the capitalist and financier. The Bill is purely commercial, and possesses no special feature of interest for the pharmacist—ordinary or otherwise. Its second reading is tabled for April 4.

AMONG OTHER FAMILIAR FRIENDS making a reappearance on the Parliamentary stage may be noted the following:—Boiler Registration and Inspection, brought in by Mr. C. Fenwick (Wansbeck), and fixed for a second reading on March 7; Midwives' Regulation, in charge of Mr. Tatton Egerton (Knutsford), to be read a second time on February 28; a Bill on the same subject brought in by Mr. Seton-Karr (St. Helens); Registration of Firms (Sir Stafford Northcote's old Bill), under the pilotage of Mr. Emmott (Oldham); Street Noises Regulation, promoted by Mr. Jacoby (Mid-Derby), which will essay its second stage on May 30; and the Shops Regulation Bill of Sir Charles Dilke, which has the uncommon good fortune to be fourth order of the day for next Tuesday. Some, at any rate, of these measures will see other Sessions before they reach the statute book, but it seems a pity the Registration of Firms Bill should be numbered with the hopeless annuals. As has been pointed out in these columns before, its passage into law would immensely facilitate the detection of fraudulent trading, and, incidentally, would considerably aid in the administration of the Pharmacy Acts.

CONCESSIONS carry their own punishment. Having wrung from the Post Office authorities at various times little departures from the strict interpretation of official regulations, Mr. Henniker Heaton and reformers of a similar kind are for ever taunting the Postmaster-General with the anomalies and inconsistencies thus occasioned. On Monday the member for Canterbury pointed to the glaring example of official wrongheadedness exhibited by the fact that "p.m." was, telegraphically, one word, whilst "P.M." was rated at a penny. He further wanted to know why "s.s." should be two words, whilst "steamship" was reckoned as one word. He finally asked that "Charing Cross" might be treated as a halfpenny-worth, on the ground that "Saint Cloud" in foreign telegrams was only charged as one word. Mr. Hanbury, in reply, declined to see the analogy between the cases, and, further, laid down the rule upon which the Department charges. As this is useful know-

ledge it may be well quoted here:—"All combinations of letters which are in the nature of cipher are charged at the rate of five letters to a word. In the case of all other letters, not being words in any European language, or in Latin, each letter is charged for." Hence, if a constituent wishes to wire to his member, and dutifully pays him the compliment of telegraphing the honourable distinction conveyed by the letters M.P., it will cost an additional penny, K.C.B. would cost three halfpence, and the despatch of the full string of letters properly appertaining to H.R.H. the Prince of Wales could only be thought of by a millionaire.

LONDON UNIVERSITY ELECTION is proceeding—not like an election at all, but more on the "sale now on" principle. The poll will be open until the end of the week, in order to give the widely-scattered electorate an opportunity of recording their votes. Up to the time of going to press Sir Michael Foster was well ahead of Dr. Collins, his nearest competitor, and there appeared to be a reasonable prospect of his election.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of this Association was held at 73, Newman Street, W., on Thursday, February 1, the President, Mr. F. W. GAMBLE, in the chair. There was a fair attendance. The preliminary business being dispatched, the PRESIDENT called upon

Mr. T. E. WALLIS to read a paper on:—

AQUATIC PLANTS.

The paper was of considerable length, illustrated by a number of cleverly-executed coloured diagrams, and was of an absorbing character throughout. The following is a brief abstract:—

Aquatic plants as a group show wide differences from the ordinary terrestrial plants, owing to the influence of the environment upon their mode of life. Roots are either badly developed or are entirely absent; root-hairs are generally wanting. A great degradation is seen both in the vascular and supporting tissues, which are not needed as in land plants for the transport of water and the maintenance of rigidity. The epidermis is usually not cuticularised, and absorption is carried on by the whole general surface of the plant. Another striking general characteristic is the large development of the intercellular space system, which allows for the more ready performance of gaseous interchange, and makes the plants buoyant, so that the leaves are brought into the upper and more brilliantly illuminated layers of water. Many aquatic plants also make special provision to ensure safety from extinction during the winter season when the upper layers of water become frozen. This is accomplished by the development of winter buds, which sink to the bottom of the pond at the end of autumn, and when spring approaches rise to the surface, where they develop into plants resembling the parent. To study aquatic plants systematically they may be divided into two great groups:—(1) Plants living in deep water. (2) Plants living in shallower water.

(1) *Plants Living in Deep Water.*—Plants require a certain intensity of light if they are to be successful in the struggle for existence, and it is found that at a depth of more than 300 or 400 feet the gloom is so great that green plant life is impossible. For this reason the ocean is, as it were, fringed with a comparatively narrow belt of vegetation, consisting mainly of algæ. The seaweeds show peculiarities in two directions—difference in colour, which is used as a basis for classification, and difference in form, which varies from a simple spherical cell to a large straggling plant with a stout and almost woody stem.

(2) *Plants Living in Shallower Water.*—These are chiefly vascular plants, and can be subdivided into two sets:—Submerged plants and semi-submerged plants.

(1) *Submerged Plants* can be further divided into two sets:—
(a) *Those rooted in the mud.* These belong chiefly to several of the

most primitive monocotyledonous orders—e.g., Najadaceæ, Potamogetonaceæ. The embryo is of the type known as macropodous or big-footed, and exhibits a peculiar method of germination. Pollination is effected either beneath the surface of the water, when the pollen has the same specific gravity as water, and is filiform or spherical; or at the surface, when special means are adopted, as in Vallisneria. (b) *Those floating freely in the water.* This set embraces such plants as Hydrocharis, the frogbit. It also includes two very interesting carnivorous plants—viz., Utricularia and Aldrovanda.

(2) *Semi-submerged Plants* are similarly divisible into two sets:—
(a) *Those rooted in the mud.* These include the well-known Nymphæas or Water-lilies and the Victoria regia, which shows curious orbicular leaves with upturned edges and a waxy cuticle to keep water from their upper surfaces, upon which are found the stomata. (b) *Swimming Plants.* A good example is found in the Nat. order Pontederiaceæ, some genera of which have rosettes of leaves with inflated petioles, so that they float on the surface, and are blown about on the lakes of S. America like little ships. A familiar swimming plant is the little duckweed, so common on the surface of neglected ponds. Here also are included two little ferns:—Salvinia and Azolla.

A general survey of aquatic vegetation has now been made, and two points stand prominently forward—viz., the many variations in structure developed to cope with their peculiar environment and the small size of the majority of these plants, a fact which may be connected with the absence of a transpiration current.

At the conclusion of the paper the PRESIDENT heartily congratulated Mr. Wallis on having produced a paper of so interesting a character. He thought that if some of the carpens who are of opinion that botany should be excluded from the pharmaceutical syllabus had been present, they would have been converted. He had always found botany to be the most interesting subject in the syllabus, and no one who took up the study failed to derive pleasure from it. He then went on to comment upon the wonderful adaptation of nature to environment, and remarked that aquatic plants, apart from forming a most interesting study, at times became almost of national importance, instancing cases where their rapid growth had caused considerable trouble in the navigation of rivers. He congratulated Mr. Wallis on the excellence of his diagrams.

A conversational discussion then ensued on the properties of water-cress, seaweed, and other aquatic plants, in which Messrs. Strother, Hymans, Evans, Morley Taylor, and others took part.

Mr. WALLIS having replied to several questions that had been put, a vote of thanks was accorded to him, and the meeting adjourned.

LIVERPOOL PHARMACEUTICAL STUDENTS' SOCIETY.

An excellent meeting of this Society took place at the Liverpool School of Pharmacy on Thursday evening, the 1st instant.

After the usual business had been transacted the PRESIDENT, Mr. Prosper H. Marsden, called upon Mr. EDWARD DAVIES, F.I.C., to give a lecture on

THE LIQUEFACTION OF GASES,

in the course of which, by means of a very effective series of experiments, the laws governing gases were illustrated and impressed upon the imagination of those present in a way that no amount of mere book study could compete with. The effect of pressure on gases, causing both diminution of volume and rise in temperature, was dwelt upon, and what is known as the "critical point" clearly explained. The result of reducing the pressure being to cause a corresponding reduction in the boiling point of liquids was shown by means of a tube containing ether and mercury and fitted with

a movable corresponding tube after the style of a nitrometer. On raising or depressing this loose tube the volume of the ether was increased or decreased by its vapour being condensed by pressure or vaporised on the removal of this pressure. The well-known experiment of making water which had been boiled and then corked up in a flask boil again on the application of cold was then shown. That the removal of pressure from a gas is attended by an increase in volume and absorption of heat was illustrated by means of compressed oxygen causing a coloured liquid to rise in a bulb tube when the gas was allowed to impinge on the bulb and cool it in escaping. By boiling or evaporating ether water was frozen, and that led to a discourse on the present methods of obtaining great cold by the evaporation of gases which have been condensed by pressure and the use of low temperatures. The work of Professor Dewar in liquefaction of gases was described and the manner of obtaining liquid air entered into. The peculiar phenomena attending the "spheroidal state" of liquids next came under attention, illustrated by using water in a platinum crucible and also liquefied SO_2 . In connection with the latter the lecturer showed the paradox of obtaining ice from a red-hot crucible by first causing some SO_2 to take the spheroidal state and then adding water, which became at once converted into ice, floating in the sphere of liquid SO_2 . The great cold attending the evaporation of SO_2 was shown also by its causing mercury to become solid. A close was put to a very enjoyable and instructive lecture by a commentary on the total change of properties and chemical effects exhibited by such gases as oxygen when liquefied, which lent considerable weight to the theory that all the so-called elementary bodies known to us are simply one fundamental form of matter in different physical states. In the future real progress in chemistry could only be looked for when both the physical and chemical properties of bodies were regarded.

A good discussion followed, in which Messrs. COWLEY and MARSDEN complimented the "students" on their privilege in being permitted to hear such a valuable lecture, and a vote of thanks was passed to the lecturer, on the motion of the PRESIDENT, seconded by Mr. H. WYATT, Jun., and supported by Mr. COWLEY.

BRADFORD AND DISTRICT CHEMISTS' ASSOCIATION.

On Tuesday, January 30, Mr. Waddington read before the members of this Association, at the County Restaurant, Bradford, a paper on:—

PROPRIETARY ARTICLES; HOW FAR IS SUBSTITUTION JUSTIFIABLE?

Mr. WADDINGTON said the subject was so important to every individual in the business that no apology was needed for introducing it. After tracing briefly the origin and development of medicine, he went on to refer to the uprising of the quack medicine maker and his penchant for extensive advertising, and spoke of the way in which the Government took advantage of this development to replenish an impoverished exchequer. He held that the qualified chemist and druggist had a heritage which it was their duty in every possible way to maintain intact and hand on to their successors in a more perfect condition than they received it, impressing upon their customers and the public generally the fact that they were an educated body of men, specially trained for the carrying on of certain work, and not merely to act as distributors of article put up by the million, a phase of the business which an errand boy could perform just as well as a pharmaceutical chemist.

Of actual patent medicines, he said, there were very few remaining, for the simple reason that no sane individual would now disclose the actual composition and mode of preparation of his specific when a 1½d. stamp will do the trick just as well. The so-called patent medicines were only "proprietary articles," subject to an *ad valorem* stamp duty, and in many instances Pharmacopœia pre-

parations with various fanciful names. After the passing of the Pharmacy Acts unqualified individuals found they were in a fix, but, unfortunately, the proverbial loophole was found in the Act, and limited liability companies became the order of the day. These folk wanted advertisement, and what could they do better than use proprietary articles at cost price as a bait to bring customers to their stores, where they would probably also buy goods put up by the firm, on which they made a handsome and altogether unusual profit, the sale of these things of home manufacture being increased by a commission on them to their assistants.

This was the origin of substitution. The stores have taught chemists a lesson that they would do well to take full advantage of. The chemist who was willing to act as the tool of an advertiser in handing over his goods, whether he got profit or not, was simply throwing away his livelihood. He was not compelled by law to go through a systematic course of training and study in order that he might sell a few so-called patent medicines. He was perfectly justified in endeavouring to prove to his customers that he was able, by personal attention to the preparation of his articles, for which he was individually responsible, to give them something better than factory-made goods. If the manufacture and sale of proprietary articles was to go on increasing as it had done, there would be no need for either doctor or chemist in the very near future. They had to consider not only how far, but in what manner it was wise to practise substitution. They must use discrimination, or they would find that, as politeness and personal attention soon told in increased returns, so an invariable effort to substitute whenever proprietaries were wanted soon told the other way. His invariable rule was that when a customer asked for a proprietary article he wrapped it up, handed it over, and then, but not till then, advised or introduced his own article—generally very dissimilar to the one wanted—and often was asked if he would mind changing it. The man who put up a specialty in such a manner as to resemble an advertised one was not justified, and was running great risks, as well as doing a mean action. Substitute, but do not condescend to a mere attempt at imitation. He would not substitute in cases where the article was really original, cannot be imitated and was the best of its kind. But in cases of compounds where the essential ingredients were well known, why should they not push their own goods as much as the firms that advertised and tried to push theirs out? One great difficulty was the medical man, and they ought all, as far as possible, try substitution with him. The progress of firms, principally of American origin, who had made a specialty of the exhibition of drugs, either particular or general, in some new form, through the recommendation of members of the medical profession, was phenomenal, and he proceeded to give instances. The number of prescriptions now written containing proprietary article was something tremendous, and most trying to the dispensing chemist. When would the doctor learn that in supporting these people he was taking away his own and the chemist's livelihood? He was convinced that the time had come when they must set their faces against these things. Discard the use of all show-cards, billheads, memorandas, etc., carrying advertisements of these specialties, and spend a few shillings in printing your own. Make their business an individual one, and the question of substitution would soon right itself. As to the P.A.T.A., which was hailed by many as the panacea for all ills, he was afraid that now he was even less sanguine than at first. The success so far as the articles protected was concerned was, no doubt, pretty nearly perfect; but where it had failed was in getting on to its list the most widely-known proprietaries. He had every possible appreciation of the ability and energy of the Secretary, but the want of success was due to the indifference of thousands of chemists. To summarise:—(1) Sell proprietaries at store prices, but not below cost; (2) Keep them in the background; (3) Let your customers know you have them; (4) Then try substitution; (5) Maintain your

standing as chemists and not storekeepers; (6) Discard all gratuitous bills and stationery and P.A. show-cards; (7) Use your own; (8) Influence the medical men as much as you possibly can. If he were asked to suggest one remedy for the ills to which he had referred, he would say that, as the Government would soon require increased taxation, there should be a large increase in the *ad valorem* stamp duty and also in the annual licences to such a figure that it would not pay the small grocer to infringe upon the legitimate business of the qualified chemist.

A discussion ensued, and Mr. Waddington was afterwards thanked for his paper.

PRESTON CHEMISTS' ASSOCIATION.

The Preston Chemists' Association held a meeting at the White Horse Restaurant, Preston, on Thursday, February 1, when a discussion took place on the question of

AMENDING THE PHARMACY ACTS.

Mr. WILLIAMSON (the Secretary of the Association), who introduced the subject, observed that a great deal had been said and written on the subject of pharmacy law, but even now it would seem they did not all appreciate to the full its object, the extent of its operation, or the principle on which it was based. It was not his intention to discuss in detail the present pharmaceutical position, preferring rather to touch upon one or two subjects with which they were most deeply concerned. Throughout the country one was constantly greeted with the appeal that when grappling with the company pharmacy problem they should employ language so clear, so definite, and so emphatic as to render impossible anything approaching misconception. This was undoubtedly a most sensible request, but at the same time any student who had followed the discussions could not deny the assertion that despite the use of plain English, as free from ambiguity "that he who runs may read," they had not thus far achieved that success and made that advancement which they felt and realised was so honestly due to the cause they pleaded. He entertained the opinion that if they hoped to redress the serious grievances which, for years had crippled their calling and at the present day threatened it almost with destruction, they must call to their aid that wonderful influence and support which history repeatedly demonstrated to be the strongest and most important factor in the realisation of any aim. Bear in mind, this question was not limited to themselves, not confined within the circle of the profession, nor alone associated with trade interests; it was a question which embraced and immediately affected the British public. Free trade in poisons did not commend itself to laymen as a rule, and for that reason Mr. Balfour's historic "man in the street" was as much interested in this matter as they. So far it might with truth be urged that the general public had not given evidence of any keen desire to support the chemists' cause. This was due to a want of knowledge on the part of laymen, and if the profession neglected to educate them in the difficulties which surrounded them they could not complain of any lack of support. Let "the man in the street" once understand that the company drug store, whatever its attractions, was not a suitable place for the sale of poisons, or for the careful and proper dispensing of medicines, and the profession overcame one of its greatest obstacles. Although the Pharmacy Act of 1868 was avowedly passed to secure "that persons keeping open shop for the retailing, dispensing, or compounding of poisons, and persons known as chemists and druggists, should possess a competent practical knowledge of their business," it did nothing of the sort. Any seven persons—be they chimney sweepers, butchers, or scavengers—could register themselves as a joint stock company to carry on the business of a chemist and druggist, and the law was powerless to prevent them. If these facts were brought home to the lay mind with all their attendant dangers, did they think the evils from which they suffered would long remain? There would!

no objection to pharmacy legislation; indeed, there would be an earnest desire to appeal to the House of Commons to prevent the frauds that were being practised upon the public. It was because the country remained in ignorance of these matters that chemists occupied the present undignified and unfair position. They had also a right, the speaker maintained, which they should insist upon with unswerving determination, to look to the Pharmaceutical Council for guidance in this crisis. From that body they hoped for much, and the utterances of members in council or in public led the registered chemists of the country to believe than an appeal to the parent Society would produce a satisfactory result. Strange to record, however, this authority had adopted an almost inexplicable attitude, which was little better than a policy of absolute inaction. The Council would appear to be "waiting for something to turn up," and the singular admission of the Law and Parliamentary Committee at the last Council meeting that they had no report to offer furnished a regrettable proof of that masterly inactivity of which they were the victims. The chemists of the country were fighting for a great principle, and it was for them to urge upon the Pharmaceutical Council the need of a Bill calculated to abolish the wrongs under which the profession had long been weighed down. From the Pharmacy Acts they gathered that the qualification of a chemist and druggist was a purely personal one, and, while recalling it, they must not forget to urge that the practice or use of titles was not confined to registered chemists and druggists, as was intended. Therefore, the original purpose of the Act had not been fulfilled, and all that the absurdly insufficient measure did was to protect the public in regard to the sale of a few poisons. It was their duty to sacrifice minor matters of difference in favour of a general campaign to secure the legal recognition of individual qualification. Local Associates throughout the country, and all registered chemists must combine and direct their efforts towards emphasising the fact that the qualification of the chemist and druggist was a purely personal one, and one not capable of being exploited for the benefit of "a business man with money." They must not listen to suggestions for a compromise, nor to anything suggesting a partial redress of the wrongs. The Council of the Society must be made to feel that from them was anticipated definite and decisive action as some amends for their present indifference and carelessness, and that the chemists further looked to that body to instruct those who made the laws.

Mr. ARKLE did not propose to go over the whole ground traversed by the Association during the last six months, as no good could possibly result from such a course. The resolutions passed and the opinions expressed had been echoed from one end of the country to the other, indeed, it must be so, as their wants were contained in a very small compass, and when considered, their remarks must to a large extent follow those spoken before. To-day they were faced with the position of a Government strong beyond any of recent years, yet unable to give one tittle of the time expected to domestic legislation, and, therefore, most unlikely to consider the just claims of only 15,000 of its constituents. Yet the chemists of the country could not afford to remain idle, and it therefore behoved them to keep their claims well to the fore. Since the Lord Chancellor executed his famous somersault a long Parliamentary holiday had supervened, so that practically nothing had been done on their behalf. Therefore, they must renew their efforts, and he did not think they ought to find much difficulty in persuading his Lordship how undesirable it was for the public at large that association of unqualified persons should be allowed to assume and use their titles which had been granted to their profession under a stringent law. To the lay mind the answer was an easy one, but to those who had given any thought to such a subject it bristled with difficulties from which they had not as yet found a satisfactory way out. They could not approach either the Lord Chancellor or Parliament on behalf of the trade; they could not mention the cutting

of prices for which, unfortunately, some registered men were the greatest sinners; nor could they exclude as such all limited companies, as many of them were old-established families of registered men; nor could they plead that chemists, and chemists only, sold the genuine unadulterated article, and that the goods sold by every registered man were always up to date in purity, and strictly B.P.! A blush would and ought to rise to the cheek of every man who read the police court cases wherein shabby defences were tendered, where arrant nonsense was talked about chemists being the only judges of the goods they sold, the B.P. to be ignored, and all the thousand and one quibbles to get out of the mire in which a man's lack of business morality had placed him. This, to Mr. Arkle's mind, had done their cause more harm than all the drug stores combined. It had "given the show away," and reduced a professional man to the level of the street hawker and gutter-snipe. He did not touch upon the recognition of companies, for that they could not admit. But he did wish to allude to the declaration of the President "that the members of the Council are agreed upon two great points—viz., to protect the titles and uphold the principle of the Pharmacy Act, 1868," and urged that meeting to lose no time in furthering by every means the accomplishment of this end. The Council could have no better work before them than to take the clause suggested in the *Pharmaceutical Journal* (Nov. 25, 1899, page 508), and bring it to maturity, or by incorporating it in a Bill of their own, as simply and yet as comprehensive as might be. To this end he proposed:—

That this Association would respectfully urge the Council to proceed at once with the drafting of a Pharmacy Bill as an independent measure, which would restrict the titles and practice of the profession to legally qualified chemists. As he had already hinted, the Parliamentary Session was not favourable for the promotion of new Bills in the direction of domestic legislation, but success might attend their efforts—in any case, the Council would watch the other Medical Bills, and push the clause he had quoted.

Mr. W. J. WATKINSON seconded the resolution.

Mr. W. F. LIVESEY said the resolution expressed what, in his opinion, was a useful measure on the part of the Council. The Bill, when drafted, would, no doubt, meet with the endorsement of the whole trade.

Ultimately the resolution was carried, and a copy was directed to be sent to the Council.

CHEMISTS' DEFENCE ASSOCIATION.

A meeting of the chemists of Liverpool, called by the local association, was held on Thursday, February 1, to hear an address by Mr. W. S. GLYN-JONES upon the

P.A.T.A. AND THE CHEMISTS DEFENCE ASSOCIATION.

The chair was taken by Mr. ANTHONY S. BUCK, who, in introducing Mr. Glyn-Jones, stated that they were interested in the new scheme, though not perhaps so much as chemists in other towns, because they had not been unduly worried in Liverpool by the authorities.

Mr. GLYN-JONES, having dealt with the work of the P.A.T.A., went on to describe the aims and objects of the Chemists' Defence Association, which have already been dealt with in these columns.

Dr. SYMES proposed a vote of thanks to Mr. Glyn-Jones, and said that the P.A.T.A. had always received his support. He thought it was work in the right direction, and if it had not succeeded quite to the extent they hoped, it was due to the fact that retail chemists did not support it as they ought. Mr. Glyn-Jones had stated that it was the experience of the Pharmaceutical Conference, of the P.A.T.A., and all local associations that the majority of the trade were prepared to accept the good results from those organisations but were not prepared to give them monetary or any other kind of support, and he was glad that the new defence association would give to those who paid a subscription substantial advantages over and above the person who was not a member. He had taken

an active part in the old Chemists' Association, which had its headquarters at Birmingham, and he thought it was the greatest pity that the Association had been allowed to fall through from lack of support.

Mr. JOHN SMITH, in seconding the vote of thanks, said that they were always glad to welcome Mr. Glyn-Jones. He had perhaps become the "naughty boy" of the Council, but though they might not agree with him at all times they must welcome, as Committee members of the Council, men who had strong convictions, and were not afraid to announce them, and to strenuously contend for them. He thought it was a compliment to the Committee who had drawn up the rules of the new association that they had met with so little serious criticism.

Mr. T. S. WOKES complimented the P.A.T.A. upon the prompt and business-like way in which it treated all matters referred to it.

The CHAIRMAN, in putting the vote, which was carried unanimously, said that he strongly supported the new departure of the P.A.T.A.

PUBLIC AND POOR-LAW DISPENSERS' ASSOCIATION.

The first meeting of the amalgamated Association was held at St. Bride's Institute, St. Bride's Lane, Ludgate Circus, E.C., on Wednesday, January 31, Mr. F. NOAD CLARK in the chair.

To mark the occasion of its first meeting, a proposal was made that Mr. R. Jones, of Poplar, should be elected the first honorary member of the Association, in recognition of his great services to dispensers during the past twenty years. This, coupled with a hearty vote of thanks to him for his services, was proposed by Mr. HEWITT, seconded by Mr. WELFORD, supported by Mr. FAIN, and carried unanimously.

The CHAIRMAN then delivered the

INAUGURAL ADDRESS.

He said: With your kind indulgence I would like to make a few remarks applicable to the commencing meeting of our newly amalgamated Associations. In reviewing our success of the past year tribute has just been paid to one of our body who has worked for the general good of his fellow craftsmen. That maxim of co-operation, "Each for all and all for each," has been carried out with some few exceptions. I refer more especially to those dispensers who have held aloof from our movement, but who are now, thanks to the successful results of our efforts to obtain better terms of remuneration, in a position to participate in the advantages derived therefrom. We have amongst us here now men who have uniformly attended our meetings and assisted in our deliberations. They may not perhaps have benefited to the fullest extent from the results of our united action, but, to quote a high authority, "'Tis not in mortals to command success, but do more, deserve it." As in our own particular instance, concessions granted to a body are of little avail to the individual unless he proves himself worthy of respect and appreciation. In this connection I sometimes think (and I refer more particularly to those of our calling in charge of institutions) that we are not sufficiently self-assertive concerning our duties and abilities as we have every just cause and right to be. "The labourer is worthy of his hire," but in whatever station of life a man may be placed his services are apt to be valued according to the price he puts upon them. There is still a large amount of ignorance amongst the powers that be respecting the nature of our duties and responsibilities, and I fear that this is in a great measure due, if I may so term it, to the innate modesty of our profession, or, as I have just called it, a want of assertiveness. So that it is obviously our duty to ourselves, as well as to our *confrères*, so to conduct ourselves and, in a manner of speaking, educate our boards, managers, or committees so as to command their respect, and in so doing render ourselves as nearly as may be possible indispensable in our office. There appears to me to be no reason why there should

not be reciprocation and mutual confidence between the medical staff and the pharmacist. It may be a question of personality on both sides, but a good deal can be said on behalf of the latter, in that he is usually a man deserving of confidence. His opinion is often of great value to the prescriber. Who of us has not had experience of this? Questions of incompatibility, ingredients and solvents suggested, and even doses corrected, to the benefit of both prescriber and patient. Of course, it is not in the province of the dispenser to dictate to the doctor what he shall prescribe, but undoubtedly the dispenser can exercise a great deal of influence in this direction. Some of us have included in our duties, or have been added thereto from time to time, work of a technical and scientific character, such as the analysis of articles of food, water, urine, etc., the preparation of microscopic sections, photographs, and other work of a nature, so to speak, on the borderland of pharmacy proper, but requiring special knowledge and skill. Such work, in my opinion, should be accorded remuneration in addition to the regular salary, unless, of course, stipulation to the contrary was made at the time of undertaking such duties. And in consideration of such extra duties the Local Government Board, or other ultimate authority, might reasonably be asked to sanction additional remuneration. Many instances might be given of individual services rendered by the pharmacist, apart from the regular routine of his duties, which would go to show that he is not "a mere compounder of drugs" in the commonly accepted sense of the term, but a gentleman of education, training, and experience worthy in every way of the confidence and respect of his superiors.

A general discussion followed, Messrs. Fain, Goodall, Trayner, Duff, Miller, and others taking part.

Mr. FORSTER (Hon. Secretary) brought forward two items of dispensing interest—one was the uncertainty of *tr. strophanthus*, the other the toxic effect of $\frac{1}{4}$ grain doses of *ext. stramonii*, and urged the need of standardisation of these drugs.

The general opinion of members was that from their experience *tr. strophanthus* could not be relied upon.

Several items of Poor-law interest were brought up and discussed, Mr. MONTAGUE SMITH, the Poor-law Secretary, answering the queries.

EXETER ASSOCIATION OF CHEMISTS AND DRUGGISTS.

The annual meeting of this Association was held on Tuesday, February 6, at the Albert Memorial Museum, Exeter, Mr. P. F. Rowsell, President, in the chair. There was a representative attendance, including Mr. C. J. Moor, the City Analyst. The annual report and the Treasurer's statement having been read and adopted, the following officers were appointed:—President, Mr. T. C. Milton; Vice-President, Mr. P. F. Rowsell; Hon. Secretary, H. Wippell Gadd; Hon. Treasurer, Mr. J. W. Lake; Committee, Messrs. H. Gadd, J. H. Lake, Lemmon, Stocker, Vinden, and Stone. On the motion of Mr. Lake, seconded by Mr. Rowsell, Mr. Moor was elected an honorary member of the Association. The question of the standardisation of drugs was then introduced by Mr. Moor, who advocated the adoption of the B.P. as a standard. A discussion ensued, in which Messrs. J. H. Lake, G. Stocker, H. Wippell Gadd, Alderman Gadd, and others took part, and it was finally resolved:—

That the Exeter Association of Chemists and Druggists is quite prepared to recognise the B.P. as a standard for drugs and in dispensing prescriptions, but the members would draw attention to the fact that certain tests and processes require modification.

Mr. Moor having been thanked for the trouble he had taken in the matter, Mr. Rowsell expressed a hope that the members would become shareholders in the Chemists' Defence Association, Ltd. The meeting then adjourned.

THE STUDENTS' COLUMNS.

THE MATERIA MEDICA OF THE PHARMACOPŒIA.

Anthemidis Flores.

CHAMOMILE FLOWERS are the dried, expanded flower-heads of *Anthemis nobilis*, Linn. (N.O. Compositæ), the common or Roman chamomile, collected from plants cultivated in England, Belgium, France, Saxony, and Hungary. They may occur in three forms—double, semi-double, and single or Scotch chamomiles, but the double and semi-double flowers alone are official. The English flowers yield most volatile oil when distilled and are usually reserved for distillation purposes; those imported from Belgium, France, and Saxony are what are chiefly met with in commerce. The entire flower-heads are collected for medicinal use and dried in a warm room. Chamomiles are tonic, aromatic, and stomachic; they are used for the preparation of *extractum anthemidis* and *oleum anthemidis*.

ANTHEMIDIS FLORES.—A, double flower head; B, single do., cut vertically through middle; C, D, flower heads of *Matricaria chamomilla*, cut vertically through thalamus; E, central floret of chamomile with, paleæ; F, ray floret of ditto, with phyllaries, F1 and F2 (A, B, C, D, natural size; E, F, enlarged).

CHARACTERS.—Chamomile flowers are from 12 to 20 Mm. in diameter, hemispherical in shape, and white or nearly white in colour, becoming buff-coloured or yellow when kept. Each flower-head is surrounded by an involucre consisting of two or three rows of overlapping oblong bracts with membranous margins, but that is almost entirely concealed when dried by the reflexed outer florets, which are ligulate, white, and pistillate. The inner florets of the semi-double variety are tubular, yellow, and hermaphrodite, but in double chamomiles the florets are all white and ligulate. Single chamomiles, which are excluded by the official description, have only a single outer row of white ligulate florets, the rest being tubular and yellow. On carefully removing the florets from a flower-head of any of the three varieties, the solid conical receptacle is seen to be covered with concave, blunt, narrow, scaly bracts or paleæ, one of which occurs at the base of each floret. The calyx limb is completely adherent to the ovary and indistinguishable owing to the absence of pappus, the calyx tube not being developed. The corolla is sprinkled with minute, yellowish, shining oil-glands on its lower part, as may be seen on closely examining it with a powerful lens. The strong aromatic odour of chamomiles is due to the volatile oil they contain, and their bitter taste to the presence of anthemic acid.

NOTES.—The distinctive characters of chamomiles are the solid elongated conical receptacle and the presence of the blunt, narrow, scaly bracts or paleæ. In German chamomiles, *Matricaria chamomilla*, Linn., the conical receptacle is hollow and there are

absent, a distinction being thus afforded between arnica and any starch-forming rhizome.

Asafetida.

ASAFETIDA is a gum-resin obtained from the root of *Ferula fetida*, Regel (N.O. Umbelliferæ), and probably other species growing in Eastern Persia and Western Afghanistan. The cortex of the stem and root contains numerous large schizogenons ducts, filled with a milky emulsion; on incision or on cutting off the stem close to the crown of the root the emulsion exudes and hardens to form the gum-resin. That is collected and conveyed to Bombay, whence it is exported to Europe. It occurs in commerce in more or less agglutinated tears and masses, but ordinary lump asafetida is excluded by the official description. The drug possesses stimulant, antispasmodic, expectorant and laxative properties, and is used in the preparation of pilula aloes et asafetidæ, pilula galbani composita, spiritus ammoniæ fetidus, and tinctura asafetidæ. The dose of asafetida is from 5 to 15 grains.

CHARACTERS.—Asafetida should be in rounded or flattened tears, from 12 to 25 Mm. in diameter, or in masses of agglutinated tears. The dull yellow colour of the fresh tears darkens on keeping, ultimately changing to reddish-brown. They are usually tough at ordinary temperatures, becoming harder when cooled and softer when warmed. Internally the tears may be yellowish and translucent, or milky white and opaque, the difference in that respect probably depending upon the relative freedom from moisture. The freshly exposed surfaces of broken tears gradually assume a pink colour, which changes to red and finally to reddish-brown, probably owing to oxidation of the volatile oil present. The strong, persistent, alliaceous odour, and bitter, acrid, alliaceous taste are due to the volatile oil and resin.

TESTS.—Asafetida forms a white emulsion when triturated with water, as it contains both resin and gum. The fine green colour assumed by the freshly-fractured surface of a tear when touched with nitric acid (s.g. 1.2), distinguishes asafetida from galbanum. It is distinguished from ammoniacum (see *ante*, p. 67) by containing umbelliferone or a substance yielding it, which causes a blue fluorescence when a small fragment of the drug is strongly heated in a dry test-tube, and, after cooling, treated with boiling water, the solution thus obtained being subsequently largely diluted with cold water, and made alkaline with solution of ammonia. Asafetida should contain not less than 65 per cent. of matter (resin, etc.), soluble in 90 per cent. alcohol, and should not yield more than 10 per cent. of ash when incinerated.

NOTES.—The distinctive characters of asafetida are the change in colour of the fractured surface, the nitric acid reaction, the intense alliaceous odour, and the presence of umbelliferone or a substance yielding it. The chief constituent of the drug is the resin—said to be a combination of ferulic acid with asaresinotannol—of which it may contain more than 60 per cent. It also contains about 25 per cent. of gum, and 3 to 9 per cent. of a volatile oil containing 20 to 25 per cent. of sulphur, in addition to ferulic acid, moisture, and various impurities, such as earthy matter, stones, etc.

Aurantii Cortex Recens.

FRESH BITTER-ORANGE PEEL is the fresh outer part of the pericarp of the Seville orange, the fruit of *Citrus aurantium*, var. *bigaradia*, Hook. f. (N.O. Rutaceæ), a small tree grown especially in the countries bordering on the Mediterranean. The fruit is collected and exported before it is quite ripe, the process of ripening being completed during the voyage from the south of Spain (Seville), whence the best oranges for medicinal purposes come, or from Sicily (Palermo). The peel is removed from the fruit after it arrives in this country; care being taken to avoid rupturing the oil-glands, which occur in the epicarp. Orange peel is used in medicine as a mild tonic and an aromatic bitter. The fresh peel which is not readily obtainable except during February, March

and April, is employed in the preparation of tinctura aurantii vinum aurantii, and, indirectly, of syrupus aromaticus, syrupus aurantii, and syrupus cascaræ aromaticus.

CHARACTERS.—The bitter orange is deep orange-red or red in colour externally, and generally rough and glandular, the glands containing the volatile oil; the sweet orange, the peel of which has been used as a substitute, is usually paler, more yellow in colour, and has a thinner and smoother peel. The peel of the bitter orange should have but a very small portion of the white, spongy "zest" or mesocarp attached, as that is lacking in bitterness. The pleasant aromatic odour of the peel is due to the volatile oil it contains, and the bitter taste to an amorphous bitter principle—aurantiamarin. Other constituents of the peel are hesperidin—a colourless, tasteless, crystalline glucoside; isohesperidin, and aurantiamaric acid, a bitter principle of secondary importance.

Aurantii Cortex Siccatus.

DRIED BITTER-ORANGE—PEEL is the dried outer part of the pericarp of *Citrus aurantium*, var. *bigaradia*, Hook. f. (N.O. Rutaceæ), and is largely imported from Malta and Spain, the Maltese forming the bulk of the imports. It is used in the preparation of infusum aurantii, infusum aurantii compositum, infusum gentianæ compositum, spiritus armoraciæ compositus, tinctura cinchonæ composita, and tinctura gentianæ composita.

CHARACTERS.—Dried bitter-orange peel should be in thin strips, the outer surface of which is deep orange-red in colour, rough and glandular; sweet-orange peel is much lighter in colour, thinner, smoother, and much less bitter in taste. As in the case of the fresh peel, and for the same reason, the dried peel should be as free as possible from the white spongy portion of the pericarp. The odour and taste resemble those of the fresh peel, but the dried peel is less aromatic.

Obituary.

BENNETT.—On January 27, George Bennett, Pharmaceutical Chemist, Southwell. Mr. Bennett had been a member of the Pharmaceutical Society since 1842, and was a constant subscriber to the Benevolent Fund.

POWELL.—On February 4, at 4, Queen's Square, Leeds, from pneumonia, William Powell, Chemist and Druggist. Aged 64 years. Mr. Powell was born at Market Weighton, and coming to Leeds, was trained for the drapery trade, which he left for the drug business, being associated with his late brother-in-law, Mr. Robert Goodall. In 1858, Mr. Goodall made a great development of wholesale business, Mr. Powell being admitted to partnership in the new firm, which then took the name of Goodall, Backhouse, and Co. The world-known "Yorkshire Relish" became its leading specialty, and was supported by such gigantic advertising as is suited to articles intended for every household. Since 1870, Mr. Powell has been sole proprietor of this extensive business, the management being shared of late years with his nephew, Mr. W. Powell Bowman. Mr. Powell's capacity for organisation, sound judgment, and a habit of commencing business in the morning two or three hours before most principals put in an appearance at their offices, were causes of his unusual success. He was unmarried. Fond of rural sports, he kept a country house at Pocklington. His fellow citizens and business connections will regret the loss of a much esteemed friend.

WILLIAMS.—On January 29, William Williams, Pharmaceutical Chemist, St. Clears, Carmarthenshire. Aged 44. Mr. Williams had been a member of the Pharmaceutical Society since 1880.

YORATH.—On February 3, Christopher Yorath, Chemist and Druggist, Swansea. Mr. Yorath, who was a member of a well-known Vale of Glamorgan family, was one of the most highly respected inhabitants of Swansea.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

MOUNTING OF AMYLOID SECTIONS.

A. B. Green describes a method of mounting amyloid sections stained with iodine, which he has found to give more permanent results than any other method he is acquainted with.

A small quantity of pure white soft paraffin is placed on a coverslip, ready for immediate use as a mounting medium; the section is then floated from water on to a slide, after which as much water as possible is removed from the specimen. Next stain the section with a few drops of Weigert's iodine, drain away the excess of liquid, and from a second drop-bottle pour over the section a fine stream of a solution of iodine in pure liquid paraffin (1 Gm. in 30 C.c.), thus dehydrating the specimen without removing any iodine from it. Again drain off excess of liquid and remove the last traces by pouring over the section a solution of iodine in xylol (1 Gm. in 30 C.c.). For the third time drain and remove the remaining liquid by the aid of blotting paper, then place the prepared coverslip in position over the specimen and ring with cement.—*Lancet*, No. 3989, 381.

RUSTS OF CEREALS.

In the "Bulletin No. 16" of the U.S. Department of Agriculture (Div. of Vegetable Physiology and Pathology). Mr. M. A. Carleton gives an exhaustive account of the Cereal Rusts of the United States, the nature of the injuries which they inflict on the crops, and the most efficient remedies. They are six, or probably seven, in number:—*Puccinia rubigo-vera Tritici*, the orange leaf-rust of wheat; *P. rubigo-vera Secalis*, the orange leaf-rust of rye; *P. coronata*, the crown-rust of oats; *P. graminis Tritici*, the black stem-rust of wheat and barley; *P. graminis Secalis*, the black stem-rust of rye; *P. graminis Avena*, the black stem-rust of oats; and *P. sorghi*, the rust of maize. By far the most destructive of these fungi are the black-stem rusts of wheat and oats. The uredospores of the orange leaf-rusts of wheat and rye do not appear to attack hosts outside the genera *Triticum* and *Secale*, while the black stem-rust of wheat occurs also on barley and on *Hordeum jubatum*.

NITROGEN AND THE ROOT GROWTH.

From a series of experiments carried on by Herr Müller-Thurgau on the effect on the growth of plants of an extra supply of nitrogen to the roots, he derives the following general conclusions:—The roots are enabled to form an abnormally large amount of albuminoids when the nitrogen is presented to them in the form of a nitrate, but only if they can obtain a sufficient supply of sugar. This is manifested in the greater length and thickness of the roots, in their greater branching, and in the increased amount of protoplasm in their cells.—*Bot. Centralblatt*, 80, 1899, p. 74.

CHLOROPHYLL ASSIMILATION BY LEAVES.

For the purpose of determining the extent to which the power of assimilation in leaves is affected by the light having passed through other leaves, M. E. Griffon has carried out a series of experiments on various plants. He finds that, as a rule, passing through a single leaf does not greatly affect the power of light to decompose carbon dioxide; while if the light has passed through two leaves this power is so weakened that respiration becomes more energetic than assimilation. The reduction in the assimilating power resulting from the light passing through a single leaf varies between 1:7 in the case of the beech and 1:20 in the case of the ivy.—*Comptes rendu*, 129, 1899, p. 1276.

SYNTHESIS OF ALBUMINOIDS.

According to Herr W. Palladin, the nitrogenous organic substances in plants may originate in several different ways. Besides the intermediate products of the primary synthesis of albuminoids, we may also have products of the decomposition of albuminoids. This takes place only in growing organs. Asparagin and tyrosin are among these products.—*Bot. Centralblatt*, 80, 1899, p. 17.

FORMATION OF RESIN IN PLANTS.

Herr A. Tschirch describes in detail the mode of formation of the oil-cells in *Cinnamomum cassia*. They are developed from small cells filled with protoplasm by the gradual suberisation of the cell-walls, accompanied by the formation of a layer of mucilage. Ultimately the inner strata of the mucilage-layer become absorbed, and the protoplasm fuses with the remainder of the mucilage; the resinogenous layer results from this fusion. Small drops of oil are formed in it, which gradually pass into the cavity, and the resinogenous layer is finally almost entirely absorbed.—*Festschrift für Schöndener*, 1899, p. 464.

INDICAN AND PSEUDINDICAN.

In the case of several indigo-producing plants—*Indigofera*, *Isatis tinctoria*, *Phajus grandifolius*—Herr H. Molisch has determined that the indican is produced chiefly, though not entirely, within the chlorophyll-grains. In the cystolith-cells of a few species belonging to the Acanthaceae he finds a chromogen which gives rise to the same reactions as indican, but very unstable, which he proposes to call pseudindicin.—*Sitzber. k. Akad. Wiss. Wien*, 108, 1899; and *Ber. Deutsch. Bot. Gesell.*, 17, 1899, p. 228.

GERANIUM OIL.

Jeancard and Satie state that, as the amount of free acid in geranium oil is always considerable, this should be determined in the course of analysis, instead of being calculated into esters and expressed in terms of geranyl acetate, as is usually done. So markedly acid is the oil that the condensers of the distilling apparatus used in its preparation are much attacked, and the hands of the workmen employed in the distillation are blistered. To determine the amount of this free acid 3 Gm. of the oil is weighed off, dissolved in 10 C.c. of alcohol, 96 per cent., and 10 C.c. of semi-normal alcoholic potash. After two minutes' contact in the cold the amount of potash used up is titrated, after dilution with water, in the usual way. Experiments show that if this time be not exceeded the saponification of the esters is a negligible quantity. The saponification number of the sample is then determined in the usual way, by heating, the amount equivalent to the free acid is deducted, and the difference calculated into terms of geranyl acetate. A series of samples thus examined gave the following figures:—

	Sp. g. at 15°	Op. Rot. 100 Mm. at 15°	Free Acid Number.	Ester Number.	Esters as C ₁₂ H ₂₀ O ₂ p.c.	Alcohols as C ₁₀ H ₁₈ p.c.
French Geranium Oil	0.8972	-9.40	26.60	54.60	9.80	61.31
Spanish "	0.9073	-7.30	43.40	65.80	7.84	66.23
Corsican "	0.9012	-8.00	40.13	60.20	7.00	68.55
African "	0.9006	-8.06	42.93	65.80	8.08	63.19
Bourbon "	0.8905	-8.20	56.00	74.00	6.65	71.28
Indian "	0.8960	-0.48	9.6	43.00	11.30	84.62

If the total saponification number were calculated, as is usually done, into equivalents of geranyl acetate, these samples would be stated to contain: French, 19.11; Spanish, 23.03; Corsican, 21.07; African, 23.03; Bourbon, 25.95; and Indian, 15.05 per cent. of that ester, results which would appear to be greatly in excess of the truth.—*Bull. Soc. Chim.*, 23, 39.

AROMATIC SPIRIT OF AMMONIA.*

WITH NOTES ON SOLUTION OF AMMONIA AND AMMONIUM CARBONATE.

BY EDMUND WHITE, B.SC.

Solution of Ammonia.

The strong solution of ammonia of the British Pharmacopœia is defined as "an aqueous solution containing 32.5 per cent. by weight of ammonia NH_3 ," and its specific gravity is given as 0.891. In determining the purity and strength of the materials to be employed in an investigation dealing with aromatic spirit of ammonia. I was unable to obtain results which agreed with this relationship between the specific gravity and strength. A large number of samples of strong solution of ammonia were examined, with the result that the percentage of ammonia appeared uniformly lower than that indicated in the official monograph. I therefore examined the published literature relating to the strength of solutions of ammonia gas, and found that the official figures were based upon the table published by Carius in 1856.† In the British Pharmacopœia of 1867, the liquor ammoniæ fortior was defined according to Carius's results, and these figures have been repeated without alteration for the same preparation in the 1885 and 1898 editions.

In 1889 the subject was reinvestigated by Lunge and Wiernik † with great care, and they published a table showing considerable variations from the table of Carius, particularly in the figures relating to the stronger solutions. They determined the specific gravities at 15° C., while Carius worked at 14° C. For comparison the following table is given:—

CARIUS (14° C.)		LUNGE AND WIERNIK (15° C.)	
Sp. gr.	Per cent. NH_3	Sp. gr.	Per cent. NH_3
0.8907	33	0.890	31.75
0.8911	32.8	0.892	31.05

By interpolation it may be seen that a solution of ammonia of sp. gr. 0.891 should contain, according to Lunge and Wiernik, 31.4 per cent. of NH_3 , while the Pharmacopœia gives the strength as 32.5 per cent. Lunge and Wiernik's results seem to have been accepted in standard works published since 1889. They are quoted, for instance, in Thorpe's 'Dictionary of Applied Chemistry,' in Dammer's 'Handbuch der Chemische Technologie,' and in several works devoted to the alkali industry. In Comey's 'Dictionary of Chemical Solubilities' both these tables are given, as well as several others in use before 1856, and preference is given to the results of Lunge and Wiernik. My own results also accord closely with these. The exact determination of the specific gravity and strength of strong solution of ammonia is somewhat difficult owing to the loss of gas which inevitably occurs unless great care be exercised. The rapid evaporation of the gas which occurs during the necessary manipulations also produces considerable reduction of temperature, so that the adjustment of the temperature at which the specific gravity is taken also requires great care. The direct titration of a given quantity by standard acid gives lower results than those obtained by adding the solution of ammonia immediately to an excess of standard acid and titrating back with alkali. The results in the table below were obtained in the following manner; the specific gravities were obtained by means of a Regnault's bottle, whose capacity had been previously determined with water twice distilled from a still constructed of Jena glass. The solution of ammonia was poured rapidly into the bottle slightly above the mark in the neck,

the bottle was immediately closed and immersed in water at 15° 5 C. When the fluid had attained a constant level in the neck of the bottle its volume was rapidly adjusted and the bottle weighed. The ammonia was determined by placing 20 C.c. N/1 H_2SO_4 in a stoppered weighing bottle; the weight of this was determined, and a quantity of solution of ammonia of rather less than one gramme added. The stopper was immediately replaced, the contents mixed by rapid rotation and the bottle re-weighed. The fluid was then washed out and titrated back to neutrality by N/1 NaOH . The results in the appended table are the averages of several closely agreeing experiments in each case.

	Sp. gr. at 15.5.	Per cent. NH_3 (M.W. 16.94)
Sample 1	0.8893	32.19
" 2	0.8902	31.85
" 3	0.8916	31.42

These figures closely agree with those in Lunge and Wiernik's table, especially if allowance be made for the difference of 0.5 C. in the temperature at which the specific gravities were determined. The direct titration of numerous samples of strong solution of ammonia gave results 0.2 to 0.3 per cent. lower than those obtained by the method described above. With regard to the liquor ammoniæ B.P. whose constants are given as sp. gr. at 15° 5 C., 0.959 and percentage of NH_3 , 10, Lunge and Wiernik's table gives sp. gr. 0.959 percentage of NH_3 , 10.19. There is therefore a close approximation in the two sets of constants for solutions of lower concentration.

Ammonium Carbonate.

In the British Pharmacopœia, 1885, it was stated that Ammonii Carbonas "is considered to be a compound of acid carbonate of ammonium (NH_4HCO_3) with carbamate of ammonium ($\text{NH}_4, \text{NH}_2\text{CO}_2$) and the compound molecule is usually regarded as containing one molecule of each of these salts." The empirical formula for the salt was given as $\text{N}_3\text{H}_{11}\text{C}_2\text{O}_5$; this corresponds to a salt containing 32.57 per cent. of NH_3 , and one gramme should neutralise 19.2 C.c. of N/1 acid. In the tests 52.3 grains dissolved in water were required to neutralise 1,000 grain measures of the volumetric solution of oxalic acid. This is equivalent to 1 gramme neutralising 19.1 C.c. of N/1 acid, and corresponds to 32.36 per cent. of NH_3 . In the British Pharmacopœia, 1898, Ammonii Carbonas is described as a "variable mixture of ammonium hydrogen carbonate, NH_4HCO_3 , with ammonium carbamate, $\text{NH}_4\text{NH}_2\text{CO}_2$," and 1 gramme dissolved in 40 C.c. of water is required to neutralise 18.7 C.c. of N/1 H_2SO_4 , corresponding to 31.68 per cent. of NH_3 . When fresh the salt is in translucent, crystalline masses but when stored under ordinary conditions it becomes opaque owing to the formation of a white efflorescent layer of ammonium hydrogen carbonate (bicarbonate), while if freely exposed to the air it becomes opaque throughout. As the result of prolonged exposure a residue consisting of ammonium hydrogen carbonate is finally obtained. This residue no longer smells of ammonia and contains only 21.58 per cent. of NH_3 . Its production is due to the disappearance of the carbamate, which dissociates into ammonia and carbon dioxide—

The percentage of ammonia contained in the salt thus falls progressively by exposure from about 32 per cent. to 21.58 per cent. In the official characters and tests (B.P. 1898) the employment for dispensing purposes of ammonium carbonate which has thus deteriorated is precluded by the statement that the white efflorescence should be only superficial and should be scraped off before the salt is used for dispensing purposes. In the volumetric test 1 Gm. dissolved in water is required to neutralise 18.7 C.c. of N/1 H_2SO_4 , corresponding to

* Read at an Evening Meeting of the Pharmaceutical Society, in London, February 13, 1900 (see page 163).

† *Ann. d. Chem. u. Pharm.*, 99, 164.

‡ *Zeit. ang. Chem.*, 181, 290.

Allowing for loss in manufacture alone, it is therefore evident that in case 3 the standard will only be slightly above the official limit, while in case 4 it will be hopelessly below. In cases of deficiency due to the ammonium carbonate the total alkalinity may be sufficiently raised by the addition of a few C.c. per litre of the strong solution of ammonia. This addition will not appreciably affect the alcoholic strength or specific gravity of the product. *In no case is it necessary to add more ammonium carbonate*, especially as an addition of this kind would tend to raise the specific gravity beyond the official limit. This point will be more fully referred to under the test for carbonate.

2.—TEST FOR DUE PROPORTION OF CARBONATE.—This test is based upon the reaction between barium chloride and ammonium carbonate. A definite volume of the test solution containing a known weight of barium chloride (B.P. Appendix, p. 504) is added to a measured volume of the aromatic spirit of ammonia. After warming to about 70° C. to promote the completion of the reaction, the mixture is to be filtered. The filtrate should then yield a further precipitate, after adding more solution of barium chloride, and again warming the liquid. The inference to be drawn from this result is that the given volume of aromatic spirit contains more than sufficient ammonium carbonate to react with the quantity of added barium chloride according to the equation:—

This test was suggested by Thresh in the paper read before an evening meeting of the society, to which reference has been already made. Thresh calculated that aromatic spirit of ammonia made according to his formula would contain 3.45 per cent. of normal ammonium carbonate, formed by combination of the carbamate and acid carbonate with water and ammonia respectively:—

Based upon this calculation Thresh stated that one fluid ounce of the spirit, after addition of 330 grain measures of solution of barium chloride (containing one part of barium chloride in ten fluid parts) should yield, after filtration, a further precipitate when more of the reagent is added. These quantities correspond in the metric system to 20 C.c. of spirit, and 15 C.c. of barium chloride solution. According to the equation (using the atomic weights of the 1885 B.P.):—

M.wt. 96 M.wt. 244

1.5 grammes of barium chloride, contained in the 15 C.c. of solution will react with 0.59 grammes of normal ammonium carbonate. But the 20 C.c. of aromatic spirit of ammonia weighing 17.92 grammes (sp.gr. 0.896 B.P. 1885) should contain 0.62 grammes of $(\text{NH}_4)_2\text{CO}_3$. Assuming that the reaction proceeded according to the equation given above, the filtrate should therefore contain 0.03 grammes $(\text{NH}_4)_2\text{CO}_3$, which would yield a further precipitate on the addition of more barium chloride. In the British Pharmacopœia of 1898 the test was slightly modified, 16 C.c. of the test solution of barium chloride being ordered in place of 15 C.c. Now 16 C.c. of the test solution of barium chloride require for precipitation, on the basis of the calculation given above, 0.63 grammes $(\text{NH}_4)_2\text{CO}_3$; but 20 C.c. of aromatic spirit of ammonia should contain only 0.62 grammes of normal carbonate. It would therefore appear either that the test had been made too stringent, or that the reaction between the ammonium carbonate and barium chloride did not proceed in the manner indicated by the equation given above. There were several reasons, to which I shall refer again, which led me to suspect that the reaction upon which the test

was founded would prove on investigation to be unsuitable for the purpose. As a preliminary step I tried the test (B.P. 1898) on several samples of aromatic spirit of ammonia prepared by myself, and containing the accurately-weighed proportion of carbonate. The test in the official monograph is described in terms which might be widely interpreted by different workers so far as the time devoted to the successive steps of the process are concerned. My method of procedure was as follows:—The reacting fluids were mixed in a flask, which was then corked and shaken for five minutes. The contents of the flask were then heated to 71° C., and maintained at a temperature of 70°-71 C. for ten minutes, the thermometer being immersed in the reaction mixture. The flask and its contents were then cooled to 15° C. by means of a stream of water and filtered. The filtrate was then divided into two parts: one half was set aside, and to the other 1 C.c. of the test solution of barium chloride was added. This mixture gave no immediate precipitate, but on again warming a faint turbidity appeared which gradually increased to a distinct precipitate. The next day this precipitate appeared still larger, and the reserved half of the filtrate to which *no further addition of barium chloride* had been made also contained a distinct precipitate as a somewhat crystalline crust on the sides of the containing tube. Two more experiments were then made using 10 C.c. and 15 C.c. of the aromatic spirit, diluted in each case to 20 C.c. with alcohol of equal strength so as to ensure the same strength of alcohol in the reaction mixture, which contained, however, in these two experiments only one-half and three-fourths respectively of the proper proportion of the carbonate. The official test was then applied to these two diluted products under the conditions described above, and with practically the same results as those obtained with the aromatic spirit of ammonia containing the full proportion of carbonate. That is to say, the filtrates gave a further precipitate after adding more barium chloride and warming, while if set aside they yielded a precipitate without the addition of barium chloride. The precipitates were not obtained quite so readily, but still distinctly enough to comply with the official test, and in other similar experiments I observed that the time required for the appearance of the turbidity was shortened in proportion as the quantity of barium chloride added to the filtrate was increased. The results of these experiments may be seen in the test tubes on the table, and they show that the test fails in accomplishing its object. Thinking, however, that the failure might be due to working in too concentrated solutions, I arranged another set of experiments in which 18, 19, 20, 21, 22, and 23 C.c. of aromatic spirit were first diluted to 80 C.c. with water. Thus diluted they were treated as before with barium chloride with the results shown in the annexed table:—

No.	Test Mixture.		Result of Adding to Filtrate.	
	Arom. Spt.	Test Solution of Barium Chloride.	More Solution of Barium Chloride.	Solution of Ammon. Carbonate.
1 ..	18 C.c.	16 C.c.	Slight Ppt.	Copious Ppt.
2 ..	19 C.c.	"	" "	" "
3 ..	20 C.c.	"	" "	" "
4 ..	21 C.c.	"	" "	Slight Ppt.
5 ..	22 C.c.	"	Distinct Ppt.	No Ppt.
6 ..	23 C.c.	"	Copious Ppt.	No Ppt.

It will be seen that in Nos. 1, 2, 3, where the barium was present in excess of the proportion represented by the mol. wts. $(\text{NH}_4)_2\text{CO}_3$, and $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$, the precipitation of the barium carbonate was incomplete. On the other hand, in cases 5 and 6, where the ammonium carbonate was in excess, no further precipitate was produced by adding more ammonium carbonate. In experiment 4

where the two salts were present in almost molecular proportions, the reaction was not complete in either direction, and a precipitate was obtained in both cases.

These phenomena may be readily explained in the following manner. It is a common rule in all precipitation reactions to add an excess of the precipitating substance. Since no substance is absolutely insoluble in water, precipitation is seldom complete, especially if the reacting substances be present in the exact proportions represented by the equation one wishes to realise. It is also found that when a substance is produced by precipitation, its complete separation requires an appreciable amount of time. The time required for complete precipitation is distinctly prolonged in the case of certain substances which, when produced, form supersaturated solutions with the fluid, in whose presence they are produced. The duration of this condition of supersaturation may be shortened by warming, by agitation, or by the addition of a substance having a basylous or acidulous radical in common with the substance to be precipitated. Translating these statements to the case under consideration, it must be noted that barium carbonate is one of the substances whose precipitation is not quickly completed, owing to a portion remaining in a condition of supersaturation. It appears, moreover, that when solutions of barium chloride and ammonium carbonate are mixed, the condition of supersaturation may be terminated more easily by the addition of excess of ammonium carbonate than of barium chloride. That is to say, the separation of barium from solution by an excess of the soluble carbonate, is more rapidly and completely accomplished than the precipitation of a soluble carbonate by excess of a barium solution. As a matter of fact, in the ordinary course of analysis barium is usually separated as carbonate by the addition of ammonium carbonate. It is recognised that this separation is sufficiently complete for ordinary purposes, but is not absolutely so, partly owing to the condition of supersaturation already referred to, and partly to the fact that barium carbonate is to some extent soluble in the ammonium salts present in solution.

It appears, therefore, that the precipitation of barium carbonate in presence of ammonium salts by barium chloride does not form a satisfactory basis for the determination of ammonium carbonate in aromatic spirit of ammonia. Possibly the test might be improved by more rigidly controlling the conditions under which it is directed to be performed, but I do not think the reaction can in any case provide a very satisfactory means of determination. For this reason I turned my attention to the subject of an alternative test. Shortly after the publication of the 1885 Pharmacopœia, Gravill* suggested that the determination of carbonate should be effected in the nitrometer by measuring the carbon dioxide evolved when the aromatic spirit of ammonia was treated with an acid. Gravill stated that brine could not be used in the nitrometer (as in the case of spirit of nitrous ether) because of the solubility of the gas in that liquid, and recommended the use of mercury instead. From my own experiments I think that the use of brine is precluded because of the impossibility of sufficiently agitating the reaction mixture without hopelessly mixing it with the brine. This agitation is very necessary in the present case, because the evolution of such a soluble gas as carbon dioxide until a condition of equilibrium is attained between the gas and liquid in the nitrometer is not thoroughly complete without thorough agitation. Gravill used a mixture of equal parts of hydrochloric acid and water, and found that the gas obtained from 5 C.c. of the spirit measured 32.5 C.c., the temperature not being stated. In my experiments with this method I have used 5 C.c. of aromatic spirit of ammonia and 5 C.c. of diluted sulphuric acid. Working with the samples of aromatic spirit prepared by myself, and at a temperature of 15° to 15.5 C. I obtained in five successive experiments 29.8, 29.7, 29.9, 29.7, and 29.8, or an average of 29.8 C.c. of carbon dioxide. In

order to determine the volume of carbon dioxide retained by the reaction mixture, equal parts of aromatic spirit of ammonia and dilute sulphuric acid were mixed. The dissolved gas was then extracted by placing the mixture in a flask which was exhausted as completely as possible, a gentle current of air being drawn through the flask to remove the expelled gas. A measured volume of carbon dioxide was then admitted into a Lunge nitrometer, and 10 C.c. of the exhausted reaction mixture run in. After thorough agitation, it was found that in four successive experiments 7.6, 7.8, 7.5, and 7.5 C.c., of gas, measured at 15.5 C., had been absorbed by the liquid, or an average of 7.6 C.c. Adding this quantity to the 29.8 C.c. actually obtained, we get a total yield of 37.4 C.c. of gas at 15.5 C. from 5 C.c. of spirit. The volume of carbon dioxide theoretically obtainable from the carbonate present would measure 35.76 C.c. at normal temperature and pressure. Under the conditions of the experiments, however, the gas was measured at 15.5 C., and its volume would be further increased by the vapour tension of the alcoholic fluid over which it stood. I have not yet determined the value of this vapour tension, and it cannot be calculated with any accuracy from the published tables given for alcohol and water. The difference between the results given by Gravill and myself is due to the fact that he employed fairly strong hydrochloric acid, in which carbon dioxide is less soluble than in diluted sulphuric acid. It would appear, however, that a method founded upon Gravill's suggestion would furnish reliable indications not only of the presence of a due proportion of ammonium carbonate, but also of the amount actually present in cases of deficiency or excess. Any objection to the necessity for employing mercury in the nitrometer may be met by using a Lunge nitrometer provided with a two-way stop cock, and filled with brine. The reaction between the spirit and acid may then be effected in a flask or bottle connected by rubber tube with the side tube of the nitrometer. The acid and spirit are kept apart in the bottle by means of a partition, or by introducing the acid into the flask in a test tube standing obliquely. When the connection and adjustment of the apparatus is complete the contents of the flask may be mixed, and the evolved gas measured with the usual precautions in the nitrometer. The agitation of the reaction mixture may be thoroughly effected in the bottle, and the solubility of the gas in the brine does not interfere very much with the results, partly because the co-efficient of solubility of carbon dioxide in that liquid is only about 0.3 at ordinary temperatures, and partly because the gas actually standing above the brine is nearly all air expelled from the upper part of the bottle by the carbon dioxide evolved at the bottom. In order to avoid altogether the solvent action of the brine upon the carbon dioxide I have, in other experiments, introduced between the evolution bottle and the nitrometer another bottle containing a thin rubber bladder arranged in such a way that the gas evolved passed into the bladder, and forced an equal volume of air from this bottle into the nitrometer. I have found, however, that it makes hardly any appreciable difference to the result. This method does not give such constant results owing to the variations produced by the effects of temperature and pressure upon the comparatively large volume of air contained in the apparatus. The volume of gas measured in the nitrometer is in this method 2 to 3 C.c. higher than that obtained by the mercury method, a result which appears to be due to the effects of the vapour tension of the liquid upon the large volume of air in the apparatus.

It is obvious that other methods of determination for the carbonate which are based upon the barium chloride reaction are vitiated by the objections I have already advanced. Among these methods may be mentioned the titration of the washed barium carbonate precipitate, or the weighing of the barium carbonate. Hoseason* employed the latter method in the examination of ten commercial samples of aromatic spirit of ammonia. He reported

* *Pharm. Journ.* [3], 17, 445.

* *Pharm. Journ.* [3], 21, 510.

that they were all, with one exception, slightly deficient in carbonate, and this result was no doubt due to incomplete precipitation. Among other methods which have occurred to me is the substitution of a soluble lead salt for barium chloride, since the precipitation of lead carbonate appears to be more complete and to yield good results in other ways. I have not, however, yet experimented with this method. Before leaving the subject I should like to point out that the condition of the ammonium carbonate as to age and reduction of total alkalinity has little or no effect upon the carbonate value of the salt. Each molecule of the carbamate and acid carbonate yield one molecule of the normal carbonate when dissolved in water in presence of ammonia:—

and the molecular weights of the two salts are nearly the same:—

$$\text{M.wt. NH}_4\text{NH}_2\text{CO}_2 = 78.49.$$

$$\text{M.wt. NH}_4\text{HCO}_3 = 77.55.$$

From this it follows that if the correct weight of the commercial salt be introduced, no deficiency of carbonate will occur in the product, since ammonium bicarbonate produces even slightly more normal carbonate than an equal weight of a freshly-sublimed specimen composed of carbamate and acid carbonate.

NOTE ON MURCIA LEMONS.*

BY FLORA C. MADGSHON.

A few months ago my attention was attracted by some unusually large lemons for sale in one of our Edinburgh fruit-shops. Having purchased some, I found that in the flavour yielded by the peel they differed from Palermo or Messina lemons. On inquiry as to their source, I was informed that they came from Murcia, in Spain. Not having hitherto had to my knowledge lemons from this source, I made a number of experiments by way of comparing them, from a pharmaceutical point of view, with the lemons ordinarily in use. Some of my results I venture to bring before you to-night. To give you an idea of the size of those which first led me to take this matter up I may say that three of them weighed $19\frac{1}{2}$ oz., $13\frac{1}{2}$ oz., and 12 oz. respectively. The first of these yielded $2\frac{1}{4}$ oz. of peel for tincture. I have made tinctures from peel of Murcia lemons with various strengths of alcohol, and I find that, compared with tinctures from Messina or Palermo lemons, they have a finer, fuller flavour and aroma. In addition to the flavour which we are accustomed to call lemon, there is associated with it what may be called a "bouquet." Palermo lemons afford an aroma and flavour suggestive in a faint way of musk and verbena. Messina lemons yield a purely lemon flavour and aroma. These Murcia lemons embody the lemon flavour of the Messinas with the scented flavour of the Palermos in a mellower form. The pharmacopœial tincture made from Murcia lemons is distinctly superior in point of flavour to any I have tried made from lemons from other sources, and the same can be said of the syrup. Samples of syrup and tinctures are shown for comparison. The juice of the Murcia lemons which I have handled is slightly "sweeter" than that of Messina lemons; the difference in citric acid content being about 4 grains in an ounce. Very large lemons, such as those which led me to take up this subject, are not in regular supply, only a few cases of them come into the market during the season. Those which are obtainable regularly are much the same in size as Messina lemons. The province of Murcia, where they are cultivated, is called the African district, the climate being quite tropical. The soil is all irrigated by a network of canals, spreading over plains of many square miles; the canals being fed by vast reservoirs. Such plains in Valencia and Murcia are known by the Spanish name huertas (gardens); the soil, on the other hand, for vines and olives being dry. The Murcia lemons reach the English markets in November, and the

supply is continuous till April; but being most plentiful during December and January. The quantities are yearly increasing, as they are coming more into favour. They bring a little higher price than the Messina or Palermo lemons, owing to fine smooth skins and clean appearance.

THE OUTLOOK IN PHARMACY.*

BY JOHN TAYLOR.

If brevity were as much the soul of an address as it is said to be of wit, I might say in a sentence, "The outlook in pharmacy is bad," and be done with it. But I feel that such a hasty generalisation, besides spoiling the object of to-night's meeting—which is, I presume, to discuss pharmaceutical politics—would not be a perfectly true summing-up of the position. It would be too bald and stark a statement, and little in accord with my own feelings. Not that I am *very* optimistic about pharmacy and its prospects, but I have an idea, as I move about and discuss the problem with my fellow-craftsmen and read in the trade journals the observations of others, that after all we are no worse off except in one respect than traders and professional men generally. The exception is certainly an important one—viz., so far as keeping open shop for the sale of poisons and the use of qualifying titles is concerned, the operation of company law inflicts an injustice on us. Financially that injustice is less than it is morally, although it is the financial aspect we think of most. Mentally it causes, as injustice ought to do, great distress and anger in those who are wronged. Perhaps some of you will not agree with what I say on the financial aspect of the injustice.

DEFINITION OF "PHARMACY."

Before going further, let me define what I mean by the title of my paper. By "pharmacy" I mean the whole of the professional and trading operations usually carried on in this country by a pharmaceutical chemist, or a chemist and druggist. I do not use the word in its strictly technical sense of preparing and compounding medicine and dispensing drugs and chemicals; for the majority of our trade pharmacy in such a narrow and technical sense has lost much of its interest and meaning. There are those who say that this is one of the principal causes of our troubles, and that if we could only get back to the time when each pharmacist did all his own laboratory work, and was far more a professional man than he is to-day, a solvent would be found for our difficulties. It is said, "That would get rid of the trading character of our craft," and with that would probably go much of the objection to a greater restriction of free pharmacy. It may be so, but it is plain that then most of us would have to look for "pastures new." Such a strictly professional class need not be large. Besides, people who so argue forget two things—first, that probably pharmacy never had such a distinctly professional status. The pharmacist always made or sold many articles besides therapeutic remedies. He was always, if not to the extent he is now, "a mere trader." I do not use the phrase in an offensive sense.

Then it is overlooked that, for good or ill, pharmaceutical research has largely passed into the hands of the experts employed by wholesale houses, and from research they have gone on to preparation. (I am not forgetting the labours of individual pharmacists in business.) The result is the flood of special preparations, and it is idle to deny that for reliability in action, elegance of form, and moderation of price few individual pharmacists can produce equal results. Even when they can they usually lack the means to place them effectually before the prescriber.

I do not think pharmacists are to be blamed for these things. If "manufacture" were an essential part of the practice of law, medicine, or any branch of art, those professions would similarly have suffered, for the change is almost entirely the result of social and economic progress. No trade now presents the same limitations in character that it did formerly, and the only difference

* Read at a meeting of the Edinburgh Chemists', Assistants', and Apprentices' Association, February 7, 1900 (see P. 161).

* Read at a meeting of the Manchester Pharmaceutical Association, February 14, 1900 (see p. 163).

from others in this breaking-down process which we as pharmacists present is that alongside our trading operations we have a modicum of professional character and work, and are the State-appointed sellers of poisons. It is of the outlook in this broader pharmacy that I am speaking.

It seems to me that in reading the discussions and correspondence relating to our trade insufficient attention is given to some

FACTORS WHICH LIE OUTSIDE PHARMACY,

and are common to all trades and professions. Yet they affect us powerfully. It is quite common to hear it said that we are suffering from keen competition. But little heed seems to be given to the causes of competition. If the cause were better understood, the thing itself might be faced with greater equanimity and probably greater unity. We have competition from two directions—one from our own ranks of qualified pharmacists, and one from outside, including company pharmacists, individuals trained but not qualified, and all the trades—drapers, grocers, ironmongers, and the rest—which can add some of our lines as side lines to their own. We complain most of this outside competition, but I fear it is not that which harms us most. Let us look at the inside competition first.

In the exceedingly valuable retrospect of the year given in the *Chemist and Druggist* of December 30, 1899, are some interesting figures. Dealing with Great Britain alone, and taking that set of figures which includes the rest, we see that in—

	Passed Prelim.	Mod. and Minor.	On Register.
1869	—	919	12,500
1879	783	282	13,551
1889	721	313	14,080
1899	887	553	15,473

The writer emphasises:—

(1) "The increasing numbers entering the business; (2) the increase of proportion of those who, after passing the Preliminary examination, go forward to the Minor, and are registered—viz., 1 in 27 in 1879, 1 in 23 in 1889, and 1 in 14 in 1899." The increase in proportion of those who qualify is due, it is said, to the more stringent enforcement of the Pharmacy Act, and it, doubtless, is so. But that does not affect the increase in number of those entering the business. That increase is due to the need of finding work for our sons and daughters. In my own town of Bolton there are annually 1,000 lads needing places. An increasing proportion of these lads are well enough educated for the business, and if only Latin occupied a place in the curriculum of Higher Grade schools, most could at once pass the first examination. An efficient system of secondary education will provide for that. Further, owing to the increased thriftiness of the better artisan class, the parents of a greater proportion than was formerly the case can find the capital needed for their education and a modest start in business. Then, I think, a smaller proportion of those who enter the ranks now look to setting up on their own account. They are more content than formerly to enter the employ of others, and the stricter enforcement of the Pharmacy Act has added to the value of their labour and its price. Time will bring better conditions of service.

So far, then, as our outlook may be brightened by a more stringent first examination, I fear there is little hope. What I call "the bread and butter" factor will force an increasing number into the trade. The higher and more thorough education which will result from the establishment of a national system will keep pace with any added stringency of examination. The same argument applies to a more stringent Minor. Moreover, it should not be forgotten that the true object of examination is to sift and attest, not unduly to prevent; and if the Minor be divided, and we introduce the practice of referring students back in weak subjects, the entrance of fresh pharmacists will be facilitated.

Turning from the competition of numbers to the competition amongst men in business on their own account, I think I observe a paradox. It is, that the cash chemist and pharmacy companies have by the extinction of weak business and incapable traders actually benefited those who are

strong enough to stand the competition. No firm or company, however big, can do all the trade. There is, and always will be, room for individual employment of capital, skill, and personal character. I do not fear the absolute extinction of individually practising pharmacists. I foresee, however, that such private businesses will want more capital than formerly, better application of it, more business energy, and above all, a high standard of ethical conduct in all their operations. I am not forgetful that in this weeding-out process, some of us may go under, but it were childish to complain of the operation of social and economic forces which, while fatal to some, were beneficial to the many, and forwarded the progress of humanity. The only manly thing to do is to strive to correspond with our commercial environment, and if we fail in that to accept with as much dignity and courage as is possible the inevitable result.

I speak with some diffidence on this point. I cannot boast of being a very successful man. Perhaps on that very account my evidence may be more disinterested. Whether so or not, I have a strong conviction that pharmacy—the broader pharmacy I mean—has not an entirely hopeless outlook. I have friends in the trade who have done as well in it as, with the same means, they would have done in any other business. In the course of business journeys extending over ten years, I have come across old pharmacists and new who were doing very well out of their craft, quite as well, in proportion to their capital, energy, and skill, as men in other trades, and I have had opportunities of comparison not given to every retail pharmacist. It goes without saying that we all find the stress greater, the struggle more desperate, and the anxiety keener than did our fathers; but that is the lot of all, whatsoever their positions or calling. I believe in my heart the outlook of our trade is as bright as that of any other.

I turn now to the

COMPETITION OF OUTSIDERS.

This is not due to any taint of original sin on their part. You will probably find Mr. Jesse Boot and Mr. Alderman Duckworth in the kingdom of Heaven, and there may be some legitimate pharmacists "left outside the gate." Neither is it because the pharmacist companies have a heaven-sent task of delivering the great British public from the extortion of the retail druggist, although some of them would like to persuade us so. It is simply due to the fact that they are capitalists or are the servants of capital. Now, it is in the nature of capital as such to know no law of humanity, to have no sense of patriotism, no tie of brotherhood, to know nothing, in fact, and acknowledge nothing, save and except the need and duty of making a return for its possession. If you needed any proof of this you can see it in the fact that Boots, Limited, having delivered the people from the high profits of pharmacists, are now delivering them from the extortion of stationers, art dealers, trunk and bag sellers, and—save the mark!—of booksellers!

Against a power like this we shall, if we seek a monopoly, fight in vain. If even, short of a monopoly, we seek to limit freedom of trading, except so far as public welfare dictates, we are doomed to defeat. Has it ever struck you that if Boots and their like were barred out entirely from the sale and dispensing of poisons, they could still do us almost as much harm. When Mr. Carteghe was in Manchester about ten years ago he hinted that the Council had cards up its sleeve, and talked of limiting the compounding of medicines to qualified pharmacists. I asked him at the time if he thought such a proposal had any chance, and the question was evaded. We never had, and never will have, such a monopoly, and we do not need it. What is the backbone of the profits of the companies? Is it not the immense sale they have for preparations of their own—substitutes, if you like—on which they have enormous profits? And most of these specialities could still be sold—it is only a question of capital, trade methods, and advertising, skilfully done—if the Pharmacy Act actually prevented their dealing in poisons. We call these concerns company-pharmacies, but they are scarcely

that more than they are company wine and spirit merchants, company sundries-dealers, or, even now, company picture and book-sellers and opticians.

However dogmatic it may sound, let it be said plainly Parliament will never limit the practice of pharmacy more than it limits the practice of law, medicine, surgery, dentistry, or divinity. What it does with regard to these professions is to prohibit the use of titles not legally possessed. Apart from that, we may sell our own houses and draw up the deeds ourselves, physic or operate on ourselves or others, and no one can prevent us. But if anything goes wrong we must bide by it.

I do not pretend to have discovered anything in setting down the beginning of company-pharmacy to the possession of capital and its need of securing a return. That is an old tale. Still it seems almost forgotten, and there is far too much writing and speaking of company-pharmacy, as if it might be suppressed like a habit or a fashion, instead of being, as it is, one expression of the aggressiveness of capital.

Should we, then, sit down and say "it is inevitable" (like the war)? By no means. If that were all that remained for us the outlook would indeed be bad. From the aggressiveness of capital we are not the only sufferers. Can we obtain any hints from fellow sufferers? I think so.

Some people advocate the

RECOGNITION AND REGULATION OF COMPANY-PHARMACY.

They say, "It is here; we cannot get rid of it. Let us recognise and regulate it." Do they think that capital will submit to their regulation, or to regulation in their interests? Surely not. Neither will the Legislature regulate company-pharmacy in our interests. It only cares for the commercial bearing of company trading. Besides, we do not want its legal recognition. If the law will not suppress, at least it may leave it to the play of forces, and not put it on a recognised basis.

From this standpoint, I do not think the proposal for a qualified directorate will, or ought, to satisfy us. If its effect would be to suppress the companies, we have no chance of getting it. If it does not suppress them, it will not help us. After much thought I have settled to the opinion that it is not our duty to regulate company pharmacy. Managers *must be* qualified, and it seems to me that we gain little, if at all, by a qualified directorate. In an article (November 11) the *Chemist and Druggist* says this proposal, *i.e.*, the qualified directorate, "holds the field (1) for stopping the evil, (2) placing companies in the same position as individuals, and (3) not giving them the splendid advertisement of being registered pharmacies." Well, in reply to this, I say that if it pays to do it, the power of capital will overcome these difficulties, even supposing we succeed in placing any in the path of the companies. The proposition will not stop the evil, and it will only lessen it by keeping out the smaller and financially weak companies who cannot afford the luxury of a qualified directorate. Thus it will leave the field clearer for the operation of the strong companies. Who would not sooner face a weak competitor than a strong one, and the presence of the weak one sometimes keeps the other away. It follows that merely to place recognised companies with a qualified directorate on the same footing as individuals will not help us much. It may legalise properly what is now outside competition, it certainly will not lessen it. Who are the proprietors of a company? The directors only, or the whole body of shareholders? The shareholders, certainly. They are not in the same position as a capitalist who lends money to a man who starts a pharmacy. The capitalist, so long as he receives interest only on his loan (the rest of the profits going to the trader), is in no sense a proprietor. But the shareholders in a company, equally with the directors of it, are proprietors. Now, it is not proposed that all shareholders shall be qualified, and I do not see that it helps us any to get a qualified directorate. If such a law were passed to-morrow, do you not suppose Boots, Limited, would at once conform to it and yet secure that their trade policy should be carried out?

What, then, should we do regarding company pharmacy? I think we should lose nothing by giving up a constructive policy towards it. Our opponents in South Africa have adopted what in military phrase is called "defensive strategy, offensive tactics." So far it has served them well and given them an opportunity of displaying national qualities which will probably preserve to them some form of autonomy. I think a similar policy may possibly serve our turn best. Let us sit tight on the principle that titles being the result of personal qualification cannot be bestowed on companies. As the whole of the proprietors of a company cannot qualify, let us resent the use of our titles by corporations. Attack with the united forces of pharmacy, and all the allies we can get, any attempt to bestow

TITLES WITHOUT QUALIFICATION,

and so, if we cannot suppress company pharmacy, at least make it keep its extra legal position. Let the Legislature deal with company law and construct it so that no injustice is inflicted on any existing interest. If a government proposes legislation which will infringe our titles, let us oppose it. Such a policy, it seems to me, offers a better chance to us than the others referred to. In time, if some new economic factor has not previously solved the problem, I believe the Legislature will recognise the justice of the plea, "A company should not do what an individual without qualification may not do," and deal with the point on that principle. It seems to me that there is no logical solution of the problem, "How shall we bestow on a corporation a personal qualification?" If I am right, it is a waste of time to try and find one.

It may be said that this position of entrenching ourselves will not drive the foe from our front, or, to drop the metaphor, do away with the outside competitor. That is true. It is equally true that the other plan will not get rid of it either. In fact, it cannot be got rid of by anything we can do. In time the capital employed in company pharmacy may find other and better channels, and the individual pharmacist once more be supreme. But the inside competition and trade necessities will prevent the restoration of the old prices and profits, and by that time the "old man with the scythe" will have settled the question for most of us.

I fear you will say, "This is a very bad outlook." Well, if we were children desiring that the order of the universe be altered so that we could have the moon to play with, it would be so. But if we are practical, courageous men it need not be. I think we can do much

TO IMPROVE OUR OUTLOOK.

Our objective is "to unite *all* qualified pharmacists in defence of their legitimate interests and titles, and to secure that in future legislation on pharmacy and poison selling the personal qualification of pharmacists be upheld."

In the first place, let us remember we are 15,000 strong. Of this number, some are in other walks of life. Still, I think their sympathy and help are available to us. Others are serving our friends the enemy, and an essential factor in an improved outlook is to detach them.

Then we have, and it is our greatest trouble, the lukewarm in our ranks, the pharmaceutical Gallios, who "care for none of these things."

I fear we could never have described the ranks of pharmacy in a parody of Macaulay's lines:—

"The druggists were like brothers
In the brave days of old."

Nor would it be all untrue if we were to say:—

"Now druggist is to druggist
More hateful than the foe,
For the poor ones beard the high,
And the rich ones 'cut' the low."

But these lines at least suggest an ideal to be attained, and an example to be avoided. One of the very first things to be done is weld together all ranks and states of qualified pharmacists. We have many and valuable interests and traditions in common. Why should we throw away through loose combination and selfish living

such sources of help, and encouragement, and hope? But tradesmen, as such, will never unite for an ideal in the abstract, however high. Nor can a corporate life be built and sustained on the abstract. Nor, again, is there any need for us to try such a futile method of subsistence. There are enough concrete things for us to strive for and live on.

These must be brought to the front. Our unity ought to focus itself on the Society, and will do if we can be led aright. But then the Society must stand to each one of us for something more than an examining and registering body. Those functions are pseudo-State functions, and that relationship is as much one to the State as to ourselves. Nor must it retain so absolutely the status of a pseudo-scientific society. It must become far more frankly and thoroughly than it is a trades' organisation.

Now it seems to me that the Society (I am not intending to blame its present Council) can maintain these three states without any inconsistency. It can be the State-appointed examiner of and registering body for pharmacists; it can keep in touch with the medical and scientific bodies, and so continue to promote the interests of pure and technical pharmacy; and it can be, and should be, the centre of trade life and unity, the representative and defender of trade interests, and the means whereby we can collectively act and do what individually we are helpless to accomplish. I am bold enough to say that this third feature of the Society should be its strongest and best. The State can, if it likes, provide a department to examine and register; the interests of medicine and science, and in an equal degree private commercial interests will not let the scientific side of pharmacy fall into the distance; but neither the State, nor medical and scientific, nor commercial, interest will see to our trade needs and craft interests if we fail through our Society to help ourselves.

I think then any appeal for unity must be based on a trade society thoroughly alive to trade requirements. We hear much of

THE LOCAL FEDERATION SCHEME.

I wish I could feel any hope that it will really help us. I wish, too, that the energy and skill of its organisers had been devoted to getting done through the Society what it seeks to do by its own agency. My point is this, that instead of having alongside the Society a number of subsidiary or complementary organisations, the Society itself should undertake these functions. I would not burden the Council with the P.A.T.A. work, but I cannot see why the Society should not undertake on sound lines chemists' defence work. The Cycling Touring Club does it, and we might do. Perhaps I am dreaming, but I cannot help thinking that when pharmacists are appealed to on behalf of the Society to join and support it, as artisans do their unions, they have a right to ask that it shall adopt more decidedly and thoroughly a Trades Union policy. Then, I think, the appeal for unity might be successful, especially with a good organising secretary to explain and canvass for it.

But, apart from what we can do for ourselves through the Society, there are other ways of improving the outlook. I must safeguard myself here from any impression on your minds that I consider myself outside what I am going to say. I am speaking to myself as well as to you.

Our outlook can be improved by the adoption in all possible ways of modern and up-to-date methods of business. As a trade, we are far too conservative in ideas. "Why do you sell seidnitz powders at a shilling per box?" said a fellow-craftsman to me some years ago. "You know the cutters sell them at 7d. here." I replied, "I cannot afford to sell them at those prices." His reply was, "Keep that tale for somebody else. You know well you can buy wholesale a reliable article at a cost of 5d." He was a Lancashire man and brutally candid. When he had gone I thought over the matter and dropped my price to a little above the cutters, sold more and stopped the grumbling. How many of us are still contending for prices on the ground that "we can't afford," when we ought to say "we don't choose to alter." So in other cases with the adoption of side lines, many profitable paths are closed because to travel them does not consort with the dignity of pharmacy. We do not need to be

pharmacists less, but we need to be smart traders and business men more. Is there no truth think you in the taunt of Mr. Boots, "that the ordinary training of a retail pharmacist does not necessarily make him a good business man on a large scale." Said a cutter to me about eight years ago, "I was a draper and knew nothing of the drug trade, but I saw there was money in it on cash store lines." Do we not want a little more of that spirit? Now for any improvement on these lines we must depend almost entirely on individual effort. But that effort may be stimulated if we got more into touch with each other. This, too, must largely depend on ourselves. It would be of little service to us to have a remodelled and reorganised Society if we do not cultivate association more. One advantage of a society which had the almost entire support of the trade would be that, instead of having purely local associations such as ours, we should have branches of the Society. So we might hope to break down the trade loneliness in which most of us spend our lives. "As iron sharpeneth iron, so doth the face of man his friend," and we may add—his business.

Then if we are ever to win back in any large degree

THOSE WHO ARE SERVING THE COMPANIES,

the terms and conditions of service must be as good and generous as trade will afford. Any new spirit or departure in this line must be the result of individual, or at all events of semi-official, effort. Success depends largely on those having large businesses. It might be worth the while of such individual employers to imitate the companies' bonus system, by which an assistant or manager gets a fixed salary and a commission on profitable sales. Rowland Hill used to say "he did not see why the devil should have all the good tunes." I do not see why the stores should have all the smartest methods. The Society might help us here by undertaking a systematic propaganda amongst qualified men not in business on their own account. It could show a determination to protect the individual title and point out to a man the value of his "trade-birthright." Here again an organising secretary might be useful. But our success with regard to this matter will, after all, not depend so much on the attitude and efforts of a central office as on the spirit and attitude of the whole trade. We hear at times proposals for a code of ethics in pharmacy. No code is needed. What is needed is a feeling of brotherhood, of oneness of aim and interest, of mutual self-sacrifice, of united effort to preserve alike all that is honourable in our tradition and all that belongs to us of right. Give us these things, and the code of ethics will crystallise around them without the aid of a draughtsman.

I have done now. I do not know how far you agree with me. I do not pretend to have shed any fresh light on the "outlook in pharmacy." I feel myself that it is not more hopeless than is the drapers', the grocers', the ironmongers', or, for the matter of that, the lawyers' or the doctors'. I cannot even in this be a pessimist, and yet I am not blind to the keenness of the struggle to live. I have been, and am, in the thick of the fight myself, and have received many a blow. But I have too often received kindnesses at the hands of others; I have too often seen a man hew his way out of the "valley of humble effort" on to the heights of success, to doubt that if we as a trade are true to ourselves as men, true to the public as servants, and true to the State as its instruments, there yet lies before pharmacists an honourable and on the whole a successful though strenuous career.

WHAT ARE THE STATUTORY FUNCTIONS OF THE PHARMACIST.*

BY J. RUTHERFORD HILL.

Some time ago a very eminent authority made the following statement:—"The restrictions of the Pharmacy Acts do not relate to trade; but to nothing more than the professional supply and manipulation of the most potent poisons, as medicine, and to such regulation of the sale of those poisons as was deemed to be expe-

* Read before the Edinburgh Chemists', Assistants', and Apprentices' Association on February 7 (See p. 161).

dient for public safety." If this is correct it defines the statutory functions of the pharmacist. But is it correct? I do not think so. On a former occasion I have said a pharmacist is much more than a pharmacist. Even in a statutory sense, if a pharmacist is to be understood as meaning only a person who dispenses and sells substances for medicinal use, he is more than a pharmacist. What was the genesis of the Pharmacy Acts? They are rooted in the Royal Charter. The Act of 1852 is a real Pharmacy Act and nothing else. It operates solely by the restriction of a title. There is much to be said for the view that it might have been wise, in the interests of real pharmacy, to have adhered to that line of policy. We may even have to go back upon it. But when you come to the 1868 Act the situation is widely different. It is a Poisons Act, intended to restrain and detect crime and accidental poisoning, as well as regulate the practice of pharmacy. On its pharmaceutical side it is rooted in the Charter, but in its poisons side it is rooted in the Arsenic Act of 1851. The Arsenic Act has nothing whatever to do with pharmacy, and deals exclusively with mechanical safeguards. But a reading of the latter along with the 1868 Act shows how closely the policy of the one is built on the policy of the other. The fatal defect of the Arsenic Act is its total disregard of competent knowledge and training on the part of the vendor. This principle is the feature which distinguishes between it and the 1868 Act. There is no mention in the 1868 Act of the purpose for which scheduled poisons are to be used. It imposes an absolute prohibition of the sale by retail of any scheduled substance for any purpose whatsoever except by the hand of a duly qualified registered person. It is therefore evident that it covers not only the practice of pharmacy, but the retail trade in all poisons. This is very well put in the excellent synopsis of the origin and position of the Pharmaceutical Society, which forms the introduction to the Society's Calendar, as follows:—"When the demand arose that certain restrictions should be placed on the sale of poisons, the Council of the Pharmaceutical Society in 1868 succeeded in obtaining a recognition of the important principle that the education and training of the vendor is the only safe foundation for a Poison Bill; and in proving to the satisfaction of the Legislature that a body of men duly educated was in existence, and registered under the Pharmacy Act of 1852." That is to say, the State was in need of a staff of men possessing certain knowledge and experience which would make them safe distributors of poisons to the public. They had been trained with a special view to supplying medicines, but were eminently fitted to fulfil the wider function of supplying all poisons for all purposes, and therefore the wider function was conferred on them. That such is the true state of the case is evident from an examination of the Poison Schedule itself. We have, for instance, oxalic acid (never used medicinally), vermin killers, weed killers, chemicals for photographic purposes, amateur lectures, chloroform to poison a cat or dissolve rubber, potassium cyanide for cleaning plate or for the well-known insect-capturing bottles, arsenic for taxidermic purposes, all scheduled poisons for use as insecticides or as antiseptics, and many others that will occur to anyone. There was a case in Edinburgh where the defence to a charge of selling poison was that they never sold anything as a medicine. If a customer asked for glycerin for chapped hands or sugar of lead for a sore leg they refused to sell it. But the Court refused to recognise such a limitation of the purpose of the Act. Therefore we say the statutory functions of the pharmacist make him more than a pharmacist. But a study of the Charter and the 1852 Act suggests something more even than this. The Charter is granted "for the purpose of advancing chemistry and pharmacy and promoting an uniform system of education of those who should practise the same," and this is repeated in the preamble to the 1852 Act. That is to say, the Charter contemplates not only those who are to practise pharmacy, but also those who are to practise chemistry, and in this connection it is interesting to note that the Society were the first to provide a laboratory course of instruction in practical chemistry. The State had no demand for a staff of men qualified to act as analytical chemists in 1852, or even, for

that matter, in 1868. But there is a very widespread demand for competent persons of that kind now. Does it not appear to be the natural charter right and function of the Society to provide such a staff of men for this State need? We know that the Institute of Chemistry aims at a function of this kind, and perhaps the field can hold two, but it seems not difficult to prove that the Pharmaceutical Society is first in the field and holds a prior title to recognition. It is true the Society has actually done much to provide such a class of men, and many of the most competent have been trained by her efforts, but they pass away from her to other organisations. Should this be so, might we not develop this side of our charter rights, and by a suitable examination grant a certificate that would be recognised as fitting the holder thereof to fill any State appointment as a trained chemist or public analyst. There can be no question that a man who has had the varied experience of a practical pharmacist possesses an immense advantage over a man whose knowledge of chemistry has been obtained exclusively in a science school or college laboratory.

NOTE ON THE DETERMINATION OF IODINE IN IODIDES.*

BY FRANK R. DUDDERIDGE.

The determination of iodine in the official iodides is directed to be performed by titration with decimolar solution of silver nitrate until precipitation ceases in the cases of potassium and sodium iodides, and in the assay of *syrupus ferri iodidi* we are told in addition to use potassium chromate as an indicator after the ferrous has been converted into sodium iodide and excess of sodium carbonate removed by neutralisation. It is usually the custom, I believe, to use the chromate as indicator in each instance, on account of the difficulty experienced in judging the exact moment of complete precipitation owing to the turbidity caused by the presence of the silver iodide formed, but whether this is any real advantage I very much question, as the change of colour is not so sharp as in the case of chlorides or bromides, necessitating an experienced eye to arrive at anything like exact results, and causing much difficulty to students. As soon as an excess of silver has been added the iodide of silver curdles very sharply—much more so than the chloride or bromide—and if the titration be carried on in a white porcelain basin, the liquid being kept well stirred all the time, it will be found that the curdled precipitate *on settling* shows a reddish tint, although no sharp change of colour may have been observed when curdling took place. Therefore the formation of the curd itself in presence of chromate may be taken to represent the termination of the reaction quite as accurately as the appearance of a distinct red, or the absence of turbidity. But in any case, the use of a correct number of C.c. of silver nitrate is not a proof of the purity of the iodide, as a salt containing both moisture and chloride or bromide might be passed as pure if the volumetric test be alone relied on. The liberation of the iodine in the free state, and its subsequent determination by means of thiosulphate would at once suggest itself as the most correct method, and various processes have been devised to effect this by different workers. Cook in 1835 suggested the use of hydrogen peroxide in the presence of acetic acid to liberate the iodine, which is taken up by successive treatments with chloroform in a separator until all has been removed, and washing the chloroform with water to take away any excess of hydrogen peroxide, then titrating with "hypo" in presence of starch paste. Mr. J. S. Hill, to whom I am indebted for most of the practical part of the work involved, has carried out experiments under my supervision to see how results obtained by this process compare with those obtained by the B.P. method. A solution was prepared containing exactly one gram of potassium iodide in 100 C.c. Ten C.c. = 0.1 gram KI were taken and treated as above, but without washing the chloroformic solution of iodine, the result, indicating iodine equal to 0.0997 gram KI or 99.7 per cent. Another 10 C.c.

* Read before the Newcastle and District Chemists' Association, Feb. 14 1900.

were taken and the process repeated, this time washing the chloroform with water. As the washings evidently contained free iodine, they were shaken out with more chloroform, and this latter added to the washed chloroform; the result this time being slightly lower, iodine equivalent to 0.0988 gram KI or 98.8 per cent. being found. Other 10 C.c. were then titrated by the B.P. method in presence of chromate, the result now was high, 0.10003 gram KI, or 100.03 per cent. being indicated by this method. The range officially permitted by the B.P. is between 98.01 and 101.96 per cent. The sample used in these experiments was faintly but distinctly alkaline to litmus, this being allowed by the B.P. characters and tests.

These results show that Cook's process is reliable; it is easily carried out, the chloroform separating rapidly and sharply, without any tendency to emulsification, and the end reaction is clearly marked, this and the elimination of error due to chlorides and bromides giving it an advantage over the B.P. method, whilst for simplicity, ease of application and accuracy, it compares favourably with other methods for liberation of iodine. It was then thought advisable to apply it to the assay of *syrupus ferri iodidi* more particularly as the B.P. process had scarcely appeared before more or less adverse criticisms had been passed upon it and alternative methods suggested. I have noticed that students almost invariably obtain low results in assaying samples of their own preparation, and to determine whether this was due to carelessness in manipulation, either during the preparation of the syrup or in the subsequent assay, I prepared 100 C.c. of the syrup. This was estimated according to the official process, and 2.5 C.c. were found to require 15.2 C.c. of decinormal silver nitrate, instead of from 16 to 16.5 C.c. as officially demanded. Cook's process was then applied, 10 C.c. of the syrup being diluted with water to 100 C.c., and 10 C.c. of the diluted syrup taken for assay, the chloroformic solution of iodine obtained being washed with water, and the washings rinsed out with more chloroform as in the second determination of KI by this method, between 6.25 and 6.3 C.c. of decinormal "hypo" being required to discharge the colour. This for 1 C.c. of the syrup equals 15.7 C.c. for 2.5 C.c. of syrup, and each C.c. of decinormal "hypo" = 0.01537 gram of FeI_2 . These results compare as follows for grams of ferrous iodide in 100 C.c. of syrup:—

Found by B.P. process	9.35 (nearly).
Found by Cook's process	9.655.
B.P. minimum required	9.84.

Ordinary resublimed iodine was used in preparing the syrup. It will be seen from these results that Cook's process is applicable equally to sodium or potassium iodides, or to *syrupus ferri iodidi*, and whilst possessing superior accuracy to the B.P. method, is more easy of application in the case of the syrup.

ACETYLENE MIXTURES.

The following is the substance of the proposed Order in Council prohibiting the admixture of air or oxygen gas, to which reference was made last week:—

Whereas acetylene when in admixture with air or oxygen is specially dangerous to life or property by reason of its explosive properties. Now, therefore, be it ordered and declared as follows:

Acetylene when in admixture with atmospheric air or with oxygen gas in whatever proportion and at whatever pressure and whether or not in admixture with other substances shall be deemed to be an explosive within the meaning of the said Act.

And whereas it is in the judgment of Her Majesty expedient for the public safety that acetylene, when an explosive within the meaning of this Order, shall be prohibited. Now, therefore, be it ordered and prescribed that acetylene declared to be an explosive by this Order shall be prohibited from being manufactured, imported, kept, conveyed or sold.

Provided that nothing in this Order shall apply to acetylene in admixture with air when such admixture takes place only in a burner or contrivance in which the mixture is intended to be burnt.

A TEST FOR PEROXIDES.*

BY FRANK R. DUDDERIDGE.

A characteristic and easily applied reaction for the detection of a peroxide of an alkali or alkali-earth metal, which I have not noticed in any of the ordinary text-books, is the addition of silver nitrate solution to a small portion of the powder in a test tube. In the case of an alkali metal brisk effervescence occurs at once, due to evolution of oxygen—easily recognised by a glowing match-stick—and a black precipitate of metallic silver is at once deposited. With the alkali-earth metals the reaction takes place more slowly, a brown precipitate of silver oxide being first produced, soon followed by evolution of oxygen, the precipitate turning to black metallic silver. The reaction in this latter instance is hastened by the application of heat. The effect produced will no doubt be due to formation of silver oxide in each instance, and its decomposition by the peroxide, similar to its well-known reaction with hydrogen peroxide.

PRACTICAL NOTES AND FORMULÆ.

Trional Emulsion.

Since trional is soluble in fixed almond oil to the extent of 1:20, Pouchet and Brisse-mort suggest an oily emulsion as an agreeable means of administering the drug. Such an emulsion may be made of:—Trional, 1 Gm.; oil of sweet almonds, 20 Gms.; sugar, 8 Gms.; powdered gum acacia, powdered gum tragacanth, of each 20 centigrammes; cherry laurel water, 2 Gms. An enema of the same may be obtained with trional, 0.5 to 1 Gm.; oil of sweet almonds, 10 to 20 Gms.; yolk of one egg; water, 150 Gms.—*Journ. de Pharm. d'Anvers*, 56, 16.

Recipes for Liqueurs.

Liquor Napoleonsis.—Gentian root, 35 Gms.; sweet flag, 35 Gms.; cinnamon bark, 25 Gms.; cloves, 25 Gms.; coriander seeds, 50 Gms.; lemons, 4; alcohol (90 per cent.), 3,000 Gms.; water, 1,500 Gms.; milk, 1,500 Gms.; white sugar, 1,000 Gms. Digest for six days, filter.
Strawberry Claret Cup.—Two litres of ripe strawberries are placed in a punch bowl and sprinkled with half a kilo of finely-powdered sugar; three bottles Moselle wine and two bottles of Bordeaux wine are poured over the mixture, which is then allowed to stand for several hours in ice. The mixture is stirred just before serving.
Walnut Liqueur.—Green walnuts, 500 Gms.; cognac, 2½ litres; and cloves, 4 Gms., are digested for several weeks; the mixture is then filtered and a syrup prepared from sugar, 500 Gms.; water, 1,000 Gms., is added. A very good syrup may be obtained by using honey instead of sugar. Another formula is:—Green walnuts, 18 in number; cloves, 20 Gms.; cinnamon bark, 20 Gms.; sweet flag, 20 Gms.; orange peel, 20 Gms.; vanilla bean, 1; sugar, 500 Gms.; alcohol (90 per cent.), 1 litre; water, 500 Gms.—*Pharm. Post*, 32, 566.

Brilliantine.

Glycerin, 10; lime juice, 10; dilute alcohol or eau de Cologne, 80.—*Pharm. Post*, 32, 721.

Indian Cream.

White wax, 3, is melted with spermaceti, 2, on the water bath, and olive oil, 20, added. This is digested with alkinet root, 20, till deep red, and while warm a little lavender oil and tincture of ambergris is added and stirred till cold.—*Pharm. Post*, 32, 721.

Label Varnish.

Sandarac, 53; Mastic, 20; Spike lavender oil, 7; Venice turpentine, 4; Ether, 6; Alcohol, 40.—*Pharm. Post*, 32, 721.

FACTS AND FANCIES.

BY AN ORDINARY PHARMACIST.

The Companies Bill Revived.

After the Lord Chancellor, Mr. Ritchie. The Companies Act Amendment Bill of 1899 is revived as the Companies Acts Amendment Bill of 1900, and introduced into the House of Commons in the identical condition in which it left the House of Lords last year, except for "a small verbal amendment, which legislation since the Bill was before the House of Lords had rendered necessary." That statement implies, among other things, that the President of the Board of Trade has been so little impressed by the lengthy epistle addressed to him by the President of the Pharmaceutical Society that he has not thought it worth while to alter the text of the measure before introducing it. Whether he will be disposed to do so if any degree of pressure can be put upon him by pharmacists and such influential friends as yet cleave to them remains to be seen: the outlook, however, is none too promising, and perhaps the most that can be done will be to get the pharmacy clause expunged from the Bill. It may be possible to convert that clause into a satisfactory and workable amendment of the Pharmacy Acts, but, in my opinion, the chances are in favour of no such conversion. Indeed, I fear that the House of Commons will be as little disposed to suppress company trading in pharmacy entirely as the Manx House of Keys has proved to be.

Vigorous Action Needed.

But that is no reason why we should sit quietly with folded hands, waiting for what Providence may choose to send us. As the status of an individual is largely based upon his opinion of his own importance, so is the social and political position of a class in great measure dependent on the impression produced by it in the public mind. That is to say, if pharmacists as a class are prepared to allow themselves to become the victims of circumstances, they may as well cease from troubling and let the wicked, *i.e.*, the limited companies, be at rest in the assurance that they hold a position which cannot be turned. But I take it that the vast majority of the pharmacists of Great Britain, to say nothing of Ireland, do not mean to acknowledge themselves beaten before defeat has actually come, any more than General Buller has done. The pity of it is, however, that—owing to the lack of agreement as to what should be attempted—opportunity after opportunity has been missed, and to-day we are apparently as far off having a clear and unprejudiced statement of our position placed before the Government as ever we were. The medical profession has been fairly successful in securing a proper official appreciation of what the public safety needs, so far as it is concerned, but poor pharmacy appears unable to overcome the prejudices which weigh against it on account of its peculiar association with trade. Where personal services alone enter into consideration, as in the case of medicine, surgery, dentistry, and midwifery, our rulers are able to grasp the seemingly obvious fact that some measure of restriction is imperatively called for in the public interest; as soon, however, as the price is in question of articles which call for skilled service in their proper distribution, the monopoly bogie is resuscitated and worked for all it is worth in the attempt to secure for its wire-pullers advantages to which they are entitled.

Division of the Qualifying Examination.

Is the proposed division of the qualifying examination really within, or even approaching, the sphere of practical politics, or is it merely serving as a subject of conversation for our leaders? The discussion at the Council meeting last week was very interesting of course, but many of the speeches expressed what I can

only regard as pious opinions rather than intentions on the part of the speakers to effect a radical change in the system of examination. The essential thing, it seems to me, is to recognise what is actually required in the matter. The plea that the examination and regulations should be altered because assistants are scarce savours too much of a desire to obtain, assistants of lower calibre at a cheaper rate, but such a notion cannot be entertained for a moment. Pharmacists who wish to be relieved of any portion of the serious cares of their business must be prepared to leave as good men as themselves in charge, and that being the case it is quite out of the question to seek to lower the standard of examination or to reduce the value of the qualification in any way. If pharmacy is to survive its present difficulties the value of the personal qualification must be increased, not lowered, and the individual who is not prepared to pay a proper price for the services of a duly qualified assistant must even be content to do his responsible work himself, in spite of any personal inconvenience that may be caused. The only sufficient ground for dividing the examination should be that the existing arrangements do not enable the examiners to form a proper estimate of a candidate's fitness to undertake duties which involve the well-being of the public. It need cause no strain on the candidate to have to study half-a-dozen different subjects at once but both he and his examiners may be at a disadvantage when the attempt is made to examine him satisfactorily in those six subjects in a single day or less. If it be proved that such a disadvantage really exists I would advocate division of the qualifying examination at the earliest possible moment, but I am distinctly averse to humouring any desire to obtain assistants with a lower qualification or at a cheaper rate.

The Registrar's Report.

The statistical report compiled annually by the Registrar of the Pharmaceutical Society is always an interesting production, including as it does full particulars regarding the strength of the Pharmaceutical Society and of the number of chemists on the Register, together with an analysis of the examinations held during the past year. The subscribing members of the Society at the end of 1899 numbered 5,820, a record figure, I believe. But there were 15,595 persons registered as chemists and druggists at that time, so that the Society included only about three-eighths of those whom it is fairly entitled to represent in their entirety. Nevertheless, it must be remembered that the position is a distinct advance upon that of the previous year, when the Society included only three-tenths of the registered chemists of Great Britain in its ranks. What the relative proportions of members and non-members will be when next year's report is presented by the Registrar will probably depend largely upon what action is taken by the Council of the Pharmaceutical Society or what happens in Parliament during the present session. Indeed, there is only too good reason to believe that, unless some agreement is shortly arrived at by the Council and decided action taken thereon, the Society will certainly lose the support of several who have become members simply with the view of adding to the strength of the force behind the executive body. With regard to the examination results of the past year there is not much I can say, except to express regret that the percentage of rejections in the qualifying examination appears to be increasing. The percentage for England and Wales has increased from 69.53 to 71.67, but that for Scotland has decreased from 64.99 to 63.91; for the whole of Great Britain there is an increase of 1.5 per cent. in the rejections for the year, a slight increase, but yet, I think, a distinctly regrettable one. A remedy may be found in division of the examination, but that, I fear, cannot be more than a partial one. More systematic study is required and better preparation generally; no amount of division or subdivision of the examination can help candidates to pass in subjects with which they are not properly conversant.

POLITICAL GOSSIP.

MOST PHARMACISTS will rejoice at Sir Michael Foster's elevation to M.P.-ship, and will join in congratulating him, as well as the House of Commons and the London University. His election was never apparently once in doubt during the whole week of election, and he beat his Radical competitor, Dr. Collins, by a handsome majority of over 400, on a poll of 2,820. Although Sir Michael has been represented in the public Press as a sort of political nondescript—unsanctified by the blessings of any party of the State—it may pretty safely be assumed that he will mostly support the Government with his vote like the staunchest party man of them all. It is, however, wholly immaterial, from a pharmaceutical point of view, whether he sits with Ministers or on the Opposition benches, but it is of some interest to know that he is, on his own declaration, going to the House primarily as a representative of "science, learning, and education." In that capacity he may do worse than commence his parliamentary career by examining clauses 2 and 3 of Mr. Ritchie's Companies Bill; for the representative of the graduates of a University who have won their degrees by laborious effort and after stringent examination may be expected to have no favourable bias towards the filching of personal titles by impersonal corporations.

THE COMPANIES BILL was introduced into the House of Commons on the 12th instant by Mr. Ritchie with the briefest possible statement by way of explaining the essential provisions of the measure, and none at all as to Government intentions. The Bill contains, as Mr. Ritchie hinted it would, the two clauses relating to pharmacy and medicine which the Select Committee of the House of Lords inserted, without comment and apparently without consideration, in last year's Bill. The reproduction is not absolutely identical, as will be seen on comparing the clause printed at page 157 of the current issue with that given at page 131 last week; a "such" being replaced by "the," and "nor" being substituted for an "and," but this verbal amendment is more a matter of taste than moment, and has probably been dictated by a praiseworthy desire to remedy the Lord Chancellor's faulty grammar. As the matter stands, then, Mr. Ritchie has followed Lord Halsbury's lead in ignoring the President's representations on behalf of pharmacy, and has administered snub number two to the Pharmaceutical Council. This action should not be without significance to those who fondly persuade themselves that it is possible to induce, or if need be to force, the Government to accept the "total prohibition" theory of Companies Acts amendment. The medicine clause is unchanged, and the veterinary surgeons have not yet been admitted within the privileged circle which hedges the divinity of surgeons, dentists, and midwives.

IN ITS COMMERCIAL CLAUSES the Bill has only had one alteration made since it left the upper House, and that is in the "winding-up" provisions; a tardy recognition being now accorded to the Preferential Payments in Bankruptcy Act—which passed in 1897 and placed the employees of bankrupt companies in a preferential position in respect to salary due. Thursday, 15th, was formally fixed for the second reading of the Companies Bill, but it was not taken then, and, so far as our information goes, the Minister in charge does not propose to proceed with it at present. He has the highly controversial Railway Couplings Bill to pilot as well as the prickly measure to restore commercial purity, and the Government has already secured first call on parliamentary time up to Easter for the discussion on and voting of supplies. Besides these considerations, there will be others, not so obvious perhaps to the public eye, urged upon Mr. Ritchie in the course of a few days from various sources—some, it may be, from Irish pharmacists, who will certainly not be content with the present casting of clause 2. Speedy progress, therefore, is not to be expected.

LIGHT COMEDY was furnished by Mr. MacNeill on Tuesday, when he asked the President of the Board of Trade, with the gravity of

the professional humourist, whether there were any objections to the insertion in the Government Companies Bill of a clause prohibiting the union of the offices of Minister of the Crown and company director. Mr. Ritchie's laconic "Yes, Sir," afforded the House immense amusement. Later on the member for South Donegal returned to the charge by asking the Speaker whether Mr. Ritchie had not been guilty of an abuse of the procedure of the House in taking advantage of the "ten-minute Rule" to introduce a measure of such first-rate importance as the Companies Bill. The Speaker, however, declined to express a definite opinion on the point raised, simply confining himself to pointing out that it did not rest with the Speaker to decide what Bills properly came within the purview of the Rule, and that he could not from the table of the Board of Trade judge as to the public importance of the measure. Mr. McNeill did not appear satisfied, and assayed a little blarney on the Leader of the House, to whom he appealed as one who never broke a pledge, even to Ireland, but he was cut short by the Speaker, to the evident relief of Mr. Balfour. The little episode was brought to a fitting termination by the correct Mr. D. A. Thomas, of judge-snubbing fame, who gently reproved the Speaker by remarking that the importance of the Bill in question was evidenced by its leading position in the Queen's Speech.

LETTERS TO THE EDITOR.

Company Legislation.

The time has arrived for pharmacists to unite in one determined effort to remedy the flaw which exists in the Pharmacy Act of 1868. Many and various have been the plans suggested for rectifying the evil, and the diversity of opinion which exists has made it difficult for anyone to formulate a plan that will meet with general approval; if we are to succeed this diversity must be exchanged for unity. In discussing the question of company pharmacy and legislation thereon, I have always advocated that pharmacy should not be looked upon as a profession only, but that the commercial aspect of it should also be kept in view; otherwise, legislation might become vexatious, and hinder genuine business development. While keeping this thought in view, and after carefully considering the matter in every phase that has been presented to me, I have deliberately come to the conclusion that the best course for us, as pharmacists, to adopt is to strenuously oppose the Lord Chancellor's clause in the Companies Bill, and as strenuously strive to get pharmacy treated in the same way as medicine and dentistry are dealt with in that measure. I have not yet seen a clause that has been drafted with a view to regulating company pharmacy that has been both just and effective, and I believe it is impossible to formulate a workable clause; that framed by the Lord Chancellor would prove both unjust and ineffective, for, in the first place, it would confer the title of chemist on those who had never earned it; if John Smith were to pass the Minor examination and then request that his qualification should pass to Thomas Brown, who could not pass the Minor, his request would be indignantly refused, for vicarious qualification is twin brother to personation, and we know that personation is a crime punishable with severe penalties under the British law, and to legalise it would be unjust. Then, secondly, the clause would be ineffective, for it does not define what is meant by a business being "*bonâ-fide* conducted by a manager, etc." Does it mean that the qualified manager is to run the drug department with as much freedom as if it were his own business? If so, what provision is made for enforcing this? What authority is to supervise the company? The clause does not provide an answer to this question, and is, therefore, ineffective, for if it become law it will leave the qualified manager under the thumb of the unqualified directors; he will be their puppet and must do their bidding, whether it be in accordance with his professional knowledge or not. The expression "*bonâ-fide* conduct the business" is a loose term which may be interpreted according to the fancy of the individual, and is worthless in an Act of Parliament.

What we need is a simple clause that will be just and effective, and will appeal to the common sense of the man in the street, and we should get such a clause by placing pharmacy on the same footing as medicine and dentistry in the Bill. In applying the word "effective" to such a clause I do not mean that it would stop company pharmacy, but it would give legal enforcement to the principle of the Pharmacy Acts which have been framed for the public welfare. To put the matter in a nutshell: "Instead of trimming the Pharmacy Acts to suit limited companies, it would compel companies to trim themselves so as to suit the Pharmacy Acts." And when the matter is looked at broadly, that is a common-sense view to take. In conclusion, let me appeal to all my fellow pharmacists to face this question fairly and see if we cannot agree on a clause, then stand shoulder to shoulder and carry it through. I do not say adopt the view I have just expressed; personally, I am prepared to back up any clause that will be just and effective and that comes within the range of practical politics. I believe the above suggestions meet these three requirements, but I do not say I will support these and no others. The Council of the Pharmaceutical Society should be in a better position than myself to judge on this matter; if they bring forth a workable clause they will have my support.

Nottingham, February 13, 1900.

WILLIAM GILL.

A Divided Minor.

The question of a division of the "Minor" is one which calls for immediate attention, in view of the increased percentage of failures, as the difficulties of obtaining qualified assistants are becoming urgent. Pharmacy offers many hardships and few recompenses to young men, and apprentices are not to be had, although premiums are nominal, and unless something is done to encourage young men, business will soon have to be conducted on different lines. The causes for failure of so many candidates may be briefly divided into three classes, viz.:—(1) Deficiency of knowledge. (2) The tendency of examiners to require a classical rather than a practical knowledge of subject. (3) Personal deficiencies caused by the strain of keeping up to examination pitch in so many subjects.

I am not in favour of a lower standard for the examination, but I do contend that to do justice to the present examination more time is required. Of the above three reasons for failure the first is very often due to students thinking that attendance at lectures will ensure success at the examination without much further effort on their part. There is an art in passing examinations, but it is founded on knowledge and ability to answer questions, and men who are desirous of success would do well to remember this, then we should have fewer of the illogical excuses for failure:—"I knew what the examiner wanted to know, but I couldn't answer him."

The second reason for failure is one which would seem to call for further inquiry, but we are assured by members of the Board of Examiners that the candidates are all submitted to a fair examination. There must be some truth in the statements of successful and rejected candidates, and at times the consensus of opinion is unfavourable to individual examiners. In botany many subjects give rise to questions on which examiners have their own opinions, and it is not reasonable that such should be included in the examination when the scope is already so wide. In chemistry there is such a vast field for examination that it is no wonder some students fail to get an adequate grip of the whole subject which will stand the test of a few minutes' *viva voce* examination unless the examination is conducted on very broad lines. The practical and theoretical chemistry examinations are not excessively severe; on the other hand, there is a tendency to leniency at times, because in the limited time it is impossible to deal with the subject fairly. In addition, the professional examiners cannot, or do not, give due consideration to the pharmaceutical applications of chemistry. Perhaps they consider that branch of chemistry should be dealt with by the examiner in pharmacy.

The third reason is the one I consider the chief factor in causing

so many failures. Candidates must be examined as they are found to exist, for it will take an eternity to cultivate ideal candidates, and I think there are no examiners but will admit the severe strain of the examination upon some men. How can this be remedied? The Council has to decide, and possibly will, when the new regulations come into force. A division of the examination seems inevitable, and present conditions would favour an examination before the final qualifying one. An examination in chemistry (practical and theoretical) and botany, for which students would be eligible at the age of twenty, and the final examination at the age of twenty-one, would divide the work suitably. The examination in chemistry and botany might be named the "Intermediate," and would certainly make students take some interest in the subjects they have to learn, and particularly the ones to be learnt "out of the shop."

The Intermediate and Final examinations might be conveniently arranged as follows:—Intermediate: First day, practical chemistry, 6 to 10 p.m.; second day, theoretical chemistry, 6 to 8 p.m.; botany, 8 to 10 p.m. Final: First day, practical pharmacy and dispensing, materia medica, and pharmacy; second day, practical chemistry, botany, and prescription-reading. The question of a written, instead of a *viva voce*, examination will commend itself to some examiners. The "Intermediate" would be very acceptable to the majority of students if held in the evening, and, although it would be a new departure, there is no reason why the examiners should not be able to attend in the evening. It is unquestionable that teaching interests would be affected, but that ought to be a secondary consideration. If, however, the Society have to get fresh powers from the Privy Council, the question of whether the Society ought to be at one and the same time a teaching and examining body is sure to crop up, and any fresh legislation will, unfortunately, savour of "self-seeking," but it will be better for the reformation to begin within the "house" than to have it forced by outsiders.

London, February 10, 1900.

C. EDWARD SAGE.

Company Trading and the Practice of Pharmacy.

Mr. Brown's letter in your last issue is very practical and pointed—the manner in which the work of the individual pharmacist, however capable, and however conscientious he may be in studying the interests of the medical profession and of the public, is treated with utter contempt by both, has long been painfully apparent to me. This attitude is, in my opinion, not only due to the unscrupulous way in which proprietary and quack preparations are pushed and advocated by their originators, but is to a very great extent encouraged by members of our own body, who foster and even assiduously cultivate the sale of such in the most suicidal manner. When I regard the way in which many conduct their business I can scarcely feel surprised that the public have been brought to look upon the chemist or pharmacist as a mere agent for the supply of other people's proprietary goods, and to place him in the same category with their other tradesmen. Many of us, I fear, give them but little reason to think otherwise.

Personally, I have always endeavoured to conduct my business as a pharmacist, and not as a mere agent; but the difficulties and discouragements are very great, and the rewards extremely scanty. Still, one can but persevere in the endeavour to do all in one's power to bring about a better understanding of our position and capabilities, and to make our customers feel that their true interests lie rather with educated and responsible pharmacists than with those who are dragging pharmacy down to a sordid trade level. It is particularly discouraging to find so little appreciation from the average medical practitioner, who seems to regard the pharmacist with mixed feelings of dislike, prejudice, and mistrust. One can only hope that this very unsatisfactory state of things may be gradually overcome and better relations established, but I fear it will be a slow process.

Enfield, February 14, 1900.

F. GOLDBY.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

Members of the Pharmaceutical Society must address all communications with reference to the transmission of the Journal, to the Secretary, 17, Bloomsbury Square, London, W.C.

LONDON: SATURDAY, FEBRUARY 17, 1900.

THE NEW COMPANIES BILL.

A BILL to amend the Companies Acts—"prepared and brought in by Mr. RITCHIE, Mr. ATTORNEY-GENERAL, and Mr. SOLICITOR-GENERAL"—was introduced and read a first time in the House of Commons on Monday. In introducing it the PRESIDENT OF THE BOARD OF TRADE said the Bill last year passed through the House of Lords, and he had thought it right to introduce it in the House of Commons with a small verbal amendment, which legislation since the Bill was first before the House of Lords had rendered necessary. The legislation referred to is understood to be that relating to preferential payments in the case of bankrupt companies. As it happens, however, two verbal amendments also occur in the clause dealing with the application of the Pharmacy Act to companies. The modified clause reads as follows:—

No company may carry on the business and use the description of a pharmaceutical chemist or chemist and druggist unless *the* business is bonâ fide conducted by a manager or assistant being a duly registered pharmaceutical chemist or chemist and druggist, as the case may require, *nor* unless the name of the person so qualified is conspicuously posted in the shop or other place in which the business is carried on, but, subject to this provision, anything which would be an offence under section fifteen of the Pharmacy Act, 1868, if committed by an individual, shall be an offence if committed by a company.

The two words in italics did not appear in the corresponding clause of last year's Bill, "the" replacing "such" and "nor" appearing in place of "and." The Bill is now down for second reading, but it is not probable that it will be proceeded with at present. Meanwhile it still remains for those responsible for the conduct of pharmaceutical affairs to decide on what lines the company trading problem shall be attacked. What can be done must be effected when the Bill comes up for second reading or during the committee stage. But in either case, a general agreement must first be arrived at, either with the view of opposing the objectionable clause—with or without the suggestion of an alternative—or, on the other hand, with the object of

of effecting such modification in the clause as may commend itself to the chief parties concerned in the matter.

SECRET REMEDIES IN GERMANY.

THOUGH uniform regulation of medical affairs for the whole of the German Empire is contemplated in the future, nothing has yet been done in that direction except in regard to the conduct of the examination of candidates for qualification as practitioners of medicine and of pharmacy. In some respects the want of uniform legislation for the whole country has been made up for by the issue of ordinances by the several governments of the federated States, as, for instance, in regard to regulation of the sale of poisons for technical purposes, and the supply of potent remedies for medicinal purposes. The sale of secret remedies, on the contrary, has not hitherto been made the subject of a uniform regulation; but an ordinance having that object has now been sanctioned by the Federal Council and will shortly be published by each government. The subject has long been under consideration, and has excited much interest in medical and pharmaceutical quarters. About two years ago there was an intention of regulating the sale of secret remedies in a somewhat drastic manner, but the plan proposed was rejected by a committee of experts. Pharmacists were especially opposed to that plan, because the regulations contemplated would have applied only to them, and also because no definition was given of the term "secret remedy." In a memorial addressed to the Federal Council the Apotheker Verein asked that the Imperial Sanitary Board should interpret the term "secret remedy" in every instance.

In the new ordinance several amendments have been introduced, and it is generally received by pharmacists with satisfaction. It provides that the respective governments of each State shall name in a special list those articles which are to be treated as coming within the designation of "secret remedies," and it is understood that this list shall be agreed upon by a resolution of the Federal Council in order to make the regulation uniform for the whole country. The Imperial Sanitary Board will of course be consulted in deciding upon the preparations to be included in this list. The regulations are not to apply to any substances or preparations mentioned in the Arzneibuch, or German Pharmacopœia, when offered for sale under the names given to them in that work; neither are they to apply to substances or preparations that are generally recognised as remedies by medical science and practice, or to substances and preparations offered solely for purposes of disinfection, as cosmetics, or as articles of food and condiments. Public advertising of secret remedies is to be altogether prohibited. All bottles and receptacles are to bear the name of the maker of the preparation, the name of the retailer, and the price of the article. No kind of recommendations or certificates may be attached to the bottles, etc. Secret remedies containing poisons or patent medicinal substances are not to be supplied in any instance except by prescription of a doctor, and the same regulation is to apply to any preparations the contents of which are not known to the pharmacist selling them. Lastly, secret remedies which are of a nature to be injurious to health or a means of defrauding the public are not to be offered for sale.

ANNOTATIONS.

THE B.P.C. MEETING IN LONDON may now be regarded as an event of the immediate future, only five months remaining in which to complete the arrangements. As a necessary preliminary to drawing up the programme for the last week in July, the Hon. Secretary, Mr. William Warren, acting on the instructions of the Executive Committee, is inviting pharmacists in the London district who have not already sent in their names to subscribe to the Entertainment Fund. There has been a liberal response to a circular letter inviting subscriptions, and it is proposed to publish the first list of subscriptions before the end of February. All persons who have not yet sent in their names and are desirous that they should appear in that list should communicate promptly with Mr. Warren, 24, Russell Street, Covent Garden, W.C. Subscriptions from individuals must not exceed two guineas each; those of firms are limited to five guineas, but smaller amounts may be subscribed in either case. Cheques should be made payable to the Hon. Treasurer, Mr. J. H. Mathews.

THE APRIL MINOR EXAMINATION has been arranged to commence, both in London and Edinburgh, on or about March 27. In all probability the oral portion of the examination will be concluded in Edinburgh during the week ending April 7, but in London it is not expected that the practical work can be completed before Easter, in which case the meeting of the whole Board to conduct the oral part of the examination will not take place till April 17. The Major dates are not yet definitely fixed, but will be announced in these columns as soon as they are known. Provision has this time to be made for the Pereira Medal competition, which, it will be remembered, was formerly held after the July meetings of the Boards, but has been transferred to April to meet the altered conditions arising from a reorganisation of the advanced course of instruction in the School of Pharmacy. The special examiners to conduct this examination are Professor Balfour, Dr. L. Dobbin, and Mr. Boa, who were appointed for that purpose at the last meeting of the Council, and it is hoped that a respectable number of members of the Society who have passed the Major examination will compete for the prizes offered by the Council. Those desirous of ascertaining the scope of examination and the conditions of competition should refer to the Society's Calendar for 1900.

AROMATIC SPIRIT OF AMMONIA has so frequently formed the subject of investigation that it might be thought to have been exhausted. That such is the case, however, is disproved by Mr. Edmund White's paper, which appears at page 144 *et seq.* It will be noticed that, in examining his materials prior to dealing with the spirit itself, Mr. White found that certain factors given in the British Pharmacopœia for strong solution of ammonia are incompatible, it being impossible to obtain a solution containing 32.5 per cent. by weight of ammonia, which shall also be of specific gravity 0.891, and *vice versa*. Lunge and Wiernik's table gives the strength of a solution of ammonia, s.g. 0.891, as 31.4 per cent., and Mr. White's results accord closely with their figures, which appear on the whole more trustworthy than those of Carius. As regards ammonium carbonate, Mr. White has not recently met with a commercial sample which complies with the official requirements, his results in that respect according with those recorded by Squire. Turning to the test for total alkalinity of aromatic spirit of ammonia, it is stated that, in cases of deficiency due to the ammonium carbonate, the total alkalinity may be sufficiently raised by the addition of a little strong solution of ammonia. Such addition will not appreciably affect the alcoholic strength or specific gravity of the product; in no case is it necessary to add more ammonium carbonate, especially as any addition of that kind would tend to raise the specific gravity beyond the official limit. The reaction

upon which Thresh's barium chloride test is based has been found to be unsuitable for the purpose, and it is stated that the due proportion of carbonate can be assured by using the correct weight of the commercial salt; no deficiency occurs, since ammonium bicarbonate produces slightly more normal carbonate than an equal weight of a freshly-sublimed specimen composed of carbamate and acid carbonate.

THE ANNUAL DINNER OF THE SCHOOL OF PHARMACY will be held on Wednesday next, February 21, in the Caledonian Salon of the Holborn Restaurant, at 7 p.m., and all past students and well-wishers of the School of Pharmacy are again reminded of that fact. The tickets are five shillings each, and the Hon. Secretaries intimate that they will be greatly obliged if all who intend to be present will notify that fact on or before Monday, February 19, in order that they may be enabled to complete the necessary arrangements. All communications should be addressed to the Hon. Secretaries, School of Pharmacy Dinner Committee, 17, Bloomsbury Square, W.C.

AN EVENING MEETING of the Society will take place at 36, York Place, Edinburgh, on Wednesday next, the 21st instant, at 8.30 p.m. precisely. The chair will be occupied by Mr. Peter Boa, and two papers will be read on that occasion. The first consists of a note dealing with "The Detection of Sulphates in Presence of Thiosulphates, which has been kindly promised by Dr. Leonard Dobbin, F.R.S.E., of Edinburgh University, one of the Society's Teacher Examiners in Chemistry under the scheme introduced by the Council in 1894. The other paper will be by Mr. J. R. Hill—the Assistant-Secretary in Edinburgh—and deals with Strychnine Hydrochloride and Potassium Arsenate.

AN EXCISE OVERSIGHT does not afford efficient protection to persons who have not paid Customs dues on spirits, as a firm of "manufacturing chemists" at Liverpool has realised on being summoned by the Inland Revenue authorities for harbouring goods which had not paid such dues. The defendants were alleged to have shipped to Australia some cases of perfumery upon which they obtained the usual allowance or "drawback" from the Customs. The goods were returned to London, and thence shipped by coasting steamer to the defendants at Liverpool. No duty had been paid at London. Defendants said there was no secrecy about the matter, the cases being plainly labelled as containing perfumes. A Customs official who gave evidence as to the passing of the invoice containing a statement of the goods said it did not occur to him that perfumes contained spirit. Ultimately, the magistrate said that the affair seemed to be the result of an oversight. It was obviously done without any attempt at concealment, and the summons would be adjourned for a fortnight in order that an arrangement might be made as to the amount of duty to be paid by the defendants.

THE TAXATION OF "STORES" is the basis of a scheme for protecting small traders in Germany, where, in recent years, huge trading establishments have become numerous, with the result that some small traders, having only a limited capital at command, have been compelled to give up business. A Government measure has, therefore, been presented to the Reichstag, with the object of protecting that class of small traders by making the carrying on of "universal stores" a costly matter. The Bill divides the various articles of trade into four groups:—(1) Eatables, drinkables, tobacco, and drugs; (2) drapery and clothing; (3) house furnishing; (4) gold, silver, stationery, objects of art, instruments, and weapons. Any concern engaging in trade in two or more of those groups of articles is a "universal store" within the meaning of the Bill. The tax begins to be levied on concerns with a turnover of £25,000, and the

annual tax which such a firm would pay is £375; a business with a turnover of £40,000 would pay £625, one with a turnover of £60,000 would be taxed to the amount of £1,100, and so on. The Bill does not touch huge concerns trading in one group of articles, no matter how great their turnover.

THE FOOD PRESERVATIVES COMMITTEE proceeds on its uneventful way, and is accumulating evidence at an appalling rate, among the most interesting recorded of late being that of Dr. Grünbaum, lecturer on chemical physiology at University College, Liverpool, who said the general opinion in Germany and Austria was against the use of preservatives. In Germany, it appears, there is definite statutory prohibition of the use of salicylic acid in wine, and there are municipal by-laws regulating the application of preservatives to foods. Instances have been brought before the German Law Courts in which boric acid has been found in milk, and in the majority of cases convictions have been obtained. One of the favourite preservatives used in Germany is, apparently, sodium sulphite, which is added to minced meat, and as that is largely used in Germany as the food of invalids, the authorities are specially keen in guarding against its contamination. In Switzerland there is a direct prohibition of the importation of meat which has borax or boric acid added to it as a preservative. It seems to Dr. Grünbaum that preservatives should be forbidden on general grounds, because, so far as is at present known, what is injurious to bacteria is also injurious to the cells of higher developed organisms; and, although in the latter case they are capable of replacement, nevertheless it does not seem to him that a highly developed organism should be called upon to replace cells which have been destroyed by disinfectants. He considers that the putrefactive organisms which are attacked by preservatives are of a lower vitality than the spore-bearing pathogenic organisms.

THE SALE OF POISONS for horticultural purposes continues to occupy attention in the gardening papers, and a correspondent of the *Gardeners' Chronicle* thinks it is quite evident a new enactment is required. He acknowledges that it was entirely in the interest of the public that the Pharmacy Act of 1868 was passed, but he suggests that the whole question of the sale of poisons ought to form the subject of Parliamentary inquiry. The suggestion is not an unreasonable one, but it is not likely to be acted on during the existence of the present Parliament. It is argued by the writer in question that the chief danger to the public consists in unqualified persons keeping poisons in bulk and selling them in small quantities, and that the restrictions imposed by the Pharmacy Act were not intended to interfere with the sale, in sealed packages, of poisonous weed killers, etc., which were not known in their present form in 1868. It is asserted that chemists now interfere with the sale of those articles in what they term public interest. "But they have not proved that there has been any danger to the public in seedsmen selling poisons for garden use; neither have they proved that the public would have any extra security were those poisons to be bought from chemists only. Horticultural poisons are made up in sealed packages, and it little matters whether these packages cross a seedsman's or a chemist's counter—the danger to the public is when they are afterwards opened and carelessly left about a place. There would be a real danger if seedsmen kept these horticultural poisons loose as they keep onion-seed, and sold them to anybody in small quantities. But they are kept only in the packages, as they are sent out by the manufacturing chemists, and as a matter of fact, which every seedsman can speak to, these poisons are only asked for by gardeners or other persons qualified to use them." The facts may be exactly as stated in the passage quoted, but the law must be obeyed, and it is the statutory duty of the Pharmaceutical Society to do its utmost to enforce that law. Chemists, as individuals, have no voice in the matter, and are far from attempting to interfere with other people's business to anything like the extent that those other people profess to know theirs.

PROCEEDINGS UNDER THE PHARMACY ACTS.

ILLEGAL SALE OF LAUDANUM.

Pharmaceutical Society of Great Britain v. Stirling.

An adjourned diet in the complaint of the Pharmaceutical Society v. David Stirling, assistant in the shop of Dr. Robert Davidson, 255, Main Street, Shettleston, was held before Sheriff Boyd at the Sheriff Court House, Glasgow, on Wednesday, February 14. Mr. R. L. Orr, advocate, instructed by Messrs. P. Morison and Son, S.S.C., Edinburgh, and Messrs. Martin and Barrie, solicitors, Glasgow, appeared for the prosecutor; and Mr. John C. Brock, writer, Glasgow, for the accused.—Mr. Brock raised a number of objections to relevancy, which were repelled.—Accused pleaded not guilty.—For the complainer Mr. J. Rutherford Hill and Mr. Joseph Tait proved that accused, not being registered under the Pharmacy Acts, unlawfully sold a quantity of opium in a bottle of laudanum on December 2 last.—Dr. Robert Davidson gave evidence for the defence, and some further objections by Mr. Brock having been repelled, the Sheriff said: "I think the case is very plain. David Stirling, the respondent in this case, is clearly not a pharmaceutical chemist, or a chemist and druggist, within the meaning of the Pharmacy Act, 1868. It is clear and not even disputed that in the shop of Dr. Robert Davidson, 255, Main Street, Shettleston, the respondent sold to Joseph Tait a bottle containing twopennyworth of laudanum, which laudanum contained opium, which is one of the scheduled poisons, and I accordingly find him guilty, and make the penalty three pounds, with two guineas of expenses."

ENGLISH NEWS.

PLYMOUTH, DEVONPORT, STONEHOUSE AND DISTRICT CHEMISTS' ASSOCIATION.—A meeting of the above Association was held on Wednesday, 7th inst., Mr. F. Maitland (President) in the chair, supported by Messrs. J. D. Turney, E. Turney, J. Cocks, W. H. Woods, H. P. Hearder, W. H. Austin, and several medical men of the Three Towns. Mr. C. G. Moor, M.A., F.I.C., F.C.S., City Analyst of Exeter, delivered a very interesting lecture on "Bacteriology," illustrated by a fine collection of lantern slides and cultures, which were shown by Mr. Turney. Mr. Moor, in the course of his address, showed a photograph of cultures on gelatin, on dishes exposed in Oxford Street and at Wandsworth Common, and explained that if a dish were exposed in a room in which there had been dancing there would be found a very large number of organisms. On one exposed on the top of St. Paul's there would not be nearly as many, while it would not be surprising to find none at all on one exposed at sea. Slides showing bubonic and cholera organisms were also exhibited, and with regard to the latter disease the lecturer explained that it was not one natural or endemic in this country, but was imported by emigrants. Owing to the excellent quarantine regulations there were but few cases, and those were soon stamped out. It was generally found that when a case of cholera was landed at a particular port it would give rise to three or four more, and there would probably be three or four more the following year, showing how readily it would spread. A peculiarity of the organisms of Asiatic cholera was that they would swim about like small fish. Diphtheria organisms were most interesting from a bacteriological point of view, because in cases under observation the bacteriologist was frequently able to give information which would be of service to the medical practitioner. The organism of influenza was extremely small, and the bacillus was very difficult to get and to keep alive when it was obtained. Dealing with the phthisis culture, the lecturer remarked that, so far from being incurable, the disease was one which was eminently curable. A far greater number suffered from the disease, without knowing it, than died from it. Taken in time with necessary precautions, such as change of climate, rest from work, and careful clothing, the disease was eminently curable. In conclusion, the lecturer showed slides

of cultures of the bacilli of typhoid.—On the motion of Mr. J. Davy Turney, seconded by Mr. Woods, and supported by the President, a hearty vote of thanks was passed to Mr. Moor.

BRITISH PHARMACEUTICAL CONFERENCE.—A meeting of the Executive Committee was held at 17, Bloomsbury Square, on Wednesday, February 7. Present:—Mr. E. M. Holmes (President), in the chair; Mr. J. C. Umney (Treasurer), Messrs. Atkinson, Bird, Bowen, Collier and Druce; Messrs. Warren and Cracknell (Hon. Local Secretaries), Messrs. Naylor and Ransom (Hon. General Secretaries), and Mr. Nightingale (Assistant Secretary). Letters expressing regret at not being able to be present were received from Messrs. Atkins, Harrington, Martin, Moss, Payne, Peck and Davy Turney. The minutes of the previous meeting were read and confirmed.—The President announced that on behalf of the Executive Committee he had written to Mrs. Stanford, expressing heartfelt sympathy with her in her recent bereavement, the high esteem in which the late Mr. Stanford, a former President of the Conference, was held by all members, and the sincere loss which the Conference has suffered by his death.—On the motion of Mr. J. C. Umney, seconded by Mr. Bowen, the action of the President was confirmed. The Secretaries were requested to send a letter of condolence to the relatives of the late Mr. T. M. Wilkinson, of Dunedin, formerly Honorary Colonial Secretary for New Zealand. The subject of the best methods of increasing the membership was discussed, and the following suggestions were adopted:—The local corresponding secretaries are to be supplied with forms of invitation, and to be requested to make personal application to likely candidates. The President and Treasurer undertook to write personal letters to all local and divisional secretaries of the Pharmaceutical Society of Great Britain who are not at present members of the Conference. It was also decided that letters should be written to the principals of the schools of pharmacy throughout the country, asking them to invite their students to support the Conference after passing their examinations. Some discussion also took place with reference to the delegates who are appointed to attend the annual meeting of Conference, and it was considered that their position should receive fuller recognition than has hitherto been the case. It was also considered desirable that a meeting of delegates and corresponding local secretaries should be held during the next annual gathering in London, at which the interests of the Conference could be discussed. It was decided that in future the meetings of the Executive should be held at 3 p.m. instead of 4.30, as hitherto. Eleven gentlemen having been duly nominated, were elected to membership.

SALE OF CAMPHORATED OIL: AN APPEAL CASE.—On Wednesday, February 7, in the Queen's Bench Division of the High Court, before Mr. Justice Channell and Mr. Justice Bucknill, sitting as a Divisional Court, the case of *Beardsley v. Walton*, which raised an interesting question with regard to the compounding of camphorated oil, was heard, and was referred to briefly last week.—Mr. Radcliffe (with Mr. Montagu Lush) said he appeared for the appellants in this case upon a case stated by the magistrates sitting at a petty sessions at Warminster, in Wiltshire, on November 2, 1899. The case stated set out that on October 21, 1899, an information was laid before one of H.M.'s justices for the county of Wilts by the appellant Frank Beardsley, an inspector under the Food and Drugs Act, against the respondents, Messrs. Walton and Co., Limited, grocers, etc., of Maiden Bradley, Wilts., charging them with unlawfully selling to the appellant camphorated oil, which was "not of the nature, substance, and quality demanded by the purchaser," the said oil only containing eight parts per cent. by weight of camphor, or less than half the quantity of camphor proper to camphorated oil, as described in the British Pharmacopœia, which should contain 21 per cent. by weight of camphor. The proceedings were taken under Section 6 of the Sale of Food and Drugs Act, 1875:—

No person shall sell to any drug which is no prejudice of the purchaser any article of food or nature, substance, and quality of the article

demanded by such purchaser under a penalty not exceeding £20, provided that an offence shall not be deemed to have been committed in the following cases:—Where any matter or ingredient not injurious to health has been added to the food or drug because the same is required for the production or preparation thereof as an article of commerce in a state fit for carriage or consumption, and not fraudulently to increase the bulk weight or measure of the food or drug, or conceal the inferior quality thereof; where the drug or food is a proprietary medicine or the subject of a patent in force; where the food or drug is compounded as in this Act mentioned; where the food or drug is unavoidably mixed with some extraneous matter in the process of collection or preparation.

—Section 7 enacted that:—

No person should sell any compound article of food or compounded drug which was not composed of ingredients in accordance with the demands of the purchaser under a penalty not exceeding £20.

—The case was heard at a petty sessions at Warminster, and after evidence the respondent submitted that as camphorated oil was a compounded drug proceedings could only be taken under Section 7 of the Act, and that no offence had been or could be committed under Section 6. The appellant, in reply, said it was open to him to proceed under either section, that camphorated oil clearly was a drug under the Act, that Section 7 was primarily intended to apply to physicians' preparations, that the penalty was the same under both sections, and that all the prosecution had to do was to prove that the sale would be to the prejudice of the purchaser, and that an offence had been committed under Section 6, under which he had elected to proceed. The magistrates were of opinion that camphorated oil was a compounded drug, that the summons could only be issued under Section 7, and that the respondent's contention was correct in law, and they therefore dismissed the information. If the Court should be of opinion that the magistrates' interpretation of the law was correct, then the order of dismissal was to stand; but if the Court was of the contrary opinion, then the dismissal would be annulled and the case remitted to the magistrates for further hearing.—Mr. Bruce Williams, for the respondents, submitted that the two sections created two totally distinct offences, and the offence charged in connection with the drug, which the magistrates had found as a fact was a compound drug, was an offence only under Section 7, and by Sub-section 3 of Section 6 was excluded altogether.—Mr. Justice Channell asked what difference did it make?—Mr. B. Williams said the words "to the prejudice of the purchaser" had been inserted in Section 6 so that a man should not be convicted for having sold a better article than asked for. The words, however, were omitted from Section 7, and he thought that distinction was intended by the Legislature. He contended the magistrates were right. They decided that the summons should have been taken out under Section 7, and the offence charged was not applicable to the Section 6 under which the charge was made.—After further argument, Mr. Justice Channell said what the magistrates had found was this: "We are unanimously of opinion that camphorated oil is a compounded drug, that consequently a summons can only be issued under Section 7." It was the word "consequently" he had a difficulty in following. If they had said camphorated oil was a drug compounded as in this Act mentioned, then "consequently" possibly would follow; but they had not found that, for the simple reason there was nothing in the Act to that effect. He thought the effect of the sections was that nothing shall be an offence under Section 6 in reference to compound drugs, unless it was also an offence under Section 7, which more specifically defined that offence. If that were so, then clearly the Drug Company (the defendants) came within it. Consequently the appeal must be allowed with costs, and the case remitted for further consideration.—Mr. Justice Bucknill concurred.

A TRADE MARK CASE.—On Saturday, February 10, application was made to Mr. Justice Stirling in the Chancery Division of the High Court of Justice, by the Hillside Chemical Company for the removal from the register of a trade mark, No. 161,543, belonging to W. H. Ashton, for medicated oil. The trade mark consisted of the word "Terraline." The applicants, who carry on business in medicines, including a proprietary medicine called "Terraline," ap-

plied in November last to register the word Terraline, and were met with the objection that the word was already registered. Every possible inquiry had been made of the principal vendors of drugs about Mr. Ashton, but no one had heard of him or his medicated oil; in fact, he seemed to have disappeared off the face of the earth. Letters addressed to him in America, where he was supposed to reside, had been returned through the dead-letter office. Mr. Sebastian appeared for the applicants. His Lordship ordered the mark to be expunged from the register.

SALE OF CALCINED MAGNESIA AND MILK OF SULPHUR.—At Southwark Police-court, on February 8, Charlotte Stowell, described as the widow of a doctor, St. George's Circus, was summoned for selling milk of sulphur and calcined magnesia to the prejudice of the purchaser.—The sample of milk of sulphur was certified by Dr. Muter to contain 45 parts of precipitated sulphur and 55 parts of calcium sulphate, instead of being composed of pure precipitated sulphur, while the "calcined" magnesia consisted entirely of magnesium carbonate, instead of magnesium oxide, as required by the B.P., 1898.—Fined £1 and 12s. 6d. costs in each case.

BORIC ACID IN BUTTER.—On Tuesday, February 6, at Oxford, Henry Cleaver, Major Solloway, and Alfred Maycock, grocers and provision dealers, of Oxford, were each fined £1 10s. 6d., including costs, for selling butter adulterated with boric acid to the extent of 1 to 1.2 per cent., which was considered by the public analyst (Mr. Fisher) to be an improper and excessive amount.

COPPER IN PEAS.—At Spelthorne (Middlesex) Sessions, held at Sunbury on Monday, February 5, Messrs. Holland and Bennett, grocers, Sunbury, were summoned for having sold green peas not of the nature, substance, and quality demanded; also on a second summons for having sold green peas adulterated with copper sulphate in a manner likely to be injurious to health, the analyst certifying that in his opinion the peas contained copper equal to 2.3 grains of copper sulphate per pound.—Dr. Dwight Morris having given evidence as to the injurious effects of copper sulphate on the human system, defendants were fined 20s. on the first summons, and were ordered to pay the court fees 8s., doctor's fee £1 1s., analyst's fee 10s. 6d. On the second summons they would have to pay the costs of the court.—John Williams, grocer, High Street, Feltham, was summoned for a similar offence, and was ordered to pay the same fine and costs as in the previous case.

SALE OF SPIRIT OF NITRE.—Thomas A. Kershaw, manager of No. 2 branch of the Clayton Co-operative Society, was fined 5s. and costs, at the West Riding Police Court, on January 25, for selling sweet spirit of nitre not of the nature, substance, and quality demanded by the purchaser.—The defendant stated that it had been in stock about two years, and must have deteriorated by the constant removal of the cork.

ADULTERATED MILK OF SULPHUR.—George Frith, grocer, Clayton Heights, sold milk of sulphur that did not conform to official requirements, and at the West Riding Police Court on January 25 was ordered to pay 5s. and costs for the offence.—He stated that it was his intention in future to insist on a written guarantee of purity from the wholesale people.—The Chairman thought that was a wise decision, and recommended it to shopkeepers in general when buying drugs.

OVERDOSE OF ANTIFEBRIN.—An inquest was held at Ulverston, on Friday, February 9, with respect to the death of Jonathan Brewer (9), who died suddenly.—According to the evidence, the boy complained of headache, and a headache powder was given to him, death occurring next day.—Dr. Campbell Brown (county

analyst) stated that he had made an analysis, and was of opinion that death was due to an overdose of antifebrin. The jury returned a verdict in accordance with the evidence, and stated that no blame attached to the parents.

PRUSSIC ACID POISONING.—A case of poisoning involving a certain amount of mystery has been investigated by the Sheffield City Coroner. It appears that early on Friday morning, January 19, a man named Beeston rushed into the Brightside Police Station and reported that he had found his wife, Edith Beeston, aged 32, dead in bed. He stated that he was employed on the night shift at Messrs. Brown and Co.'s works, and he had consequently been away from home since 5 o'clock the previous evening. An empty bottle, which had contained poison—prussic acid—was found on a table close to the woman's bedside, but there was no indication as to where the poison had been purchased. The subsequent inquest was adjourned until Friday, January 26, in order that the bottle might be traced, and on that date Detective Flint stated that by means of an old label he found that the bottle was originally purchased from Messrs. Hirst, Brooke and Hirst, of Leeds. It was not suggested, however, that they had supplied the poison. He had been to chemists' shops all over the town, but had not been able to trace the bottle.—The husband gave evidence, and was closely questioned as to his habit of taking medicine and of causing his wife to take medicine prepared by himself, it being suggested that they had not lived happily together. He denied all knowledge of the bottle in question.—The inquest was again adjourned, and on February 9 Detective Flint told the jury that he had not been able to trace the shop from which the bottle had been obtained, and he believed it would be impossible to do so.—Further evidence having been given as to the husband's practice of mixing medicine for his wife, the Coroner advised the jury to bring in a verdict that "Deceased died from prussic acid poisoning, but by whom administered, or for what purpose, there is not sufficient evidence to show."—A verdict to that effect was accordingly returned.

SCOTTISH NEWS.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.—At a meeting held in the Pharmaceutical Society's House, 36, York Place, Edinburgh, on Wednesday, February 7, Mr. Fraser McDiarmid, President, in the chair, Miss Flora C. Madgshon contributed a "Note on Murcia Lemons," which is printed on page 148. Miss Madgshon expressed her indebtedness for the commercial information contained in the note to the courtesy of Messrs. J. Lindsay and Son, fruit importers. The next paper was by Mr. Harry Smith, on "Serums." The author gave a sketch of the life-history of bacteria, and explained the principles of serumtherapy and the process by which immunising serums and antitoxins are obtained by inoculation of a horse free from any infectious disease. He also described the method by which the antitoxic value of the serum was tested before being sent out from the manufactory, and the precautions adopted to ensure its continued activity. In describing the various serums and antitoxins he mentioned that the Yeomanry about to proceed to South Africa had been inoculated with enteric fever antitoxin. A third paper was by Mr. J. Rutherford Hill, on "The Statutory Functions of the Pharmacist," and is printed on page 151. The reading of the papers was followed by a discussion, and, on the motion of the Chairman, votes of thanks were awarded to the authors.

GLASGOW CHEMISTS' AND DRUGGISTS' ASSISTANTS' AND APPRENTICES' ASSOCIATION.—This Association held its second "At Home" for the season in the Masonic Halls, 100, West Regent Street, on Friday evening, 9th inst. Mr. J. P. Gilmour (President) acted as

chairman, and, notwithstanding the Arctic severity of the weather, there was a good muster of members and their friends. An unusually inviting programme of songs, recitations, and dances was presented with unbroken success, and the merry-making was prolonged until after 1 a.m. The following ladies and gentlemen contributed to the evening's entertainment—viz., Misses Hannah, Lynn, Williams, and Barr, and Messrs. Taylor, McNish, Leckie, and McGowan. In the unexpected absence of the Association's honorary pianist, Mr. Kennedy, the Misses Hannah and Lynn played the dance music and accompaniments with ability and resource. When making the intimations during the interval, the Chairman announced that the gratifying success of the social evenings had induced the committee to arrange for a final festival on a big scale in March.

TROOPER ALEXANDER RENNIE, of Bethune's Horse, now on active service in South Africa, is a member of the Pharmaceutical Society, and prior to the outbreak of hostilities was in business on his own account in Johannesburg. He is a native of Aberdeenshire, and served his apprenticeship with Messrs. Davidson and Kay, chemists, Aberdeen, afterwards acting as an assistant in the West-end of London. He went to South Africa in 1894 as manager of a large business in Johannesburg, subsequently commencing business for himself.

THE SALE OF FOOD AND DRUGS ACT, 1900.—According to the *Lancet*, circulars similar to those issued some months ago by the Board of Agriculture in London have been issued by the Local Government Board in Edinburgh to the local authorities of burghs in Scotland. It is pointed out that by Section 23 of the Act now in force all the powers and duties vested in or imposed upon the Secretary for Scotland in relation to the Sale of Food and Drugs Act are transferred to the Local Government Board in Edinburgh. The circulars contain much the same useful information as those which were issued by the Board of Agriculture in London, and which were dealt with in an annotation in the *Lancet* of November 18 (p. 1389). The better control over the manufacture and sale of margarine is the subject of an attached circular. The chief points to be noticed by the authorities who are entrusted with the carrying out of the purpose of the Act are as follows:—The power of the Board, whether in Scotland or England, of securing the execution and enforcement of the Act, the definition of food, the provision of more stringent fines, the enforcement of the Act where negligence is evident, and the fact that it is imperative on every local authority now to appoint a public analyst without reference to a central authority.

IRISH NEWS.

CHEMISTS' AND DRUGGISTS' SOCIETY OF IRELAND (NORTHERN BRANCH).—The annual meeting and reunion of this Society was held on Friday, February 2, in the minor hall of the Y.M.C.A., Belfast. The attendance was large and representative. In the unavoidable absence of the President, Sir James Haslett, M.P., Mr. Wm. Jameson (Vice-President) occupied the chair.—The Chairman extended a cordial welcome to those present, and expressed his gratification at seeing such a large number of their country friends.—The annual report of the Committee was read by the Honorary Secretary, Mr. Rankin, and complimented the members on the progress and prosperity enjoyed by the Society during the year. The Committee recommended members of the trade to affiliate with the Council, with the view of securing, in addition to Mr. Jameson, further representation on the Pharmaceutical Council. The Honorary Treasurer's statement was submitted by Mr. W. J. Gibson, and was of a highly satisfactory character.—The Chairman, in moving the adoption of the reports, dealt at length with the various matters referred to.—The reports were unanimously adopted.—The election

of officers and committee for the ensuing twelve months resulted as follows:—PRESIDENT: Sir James Haslett, M.P. VICE-PRESIDENTS: Thomas M'Mullan, William Jameson, William Doig, John Watson, Samuel Clotworthy. HON. TREASURER: Samuel Gibson, 71 and 73, King Street, Belfast. HON. SECRETARY: W. J. Rankin, 27, Newington Street, Belfast. HON. SOLICITOR: Robert Diamond, 46, Donegall Street. COMMITTEE: Samuel Acheson, Belfast; Henry Backhouse, Dundalk; James Brown, Belfast; John McConkey, Belfast; John Frackleton, Belfast; Robert Cambridge, Carrickfergus; A. R. Hogg, Belfast; Thos. Campbell, Belfast; W. J. Gibson, Belfast; Thomas Gillespie, Banbridge; William Lyttle, Belfast; Samuel Hill, Belfast; John M'Clements, Newtownards; James Gillespie, Lurgan; Samuel M'Dowell, Belfast; Thomas W. Reynolds, Dungannon; James Richardson, Belfast; John H. Shaw, Belfast; Samuel Suffern, Belfast; Jacob Walsh, Belfast; J. D. Carse, Belfast. An interesting programme of music and reading, and a cinematograph display, the latter under the direction of Mr. A. R. Hogg, R.D. of Messrs. Lizars, occupied the remainder of the evening, which was brought to a close by the usual vote of thanks to all who had contributed to the enjoyment of those present.

DUBLIN CHEMISTS' FEDERATION.—A general meeting of the Dublin Chemists' Federation was held (by permission of the Pharmaceutical Society) at 67, Lower Mount Street, on Friday evening, January 26. There was a fair attendance of supporters, although the chairman (Dr. Walsh) took occasion to point out that the attendance was far from satisfactory, and that the chemists of Dublin would be working for their own interests in more heartily supporting the work of the Federation. Several important matters were brought before the meeting, amongst others the Defence and Insurance scheme of the P.A.T.A., and it was the unanimous opinion of those present that the scheme was worthy of all support. A resolution was also passed repudiating the views recently expressed in the *Medical Press* that chemists could not be trusted to compound prescriptions containing minute doses of potent drugs, and that consequently the medical profession had to rely on factory-made tablets and pills. The Secretary was directed to forward the resolution to the *Medical Press*. The former office-bearers were re-elected. Mr. F. J. Jackson (Marshall's Pharmacy) and Dr. McWalter were added to the committee. Mr. W. Vincent Johnston was elected a member of the Federation.

PHARMACEUTICAL SCHOOL OF CHEMISTRY.—The class for theoretical chemistry and physics at 67, Lower Mount Street, Dublin, is now open, the inaugural lecture having been delivered on Thursday evening, the 1st instant, by Professor Binks, late "Young" Scholar of Anderson's College, Glasgow.

MEDICINE CONTRACTS.—The Local Government Board has requested the Castleblaney Guardians to warn the medicine contractors formally that their services would be dispensed with if they again supplied inferior drugs. On the report of the analyst that the drugs were of an inferior quality, they should be returned and fresh ones obtained in lieu thereof.

A DISPENSER EXPLAINS.—At the last weekly meeting of the Guardians of the Cork Union a letter was read from Mr. Lee, dispensary officer at the North Dispensary, Cork, in reference to the case of a patient named Eugene O'Sullivan, who was poisoned by drinking a liniment supplied from the dispensary. He stated that the liniment was labelled "Caution—for external use only," and that if the patient did not read the "caution" label it is not likely that a "poison" label would have averted the unfortunate result. In future, however, he would be most careful to attach a "poison" label to all medicines for external use. In consideration of the high character of Mr. Lee, who for years has been a most careful and efficient officer, the Guardians deemed his explanation entirely satisfactory.

PHARMACEUTICAL SOCIETY.

Evening Meeting.

The third evening meeting of the session in London was held in the Pharmaceutical Society's house, 17, Bloomsbury Square, W.C., on Tuesday, February 13. The PRESIDENT, Mr. W. Martindale, took the chair at 8 o'clock, when a paper was read by Mr. EDMUND WHITE, B.Sc., on:—

AROMATIC SPIRIT OF AMMONIA.

The full text of the paper will be found at page 144 *et seq.* In opening the discussion on the paper,

The PRESIDENT said they had heard a very interesting paper by Mr. White. The subject of sal volatile had been a fertile one for amateur analysts to experiment upon ever since he could remember. Thirty-five years ago a number of specimens of sal volatile were obtained from various pharmacists of good repute, and many of them were condemned as not being up to the proper standard. It was a matter open to debate whether they were or were not as good specimens of sal volatile as those shown by the process of the London Pharmacopœia. The process then used was different to the one now employed. Ammonium carbonate and ammonium chloride was mixed with a certain quantity of alcohol, and the aromatics, cloves, cinnamon, and fresh orange peel were added. That indefinite process gave a very uncertain result, and the consequence was that the preparation of sal volatile was an art that got into very few hands. It contained, in addition to a certain amount of ammonium carbonate in the neutral condition, a quantity of free ammonia gas. When the Pharmacopœia of 1867 was produced the process was altered. Professor Redwood and other authorities revised the process, and seeing that the object was to obtain as large an amount of normal carbonate without being caustic in the liquid preparations, that mixture was obtained by reversing the proportions of ammonium carbonate and strong solution of ammonia that were now ordered by the Pharmacopœia. Instead of 4 oz. of ammonium carbonate and 8 oz. of strong solution of ammonia, they were ordered to use 8 oz. of ammonium carbonate and 4 oz. of strong solution of ammonia, to which were added the lemon, nutmeg and a certain quantity of water, and the mixture was then distilled. In that distillation there was always a large loss of carbonic acid, but that was not taken into consideration by the amateur analysts at that time. He remembered that about 1871 the matter was taken up by an analyst, who reported on specimens obtained at various pharmacists' in London, and the result showed that even by that crude process of 1867 they were very deficient, both in the amount of ammonia gas that could be obtained from them—the amount that was capable of being utilised by the acid—as well as in the amount of carbonic acid to be obtained from them. He conducted some experiments himself, and showed that using those proportions, 8 oz. of ammonium carbonate and 4 oz. of strong solution of ammonia, which nearly produced a normal carbonate of ammonia solution, when that was mixed with the required amount of alcohol it produced a magma which contained a quantity of crystals. It was not a clear solution. It was not possible that the amount of ammonia that was theoretically given by the formula could be in solution in alcohol. To free the volatile oils from the resinous matter they were apt to show by keeping, especially oil of lemons, and oil of nutmegs to a certain extent, Dr. Thresh said it was better to distil the oil and add that to the solution obtained by dissolving the carbonate of ammonia by the aid of a strong solution of ammonia in as little water as possible, and then mix them together. Although that purified the sal volatile from the resinous matter present in the essential oils, which tended to darken the colour, it was objected that the carbonate of ammonia then in commerce and the solution of ammonia were not sufficiently pure to give a good-flavoured sal volatile by distilling in the way intended by the Pharmacopœia process of 1867. Theoretically, that process did not work badly on a small scale; but on a large scale the ammonia salts were apt to get up in the worm of the still and

block the tube and render it impossible to carry out the process. Since Dr. Thresh read his paper in 1883 the purity of the carbonate of ammonia had very much improved, and the strong solution of ammonia was also much purer than it had been up to that period. Therefore, the process in the Pharmacopœia he thought now gave fairly good results. In some respects the present process was a little easier than the previous one. Mr. White had told them that if it were deficient in the amount of ammonia it was easy to remedy that by adding strong solution of ammonia to the sal volatile. In his very interesting paper he had not given any of the results tested by the lead process.

Mr. UMNEY said that they were all glad to have the opportunity of listening to so excellent a pharmacist as Mr. White, more especially on a really pharmaceutical subject. The ventilation of vexed questions of that kind would be of very considerable assistance to those who might have to compile the next Pharmacopœia. In the 1885 Pharmacopœia the specific gravity was recorded as 0.886, but he remembered that after correspondence between the late Mr. Conroy and Dr. Thresh it was altered to 0.896. He had made many experiments which showed that if the volume of sal volatile were adjusted to one gallon the specific gravity was at least 0.899, whilst if the volume were left without making up it was about 158 ozs., and the specific gravity 0.896. They imagined that when the Pharmacopœia, 1898, was issued that it was in every respect perfect. Mr. White had shown, however, that the monograph was fallacious in certain respects, and he could confirm two of the points to which he had referred. In the first place he had also ascertained that liquid ammonia sp. gr. 0.891 had not the true ammonia strength required by the British Pharmacopœia, and it was necessary to substitute liquid ammonia of specific gravity 0.880, and in making sal volatile, using powdered ammonium carbonate, it had been their custom to make due allowance, using 4 lbs. instead of 3½ lbs., making a difference of 13 or 14 per cent., so as to bring it on the right side. Mr. Martindale had referred to the darkening of the sal volatile, and attributed it to the resinous matter in the essential oils used; but he was inclined to think it was due to traces of aldehyde, which formed aldehyde-ammonia compounds. He congratulated Mr. White on his very able paper, which they would be able to follow better when they saw it in print.

Mr. MACEWAN said he should regret to see Dr. Thresh's test given up, as it was exceedingly convenient for the ordinary pharmacist; and he thought Mr. White had given them a point in his paper upon which they might retain it. He showed that by using the Pharmacopœia quantity of the spirit, with the prescribed amount of barium chloride solution, and, after filtration, adding a little ammonium carbonate, the filtrate remained clear; but with 1 C.c. more of the spirit, distinct milkiness was produced when the carbonate was added. Why not make a slight alteration to take advantage of that? Nine out of ten ordinary pharmacists had not sufficient mercury for the nitrometer test, and they had not a nitrometer. It was desirable to retain these simple methods in order to encourage them to test their preparations. He thought the paper one of great value, but if Mr. White attempted to reckon up the vapour tension in the gasometric test, he was afraid he would never get through it, because the tension of the essential oils would very much complicate the reckoning.

Mr. BIRD said most of them had been struck with the uncertainty of the present barium chloride test. Sometimes it gave a response, and at other times, under apparently similar conditions, it refused to give an immediate indication. Of course it was possible, by adding a little more ammonium carbonate or strong solution of ammonia, to make any spirit answer the Pharmacopœia requirements in the matter; but the light which Mr. White had thrown on the subject came quite as a surprise to most of them. They had never suspected the accuracy of the test. With regard to the darkening of the colour which Mr. Umney mentioned as being generally due to other substances than the resins contained in the essential oils, he could not agree with him as to that. He thought sal volatile prepared by dissolving the ammo-

nium salt and strong solution of ammonia in a mixture of spirit and water, rather than in the last separately collected portion of distillate, kept much whiter than that prepared according to the strict letter of the Pharmacopœia process. They were all indebted to Mr. White for having brought this important subject forward.

Mr. HOLMES expressed his regret at seeing so few of the leaders of pharmacy present to hear Mr. White's valuable and interesting paper. There had been a few years ago complaints of the scarcity of papers on practical pharmacy, and it was unfortunate that when a good one was read, which must have cost its author a great deal of time and trouble, only one member of Council and one examiner and none of the professors were present. Possibly the very inclement weather and the prevailing epidemic accounted for it. Twenty-five years ago the reader of a paper of this kind would have been encouraged by the presence of all the professors and their demonstrators, many of the members of Council, and some of the examiners. It was also to be regretted that the editor of the Pharmacopœia was not present. It was, however, a good sign that so many of the rising generation were present, and he hoped that Mr. White would feel encouraged by the attentive reception they accorded his paper, and be willing to give them another paper on a future occasion.

Mr. WILSON said he felt sure it was more the very bad weather than any lack of interest in the subject which accounted for the attendance not being larger. Referring to Mr. MacEwan's remarks, he said he thought it was rather going out of the way to propose to simplify tests merely to save trouble when there were tests which were really accurate, and which no one who would take the trouble would have any difficulty in applying.

The PRESIDENT moved a cordial vote of thanks to Mr. White for his able and exhaustive paper, which was carried by acclamation.

Mr. WHITE acknowledged the vote of thanks and commented briefly on the remarks of those who had taken part in the discussion.

RECENT DONATIONS TO THE MUSEUM.

Mr. HOLMES then drew attention to some recent donations to the Museum, which were exhibited on the table. One consisted of a series of caffeine and some of its salts—viz., citrate, hydrobromide, hydrochloride, oxalate, and salicylate, which were presented by the manufacturer, Mr. Geo. Whiffen, who had also added an instructive series of the cheap forms of tea from which the alkaloid was prepared. These consisted of tea fluff, tea dust, denatured tea, and the sweepings of the warehouses. Attention had already been directed to the commercial sources of caffeine in the *Pharmaceutical Journal* [4], 9, p. 495. Another exhibit consisted of specimens of dried English aconite root, in two forms, from Miss A. H. Squire, of St. Neot's. This lady found that the root was not easily dried unless sliced, and the usual practice was therefore to slice it longitudinally before drying. The quality of the root was easily observed in this form of the root, although the whole root might possibly be more convenient for students to examine its structure. It had been stated that there was some difficulty in obtaining English-grown root, but he had been assured by Miss Squire that there would be no difficulty whatever in supplying the wholesale trade at 1s. per lb. It was simply a matter of price. A third exhibit consisted of specimens illustrating the application of betulin and its pyro-derivatives in pharmacy and in the arts. These were presented by Mr. J. Wheeler, of Ilfracombe, who had already shown by the application of the natural mucilage present in the seaweed *Laminaria saccharina*, as an emulsifier containing iodine, for cod liver oil, and by the application of cleanly preparations of wood tar as insecticides, how a country pharmacist may turn to account his scientific education. Mr. Wheeler had sent specimens of plaster and of lint and of boric acid powder filmed with pyro-betulin by his patented processes. These preparations had been experimented with by medical men, and had been shown to possess very marked antiseptic advantages, whilst having an agreeable odour recalling that of Russia leather. Mr. Wheeler had also patented the applica-

tion of pyro-betulin for the purpose of forming ornamental patterns on glass, which bore resemblance to those made with ground glass, over which they possessed certain advantages.

Donations to the Library and Museum.

At a meeting of the Library, Museum, School, and House Committee, on Wednesday, February 14, the Librarian and Curator presented the following reports of donations:—

TO THE LIBRARY (LONDON).

Street Brothers, London:—Street's Newspaper Directory, 1900.
T. B. Browne, Limited, London:—The Advertisers' A.B.C., 1900.
F. Manson Bailey, F.L.S., Brisbane:—Contributions to the Flora of Queensland, etc., five pamphlets.
Koloniaal Museum, Haarlem:—Gids voor de Bezoekers, 1900.
Université libre de Bruxelles:—Rapport sur l'année académique, 1898-99.
Ecole supérieure de pharmacie de Paris:—Thèses par MM. G. Baudran A. Jaboin, L. Feltz.
Mr. W. Harvey, London:—Pharmacopœia of the City of London Hospital for Diseases of the Chest, Victoria Park, 1900.

TO THE MUSEUM.

Mr. Geo. Whiffen, Battersea:—Specimen of Caffeine and the following salts, Citrate, Hydrobromide, Hydrochloride, Oxalate, and Salicylate. Also specimens of Tea Fluff, Denatured Tea, Tea Dust, and Tea sweepings.
The African Lakes Corporation, Ltd., Glasgow:—Specimen of *Strophanthus* with flowers, leaves, and fruit.
Messrs. Hearon, Squire, and Francis:—Specimen of B.P. Asafetida in the tear; genuine *Pareira brava*; and flat Bolivian Calisaya Bark.
Messrs. Wright, Layman, and Umney:—Specimen of genuine *Pareira brava*
Dr. E. Ormerod, Boulia, Queensland:—Specimen of Pituri.

TO THE MUSEUM (EDINBURGH).

Miss F. C. Madgshon, Edinburgh:—Bark of *Melaleuca leucadendron*.
Messrs. Duncan, Flockhart and Co. (per Dr. Geo. Murray, Edinburgh).—Seeds of *Cassia absus* and *Cassia auriculata*.

PHARMACEUTICAL SOCIETY OF IRELAND.

Meeting of the Council.

On Wednesday, February 7, the monthly meeting of the Council was held at the Society's House, 67, Lower Mount Street, Dublin, the PRESIDENT, Mr. George D. Beggs, in the chair.

The PRESIDENT, who took the chair for the first time since his election, thanked the Council for electing him, and expressed regret at Mr. Downes' retirement.

A letter from Mr. Robert J. Downes, the late President, acknowledged the receipt of the resolution passed at the last meeting of the Council in reference to his retirement from office, and he thanked the members of the Council for the terms in which they had referred to his services. He hoped to be able after a while to resume his labours as a member of the Council.

A letter from the Secretary of the Congested Districts Board of Ireland stated that one of the industries which that Board encouraged was bee-keeping; and in the working of the hives on the modern system it was necessary, for the purpose of subduing the bees, to use a solution of Calvert's No. 5 carbolic acid. That particular form of the acid could be had of very few chemists or druggists in the Congested Districts. The Board would therefore be much obliged if the Council would be good enough to obtain authority for them to supply bottles of the acid along with the appliances to accompany the hives. The bottles would be supplied at cost prices and unopened.

The Registrar was directed to reply that it was not in the power of the Council to comply with the request.

Reports from the examiners showed that at the last Preliminary examination twenty-four candidates presented themselves, of whom eighteen passed; that at the last License examination sixteen candidates presented and six passed; that at the Registered Druggists' examination, held in Dublin, four candidates presented, and all passed; and that at the examination for Pharmaceutical Chemists' Assistants three candidates offered themselves, of whom two passed.

Dr. WALSH directed attention to the fact that the *Medical Press and Circular* had made some observations to the effect that pharmaceutical chemists were incapable of making up prescriptions con-

taining minute doses of potent drugs. The *Pharmaceutical Journal* very creditably took the matter up, and then the *Medical Press* published a further article on the subject. It was headed "Tabloids v. Prescriptions," and was as follows:—

The *Pharmaceutical Journal* in its last issue charges us with having "impudently asserted that compressed tablets afford facilities for the administration in minute doses of the very active alkaloids which the practitioner prudently hesitates to order in a prescription." We did say so, and we adhere to the statement, and call the general practitioner as our witness. We never had the remotest intention to belittle the skill of the pharmacist, but we should like to see the general practitioner who would venture to hand to a patient from the country a prescription for half-a-dozen pills, containing each of them, say, a thirtieth of a grain of strychnia, or phosphorus, or strophanthin, or cocaine, or atropine. Our contention is simply that such drugs as these cannot be compounded even by the most capable and conscientious chemist without the risk that the entire dose will be concentrated in one or two pills, and we are convinced that the Editor of the *Pharmaceutical Journal* knows this perfectly well. The tabloid makers can grind a drachm or an ounce of strychnia into a multitude of tabloids, but the individual dispenser cannot be certain of effecting the same subdivision with safety for half-a-dozen pills, no matter how hard he tries.

Dr. Walsh said he had mentioned the matter that day to a past President of the College of Physicians, who said the statement was ridiculous, and that if he wanted a dose containing a potent drug to be accurately made up he would far rather send it to one of the Dublin pharmacies that he had confidence in than have recourse to some of those tabloids, made wholesale, the making up of which he knew was attended with far greater risk. The statement against which they protested had been made without a shred of evidence to support it. There was not a day in any of the three or four large cities in Ireland—to say nothing of the rest of the United Kingdom—on which hundreds of such prescriptions were not made up, and how was it that they had never heard of such doses injuring anyone? It was a case of setting the wholesale dealer against the retailer, but he maintained that a careful pharmacist, working with a small quantity of the drug, was more to be relied on than the girls who were usually employed by the wholesale makers to carry out the details of their work.

The PRESIDENT said his experience was that the medical practitioner much preferred to get his prescription made by a chemist whom he knew, rather than to depend on the manufactured tabloids or tablets that are now flooding the market. He hoped some means might be found of disseminating the views of the Council so that medical men might read them.

Mr. WELLS thought the Council owed it to its licentiates; to the medical profession, who had ably supported the pharmacæutists of the country; and to the public, to refute the statements that had been published in the *Medical Press*. If the writer of the article had looked about him in Dublin he would have found many eminent medical men who preferred to trust the pharmacæutists to deriving medicines from other sources, and who did not seek to degrade the pharmaceutical profession by saying that its members were not able to make up prescriptions. There was no difficulty in subdividing things, and when prescriptions were made up by the pharmacist the patient and the physician were sure to get fresh drugs, which could not be said of the ready-made pills. It was a much greater difficulty accurately to subdivide active remedies where large masses were dealt with.

After further discussion, it was decided to send an official letter and a copy of the report of the discussion to the *Medical Press*.

Evening Meeting.

At Dublin, on Monday, February 12, the usual fortnightly meeting for the discussion of scientific and practical subjects was held at 67, Lower Mount Street, Mr. P. K. LLY, M.C.P.S.I., in the chair.

Mr. J. SMITH read some

NOTES ON BOTANY AND MATERIA MEDICA.

He said the technical terms used in botany were great stumbling-blocks to the beginner. That was not to be wondered at, as the

foreign words used in descriptive botany were quite out of keeping with the words used in any of the other sciences. It was a great pity that the study of botany should be rendered difficult by an indefinite multiplication of Greek and Latin words when their English equivalents answered the purpose equally well. To interest the student in plant life the English equivalent of foreign words should be used, then he would by degrees master the technical terms generally; so long as the description of drugs appeared in the Pharmacopœia in technical language it was necessary to know the meaning of the words occurring in the B.P., although that did not by any means exhaust the vocabulary. There was such a thing as pharmaceutical botany just as there was pharmaceutical chemistry, and to be able to study *materia medica* intelligently it was absolutely necessary that pharmacists should know a good deal of botany and be able to recognise plants used in the cure of disease by their descriptions.

MANCHESTER PHARMACEUTICAL ASSOCIATION.

At a meeting of this Association, held at the Victoria Hotel, on Wednesday, February 14, the PRESIDENT, Mr. G. S. Woolley in the chair, a paper was read by Mr. JOHN TAYLOR, of Bolton, on

THE OUTLOOK IN PHARMACY,

and is printed in full at page 148.

Mr. JOHNSTONE said he did not agree with much of what Mr. Taylor had said. At the same time they had to be practical in every-day life, and much of what he had said in regard to the trading part of the business was essential. It would be necessary for them to stick to the question of personal qualification in the future, but how it was to be managed he did not know. Whether it would be a hindrance to what had been presented in regard to the qualified directorate and the qualified men he could not say, but there was one thing he should like to say, that was that the success of a business lay very much in personal effort, and when they found a man attending to the business and giving personal effort there was a living. Chemists were too much inclined to look to the Government to help them, rather than putting their shoulders to the wheel. He urged also that they should make friends of their customers, and act as friends to them, and thereby secure public appreciation. Another matter was *esprit de corps*. If they could impress upon their young men that it was wrong to take a situation under a company carrying on business in an irregular manner, they would have a considerable advantage, and that would gradually widen and extend.

Mr. HARRY KEMP spoke of the attitude of the Society in regard to personal qualification in reference to the Pharmacy Bill. In this connection, he took it that they had all seen that the President of the Society had within the last two months communicated with Mr. Ritchie concerning the Companies Bill. Either Mr. Martindale had acted on his own initiative or he had acted at the instigation of his committee, but he failed to get an answer as to which it was, and he thought they as pharmacists, and especially as members of the Association, should have an answer to that question. The reason why they in particular should have an answer was that they would remember the Council of that Society in November met and discussed the proposals sent by the Federation. The Council of the Manchester Association took its stand, and passed a resolution embodying a petition to the Council of the Pharmaceutical Society, and to that no less than 189 signatures of qualified chemists were added in two days as representing their opinion. That opinion, it seemed to him, had been set aside, and he thought it was necessary that they should have an explanation of the reason why the Council or its President had written a letter to Mr. Ritchie without embodying the strong point which was urged by that Association.

Further discussion followed, and a vote of thanks was passed to Mr. Taylor for his paper.

NORTH STAFFORDSHIRE CHEMISTS' AND DRUGGISTS' ASSOCIATION.

At a meeting of this Association, held at the Roebuck Hotel, Stoke-on-Trent, on Thursday, February 8, the chair was taken, in the unavoidable absence through illness of the President, Mr. Averill, by Mr. T. C. CORNWELL.

Mr. JOHN SMITH, of Liverpool, President of the Federation of Local Pharmaceutical Associations, delivered an address on

Present Pharmaceutical Politics.

Speaking of the Federation, he said he held very strong views as to its capabilities and possibilities. As an organisation it was representative of practically all the pharmaceutical associations in the country. Prior to the formation of the Federation, local associations had been working separately without any connection with other similar bodies, and there had thus been a considerable waste of power. Mr. Thompson, of Birmingham, conceived the idea of the Federation with the object of bringing the associations together to enable them to form a body which would focus the opinions of the associations and concentrate their forces. The Federation had no connection whatever with the Pharmaceutical Society, though each local association was composed chiefly of men connected with the Pharmaceutical Society. The local associations could do very little without the Pharmaceutical Society. They might hold their meetings and discuss matters; but they could not initiate legislation; they could not exercise any influence on any of the Government departments; in fact, no local association had any power whatever outside the Pharmaceutical Society. He thought, therefore, that the local associations should work along with the local secretaries of the Pharmaceutical Society. With regard to the election of the Council of the Pharmaceutical Society, his own view, up to within the last few months, was that the Federation of Pharmaceutical Associations would make a mistake in interfering with the election of members of the Council. But it was quite possible that circumstances might alter cases. The Council was their representative body, and if the members of Council did not do what they ought, then it might possibly be the duty of the Federation to use some sort of pressure in the matter. After speaking of the representative character of the Federation, and of the necessity for funds to cover working expenses, Mr. Smith said there was a great future for the Federation, and he thought it was capable of very extensive developments. Proceeding, Mr. Smith said the question which they were all interested in at the present time was

THE COMPANY TRADING QUESTION.

At the present time there appeared to be a deadlock. There had been a difference of opinion in the Pharmaceutical Council as to what position should be taken up in the matter. There had been resolutions passed by a large number of associations in the country, and the President—Mr. Martindale—had recently written a letter to Mr. Ritchie, the President of the Board of Trade, in which he related the history of this pharmaceutical question, and had crystallised the opinions of the Council in these words:—

That inasmuch as a limited liability company could not be examined and registered in accordance with the provisions of the Pharmacy Acts, it should be unlawful for any such company to assume or use any title implying registration under those Acts, and that it is not desirable, in the public interests, that any person not registered under the Pharmacy Acts should be permitted to exercise any control over the retailing, dispensing, or compounding of poisons.

That was all very well if it had been a little more definite. There was that one word "control," which was subject to many different meanings or applications. Everything depended upon

what significance was given to the word "control." Mr. Glyn-Jones had taken up the view of the *Chemist and Druggist*, that it would be sufficient to have the directors qualified, and there had been other suggestions put before them. The question would be submitted to the Houses of Parliament in the Companies Bill, and it was for chemists to consider what steps they would take in regard to the matter. Were they willing to accept that clause of the Lord Chancellor's as a solution of the difficulty? If not, what should they do or what proposals had they to submit in opposition to it? Well, they had the choice of three different proposals as far as he could see. One was simple opposition to the proposals of the Lord Chancellor, but if they opposed without offering alternative proposals they would simply be placed out of court, because there was an admitted evil to be remedied. The alternative of Mr. Glyn-Jones and the *Chemist and Druggist* was that qualified directors would be sufficient. The third plan was the Scotch proposal that each shop should be subjected to certain regulations, and that any company should be allowed to carry on the business of a chemist and druggist, provided it had the name of the manager fixed over the shop door, showing that it was in his name and that the business was carried on for the company. His own view was that it was not desirable that which was simply a money-making concern should have any control over the business of dispensing medicines and selling poisons. He thought that no unregistered person should have any control over dispensing, and if the President's letter to Mr. Ritchie was to be taken in that sense he would agree with it; that no unregistered person, no company of persons who were not registered, should in any way exercise any control over the dispensing of medicines. The Council was divided, however, and many of the members did not know where they stood. It became necessary to consider, therefore, what was the duty of the Federation at the present time. Any action taken must be through the Council, but the members of Council were not agreed. He thought the first duty of the Federation was to recognise the fact that if anything was to be done it must be done with some show of unanimity. One of those present at the meeting had spoken to him about "An Ordinary Pharmacist" who had been writing in the *Pharmaceutical Journal*. He was certainly a man who had a very wide knowledge of pharmaceutical affairs, and from the time he commenced writing, about three months ago, he had been an out-and-out supporter of the idea of not recognising companies in any form whatever; but even he seemed to think it might be necessary to effect some compromise. It would perhaps be sufficient to show in the House of Commons and the House of Lords the difficulties that at present exist in the pharmacy law, if they were to publish reasons for an amended Pharmacy Act. He would like to mention some of them. In the first place, where a company of unregistered persons, through a qualified individual, sold poison, the company could not be got at. That was the only instance he knew in common law where the employer was not responsible for the actions of his servant. Another point was raised by the recent decision in a weed-killer case, where the defendant, in his opinion, most distinctly kept open for the sale of poison. There was also the question of penalties. In England there was a stated penalty of five pounds for each offence under Section 15, but in Scotland the judges had power to reduce the amount, and the Pharmacy Act in Scotland was practically a dead letter. Another matter for consideration was the

DISPENSING OF MEDICINES IN DOCTORS' SURGERIES.

Restrictions were imposed upon registered chemists as to the compounding of poisons and the selling of them, and yet medical men could employ their grooms, housemaids, or anybody else to dispense their medicines—any unqualified person, but they were outside the Pharmacy Act. The Pharmacy Act expressly excused medical men and veterinary surgeons, but they certainly ought, in the public interest, to be included. Any establishment where medicines were compounded or dispensed ought to be regulated

by the Pharmacy Act. He certainly thought that if the public interest required, the dispensing in chemists' shops should only be done by qualified men. The public interest certainly required that that should be so in doctors' surgeries. After speaking of the question of titles, Mr. Smith said he thought he had said sufficient to show that there were a great many things that wanted altering in the Pharmacy Law, and that they could only be met in

A NEW PHARMACY BILL.

As far as he could see, the line upon which they would have to work was to actively work the Parliamentary representatives. He had mentioned something which appeared in the *Pharmaceutical Journal* about the possibility of some compromise being arrived at, and they might say that perhaps some compromise would be necessary. He strongly objected to any compromise which would allow companies to do that which individuals could not do, but he thought a basis for a new Pharmacy Act could be found more on the lines of the Irish Pharmacy Act as it is now. He thought there ought to be a rearrangement of examinations, for one thing. There ought to be a systematic course of study; and then as to the mixing and compounding of poisons he was prepared to go with the majority simply because he represented the Federation, and the Federation must go with the majority, whatever his personal opinions might be. If the majority of the local associations said that they were in favour of one set of notions, it would be his duty to endeavour as far as he possibly could to carry out the wishes of the majority of the associations. But personally he thought the solution was to be found in a compromise which should provide that the dispensing of poisons and other medicines should be absolutely restricted to properly-qualified individuals, and there should be some guarantee that such work was done by qualified individuals in every establishment. He thought they must insist as far as they possibly could upon the mixing of poisons and the dispensing of medicines by qualified persons, and by persons who had a reputation to lose. A company had no body or soul or anything else, but an individual had a reputation at stake. If active work were done in nearly every Parliamentary constituency, then something might be done to show that the feeling was very strong in the pharmaceutical community against the solution of the problem proposed by the Lord Chancellor. In going before Parliament, however, they must take up a strong position, and, in opposing the proposals of the Lord Chancellor, be prepared to give an undertaking to deal with the whole question at an early date.

In the discussion which followed, the views expressed by Mr. Smith were generally supported, and a vote of thanks to him, proposed by Mr. CORNWELL and seconded by Mr. POOLE, closed the proceedings.

CHEMISTS' ASSISTANTS' ASSOCIATION.

There was but a poor attendance at 73, Newman Street, W., on Thursday, February 8, doubtless owing to the fact that many of the members had the previous evening assisted in making the Junior Pharmacy Ball the success it was, and were recuperating. In the absence of the President, the chair was taken by the VICE-PRESIDENT, Mr. H. Hymans.

The HON. SECRETARY, Mr. J. EVANS, having read the minutes, which were confirmed, Mr. H. A. MARTIN communicated a paper on

QUININE.

In his introductory remarks, he said that whilst looking up the subject of quinine, he found the history connected with the barks so full of interest that he thought to all pharmacists it would be equally as interesting as to himself, hence he intended to give a brief summary. The paper, which will be printed next week, was supplemented by a number of very fine specimens of succirubra, calisaya, and officinalis barks, and the barks obtained by the processes of mossing, coppicing, and shaving. In concluding his paper, Mr.

Martin expressed his thanks to Messrs. Willows, Francis, Butler, and Thompson for specimens lent.

Mr. HYMANS, having voiced the pleasure experienced by those present in listening to the paper, referred to artificial quinine, and remarked that it was a curious thing that up to the present chemists have not been able to synthesise it except as quinidine. With regard to the usefulness of quinine, he supposed to Imperial England it was invaluable, as only by its use was colonisation possible in some parts of the world, especially on the West Coast of Africa. The question of doses was an important one, and it was curious to note how in different countries the dose varied. He believed that in West Africa ten to twelve grains of quinine sulphate was a usual dose. The absorption of water by quinine was a point of interest, as it frequently happened that on turning into the scale what had been bought as 100 oz., only 97 oz. or 98 oz. would be found, the deficiency being due to loss of water. He then referred to the fluctuation in the price of quinine, and remarked that there seemed to be a great deal of gambling done in it.

Mr. A. LATREILLE, in proposing a vote of thanks to Mr. Martin, said mention was made in the paper of oleate of quinine. He should like to know if the author had any experience of the use of quinine in hair lotions. Personally, he was rather dubious about its efficacy.

Several other members having spoken as to the merits of the paper and of cinchona alkaloids, Mr. MARTIN replied, and in answer to Mr. Latreille, said he was of opinion that in hair washes and lotions quinine was decidedly useful as a tonic.

A hearty vote of thanks was then accorded to Mr. Martin by acclamation, and the meeting terminated.

CHEMICAL SOCIETY.

At a meeting held on Thursday, February 1, Professor THORPE, F.R.S., President, in the chair, a paper on

THE CHLORINE DERIVATIVES OF PYRIDINE

was read by W. J. SELL, M.A., and F. W. DOOTSON, M.A., dealing with the constitution of citrazinic acid, and the formation of *aa'*-dichloropyridine and *aa'*-di-iodoisonicotinic acid.

Although it was already known with little doubt that the hydroxyl groups present in citrazinic acid occupy the *aa'* positions relative to the nitrogen atom, the authors thought it desirable to obtain the confirmatory evidence offered by the experiments undertaken. By the action of phosphorus pentachloride on the diamide of β -oxyglutaric acid an amino-tetrachloropyridine was obtained, in which the nitrogen atoms must be adjacent. By acting on citrazinic acid with phosphorus pentachloride a dichloroisonicotinic acid is formed, which exchanges one of the chlorine atoms for an amido group by treatment with ammonia, and on treating this product with phosphorus pentachloride the carboxyl group goes out, an amino-tetrachloropyridine being formed, which is identical with that obtained by the first method. This shows the position of one of the hydroxyl groups.

Then it was shown that the two hydroxyl groups occupy similar positions in the molecule relative to the nitrogen atom. The amino-chloroisonicotinic acid being treated with nitrous acid gave up the amino group in exchange for hydroxyl. This substance by treatment with aqueous ammonia exchanged the chlorine atom for an amino group giving an amino-hydroxyisonicotinic acid, which was converted by phosphorus pentachloride into the same amino-tetrachloropyridine obtained when dealing with the first hydroxyl group. Di-iodoisonicotinic acid is produced as an intermediate compound in the reduction by hydrogen iodide of dichloroisonicotinic acid to isonicotinic acid. The production of *aa'*-dichloropyridine by heating the silver salt of the corresponding dichloroisonicotinic acid in a stream of carbon dioxide was also described.

Dr. RUHEMANN rose to point out that the work of Behrmann and Hoffmann, as well as the knowledge respecting the carboxylic acids of dihydroxypyridine had already proved conclusively the constitution of citrazinic acid.

In reply to this observation Mr. SELL expressed the opinion that it was important to have the evidence of experiments in which the yield was almost theoretical, while the work of other authors had left something like 80 per cent. of the products of reaction unidentified.

A paper by S. Ruhemann and H. E. Stapleton on

THE FORMATION OF HETEROCYCLIC COMPOUNDS

was next read.

This work is the continuation of a research upon the interaction of organic bases and ethereal salts of acids of the acetylene series, the present paper dealing chiefly with products derived from ethyl phenyl propiolate. With benzamidine it gives, in addition to the benzal phenyl glyoxalidone, described in a former paper, a second compound, namely, diphenylpyrimidone. The peculiar interest attached to this reaction is that the substituted amide first formed condenses a part in one way and the remainder in another at the same time. In the first case the first atom of the chain becomes joined to the sixth, forming a ring of six links, and in the second the first atom becomes joined to the fifth, forming a ring of five links. The compounds formed with urea, thiourea and guanidine were also described. The ethyl salt of acetylene dicarboxylic acid interacts with *o*-phenylenediamine, giving ethyl quinoxalidone acetate, which is hydrolysed with loss of carbon dioxide to form methylquinoxalidone. Ethyl malonate and the ethyl salt of acetylenedicarboxylic acid react to form ethyl propenetetra carboxylate; by the action of ammonia on this substance there is produced the ethyl salt of *aa'*-dihydroxypyridine- β -dicarboxylic acid, which on being hydrolysed with hydrochloric acid loses the β -carboxyl group and gives citrazinic acid.

A paper by William Jackson Pope and Stanley J. Peachey, on

THE SPACE CONFIGURATION OF QUADRIVALENT SULPHUR DERIVATIVES,

was then read by Mr. POPE.

The materials chosen for the work were methyl-ethyl-thetine-dextro-camphorsulphonate and dextro-*a*-bromocamphorsulphonate. Hitherto attempts to obtain salts of asymmetric thetines and sulphonium compounds with optically active acids have always yielded uncrystallisable products, but the authors were able to obtain microscopic prisms of the methylethylthetine dextro-camphorsulphonate by crystallisation from alcohol diluted with ether. The dextro-*a*-bromocamphorsulphonate crystallised also in silky white needles. It was found that the molecular rotatory powers of these salts in dilute aqueous solutions corresponded with the rotatory powers of the optically active acid ions; hence the basic thetine group possesses no optical activity. There is no resolution of the asymmetric thetine into optically active components, since it was possible to isolate more than one-half of the thetine bromide as the pure optically active sulphonate, and it was considered extremely improbable that the both salts should be partially racemic, containing a dextro- and *l*ævo-thetine radicle; and the conclusion must follow that if sulphur exists as a quadrivalent element in these salts, the four atoms attached directly to the sulphur atom lie in the same plane with it, and that quadrivalent sulphur cannot yield enantiomorphous configurations.

A paper by Mr. O. Forster was also read, on

NITRO-CAMPHANE.

This paper described the properties of nitro-camphane and some of its derivatives. By the action of potassium hypobromite on camphoroxime the product obtained is a bromo-nitro-camphane, although it gives Liebermann's reaction for nitroso-compounds. Nitro-camphane is obtained from this bromo-derivative by reduc-

tion with alcoholic potash. Pseudo-nitro-camphane is obtained by acidifying a solution of nitro-camphane in potash; it is distinguished from nitro-camphane by its melting point and behaviour towards ferric chloride. It is transformed into the normal modification either in the solid or dissolved state, the presence of alkalis or piperidine and the influence of sunlight accelerating the change. Chloro-nitro-camphane is produced by the action of sodium hypochlorite on camphoroxime; iodo-nitro-camphane is formed as a precipitate when iodine dissolved in potassium iodide is added to nitro-camphane dissolved in potash. All these substances give the Liebermann reaction. Hydroxylamino-camphane is obtained when nitro-camphane is reduced with aluminium amalgam. It reduces ferric chloride, ammoniacal silver nitrate, and Fehling's solutions rapidly in a cold solution.

Several papers were then taken as read.

Obituary.

ATKINSON.—On February 2, Joseph Atkinson, Chemist and Druggist, Tynemouth. Aged 56.

BATES.—On January 19, William Isaac Bates, Chemist and Druggist, Macclesfield. Aged 77.

HESLOP.—On February 7, John Heslop, Chemist and Druggist late of Hornsea, Hull. Aged 53. Mr. Heslop belonged to an old Holderness family, and practised in Hornsea as a chemist and druggist until 1892, when owing to ill-health he retired, the business being taken over by Mr. Charles Morrow, M.P.S. He took an active interest in local affairs, was a member of the old Local Board, and retained his seat on its conversion to the Urban District Council until illness compelled him to retire. He was also connected with the Parish Church, being the Vicar's Churchwarden from 1870 up to the time of his death, and was treasurer of the Church Expenses Fund from 1881 until 1899.

OGLE.—On February 3, William Henry Ogle, Chemist and Druggist, Cheltenham. Aged 80.

PERKS.—On February 1, at Inkberrow, Worcester, Alfred Perks, Pharmaceutical Chemist, Birmingham. Aged 32. Mr. Perks who had been a member of the Pharmaceutical Society since 1890, went to Birmingham in 1884 as an assistant to Mr. H. T. Done, and subsequently married his daughter. He succeeded in qualifying as a pharmaceutical chemist in the space of two years, although engaged in business during that time. As a student he was very painstaking and on one occasion was awarded the first prize in analytical chemistry in the competitions organised by a contemporary. He took a business at Beeston, Notts., but had to give it up a few years later on account of his health, having developed signs of consumption.

REDMAN.—On February 9, Henry Redman, Chemist and Druggist, Tuxford, Notts. Aged 77.

SONLEY.—On February 3, Walter Sonley, Chemist and Druggist, Ilkeston. Aged 31. Mr. Sonley had been connected with the Pharmaceutical Society for several years, formerly as an Associate, and latterly as a member.

TRANSLATIONS OF THE ROYAL ACADEMY OF MEDICINE IN IRELAND, Vol. XVII. Edited by JOHN B. STORY, M.B., F.R.C.S., pp. xl. + 683. Dublin:—Fannin and Co., Limited, 41, Grafton Street. 1899, From the Editor.

THE STUDENTS' COLUMNS.

THE MATERIA MEDICA OF THE PHARMACOPŒIA.

Balsamum Peruvianum.

BALSAM OF PERU is the product of *Myroxylon pereiræ*, Klotzsch (N.O. Leguminosæ), a tree which grows in various parts of Central America, particularly in the forests of San Salvador, on the so-called "balsam coast." It is a thick resinous liquid, which owes its name to the fact that it was originally exported by way of Peru. It is now shipped from Acajutla and Belize, *viâ* New York and Hamburg. The bark of the young twigs contain schizogenous secretion ducts, but those are soon thrown off, and no fresh ones are formed. The balsam, therefore, is probably not a normal secretion, but a pathological product, the formation of which is caused by beating the bark and stimulated by subsequent scorching with torches. The exuding balsam is absorbed by cotton rags inserted beneath the loosened bark, and afterwards separated by boiling the saturated pads with water and straining, or by allowing the balsam to deposit by standing. The drug possesses stimulant and disinfectant properties, and is usually dispensed in the form of an emulsion with mucilage, or with sugar, yolk of egg, and water. It is also used externally as a parasiticide. The dose of the balsam is from 5 to 15 minims.

CHARACTERS.—Balsam of Peru is a viscid liquid of s.g. 1.137 to 1.150, which appears nearly black in bulk, but in thin layers is seen to be transparent and of a deep orange-brown or reddish-brown colour. It consists of about 60 per cent. or more of an oily fluid portion (cinnamein)—chiefly benzyl benzoate with a little benzyl cinnamate and about 30 per cent. of dark resinous matter—an alcohol (peru-resinotannol) combined with cinnamic acid and a little benzoic acid; traces of vanillin and free cinnamic acid are also present. Those constituents give the balsam a fragrant, agreeable odour and an acrid taste, a burning sensation being left in the throat after swallowing the drug. It is practically insoluble in water, which only dissolves a little of the cinnamic acid present and traces of benzoic acid, but it is soluble in all proportions in chloroform. Mixed with an equal volume of 90 per cent. alcohol a clear solution is formed, but when the alcohol is added in the proportion of more than 3 to 1 of balsam the mixture becomes turbid. The cause of the turbidity does not appear to have been explained.

TESTS.—The absence of copaiba and resins is indicated by the production of a permanently soft mixture on triturating 10 drops of the balsam with 0.4 Gm. of lime; on warming the same mixture until all volatile matter is driven off and charring commences a fatty odour will be perceived if castor oil or other fixed oil be present. If ethylic alcohol has been added to the balsam, the specific gravity will be affected, and on shaking the drug with an equal bulk of water a diminution in volume will be caused by the water removing the alcohol. On treating the balsam with three times its volume of carbon bisulphide, about forty per cent. of resin should separate, and the clear supernatant liquid should be of a pale brown colour with only a slight fluorescence, thus indicating the absence of gurjun oil; if the latter be present a violet coloration will be produced on adding one drop of a freshly-prepared and cooled mixture of nitric and sulphuric acids to 20 drops of the liquid, but a similar colour is occasionally yielded by genuine balsams. As a quantitative test, 5 Gms. of balsam of Peru should yield from 2.85 to 3 Gms. of aromatic, oily residue, after shaking with 5 C.c. of sodium hydroxide solution (s.g. 1.16) to remove resin, then washing with three successive quantities (15 C.c. each) of purified ether to separate the cinnamein and other aromatic bodies. After separation and evaporation of the ether, the residue should be cautiously dried until the loss in weight in two weighings,

at five minutes' interval, does not exceed 1 Cgm. The oily residue should require from 11.9 to 12.8 C.c. of normal volumetric alcoholic solution of potassium hydroxide to decompose the esters of cinnamic and benzoic acids (benzyl cinnamate and benzoate) present, 20 C.c. of the volumetric solution being added to the residue, together with 40 C.c. of 90 per cent. alcohol, and saponification effected by heating the whole under a reflux condenser for one hour, after which the amount of uncombined alkali can be determined by titration with volumetric solution of sulphuric acid.

NOTES.—The distinctive characters of balsam of Peru are its odour, taste, and specific gravity. The last-mentioned is lowered by the addition of alcohol, fixed oils, turpentine, copaiba, etc. The lime test and other qualitative tests are unsatisfactory; thus, it is found that absolutely pure balsam of Peru becomes quite hard on keeping, whether lime be added or not, but that the addition of a little liquid paraffin results in the production of a permanently soft mass. Balsam which does not harden, therefore, even after lime has been added, is probably not pure. The quantitative determination of the resin and aromatic constituents affords more information, both regarding probable adulteration and the actual value of the drug. The term "cinnamein" is applied in the B.P. monograph to the oily mixture of benzyl benzoate and cinnamate, and not to the latter only. The term "balsam," it may be noted, is properly limited to oleo-resinous substances containing cinnamic or benzoic acid.

Balsamum Tolutanum.

BALSAM OF TOLU is obtained from the trunk of *Myroxylon toluifera*, H. B. and K. (N.O. Leguminosæ), a native of New Granada. The drug derives its name from Tolu, a small town near Cartagena, and is exported chiefly from Savanilla and other Colombian ports, *viâ* New York. As in the case of *M. pereiræ*, the twigs of *M. toluifera* contain schizogenous secretion ducts, which are soon thrown off and not replaced; the bark of the trunk contains no secretory tissue, and the balsam is probably formed by the transformation of part of the young wood or bark tissue, as a result of incisions made in the tree. From those incisions the balsam flows, and is collected in gourds, which are subsequently emptied into skin bags or tins, the shape of which is taken by the soft, tenacious, yellowish-brown, resinous mass. The balsam possesses stimulant, disinfectant, and expectorant properties; it is used for preparing Tinctura Benzoini Composita, Syrupus Tolutanus, Tinctura Tolutana, and, indirectly, Mistura Ammoniaci, Trochiscus Acidi Carbolici, Trochiscus Morphinae, and Trochiscus Morphinae et Ipecacuanhæ. The dose of balsam of Tolu is from 5 to 15 grains.

CHARACTERS.—Balsam of Tolu, though a soft and tenacious solid when first imported, gradually hardens on keeping to a brownish, brittle, and easily powdered mass (s.g. 1.230 to 1.258), the brittleness being more pronounced in cold weather. When warmed, however, the hardened balsam readily softens. In thin films it appears transparent and of a yellowish-brown colour; if a small piece be warmed and pressed between two glass slides, so that a very thin film is obtained, numerous colourless crystals of cinnamic acid and some vegetable debris can be seen, imbedded in a transparent mass, on examining the specimen with a lens or microscope. The balsam is soluble in its own bulk of 90 per cent. alcohol or glacial acetic acid, in half as much chloroform, and in three times its bulk of benzene, but it is insoluble in petroleum spirit, and nearly so in carbon bisulphide, yielding cinnamic acid principally to the last-named solvent. The balsam contains as much as 12 to 15 per cent. of free cinnamic acid, as well as about 7.5 per cent. of an acid, aromatic, oily liquid (cinnamein), consisting principally of benzyl benzoate, with a little benzyl cinnamate and 0.5 per cent. of vanillin. The resinous portion of the drug, amounting to about 80 per cent., yields on saponification an alcohol—tolu-resinotannol—and cinnamic acid, together with a little benzoic acid. The aromatic constituents of

the balsam impart to it an agreeably fragrant odour, which is especially marked when the drug is warmed; the taste is also somewhat aromatic and slightly acid.

TESTS.—The alcoholic solution of balsam of tolu has an acid reaction, owing to the presence of cinnamic and benzoic acids. If 5 Gms. of the balsam be gently warmed with two successive portions of 25 and 10 C.c. of carbon bisulphide, and the mixed solutions evaporated, the crystalline residue of benzoates and cinnamates left should require not less than one-third of its weight of potassium hydroxide for its saponification.

NOTES.—The distinctive characters of balsam of Tolu are its odour, taste, and slight solubility in carbon bisulphide. The solubility test is particularly important, as the balsam may be adulterated with resinous substances soluble in carbon bisulphide; such substances will leave a resinous instead of a crystalline residue, and require less potassium hydroxide to effect complete saponification. The balsam is more liable to adulteration than balsam of Peru; among the substances which have been employed as adulterants are exhausted balsam of Tolu and dried Canada turpentine or "balsam," as it is usually, but incorrectly, termed.

Belladonnæ Folia.

BELLADONNA LEAVES of the British Pharmacopœia include the fresh leaves and branches of the deadly nightshade, *Atropa belladonna*, Linn. (Solanaceæ), a tall branching herb with a perennial root, which is widely distributed over Central and Southern Europe, and cultivated for medicinal purposes in the South of England and Germany. The leaves must be collected when the plant is in flower, as they are then richest in alkaloid. Belladonna possesses anodyne, mydriatic, and local anæsthetic properties; the fresh leaves and branches are used to prepare Atropine, Extractum Belladonnæ Viride, and Succus Belladonnæ.

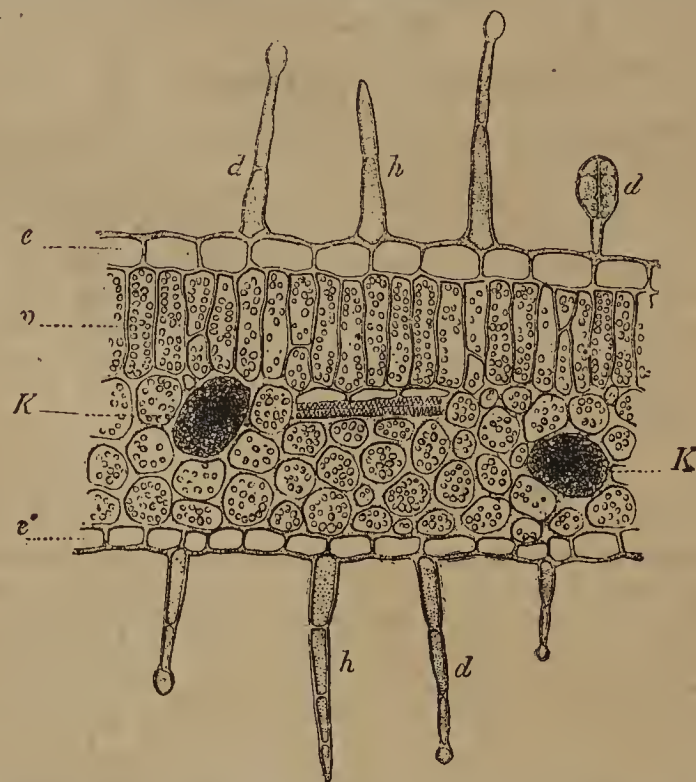

BELLADONNÆ FOLIA.—Upper leaf, half natural size, showing outline and venation.

CHARACTERS.—Belladonna leaves have short stalks, and are alternate below, but the upper leaves are in unequal pairs. In shape the leaves are broadly ovate, varying from oval-lanceolate to ovate-lanceolate, acute at the apex, entire at the margin, and tapering at the base into a slightly winged petiole. They vary in length from 8 to 20 Cm., and appear quite free from hairs (glabrous) as a rule, though a few hairs may usually be found near the midrib, while on the pedicel and calyx of the flowers and on the upper portion of the stem hairs occur in abundance. The midrib of the leaf is prominent below, but depressed on the upper surface, and a transverse section of the leaf, when examined under the microscope, exhibits bi-collateral bundles in the midrib, *i.e.*, strands of bast occur both above and below the wood. The lateral veins leave the midrib at an angle of about 45° to 60°. The fresh leaves are somewhat fleshy, and the mesophyll contains numerous very minute sandy crystals of calcium oxalate; when the leaf is dried, the shrinkage of the tissue causes the cells filled with the crystals to appear as whitish prominences when examined with a lens. The corolla of the flower is gamopetalous (the petals cohering laterally), bell-shaped, and of a dingy purple colour.

NOTES.—The distinctive characters of belladonna leaves are their arrangement in unequal pairs on the upper part of the stems, their

glabrous surface, and the presence of bright points on the upper surface of dried leaves. Carefully dried leaves should be of a pale greyish-green hue rather than brownish, also very thin and brittle. Dried stramonium leaves become curled and twisted as they dry,

BELLADONNÆ FOLIA.—Showing (e) upper, (e') lower epidermis, (h) hairs, (d) glandular hairs and stalked septate glands, (k) cells filled with sandy crystals, (p) palisade cells. After Vogl.

their lateral veins make a more acute angle with the midrib than those of belladonna, and they have a characteristic disagreeable odour. Foxglove and henbane leaves are both hairy. The chief constituents of belladonna leaves are the alkaloids hyoscyamine and atropine; the proportion of total alkaloid present in the dried leaves varies from 0.3 to 0.7 per cent., the greater proportion being hyoscyamine. Belladonnine and other alkaloids of less importance are also present, together with a fluorescent principle - β -methyl-æsculetin or chrysotropic acid, which is also found in gelsemium root.

NEW REMEDIES.

PARAFORM FOR WARTS.—Unna finds that paraformaldehyde suspended in collodion forms a useful application for cauterising small soft warts and excrescences of the skin. The application employed consists of paraform, 2; castor oil, 1; collodion, 40. Mix. Similar results have been obtained independently by Meuse (See *P.J.* [4], 9, 623).

CHELIDONINE SULPHATE IN CANCER.—N. Ivanow records a case of gastric cancer, in which daily doses of 10 to 15 centigrammes of chelidone sulphate had a markedly beneficial action, pain being relieved, the appetite increased, and vomiting controlled. It was prescribed as follows:—Chelidone sulphate, 60 centigrammes; bitter almond water, 5 Gms.; distilled water, 60 Gms.; syrup, 2 Gm. A tablespoonful and a half to be taken twice daily.—*Now. Rem.*, 15, 538, after *Klin. Therap. Woch.*

BROMOFORM WATER.—A. Mathieu and A. Richaud consider bromoform water worthy of a more extended use, since it is valuable in relieving intestinal pains and vomiting, particularly in tuberculous cases. In these, too, it has the advantage of easing the fits of coughing. By thorough agitation in a large vessel bromoform will slowly dissolve in water to the extent of 3 to 3.5: 1,000, and may be employed in the same manner and for the same purposes as chloroform water.—*Bull. de Pharm. de Sud-Ouest*, 22, 136.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

R. H. Adie and T. B. Wood determine **VOLUMETRIC DETERMINATION OF POTASSIUM.** potassium volumetrically by precipitating it as cobaltinitrite—usually represented as $K_6Co_2(NO_2)_{12} \cdot 3H_2O$ —and titrating with a standard solution of potassium permanganate in acid solution. The authors' experiments appear to show that there are three, instead of two, nitrite groups for each atom of potassium, and that the precipitate obtained is an acid salt. Other bases being removed as far as possible, by means of sodium carbonate, the solution is then concentrated if at all weak, acidified with acetic acid, and excess of sodium cobaltinitrite solution added. After the mixture has been allowed to stand for twenty-four hours, the precipitate is collected on a Gooch filter, washed several times with 10 per cent. acetic acid and, finally, once with water. The asbestos filter and the precipitate are then transferred to a beaker and boiled with a dilute solution of soda, filtered; and made up to 100 C.c. Of the finished solution take 20 C.c., acidify with dilute sulphuric acid and rapidly titrate with the permanganate solution; then take a second fraction of 20 C.c., add the amount just found of permanganate solution, acidify, and again determine the end point. In one experiment, the volumes required were 16.3 and 16.4 C.c. respectively. The end of the reaction is more easily obtained if the permanganate be added to the nitrite solution in excess and the excess determined by potassium iodide and thiosulphate solution. The formula indicated for the precipitated salt is $K_2HCo(NO_2)_6$.—*Proc. Chem. Soc.*, **16**, 17.

E. Debuchy employs the following formulae in the preparation of antiseptic gauzes: **ANTISEPTIC GAUZES.** —**CARBOLIC ACID GAUZE:** Phenol, 255; alcohol (90 per cent.), 1,500; glycerin, 20; purified gauze, 1,000. This gauze will contain 20 per cent. of phenol; it keeps supple and fresh provided it be stored in air-tight boxes. **IODOFORM GAUZE:** Purified gauze, 2,500; glycerin, 50; ether, 3,000; iodoform, 283 or 637, according as a 10 or 20 per cent. gauze is required. Ether alone is found to give better results as a menstruum than the mixture of ether and alcohol generally used, since the drying is more rapid, and, therefore, the time of exposure to the air reduced to a minimum. The gauze should be dried in a dark place and stored in air-tight boxes.—*Jo rn. de Pharm.*, [6], **11**, 1.

In many diseases of the nervous system degeneration of the nervous tissues takes place. On the degenerated side of the spinal cord in simple hemiplegia (apoplexy, etc.) the following changes are found:—(1) A breaking up of phosphorised fat; (2) the amount of lecithin is diminished; (3) the amount of fat present is in excess; (4) the amount of extractives soluble in ether is increased; (5) the proteid residue diminishes in amount *pari passu* with the increase of extractives; (6) the phosphorus in the residue diminishes at a still greater rate than the residue itself; (7) the percentage of phosphorus in the half cord as a whole is diminished; (8) the ether extract has an appearance of butter instead of being crystalline. In general paralysis of the insane the amount of water in the cerebral hemispheres is increased, while the phosphorus undergoes an actual diminution, corresponding closely to the wasting of the hemispheres.—*Archives of Neurology*, London County Council, Mott and Barratt, p. 346, and Barratt, p. 270.

NON-BRITISH GRASSES IN THE CHANNEL ISLANDS.

C. R. P. Andrews exhibited at the last meeting of the Linnean Society two non-British grasses which he had found last year in the Channel Islands—*Phala is minor*, Retz., from sandy shores and fields in Guernsey and Alderney, and *Milium scabrum*, Merl., from the cliffs of Guernsey. He maintained that they were both native plants, as the former is indigenous on the west coast of France and on the north coast as far as Cherbourg and Barfleur, while the latter is a native of West France as far north as Vendée, and reappears on the coast of the Netherlands. He suggested that the former had been passed over owing to its resemblance to *P. canariensis*; the latter owing to its inconspicuous habit, its early flowering, and the fact that it grows on the lower slopes of the cliffs in an unfrequented part of the island.

ALKAPTONURIA.

A curious condition of the urine is occasionally met with known as alkaptonuria. Its chief interest is that the urine contains a reducing body which may be mistaken for sugar. The urine, when first passed, is normal in colour, but afterwards becomes deep brown; it reduces Fehling's solution and ammoniacal silver nitrate, but not bismuth; it has no rotatory power and does not ferment. The anomaly in the majority of instances dates from early childhood; it may last for life, and sometimes occurs in families; on the other hand it may be quite a temporary feature. Various substances have been isolated from the urine—pyrocatechin, uroleucic acid, and homogentisinic acid. It would seem that the main characters of the urine in alkaptonuria are due to the last-named substance, homogentisinic acid. This is hydroquinone-acetic acid with the formula $C_8H_8O_4$. It may be separated from the urine by two methods: the first (Wolkow and Baumann) is acidification with dilute sulphuric acid, repeated extraction with ether, distillation of the ether, solution of the syrupy residue in water, and addition to the boiling solution of a concentrated solution of basic lead acetate. A simpler method (Garrod's) is to heat the urine to boiling, add five or six grammes of solid lead acetate to every 100 C.c., and filter off the bulky precipitate. By either method the resultant fluid on standing deposits acicular or prismatic crystals of lead homogentisinic acid.—Garrod, *Medico-Chir. Trans.*, 1899, vol. 82, pt. iii., p. 367.

ASYLUM DYSENTERY.

A disease of a dysenteric nature is of common occurrence, and causes considerable mortality among the inmates of asylums, but is rarely seen elsewhere. It is characterised by ulceration of the colon or large bowel with dysenteric symptoms more or less acute. In seven out of eight cases examined, Durham has isolated a hitherto undescribed micrococcus. The organism is extremely minute, stains with the ordinary staining solutions, and also by Gram's method, though not very well by the latter. It has been isolated from the blood, spleen, liver, kidney, and bile. So far it has been cultivated only in broth, and sub-cultures from the original cultures have not been obtained. As the organism did not grow on solid media, plate cultures could not be made use of to obtain pure cultures, and the following method was adopted. Small Berkefeld filters were fitted into a large rubber cork, provided with a single perforation, into the lower end of which a short piece of glass tube was fitted; sufficient cotton wool was next wound round the latter to fix on a test-tube with some firmness. Several such were sterilised in the autoclave. The rubber cork was then inserted into an ordinary conical filtration flask, the tube and test-tube being thus inside the latter. On exhausting, the fluid passed through the filter and collected in the test-tube. The coccus was so minute that it passed through the pores of the Berkefeld, whereas other organisms did not. The method may be of use in other cases.—*Archives of Neurology*, London County Council, I, p. 403.

SUGGESTED STANDARDS OF PURITY FOR FOODS AND DRUGS.

BY C. G. MOOR, M.A., F.I.C.

Under the Sale of Foods and Drugs Acts the public analysts throughout the country have to examine such drugs as may be submitted to them by the inspectors appointed under the Acts. It is well known that there is at present no legalised standard by which either foods or drugs can be judged, and, though it would no doubt be a great convenience to public analysts if there were official standards by which their work was regulated, the adoption of such legalised standards would not be without certain disadvantages. The fact remains that every public analyst appointed under the Sale of Foods and Drugs Acts is liable to have submitted to him by the inspector acting for the local authority a sample of almost any food or drug which is sold, and he is by law required to analyse this and state his opinion on the same. A section of the Sale of Foods and Drugs Acts compels him also to perform the same duty for any private purchaser who may choose to buy an article within the district for which that analyst is appointed, and who chooses to submit the said article for analysis and to pay the statutory fee.

The obligation on the analyst to examine and report on the sample is clear. We will next consider what means he possesses of executing the work that he is bound to carry out. There are no fixed standards of purity fixed by law in the case of any foods or drugs whatever except in the case of spirits, where it is defined by Act of Parliament that the strength of brandy, rum and whisky shall not be less than that which is indicated by 25 degrees below proof, and in the case of gin, which may be 35 degrees below proof. In the case of one or two other articles a standard having almost the force of law has been arrived at by common consent or because it is known to be that which has been adopted by the authorities of Inland Revenue, who are the referees under the Foods and Drugs Acts. Apart from these standards there are none that are legally fixed, with the exception of the Pharmacopœia, but that work has not been specified as a standard under the Sale of Food and Drugs Acts, and therefore is not a legal standard for the purposes of those Acts. The Pharmacopœia was issued long before the Foods and Drugs Acts were thought of, and would require considerable alteration and additions before it could be adopted as a general legal standard. The Pharmacopœia, however, is accepted by magistrates as evidence, and hence the limits laid down in that work have, in many cases, been accepted as standards under the Foods and Drugs Acts. Many of the tests laid down in that work will be found on examination to require further details to bring them within the limit of actual practical utility.

These further details have at present to be filled in by each analyst according to his experience, and may, therefore, be interpreted in many varying ways. Directions are also given in the Pharmacopœia for the preparation of many articles, but no tests are suggested for the finished preparations. Yet these finished preparations may frequently be submitted for analysis. It becomes necessary, therefore, for each analyst to endeavour to supplement the official directions or tests as his experience directs so as to arrive at some standard by which he can judge of the interpretation of the data yielded by his analysis. To do this with any approach to correctness it will in most cases be necessary that he shall have had experience, not merely of the sample that is before him, but of other samples, some, at least, of which are of known sources, or, in the case of preparations, made by reliable people. Knowing the results yielded by drugs or preparations which conform to the Pharmacopœia directions, he can then decide whether, in his opinion, the sample submitted fulfils the Pharmacopœia requirements if that is the question he has to answer. This latter consideration opens up a much wider question—namely, how far are articles in everyday use to be judged by the stricter standard applicable to those articles intended to be used for dispensing? It appears to me that

in this case, as in most others, a broad view must be taken, for if the question is pushed to either of the two extremes the situation becomes impossible.

To state the case briefly, it appears to me that when a purchaser desires an article corresponding to the requirements of the Pharmacopœia he should ask for it as answering the B.P. requirements. It may be objected that ignorant persons will not readily be brought to do this, but that they, nevertheless, deserve protection. A very little inquiry, however, on the part of the vendor, if he is an honest man, should enable him to supply the purchaser with what that purchaser actually wants by eliciting for what purpose the article is required. For example, supposing a person entered a chemist's shop and asked to be supplied with beeswax, and on inquiry it is found that the beeswax is intended for polishing or for the waxing of thread, it is clear that the purchaser does not wish for a medicinal beeswax, nor, indeed, does he really wish for beeswax at all, but for a mixture of beeswax and paraffin, which is sold at a cheaper rate. The proper course to pursue under such circumstances is for the vendor to say, "I think that what you want is not the pure beeswax used in medicine, but a mixture of beeswax and turpentine, which is cheaper, and commonly used for the purpose you mention." Then if the purchaser desires pure beeswax he has the opportunity of saying so and of paying a proper price for that article. If, on the other hand, he requires the cheaper mixture, he has been plainly told what he is getting, and cannot possibly be considered to be prejudiced by his purchase.

In some cases the supplying of the pure article indiscriminately might be to the prejudice of the purchaser, as in such a case as this: If a person who is accustomed to take "Juniper oil," which would probably be "Ol. Juniper Liq." (which appears to be a mixture of a small quantity of "Juniper oil" with turpentine) were to be supplied with pure "Juniper oil, B.P.," and were to take the same quantity as he was accustomed, the consequences might be unpleasant. As in the former imaginary case, it appears to me that the vendor should explain to the purchaser that the article he probably was inquiring for was a mixture of pure "Juniper oil" and turpentine, and that he could have it if that was what he wished for, and that if he supplied it he should label it accordingly. If, on the other hand, he wished for pure "Juniper oil" he could have it, but that the price was naturally higher than that of the mixture. It may be that many retailers will not agree with my views in the above imaginary cases. On the other hand, I feel strongly that any attempt to compel those who sell articles of food or medicine to deal only in the pure and unmixed articles, to the exclusion of all others, can only end in failure. In many cases it is absolutely necessary for the shopkeeper to have more than one quality of an article, because the public demands more than one quality.

The only thing that should be insisted on is that its true nature, substance, and quality should be clearly stated. The Sale of Foods and Drugs Acts permits the sale of mixtures providing the fact is clearly stated on the label. Where, however, an article is marked "pure," the presence of any admixture constitutes adulteration. In the case of drugs it is known that the Pharmacopœia is a standard for those drugs which are used in dispensing, and though it does not apply by law to them when they are not used for dispensing, in the majority of cases the purchaser would expect to get drugs of a quality and purity not less than he would get them if they were dispensed in mixtures. In view of this, and of the general acceptance of the Pharmacopœia as a standard by magistrates all over the country, all pharmacists would do well to see that the drugs they deal in are in accordance with the requirements of the Pharmacopœia. In spite of the deficiencies of the Pharmacopœia, it will be admitted that, generally speaking, the tests prescribed by it are sufficient to exclude most of the substitutions or deficiencies to which drugs and their preparations are subject. Pharmacists will find no difficulty in obtaining from wholesale houses definite guarantees that the articles they order are in accordance with the require-

ments of the Pharmacopœia, and they should always ask for a definite guarantee that this is so. Where there is a reluctance on the part of any wholesale house to give such a guarantee, the cause of such reluctance is probably the fact that the price paid does not admit of an article up to the standard of the Pharmacopœia being supplied.

The adulteration of foods—namely, the adding of water to milk, or the selling of margarine as butter, or of the mixture of coffee and chicory as coffee, does not appear to me to find an exact parallel in the case of drugs. The adulteration of drugs by retailers is, in my opinion, exceedingly unlikely; in fact, the word "adulteration" does not truly convey the meaning intended. Take the case of articles that are liable to natural deterioration; for example, sweet spirit of nitre and lime water, though I do not mean to say that such natural deterioration may not largely be due to carelessness. If a pharmacist is prosecuted under the Foods and Drugs Acts for a deficiency in either of these articles, it is by the public regarded as an offence or form of cheating similar to that indulged in by the milkman who waters his milk. This is an exceedingly unfair view of the case, because the milkman commits a deliberate offence and intends to cheat his customer, whereas I cannot conceive a pharmacist deliberately selling limewater or sweet spirit of nitre which he knew to be deficient in their active principles. The retailer, however, may obtain drugs from the wholesale houses which the analyst, on examination, would pronounce to be adulterated. In a few cases, such as camphorated oil, the article is deliberately compounded not in accordance with the Pharmacopœia, and is probably not invoiced as such. In this case the retailer may have been negligent, so that he does not know what he is selling; or he may be intentionally selling this article because he makes more profit on it than on the Pharmacopœia article. If, however, his customers were sufficiently educated to ask for camphorated oil, B.P., and were willing to pay the price for it, he would certainly stock the higher price article, and derive a profit from so doing. If he sells a mixture as "camphorated oil," that mixture should certainly be prepared in accordance with the Pharmacopœia directions. If he thinks proper to keep another and a cheaper mixture, it appears to me that he is perfectly at liberty to do so, providing he does not allow his customers to be misled into thinking that it is the camphorated oil of the Pharmacopœia. The correct labelling of this and of many other articles would do away with the majority of those cases in which retailers feel themselves oppressed by what they not unnaturally think vexatious prosecutions on the part of public officials. It is in many respects the public that require educating. They do not at present understand that if they insist on paying a low price they are certain not to get the best quality drugs. But the mere fact of labelling articles correctly, which is what I desire to urge, is sufficient to show them that there are two qualities, and then, I think, it will be found that a great many people are sufficiently wise to wish for the better quality, and will be ready to pay the price for it. At present, the public often demands certain articles at such low prices that the retailer is forced to ask the wholesale dealers to supply such-and-such things at prices at which the best qualities cannot be obtained. This leads to inferior qualities being supplied; perhaps, in the case of some drugs, even substitutions of a drug which may not have the same medicinal qualities, and the desired effect not being produced the patient has recourse to secret remedies and patent medicines.

The demand for cheap stuff is very largely at the bottom of the whole difficulty. There are, however, special difficulties which affect each one of the three classes of people most concerned in the administration of the Acts. First, the analysts have not got fixed standards nor definite information to enable them to carry out their duties properly. Retailers suffer from the desire of the public to obtain drugs at the lowest possible price, and have to face the fact of either losing customers or selling the genuine article at an unreasonably small profit. Wholesale houses, on the other hand, being asked by many retailers to supply them at the lowest possible

rates, find it difficult to obtain proper prices for drugs of the best quality, so that while they are obliged to keep stocks of the best qualities, a relatively small proportion of the better qualities are sold, so much so that in some cases they become more curiosities than articles of commerce. Wholesale houses also have their own difficulties; they are often unable to control the method of collection of drugs so that they may contain amounts of mineral or vegetable admixtures which an analyst would consider adulteration, but which is in some cases unavoidable in practice.

With regard to educating the public as to the necessity of paying proper prices for pure drugs, I am, with the consent of my local authority, publishing a circular, which will be freely distributed in the district, and, I hope, subsequently reprinted in the *Pharmaceutical Journal*. Regarding the difficulties of analysts which I mentioned above, I have been engaged for some time past, in the company of two fellow-workers, Mr. Cecil H. Cribb and Mr. Martin Priest, in collecting information as to the average composition of all the foods and drugs likely to be submitted to the public analyst—that is to say, in compiling sets of figures of reliable specimens of all the ordinary foods and drugs. In doing this I have had occasion to ask the assistance of many persons well known in the pharmaceutical world, and it has in every case been most kindly given. The object of these suggested standards, the first instalment of which will be published next month in the *British Food Journal*, is not that of increasing the number of prosecutions under the Sale of Foods and Drugs Acts; my object is to endeavour to obtain correct ideas regarding the composition of pharmaceutical preparations, and within what limits they may reasonably vary, providing the official directions for their preparation have been carried out. To this end I would invite the assistance of all who are engaged in the analysis of drugs, and shall be glad to furnish any person interested with the proof dealing with any article in which he may be interested. I need hardly say that any figures or information that may be given me would be duly acknowledged, and I trust that it will be admitted that the work on which I am engaged will be for their general benefit.

THE MICROSCOPE IN THE SHOP.

BY A PHARMACIST.

To the pharmacist who is so in something more than name the microscope is perhaps the most useful scientific instrument which can find a place in the shop. Too frequently its aid is not requisitioned even by the possessor of one, and the cause is in many cases due to it being kept carefully locked up in its cabinet out of reach of the inquisitive apprentice. If, instead of being so carefully preserved, a moderate-priced instrument were placed under a bell glass, and always had attached to it a double nose-piece, a half-inch and a sixth-inch objectives, its true value would be soon appreciated. The value of it is not the amount of money it costs, but the amount of usefulness which can be got out of it. The amount of information which may be obtained by submitting all doubtful substances, and also many substances of good repute, to the scrutiny of the microscope is astonishing. It will often solve the strangest problems in the most unexpected way. Quite recently several bottles were returned containing liquids and deposits which were said to have formed in each. The said deposits were quite foreign to the original contents of the bottles. A microscopical examination proved the sediments in the different bottles to be absolutely identical in character and certainly of a common origin. This fact led to inquiries, which proved that the sediment had been found in one bottle only, and in some unexplained way had been distributed among the other bottles by a servant. At the dispensing counter the microscope should, and in the hands of resourceful pharmacists does, frequently give good service. To place on a glass slip the deposit which has formed in a mixture and ascertain whether it is amorphous (perhaps mucilaginous) or crystalline is but the work of a few minutes, and information is gained as to chemical incompatibility or the mere precipitation of inert matter of vegetable origin. Although the microscope may fail in some

instances to solve the problem forthwith, yet it very rarely happens that it does not give speedy assistance in indicating the direction whence the final solution will come. On one occasion a parcel of citrate of iron and quinine failed to yield a bright solution with water. The usual causes of cloudiness were investigated without avail. A second lot was obtained from the manufacturers, but it turned out equally bad, and the makers could not give any explanation; they contended that their methods were such as they had always adopted. On submitting the carefully collected deposit to the microscope it was seen to consist of ordinary dust and minute fragments of straw. The manufacturers were then able to trace the source of the trouble to a defect in the partition between the room in which the drug was put into bottles and the contiguous room which was used for packing purposes. Doubts sometimes arise as to the correct dispensing of medicines, and the microscope will be found of great use in helping to determine the composition of mixed powders and pills.

It is so common for the pharmacist to buy his drugs in the form of powder that one would think that the microscope would be indispensable if he is to be, as he ought to be, surety for the drugs he sells. The wholesale druggists of this country are as a class above suspicion, and upon their reputation the retail pharmacist leans with an assurance which is very praiseworthy. There is no necessity to say a word to shake so estimable a confidence in the wholesale dealers, especially as the temptation to adulterate powdered drugs is extremely small. But the retailer ought, in these days of contentious commerce, to be in a position to demonstrate the grounds of his confidence to his customers if need be. In the matter of spices and condiments the druggist is on different ground, and must be content to see the greater part of his trade pass into the hands of the grocer, unless he can compete with him in price or sell a superior article. In order to be master of the situation the pharmacist must be certain of the quality of his goods, and he cannot do better than submit all his ground spices to microscopical examination. Cinnamon is sometimes mixed with starch, of which there should be normally present only a small quantity. Powdered walnut shells and the ground twigs of the cinnamon tree are also used for the same purpose. All these substances would be at once revealed by the microscope. Ground white pepper is not infrequently found mixed with other substances such as foreign starches, ground olive kernels, walnut, almond and hazel-nut shells. Exhausted coriander, fennel and anise fruits are also said to have been used for adulterating pepper. Ground mustard may contain an unusual amount of added starch, and it occasionally happens that such diluted mustard is fortified with cayenne pepper. Cheap arrowroot is not always what it pretends to be. Having a complaint as to the price of arrowroot, and hearing that a neighbouring grocer was selling it at a low price, it was decided to investigate the matter by making a purchase from the said grocer. Accordingly a small quantity of each of his two qualities was obtained. The difference between them was only the difference in the retail price; the arrowroot was adulterated to the extent of between 30 and 40 per cent. of sago meal. In justice to the grocers as a class it should be said that the investigation was then extended and samples obtained from ten other establishments; these samples were all pure and of good quality. Linseed meal may sometimes be found to have an admixture of starch, and at other times, especially when old, it may contain large numbers of a mite (*Tyroglyphus siro*). Powdered cantharides is also found sometimes to harbour mites, as is also saffron, especially when kept in a moist condition in tins. About ten years ago a friend sent a quantity of colourless powder from the bottom of a tin in which he had kept his saffron, of which he used considerable quantities. His suspicions were aroused as to the possibility of having been supplied with an adulterated article. The microscope at once revealed the nature of the powder; it consisted of innumerable mites, their eggs, and the debris of dead ones. Insects are much more common in the stock of the druggist than is generally supposed, and would be much

more generally detected if the handy microscope were brought into use.

Another direction in which the microscope is rarely turned is towards the filtering papers. The nature of the liquids which a pharmacist has to filter is so various that it is of considerable importance to him that he should use filtering paper composed of suitable material. A microscopical examination will reveal such differences in the composition of the filtering papers in the market that he will be tempted to consider the whole question of filtration from another standpoint than that of price—namely, that of efficiency.

Besides the utility of the microscope in the immediate concerns of the shop, which have been merely indicated in the foregoing remarks, there is the wider application to the concerns of the community at large. This is a work the pharmacist is pre-eminently fitted to undertake. No other class of professional men has the same opportunities of acquiring so extensive and varied a knowledge of the minutiae of vegetable and animal substances. Medical men are generally very glad to avail themselves of the opportunity of sending urinary deposits to a skilled microscopist; and a pharmacist may, with a very small expenditure of time and money, soon make himself so proficient as to meet all the demands of his medical friends, and thus earn their gratitude and perhaps something more tangible. In many commercial centres where textile fabrics are handled there is a constant need for assistance in discovering the component parts of fabrics. Merchants are often dependent upon tricks, which have no scientific basis, to guide them in appraising the value of the textiles they handle. Whenever they can obtain demonstrative evidence of the presence or absence of certain fibres in their fabrics, they are quick to appreciate the help. This is a field of usefulness the pharmacist who lives in the proper districts should at once annex to his domain. The characters of cotton, silk, wool and linen, as seen under the microscope, are easily apprehended. Now that lustrous-cellulose, mercerised cotton and weighted silk are so common, the aid a pharmacist can render by the use of his microscope should have a distinct commercial value.

The microscopical examination of articles of food such as coffee, cocoa, flour, and tea can very well be undertaken along with the general work of the pharmacy. In the case of coffee, cocoa, and flour, when the characteristics of the tissues of the genuine materials are mastered, the detection of adulteration is easy, and the substances used for falsification are so few in number that it soon becomes easy to name the adulterants. Where tea is concerned the microscopical examination may entail somewhat more trouble, as in some instances it may be necessary to make sections, and in all cases a careful investigation of the venation is required. There are, however, several works published which will help the microscopist over these difficulties very quickly.

The examination of water has been purposely avoided, because it demands expensive apparatus and a certain amount of technical training outside the ordinary curriculum of the pharmacist. There is no reason why the investigation of deposits in potable waters should not be undertaken by the pharmacist; but unless the bacteriological character of the water is also ascertained, such an investigation is of little value. The phases of microscopy that have been exhibited here are just those which should commend themselves to the pharmacist who is willing, without any extra training or any increase in laboratory equipment, to turn to account the reserves of his scientific knowledge.

ASSAY OF THE OFFICIAL NUX VOMICA PREPARATIONS.

BY F. H. ALCOCK.

A process which was suggested for the assay of certain liquid extracts has been tried with the official preparations of nux vomica and is now offered to workers for trial.

EXTRACT OF NUX VOMICA.—One Gm. of the extract is dissolved in 5 cubic centimetres of water and 10 cubic centimetres of

rectified spirit, using if necessary a little warmth. Generally, solution is nearly complete, what remains being flocculent matter easily separable by passing the liquid through a little cotton moistened with the solvent. Now add 20 cubic centimetres, and, after vigorous shaking and subsequent rest, it will be found that the separation of the ether is very slow; 10 cubic centimetres of diluted sulphuric acid are next added, and agitation and rest follow, when the ethereal layer separates very rapidly, and is removed. A second quantity of 10 cubic centimetres is added and removed after agitation and separation. As the volume of the ethereal layer increases on the second washing, it shows that the spirit is removed with the ether. On evaporation of the ethereal solution, after washing it with a few cubic centimetres of water to remove dissolved acidulated water, which if not removed causes slight charring of the residue as it approaches dryness, the amount of fat, resin, and other substances is obtained. The quantity of these removed from commercial extracts varies greatly, but is relatively large; in the sample experimented with it was 0.27 Gm. The aqueous layer from which the resin has been removed by the ether treatment is always clear and bright, and contains all the alkaloids and very little colouring matter. It is rendered alkaline by ammonia and extracted with chloroform in 10 cubic centimetre quantities, 2 being sufficient. To show this the first washing gave 0.095 Gm. total alkaloids, and the second increased the yield to 0.118 Gm., and the third washing caused no further increase of product. As a rule, the alkaloidal residue is not crystalline, but sometimes it is partially so. The sample with which the bulk of the experiments was made was not made according to the present plan (1898), but it has not been found that with the new preparation any variation is required. The milk sugar does not affect the process in any way.

LIQUID EXTRACT OF NUX VOMICA.—Five cubic centimetres of the liquid extract was taken, 5 cubic centimetres of diluted sulphuric acid, and 20 cubic centimetres of ether, with a subsequent quantity of 10 cubic centimetres of ether. The alkaline aqueous solution was washed with 20 cubic centimetres of chloroform in two equal portions, and the yield of total alkaloid was 0.140 Gm. Half of this quantity was subsequently shown to be strychnine. The ethereal liquid on evaporation gave a residue weighing 0.065 Gm., and did not contain alkaloid.

TINCTURE OF NUX VOMICA.—Ten cubic centimetres of the tincture is mixed with 20 cubic centimetres of ether and 5 cubic centimetres of diluted sulphuric acid, with a subsequent addition of 10 cubic centimetres of the ether. The mixed ethereal liquids on evaporation gave 0.229 Gm. of dried residue, and was free from alkaloid. Diluted hydrochloric acid abstracted from this a little colouring matter, and with nitric acid gave a faint-red colour, and with potassium bichromate and sulphuric acid a deep crimson colour. The aqueous solution after removal of ether was rendered alkaline and extracted with 10 cubic centimetre quantities of chloroform, the first washing removed 0.030 Gm., the second increased the yield to 0.049 Gm., and the third caused no increase, nor was any alkaloid left in the aqueous liquid. Ten cubic centimetres of the same sample of tincture reduced to extract and dealt with according to the B.P. plan yielded 0.0488 Gm. alkaloids. The residue from this tincture was used to ascertain how much was strychnine, and whether so small a quantity was sufficient for the process. It was dissolved in 3 cubic centimetres of diluted sulphuric acid (B.P.) and made to 30 cubic centimetres with water, then 20 cubic centimetres of water containing 0.3 Gm. of potassium ferrocyanide was added, the whole shaken up in a stoppered flask, and subsequently dealt with in the prescribed way, with the result as follows:—Yield of strychnine 0.021 Gm., and of brucine 0.027 Gm., each being actually obtained and not calculated by difference. By this process the strychnine residue is always free from colour, and is crystalline, but invariably becomes coloured on the addition of nitric acid, thus showing the probable presence of a small quantity of brucine. For

such experiments as the above, in which so much volatile immiscible solvent has to be used, a small two-ounce carbonic acid flask has been used to collect the residue in, and the solvent has been regained by distillation process, a miniature Liebig's condenser being kept for the purpose, the heat used being hot water contained in a small beaker, and in which the flask could be comfortably imbedded.

THE OFFICIAL PROCESSES FOR THE ASSAY OF IPECACUANHA, BELLADONNA, AND NUX VOMICA.

BY F. C. J. BIRD.

(I.) Ipecacuanha.

LIQUID EXTRACT.—The process given in the British Pharmacopœia for the standardisation of this preparation has almost from its first appearance been subjected to a good deal of criticism, chiefly adverse. The two most forcible objections urged against it have been its tediousness (due to the length of time necessary for the washing of the precipitate, separation of the chloroform, etc.) and its inaccuracy owing to the loss of alkaloid, and the impure condition of the residue finally weighed. The waste of material involved in operating with the quantities given in the Pharmacopœia has also been alluded to, although this can hardly be termed an objection, as it is open to anyone to use what quantity of material they may find convenient, provided concordant figures are arrived at. Several excellent analytical methods have been put forward which claim to be either more expeditious or more accurate than the official process, but as the figures hitherto published show a considerable variation when compared with the same assay by the B.P. method it is a matter of some perplexity to select an alternative process which can be used for standardising ipecacuanha preparations.

Whatever the inaccuracies and imperfections of the Pharmacopœia process, the fact remains that it is the standard by which the liquid extract must be tested and judged. The B.P. is very definite on this point. It distinctly orders the proportion of alkaloid in the liquid extract to be determined and adjusted by the analytical method described in the monograph, and if any other process be selected as a substitute it is absolutely essential that the result obtained by the new process shall bear a constant relation to the result given by the B.P. method, and be capable of accurate translation into the official figures. Any process not fulfilling this condition, however convenient or simple, is not available for the purpose of standardising the liquid extract, for if a certain sample of that preparation be found to yield but 1.8 per cent, alkaloid by the B.P. method surely no adequate defence of such deficiency in strength can be based on the statement that the process employed for its standardisation was more accurate than the official one, and capable of yielding more alkaloid.

Perhaps the tediousness which has generally accompanied the working of the official process appeals most strongly to the busy pharmacist. This, however, has been entirely overcome in the following method of assay, which is the practical result of experience derived from the examination of a large number of samples by the B.P. analytical process. As will be seen, details of manipulation quite in accordance with a close interpretation of the B.P. directions are responsible for the improved celerity of the method, and the results are in close agreement with those obtained by following the official instructions in their strictest sense. Working with 20 C.c. liquid extract, the average time occupied in the actual analysis, exclusive of the drying of the residue, is about one hour, but taking only 10 or 5 C.c., all the operations are performed more quickly and the time is naturally shortened. The quantities given below, refer to the process as it stands in the B.P. If 10 C.c. or 5 C.c. be selected as the starting point, one half or one fourth respectively of the quantities mentioned are employed, and the special apparatus is more conveniently of only half the figured capacity throughout.

Liquid extract of ipecacuanha, 20 C.c.; distilled water, 20 C.c.; acetic acid, *q s.* to faint acid reaction. Evaporate off the alcohol and add distilled water, 20 C.c., liq. plumbi subacete, 10 C.c. Keep the mixture on the water-bath for a few minutes until the magma which at first forms changes to a thin liquid, and the precipitate assumes a finely granular condition. Transfer to filter B, and connect A with a water pump. (In the absence of the latter

APPARATUS FOR THE ASSAY OF IPECACUANHA, BELLADONNA AND NUX VOMICA PREPARATIONS.

exhaustion of the air by forcibly sucking with the mouth at A, retaining the vacuum by the clip C, ensures a very fair rate of filtration.) Wash the nearly dry solid cake remaining on the filter with distilled water, 30 C.c., added in small portions. To the filtrate in C add acid sulph. dil., 25 C.c.; change the filter paper on B; transfer B to another filter flask (see note), and pour upon it the liquid in C, aiding filtration by a vacuum as before. Wash the cake of lead sulphate with distilled water, 15 C.c. To the filtrate in the same flask add chloroform, 5 C.c. ammonia, excess. Cork the flask, agitate vigorously and transfer contents to D (see note).

Connect D with H by the rubber cork G, and, having inflated the pressure-ball H, force the chloroform and a portion of the aqueous liquid in D through the filtering medium shown, into E. Draw off the chloroformic layer, which should be perfectly clear and bright, into the tared glass dish F. Return the aqueous liquid in E and D to the filter-flask, add chloroform, 25 C.c.; and proceed as before. Repeat a third time with chloroform 25 C.c. Finally collect the three chloroformic layers in F. Evaporate and dry the residue below 80° C.

NOTES.—B. Buchner's funnel 7.5 Cm., internal diam., has upright sides, and a flat perforated plate in one piece with the funnel. It carries a moistened filter paper, 7.5 Cm. diam., laid flat on the perforated plate. For the filtration of the acid solution from the lead sulphate, a very close filter paper must be used, or what will generally be found more convenient, a pinch of purified asbestos is rubbed with water and poured on the filter paper first, when the acid liquid passes through bright at once. D is an ordinary separator, prepared in the following manner:—Moisten a plug of cotton wool with chloroform, and place it in the neck of the separator above the tap. Upon this pour a layer of purified sand. Rub a little purified asbestos with a few C.c. of chloroform in a small mortar, and pour into separator and add a thin layer of sand. This filter once prepared will serve for a number of assays of the same drug. It is cleansed after use by rinsing off any deposit without disturbing the compact mass of sand, and then forcing a few C.c.'s of dilute ammonia through, until the liquid passes colourless. Should the chloroformic solution of the alkaloid not come through quite bright, the addition of a little more asbestos saturated with chloroform will overcome the difficulty. The asbestos and sand are purified by successively extracting powdered asbestos and silver-sand with hot hydrochloric acid and ammonia.

The washing of the lead precipitate usually takes less than a quarter of an hour. At the Plymouth Conference meeting, several speakers having complained of the length of time consumed in the washing of this precipitate, I stated that with a filter pump it could be done in a quarter of an hour. This remark was incorrectly reported as referring to the whole process.

The Preliminary Removal of the Alcohol.—To ascertain if the presence of alcohol in a sufficiently diluted condition would affect the yield of alkaloid, the B.P. process was modified as follows, and applied to two samples of liquid extract:—Liquid extract 20 C.c., water 60 C.c., solution of subacetate of lead 10 C.c. Warm for a few minutes on the water-bath, and proceed according to the details for B.P. process already given.

		Per Cent.	
		Weight.	Titration.
Sample No. 1.	Alcohol, not removed	1.955	1.785
	B.P. process	1.95	1.78
Sample No. 2.	Alcohol not removed	2.21	1.49
	B.P. process.....	2.13	1.45

A sufficient number of samples have however not yet been examined to allow of the statement that the removal of the alcohol is unnecessary.

Loss of Alkaloid in the Pharmacopœia method of Assay is chiefly due, as shown by H. Wilson, to retention of alkaloid in the lead precipitate. It is also influenced by the composition of the sample under assay, and by the thoroughness of the washing. The liquid extract of the Pharmacopœia probably contains in solution the alkaloids emetine and cephaeline combined with ipecacuanhic acid and in the free state, the peculiar intense brownish yellow decomposition product resulting from the alteration of the free alkaloid (principally cephaeline) by heat, fat, resin, traces of volatile oil, and sugar. On the evaporation of the alcohol, the fat, resin, and a portion at least of any alkaloid existing in the free state is precipitated, the greater part of the combined alkaloid remaining dissolved. Basic acetate of lead is then added, which throws down the ipecacuanhic acid and leaves the alkaloids in solution. On filtering, the precipitate will consist of the insoluble lead compound together with the substances precipitated by the removal of the alcohol and all the free alkaloid which is not soluble in the volume of liquid present. Paul and Cownley* state that emetine (and presumably cephaeline also) is sparingly soluble in water, sufficient washing ought therefore to remove the whole of the alkaloid from the precipitate. This has already been shown to be the case by W. A. H. Naylor.† But the ease with which this takes place greatly depends on the physical condition of the lead precipitate. When the solution of subacetate of lead is first added to the warm evaporated liquid extract a gelatinous magma is formed highly favourable to the mechanical retention of alkaloid and of the strong mother liquor, and which renders effective washing extremely difficult. If, however, the liquid be diluted somewhat before the addition of the lead

* *P.J.* [3], 25, 691.

† *P.J.* [4], 9, 87.

solution and the whole kept at a gentle heat on the water-bath for four or five minutes, the previously thickened liquid gradually becomes thinner, and the precipitate aggregates to a finely granular condition, very amenable to rapid filtration. Until this occurs filtration should not be attempted. Using Buchner's filter and a vacuum of 8 or 10 in. of mercury, the separation of the mother liquor from the lead precipitate can usually be accomplished in two or three minutes.

It appeared possible that the basic nature of the lead subacetate might account in part for the retention of alkaloid, but experiments made to ascertain this point apparently show that this is not the case. The amount of washing required is naturally largely influenced by the proportion of free alkaloid in the original extract, also if the original extract be not distinctly acid, the presence of the highly coloured decomposition product of the alkaloid resulting from the exposure of its alcoholic solution to heat affects the washing to some extent. This altered alkaloidal substance communicates a very marked fluorescence to alkaline liquids containing it, as pointed out by Paul and Cownley, and it appears to behave very much as the alkaloid itself towards solvents in passing from acid to the alkaline solution; yet it does not possess the power of neutralising acids and precipitating with alkaloidal reagents like an alkaloid, or, at all events, not to the same extent. A liquid extract containing a comparatively large proportion of the evaporated products prepared from lime and ipecacuanha yields a highly coloured alkaloidal residue, possessing a comparatively low titration value.

The analysis of an extract prepared from ipecacuanha root by simple percolation without the use of either heat or lime shows that, on account of the absence of free alkaloid or the brown decomposition product already alluded to, the loss in the lead precipitate is very small, and the alkaloidal residue extremely pale in colour, with a high titration value. For example, a sample of strong percolate from Rio root gave—

	Weight.	Titration.
Percentage of alkaloid retained by lead precipitate	0.02	0.01
Percentage of alkaloid in strong percolate	1.75	1.62

If an allowance in the last figure be made of 0.56 for the titration value lost in the evaporation of the chloroform and drying the residue at 79° C. (see below), the percentage becomes 1.67, being a difference between weight and titration of less than 5 per cent.

For the purpose of the following experiments two samples of B.P. liquid extract of ipecacuanha were selected, A and B. The one (A), from its dark colour and general appearance, evidently contained a considerable proportion of free alkaloid altered by the effect of heat. The other was a typical extract agreeing in general characters with those usually found in a carefully prepared product.

The retention of alkaloid by the lead precipitate being chiefly due to the presence of free alkaloid and possibly to a less extent to mechanical entanglement of the strong mother liquor, the following method* of washing might be expected to reduce the loss considerably. The lead precipitate was removed from the Buchner's filter after the whole of the mother liquor had been sucked through, and an almost dry cake remained, and triturated in a mortar with 30 C.c. of warm water. It was then returned to the filter and a further quantity of 20 C.c. water passed through—making 50 C.c. wash water in all.

In a second experiment sufficient acetic acid was added to the liquid extract before evaporation to give it a very faint acid reaction.

ALKALOID RETAINED BY LEAD PRECIPITATE
Per Cent.

SAMPLE B (20 C.c.).	By Weight.	Titration.
Precipitate washed by trituration as described above..	0.10	0.06
Liquid slightly acidified before addition of lead solutions, 30 C.c. wash water	0.08	0.04

Clearly, therefore, slight acidification of the liquid before addition of the lead subacetate is as effective in preventing loss as the method of washing described. As the B.P. simply directs the

precipitate to be washed, leaving the manner of washing entirely to the discretion of the operator, the faint acidification is quite permissible, as it is only equivalent to the more troublesome process of washing, and cannot, therefore, be called a departure from the official process.

Similarly, sample A (20 C.c.) gave alkaloid retained by lead precipitate—

	Per cent. Weight.	Titration.
Lead precipitate, washed with 30 C.c. water without trituration	0.32	0.18
Acidified before evaporation, 30 C.c. wash water	0.09	0.05

The average loss of alkaloid in the lead precipitate is about 0.08 per cent. (weighed residue), using the above quantity of wash water. This probably, however, is higher than the truth, on account of the difficulty with such a small residue of obtaining the ether-chloroform solution quite free from extraneous matter.

The Chloroformic Solution of the Alkaloids.—In all processes of alkaloidal determination depending on separation by immiscible solvents, it is essential for accurate and concordant results that a perfectly sharp separation and clear solution of the alkaloid be obtained. If allowed to stand sufficiently long, the chloroform will generally separate completely and bright, but when time is an object there is often a temptation to draw the chloroform off before a satisfactory separation has taken place. By the method of manipulation described the separation of the chloroform is absolutely sharp, and occurs immediately—the solution at the same time being perfectly clear and brilliant.

The Alkaloidal Residue.—The mixed chloroformic solutions are directed to be evaporated and dried at a temperature below 80° C. The varnish-like layer of dried total alkaloids retains chloroform with great pertinacity, and as a rule several hours' drying at the prescribed temperature is necessary before the successive weighings cease to differ. This renders the drying process tedious and lengthy. A much quicker plan is to evaporate the mixed chloroformic solution until but 1 or 2 C.c. remain, and then add about 5 C.c. of 0.717 ether, the mixed liquid, by inclining the dish, being allowed to run over the interior and form a thin film on the inner surface. If the dish be kept moving the ether evaporates in a few minutes, and the weight of the residue will now be found to become constant in a very short time.

Continued heating must be avoided in any process dependent on final titration. Paul and Cownley, in studying the action of heat on the alkaloids of ipecacuanha, found that cephaeline was rapidly decomposed when boiled with ethyl alcohol, and probably emetine would be acted upon in the same manner. Solutions of the two alkaloids in chloroform are very sensitive to light, and presumably to heat as well; the darkening in colour of the chloroformic solutions of the alkaloid when evaporated has frequently been remarked. To ascertain if this fact had any bearing on the deficiency in titration value of the B.P. residue pointed out by several observers, a pale alkaloidal residue representing 40 C.c. of liquid extract, which had been dried at a low temperature, was dissolved in 150 C.c. of chloroform, and the solution divided into two equal parts, (a) and (b).

CHLOROFORMIC SOLUTION OF THE ALKALOIDS (75 C.c.)
Per cent. titration.

(a) Evaporated spontaneously in vacuo	2.006
(b) Evaporated in water oven at 79° C.	1.95

This shows a loss of 0.05 per cent. in titration value on an average 2 per cent., result ascribable to alteration of the alkaloid during evaporation of the chloroform and drying below 80° C. till constant in weight.

Impurity of the B.P. Alkaloidal Residue.—The composition of the alkaloidal residue appears to be regulated by the proportion of altered alkaloid in the sample of liquid extract under examination, different samples furnishing residues which vary greatly in the discrepancies exhibited by the gravimetric and volumetric figures. Treatment with lead subacetate, etc., excludes, practically all matter not either alkaloid or of alkaloidal derivation

* This has been referred to by H. J. Henderson, P.J., December 23, 1899, 602.

and the difference between the amount of alkaloid indicated volumetrically and the weight of the residue, as far as the B.P. process is concerned, appears to be made up of alkaloid, which under the influence of the heat employed in the process of manufacture has probably undergone some molecular change not as yet thoroughly understood. In support of this assumption it was found that a liquid extract prepared by percolation, without the use of either lime or heat, yielded an exceedingly pale residue, indicating by weight 2.14 per cent., and by titration 2.06 per cent. of total alkaloid, a difference of less than 4 per cent. Whether the altered alkaloid is entirely without physiological activity is not known, and until this point is settled it seems a little doubtful whether titration alone can accurately determine the medicinal value of a preparation of ipecacuanha. Paul and Cownley have shown that when cephaeline undergoes change by being heated with acetic acid, a larger quantity is required to produce emesis, but, on the other hand, although attention has been called to the serious deterioration in strength on keeping certain samples of liquid extract (presumably containing a very notable proportion of free alkaloid), no cases of corresponding deficiencies in emetic effect have been reported.

The Relation of the Results of the Official Method to Those Given by Other Processes.—The figures hitherto published indicate a very wide variation between the gravimetric determinations of the Pharmacopœial process and the gravimetric and volumetric results of other methods. H. Wilson* obtained figures higher by about 8 per cent., and Farr and Wright† found that Wilson's process gave an excess of from 7 to 16 per cent. W. A. H. Naylor,‡ on the contrary, records one instance in which Wilson's process came out below the B.P. method, the deficiency amounting to about 0.5 per cent. Farr and Wright and W. A. H. Naylor have given examples of results obtained by their respective processes in which the gravimetric figures have been in most cases very much higher and the titration figure generally lower than the corresponding ones by the official method. No constant relation has therefore been shown to exist between the weight of the residues obtained by the several published processes and those of the B.P. method, although there is an exception in the statement by H. J. Henderson§ that Alcock's method yields a residue corresponding very closely in weight with the residue yielded by the B.P. method. The variable composition of the samples of liquid extract used for comparison would prevent any accurate deductions being made from the figures referred to above. Therefore, in order to observe the working of the various processes with the same sample of liquid extract the two extracts A and B were assayed by all the published methods and the results tabulated.

(To be continued).

BACTERIOLOGY FOR PHARMACISTS.

BY C. EDWARD SAGE.

The trite sayings "Small beginnings have big endings" and "Many a mickle makes a muckle" can be most aptly applied to the work of a bacteriologist.

It is difficult to conceive the possibilities which bacteriological research open up, and the wonderful discoveries of this science have astonished even the investigators who have made them. Just as the cultures and products obtained by a bacteriologist are generated from the most minute quantities of matter, so the beginner must commence his studies with small and simple experiments, and wait for experience to lead him to fresh fields of research and new discoveries by means of the material at his disposal.

That pharmacists should possess a knowledge of bacteriology is essential in these advanced days of antiseptics and disinfection.

Medical students are instructed in bacteriology, brewers study it for business purposes, and the professional chemist uses his knowledge of the subject in many ways which benefit mankind.

Although pharmacy students are not taught anything of a definite nature relating to bacteriology, they cannot do less than show an interest in the causes of fermentation and decomposition and the methods which are used to prevent these organic changes in saccharine and vegetable solutions, and even if the medical aspect of bacteriology is beyond their province a knowledge of it should be of some service in business.

A little knowledge is a dangerous thing if wrongly applied, but if the little is only a nucleus for acquiring more, then its utility is obvious.

Now, although it costs a considerable sum to equip a working laboratory in which to deal with scientific investigations relating to diseases and their prevention or cure, yet the apparatus by means of which a student may commence his studies need not cost an extravagant amount.

Pharmacists are peculiarly well fitted for the study of bacteriology, their knowledge of chemistry and botany are useful, and their intimate acquaintance with making solutions and the handling of apparatus is a great help, while habits of neatness and cleanliness are essential.

The apparatus necessary to commence with includes the following:—A good microscope, an incubator, a steriliser, and flasks, test tubes, and sundry oddments such as are always at hand in a pharmacy.

FIG. 1.—WATSON'S "F AM" MICROSCOPE.

The incubator and steriliser can be improvised, and all the other things are inexpensive except the microscope.

The best advice the writer can give regarding the choice of a microscope is summed up briefly as follows:—Find out what you want, then how much you have to spend, then go to a good maker's and tell them the facts of the case. Pharmacists expect customers to come and ask for what they want and trust to them to supply what is right, and ought to be prepared to show an equal trust in their fellow-tradesmen.

It is perfectly possible to conduct many of the experiments without the use of a microscope, but sooner or later the student will be certain to want one, and it is therefore best to have it to start with.

The essential points in selecting one for bacteriological purposes are:—A firm and heavy stand, with a clamp to keep the tube at any angle; a good fine and coarse adjustment; an easily manipulated stage; three objectives, namely, 1 inch 1/6 inch, and 1/12 inch; a sub-stage condenser.

Such an instrument is supplied by Messrs. Watson, High Holborn (Fig. 1), for between £13 and £14, and for a student who can afford it the money would be well spent; a microscope is.

* P.J. [4], 7, 3.

† P.J. [4], 9, 86.

‡ P.J. [4], 9, 88.

§ P.J. [4], 9, 602.

or should be, one of a pharmacist's most prized possessions, and a student should want one continually.

Let it be remembered, however, that it is not necessary to possess a microscope before work is commenced, for there are many other means by which organisms are differentiated. Some grow best in acid media, some in alkaline, some in air, others in absence of air, some in milk, others in broth, on jelly, potatoes, or bread, and the characters they present while growing on these media are often observable to the naked eye, and permit the student to make numerous observations on the organism under examination.

As micro-organisms are omnipresent, some can always be obtained with which to make experiments, but the methods for getting few enough to start with and their subsequent culture require the preparation of vessels and media free from organisms, and means of growing the organisms at a slightly elevated temperature—viz., 36° to 37° C.

To illustrate some of the requirements and methods let us take seven 4 oz. flasks and proceed with some simple experiments, as follows:—

Make a quart of fresh infusion of gentian and let it cool in the pot. Number the flasks, and then into—

No. 1 pour about 3 oz. of the infusion, and put it aside uncovered;

No. 2 pour about 3 oz. of the infusion, then boil it, and put it aside uncovered;

No. 3 pour about 3 oz. of the infusion, boil it, and afterwards plug the neck with cotton wool, and then put aside;

No. 4 pour about 4 oz. of the infusion, then boil it, plug with cotton wool as before, and put aside for twenty-four hours, then bring it just to the boil again on two successive days, removing the plug and re-inserting it each time;

No. 5 pour about 3 oz. of the infusion, add 1 grain of salicylic acid, plug with wool and set aside;

No. 6 pour about 3 oz., and add ʒss. liq. hydrarg. perchlor., plug with wool and set aside;

No. 7 place about 4 oz., and plug with wool, then put it in a warm place where the temperature is about 37° C. or 97° Fht.

Place all the first six flasks in a warm place together where they will be exposed to the same conditions, and the following observations may be made after a few days:—

Flask No. 1.—The contents will soon become cloudy, and probably the surface covered with moulds. The changes will have been brought about by the organisms attached to the particles of dust floating in the air or by organisms already present in the flask when the infusion was placed in it.

Flask No. 2 will remain clear and fresh for longer than No. 1, but the dust in the air will soon contaminate the infusion, and growths will soon appear or cause the infusion to "go wrong."

Flask No. 3 will remain good for several days, but will eventually go cloudy, owing to the development of spores, which were not destroyed by at once boiling the infusion.

Flask No. 4 will keep indefinitely, and if the cotton wool plug is singed the contents of the flask will keep for a very long while, for all the organisms have been killed by repeated boiling.

Flask No. 5 will keep good for some weeks, showing the preservative action of the salicylic acid, but moulds will develop eventually.

Flask No. 6 will probably become turbid, owing to the precipitation of some of the albuminoid matter by the mercury, but the solution will remain free from organisms for a long time, showing the germicidal action of the mercuric chloride

Flask No. 7.—The contents will "go wrong" very quickly, probably in twenty-four hours, due to the rapid development of organisms at the warmer temperature.

These experiments show the presence of organisms in the air, and indicate how they may be killed or kept out of the infusion, also how their growth may be retarded by antiseptics, hastened by

warmth, or prevented by a germicide, and give the student an elementary idea of the nature of the work before him.

To be enabled to examine organisms and grow them rapidly an incubator is necessary, for otherwise the examinations would take too long; and in order to incubate cultivations at a uniform temperature some means must be devised for maintaining the proper degree of warmth. To do this satisfactorily one of Hearson's Incubators is perhaps best, but with a little ingenuity a beginner can easily make a warm cupboard which will answer all his purposes. Before making anything, however, it would be well to make a tour of inspection in the house, for often there is a cupboard warmed by the hot water supply for the bath-room, or a drying cupboard, in which the desired temperature may be maintained without any effort. If no such convenience is at hand the following is a cheap way to improvise an incubator (Fig. 2):—

FIG. 2.—AN IMPROVISED INCUBATOR.

Get a stout box with a good hinged lid, and fix it up against a wall like a cupboard. Drill a number of holes in what is then the bottom; cover the outside of the bottom with tin; on the bottom inside place a tin tray, about 2 inches deep, and covered with sand, and in it stand two bricks; on the bricks and inside the box fit another box, with a lid, only a size smaller, leaving an inch or two all round in between the sides; in the top of the outer one drill a small hole for ventilation. On a shelf a little way beneath the whole place a small paraffin lamp; and, having placed a thermometer inside the inner box, notice at what height the wick of the lamp must be kept in order to maintain the temperature at 37° Centigrade. The temperature will not remain constant, but its construction will not allow it to radiate much heat, and its average

temperature may always keep about what is required with a little attention.

So much for an improvised incubator. It is a simple contrivance only, and does not compare with one sold by Messrs. Hearson for £8 8s. ; but when the uses of the simple one are appreciated it will be time to purchase the other.

The Hearson's incubator (Fig. 3), depicted below, is the form most generally used in small laboratories, and is a neat-looking piece of furniture. The temperature is wonderfully constant, even in winter, and, provided the lamp is kept clean, there is no odour from it at all.

FIG. 3.—HEARSON'S INCUBATOR.

Next for some means of sterilising apparatus for use in the experiments. First of all it is necessary to have something to sterilise with by means of dry heat. All flasks, bottles, and dishes which are to be used must be carefully washed, and although in a laboratory it is best to have a hot air steriliser, yet a student can generally make the kitchen oven answer all his purposes, provided it is quite clean. After the apparatus is washed and drained it can be heated in the oven for an hour at a moderate heat, and that suffices to kill all organisms which may happen to be present.

Sterilisation will be dealt with more fully later on, but some word must be said about a steam steriliser before closing this column.

Culture media such as broth, gelatine, jelly, and agar agar jelly, cannot be safely sterilised in a hot oven, so a steam steriliser must be made or obtained. For economy's sake it is best to let a tinsmith make a vessel (Fig. 4) on the following lines:—

A circular tin vessel, about 12 inches in diameter, and 24 inches deep, with a loosely-fitting cover. At about 8 inches from the bottom is fitted a ledge, on which rests a wire netting shelf.

To use the apparatus it is filled with water to a depth of 6 inches, placed on a tripod, and the water boiled over a gas stove or bunsen burner. Anything to be sterilised is placed on the wire netting in the steam, and allowed to stay there for thirty to sixty

minutes. Test tubes and small tubes and flasks can be stood in small crates on the netting.

The foregoing remarks will give a little insight into the possibilities of interesting and instructive work for students, and subsequently articles under this heading will deal with the following parts of the subject:—Methods of sterilising and working, preparations of culture media, varieties of organisms, how to stain and mount specimens, simple cultivation experiments.

FIG. 4.—A SIMPLE STEAM STERILISER.

BHAMO VISITED BY A PHARMACIST.

BY FREDERIC S. MASON.

Even a drug traveller wants a change sometimes, and more especially after months of wrestling with native buyers in the bazaars. So for Christmas week I went to Bhamo, not with my usual commercial instincts (although fifteen years in the East had made me secretly hope to find business even in this end-of-the-world sort of place), but for rest!

Bhamo has long been the objective centre of the trade filtering through the mountain passes of Western China (Yunnan) to the head waters of the Irrawaddy, that wonderful stream coming from an ill-known source, and fertilising the rich plains stretching nearly one thousand miles from the snow mountains of Western China and the unknown country due north from Rangoon to the sea.

As a stepping-stone to trade with China, much has been, and is still hoped for, by the Indian Government; and to inquire into the possibilities of a trade in drugs was a task I imposed on myself, while resting and seeking health on the Irrawaddy steamboat.

It is useless to give a description of the very fine and interesting scenery of the Irrawaddy, as so many books have been written on the subject of the fascinating country and people of Burma by competent authorities. I shall try, therefore, to confine my observations to points of interest to pharmacists.

As soon as Mandalay is left behind, the golden pagodas—such a constant and almost tiresome feature of lower Burma—become

rarer, and when the second defile beyond Katha is passed, it is only here and there that one bright spire, and, perhaps, a golden shrine of Buddah, shines out amongst a few old mouldy ones, richly decorated with orchids and other parasites. The villages become wretched, and the people are no longer Burmese, with clean bright-coloured silks (for even one's coolie girls, who carry the luggage to the steamer, wear silk as far up as Sagaing).

The Burmans are here replaced by dirty Shans, with wide blue trousers, immense sun hats, which serve as umbrellas, and blouses, who seem to be born tired, and to have never got properly rested by lying (as they do all day) on the floors of their huts, amidst the ancestral slime of generations. This proved to be a foretaste of Bhamo! The town itself and its surroundings are distinctly disappointing, and beyond a white bell-shaped pagoda, and a fine carved Chinese temple, there is nothing whatever to see of interest.

Although there is a large resident, and, at certain seasons, a still larger floating population of Shans and Chinese, the jolly Burman is almost as much a foreigner as the troops stationed here. The great bulk of the population is made up of the Shans, Kachins, Palungs, and Meinthas, or Chinese Shans (Mahomedans), who come here with thousands of mules laden with produce, and take back kerosine, cotton, and other goods of European and American manufacture, but little or no medicines beyond opium for smoking. A good many of these Meinthas—wild, fierce-looking chaps they are—armed with great "dahs," go down to Katha, and from there to work in the ruby and jade mines, and when the Government allows the immense mineral resources of Upper Burma to be opened up by Europeans (which cannot be done at present), they will form a most valuable aid, as they are hardy and industrious, whereas the people from the Shan hills, the Kareens, Kachins, and similar tribes, are without ambition of any kind. As an opening for pharmaceutical enterprise, therefore, I cannot recommend Bhamo as a field for any young enthusiast. There is a civil hospital, in charge of the military surgeon, but no chemist (native or otherwise), although all sorts of medicines, such as Epsom salts, carbonate of soda, and such specialties as santal midy and chlorodyne are sold almost in every shop in the bazaar, and I may add with some satisfaction that I found quite one-third of the pharmaceuticals exposed for sale bearing the name of our firm.

The merchants are mostly Chinese or natives of India, and there is that peculiar smell peculiar to Indian bazaars, combined with that equally peculiar Chinese smell, so that exploration amongst these dirty-holes-in-the-wall is not inviting. I was shown large quantities of orpiment, beeswax, and fine white honey, packed in a sort of paper bag, which fits over the mule's back, and thus travels hundreds of miles over the mountain passes. Considerable trade is done, however, but the big Chinese merchants are in Rangoon—the men here are mostly simply forwarding agents—so that no musk or any articles of value could be found. I took some pains to talk with some of the leading Chinese merchants' agents—my conversation in very poor Urdu being translated into Burmese, and then into the Yunnan dialect of China—in order to learn what could be expected from the security enjoyed for trade under British rule. A boundary commission is now at work, and will probably stretch this as far as possible. I learned that prospects were not very encouraging, the Kachins, Northern Shans, Kareens, and similar tribes were unlike the Burmese, who are splendid buyers, and love every modern luxury and comfort of civilisation. These people, while perhaps not so poor and wretched as the English lower classes living from hand to mouth in the slums of London, have been so long without what we consider the necessaries of life, and seem to live on fresh air, and things of that sort so well, that they continue, without further ambition, to exist by privations, and while it is quite cold (5° C. in the morning), one sees babies and children, up to eight and nine years, quite naked, while the adult Zanpyaws (Eastern Kachins) wear girdles of twisted rattan round the waist only. With such races, generations of mis-

sionaries could hardly make any progress (except with the most degraded, such as the Kareens), as they are Buddhists or Mahomedans, who cannot be converted unless cast off by their own people for crime.

Agam, the people (unlike the Burmese and Indian races) have not developed a civilisation of their own which can be "canalised," as has been done with these higher races of India for the benefit of trade, so that without wants or aspirations beyond a bare existence, little is to be hoped of them for many many years.

With the energetic and hardy Meinthas from Chinese territory something might be done if they could be got to settle in the country, but at present they are simply wandering traders, and many years must pass before they can be educated into buying medicines.

As a holiday jaunt, a more delightful trip cannot be taken, and the wonderful mingling of races in this remote corner of the East is in itself well worth the visit, but as a permanent residence I can understand the military aristocracy of India's dread of it as a station, and their devotion to tennis, polo, and sports, which is so plentiful in the hills.

STUDENT LIFE IN THE QUARTIER LATIN.

AS IT APPEARS TO A PHARMACIST.

The Latin Quarter of Paris! Mysterious to the stranger, loved by the initiated, rarely deserted from October to July by the thousands of students who revel in its delights. Here these young men, representative types of nearly every civilised nation in the world, are perfectly "at home," which means that they are free to do as they like, to come and go as they like, to dress as they like, but always according to respected traditions. With the long hair streaming down over their shoulders, hats of curious shape well back on the head that the front hair may fall in a matted fringe over the forehead, trousers "elephant"—i.e., shaped like piano-legs, the flowing necktie, they reek of picturesque untidiness. They have their clubs, and good ones, too, where the more studious may pass their time in tolerable tranquillity, while for the others the "Quartier" makes the evenings one long enchantment.

From dinner till early morning, the cafés of the "Boul. Mich.," as the Boulevard Saint Michel is familiarly known, are full of members of the medical and art student world and the strangers who come to "look on," while on "Bal Bullier" nights dancing is kept up late, and, of course, everyone comes home with the milk. Nearly all are young men of small, if any, means, and such of them as possess a fair amount of the needful are soon taught how to spend it. Among them are serious youths, for, as a rule, the students study, although the silent onlooker would scarce think them capable of aught but noisy frolicking.

But the painter! In ninety-nine cases out of a hundred his artistic temperament forbids work. The medical student has a definite purpose. He studies for a profession, and hopes some day to establish himself and have a lucrative practice. The case of the painter is settled in advance, is generally hopeless, and he knows it. He loves to wander about, paint-box in hand, a canvas under his arm. He loves to think he is going to be a great artist. In winter he frequents the day and night schools, where he can be warm, where he can have models, dressed and undressed, and where once a week a man of renown will pass a "mauvais quart d'heure" in trying not to tell him what a fool he is.

Then he'll fling palette and paint-brush *au vent*, and, descending his dark and narrow staircase, will hie himself in search of amusement in company with his medical chums. A question often asked is: How do all these students live? Their rooms are barely furnished. A couch serves as a lounge by day and a bed by night; a cheap washhandstand, one or two chairs, some linen, all usually borrowed or hired, make up their little paradise. They get their meals at one of the thousand and one cheap restaurants, where they usually pay cash at first, then pay monthly, then only half

each month, and finally forget to pay at all. But, taken big and large, the student as a rule is honest. The medico is, if anything, a trifle less scrupulous than his chum the art student. The latter idles away his time in his own lazy way, amusing himself by thinking he is looking into the "soul of art," and in postponing his current debts, because otherwise he would have no pocket money. This he must have, or he could not occasionally stand treat to the girl models of his acquaintance; and the nip of absinthe is so necessary to put fresh life and vigour into the jaded palette!

One of the best and most celebrated of these "creameries" is kept by Madame Charlotte, 13, rue de la Grande Chaumière. She has friends all over the world and has saved many a worthy and unworthy student in his days of dire distress. In this short and noisy street she has succeeded in creating a pleasant little restaurant, where rich and poor may safely eat, and where everyone admires her attractive face, the beauty of which is not diminished by her fifty years of toil. Her only child resembles her sufficiently to guarantee his origin. She has brought him up herself and provided him with a good education. Her husband was a quantity to be neglected, for he left her early penniless and with this one child. How many women succeed under such conditions? Now she can show you the fruits of her hard toil, the fruits of a life so honest and upright that the odour of it is simply refreshing—the work of a woman who, after all her trials, can look you in the face and say: "I never did wrong to anyone." And it is she whom the students worship, and call "Mother," 'tis she to whom they flock for counsel and for money, and she freely bestows both, and never by any chance refuses either. She deserves to be thusly styled, for she cares for them all as though they were her own brood. Many a student has had a free meal at her board when he has been penniless. She has even paid their washing, their rent, and for their clothes also. She sometimes gets some of it back, but not always. Frequently these youths come to her, crying: "Oh, Madame Charlotte, you alone can save me, I must have some money, they send me none from home!" And again she lets loose another 500 francs into the everlasting gulf. The student is saved for the time being; her inability to say No! and her generous disposition have helped another waster of time over the stile. The courage of the woman is much to be admired. She has an indomitable will. It is probable that in no country but France are women found who, being of the people and without education, have succeeded, not only in securing a competence, but have developed in themselves a keen desire to do good—for themselves and others. Such a good and merry soul is Madame Charlotte; she keeps a bed or two at the disposal of any sick student of her acquaintance, because "they can be better taken care of here than in hospital, and when they are sick they are so lonesome far away from home," she touchingly remarked.

After the 1900 Exposition is over, she intends to take one short year to wind up her affairs, and will then retire to her native land in Alsace-Lorraine. Paris will then lose another of its notabilities, who, in a humble way, has done much to make its life easier, cheerier, and more lovable. She will not be forgotten for many a day; no one can exactly take her place, and many a struggling young woman, many a penniless student will wish again and again that good old Madame Charlotte were still in the Quartier Latin to dole out her motherly counsel, to strengthen them in their despairing hours, to feed them, keep them and care for them "in sickness and in health."

SODIUM ETHYLATE IN MOLLUSCUM CONTAGIOSUM.—T. F. Raven has found the application of sodium ethylate thoroughly satisfactory in a case of molluscum contagiosum. The ethylate was applied directly to the growths, and was most successful when not covered by any protective plaster.—*B. M. J.*, 1/1900, 16.

NOTE ON THE DETECTION OF SULPHATES IN PRESENCE OF THIOSULPHATES.*

BY LEONARD DOBBIN, PH.D.

In the determination of sulphuric acid by precipitation and weighing as barium sulphate, it is well known that accurate results cannot be obtained in presence of any considerable quantity of certain salts, on account of the influence which the latter exert in preventing the complete precipitation of the barium sulphate. Nitrates, in particular, are known to produce this effect; and for this reason hydrochloric acid is employed in preference to nitric acid to acidulate the solution to be precipitated, and the precipitation is effected by the addition of barium chloride, rather than of barium nitrate.

The striking effect of the presence of thiosulphates in likewise interfering with the precipitation of barium sulphate is not by any means so well known, and, so far as I have been able to ascertain, it is not referred to in any of the standard text-books of qualitative or quantitative analysis.

In ordinary qualitative examination for sulphate and sulphite, or either of them, in the known presence of thiosulphate, it is customary to add barium chloride to the dilute neutral solution, to filter off any precipitate that may be formed, and to examine the latter, after thorough washing, for sulphate and sulphite. The filtrate and washings contain the thiosulphate. This method, even when carried out with care, may entirely fail to reveal the presence of sulphate when the latter is only present in small quantity along with a moderate quantity of thiosulphate; because if the thiosulphate preponderate sufficiently, there will not be any barium sulphate precipitated, even after the lapse of a considerable time.

In order to illustrate clearly the risk of error that exists in such a case, the following solutions may be employed:—

(A) Decinormal Sodium Thiosulphate solution

(B) Sodium Sulphate solution of the same sodium concentration as solution (A)

(C) Decinormal Barium Chloride solution

EXPERIMENT I.—(a) 100 C.c. of A and 4 C.c. of B are mixed in a beaker; (b) 100 C.c. of water and 4 C.c. of B are mixed in another beaker; (c) 1 C.c. of C is then added to the contents of each beaker.

A precipitate of barium sulphate is immediately produced in the solution which contains sulphate alone. In the solution containing thiosulphate and sulphate there is no precipitate, even on standing for some time, although the quantity of sulphate approximates to four per cent. of the total salts present. After prolonged standing, partial precipitation does take place in this solution also.

The solubility of barium sulphate in dilute nitric acid is also remarkably increased by the presence of a moderate quantity of dissolved thiosulphate. To illustrate this, the standard solutions already described may be employed.

EXPERIMENT II.—(a) 10 C.c. of A, 10 C.c. of water, and 1 C.c. of B are mixed in a beaker; (b) 20 C.c. of water and 1 C.c. of B are mixed in another beaker. (Each beaker contains the same quantity of sulphate in the same volume of solution.) (c) A small quantity of C is added to the contents of each beaker, and a precipitate is quickly formed in each. Then 20-30 C.c. of dilute nitric acid (20 per cent.) are added to each, when the precipitate in the beaker containing the thiosulphate slowly but completely dissolves. There

* Read at an Evening Meeting of the Pharmaceutical Society in Edinburgh, February 21, 1900.

is not any perceptible diminution in the quantity of the precipitate in the other beaker. At the temperature at which this experiment was tried (10° C.) the interval between the addition of the nitric acid and the first appearance of a precipitate of sulphur, due to the decomposition of the thiosulphate, was at least two minutes; and the barium sulphate precipitate had entirely disappeared some time before any sulphur was precipitated. It is possible that at a somewhat higher temperature the experiment may not succeed without further dilution to retard the decomposition of the thiosulphate.

I have only been able to find two references to the interference of dissolved thiosulphate with the precipitation of barium sulphate. One is in a paper by Fresenius*, in which the effect of a strong solution (25 per cent.) of sodium thiosulphate is mentioned as preventing its precipitation, and as thereby explaining certain discrepancies observed in a quantitative separation of baryta from lime, which is there under review. Fresenius does not refer there (nor elsewhere, so far as I have been able to ascertain) to the bearing of the matter upon qualitative analysis, nor does he enlarge upon it in any way. The other reference occurs in a paper by Salzer† upon the determination of iodine; and there, also, no remark is made about the bearing upon qualitative analysis.

The detection of a small quantity of sulphate in presence of much thiosulphate nevertheless presents considerable difficulty. One method would be to convert all the thiosulphate into tetrathionate by adding an excess of a solution of iodine in potassium iodide (which must be free from traces of sulphates), and then to add barium chloride (Salzer). But the detection of sulphate could probably be best accomplished by employing the method devised by Grossman‡ for quantitatively determining sulphate in presence of sulphite and thiosulphate. In this method the solution is placed in a suitably-fitted flask, the air is displaced by means of carbonic anhydride, and the liquid is heated. Excess of hydrochloric acid is added, and the liquid is boiled down to one-fourth of its original volume, a current of carbonic anhydride being passed into the flask all the time. The whole of the sulphurous anhydride set free is carried off by the escaping carbonic anhydride and water vapour. The liquid remaining in the flask is filtered from the separated sulphur, and the sulphate remains in the filtrate, where it can be detected and, if desired, quantitatively determined.

POTASSIUM ARSENATE§.

BY JOHN LOTHIAN.

Of the three potassium salts of orthoarsenic acid, K_3AsO_4 , K_2HAsO_4 , KH_2AsO_4 , the latter, or mono-potassium arsenate, is the only stable one.

There is very little information concerning this salt in English works. It is briefly mentioned in Watts' 'Dictionary of Chemistry.' It is more fully described by Hager ('Handbuch der Pharmaceutischen Praxis') and by Alessandri ('Manuale del Farmacista').

It is most readily prepared by fusing at a low red heat in a porcelain crucible a mixture of equal parts of dry potassium nitrate and arsenious anhydride, when cold dissolving the fused mass in water, evaporating and setting aside to crystallise. The reaction may be represented by the following equations, potassium metarsenate being formed, which, on solution, is converted into mono-potassium arsenate.

The salt crystallises out in dimetric octohedra. The crystals are anhydrous and permanent in air, have an acid reaction, are soluble

in about 5 parts of water and almost insoluble in 90 per cent. alcohol. They contain 63.8 per cent. As_2O_5 .

I examined two samples, one bought and the other prepared by myself. The powdered crystals dried for several hours at 105° C., only lost 0.1 per cent., a trace of interstitial moisture. I determined the As_2O_5 by precipitating as ammoniomagnesium arsenate, washing with ammonia water, igniting to magnesium pyroarsenate in a current of oxygen, and weighing.

The result of two determinations agreed exactly, and on adding the correction for wash water accorded closely with the theoretical requirement. I did not find the method of determination by weighing as ammonio-magnesium arsenate satisfactory, as the precipitate so rapidly absorbs moisture when removed from the drying oven.

The As_2O_5 can also be accurately determined volumetrically by means of uranyl acetate solution. 1 C.c. uranyl acetate solution, standardised to represent 0.005 P_2O_5 , is equivalent to 0.00809 As_2O_5 .

I found the solubility of the salt in water 20.72 grammes in 100 grammes of solution at 15° C.

I made the following observations while preparing monopotassium arsenate from arsenic acid.

When arsenic acid is neutralised by potassium bicarbonate (I used the bicarbonate as purer than the carbonate or hydroxide) the salt K_2HAsO_4 exists in solution. On evaporation, however, crystals of KH_2AsO_4 are deposited, and as the crystallisation proceeds the mother liquor becomes very alkaline. If the mother liquor is now neutralised with more arsenic acid a fresh crop of KH_2AsO_4 crystals is obtained, and the mother liquor again becomes alkaline.

This is explained by the hydrolysis of the K_2HAsO_4 in solution.

On evaporation the equilibrium is upset by the greater stability of the dissociated molecule KH_2AsO_4 (the salt K_2HAsO_4 does not crystallise), which, although an acid salt, crystallises out in the presence of the alkali.

Similarly, when arsenic acid is neutralised by sodium bicarbonate, the salt Na_2HAsO_4 is formed, and may also be assumed to exist in solution hydrolysed. $Na_2HAsO_4 + H_2O = NaH_2AsO_4 + NaOH$. On evaporation, however, the salt $Na_2HAsO_4 \cdot 7H_2O$, or $12H_2O$, continues to crystallise out, a reassociation of the dissociated molecules taking place, owing to the greater stability of the salt Na_2HAsO_4 .

I consider that the hydrolysis of the sodium arsenate is the correct explanation of the deposition of the strychnine in the liq. sodii arsen. and liq. strychninae hydrochlor. prescription discussed at the two previous meetings. In this case the equilibrium is upset in the opposite direction, the dissociated $NaOH$ being neutralised by the hydrochloric acid of the strychnine hydrochloride, strychnine deposited, and the salt NaH_2AsO_4 left in solution.

I mixed solutions of strychnine hydrochloride and sodium arsenate containing these salts in molecular proportions—that is, in the proportion of 403.7 parts of strychnine hydrochloride to 184.7 parts sodium arsenate anhydrous.

The strychnine, which was very rapidly deposited, was removed from solution by filtration and repeated agitation with chloroform. The solution, on examination, was now found to be acid in reaction and to contain the salts $NaCl$ and NaH_2AsO_4 .

METHYL SALICYLATE AS AN ANTISEPTIC DRESSING.—Gallois has found that the local application of methyl salicylate is a most effectual method of treatment for furunculosis, ulcerated legs, and contused wounds. A few drops of the liquid are applied directly to affected part, which is then covered with a linen bandage and gutta-percha. The first application gives rise to a little discomfort, but subsequent dressings are painless. The only objection to the use of the drug is its powerful odour.—*Bull. gen. de Therap.*, 128, 657.

STRYCHNINE HYDROCHLORIDE AND POTASSIUM ARSENATE.*

BY J. RUTHERFORD HILL.

While working at the subject treated in my last communication (*Pharm. Journ.*, page 45) I came across references to the salt KH_2AsO_4 , but the information regarding it was very meagre. Mr. Lothian drew my attention to the fact that the commercial salt was the dihydrogen potassium arsenate. Reasoning from the results obtained with sodium arsenate and the equation showing the result of interaction between it and strychnine hydrochloride in aqueous solution, and observing that potassium arsenate gave an acid solution with water, it occurred to me that it would not cause precipitation of strychnine from liquor strychninæ hydrochloridi. When proceeding to dry the salt, in order to make a 1 per cent. solution, I observed very faint evidence of any water of crystallisation. Half an ounce of liquor potassii arsenatis (1 per cent.) was mixed with half an ounce liq. strychninæ hydrochloridi. A similar mixture was made, substituting a 1 per cent. aqueous solution of strychnine hydrochloride for the official liquor, which contains 25 per cent. of alcohol (90 per cent.). In both cases the solutions were perfectly clear, and have remained so for more than a week. There is not the slightest indication of any precipitate. On washing out the mixture with chloroform it was found that in the case of the purely aqueous mixture 0.3 grain, and in the case of the mixture containing alcohol 0.34 grain, had been dissolved out, using about four separate fluid drachms of chloroform in each case. This was a surprise, as, theoretically, it seemed as if no alkaloid should have been washed out. It was found, however, that by washing out half an ounce of aqueous liquor strychninæ hydrochloridi with a similar quantity of chloroform 0.38 grain had been dissolved out. The above residue was neutral to litmus, soluble in water, gave the reactions for strychnine hydrochloride, and, as is shown by a later experiment, was due to the solubility of strychnine hydrochloride in chloroform. The residue from the mixed solutions of strychnine hydrochloride and potassium arsenate, which, it will be noted, was smaller in quantity, consisted of free alkaloid with a trace of arsenate, indicating that the solution probably contains strychnine arsenate, and that the free alkaloid is obtained by slight decomposition of the arsenate by the chloroform, as is indicated in a later experiment.

It will be seen from the foregoing that the dispensing difficulty dealt with in Mr. Dunlop's note (*Pharm. Journ.* [4], vol. ix., page 604) is entirely obviated by using a solution of potassium arsenate instead of sodium arsenate. It is rather curious that the former salt appears to have received so little attention, at least, in this country. I am told it is used in homœopathic medicine, under the name of kali met., in the form of a dilute solution, but beyond that it does not appear to be used in British medical practice. One object of this note is to suggest that it should be inserted in our Pharmacopœia instead of sodium arsenate. It possesses several advantages. It is always anhydrous, and the necessity for drying and liability to variation on this ground in the case of the sodium salt are avoided. It is very stable. When heated to about 400° C. it undergoes no change beyond fusing into a glassy mass of metarsenate, which yields KH_2AsO_4 again when dissolved in water. Its acid aqueous solution has a much wider range of compatibility than the alkaline solution of the sodium salt. It contains 41.6 per cent. of arsenicum, as compared with 40.23 per cent. in the anhydrous sodium salt. The dose of a 1 per cent. solution would therefore be practically the same. The 1 per cent. of moisture helps the approximation.

It may also be well worth considering whether a liquor potassii arsenatis might not take the place of all the three 1 per cent. arsenical solutions, including the old liquor arsenicalis and the liquor arsenici hydrochloricus. The strongly alkaline and acid characters of the latter respectively are often a disadvantage and apt to be forgotten by prescribers. Liquor arsenicalis is said to

lose arsenic occasionally by precipitation on standing. Both solutions are more difficult to prepare, and more liable to error in process of making, than a liquor potassii arsenatis would be. The presence of compound tincture of lavender in liquor arsenicalis protects by colour and odour against the danger attending the use of a clear water-white arsenical solution. It has often occurred to me that this was a danger attending liquor arsenici hydrochloricus and liquor sodii arsenatis when dispensed alone as drops. For this reason it is suggested that the liquor potassii arsenatis should be coloured and perfumed before being sent out when dispensed alone. Compound tincture of lavender is not available for this purpose because the colouring matter of the red sandal wood is precipitated, being only soluble in an alkaline solution. Tincture of cochineal may be used instead. It has about eight times the tinctorial power of compound tincture of lavender. An imitation of liquor arsenicalis can therefore be made by adding to tinct. cocci, B.P., the same proportion of ol. lavand. (45m to ʒxx.) and ol. rosmarini (5m to ʒxx.) as is contained in tinct. lavand. co. Of this tincture add ʒ8 minims to each pint of liquor potassii arsenatis, or about 2 minims to each ounce. Some may think double this quantity not too much. A very pretty coloured liquor can be made by adding 5 minims of a 1 per cent. solution of fuchsin to each pint of liquor and perfuming with ol. lavand. The quantity of volatile oil in both these liquors is considerably less than in liquor arsenicalis, and this is an advantage, patients sometimes complaining of nausea, caused by the presence of the volatile oils in the present liquor.

This suggestion raises an important point as to the relative toxicity or therapeutic value of the arsenious and arsenic compounds. On this point I am indebted to Professor Stockman, of Glasgow, for the following references. The comparatively mild action of arsenates as compared with arsenites and arsenious anhydride is noted by Garrod in his 'Essentials of Materia Medica.' The matter is also very fully treated by Ringer and Sainsbury (*British Medical Journal*, 1882, vol. ii.), and also by Jones (*British Medical Journal*, 1885, vol. ii., page 99). It seemed probable that the reducing action of arsenious anhydride might materially modify the therapeutic action, but Husemann (*Deutsche medicinische Wochenschrift*, 1892) says oxidation of arsenites to arsenates in the body has never been demonstrated. He also says that the amount of arsenicum in arsenic and arsenious oxides is as 2 to 3 (6 to 7 is more correct), and that the relative toxicity in mammals is as ½ to 1. The whole tendency of the evidence seems to be that arsenious and arsenic compounds do not differ specifically, but only in degree, in therapeutic action, and that the arsenic in the "ous" condition is about twice as active as in the "ic" condition. Why arsenates are only about half as poisonous as arsenites has never, apparently, been explained. They are constantly prescribed indifferently in the same maladies, and if the above is correct the substitution of liquor potassii arsenatis for liquor arsenicalis and liquor arsenici hydrochloricus involves nothing more than an adjustment of dosage to secure identical results. But this latter point is obviously more in the department of the pharmacologist than the pharmacist. There can be no objection to its taking the place of liquor sodii arsenatis. The solution need not be coloured, when dispensed in a mixture with other ingredients. Should the salt receive official recognition, the following, based on Mr. Lothian's results, would be suitable as

CHARACTERS AND TESTS.

In colourless dimetric octohedral crystals, anhydrous, permanent in air, soluble in 5 parts of water, and yielding an acid solution; almost insoluble in alcohol (90 per cent.). A solution of 1 gramme of potassium arsenate, with 1 of glacial acetic acid, in 50 C.c. of water, should require 2.10 grammes of lead acetate for complete precipitation. The powdered crystals should not lose weight more than about 1 per cent. when heated to 300° F. (148.9° C.) (limit of interstitial moisture). The other characters are similar to those applying to sodium arsenate.

* Read at an Evening Meeting of the Pharmaceutical Society in Edinburgh, February 21, 1900.

STRYCHNINE SALTS AND CHLOROFORM.*

BY J. RUTHERFORD HILL.

While working on the topic of strychnine hydrochloride and potassium arsenate, some interesting notes were made on the action of chloroform on various salts of strychnine. They are imperfect, but may be of interest and suggest lines of enquiry for others who may have time to follow up the work. As already mentioned, when $\frac{1}{2}$ oz. of a 1 per cent. neutral aqueous solution of strychnine hydrochloride was washed with four fluid drachms of chloroform 0.38 grain of strychnine hydrochloride was dissolved out and separated by the chloroform. That indicates that the chloroform which separated contained about 1 of strychnine hydrochloride (anhydrous) in 868 parts. When 10 minims of dilute hydrochloric acid was added before washing out with chloroform, 0.71 grain was removed, equal to 1 in 460 parts. When large excess (5ii.) of dilute hydrochloric acid was added the chloroform removed 1.48 grain, equal to 1 in 220 parts of chloroform. An excess of the salt strychnine hydrochloride was left in contact with chloroform for several hours at 15° C., with frequent agitation, and filtered. 12.396 Gm. of the resulting chloroformic solution left on evaporation 0.073 Gm. of strychnine hydrochloride. Therefore 12.323 Gm. of chloroform dissolved 0.073 Gm. = 1 in 169. The residue was neutral, soluble in water, and, when treated with excess of ammonia and washed out with chloroform, yielded 0.050 of alkaloid. 0.073 of $C_{21}H_{22}N_2O_2HCl$ require 0.066 of strychnine, a difference of 0.016. The residue was, therefore, evidently $C_{21}H_{22}N_2O_2HCl$. Probably it was not quite anhydrous, and that may account for the small discrepancy between the amount actually found and that required by theory. It was thought that possibly the alcohol in official chloroform might have something to do with the solution of the strychnine hydrochloride. But assuming that it contains 1 per cent. of absolute alcohol that would not dissolve more than about 0.067 grain of strychnine hydrochloride for each zss. of chloroform, and that does not account for the solubility of the salt in chloroform.

At last meeting Mr. Cowie suggested that chloroform decomposed strychnine arsenate, removing the alkaloid. When aqueous solution of strychnine arsenate is washed out with chloroform the residue from the separated chloroform is very small, and seems to consist of free alkaloid with a faint trace of arsenate. The remaining solution is acid. When dry strychnine arsenate was left in contact with chloroform, and the latter filtered off, it was found that 15.3 Gm. of chloroform had dissolved 0.013 Gm. = 1 in 1178. This residue was alkaline and appeared to consist of free alkaloid with a quite perceptible proportion of arsenate. The remaining salt was distinctly acid apparently from the presence of free arsenic acid. It thus appears that chloroform does decompose arsenate of strychnine, but only to a very small extent at 15° C.

When aqueous solution of neutral strychnine sulphate ($C_{21}H_{22}N_2O_2H_2SO_4$) is washed out with chloroform there is a residue which appears to consist mostly of free alkaloid, and the remaining solution is acid. It would seem that some alkaloid is removed with formation of the more soluble acid sulphate. When neutral sulphate of strychnine was left in contact with chloroform it was found that 10.551 Gm. of chloroform dissolved 0.010 Gm. = 1 in 1055. The residue was mostly neutral sulphate with a little free alkaloid, indicating probably that acid sulphate is partially formed.

When an aqueous solution of acid sulphate of strychnine, $C_{21}H_{22}N_2O_2H_2SO_4$, is washed out with chloroform a very small and negligible quantity is removed. When there is distinct excess of sulphuric acid practically nothing at all is removed. The bearing of this on the official process for standardising fluid extract of nux vomica will be obvious. When the dry salt was left in contact with chloro-

form it was found that 14.231 Gm. of the latter had dissolved 0.005 Gms. = 1 in 2846. This gave a distinct reaction for sulphate but was neutral, and appeared to be the neutral and not the acid sulphate. The remaining salt was very strongly acid.

The bearing of the foregoing on a very common method of analysis in dealing with alkaloids, such as strychnine, is obvious. That method is based on the dictum that while the alkaloid strychnine is freely soluble in chloroform, its salts are insoluble. It will be well to bear in mind that the dictum is only true to a limited extent, and so far as these notes show applies strictly only to the sulphate when a distinct excess of sulphuric acid is present.

COMMERCIAL EDUCATION FOR PHARMACISTS.*

BY H. W. RIETZKE.

"He couldn't make money even in the drug business." This quotation was often used in the past to show that if a man could not succeed in any other line he could still get along in the drug business. Such is not the case at the present day. Competition is far keener than ever, not only between druggists, but the keen and ruinous competition of the department store, whose business is watched with an attention as close as that which the engineer gives to pressure of the steam and the number of revolutions of the screw on a record-breaking ocean voyage. In this state of facts every possible mode of promoting the commercial success of the pharmacists in the fierce competition which we witness begins to be studied and discussed. One such mode is the cultivation of the attitude and skill of the individual man, who is the ultimate factor in this competition.

Commercial education is a branch of technical instruction in general, and may be described as the branch of it which is concerned not so much with the methods of production as with the methods of distribution—that is to say, with the process of sale and purchase. It is concerned with them on their practical side. Years ago it was not supposed that any special commercial training was needed for the business of a pharmacist. Many men of good ability, who have had the best instruction money can buy, do not succeed, either in business, or in law, or any other line, because a host of other things besides ability and education are elements in success—industry, sobriety, steadiness of application, pleasant manners, social tact and knowledge of human nature, the power of inspiring confidence. This is especially necessary in pharmacy. All these things count for much in winning success. Some may fail for want of some of these gifts, but that is not deemed a reason for omitting to get all the knowledge needed. The power of rapid calculation, and especially of calculating without the aid of paper, is well applied to both sides of a pharmacist's work, and always profitable. The habit of observing quickly, keenly, and accurately, a habit precious in all walks of life. This, no doubt, is largely a natural gift; it is one which may be greatly improved by appropriate training, and may be trained from very early years. The mental habit of reflection on facts observed is a faculty and habit of the utmost utility to practical pharmacy.

We should arrange our business with the understanding that it is to be our life work, trying to establish it so firmly in our younger years that it will run itself when we will want to shift some of the burden. The question is, can we do this unless we sell goods at any other than market prices? It is true we have not the great variety of stock of the department store, but is it not also a fact that we have not nearly so large an expense roll? I trust you will not form a misconception of what has been said. This paper is not intended to argue on behalf of what is called a modern or non-classical education, holding that the success will be greater on account of a thorough and wide training in pharmaceutical colleges than to the provision which may be had for technical and commercial education; but claim that technical and commercial education succeeds in proportion to the soundness of the pharmaceutical education.

* Read before the Minnesota Pharmaceutical Association, and reprinted from the *National Druggist*.

INSECTS WHICH INFEST CRUDE DRUGS.*

BY W. A. KNIGHT.

Whilst zoology is not yet a separate subject in the Pharmaceutical Society's examinations, it is nevertheless necessary, for at any rate Major students, to have a passing acquaintance with the science, since they are required to have a knowledge of the microscopic structure of all organised drugs, amongst which must be included *Cantharis*, *Coccus*, and *Thyroid*, and hence I make no apology for introducing to your notice a zoological subject.

The preservation of drugs from the attacks of insects is a subject to which little or no attention has been shown in this country, although doubtless every retailer loses a certain amount every year from the depredations of these pests.

In attempting to fight these destructive creatures it is necessary first of all to know the habits and favourite food of the insect. Having acquired this knowledge the pharmacist will then be in a position to meet its attacks, and I therefore propose to-night to give a short classification of the large class of insects, indicating those which are specially harmful, and finally giving a few suggestions as to the remedies I have found most suitable.

The word insect is derived from two Latin words, *in*—in, and *secto*—I cut, the thorax being almost entirely severed from the abdomen by a constriction.

The word entomology has a similar meaning being derived from the Greek *εν*—in, and *τεμνω*—I cut.

The group of insects forms one class of the great phylum *Arthropoda*, which is distinguished by having a "metameric segmentation," or repeated appearance of similar parts. This segmentation is particularly well seen in the grub or larval stage of the Beetles.

A true insect is defined by zoologists as "An articulated animal breathing by tracheæ, divided into three distinct portions, *i.e.*, head, thorax, and abdomen—passing through a series of transformations, and having in the perfect or winged state six articulated legs and two antennæ." Although such animals as spiders and centipedes are usually included under insects, the above definition will show that they have no right to the title.

Fig. 1.

Book Louse, a species of *Atropos*.

Fig. 2.

House Moth, *Tinea pelionella*.

(4) Order Hymenoptera (*ὑμην*: membrane, and *πτερον*). This order includes the saw-flies, the gall-flies, ants, bees, and wasps.

(5) Order Heteroptera (*ἕτερος*: other, and *πτερον*). This comprises the water-fleas and bed-bug. The wings are partly leathery and partly membranous.

(6) Order Orthoptera (*ὀρθος*: straight, and *πτερον*). These insects have four wings, the anterior pair of which are leathery, the posterior pair folding longitudinally like a fan. The order includes the cockroaches, grasshoppers, and locusts.

(7) Order Neuroptera (*νευρον*: nerve, and *πτερον*). This order includes the beautiful dragon-flies and stone-flies. The wings are naked and reticulated with nerves.

While this classification will be found useful for obtaining the name and relations of the insect, from the pharmacist's point of view the only classification necessary is into harmless and injurious insects. Evidently only those insects which have strong biting mouths can deleteriously affect hard, dry drugs, insects with sucking mouths having a much more restricted baneful effect. To the former category belong the beetles and cockroaches, whilst the bugs and moths constitute the sucking insects. In some cases, *e.g.*, mites and ants, the mouth is adapted for both biting and sucking, and is hence injurious.

Although in the adult stage these sucking insects are harmless, many of them have, in the larval or grub stage, biting jaws and are hence injurious. A good example is the House-moth, *Tinea*

Fig. 3.

Sitrodrepa panicea.

Fig. 4.

Grub of *Sitrodrepa panicea*.

Fig. 5.

Ginger infested with *Lasioderma*.

pelionella (Fig. 2) which is quite harmless in the winged stage, but in the grub condition has a terrible combination of a tremendous appetite and sharp powerful jaws.

The most serious and common pests of a collection of drugs belong to the family Ptinidæ of the N.O. Coleoptera. They are cylindrical, pubescent insects, and eat anything and everything. They are responsible for worm-eaten furniture and many drugs. I have here a specimen of Pyrethrum attacked by this pest. The commonest member of this family is *Sitrodrepa panicea*, of which both the adult (Fig. 3) and larval (Fig. 4) stages are shown. A closely-allied insect is *Lasioderma*, the ginger beetle, and is often found in ginger (Fig. 5).

Another member of the Ptinidæ, *Bostrichus sp.* attacks sweet almonds.

An allied family, the *Cucujidæ*, furnishes a light-brown, flattened beetle with clubbed antennæ. It belongs to the genus *Silvanus* (Fig. 6), and is sometimes found in Senega root and Quince seed. The families Tenebrionidæ and Hesteridæ also have representatives among the pests. *Tenebrio obscurus* and *T. molitor* are dull-brown, flattish, square-bodied beetles with extremely hard elytra which are not easily pierced with a pin.

Several weevils—*Ceutorynchus sp.* and *Calandra oryza*—are also often found in seeds; the latter, as its name implies, infests rice, whilst the former is often found in maw seeds.

* Read before the Chemists' Assistants' Association, London, February 15, 1900. (See page 215.)

The Lepidoptera are represented amongst the pests only by their larvæ, the adult butterfly or moth being harmless. The larvæ of this order have usually eight pairs of legs, the anterior three being thoracic and the posterior pair attached to the last segment of the body, whilst the larvæ of beetles (Fig. 4) have usually only three pairs of thoracic legs.

To this order belongs the moth, the well-known grub of which causes such serious loss. It belongs to the family Tineidæ, but no member of this family is found in drugs.

Gelechia cerealella, the grain moth, is another lepidopteron, which, in the larval condition, attacks wheat and other kinds of grain.

The N.O. Diptera is represented by *Trypeta arnicivora*, sometimes found, as its name implies, in arnica. A wingless insect, *Lepisma sp.* (Fig. 7) of the N.O. Thysanura, has been found in mezereon bark.

Fig. 6.
Silvanus.

Fig. 7.
Lepisma.

The N.O. Hymenoptera is represented by *Cynips kollari* (Fig. 8), often found in galls. This insect however belongs to the group Entomophaga (*έντομος*: insect, and *φαγειν*: to eat), and is hence beneficial. They lay their eggs on the larva of the beetles, and the young hymenopteron, when formed, lives on its host.

Finally we have the mites (N. O. Acarina). These are minute creatures, with piercing beaks. They have eight legs, and are therefore not true insects. Many species are found in flour, cheese, sugar, and even cantharides. The species *Glyciphagus spinipes* (Fig. 9), is often found in cantharides.

Fig. 8.
Cynips kollari.

Fig. 9.
Glyciphagus spinipes.

With regard to the remedies which may be applied, many anti-septics have been proposed. Many of the remedies are toxic, and are hence almost worse than the disease. The vapour of carbon

bisulphide is fatal to insects in all stages except the egg stage. If the drugs are placed in a tightly stoppered vessel and a few drops of carbon bisulphide sufficient to charge the vessel with vapour, poured in, any larva or adult beetle will be killed. After allowing time for the eggs to develop, the bottle should be again examined and if any larvæ are present the process should be repeated.

One great advantage of carbon bi-sulphide is its ready volatility, an hour or two's exposure being sufficient to eliminate any trace of its vapour.

In conclusion, I have to thank Mr. E. M. Holmes for several specimens of infected drugs, and my friend and co-worker, Mr. A. Kirkland, for the trouble he has taken in preparing the illustrations.

BRITISH PHARMACOPŒIA, 1898. INDIAN AND COLONIAL ADDENDUM.

INDIAN SECTION.

The following preliminary report has been received from the members of the Indian Drugs Committee (Madras) appointed in 1894, on the several points on which an opinion was asked by the Pharmacopœia Committee of the General Medical Council.*

1. ACACIÆ ARABICÆ CORTEX.—As oak bark and its decoction have been omitted for substantial reasons from the British Pharmacopœia of 1898, and as in India we have already other equally good astringent liquid preparations more easily manipulated, we think that this drug may be omitted from our former list. As a matter of fact it is chiefly as one of their numerous internal tonics that the natives have been accustomed to use this bark. It is also applied as a strong astringent application to old and chronic ulcers.

2. ACALYPHA.—We have ourselves made preparations of this drug, and can say, therefore, that the "succus" should be prepared as suggested, namely:—"Bruise; press out the juice," to every three volumes of juice add one volume of alcohol (90 per cent.); set aside for seven days; filter." The result is a very stable liquid capable of being kept apparently an indefinite time. As, according to Hooper, alcohol extracts all the active principle, the "liquid extract" might be made official. It should be prepared as follows:—Mix 20 ounces of the powdered dry plant with some alcohol (90 per cent.), and set aside in a closed vessel for forty-eight hours; transfer to a percolator and exhaust, etc., as usual; make result up to 1 pint. Dose of the juice 1 to 4 fluid drachms; of the liquid extract, 5 to 30 minims.

[For a description of *Acalypha indica* Major Crawford has already drawn attention to Roxburgh's 'Flora Indica,' vol. iii., page 675. Surgeon-General Bidie also has sent to the Pharmacopœia Committee a botanical description of the plant, and recommends that it and its preparations be officially recognised. Dr. Van Dort makes a similar recommendation as regards Ceylon, and states that the plant is very common there in cultivated ground. *Acalypha* is an expectorant, an emetic, and a laxative.]

3. ANDROGRAPHIS.—We have in hand the tincture, liquor concentratus, and infusion of this drug—prepared by Lieut.-Col. Carruthers, of the Government Medical Stores—and so far they appear excellent stable preparations. Only the infusion deposits a very small quantity of sediment. Samples of these will be later on sent to you. Our present opinion is formed after keeping them under daily observation for just three weeks.

[Bidie and other authorities for India, and Van Dort for Ceylon, are strongly in favour of the official recognition of *Andrographis*. See also *Exacum*.]

THE TINCTURE.—Take 2 ounces of the dried plant, powdered (No. 40); moisten with two fluid ounces of alcohol (60 per cent.); percolate; using sufficient of the menstruum to produce 20 fluid

* The notes within brackets are by the Editor of the Indian and Colonial Addendum, Dr. John Attfield.

ounces.—Dose, 30 to 60 minims. LIQUOR CONCENTRATUS.—Take 10 ounces of powdered drug; moisten with 5 fluid ounces of alcohol (—per cent.); pack in a closed percolator for three days; percolate with the remaining alcohol in 10 equal portions, at intervals of 12 hours. Continue as usual so as to produce 1 pint. Dose, $\frac{1}{2}$ to 1 fluid drachm. INFUSION.—1 ounce cut small; distilled water, boiling, 1 pint. Infuse 15 minutes in a covered vessel; strain. Dose, $\frac{1}{2}$ to 1 fluid ounce.

4. ARISTOLOCHIA.—This is a climbing plant. Root and stem are the active parts. We have not yet prepared the liquor concentratus. It will be taken in hand at once. A tincture contains the active principle, and we would infer that the concentrated liquor also would contain it. We feel sure it would be perfectly safe to include a liquor concentratus in the official preparations. As there is a resinous substance in the drug, we think that the infusion would not contain the active ingredient, but that the tincture and liquor concentratus would be the most suitable official preparations. These might be prepared as those of serpentaria, namely, liquor concentratus:—10 ounces of the powdered drug to give a result of 1 pint, after first moistening with 5 fluid ounces of alcohol (20 per cent.) and packing in a closed percolator for three days; the remainder of the alcohol being used in 10 equal portions at 12 hours interval each. The tincture is made from 4 ounces of No. 40 powdered drug, moistened with 4 fluid ounces of alcohol (70 per cent.). Complete so as to produce 1 pint.

[Van Dort states that Aristolochia is abundant in Ceylon, and is often prescribed in native practice as a stomachic and tonic.]

5. BERBERIS.—Some difficulty and delay have been experienced in obtaining samples of this from the Nilgiris at this time of year. The root bark is the official part (Indian Pharmacopœia), stripped at the fall of the year and dried. The Indian Pharmacopœia makes a tincture, 12 ounces to 2 pints of alcohol (—per cent.); and an infusion, $\frac{1}{2}$ ounce of the dried root bark to boiling water 10 fluid ounces; infuse 1 hour; strain. Tincture, dose (tonic), $\frac{1}{2}$ to 2 fluid drachms; (antiperiodic), 3 to 6 fluid drachms; infusion, $1\frac{1}{2}$ to 3 fluid ounces. With reference to the liquor concentratus we must put off our recommendation until we have had an opportunity of applying the proper tests to this solution.

This is a very well-established drug. Berberine exists in great abundance in it. All authorities give references to its value. Samples will be submitted later on of all preparations we get made.

6. BETEL.—We experimented with the succus, and endeavoured to obtain the oil, but not altogether successfully. As suggested, however, the leaves, being universally distributed, and easily obtainable, might be officially recognised as an external warm application to the chest in inflammatory chest affections, more especially those accompanied by dyspnoea. It is highly spoken of in this connection by Shortt, Wood, Waring, and Gibson.

[Bidie, and other authorities, for India, and Van Dort, for Ceylon, strongly recommend the official recognition of this widely used stimulant. The leaves alone are prescribed.]

7. BUTEÆ GUMMI, official in the Indian Pharmacopœia (inspired juice, obtained from the stem by incision), occurs as irregular shining fragments becoming dull and blackish on keeping. It is referred to as an efficient substitute for kino. The tree occurs throughout India and Burma, and if a demand were active, the drug could be obtained with ease all over the country. Half the weight of the drug consists of kino-tannic acid. Roxburgh says that its solution in water is more astringent than its solution in spirit. The result of our inquiries is that buteæ gummi is most readily obtainable in the drug stores of Madras, and our advice is that it be made official in the places where it can be obtained. Of course, on the West Coast, and Malabar and Bombay, the official kino—*Pterocarpus marsupium*—is in the greater abundance. It might, therefore, be an official equivalent of kino.

[Bidie, for India, and Van Dort, for Ceylon, favour the official recognition of buteæ gum. Is it fairly soluble?]

8. BUTEÆ SEMINA.—We have decided to advise that these seeds cannot actually take the place of the official santonin. All medical officers, and we have consulted many on the point, draw attention to the eagerness with which natives resort to the hospitals for the English santonin. True, the General Hospital here mix 1 of santonin, 1 of powdered ginger, and 20 ozs. of powdered buteæ seeds to form their "compound powder of buteæ," nevertheless we certainly think the drug should find a place in the Addendum as an anthelmintic. The proportion of 1 of santonin in 22 is small, yet the action of our hospital compound powder is marvellously effective in expelling masses of round worms.

PREPARATIONS.—The seeds should be soaked in water; the testæ carefully removed; the kernels should then be dried and reduced to powder. Dose—20 grains three times a day for three successive days. Subsequently a dose of a purgative may be necessary, because some authorities think that much purgative action (in case of a single large dose) might interfere with the anthelmintic action of the drug. The powder made into a paste with lime juice (fresh) has a considerable reputation in parasitic skin diseases, more especially in the form of herpes known as "Dhoby's Itch." The infusion, of the seeds, has been referred to as having anthelmintic action, but we do not consider there is at present sufficient evidence in favour of this preparation being officially recognised.

9. CISSAMPELOS.—Our experience of this drug is practically what we have obtained from the many authorities who have written regarding it. It is very common throughout India, and easily obtained. Ainslie speaks very favourably of its use as a diuretic and tonic in Southern India. In nephritic disorders and inflammatory affections of the bladder and kidneys the drug has a reputation. The drug has a very similar composition to the official pareira, and we recommend a decoction, $1\frac{1}{2}$ ounces of sliced root to 1 pint water; boil for fifteen minutes in a covered vessel; strain and make up to 1 pint. Dose—1 to 3 fluid ounces.

[Van Dort states that this drug is very common in Ceylon, and is used by the natives in fever and diarrhoea.]

10. COSCINIUM.—A valuable bitter tonic. It has been investigated on a large scale (Waring), the preparations used being the same as of calumba, namely, tincture and infusion. It was found to be a valuable equivalent of calumba. Three weeks ago we got from Col. Carruthers a tincture, infusion, and concentrated liquor of this drug, and after daily observation we recommend that the following be officially recognised. Tincture, 2 ounces to the pint, maceration being alone carried out. Dose— $\frac{1}{2}$ to 1 fluid drachm. Liquor concentratus, 10 ounces of No. 5 powder, $4\frac{1}{2}$ fluid ounces of alcohol (90 per cent.), 20 fluid ounces of distilled water. Macerate the powder for 24 hours with 10 fluid ounces of water; press; again macerate the residue for 24 hours in the remaining 10 fluid ounces of water; press strongly; mix the expressed liquids; heat for 5 minutes to 180° F.; when cold add the alcohol; set aside; decant; make up to 1 pint. Dose— $\frac{1}{2}$ to 1 fluid drachm.

In this case we recommend a slightly greater proportion of alcohol to make the resultant clearer, namely, 9 fluid ounces instead of $4\frac{1}{2}$. With regard to the infusion, though our infusion made three weeks ago is now quite muddy, it was quite clear when fresh. It is referred to, as was the tincture (supra), by Waring, as having been successfully used on a large scale. It was made in the same way as infusion of calumba. The infusion therefore may be officially recognised. The mode of preparation and dose are similar to those of calumba. Samples of the above will be submitted.

[Van Dort states that this drug is common in Ceylon, and is a popular remedy in fever and dyspepsia.]

11. CRINUM.—Some misapprehension exists regarding our opinion on the value of the substitutes for the official squill, *Urginea scilla*. Preparations of *Scilla indicæ* and *Urginea indica* are now made in

the Government Medical Stores, and issued as fulfilling all the requirements of the official squill preparations. The official squill from the South of Europe is not utilised at all for the manufacture of preparations. Both of our kinds are used indiscriminately. Preparations of them will be submitted. The appearance of the sliced dried bulb is similar to the official squill, but has a brownish-yellow colour. The physical and chemical characters of the Indian squill are very similar to the official kind, and, as we have said, the official directions are followed in preparing Indian squill for issue from the Government Stores. No modification, therefore, seems needed or advisable in the mode of preparation. The name presents a difficulty, because we think the word *scilla* should be limited to the official drug, and we recommend that preparations of the Indian squill should be called *acetum urginæ*, *tinctura urginæ*, etc.

As regards *Crinum asiaticum* it is official in the Indian Pharmacopœia, but the weight of authority seems in favour of the other kinds. These latter, we find, are also utilised in the Bombay Stores, and have been, in fact, used for a number of years in both Government Stores. Dymock (one of the authorities), who was Storekeeper himself for some years, says they were used instead of the official squill for quite ten years, and were quite satisfactory. [Is "small squill" much used?]

[From the foregoing it would appear that the "crinum" of the Report on the Indian and Colonial Addendum should be displaced by "Urginea." Bidie supports this view.]

12. DATURA.—Two tinctures, the one of seeds, the other of leaves, are unnecessary. The seeds are preferable in the manufacture of the tincture for several reasons. The seeds may be obtained at any time in the bazaars, and may be gathered readily. *Tinctura daturæ*:—2½ ounces of the bruised seeds to 1 pint of alcohol (—per cent.), prepare by maceration and percolation. Dose—10 to 30 minims. We do not recommend any other preparations of this Indian drug.

[Bidie and other authorities write in support of the official recognition of *datura* (*D. fastuosa* and *D. metel*) for India, and Van Dort for Ceylon, as the equivalent of belladonna.]

(To be continued.)

AFTER AUGUST, 1900.

In a few months the time-honoured reproach that the Pharmaceutical Society's entrance examination is a delusion and a snare—inefficient as a test of preliminary training, and obsolete in its relation to the qualifying examination—will have been removed forever. A new era will be inaugurated which it is hoped will mark the commencement of a period of real progression in the evolution of pharmacy as a profession. The coming change has had the ample advertisement of three years' notification; but this tolerably long lease of warning is not altogether an unmixed blessing, for some of those interested have forgotten it, and many others have come upon the scene subsequent to its announcement. It appears appropriate, therefore, in the present special issue of the Journal—which will be sent to every registered person—to refer somewhat fully to the new conditions shortly to become operative, and to recapitulate not only what they are, but to explain what they mean, as well as what effect they may have upon students at present preparing for examination, in case they fail to secure their qualification under the fast dying régime.

WHAT THE NEW CONDITIONS ARE.

The bye-laws designed to effect the alteration in the examinations are those numbered 11 and 17 in Section X. of the Society's bye-laws, and they are published in full in the official calendar. Unfortunately, administrative excellence has not yet reached the point of devising means whereby every chemist and druggist in Great

Britain might be furnished with a copy of that useful compilation, and it is, therefore, necessary to reprint here the bye-laws in question. No. 11 deals with the registration of pharmaceutical students, and is as follows:—

After August, 1900, persons desiring certificates of competent skill and qualification to be registered as Chemists and Druggists under the Act, 1868, shall deliver to the Registrar on behalf of the Board of Examiners a certificate of having passed an Examination in English Grammar and Composition, in the Latin language, and in one Modern Foreign language, and also in Algebra, Arithmetic, and Euclid, conducted by any or either of the examining bodies which shall have been previously approved for the purpose by such regulations as are specified by the last preceding Bye-law, and shall pay to him a fee of Two Guinea, whereupon, if the Board of Examiners shall so see fit, they shall be registered as "Apprentices or Students."

No. 17 applies solely to the qualifying examination, and defines the fee to be paid for examination and registration.

All persons desiring registration as Chemists and Druggists shall in respect of an examination, to take place prior to September, 1900, pay a fee of Five Guinea, and shall in respect of an examination, to take place after August, 1900, pay a fee of Ten Guineas, and shall in either case pass the Minor Examination or the Modified Examination, whereupon they shall be registered accordingly.

WHAT THE NEW CONDITIONS MEAN.

To take the registration of students first, it will be seen that such registration is a precedent condition to obtaining a certificate of competent skill within the meaning of Section VI. of the Pharmacy Act, 1868—in other words, no person unrecorded on the Register of "apprentices or students" can be permitted to sit for the Minor examination. Now, what does this lead to? A little thought will bring the conviction that it will be impossible—and it is important enough a fact to be emphasised by italics—for a pharmaceutical aspirant to deliver his certificate of preliminary training to the Registrar and enter for the Minor at the same time. In fact, it will be found in practice that a period of at least three months must elapse between the presentation of the certificate of having passed the preliminary examination, and admission to the Minor. By way of concrete example, suppose a certificate, duly in accordance with the regulations, be delivered to the Registrar on September 1, 1900; the Board of Examiners not being in session until October could not authorise the registration, as a student, of the person named on the certificate until then, and he could not, therefore, become eligible to enter for any earlier Minor examination than that held in the following January. A good deal of disappointment will be obviated and much senseless twaddle about "red tape" may be prevented if this particular corollary to Bye-law 11 be borne in mind.

Another point to note is that the registration fee of two guineas is to be paid to the Registrar prior to the Board's sanction to registration. That is to say, *the fee must be paid at the time the certificate is tendered.*

The bye-law contemplates a list of approved examining bodies, and such a list has been compiled and adopted by the Council. There does not appear to be any necessity to print this list again in the *Pharmaceutical Journal*, as it does not require explanation, nor does it aid in the elucidation of the points which it is the object of this article to make comprehensible. Besides, a post-card to the Registrar will always procure an official copy of the list. But there are conditions appended to the enumerated certificates which do call for careful consideration. First, each certificate (or

the certificates, as the case may require) must include in the subjects for which it is (or they are) granted the following :—

English grammar and composition, Latin, a Modern Foreign language, Arithmetic, Algebra, and Euclid.

and, secondly, these six subjects must have been passed at not more than *two examinations of the same examining body*. The necessity for the parenthetical employment of the plural in the commencement of the preceding paragraph is thus apparent, for in most instances there will be two certificates presented by a candidate for registration; the reasonable assumption being that few persons will sit for six subjects at one time, when easy stages of three will suffice. No limit, it may be noticed, is imposed as to the interval between the parts, and no restriction is placed upon the choice of subjects or the number to be taken in one part. Thus, a youth may, on leaving school—say, at 15—secure a College of Preceptors' second-class certificate covering Latin, English, Arithmetic, Algebra, and Euclid. He may then forget most of them, till he is twenty and thinks of coming up for the Minor. By taking French or German under the same examining body (assuming that to be allowable according to its rules), the pharmaceutical regulations would be fulfilled. This is purposely an extreme case to illustrate the range of freedom allowable, making an entirely new principle in pharmaceutical requirements, and has not inaptly been termed the "instalment system" of examination. The reasons for its introduction were given when the Council adopted the new regulation in May last, and discussion as to the wisdom or unwisdom of the step would now be as futile as it would be inopportune. The "same examining body," then, must grant both the certificates in cases where the six pharmaceutical subjects are taken in two examinations, but there is an exception in favour of Scotland. Without going into the somewhat complex reasons involved, it may be stated that the Scotch Universities are permitted to accept, in relation to registration as medical students, certificates which, technically, would not come within the strict letter of the pharmaceutical regulations. On the principle that what is good enough for the Medical Council ought to be good enough for the Pharmaceutical Society, the following became a part of the regulations :—

Certificates which are accepted by the Scotch Universities for registration as medical students may be received by the Registrar for registration as "Apprentices or Students."

Provision is made for the special consideration of certificates granted by examining authorities outside the United Kingdom, and others not specified on the official list, and each individual case will be considered on its merits. But a word of warning may, perhaps, be uttered here as to the length of time involved in bringing an "outside" certificate within reach of acceptance. With an ordinary valid certificate there is little formality, as the Registrar accepts it on behalf of the Board without delay; but in the case of a foreign certificate the Registrar would have to submit it to the Board, and the Board would have to signify its approval to the Council in order that the latter might, in its turn, authorise the Registrar to receive it. Now, as the Board meets once in three months, and the Council once a month, it is not difficult to imagine that some patience will be required by a student desiring to register such a certificate. Of course, it is essential that "outside" certificates must cover the six subjects before enumerated.

MINOR.

The increased amount payable on entering for any minor examination after that terminating in July next is made up of five guineas examination fee and five guineas registration fee, paid in advance. An appreciation of this fact will render it easy to realise that the registration portion of the composite amount is only payable once. In other words, the ten guineas is only applicable on first entering for the qualifying examination, and the reduced fees

for re-examination will not be raised. The major fees are unaffected, and the nature and scope of the minor examination are not in any way changed by the new bye-law—there will not necessarily be a desire on the part of the Board to give candidates a more stringent straining for their money.

EFFECTS, UNTOWARD AND OTHERWISE.

Naturally the new order of things will bear heavily on a few individuals, but every change must entail some disappointment, or even hardship, and the unfortunate part of it is that the Council are not make laws for hard cases. The only thing possible is to forewarn those who may have to suffer disabilities. On Tuesday, July 10th the final "First" examination will take place at the usual centres, and some candidates will pass, while some will fail. What is to become of the failures? Will they receive preferential treatment? No, the answer is that they *cannot* receive any preference, for they will occupy precisely the same position as a person who has never presented himself for the examination: in fact, they must comply with the new conditions; *i.e.*, submit approved certificates, and pay two guineas registration fee. Similarly, candidates who have entered for the July examination, and fail to attend from any cause whatever, will forfeit their fees; for it will be physically impossible for them to attend an examination subsequent to the *last!* The sick, the absentee, and the failure, in connection with the July examination will, therefore, all pass into the category of those who must conform to the increased requirements, in spite of medical certificates, attacks of nervousness, delayed trains, and the various other valid and invalid excuses with which all Boards of Examiners are familiar.

With regard to the minor examination, the hardship is principally on the Society, inasmuch as scores of men whose studies should properly keep them from presenting themselves for examination until October or January, will enter in July, and save five guineas. But there is one unfortunate class of candidate—or rather would-be candidate—even here, that is the one born too late to enter for the July examination. As is well known, entries for this examination close on June 15, and on that date all candidates must be of the full age of 21 years—a matter which must be supported by the testimony of a Registrar's certificate of birth. Now, there are sure to be one or two students who will not be 21 till the 16th or the 17th, and who may consequently address pathetic appeals or indignant remonstrances to Bloomsbury Square; to these unfortunates sympathy is due, but their position cannot be altered. The accident of birth, that gives some wealth and others power, has saddled them with a ten guinea composite minor fee, and there's an end of it. The writer has been asked, will those students who pass the First examination in July next escape the composite fee. Certainly not, why should they? Such students cannot enter for a Minor examination to be held before August, 1900, and they necessarily must come under the regulations applicable to examinations held after that date. Conversely, a curious but more persistent idea seems to have taken root in the minds of some students who have already passed the "First" examination, that in the event of not entering for the qualifying examination before August, 1900, they will be required to submit to the new preliminary educational requirements. To relieve this species of anxiety, it may be stated that a person registered as an "Apprentice or Student," by passing the "First" examination previous to August, will not cease to be so registered when September arrives—in fact, he will not be expected to pass two preliminary examinations.

DATES EXPLAINED.

The date of nominal operation of the new conditions is according to bye-law September 1, but the exigencies of administration modify that date in one or two instances. For example, in the discontinuance of the "first" examination, the operative date of change is actually June 26, which is the day on which entries close for the final examination. For the minor examination, the change

practically operates as from June 15, which is the last day for receiving entries for the July examination. In the case of the reception of certificates, at present accepted in lieu of the "First" examination, it would appear at first sight that, provided they were in the Registrar's hands before September 1, the Board would be empowered to accept them. Such, indeed, would be the case if the Board met on August 31, but, as a matter of fact, the last meeting of the Board previous to the maturing of Bye-law 11, will be on August 1, or thereabouts, when a quorum of members will be in attendance to receive the College of Preceptors' report on the final "First" examination. It is evident, therefore, that the reception of certificates under the old régime must cease on July 31.

PHARMACEUTICAL SOCIETY.

Evening Meeting in Edinburgh.

The fourth evening meeting of the session was held at the Society's House, 36, York Place, Edinburgh, on Wednesday, February 21, Mr. PETER BOA, Chairman of the Executive of the North British Branch, in the chair. The minutes of the last meeting were read and approved. The CHAIRMAN read a letter from Miss Frazer (Garelochhead), in acknowledgment of the letter of sympathy sent by the last meeting.

A paper was read on

"THE DETECTION OF SULPHATES IN PRESENCE OF THIOSULPHATES," by Dr. LEONARD DOBBIN. The paper was illustrated by experiments, and is printed at page 182.

Mr. LOTHIAN said there was a compound in the Pharmacopœia, CaX sulphurata , to which Dr. Dobbin's remarks would apply. It contained sulphide, sulphite, thiosulphate, and sulphate, and this process might be available in its analysis.

Mr. COWIE asked how the thiosulphate dissolved the sulphate, and what was formed. He also asked if the nitric acid did not oxidise the thiosulphate to sulphate.

Dr. DOBBIN, in reply, said Fresenius in his paper referred to was dealing with a suggested process for separating calcium sulphate from barium sulphate, founded on the assumption that thiosulphate would dissolve the former, but not the latter. He used a concentrated solution and found that barium sulphate did dissolve, and that the assumption was not justified; probably a double salt was formed, but on that point he could not give a definite opinion. Nitric acid did oxidise thiosulphate, but only to a small extent in a cold dilute solution.

The next paper was on

"POTASSIUM ARSENATE,"

by Mr. JOHN LOTHIAN. It is printed at page 183.

Dr. DOBBIN said this salt was of considerable historical interest; it was carefully examined by Mitscherlich in connection with his theory as to isomorphous salts. Graham carefully re-examined this salt from another point of view in his wholly original investigations which led to the discovery of monobasic, dibasic, and tribasic acids. Those were of the nature of turning points in chemical theory. Mr. Lothian had determined and collected interesting particulars, which thoroughly spoke for themselves.

Mr. DUNCAN said the potassium arsenate he had was different from Mr. Lothian's. It was in feathery crystals, and an aqueous solution when boiled became alkaline. It seemed to be a different arsenate; he thought potassium should replace the sodium salt officially if it was necessary to have arsenate in the Pharmacopœia.

Mr. D. MACEWAN said he could confirm the statement as to the stability of the salt, he having a specimen at least twenty years old. There was a process for its preparation in Gray's 'Supplement.'

Mr. HILL said this paper represented a large amount of very careful work, and filled a blank in British chemical literature,

which was very meagre in information regarding this salt. He agreed with the author as to the probable process by which the strychnine was liberated in Mr. Dunlop's mixture.

Mr. LOTHIAN, in reply, said it was surprising that a salt which had been so fully investigated scientifically, should have been ignored so much in pharmaceutical literature.

Papers were then read on

"STRYCHNINE HYDROCHLORIDE AND POTASSIUM ARSENATE,"

and on "Strychnine Salts and Chloroform," by Mr. J. RUTHERFORD HILL (see pp. 184, 185).

Dr. COULL asked if Mr. Hill had in mind a paper by him in which he indicated that a solution of acid sulphate of strychnine deposited crystals of neutral sulphate.

Mr. DUNCAN said all that was required in the Pharmacopœia was an aqueous solution of arsenious oxide. It was soluble 1 in 100, and a little glycerin increased the solubility. An objection to using magenta dye for colouring galenic preparations was that it appeared in the urine of patients for several weeks after use.

Mr. ROWLAND said his salt seemed similar to that referred to by Mr. Duncan. It was only used in homœopathic medicine by faddists. Why have an arsenate at all? A simple solution of arsenious oxide was sufficient.

Mr. LUNAN said arsenious seemed to be preferred to arsenic compounds by prescribers because the latter were not found so effectual. The potassium arsenite might perhaps be examined before quite deciding upon the arsenate. It was a valuable suggestion to substitute the potassium salt for the sodium.

Mr. COWIE, while preferring the mono-potassium to the di-sodium salt, thought it was too sweeping a proposal to adopt it in place of the other two official arsenical solutions. He thought the enforcement of a better chemical knowledge in the medical curriculum would save pharmacists much trouble.

The CHAIRMAN said he was not in sympathy with the proposal to substitute a solution of potassium arsenate for the present official alkaline and acid arsenical solutions, which he fancied met all the requirements; too much importance should not be attached to isolated cases of badly-equipped and ignorant prescribers.

Mr. HILL, in replying, said he had noted Dr. Coull's paper, and founded on it an explanation why chloroform separated neutral sulphate from the acid sulphate of strychnine. The proportion of magenta—a three-thousandth of a grain per ounce of liquor—would be so small in each dose that it could hardly be objectionable. Potassium arsenite had been shown to act exactly like arsenious oxide. It was more rapid and intense than the arsenate, but the action seemed specifically the same. He quite realised the sweeping nature of his suggestions, but they would do good by stimulating fuller consideration.

The next paper was a

"NOTE ON MESCAL BUTTON,"

by Mr. J. RUTHERFORD HILL. The author pointed out that in some books Mescal Button was described as the fruit of *Anhalonium lewinii*, but it consisted really of the entire above-ground part of the plant. In examining the specimen recently presented by Mr. MacEwan, he had steeped one of the buttons in water and found that there were only eight of the characteristic convex ribs with rows of tubercles. In general appearance it seemed to be a closer resemblance to *Anhalonium williamsi* than *A. lewinii*, and it seemed that both species were met with in commercial samples of Mescal Button. After referring to the information in the *Pharmaceutical Journal* [4], 5, p. 520 534, and 7, page 457, he said he had, on inquiry, got some interesting information from Mr. E. M. Holmes, along with the living plant sent from Sevenoaks. In regard to cultivation, the plants were grown in limestone rubble and sand, and the pot placed in a larger pot with a layer of sphagnum between. In summer the sphagnum is kept wet, but in winter quite dry. The largest speci-

mens are about $2\frac{1}{2}$ inches across and one inch high. There are from ten to twelve rays, dividing transversely into six verrucæ. The centre of each areola, or verruca, has a tuft of hair in the centre. The tufts are crowded in the centre, where the areola are smaller. The flowers are produced in August on the summit, and are pink and about half an inch long. The expanded flower is about the size of a threepenny-piece, with a fine one sometimes as large as a sixpenny-piece, like a miniature cactus. The fruit is like a barberry in shape, and of a pretty orange pink colour. The seeds are small black cylindrical bodies about the size of black mustard seed, and having the surface marked with raised lines. There seems very little real difference between *A. lewinii* and *A. williamsi*, and whether the plant now exhibited is the former or the latter is a little doubtful. The chief distinction seems the number of convex ribs, of which there are usually thirteen in the former and eight in the latter; but the number is not constant.

The paper was illustrated by a living specimen and a dried flower of *Anhalonium lewinii*, and drawings of *A. lewinii* and *A. williamsi*, sent by Mr. E. M. HOLMES, who had the plants under cultivation at Sevenoaks, and who also sent a twig of *Rhamnus californica*, bearing leaves, while *Rhamnus purshiana*, growing in the same greenhouse, had shed its leaves. There were also exhibited the bark of *Melaleuca leucadendron*, presented by Miss Madgshon, and the tea and caffeine specimens of Mr. Whiffen, from the London Museum; additions to the Library were also referred to.

The CHAIRMAN said they were much indebted to the Council for having the interesting specimens from the London Museum sent to be seen by the members. He moved a vote of thanks to the authors of papers, to Mr. Holmes for information and specimens from Sevenoaks, and to donors of books and specimens.

The meeting then closed.

LETTERS TO THE EDITOR.

The Outlook in Pharmacy.

Since writing the paper published in last week's Journal, in which I argued that the Legislature should deal with company law and construct it so that no injustice is inflicted on any existing interest; but that if the Government proposes legislation which will infringe our titles we should oppose it, the Companies' Amendment Bill has again been laid before Parliament. As before, the clause dealing with the matter in question distinctly permits the use of our titles by corporations, provided they have a qualified Major or Minor man, as the case may require, as manager. Surely registered chemists must all be of one accord in believing that "no company—which is not composed of persons who are registered under the Pharmacy Acts—should use the description or titles conferred by those Acts." There may be some difficulty as to what we should suggest in place of the clause in the Companies' Bill, and it would seem that even the members of Council have not been able to agree upon a definite policy. But in my opinion there cannot be any doubt either of our individual duty as pharmacists or as to the duty of the Council, as the official guardian of our interests, to oppose that portion of the clause as it stands.

Though I am strongly of opinion that too much should not be made by registered chemists of the claim to professional position, since the majority belong more to a trading than a professional class, and though I think it would, therefore, be unwise to press for what is generally considered to be more of a monopoly than the law gives to medicine, surgery, or dentistry—though I do not even think it is our business to regulate company pharmacy and, least of all, to acquiesce in the project of a "qualified directorate"—still I am convinced that we should strenuously oppose the proposition that "a company may do what an individual without qualification may not do," which it is the object of the Companies Bill to con-

cede. Let us, therefore, sit tight on the principle that our titles—being the result of qualification—cannot be bestowed on companies. The attempt to bestow titles without qualification we should attack with the united forces of pharmacy, with all the allies we can get, so that if we cannot suppress company pharmacy, we may at least make it keep its extra legal position.

The brightness of our outlook in this matter will depend largely upon our unity. We are 15,000 strong, and our necessity is to unite all qualified pharmacists in defence of their legitimate interests and titles. In this case the best defence is to attack the injustice.

One of the first things to be done is to weld together all ranks and states of qualified chemists. Why should we, through loose combination, lose valuable sources of help and hope? I hold the opinion that tradesmen, as such, will never combine for an ideal in the abstract, however high. Nor can corporate life be built on the abstract. Nor, further, is there any need to try such a futile method of subsistence. The proposition of the clause in the Companies Bill is a very concrete thing and, as such, it needs to be demolished. Nor is that appropriation of titles, representing a qualification, the only concrete thing to be fought. There are positive interests to be defended. Our unity ought to focus itself on the Society and, I believe, it would do so if we could be led aright. But then I also think that the Society must become far more frankly and thoroughly than it has been, a trades organisation.

The interests and the qualifications in danger are not merely those of persons in business on their own account. They are as vital and important, in all respects, to those who are now serving companies. Can we win over these men? An important factor in such a process will be the attitude of those in the position of proprietors. The terms and conditions of service for assistants and managers should be as good and generous as trade will afford. The Society might help here by undertaking a propaganda amongst qualified men not in business on their own account. By showing determination to protect the individual title and, thus, indicating the value of the "trade-birthright," it might do much to lessen the hold of companies on these men. Here and in the matter of trade unity an organising secretary would be very useful.

It is perhaps doubtful, in the present state of Imperial politics, whether the Companies Bill will have a better chance than other domestic legislation of getting through Parliament. But it will never do for chemists to trust to such a consideration. The clause in the Bill dealing with their interests—in the very material point of titles—calls for instant and unceasing opposition. It gives us a good opportunity to state our position to the Legislature and to the public. To my mind, the Society, as well as the Council, is on its trial. If they fail the trade in this matter, I think we may cease our appeals to non-members to become members. But then the Council has a right to expect not only the moral support of the trade, but also the material support of every qualified pharmacist, whether or not he is serving the companies. I believe also that if the Council shows itself alive now to our interests it will lend immense strength to all attempts to secure, as regular subscribers, those who now stand outside.

Bolton, February 17, 1900.

JOHN TAYLOR.

Proposed Division of the Minor Examination.

Considerable attention has been given of late to the advantages that might accrue to "Minor" candidates by the division of that examination, but little has been said as to the disadvantages, both to them and to the craft generally, that might also be entailed.

It is argued on behalf of a division of the examination that the medical examinations are divided. That is so, but the conditions are dissimilar. There is a compulsory medical curriculum, and the minimum course of study for a medical qualification occupies five years. It would manifestly be undesirable, in that case, for

a candidate to be obliged to satisfy the examiners at one and the same examination in the rudimentary, the intermediate, the advanced, and the special knowledge of many subjects that is gained during the five years' course. Naturally, the examinations are so divided as to order the studies of the student, who otherwise would be utterly bewildered.

But in no case, so far as I know, does an examination comprehend the scope of less than one year's work. Take the examination for the London M.B. After matriculating it is necessary to pass, during the five years' curriculum, three examinations—viz., the Preliminary Scientific, the Intermediate Medicine, and the Final M.B.

Now, in the case of the Minor, the syllabus is such that any student who has devoted a reasonable amount of time to study during apprenticeship can with ease gain an intelligent and sufficient knowledge of the subjects in one academical year's study at a good school of pharmacy. In my experience as a teacher I have found three main types of unsuccessful Minor candidates—(1) men of inferior mental calibre, (2) men who idle away their time during the school course, (3) those who enter on a course almost or entirely ignorant of the subjects they are about to study. The first type will be eliminated by the new regulations for the entrance examination; the second is beyond the province of legislation; but the third type is, and promises under present conditions to continue to be, extremely common. The main reason for the prevalence of this type is, in my opinion, the lack of time for study during apprenticeship. The over-long hours of business are seldom mitigated for the apprentice, and it is unreasonable to expect him to study during the very short leisure time that comes between the closing of the pharmacy and bedtime.

It is clear to those who as teachers have come in contact with a large number of Minor candidates, that it would be better to encourage moderate study during apprenticeship than to lower the standard of the examination, which may be the result of dividing it. Obviously the standard of the examination would be reduced if the percentage of marks to be obtained in the divided examination were the same as the standard in the examination as at present conducted. Supposing a candidate has now to get 600 marks in his six subjects at one examination, it hardly needs stating that it would be much easier for him to get the other 300 marks on three subjects at one time, and the remaining 300 marks on the other three subjects at a subsequent examination—say, after an interval of six months. Rather than incur so grave a risk, let those who deplore the dearth of qualified assistants see that the apprentices committed to their charge enter a school reasonably well acquainted with the various subjects with which they will have to be familiar in the examination, and the result will be that the percentage of passes in the Minor will sensibly increase.

In speaking of the percentage of passes it is instructive to consider the Matriculation examination of the London University, which is now looked upon as the natural entrance examination for most professions. It includes (1) Latin author, grammar, unseens, and prose composition; (2) English grammar, literature, history and the geography relating thereto; (3) mathematics (including Euclid, books I. to IV.), algebra (up to and including progressions), and the whole of arithmetic (excepting cube root); (4) general elementary science, including the rudiments of mechanics, light, heat, magnetism, electricity, and chemistry; (5) either an additional language (*e.g.*, Greek, French, or German) or a science treated more fully than in (4). Now, these subjects must all be passed at one and the same examination, and yet the matriculation is only an entrance examination. Did anyone ever hear of a suggestion to divide this examination? How much more necessary should it be that a qualifying examination, which carries with it serious duties involving life and death, should not fall in standard below that of a mere entrance examination! Thirty-four was the percentage of passes in the last Matriculation examination. It is obvious, therefore, that the Minor is not alone in showing a low percentage of passes.

I have said that the division of the Minor might have the effect of lowering the standard, but, of course, I recognise that there is an alternative to this—viz., the tightening up of the individual subjects. But if this be done it follows logically that the percentage of passes will have a tendency to still further diminish.

The extension of the time occupied by the examination would not, therefore, be of much assistance to the candidate or to the craft. This point should be considered by those who propose a division of the examination. I consider that to divide the examination, or to extend the time occupied thereby, is a step that should not be taken apart from the enforcement of a curriculum.

Until it is found possible to enforce a curriculum these proposed modifications cannot be anything but unsatisfactory alike to the candidate and to the craft—to the former because of the possibly increased stringency in the individual subjects without increased means of preparation, and to the latter by reason of the consequent greater scarcity of qualified assistants. It is urgent, therefore, that the matter be looked at squarely from all points of view.

Who desire these changes, and for what purpose? The master pharmacists, probably, because they find it difficult to obtain qualified assistants. They wish to meet the difficulty by rendering it easier for candidates to qualify, instead of *striking at the root of the matter* by doing their part in the work of education. It will certainly not lead to advancement in the status of the craft to remedy a deficiency in the supply of qualified assistants by the acceptance of half-trained or imperfectly educated men.

To sum up in a few words, the proposed modifications, in the absence of a curriculum, will not necessarily furnish a larger supply of qualified assistants: it may have the opposite effect; and may at the same time give the student real cause for dissatisfaction. The frequent neglect of apprentices by their masters is one of the causes of the dearth of qualified assistants. As I am engaged in teaching it is obvious that it would be inexpedient for me to append my name.

London, February 19, 1900.

MAGISTER (21/20).

The Government and the Companies Bill.

On the 12th inst., to my surprise, I found the Companies Bill was down for the second reading on Thursday, the 15th inst., and, on behalf of the Bristol Pharmaceutical Association, I wrote a letter to Sir Michael Hicks-Beach, Chancellor of the Exchequer, and Mr. Lewis Fry, member for Bristol. The letter and reply I enclose herewith. As a matter of fact, the Companies Bill was not read the second time on Thursday last, but will no doubt very soon. The reply to my letter is very significant, and it is to be hoped the Law and Parliamentary Committee of the Pharmaceutical Society, to whom the eyes of all pharmacists in Great Britain are turned, will take steps for an amendment to be moved when the Companies Bill is in Committee, taking a firm stand and no compromise for the title and practice of pharmacy to be safeguarded to the qualified pharmacist.

Bristol, February 19, 1900.

G. T. TURNER.

[ENCLOSURES.]

Lynne, Osborne Road, Clifton,

February 14, 1900.

To the Right Honourable Sir Michael Hicks-Beach, Bart.

Sir,—On behalf of the above Association, representing some seventy chemists in Clifton and Bristol, I beg most respectfully to solicit your interest in the Companies Act Amendment Bill, which is to be read for the second time in the House on Thursday night. Knowing what heavy demands are made upon your time, I will as briefly as possible show how the Bill, as it at present reads, affects very seriously chemists generally and the public at large. The 1st Section of the Pharmacy Act, 1868, reads thus:—

From and after the 31st day of December, 1868, it shall be unlawful for any person to sell or keep open shop for retailing or compounding poisons, or to assume or use the title of Chemist and Druggist, or Pharmacist, or Dispensing.

Chemist in any part of Great Britain, unless such *person* shall be a Pharmaceutical Chemist or Chemist and Druggist within the meaning of this Act, and be registered under this Act, etc.

No one can be registered who does not pass a qualifying examination, as you are well aware.

But by the language as manifested in the Companies Bill, if it becomes law, it will enable a company to do what a private *person* is prohibited from doing.

The point at issue hinges on the word "person."

It is manifestly a great injustice to many thousands of highly educated pharmacists in Great Britain that by wording of this Act after years of study, and at great expense, to acquire the title of Chemist and D. or Ph.C., and to practise pharmacy, that both the title and practice can be usurped by a number of unqualified men who form themselves into a company.

In the interest of the general public, and for their protection, I respectfully submit that a qualified pharmacist, who gives his personal attention and skill to his business, and has a reputation at stake, is a greater guarantee for the safety of the public than a business, or a member of such, carried on by a body of unqualified men whose only interest in it is what dividend they can declare. Lastly, it is a matter of deep regret, after all the efforts put forth in this country in raising the standard of pharmaceutical education to the high level it has attained, that by any phrasing of this Act a loophole may be given whereby unprincipled and unqualified persons may usurp the title and practice of men who have spent the best years of their lives to attain. As one of your loyal constituents, and representing a number of others, I beg to solicit your powerful influence in this matter.—Yours respectfully,

G. T. TURNER,

President, Bristol Pharmaceutical Association.

Copy of Letter from Secretary of Sir Michael Hicks-Beach.

Treasury Chambers, Whitehall, S.W.,

February 17, 1900.

Sir,—I am desired by Sir M. Hicks-Beach to acknowledge the receipt of your letter of the 15th inst. on behalf of the Bristol Pharmaceutical Association with reference to the Companies Bill, which has been introduced in the House of Commons. I am to say in reply that the particular point about which you write has not escaped the notice of Mr. Ritchie, who is in charge of the Bill, and should the interest affected take steps for an amendment to be moved when the Companies Bill is in Committee, H.M. Government will give careful consideration to its terms and to the arguments urged in its support.—I am, Sir, your obedient servant,

W. A. MOUNT.

Mr. G. T. Turner.

Chemists and the Legislature.

It is well that we have in the Legislature, as well as on the Council of the Pharmaceutical Society, a better kind of representation than most of those who write in the trade journals on the topics of the day seem to be aware of. If the lugubriousness of some who figure in this week's Journal had any foundation, in fact, the outlook would be most gloomy.

The new Companies Bill now before Parliament is on all hands admitted to be an effort—an honest, but complicated, effort—to restrain some of the roguery that accompanies always the march of progressive civilisation—the progress of freedom. The clause that we are, as pharmacists, so deeply interested in may certainly be regarded as one of quite minor importance to the general drift of the measure, and one which may, therefore, be boldly attacked with a direct negative if it can be shown that it will perpetuate an injustice or further entangle the working of another important Act of Parliament—namely, the Pharmacy Act of 1868.

Our President's letter to the President of the Board of Trade should, I think, be regarded with unqualified satisfaction. Sooner or later some good must result therefrom. The strictures on this

head of the President of the F.L.P.A. seem to me amazingly flimsy and ill-timed. (See *ante*, page 166.)

Of all the stream of explicit words, and definite, that came in to enrich our mother-tongue in the middle period of the English Literature, the word "control" stands forth amongst the most explicit and useful ones, and, when clenched by the expressive "any," leaves nothing to be desired in the way of perspicuity. "Control M.E. from M.L.=*contra rotulum*=a counter roll or register"—*vide* Century Dictionary, page 1,237. It implies most definitely any check or restraint, or any power to check or restrain. Yet Mr. Smith is reported to have said that "everything depends upon what signification we give to that word 'control,'" which he goes on to condemn as ambiguous, which it certainly is not.

I pity anyone in Mr. Smith's position; he is evidently forced to a change of front at a critical period of the campaign. When one has a lot of intricate wire-pulling to do all of a sudden, and has others things of far more importance to occupy his best attention at the same time, every allowance should be made for his perilous situation, but not to the abandonment of straightforward criticism. A most serious flaw is reported a little earlier in his speech:—"With regard to the election of the Council of the Pharmaceutical Society, his own view, up to within the last few months, was that the F.P.A. would make a mistake in interfering with the election of members of the Council. But it was quite possible (*sic*) that circumstances might alter cases." To which the reply is—yes, circumstances do alter cases; but circumstances do not alter principles of conduct. It is either right or wrong for another organisation to interfere with an election of the Council, and what was wrong a few months ago cannot very well be right now.

The balderdash so common just now that we must "bring pressure to bear upon our representatives" in Parliament or elsewhere very often over-reaches itself. A representative surely has enough to do to attend to our business for us, in his own manner, without being worried by extra pressure from without, and by a semblance of control which has every likeness to an impudence that must damage any good cause instead of helping it on.

If we search the records, we shall find that association life woke up from a long slumber about ten years ago, when the Council first began to appoint and organise divisional secretaries for the different boroughs in and around London. An army of about fifty can now attest the general amelioration and the augmentation of interest consequent upon that movement. It is no mere "show of unanimity" such as some pretend to pine after still, but a real unanimity, resting upon a brotherly sympathy and a candid view of things as they really do exist.

During this period old associations have begun to assume a new life and new ones to arise in different parts of Great Britain. Altogether, independently of any federation whatever, associations have, indeed, become fashionable, with the usual result of anything fashionable; the bogus—the sham—rise up beside the valid and the genuine. There are thus bogus associations of chemists as well as bogus companies opposed to chemists, and what truth demands is that, instead of tying up in one bundle the good and the bad, each should stand on its own base and either flourish or explode, as time determines its true character and the elements of cohesion or of revulsion that lurk within. Federation of pharmaceutical associations is likely to prove a mere sham, and our representatives at Westminster, as well as at Bloomsbury, know well how by a touch to knock out the wadding and sawdust from such a bogey.

Am I asked what I would have to be done or attempted at the present juncture? I would answer, Go with clean hands and an open breast for pharmacy; let trade and the perennial curses that rest upon what is nicknamed the turning of an honest penny take care of themselves.

The members of the Pharmaceutical Society, increased in numbers, surely have increased, likewise, in the knowledge of the fact

that no benefits can possibly be brought about comparable to those which it is the main object and essential nature of the Society to evolve. The clause of the Companies Bill should be vigorously opposed as unnecessary and likely to work mischief to the public generally. It will, if passed, perpetuate an injustice that we have been the victims of since the law lords decided that our Pharmacy Act, 1868, was a faulty one.

The phrase, "*bona-fide* managers" is indefinite, complicated, and illusory. The idea of a man becoming educated, examined, and legally qualified to perform important functions for the public benefit, and then having to submit to any sort of control on the part of others who have no status whatever in his vocation, is ridiculous and unbusinesslike. Qualified directorship would seem to come nearest to a workable compromise; but where is the necessity of swerving from the solid front of individual proprietary qualification? If this is needed as far as the older branches of medicine are concerned, surely young pharmacy needs it too; and thus we might ask, having got rid of one obnoxious clause, to have the one lower down slightly amended by the insertion of the words "Pharmaceutical Chemist" immediately before the word "Dentist."

Marylebone, N.W., Feb. 20, 1900.

J. C. HYSLOP.

Wanted, a Chemists' Club.

"An Ordinary Pharmacist" has struck the right key in saying that a chemists' club, conducted on proper lines, is wanted. The great mistake that was made in the one near Ludgate Circus was in admitting certain advertising ideas. Though the support of the wholesale cannot be ignored—indeed, their patronage and influence is needed—to encroach upon the space and comfort of a club by the show-case of any firm is certain to lead to jealousy and to prevent that success which should ensure attention from the trade. A well-appointed club, situated within easy access to all parts of London—say, near Charing Cross—would prove a boon to every London chemist or to his *confrère* from the provinces. It should be no difficult matter to found such an institution on self-supporting principles, and if some of the trade will communicate with me the scheme can be put in hand forthwith, and no doubt will be greatly welcomed.

London, February 12, 1900.

C. E. PICKERING.

The Worcester Weed-Killer Case.

The defendant in the above case accepted an order for weed-killer, but not being qualified to sell poisons, transferred the order to a firm who supplied the article, the defendant making a trade profit by the transaction. The verdict was in favour of the defendant, it being held that he acted as an agent only, and had not control and management of the sale. In the Exeter methylated spirit case the defendants (oil and colour merchants) received an order from a customer for methylated spirit, but not having a methylator's licence, passed the order to another firm, who supplied the spirit, but in this case the verdict was *against* the intermediate parties, the defendants, who were held to be the actual sellers, and so to have broken the law, the argument for the defence that the defendants only assisted at making a contract between a third party and the buyer not being accepted. These transactions, so far as actual buying and selling are concerned, appear to me to be analogous, and the legal decisions most contradictory.

M.P.S., Ph.C. (21/41).

The Company Pharmacy Problem.

The Council might utilise the great advantages they possess for influencing, all over the United Kingdom, Members of Parliament, by printing and distributing leaflets and literature for the use of local secretaries, and where there are none, local chemists, when interviewing their respective Members of Parliament, and at the

proper time an urgent whip should be sent from the office at Bloomsbury Square to all chemists to urge their Members to oppose the objectionable clause in the Companies Bill. If it be left to local initiative our opposition will fail, through the usual apathy of chemists. The Lord Chancellor is an astute politician, and will prefer to drop the pharmacy clause than lose his Bill. We must be prepared for that, and persist in our opposition unless our titles are protected in the same manner as medical practitioners and dentists. Those two professions have the same amount of love and respect for us that Continental nations have for Britishers. We must be "slim" enough to compel those professions to include us or lose the opportunity of securing their own titles. By so doing we treble our pressure upon the House of Commons, as medical practitioners and dentists especially are injured by trading companies; and, as our inclusion will not harm these professions, they will press their representatives to include us that they may secure their own titles.

St. John's Wood, N.W., February 20, 1900.

J. HICK.

The Companies Bill.

This Bill awaits its second reading. The obnoxious pharmacy clause is practically the same as passed by the House of Lords last year. In the Journal of 17th inst. we are advised that we should agree whether to oppose the clause or work for its modification. I think the former is the only course open, nor should the idea of a qualified directorate be entertained. Companies have over-ridden the spirit of the Pharmacy Act for years, and now they will, if the Bill passes, destroy its substance, because (1) The Pharmacy Act was passed for the "safety of the public." No mention is made of benefit to the chemist—the reason for the Act should be kept in mind. Years ago the judges decided that the public was sufficiently protected if a company employed a qualified assistant to sell (and by assumption to dispense) poisons. It was curious reasoning to find that companies were outside the terms of the Act, and then to sanction their practising the art thereof, entirely contrary to what an individual might do. (2) If the safety of the public is the only consideration, then I claim that my nearest grocer, a very respectable and conscientious man, should, if he chose, open a chemist's department with a qualified assistant. The public would be as safely studied, probably more so. (3) Scattered over the country are some hundreds of rejected Minor candidates, some in despair, others "waiting for something to turn up," who have all served an apprenticeship of several years in the business. I contend that these should be allowed to open shop by keeping a qualified assistant. Certainly the safety of the public would be greater than in either of the cases just considered. (4) Then the Pharmacy Act is practically a dead letter. It is for the Council to decide the best procedure—probably a leaflet showing our arguments sent to each Association, through the local secretaries, to be by them brought to the notice of the M.P.'s for their districts, would be desirable.

Northampton, February 19, 1900.

J. CLOWER.

ANSWERS TO QUERIES.

Special Notice.—Scientific, technical, legal, and general information required by readers of the *Pharmaceutical Journal* will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured. Not more than six plants should be sent for recognition at one time.

NAME OF PLANT (J. E.—39/10).—It is from *Juniperus sabina*.

BOTANICAL (W. L. M.—38/33).—Yes, they are all named correctly.

PRELIMINARY EXAMINATION (M. P. F.—39/4).—Certainly. See article at page 189.

CHARGE FOR ADVERTISEMENTS (C. B.—19/47).—The matter is not one which concerns the Editor.

CIRCULAR (A. W. H.—39/6).—There is no question of legality involved; it is purely a matter of taste and expediency.

MERCURIC CHLORIDE TABLETS (W. B. B.—38/34).—They should be dealt with as coming within Part 1 of the Schedule.

CLASSES IN BACTERIOLOGY (S. E. D.—39/3).—At the Jenner Institute, Grosvenor Road, S.W., and at King's College, Strand.

EXPOSURES OF QUACKERY (A. A.—39/7).—The two pamphlets were published by the Savoy Press, Limited, 115, Strand, W.C., at 1s. each.

MATRICULATION EXAMINATION (H. F. W.—39/11).—Yes, the choice of subjects does not affect the matter, so long as you pass your examination.

GERMAN JOURNAL (W. R. W.—39/2).—The *Apotheker Zeitung*, published at Spandauerbrücke 14, Berlin C. 22. There is no London agent. Why not advertise in the *P.J.*?

BOTANICAL (C. S. H.—39/10).—(1) A lichen, *Cladonia pyxidata*; (2) a moss, *Barbula unguiculata*; (3) A fungus, probably *Stereum purpureum* in an early stage of growth.

SCHOLARSHIPS (W. E. B.—39/1).—You will find the information you require in the Educational Number of the *British Journal of Dental Science*, published in September last. It can be referred to in the Society's Library.

BLOCKS OF LINEN GLAZE (H. E. S.—38/3).—The majority of these are nothing but hard paraffin, which is melted, added to the starch, and well mixed. Probably a solid block made on the lines of the formula given at p. 101 (*P. J.*, Feb. 3, 1900), evaporating only to a stiff paste instead of to dryness, would give a good result.

VIOLIN VARNISH (J. W. B.—39/8).—We do not know the address you mention. The following formula is said to give very good results:—Copal resin in coarse powder, 2 ounces; camphor, 120 grains; mastic, 120 grains; Canada balsam, 120 grains; methylated spirit, 10 fl. oz. Mix and let stand, in a well-corked bottle in a warm place for several days, with frequent agitation, until all the resins have dissolved, then shake up well with coarsely powdered glass, and allow to stand until bright; then decant the bright liquor.

LIQUOR AMMON. AROMAT. (W. H.—38/24).—The following has something of the flavour and the greater part of the stimulating effect of sal volatile:—Ammonium carbonate, $\frac{1}{2}$ oz.; strong solution of ammonia, 1 fluid oz.; oil of nutmeg, 34 minims; terpeneless lemon oil, 5 minims; alcohol, 90 per cent., 1 fluid oz.; kieselguhr, *q.s.*; distilled water to produce 1 pint. Add the oils to the spirit and rub down with a little kieselguhr. Dissolve the ammonium carbonate in 15 fluid ozs. of the water, and add the solution, with constant rubbing to the oily triturate; transfer to a well-stoppered bottle. Add the solution of ammonia and enough water to make up to 20 fluid ozs. Let the mixture stand, with an occasional thorough agitation, for 24 hours, then filter.

THE SCHOOL OF PHARMACY.—SESSION 1899—1900.

BY ONE OF THE STUDENTS.

As far as the work goes there is little difference between one session and another. There is the student who only works when he has nothing else to do, the average student whose spirit is willing but whose flesh is weak, and the "swot" who will not desert the study of cinchona bark even for the latest war news, who is bending over his burette when you go to dinner and in the same position when you return. As of yore, the Lord Mayor's Show attracted those from the country to their inevitable disillusionment, at the expense of a lecture. The departure of the Guards for South Africa also caused the laboratories to be deserted. There was the usual struggle with the Magdeburg hemispheres in the physics lecture, and explosions in the chemistry laboratories are greeted with the same interest. The novelties that attracted the greatest attention were the two electric ventilating fans in the lecture theatre, which ventilated with such vigour that several people caught bad colds and overcoats became the fashionable wear for lectures. They have now, however, been provided with covers, and only work when required.

The social side of the Square has been carried on with success, and many students gained useful experience in the process. The Football Club has had a successful season, having so far won eight matches and lost three. They have scored forty-three goals to their opponents' thirteen. The Inter-Pharmacy Football League has created great interest, and the Square team is hoping to win the Cup. Of the six matches played they have won four, lost one, and one, which was won, has to be replayed owing to a protest on a technical point. There is only one other club in the League in such a favourable position, and if it comes to a deciding match with them the team, under the capable leadership of Mr. W. Owen, look forward to the struggle with confidence.

A very good programme was provided for the Football Smoking Concert, and it resulted in a great success. A collection, which realised nearly £9, was made, in conjunction with one among those students who did not attend the concert, for the benefit of the War Funds. The Football Club also subscribed to the collection made by the Middlesex County Association for the same purpose.

The Students' Association, under the management of the energetic secretaries, Mr. C. W. B. Heslop and Mr. C. T. Allen, has had record attendances at its meetings. An innovation that has been much appreciated is the provision of tea before the meetings, thus enabling members to attend without going outside to get refreshment or else suffering the pangs of hunger during the proceedings. The papers have been well above the average, and the discussions on them have been good. One debate has been held, on the question of a compulsory curriculum, which showed a surprising amount of debating power in the School.

The interest taken in the working of the Association is shown by the fact that a committee has been appointed to revise the Rules, some of which are ambiguous.

The annual School Dinner, which came off on Wednesday, was a great success, and Messrs. E. Chapman and J. Lawson are to be congratulated on the result of their hard work in organising it.

The hearty good wishes of all the students are with Mr. J. S. Hills, who has gone to South Africa with the battery of Vickers-Maxim guns attached to the C.I.V., and while they are searching for the elements in vascular tissue they think with envy of Driver Hills in his more exciting and interesting task of seeking for Boers among the kopjes. The football team also deplore his loss, as he was one of their best players.

The taking of the annual School photograph this year precedes the Major examination, for which students are at present preparing. This year another photograph has also been taken, and affords further evidence of the influence of the war. The proposal, made in this Journal by Mr. F. A. Upsher Smith, for the formation of a Drill Class among the students, has been carried by its originator

SCHOOL OF PHARMACY—CLASS OF 1899-1900.

From a Photograph by W. S. Bradshaw & Sons.

SCHOOL OF PHARMACY DRILL CLASS.

From a Photograph by W. S. Bradshaw & Sons.

to a successful issue. Every Wednesday evening those who appear on the annexed page assemble in the Examination Hall, the use of which has been granted to them for that purpose by the Council, to drill under the direction of Colour-Sergeant Jones, of the 2nd Battalion of the Grenadier Guards, whose stalwart form may be perceived in the centre. They thus increase their store of health with which to face the less pleasant, but swiftly-approaching, meeting which will take place in the same room. The support the scheme has received leads the promoters to hope the class will be continued in future sessions.

Annual Dinner.

The annual dinner of the students of the School of Pharmacy of the Pharmaceutical Society was held in the Caledonian Salon, Holborn Restaurant, on Wednesday, February 21, Professor J. Norman Collie (Dean of the School) in the Chair. He was supported on the right by Mr. William Martindale (President), Professor Greenish, Mr. C. B. Allen, Dr. J. Attfield, and on the left by Mr. Michael Carteighe (School Visitor), Professor J. Reynolds Green, Mr. Walter Hills, Dr. A. P. Luff, Professor J. P. Farmer, and by other gentlemen well-known in pharmaceutical circles.

After an excellent dinner, and the toast of "The Queen," Mr. H. DEANE (Bell Scholar), proposed the toast of

THE PHARMACEUTICAL SOCIETY.

He referred to the work of the Society, and said that from the commencement it had worked for the improvement of the position of pharmacists. Some people thought that it had not been successful in that, and that it should be more energetic in connection with the company pharmacy problem, especially with regard to the Companies Bill. Whatever might be the opinion of those people, it remained the fact that the Society is the only organisation whereby the position of pharmacists can be improved. He then went on to speak of the interest the Society takes in the "Square" students, and mentioned, as an instance, that when they applied for the use of the Examination Hall for the recently formed drill class it was at once granted. He had pleasure in asking all to drink the toast of the Pharmaceutical Society.

The PRESIDENT, in reply, thanked all for the hearty manner in which the toast had been received, and recalled the fact that the Society has been established over half a century, has done good work, and is still capable of doing more. It should be remembered that the Society was founded by pharmacists for pharmacists, and has been kept up by pharmacists. Referring to the School of Pharmacy, he expressed the hope that the students would continue to improve upon the good work he understood they were doing this session, and that in years hence they would not be ashamed of their work. It was a beneficent work done to relieve human suffering, than which there was no nobler work. He also hoped they would be true to their *alma mater*; not only to the school and its associations, but to each other, and that they would have that *esprit de corps* towards their fellows which is so essential to the success of any body of men. Nothing created that *esprit de corps* so much as work, whether in the school, or at football, or at drill, so necessary to the discipline which is being so nobly exemplified by the British Army at the present time. The Council was proud to think that the students were taking up drill, and were being enthusiastic in that work. He hoped it would not be the least important part of their duties at the "Square."

The CHAIRMAN then called upon Mr. M. Carteighe to propose the toast of

THE SCHOOL OF PHARMACY.

Mr. CARTEIGHE, who was received with almost deafening applause, said he hoped they would reserve a little of their energy for a later period of the evening, as he had come there to enjoy

himself. That he proceeded to do by delivering an entertaining speech of some considerable length. He considered that the greatest benefaction that the founders of the Society bestowed was the founding of the School of Pharmacy. Pharmacists were all subject to competition, and all were generally badly used, but in that respect they were not much worse off than in sundry other branches of trade and professions. Competition was a factor in all professions, but the students in the school were receiving instruction—based really on the excellent curriculum laid down in 1842, when the school was established—which would assist them greatly in after life. Mr. Carteighe then briefly sketched the history of the School of Pharmacy—which he described as the backbone of the Society in the old days—and stated that it was largely due to the recognition of the educational value of the Society that it obtained from Parliament the charter of 1852. At that time, and again in 1868, there was a disposition in every part of the House of Commons, and in every department of the Government, to receive any proposal that the Society brought forward in regard to Pharmacy laws on the basis of education. Those who were associated with the school at the present time would do well to remember that the most important factors to success in pharmacy were capability and proper training. However brilliant a man might be, success could only come by steady drilling in that curriculum which the Society had vainly tried to make compulsory. He believed, however, that the time will come when it will be compulsory. Mr. Carteighe then referred to the election of a distinguished honorary member of the Pharmaceutical Society as a member of the House of Commons, namely, Sir Michael Foster, an educationalist of world-wide fame, who had been associated with the educational work of the Society for several years. The founders of the Society thought that a good school was the first essential in their programme, and he hoped that within a measurable distance of the present time the Council would be able to announce that arrangements have been made whereby students of the school shall be able, on easy and equitable terms, not only to obtain a university degree, but to be associated with the University of London. Mr. Carteighe then referred to the change made a year or so ago in the curriculum, and said it had not only been successful, but had brought about a change in the disposition of educational bodies towards the school. He hoped the time would come when second year's students would see the advantage, pecuniarily, of a third or even a fourth year at the school in order to work at some particular branch of knowledge under the direction of the professors. Mr. Carteighe went on to speak in high terms of the professors and demonstrators. He asked all to drink success to "the dear old School of Pharmacy," with which he was himself associated for so many years.

The CHAIRMAN (Professor Collie), replied. With regard to the lengthening of the curriculum, he thought the Council had acted wisely. It not only gave students a better chance in getting that necessary training so essential to their success, but it also helped the professors. The school was certainly in a very efficient condition, not only from an educational point of view, but also in its manlier aspects. He referred to the football team, and said it had only suffered one defeat during the present season, and he thought it was extremely likely that the cup which was being offered for the best pharmaceutical team would find a home at the "Square." In regard to the drill class, he hoped it would be carried on with the success attending its commencement, it would certainly be productive of one thing—a good healthy perspiration. Professor Collie then made a few remarks respecting the teaching in the school, stating that some of the students were very scientific, in that they looked at things from different points of view. Science was a very curious and somewhat elusive study, and he found that students could look at it from various standpoints. Professor Collie gave several humorous illustrations, and concluded by thanking all for the hearty way in which the toast had been proposed and received.

The toast of

THE PAST "SQUARE" STUDENTS

was proposed by Mr. WOOLCOCK in a clear and deliberate speech—displaying decided elocutionary ability—which appeared to be enjoyed both by speaker and audience. Referring to Professor Greenish, he said they were proud to call him an "old boy." Notwithstanding the great value of botany and physics, it was from Professor Greenish they received the instruction which fitted them for the work of pharmacists, and the great care he took with the students fitted them for that duty, while he did not forget that the Minor examination was a necessity. They all owed him a deep debt of gratitude. Then there were also Mr. Upsher Smith and Mr. T. E. Wallis, both old boys. To Mr. Smith they were indebted for the formation of the drill class, and in this connection he quoted Shakespeare's well-known lines:—

If England to herself be true,
Come the four corners of the world in arms and we will shock them all.

There were those who would have been with them that night, but they were out on active service. He alluded to Mr. Lorimer and Mr. J. S. Hills. They had not all the pleasure of knowing Mr. Lorimer, but they had associated with Mr. Hills for three months, and in that time had learnt to respect him and to regard him with affection. They all hoped he would come back safely, when they would give him a hearty welcome. He coupled with the toast the name of Dr. A. P. Luff. He also referred to "the ever genial Mr. Carteighe, of whom they had heard ever since they had been connected with pharmacy.

Dr. LUFF having replied, songs were rendered by Messrs. C. H. Baker, C. Morley, E. Jenkin, W. Owen, and C. Davis; a character sketch, "The Beano," was given with good effect by Mr. T. Morley Taylor. The accompanist was Mr. A. Newton, who also performed a well-executed pianoforte solo.

Dr. JOHN ATTFIELD, in a brief speech, proposed the toast of "The Chairman."

After Professor COLLIE had responded, the programme was continued, an extra item being added towards the end, Mr. Michael Carteighe having been persuaded to sing one of his well-known songs.

PROCEEDINGS UNDER THE PHARMACY ACTS.

CASE UNDER SECTION 17.

Pharmaceutical Society v. J. and J. Thompson, Limited.

At the Oldham Police-court on Wednesday, February 21, this case came on for hearing. The magistrates on the Bench were Dr. Yates (in the chair), Mr. T. T. Taylor, and Mr. C. C. Spencer.

Mr. Robson, solicitor, Manchester, appeared for the prosecution, and said in his opening that he appeared to prosecute on behalf of the Pharmaceutical Society. This was a charge of poison being sold without having the name and address of the seller put on the bottle or wrapper containing the poison. Having recited the section of the Act, he stated that on January 29 a sale was made of Dr. J. Collis Browne's chlorodyne, and he had received a letter from Messrs. J. and J. Thompson's solicitor admitting that Dr. J. Collis Browne's chlorodyne contained chloroform and morphine, so that it would not be necessary for him to prove that this medicine contained poison. In this, as in many other cases, the mere fact that they were able to find evidence of medicines having been sold without a label was an indication, or, at any rate, a fair assumption to draw, that this was not the only case that had occurred, and although he did not ask for a vindictive fine, he hoped they would show in a substantial

way that this dispensing and sale of medicines must be carried on in a more careful manner than appeared to be the case in the present instance.

Arthur Foulds gave evidence that on January 29 last he went to the shop of Messrs. J. and J. Thompson, Limited, and bought a bottle of Collis Browne's chlorodyne, for which he paid 9d. He produced the bottle, which had on it no label showing the name and address of the seller by which it could be identified. He bought a bottle of glycerin at the same time. That bore the seller's name.

Mr. Sixsmith, in defence, said he found no fault except that this was a prosecution, not in the interests of the public, but in the interests of a particular Society. His clients had a system by which the manager of each shop sent an order to the general manager, and there was a requirement that these proprietary articles should not be supplied over the counter by any assistant who might be there, but through the responsible manager, and, in corroboration of this, he should call the manager himself to give evidence. In respect to the labels, each assistant was personally cautioned against selling those poisons without the bottles being labelled. Possibly one might have been overlooked, and in that instance it seemed to have been the case, because there was evidently not the name and address of the seller upon the bottle. He put it that this was an oversight, and he asked the magistrates to deal very leniently with the case.

After the Bench had consulted, the Chairman said no doubt a bottle of chlorodyne had been sold without label, as required by the Pharmacy Acts. Whether it was carelessness or not he could not say. The defendants had neglected their duty, and they had no alternative but to inflict a penalty. It would not be a vindictive one—20s. and costs.

Mr. Robson: Will you allow the advocate's fee?

The Chairman: We take it this is a proper thing to bring into Court, and we shall allow you a guinea.

PRACTICAL NOTES AND FORMULÆ.

To Remove Tattoo Marks.

Salicylic acid massed with glycerin to the consistence of dough, applied over the marks with a compress and strips of adhesive plaster, and allowed to remain in contact for a week, will, according to T. H. Whiting, eventually remove tattoo marks. After the first dressing, the epidermis over the marks is removed, and a fresh application of the salicylic acid applied. Usually this second application removes the marks, but sometimes it is necessary to make a third.—*Med. Brief.*, 27, 1803.

Dose of Scopolamine.

Windscheid calls attention to the fact that the doses of scopolamine (hyoscyne) generally given are too high. From his own observations he concludes that the initial dose, whether by the mouth or by injection, should not exceed one tenth of a milligramme. To counteract the nocturnal transpiration in phthisis, he gradually increases this to 0.0004 Gm.—*Journ. de Pharm. d'Anvers*, 56, 17, after *Oesterr. Zeit. für Pharm.*

Epichlorhydrin and Dichlorhydrin as Solvents.

E. Valenta, who has found the above useful as solvents for resins, gives the following recipe for a copal varnish:—Manilla copal, 20, is dissolved in epichlorhydrin, 70, on the water bath; absolute alcohol, 100, is added, and the whole filtered. The varnish may be applied either hot or cold, and may be diluted with a mixture of epichlorhydrin, 1, alcohol, 5. It dries hard and bright, and stands well.—*Pharm. Centralh.*, 40, after *Photogr. Corres.*

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australia, South Africa, etc.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

Members of the Pharmaceutical Society must address all communications with reference to the transmission of the Journal, to the Secretary, 17, Bloomsbury Square, London, W.C.

LONDON: SATURDAY, FEBRUARY 24, 1900.

THE PRESENT NECESSITY.

THE circumstance that a copy of this week's Journal will be sent to every individual on the Register of Chemists and Druggists, affords an opportunity of bringing under the notice of the entire body, the necessity of immediate action in regard to the intentions of the Government embodied in Clause 2 of the Companies Bill which is now awaiting a second reading in the House of Commons. As stated in last week's Journal, the nature of the clause is essentially the same as that in the Bill which passed through the House of Lords last session. However inconsistent the effect of its provisions may appear to be with the declared opinion of the LORD CHANCELLOR that "the idea of an ideal personage—such as a company—practising and undergoing an examination is absurd and cannot cohere with the language of the Statute"—whatever may be the purport of his Lordship's further statement that he is "very strongly convinced that a company ought not to be permitted to do what a private person is prohibited from doing" the fact is beyond question that this Clause of the Companies Bill—presumably introduced at the instigation of the LORD CHANCELLOR—proposes to enable, and authorise, a company to do the very things that the LORD CHANCELLOR has declared to be absurd, contrary to common-sense and to his conviction as to what should be permissible. The effect of the clause, as it stands, is not merely to bring companies within the scope of the Pharmacy Act by providing that anything which would be an offence if done by an individual should, if done by a company, be an offence for which the company is to be liable; but it also implies that, under certain conditions, a company may carry on the business of a pharmaceutical chemist or chemist and druggist. As a company cannot be qualified, the effect of the clause would be to break down the statutory provision that it is unlawful for any unqualified person to keep open shop for the purposes to which the Act relates. That invasion of the privileges attaching to qualification under the Pharmacy Act, is considered by many quite sufficient to justify opposition to the measure; but unfortunately the opinions of registered chemists are divided as to the course to be

adopted, and that want of agreement has hitherto found expression in the Council so as to prevent representative action on any line commanding general support.

But a far more serious invasion of the privileges attaching to qualification under the Pharmacy Act is the implied provision that a company may not only carry on the business of a pharmaceutical chemist or chemist and druggist, but may also use the titular designations now obtainable only by individual qualification. That would be a personal injustice to all legally qualified persons, and it would also be contrary to public policy, inasmuch as it would abolish the value of the criterion provided by the Pharmacy Act, 1868, for the express purpose of enabling the public to recognise the persons certified as being competent to discharge the functions to which the legal qualification relates. For both these reasons the clause in the Companies Bill should be strenuously opposed. On this point of title it may be anticipated that there cannot be any difference of opinion among legally qualified persons, nor can there be any reasonable objection to their claim to exclusive use of titles representing the statutory qualification demanded in the interests of the public. It is unnecessary, in connection with this point, to consider the conditions subject to which the proposal is made to legalise the use of titles by companies. If companies of unqualified persons are to be permitted to carry on the business of pharmaceutical chemists or chemists and druggists, and legally authorised to do so, the propriety of the stipulation that such business should be *bona fide* conducted by legally qualified persons may be maintainable; but that cannot be used as an argument for allowing companies to use titles they cannot acquire. Under existing conditions it seems desirable, therefore, that in the sense of the remark in Sir MICHAEL HICKS-BEACH's reply to Mr. TURNER (see p. 194) as to "the interest affected taking steps for an amendment to be moved when the Companies Bill is in Committee," every registered chemist who desires to protect his title from misuse should at once put himself in communication with his parliamentary representative and urge upon him the very simple arguments requisite for the purpose of securing opposition to that part of the clause.

It appears from the letter of Sir MICHAEL HICKS-BEACH that this particular point has not escaped the notice of Mr. RITCHIE, who is in charge of the Bill, and it may be useful, in showing the difficulties of the position, to state that the reply made, on behalf of the Government, to urgent appeals for an amendment of the clause that would place registered chemists in the position they occupied before 1880, has been that such a proceeding is considered to be absolutely impossible. The position taken by the Government is that the condition of things, actually existing at the present moment, requires to be regulated, and from that point of view the question presents itself whether the public is any better served or protected when registered chemists carry on branch shops, even without qualified assistants, than in the case of limited companies. That is the answer given to every argument brought forward and, to the disadvantage of qualified chemists, the legalisation of companies is justified, on the ground that they would be compelled to have legally qualified persons to conduct their business, and to ex-

hibit their names in that capacity, while there is no certainty that such is always the case in the shops of registered chemists. In fact, the mind of the Minister who has charge of the Companies Bill appears to be impressed with the opinion that though chemists, legally qualified under the Pharmacy Act, 1868, are privileged persons, they cannot, as a body, be treated by the Government in the same manner as professional men. It appears to be thought that in very many instances registered chemists have neglected their privileges, have omitted to take advantage of the opportunities of self-protection which the Act afforded them, and desire the Act to be put in force only as a means of obtaining for themselves a trade monopoly. That is a lamentable position to have reached, and the more so since there are many who are not open to any such condemnation; but it is not the less urgently necessary that those who are earnest in desiring to uphold the credit of the craft and defend their own rights, should make a vigorous effort to put the pharmaceutical house in order, and bestir themselves in devising protection from enemies within as well as without their ranks.

CHEMISTS AND THE COMPANIES BILL.

In view of the fact that the *Pharmaceutical Journal* will circulate much more widely than usual among registered chemists this week, it appears opportune to point out again that the Companies Bill, introduced into the House of Commons last week by Mr. RITCHIE—the President of the Board of Trade, contains the following clause, which, if it becomes law, will give legal sanction to unqualified persons who form themselves into limited or joint-stock companies to carry on the business of a chemist and druggist, and to misuse chemists' titles:—

2. No company may carry on the business and use the description of a pharmaceutical chemist or chemist and druggist unless the business is bona fide conducted by a manager or assistant being a duly registered pharmaceutical chemist or chemist and druggist, as the case may require, nor unless the name of the person so qualified is conspicuously posted in the shop or other place in which the business is carried on, but, subject to this provision, anything which would be an offence under section fifteen of the Pharmacy Act, 1868, if committed by an individual, shall be an offence if committed by a company.

In a subsequent clause it is provided that such companies shall not practise as medical practitioners, dentists, or midwives. Thus:—

3. It shall be unlawful for a company to carry on the profession or business of a physician, surgeon, dentist, or midwife, and if any company contravenes this enactment it shall be liable, on summary conviction, to a fine not exceeding five pounds for every day during which the contravention happens.

The Bill is now down for second reading, and may come up for discussion in the House of Commons at any moment when the state of public business permits. At that or a later stage, it is not improbable that the registered chemists of Great Britain may need to call upon their representatives in Parliament to offer opposition to the progress of Clause 2, and, that being so, they ought to be prepared with good reasons for asking that the Clause should be rejected or amended.

In the first place, they may point out that it is contrary to public policy that any person who does not possess a competent practical knowledge of the business of a chemist and druggist should be permitted to use the titles mentioned in the Clause, or to exercise any control over the retailing, dispensing, or compounding of

poisons. Further, the individual actually conducting each establishment where poisons are retailed, dispensed; or compounded, should be personally responsible to the public in respect to all business carried on in that establishment, and no manager or assistant should exercise such control over the business as alone would suffice in the public interest. Over and above that, in the event of the Clause referred to becoming law as it stands, it would be in conflict with the decision of the House of Lords that the seller of poisons under the Pharmacy Act is the individual who actually conducts the sale, and not the proprietor of the business on whose behalf the sale is effected. It may also be urged with even greater force that it is unjust to sacrifice the vital vested interests of a legal qualification for the sake of a number of unqualified traders who have invested a certain amount of capital in a business which they are not legally entitled to carry on as individuals, but that would be the position if the Clause became law in its present form.

Last, but not least, stress might be laid on the fact that it is as important to a patient that his medicine—particularly if containing potent remedies—should be dispensed by a competent person, as that his medical attendant should be properly qualified, and that, whilst registered chemists do not seek to interfere in any way with the existing free trade in drugs and medicinal preparations, they consider that—so far as their strictly professional duties are concerned—they are entitled to be placed on the same footing as medical men, dentists, midwives, etc., whose practice it is proposed to protect, as against companies, by Clause 3 of the Companies Bill. But Clause 2 proposes that an individual qualification—restricted by Statute during the past thirty-two years to persons who have proved their fitness to retail, dispense, or compound poisons—is to be thrown open to use by companies and consequently to any unqualified individual who can associate with him six other unqualified individuals, on the sole condition that he procures a duly registered person to act as cover.

AFTER AUGUST, 1900.

UNDER the above heading will be found, at page 189, a very full explanation of the coming changes in the examination arrangements of the Pharmaceutical Society, advantage having been taken of the fact that this week's Journal will be sent to every person whose name appears on the Register of Chemists and Druggists, to state in the fullest manner possible that after the month of August next, the "First" or preliminary examination of the Pharmaceutical Society will cease to be held. The fact has been stated over and over again, but many correspondents seem to think there must be an examination *after the last*, and—however unnecessary the step may appear to logically-minded persons—it has been decided to explain in detail why that cannot be. Readers are told in the article referred to what the new conditions are, what they mean, and what the probable effects of the coming changes will be. But the main point to be noticed is that the "First" examination will be held for the last time in July next, and that the existing arrangements for testing the general education of candidates for the Minor examination will then be superseded.

ANNOTATIONS.

THE REGISTER OF CHEMISTS AND DRUGGISTS doubtless ought to be, as many amateur critics insist, much more free from inaccuracies than it really is, but it is not generally recognised that the remedy rests with the persons who are registered and not with the Registrar. It is essential that every registered person should clearly recognise the fact that the Registrar is not omniscient, and that he is only in a position to correct inaccurate addresses when the individuals directly concerned supply him with the necessary information. As soon as a registered person changes his permanent address he should promptly notify that fact to the Registrar, or the chances are that he will forget to do so later and, at the next revision of the Register, his name will be omitted. The additional fact that inaccurate addresses may be found in the Register, having apparently been overlooked when the periodical revision took place, is explained by the circumstance that official communications are frequently taken in at the places to which they are addressed, although the persons for whom they are intended have been gone from there some time. If those communications are not acknowledged or returned through the Dead Letter Office, the Registrar is obliged to conclude that they were properly addressed. They may or may not ultimately reach the hands they are intended for, but in a large proportion of instances neglect to deal with them proves fatal to the accuracy of the Register. The only efficient remedy, it is to be feared, is the oft-suggested one of an annual registration fee.

THE FEDERATION OF LOCAL PHARMACEUTICAL ASSOCIATIONS has held a meeting in London this week, at which it was decided to suggest to the federated associations a list of suitable topics for discussion during the remainder of the current session. It was also resolved to recommend the associations to take action in regard to the Companies Bill, by interviewing members of Parliament, and pressing them to vote for the rejection or amendment of Clause 2 of that measure. As an aid in the matter it was decided to draw up a set of reasons why the Clause should be rejected or amended, for the information of Parliamentary representatives. It is to be suggested to the associations that they should adopt one of two courses:—(1) Ask members of Parliament to vote for the restriction of chemists' titles to duly qualified individuals, and that companies of unregistered persons should be prevented keeping open shop for retailing, dispensing, or compounding poisons; or (2) Ask for protection of titles and insist upon the need of a qualified directorate, each establishment where poisons are retailed, dispensed, or compounded, being in charge of a qualified manager whose name shall appear in a prominent position. It will thus be seen that the Federation Executive, recognising the want of unanimity which prevails in pharmaceutical circles throughout Great Britain, finds itself unable to recommend a single definite course, and leaves the associations to select their own. It is significant, however, that no intention is shown of being content with protection of titles only, though that in itself is regarded as indispensable in any case.

DIVISION OF THE MINOR EXAMINATION may be a generally desirable thing or it may not; but there is a strong feeling on the part of those who are best qualified to judge that such a change in the existing examination system of the Pharmaceutical Society is undesirable unless accompanied by the adoption of a compulsory curriculum. The arguments against the proposed division are ably put by a correspondent, who is precluded by his position from signing the letter which appears at page 192, but whose expression of opinion is none the less valuable on that account. It is noteworthy that he insists upon the necessity of the standard being raised in each subject if division of the examination

is to become an accomplished fact. With that view anyone who is conversant with the difficulties encountered in conducting examinations will perforce agree. The object of effecting any change in the examination must always be to secure increased efficiency, not to enable candidates to pass with greater facility. In considering this subject it is necessary to bear in mind that the duty of the Pharmaceutical Society is to prevent the registration of incompetent persons as chemists and druggists, and that object is not likely to be attained by splitting up the qualifying examination in such a way that candidates can pass piecemeal after cramming the minimum amount of information in one or two subjects at a time. The experience of other examining bodies—notably the University of London—goes to prove that no undue strain is imposed on candidates by the necessity of studying a number of subjects at one and the same time. It is the methods of study adopted which make the difference, and if a compulsory curriculum were in force there would be few, if any, complaints such as are voiced by those who advocate division of the Minor examination. If anything is really amiss in the existing system of examination, it is that the candidate is examined in too many subjects in a limited time, but that can be remedied without dividing the examination on such lines as have been proposed.

REFERENCE MAY BE MADE, while on this subject of examinations, to an amusing letter which appears in the *Harrogate Advertiser*, of all places in the world, protesting against chemists being examined in anything except a knowledge of poisons. So far as botany, chemistry, etc., are concerned, the anonymous writer of the letter is assured that "the whole affair has been simply arranged . . . to keep as many out as possible!" And that in spite of the fact that some five hundred and fifty candidates passed the Minor examination last year. The ignorance of the writer of the letter may be judged from his statement that the questions at the Minor examination are only asked in order to make it difficult for the candidate to become a chemist, the following fearful example of the questions asked being gravely propounded:—"How to make *infusum rosæ audum* (*sic*), a perfectly harmless preparation, which it is not necessary for anyone to have to learn, as one would have the books that would contain all such information." If, as appears not unlikely, the writer of this curious epistle has been plucked at the Minor examination, or anticipates being so shortly, we can only suggest that it is a distinct misfortune to the British public if he has been permitted to pass the First examination or one of its equivalents. And whether he has or not, he would become decidedly less absurd if he were compelled to go through a prolonged course of scientific, technical, and general education.

THE CHEMISTS' ASSISTANTS' ASSOCIATION will hold its twenty-second annual dinner in the King's Hall, Holborn Restaurant, London, on Tuesday, March 8, and tickets (5s. each) may now be obtained of Mr. Herbert Hymans, 34, Devonshire Street, W. The chair will be taken on this occasion by Mr. F. W. Gamble, President of the Association, who expects to be supported by Mr. William Martindale, President of the Pharmaceutical Society; Mr. E. M. Holmes, President of the British Pharmaceutical Conference; Dr. William Murrell, and many other friends of the Association.

THE FORTHCOMING INDIAN AND COLONIAL ADDENDUM to the British Pharmacopœia is the subject of a further report to the members of the Pharmacopœia Committee of the General Medical Council, and part of that report is reprinted in the current issue of the *Pharmaceutical Journal* (see p. 187). The Editor of the Addendum anticipates the production of a satisfactory Indian Section within the next few months, and a well-developed Indian Appendix of the next British Pharmacopœia.

THE METRIC SYSTEM OF WEIGHTS AND MEASURES appears likely to be introduced shortly in Russia, a scheme to that effect, prepared by the Ministry of Finances, having already received the approval of the Council of State, on the condition that it should be supplemented by a scheme for organising the aid which different scientific societies and the universities are ready to render, in the verification of the new weights and measures for commerce. According to *Nature* the latter scheme is nearly ready, and will shortly be brought before the Council of State. In the military pharmacopœia, published in 1896, all measures are already given in the metric system, which has thus been rendered obligatory for the medical staff of the army.

THE "MEDICAL PRESS," having been reproved by the Pharmaceutical Society of Ireland (see *ante*, p. 165) for suggesting that pharmaceutical chemists are "incapable of dispensing minute doses of potent drugs," trusts it will not be considered disrespectful to say that the statement attributed to it was never published in its columns. But that is a mere evasion. It is true that the words we now quote from the letter written by the Registrar of the Irish Society were not those which actually appeared in the *Medical Press*, but it was asserted in an editorial note which appeared in that paper that the very active alkaloids "cannot be compounded even by the most capable and conscientious chemist without the risk that the entire dose will be concentrated in one or two pills."

THE STANDARDS OF PURITY FOR DRUGS suggested by Mr. C. G. Moor are of such great interest to chemists and druggists that Mr. Moor has been asked by the Editor to explain what is the exact position taken up by him in the matter. Reference to the paper printed at page 172 will show that Mr. Moor's proposals are far from revolutionary, though their effect should be beneficial to everyone concerned. Briefly, what is proposed is that an agreement should be arrived at between registered chemists and analysts to establish informal standards for articles which cannot at present be judged by any legal standard. The British Pharmacopœia is not a legal standard under the Sale of Food and Drugs Acts and, indeed, is not fitted to be so. It requires to be much more accurate and clearly written before it can be accepted as a general standard for drugs; above all else, it needs to be planned, and the work of compilation supervised, by experts. How the Pharmacopœia fails as a standard is explained by Mr. Moor, who also gives good advice to traders and points out that the demand for cheap stuff is probably the root of much evil which afflicts chemists in connection with the administration of the Sale of Food and Drugs Acts. With regard to Mr. Moor's suggested standards, it will be time enough to speak of those when they are before us, but his scheme may safely be commended on general grounds, and we trust our readers who are engaged in the analysis of drugs will respond readily to his invitation for assistance. It is high time that registered chemists and public analysts should work together amicably, rather than regard each other with mutual distrust, and if the only outcome of Mr. Moor's work should be to engender better feelings than have prevailed in the past, he will have done good service. At the same time, his scheme for the establishment of standards is quite good enough to secure for him the recognition which is his due.

THE DIFFICULTY OF SECURING CONVICTIONS under the Pharmacy Act, 1868, was once more illustrated by the proceedings at the Glasgow Sheriff Court last week (see *ante*, p. 159), when an unqualified assistant employed in a shop kept by a medical man was sued for a penalty incurred by illegally selling laudanum. The difficulty experienced was in connection with the numerous trivial objections to relevancy which were raised by the defender's agent. In the first place it was urged that the charge could not be maintained because a charge had been made for the same act against another individual, the fact of the matter being that the usual difficulty had been experienced in securing the assistant's name and another name had inadvertently been inserted in the complaint. Then the

agent demanded to know the exact hour at which the purchase was effected, the quantity purchased, the probable effects of the laudanum, and the actual harm it had done. He also asserted mistakenly that the reason for which the purchase was made should have been disclosed, and objection was taken because a man had been sent specially to make the purchase. Evidence of the fact that analysis had disclosed the presence of opium in the preparation sold was declared to be insufficient, and the results of a complete analysis were asked for. Finally, the agent demanded that the minute of Mr. Bremridge's appointment as Registrar under the Pharmacy Acts should be produced, and protested because only a printed copy of the Register was forthcoming. Ultimately, however, the Sheriff disallowed all the objections, and gave the most favourable judgment the Pharmaceutical Society has yet had recorded in such a case, the unqualified seller being fined three guineas, with two guineas costs, an exceptionally severe penalty to be imposed in Scotland.

THE BIRMINGHAM MAGISTRATE whose remarks are reported at page 207 is evidently under no misapprehension as to where the best drugs and medicinal preparations are to be obtained. A firm of druggists' sundrymen was charged with selling seidlitz powders which were deficient in tartaric acid and tartarised soda. The label on the packet containing the powders bore a warning, which was distinctly impudent on the face of it, to the effect that "thousands of boxes of common imitations of genuine seidlitz powders are sold by unprincipled traders for the sake of extra profit. We guarantee all ours to be genuine." It is not surprising to find that the magistrate described this as an abominable fraud, and fined the defendants heavily. It is satisfactory to find that he also advised the public to go to chemists if they desired to obtain proper articles.

THE EXPORTATION OF CARBOLIC ACID was the subject of a question by Sir C. Quilter in the House of Commons on Tuesday, when he asked the First Lord of the Treasury if he could explain to the House the circumstances which had influenced the Lords of the Treasury to authorise her Majesty's Board of Customs to allow, upon certain conditions, the exportation of carbolic acid and other similar articles, the exportation of which was recently prohibited by Royal Proclamation. He also asked whether the bulk of those articles was exported in a crude state, and was refined on the Continent (frequently being mixed with other raw material produced there), so as to make it impossible to trace the ultimate destination of any particular consignment after it had been refined or converted; and whether, as the object of that proclamation was to prevent articles which were capable of being converted into lyddite, melinite, and other high explosives, and for the supply of which Continental and other nations mainly relied upon this country, from reaching the Queen's enemies, he would rigidly enforce the original forms of the Royal Proclamation. Mr. Balfour, in reply, said he was informed that very careful inquiry was made into the export trade in carbolic acid and other similar articles. It was proved to the satisfaction of the Government that there was a large and innocent trade in those articles in foreign countries and in the colonies, with which it was clearly inexpedient to interfere. But the destination of those consignments can be traced very accurately, indeed, a large proportion of the exported material comes back to this country. The hon. gentleman might rest assured that the instructions which have been given will not in any way defeat the object of the proclamation.

GROGERS ARE IN FULL SYMPATHY with the P.A.T.A., a representative meeting having been held on February 8 under the auspices of the Grocers' and Allied Trades' Proprietary Articles Trades Association, at the Holborn Town Hall, when a resolution was passed in favour of joint action with the chemists' section of the P.A.T.A. to obtain a uniform rate of charge for all proprietary articles from the manufacturers, with a view to stopping the cutting of prices.

FACTS AND FANCIES.

BY AN ORDINARY PHARMACIST.

The Company Trading Difficulty.

By the omission of the word "not" at the end of one of my notes last week, I was made responsible for a statement which was the exact opposite of what I meant. Writing about the apparent difficulty of persuading the Government that pharmacists are entitled to similar treatment—in the matter of protection against companies—to medical men, dentists, and midwives, I wrote that where personal services alone enter into consideration, our rulers are able to grasp the seemingly obvious fact that some measure of restriction is imperatively called for in the public interest; as soon, however, as the price is in question of articles which call for skilled service in their proper distribution, the monopoly bogie is resuscitated and worked for all it is worth in the attempt to secure for its wire-pullers advantages to which they are *not* entitled. What we require is to have Mr. Ritchie and other members of the Government impressed with the idea that it is no mere question of trade interests which is at stake, but that we mean to persist in a thoroughly justifiable struggle to maintain, in the public interest, the value of a legal qualification which is as much a professional one as those which are dealt with in Clause 3 of the Companies Bill. Pharmacists do not ask for anything in the nature of a trade monopoly; they are content that free trade in drugs should continue to prevail, but they feel that it would be a grave error of judgment to undo the work of the past thirty-two years by giving legal sanction to seven unqualified traders to do as an association what it is, and must continue to be, illegal for any one of them to do as an individual.

The Necessity of the Moment.

What I, in common with other pharmacists, desire is that our position should be fairly stated to the Government, and that, in the event of our claims being regarded as of but trifling moment, we should press them upon the Legislature with the not inconsiderable forces at our command. It is not enough that a Minister of the Crown should say "No" in answer to our request for justice, nor ought we to consider that our attack has failed because the large number of votes at the command of the Government may enable the Minister in charge of the Bill to overcome the opposition that may be offered at any particular stage in the progress of the measure through Parliament. I contend that we must fight on to the bitter end and decline to acknowledge defeat until there is absolutely no further ground left upon which we may assemble our forces—that is to say, until the Bill has passed through all stages in both Houses of Parliament. And even then we ought only to stop for a brief breathing space preparatory to drafting and getting introduced a new Pharmacy Bill, with the object of securing the removal of the anomaly for which the fortune of war may enable the Government to secure prolongation of existence by forcing through the monstrously unjust clause in the Companies Bill.

Not Time for Compromise Yet.

It is greatly to be feared that this question of company trading has been permitted to drag so long that many amongst us, including some of the foremost pharmacists of the day, have arrived at the conclusion that the battle is already lost. We have all discussed the matter, and re-discussed it, until all but a few extreme enthusiasts have become thoroughly sick of the whole question. Every point has been carefully weighed and its significance duly considered so frequently that, as a result, I have noted a tendency to sum the matter up as though it had been fully considered in the proper quarter. After that, I find, many self-constituted judges of the case appear to think there is nothing more to be said or done, except to throw up the sponge and allow judgment to go by default. But what does it matter to me that any particular pharmacist, however eminent an authority in his own proper sphere, has settled

everything to his own satisfaction and decided that it is no good continuing the struggle? If even the whole Council of the Pharmaceutical Society had arrived at that position and unanimously decided to take no further action, I should deny the right of that body to commit me in the matter until the question at issue had been fairly and squarely stated in Parliament. To put the thing in a nutshell, the obvious duty of the Council—which it is doubtless doing its best to fulfil—is to state the company trading problem to the Government, and subsequently, if necessary, to Parliament, in such a way that it can only be solved by an absolute prohibition of the use of pharmaceutical titles by corporate bodies, and by making it a punishable offence for any unqualified person or association of unqualified persons to attempt to exercise any control over the sale, dispensing, or compounding of poisons.

The Qualified Directorate Fallacy.

An ill-conceived and audacious attempt to induce pharmacists to commit themselves to a very stupid proposal for solving the company trading problem, which has emanated from the brains of the conductors of a trade paper that does not suffer from lack of self-advertisement, should not be taken seriously, as the remedy proposed is about as hopeless a one as could well be suggested. The proposal to which I refer is that if the directors of a company were severally qualified under the Pharmacy Acts the necessities of the case might be met. But, as I have pointed out on a previous occasion, no company is required to have any directors, and the only effect of legalising such a provision would be to secure the immediate removal or self-immolation of all the directors of existing drug companies, while future companies would take good care to start operations without any. Moreover, it will be found every whit as difficult to persuade the Government and Parliament to compel all directors of drug companies to be qualified under the Pharmacy Acts as it would be to secure the prohibition of company trading in pharmacy. Every pharmacist, therefore, who takes the trouble to send to his Parliamentary representative a copy of the speciously worded document issued by the trade paper to which I have referred will have all his pains for nothing, except that he may, to some extent, have produced a bad impression upon the mind of his representative and caused him to prejudge the matter more or less unfavourably. It is difficult to imagine what right any trade paper has thus to spoil the case of those in whose interests it is alleged to be conducted, and I for one am disposed to resent such action as an impertinent interference.

The Position of the Federation.

I was disagreeably surprised, on reading the report of the Stoke-on-Trent speech of the President of the Federation of Local Pharmaceutical Associations, in last week's *P.J.*, to find that he had suggested the possibility of the organisation of the Federation being employed to interfere with the election of the Council of the Pharmaceutical Society. To quote the exact words of the report, Mr. Smith said: "With regard to the election of the Council of the Pharmaceutical Society, his own view, up to within the last few months, was that the Federation of Pharmaceutical Associations would make a mistake in interfering with the election of members of the Council. But it was quite possible that circumstances might alter cases. The Council was their representative body, and if the members of Council did not do what they ought, then it might possibly be the duty of the Federation to use some sort of pressure in the matter." No explanation is given of the reason of Mr. Smith's remarkable change of views on this important point, but it may be presumed that it is not unconnected with a desire on the part of some individuals, of whom Mr. Smith can hardly be regarded as one, to convert the Federation into a sort of caucus. Any attempt of the kind, however, is strongly to be deprecated, as nothing could be more fatal to the continued success—nay, to the very existence—of the Federation. As an organised body it has no more right to interfere in the election of

the Council of the Pharmaceutical Society than has the British Pharmaceutical Conference, the Grocers' Federation, or the Anti-Vivisection Society, and any serious attempt to convert the Federation of Local Pharmaceutical Associations into a caucus is certain to involve that organisation in irretrievable disaster. Such, at least, is my opinion, and as a well-wisher of the Federation from the time it commenced operations, I deem it a duty to make this protest and to express the hope that wiser counsels may prevail.

POLITICAL GOSSIP.

THE LOBBY has acquired quite a pharmaceutical flavour of late, and the President of the Society seems to be fast developing into what is termed in journalistic parlance "a familiar figure in politics." He has had, too, the support of a past President, who holds strong views as to the necessity for maintaining the principle of the Pharmacy Act, 1868, and who has been seen within the precincts of the House on many previous occasions. As a trade publication, in an exuberant spirit of commercial enterprise, has been good enough to supply each member of Parliament with instructions how to knock the bottom out of the aforesaid principle, it is pretty obvious that the original confusion in the minds of legislators concerning the true inwardness of pharmaceutical aspirations must have been rendered worse confounded. Now, Ministers will not listen to the impotent frettings and fumings of a disunited craft, and there is every reason to believe that Mr. Ritchie's views of the situation are not flattering to the calling. They may be summed up in three sentences—viz., (a) public convenience requires and public safety needs the regulation, not the extinction, of the existing conditions; (b) a well-conducted company pharmacy can be no more menace to the safety of the community than the branch establishment of a registered chemist who runs a dozen shops; and (c) Parliament will not look at any project for prohibiting company trading. We happen also to know that Mr. Ritchie would not be keenly disappointed if the Government were forced to drop Clauses 2 and 3 from the Bill, nor has he ever disguised his opinion that they should not have been inserted in a Companies Bill; he may eventually succeed in converting the Lord Chancellor to a similar opinion.

THE SITUATION is not pleasant, but it is distinctly clearer now that the mental attitude of the Minister in charge of the Bill has been ascertained—that is to say, so far as the inner consciousness of a statesman can be fathomed. Under existing conditions the choice is between regulation and nothing. A wise course of action on the part of the Council, supported by the chemists and druggists of the country, or, at any rate, not hampered by them, could secure an equitable and reasonable regulation, whereas an unwise or precipitate line of conduct will result in the elevation of pharmaceutical registration by company machinery into a recognised public position. When the inexorable logic of the Board of Trade is realised amongst pharmacists, it should do much to promote agreement within their ranks, and it is to be hoped that even the free and ultra-independent "prohibitionists" of an important provincial centre will now see the futility of "kicking against the pricks." There is, however, no cause for anything in the nature of panic as a sequel to Mr. Ritchie's conception of "reasonable and logical" treatment of the company pharmacy question; for the Companies Bill, though it appears on the notice paper twice or thrice a week, will not be taken to its second stage for some time to come. It was last amongst the orders of the day for Thursday, and it is somewhat significant, and perhaps reassuring, that the Railways (Prevention of Accidents) Bill is given precedence by Mr. Ritchie over the Companies Bill.

THE THREE MEASURES regulating boilers, their makers, their proprietors, their users, and all thereunto pertaining are still, fortunately, in somewhat forlorn positions in relation to a second reading, and Sir J. Fortescue Flannery (Shipley) has further damaged whatever chance the Boilers Registration and Inspection Bill had, by intimating that whenever the second reading stage of the Bill is reached, he will move that no Bill is satisfactory which does not provide for the appointment as boiler inspectors of engineers of not less than two years' workshop experience. In short, the honourable gentleman holds the view that if it is necessary to have State regulation of boilers, it should be effected by means of men who know their business, and have acquired their knowledge in the laborious and often painful school of Experience.

BEFORE THE MILLENNIUM dawns Society will be divided into two classes only—the inspectors and the inspected. At any rate, one is tempted to say so in looking through the list of House of Commons Bills, either introduced or notified. The latest intimation on the paper relating to inspection—which word, by the way, was only a few years back regarded as synonymous with pokenoiseism—is by Mr. Thornton (Clapham), who, on the 23rd, will introduce a Bill to amend the law as to the qualification and tenure of office of sanitary inspectors. Mr. Thornton is, however, not a faddist, and his Bill will not be of a very revolutionary character, but aims rather at improving existing sanitary organisation than setting up new methods.

THE SHOPS BILL of Sir Charles Dilke and Co., which is sometimes apt to be confused with the Shops (Early Closing) Bill of a former Session, is checked by a blocking motion placed on the Paper by General Goldsworthy, the member for Hammersmith, who suggests the second reading of the measure "this day six months." The gallant member represents a constituency in which the small shop-keeper is strongly in evidence, and it is not surprising that this class should be somewhat alarmed at the extinguishing effect upon small businesses which the passage into law of the Shops Bill might produce. Retail chemists ought not to encourage Sir C. Dilke's proposals for shop regulation in any way, for that way lies disaster.

THE COMMITTEE ON PETITIONS just formed is an annual institution, and performs a very useful function. It examines all the petitions presented to the House of Commons, except Private Bill petitions, and classifies, sorts, and abstracts the same, so that the information sought to be conveyed to the House may be clearly grasped. In reporting, the Committee enumerates the number of signatures to the petitions which are valid, that is to say, those to which addresses are appended, and makes such observations on the petitions as may seem to be called for. The *personnel* of the Committee is as follows:—Messrs. E. Barry (S. Cork), Biddulph (Ross, Hereford), Brymer (S. Dorset), H. Lewis (Flint), C. Morley (Brecknock), T. P. O'Connor (Scotland, Liverpool), W. F. D. Smith (Strand), Tollemache (Eddisbury), and H. J. Wilson (York, W.R.), together with Sir T. Carmichael (Edin.), Col. Cotton-Jodrell (Wirral), Sir C. Dalrymple (Ipswich), Col. Kenyon-Slaney (Newport, Salop), and Sir H. Meysey-Thompson (Handsworth, Staffs.). Three members form a quorum with power to direct the printing of the petitions in full or such pertinent parts thereof as may be deemed fitting.

THE IMPERIAL INSTITUTE deal seems a highly economical arrangement, according to Mr. Balfour's reply to Sir M. Bohnagreg on Monday. The Indian Government will, it seems, occupy part of the east basement of the Institute Buildings, together with the

Bhownagrec corridors, rooms, and passages adjacent thereto; the Institute will occupy the western portion and some galleries; whilst the London University will occupy the rest. The Great Hall and the Cowasgee Jehanghir Hall are to be at the disposition of all three authorities conjointly, the Indian Government using them when the University and the Institute do not require them, and so forth; which strikes one as a farcical arrangement, strongly reminiscent of the tactics of Mrs. Bouncer in accommodating her lodgers, Box and Cox. The plan did not work in Mrs. Bouncer's case, and it does not seem likely to prove more successful with an additional rival thrown in. Nevertheless, the official view is that the future will be undisturbed by the smallest *contretemps*, and it is even intended to conduct at South Kensington from time to time, as opportunity allows, the examination of Civil Service candidates. If there are any leisure moments left unappropriated by the India Office, the University, or the Institute, perhaps the Government authorities might be disposed to entertain a proposal to hold the Minor examinations in the Institute Buildings in April and July!

UNREGISTERED SURGEONS in the Army formed the subject of a question some little time back by General Laurie (Pembroke), who was rather alarmed at the increase of unregistered practitioners acting with the military forces. Mr. Wyndham, in reply, said the Medical Act, 1858, prohibits the appointment as Army surgeon of a practitioner not registered in the United Kingdom, but it did not prevent an unregistered surgeon from rendering assistance under the orders of the Medical Staff. The question of Colonial reciprocity was also touched upon by the gallant Member, and in reference to that Mr. Wyndham thought that, as regards medical qualifications, it was too broad a question for the War Office to deal with. This subject of reciprocity between the mother country and various parts of the Empire is likely enough to be revived later on in the Session as the outcome of a desire to express in some way the nation's sense of the loyalty and practical patriotism exhibited recently by the Colonial Governments, but one cannot be sanguine enough to anticipate a favourable result, seeing that inter-Colonial reciprocity is far from being an accomplished fact.

MUNICIPAL TRADING is the new danger threatening the retailer, and especially the smaller class of tradesmen. The seriousness of municipal competition is much more pronounced in some callings than it is in pharmacy, but even here the malignant germ has appeared, and the Council would be well advised to watch the progress of the attempt now being made in Parliament to define the limits beyond which local authorities should not go. The subject cropped up several times last Session, and Mr. Balfour promised, just before the prorogation, to appoint a Committee of enquiry as soon as possible. Mr. Kimber (Wandsworth) on Monday reminded the First Lord of the Treasury of that promise, and obtained a reply to the effect that it was proposed very shortly to put upon the Notice Paper a motion for the appointment of the Committee of Enquiry. Mr. Kimber may be said to represent the banking interest, as he is closely associated with the Capital and Counties Bank, and presumably he does not desire to foster a condition of things that might end in the nationalisation of banks.

REPLYING to Mr. Provand in regard to the Government's intentions respecting petroleum legislation, the Home Secretary stated on Monday that he could hold out no hope of anything being done this Session, the matter being too controversial and contentious. That should be sufficient for Mr. Ure to withdraw his Bill, for it must be quite obvious that the Ministerialists will not allow the passage of any measure not on the lines of the unrevealed official draft now at the Home Office.

ENGLISH NEWS.

COMPANY PHARMACY AND JOINT-STOCK DOCTORING.—The *Medical Press* states that, as the President of the Board of Trade, Mr. Ritchie, has introduced into the Commons the two Bills which passed the Lords last session promoted by the Lord Chancellor, it seems obvious that the Government is determined to pass them if the exigencies of Parliamentary work permit. "These Bills are designated to amend the Companies Acts, and, in the case of pharmacy trading, it is provided that no company or syndicate shall dispense unless under the supervision of a fully-qualified pharmacist. This provision, when supported by the Lord Chancellor in the Upper House last year, by no means satisfied the chemists, because it allowed co-operative companies and such like to carry on business freely as dispensers by the agency of any number of unqualified assistants as long as one qualified man is in control and supervision. We sympathise with their protest, but we cannot see how the proposed new law can be resisted on public grounds. The second Bill, or portion of a Bill, refers to joint-stock doctoring, and absolutely forbids any company or syndicate to carry on business as physicians, surgeons or midwives, unless each and everyone of the members is a duly registered practitioner. Such a provision is essentially in conformity with the existing law. Every individual, whether member of a company or not, can practise as widely as he pleases, but always on his own responsibility, and subject to the disabilities which the medical Acts impose upon unqualified practitioners, and the ostensible supervision of his practice by a qualified doctor cannot relieve him of these. If such practitioner attempts to shield the unqualified man by signing death certificates, or performing other function which is reserved for the legitimate profession, he forthwith brings himself within reach of the law, and can be debarred by the Medical Council. It is thus obvious that the cases of the chemist and the doctor are not on all fours, and the chemist should not be jealous if Government makes a distinction which the existing law as already made."

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.—The seventh meeting of the session was held on Friday, February 9, at 17, Bloomsbury Square, W.C., Mr. W. Garsed in the chair. The minutes of the last meeting having been read and confirmed, the Chairman called upon Mr. T. E. Wallis to read his paper on "Aquatic Plants." Mr. Wallis classified the water plants under several heads, and mentioned examples. The paper was illustrated by means of several excellent diagrams, which attracted the special notice of those present, and were remarked upon by the subsequent speakers. The Chairman thanked Mr. Wallis for his interesting paper, and requested members to bring forward any question which had occurred to them. The invitation met with a hearty response, and seven gentlemen, in the following order, rose to thank Mr. Wallis for his paper, and to ask various questions:—Messrs. Woolcock, Gompertz, Finemore, Pollard, Harris, Chapman, and Hellyer. Mr. Wallis having responded, the meeting terminated. Thirty-seven members were present.

CHEMISTS WHO RENDER FIRST AID to the injured were advised by a jury at the Lambeth Coroner's Court, on February 16, to send all injured persons to properly qualified medical men after doing what they can to relieve them. The circumstances which brought out that advice were, briefly, that Thomas Dudman (32), labourer, cut his thumb in throwing a snowball. He washed the wound, banded the injured member with a rag, and went to the shop of Mr. W. Power, chemist and druggist, High Street, Walton-on-Thames, where he was attended by John Edward Marshall, who stated at the inquest that he was an unqualified assistant. The thumb was dressed, and the man was told to call again in two days. In the meantime his jaw became stiff, but when he again

visited the chemist's shop he made no complaint about the stiffness. Later, a Dr. Mason pronounced that he was suffering from lockjaw, and sent the case on to St. Thomas's Hospital, where he died.—The house surgeon, in reply to the coroner, said that the bacillus of tetanus was introduced probably by a piece of glass or stone. It would be difficult to say whether the injury would have proved fatal if the wound had been treated antiseptically at first. A verdict of "Accidental death" was returned.

WESTERN CHEMISTS' ASSOCIATION OF LONDON.—A meeting was held at the Westbourne Restaurant on Wednesday, February 21, the President, Mr. J. F. Harrington, in the chair. There was no definite business before the meeting, and the first subject of discussion was introduced by Mr. Warren with regard to the forthcoming visit of the British Pharmaceutical Conference. Mr. Parker then spoke on the position of chemists as recognised by the public and by Government, and advised more self-assertion with a view to improving their position. Mr. Gaubert pointed out that

"Chemist" is one of the very few titles which are protected, and is, therefore, valuable. He also mentioned the anomaly of requiring a qualified person to hand a medicine over to the purchaser, while an unqualified person might dispense it. Mr. Barnett raised the question of poisons. He said we have no exact definition of a poison, and compared our standing with that of apothecaries. Mr. Hick hoped the present Council would as successfully oppose the Companies Bill as the Council of former days did the first Apothecaries Bill. Mr. Bright also spoke of the Apothecaries Act in relation to chemists; our weak point is that we have no recognition by the public, medical men and dentists have. The President spoke of the prime necessity of securing the title of chemist to individuals, as that would give chemists a better recognised position than they have at present. He also introduced the subject of the recently established Chemists' Defence Association, which he thought would be of great service to chemists; he had known a similar organisation amongst members of another calling which was very successful. Mr. Cooper then explained the objects of the Defence Association, saying that it had no sympathy with dishonest trading, but was established as a protection to those who, while endeavouring to carry on their business in a proper manner, were subject to vexatious interference: while a prominent feature was insurance against dispensing accidents, which, however rare, might occasionally happen. He said that the Association only required extensive support to be a great success. Mr. Warren supported the principle of the Defence Association, and advocated chemists looking very sharply after their own interests, as neither the public nor the Government seem to appreciate them. Mr. Andrews also supported the Defence Association, and hoped it would receive greater support than a similar organisation which existed some years ago. Mr. Barnett then suggested that all present should, if not already members, give him their names, and succeeded in obtaining ten signatures. The proceedings then terminated.

MANCHESTER AND NORTHERN GROCERS AND THE P.A.T.A.—At the monthly meeting of the Northern Council held last week in Manchester, our correspondent says, something was at last found for the P.A.T.A. to do. Mr. John Williams in a burst of virtuous indignation, produced a nice little bundle of soap wrappers, which he placed upon the table, and he said they were to be given in exchange for a bottle of scent at certain grocers' who sold the aforesaid soap. But he objected to being made a tool of by the manufacturers—a sentiment greeted with loud cries of "Hear, hear" by the meeting. A long discussion took place, in the course of which Mr. Williams said the P.A.T.A. had a scheme for getting over the difficulty. They could take it from him that the resolution passed and adopted at the committee meeting of the P.A.T.A., which was that nothing could be

sold with less than a 12½ per cent. profit would be carried out. Mr. Perkins said if the Council called the attention of the P.A.T.A. to the soap business, he thought it would serve a useful purpose. After further discussion, in which strong language was used as to grocers being automatic machines, etc., it was decided that the Council should empower Mr. Williams to confer with the secretary of the P.A.T.A. as to some action being taken by the P.A.T.A. in regard to the price of Messrs. Lever Bros.' productions.

THE CLAIMS OF SCIENTIFIC EDUCATION were clearly put by Mr. A. J. Balfour at the festival dinner, held on February 14, in aid of the new scientific laboratories of King's College Hospital, London. He said it was his view that it was the bounden duty of all great places of university education that they should keep before them not merely the immediate practical needs of technical or other education, but that they should never permit the ideal of university investigation to be for one moment clouded in their eyes, or to lose interest, or cease to be the object of worthy effort and endeavour. But that great object must increasingly require the generous and liberal co-operation of all classes of the community, whether they be immediately interested in science, intimately acquainted with scientific details, or whether they be merely part of the general public. Men of science themselves were not always in a position to give that pecuniary aid necessary to establish the modern laboratory and to equip it with modern appliances; and they were right to call upon all those who take any interest in their subjects to aid them with that pecuniary assistance which in many other countries was extended to them by the Government, but which in this country, rightly or wrongly, by an almost immemorial tradition, has been left chiefly to the energy of private enterprise. He thought London had been somewhat remiss in the support which it has hitherto given to scientific investigation in the commercial metropolis of the world. Technical education has in it almost necessarily some element of competition. We heard it said that Germany is doing this, France is doing that, some other country is doing the other, unless you keep abreast of them in your methods of education you will fall behind them in your industrial enterprises. That was a very proper and patriotic argument, which he had used before and should use again; it was an argument he should think himself justified in using; but he was appealing on behalf of a case which had in it none of that inferior and lower element of competition whatever. Every scientific discovery, as soon as it is made, is the common property of every man of science. To that great common fund of knowledge London should contribute its full share. It take a well-earned tribute from every discovery made throughout the world for the advancement of civilisation; therefore let those who are dwellers in London feel that they have some obligation to the world at large corresponding to the great international position they occupy.

EXPLOSION AT A CHEMIST'S.—On Saturday, February 17, an explosion occurred in the office of the shop of Mr. J. Wharton, chemist and druggist, 73, Freeman Street, Grimsby. Mr. Wharton, who at once went to discover the cause of the explosion, found the office on fire, and in extinguishing the flames scorched his head and hair. A considerable amount of damage was done before the fire was got under. The cause of the explosion is not known.

POISONING BY VERMIN KILLER.—Mary Ann Rose (53), of Annie Road, Booth Street, Handsworth, complained of pains in the head, and on Wednesday, February 14, swallowed a small quantity of vermin killer, which had been purchased by her husband for the purpose of destroying mice. Medical assistance was requisitioned, but death occurred within an hour.

SOLUTION OF CARBOLIC ACID FOR MEDICINE.—On Wednesday, February 14, Joseph Morris, a labourer in Crewe railway works, who had been ill for some weeks, took some solution of carbolic acid, used for domestic purposes, in mistake for his medicine, the bottle containing the solution having been inadvertently placed near to the medicine bottle. Police-constable Roberts, who was called to the house, administered some olive oil, thereby practically saving the man's life, the medical man who subsequently attended expressing satisfaction with the prompt action of the constable.

SALE OF METHYLATED SPIRIT.—On Saturday, February 10, at the County Sessions, Chesterfield, James Harry Toplis, chemist and druggist, of Chesterfield and Staveley, was charged by the Inland Revenue authorities with unlawfully selling one pint of methylated spirit at his Staveley shop on December 18 last without a licence.—Defendant stated that it was a mistake on the part of his manager, who thought there was a licence, and that it was at the Chesterfield shop.—Mr. T. Good, of the Inland Revenue, proved purchase of the spirit and that defendant had no licence.—Mr. Stanton, defendant's manager, said when he sold the methylated spirit in question he was under the impression that they had a licence.—Defendant was fined £2 and costs.

THE SALE OF SEIDLITZ POWDERS.—At Birmingham Police-court on February 16, Magor, Limited, chemists, 318, Broad Street, were summoned for selling effervescent tartarated soda powders containing only 85 per cent. of the tartaric acid required by the British Pharmacopœia.—Dr. Hill (medical officer of health) stated that the absence of the full proportion of the acid would not be harmful, but unless the powder fulfilled the prescription it would not have the effect on the system that was intended.—Mr. Bailey, managing director for the defendants, said that the powders were bought from Messrs. G. Wilton, Son, and Co., Limited, Doncaster. A representative of the firm told him that there would be a guarantee given with the goods. The guarantee was not sent, however, but a packet was tested by the defendants, and was found to be correct within a grain or so, and they presumed the rest were correct. The defendants complained to the firm that proceedings were being taken against them, and Messrs. Wilton wrote stating that every packet was weighed, but they could only suppose that one of the three who packed them had not been sufficiently careful. Fined 20s. and costs.—George Turley, sen., and George Turley, jun., druggists' sundrymen, Edgbaston Street, were summoned for selling seidlitz powders containing only 47 per cent. of the quantity of tartaric acid, only 33 per cent. of the quantity of sodium potassium tartrate, and 213 per cent. of the quantity of sodium bicarbonate (or 113 per cent. in excess) required by the British Pharmacopœia.—Mr. Cross prosecuted, and said that on each packet the defendants cautioned the public, stating that "thousands of boxes of common imitations of genuine seidlitz powders are sold by unprincipled traders for the sake of extra profit. We guarantee all ours to be genuine."—Mr. Fisher (magistrate) stated that the defendants were the worst offenders they had had before them for a long time. It was an abominable fraud. The public were willing to pay for an honest article, but the defendants choose to mix up anything and palm it upon them. The best advice he could offer to the public was to recommend them to go to chemists who would give them proper articles. Defendants would be fined £10 and costs, or in default a month's imprisonment.

IS SAVIN OIL NOXIOUS?—At the Gloucestershire Assizes last week, Henry Sturge Young, 29, brewers' traveller, of Alveston, Thornbury, was charged with having on several days during September administered to Ethel Lippiatt, a certain drug for an unlawful purpose. Mr. Lawrence, Q.C., for the defence, submitted that the drug (savin oil) in the quantity in which it had been

administered was not noxious, and therefore did not come under the Act. Dr. Campbell, who had been called for the prosecution, had admitted that this was so. He quoted cases in support of his contention. Justice Bruce supported this view, and directed the jury that they must leave the question of intent out altogether, and say the drug administered was not noxious. Acting on this instruction, the jury returned a verdict of not guilty, and the accused was discharged.

LIVERPOOL PHARMACEUTICAL STUDENTS' SOCIETY.—A well-attended meeting took place at the Liverpool School of Pharmacy on Friday, February 16, the President, Mr. Prosper H. Marsden, in the chair. A series of specimens of asafetida and sagapenum was exhibited by Mr. Marsden, who had received the samples from Mr. J. C. Umney. The asafetida samples were No. 1 finest tears carefully picked from an exceptionally fine case of asafetida—one of a lot of ten cases picked from over 500 imported into London. These tears only exist to about four or five per cent. in the very finest cases, and answer all the B.P. tests as to ash and solubility. No. 2 was a fair bulk sample from one of the finest cases on the market. No. 3 a fair average sample from a case of rough asafetida, unsuitable for pharmaceutical use, but used for other economic purposes. The sagapeum was similar to that mentioned in the *Pharmaceutical Journal* recently. In a letter to Mr. Marsden, Mr. Umney said that an asafetida similar to No. 1 could be supplied if persons would pay to higher price for a superior article. As bearing on animal remedies, Mr. Marsden produced for inspection some "Crabs' eyes"—a calcareous deposit from the cray-fish, *Astacus fluviatilis*—and some dried woodlice, *Oniscus asellus*, used on the Continent in the form of a syrup under the name of "Sirop de Cloportes." The lecturer of the evening was Dr. J. D. Nevins, who delivered an excellent and entertaining discourse on "The History of Materia Medica from the Earliest Times." Beginning with ancient Egyptians, the lecturer stated that doctors with them were regarded as persons who held communion with gods or spirits, whose aid they could invoke for curative purposes, and consequently the substances of their materia medica were more as adjuncts to the supernatural aid afforded than as articles of curative power. The result of all this was that the doctors were held to be magicians, as witness the scene between Moses and the Egyptian soothsayers, where he confounded their so-called miracles. In the original Greek, the lecturer said that the word "Oharmatroi" meant doctors and magicians, and in this latter adaptation it was used in the list given in the Bible of persons who could not enter the Kingdom of Heaven. The use of burnt offerings of incense was evidently intended to provide a ready and efficacious means of antiseptic-treatment, for the essential oils, creosote and aromatic bodies produced by burning the fragrant gums used were ideal disinfectants, and, moreover, were decidedly effectual. That antiseptics were thoroughly understood by the Egyptians we have proof in their wonderful methods of embalming the dead. Practically the chief diseases, or rather affections, among the Egyptians were indigestion, obesity, and constipation, owing to their doing little or no work so long as they had their bondmen, the Israelites, to slave in their stead. To combat indigestion, carminatives, to all intents and purposes the same as we use nowadays, were employed—aniseed, cumin, dill, caraway, etc. For obesity emetics held first place, together with exercise, whilst for constipation some mechanical means was adopted, such as clysters, administered by means of a bone tube with a bladder attached. Various nauseating animal bodies were used for the sake of their emetic properties, such things as lizard's blood and animal fœces being very common. As Moses was "learned in all the wisdom of the Egyptians," he must have been acquainted with their medical treatment, but he certainly never used these animal remedies. The attention of doctors then seemed to be fixed chiefly on the cure of wounds, which they effected by means of dressings of balsams, tar, etc., all of which were ex-

cellent for the purpose. The odour of burnt incense in the Temple sacrifices was possibly used for the very purpose of hiding that of the blood of the slain animals, and in lesser degree the odours arising from the crowded congregations. The lecturer drew parallels between these ancient remedies and those in use by the Hindoos down to the present day. He also rapidly ran through the changes in treatment, and the substances used in the days of Hippocrates, Celsus, Galen, Paracelsus, etc., and then discoursed upon the "Doctrine of Signatures," which he thoroughly explained by reference to the Lung Wort, Serpentary, Eyebright, and, lastly, the Coco de Mer, of which he showed two very fine specimens. The ordinary double nut is common enough, he said, at the present time, but formerly in India it fetched fabulous sums of money from the native princes, who imagined it would secure them male succession. An unusual development of the nut was exhibited when the whole of the six ovules had become equally developed, forming a fruit some fifteen inches high and eighteen inches across. This was brought by Bishop Royston from the Seychelles Islands, and was believed to be unique of its kind. After touching upon the changes in materia medica and prescribing within his memory, the lecturer brought a very interesting and valuable educational treat to a close. The proceedings finished with a discussion and a hearty vote of thanks to the lecturer.

SCOTTISH NEWS.

THE PAISLEY CHEMISTS' ASSISTANTS held a very successful gathering in the Art Gallery, Paisley, last week. Mr. Halley, Glasgow, occupied the chair at supper, and was supported by Drs. Russell, Duncan, and J. Bruce; Messrs. Stewart and Hannah, Paisley, and Messrs. Dykes, Wright, Thomson, Surgenor, Cairncross, Percival, representatives of the wholesale trade. After supper, and the usual loyal toasts, Mr. Munro proposed "The Medical Profession," Dr. Duncan replying to the toast; "Chemists and Druggists" being proposed by Mr. Cairncross, Mr. Stewart replying. Mr. Hannah most efficiently discharged the duties of M.C. at the dance, music for which was supplied by Mr. Loughton's band. Songs were rendered during the evening by Mrs. Kennedy, and Messrs. Dykes, Thomson and A. Reid. The arrangements, which had a successful termination, were in the hands of a committee composed of Messrs. Reid Alexander, M'Kay, M'Donald, Paton, and G. Hair, Secretary.

WEST OF SCOTLAND COLLEGE OF PHARMACY.—A post-graduate course on Urine Analysis has this month been inaugurated at this College by Mr. T. Maben, F.C.S., and, as it is the first of its kind, considerable interest has been shown in it by the more wide-awake pharmacists and the students of the College. The first lecture dealt with the secretion of the urine by the kidneys from the blood, and the physiology of the subject was expounded. The constituents of urine, both normal and pathological, were enumerated, and attention was drawn to the effect of diet, exercise, mental anxiety, etc., on the nature of the excretion. The physical characters, colour, smell, and specific gravity were discussed, and their significance indicated, and a general view was given of the importance of urine analysis, the hope being expressed that some day this work would fall into the hands of pharmaceutical experts. The second lecture dealt with the detection and estimation of glucose in urine. Experimental demonstrations were made of Pavy's and Gerrard's processes, the lecturer stating that for simplicity and accuracy the latter was by far the best that had hitherto been proposed. The estimation of albumin next claimed attention, and the various processes were discussed, Esbach's picric acid process being regarded as the most suitable for general use. Reference was made to Purdy's improvement, whereby the picric acid deposit was estimated in a few minutes by means of a centrifugal machine, instead of waiting for twenty-four hours. The estima-

tion of urea and uric acid were dealt with in the third lecture, the former being determined by the hypobromite of soda process, and uric acid by Haycraft's method. The processes for the estimation of chlorides, sulphates, and phosphates were fully described, thus completing the chemical section of the course, the microscopy and bacteriology of the subject being dealt with later on.

IRISH NEWS.

ARMY DISPENSERS.—A number of Irish pharmacists who made application for Army dispenserships in South Africa found that the offers of the War Office had all been appropriated. They were, however, informed that they would be privileged to join as private soldiers, if still under twenty-eight, and could thus place their intelligence and experience in compounding (at the lowest rates) at the service of a grateful country.

PROFESSOR E. J. McWEENEY, Dublin, has been appointed bacteriologist to the Local Government Board. The post is a newly created one in this country, and the duties include the inspection of all lymph issued by the L.G.B. to the various public health departments in Ireland. Dr. McWeeny is a well-known figure in Hibernian chemical circles.

MR. G. JAMESON JOHNSTON, visiting surgeon to the City of Dublin Hospital, Baggott Street, Dublin, and a former member of the Irish pharmaceutical craft, met with a serious mishap the other evening. Dr. Johnston, while operating in a case of diphtheria, happened to lean over the patient, and unfortunately received the discharge of matter fairly in his face. Realising the extreme gravity of the occurrence, he quickly took steps to disinfect himself from the virus of the disease, but notwithstanding his precautions, he was soon afterwards attacked by the malady, and for some days it was a question whether he would survive. Happily, however, youth and a good constitution have enabled him to safely pass the crisis, and his many friends in pharmacy will be glad to learn that their former colleague is now on the road to recovery.

SUPPOSED STRYCHNINE POISONING.—On January 13, Patrick Dunphy was charged, before Mr. Burke, R.M., at the Waterford City Police Court, with causing the death of his two children by means of strychnine (see *ante*, p. 86). Mr. Alfred Parker, assistant in Messrs. Poole's, druggists, identified the prisoner, who came into the shop and asked for a small quantity of poison. He cautioned him, pointing out that the poison was dangerous, and gave him four grains of strychnine, which he stated he required for killing rats. Prisoner returned on November 8 and made a similar request. The entry was as follows: Six grains for the purpose of poisoning rats; but witness did not supply the poison on that occasion, and cancelled the entry. Henry M'Adams, assistant in Messrs. George White and Sons, druggists, said, on December 12, 1899, the prisoner was supplied with five grains of strychnine. Further consideration of the charge was postponed until January 23, when prisoner was committed for trial at the assizes.

THE CHEMISTS' AND DRUGGISTS' SOCIETY OF IRELAND has held its annual reunion. In the absence of Sir James Haslett, M.P. (President), Mr. W. Jamison presided. The annual report referred to the honour conferred on the Society by the election of their Chairman to a seat on the Pharmaceutical Council. The Chairman referred to the legislation in force regarding the sale of poisons by unqualified persons, and hoped the work of the Society would redound to the welfare of all its members in the future as in the past.

MEDICINES NOT ON THE LIST.—Dr. Taylor, Tandragee Dispensary, wrote the Banbridge Guardians that the drugs ordered by him and disallowed by them were not patent or proprietary medicines, and though not on the prescribed list, were not liable to be surcharged. By refusing them they deprived the poor of a very efficacious means of treatment. After some discussion, the drugs were allowed.

WHETHER AN ANALYST'S CERTIFICATE can be tendered as evidence was a subject of dispute before the Belfast Recorder in a case of milk analysis. Mr. Whitaker contended that the analyst should be produced in Court, but his Honour decided that until the appellant proved the certificate wrong, it was binding.

BELFAST BOTTLE EXCHANGE LIMITED.—The above association has held its first annual meeting. Mr. William Rankin presided. The report, among other matters, referred to the various prosecutions instituted under the Merchandise Marks Act; whilst in nearly all cases convictions were obtained, it was regretted that many benches of magistrates seemed to look upon the illegal filling of bottles as a very trivial offence, and imposed merely nominal fines. It was stated that during the year three and a-half million bottles were received at the clearing-house.

CONTRASTS AND ANALYSES.—The Ballymoney Guardians have received a communication from the Local Government refusing recoupment for medicines under article 36 of the dispensary rules, because certificates of analysis had not been despatched in proper time. The Guardians have replied that the delay was due to the Local Government Board in not sanctioning the appointment of Mr. William Redpath as analyst when elected by them. As the ratepayers would lose to the extent of £47 7s. 2d., they urgently request the Local Government Board to reconsider their decision.

MR. ROBERT F. BLAKE, Antrim analyst, has reported analysis of two samples of drugs, one of which was not pure.

THE LOCAL GOVERNMENT BOARD forwarded to the Irvinestown Guardians the following return of the Trillick medical officer:—"The medicines are delivered promptly, but I think should be more carefully packed." The contractor was notified.

THE DOWNPATRICK UNION received from Sir Charles Cameron a report relative to the Killough dispensary, from which it appeared that the sample of glycerin of pepsin had no digestive properties. Dr. Tighe also wrote complaining of the non-arrival of medicines ordered from the Cork Chemical and Drug Company, and saying that the want of a certain drug had put him to considerable inconvenience for a number of weeks. The contractors were to be communicated with in both instances.

CARBOLIC ACID FOR SPIRITS.—While attending a patient recently, Dr. Charles P. Tenant (35), of Portnard, near Cappamore, County Limerick, accidentally swallowed a quantity of carbolic acid in mistake for some spirits, a bottle of each being in his pocket at the time. The doctor at once took an emetic, but without effect, death resulting about two hours later. A verdict of "death from misadventure" was subsequently returned by a coroner's jury.

FOREIGN NEWS.

A DOCTOR'S BOLD EXPERIMENT.—The Paris *Herald* is the authority for the startling announcement of a test with cyanide of mercury by Professor Walter T. Scheele, the well-known authority on chemistry. The murder for which Molineux has been on trial is alleged to have been accomplished by means of cyanide of mercury

mixed in a bottle of bromo-seltzer, which was given to the unfortunate Mrs. Adams. Although this trial has been dragging longer than any previous murder trial in the history of New York, the thought apparently never occurred to anyone that cyanide of mercury, when mixed with bromo-seltzer, was not deadly. Professor Scheele, it appears, called recently at the *Herald* office and announced that he had discovered in an eminent German chemical work the fact that any cyanide of mercury in the presence of the smallest possible quantity of carbonic acid gas is immediately decomposed, thus allowing the hydrocyanic acid to escape. Bromo-seltzer is composed (or supposed to be) of tartaric acid, bromide of sodium, bicarbonate of soda, and phenacetine. The moment bromo-seltzer is added to water its effervescence, liberating carbonic acid gas, decomposes, so Dr. Scheele contends, and renders comparatively harmless the cyanide of mercury which may have been mixed with it. So certain was he of the accuracy of this theory that he was willing to stake his life upon it. But the *Herald* declined to have experiments of this kind made under its auspices, where a mistake might result so fatally, but suggested that the truth or fallacy of the theory could be equally well demonstrated upon guinea-pigs or rabbits. Dr. Scheele agreed to this, and the animals were obtained. One guinea-pig was then inoculated with the pure cyanide of mercury, and it, of course, died within a short space of time. Cyanide of mercury was then mixed with bromo-seltzer, and preparations were made for inoculating the second animal, when Dr. Scheele suddenly raised the mixture to his lips, despite the excited protests of his bewildered witnesses. He then calmly poured into half a glass of water a tablespoonful of tinct. ferri perchlor., and remarked to those present, "Gentlemen, this thing is coming out all right, but in case I show any signs of collapse, force this solution down my throat. It is the recognised antidote for cyanide of mercury, and will pull me through all right." After resting a few minutes he proceeded to inoculate the other guinea-pigs with the same mixture of which he had drunk. Dr. Scheele and the animals are alive and well, and apparently suffer no ill-effects from their risky dose. It is thought that this demonstration had a direct bearing on the Molineux trial. Needless to remark, many doctors are sceptical and hardly credit the story.

THE PARIS INTERNATIONAL ASSEMBLY.—A feature of special interest of the Paris Exhibition of 1900 will be the learned and scientific congresses, some 200 in all, which are to be held under its auspices. A large number of those will be devoted not to pure science only, but to the application of the sciences to the various branches of art and industry. Among other meetings may be mentioned the congresses on medicine, on medical ethics, on hygiene and first aid to the injured, all of which will be held during the first fortnight in August. The congress on pharmacy will begin on August 8. In order to give the congresses a really representative character and a wide sphere of usefulness, committees of scientific workers have been formed in Great Britain, France, Germany, and the United States to disseminate information, and to recruit members in each country. In Great Britain the work has been undertaken by the Paris International Assembly, whose President is M. Léon Bourgeois, Ex-Premier of France, while Sir Archibald Geikie, F.R.S., and the Right Hon. James Bryce, M.P., are Vice-Presidents, and Prof. Patrick Geddes, Secretary. In addition to the task of spreading information regarding the congresses, the Paris International Assembly is organising a department of guidance to the Exhibition itself, in order to increase its interest and educational value to the British visitor. Lectures and demonstrations by experts on every subject will be arranged with special reference to the exhibits, so that visitors who avail themselves of the assembly arrangements will be able to see the things they are interested in to the best advantage, and with the least expenditure of time and energy. The assembly also aims at providing a rendezvous where members of any profession

in this country may be brought into touch with their colleagues in France, at other times besides the short sittings of special congresses. A number of receptions and social gatherings are also being organised, to which members of the assembly will receive invitations. Any further information with regard to congresses and assembly arrangements may be obtained from the secretaries, *nrietta Str eet*, Covent Garden, W.C.

CERTAIN FRESH-WATER ALGÆ named by a French botanist, Monsieur R. Bouillhac, are claimed to be able to absorb arsenic without injury, at least one species appearing to derive more benefit in growth from arsenic acid than from phosphoric acid.

A FRENCH PHYSICIST, Monsieur Perreau, has found that selenium is not acted on by Hertzian electric waves in the atmosphere as it is by light—that is to say, its electaric resistance is unaltered. The Röntgen rays, however, diminish the resistance of selenium after the manner of light.

LIQUEURS IN FRANCE.—When did liqueurs come in vogue? At the present time all classes in France have their stock of liqueurs—the rich their “Benedictine” and their “Chartreuse,” the peasants their home-distilled peach brandy, anisette, and so on—in fact, an infinite variety of cordials. In his new volume, ‘*Le Mécanisme de la Vie Moderne*,’ that most interesting of statisticians Monsieur d’Avenal tells us that until the sixteenth century hypocras was the only liqueur known to French *von vivants*. Nowadays, next to the famous Chartreuse, the so-called Benedictine enjoys greatest favour. The history of this liqueur is curious. It was invented by a wine-merchant of Fécamp in 1863, who had so much confidence in his cordial that he spent 800,000 francs upon advertisements. Success was not only rapid but complete. Only 23,000 litres were disposed of in 1864; at the present time the annual sale is considerably over a million litres. The inventor, however, had not reckoned with the clergy. Clerical protests were raised against such association of a trade in liqueurs with the name of a once-famous monastery. Cardinal de Bonnechose approached Napoleon III. on the subject, but Monsieur Le Grand, a pious Catholic, knew well how to overcome the dilemma. He would not give up the name, but he most ingeniously contrived to render the connection of Church and cordial pleasing. Adjoining the distillery, and surmounted by a Gothic spire, now stands a small museum devoted to relics of the Benedictine order—stoups, reliquaries, missals, statues, jewellery, vestments, and the like. The present Archbishop of Rouen blessed the new building, and after the banquet compared its author, Monsieur Le Grand, to various heroes of Christianity. In a liqueur distillery (writes Monsieur d’Avenal) we are tempted to ask ourselves whether we are on the premises of a chemist, grocer, or perfumer. Roots, dried flowers, and fruit of every kind and from every part of the world are here, with spices, essences, and chemical substances. The majority of the herbs used in liqueur-making may be had at the rate of a hundred kilos for forty francs; tropical plants, however, sometimes cost three times that price. The green colour of absinthe is artificial. It is made by an admixture of hyssop, peppermint, and a certain preparation called “*Melisse de Moldavie*.” Why absinthe, so-called—the plant itself representing only a third element of that liqueur—should be so injurious to the system is explained by the exciting nature of the oil. Unfortunately, this seductive poison is absorbed more and more. Within the last fifteen years the sale of absinthe in France has tripled.

DEATH IN A PHARMACY.—As the Abbé Delville was walking along the Rue Castiglione, Paris, last Thursday, he was seen to stagger and fall into the roadway. At once passers-by picked him up and bore him to the Pharmacie Hogg, being close at hand, where restoratives were administered. Having regained con-

sciousness, he was permitted to remain quietly alone. However, a few minutes later he was noticed to faint off again, and ere anything could be done for him he died. Then arose a disagreeable dilemma for the pharmacien, the law compelling him to keep the corpse until all the formalities were duly gone through. The police were at once acquainted of the affair, and the Commissaire summoned. There being no annexe to the pharmacie wherein to put the corpse, it had to be laid upon chairs. But the news soon spread throughout the quarter, and business for the rest of the day was soon vetoed, for clients little cared to transact business alongside a corpse. The ambulance was summoned, but when it arrived the doctor in charge simply said, “*Déad is he?* Then you can keep him!” and quickly vanished. The hours rolled on, and at last, before closing time arrived, a handcart rumbled up in charge of two men. In it they placed the remains of the poor priest, and bore them off to the “*Morgue*.” It is hard lines that better arrangements do not exist, and that pharmaciens should bear the brunt as they do in cases of accidents, etc., and not receive any recompense.

ILLEGAL EXERCISE OF MEDICINE AND PHARMACY IN FRANCE.—Despite the fact that laws exist, and are sometimes enforced, to suppress the illegal exercise of medicine or pharmacy, a certain class of individuals enjoy singular immunity in their barefaced contravention of these laws. Not that they are without the pale of the law, by any means. Those individuals are none other than the Catholic clergy, who throughout the country carry on a most lucrative business in “quacking,” and use the up-to-date methods to advance their interests. Their consummate “cheek” knows no bounds, and is all the more appalling inasmuch as the money raked in goes to no charitable institution, but swells the coffers of the various orders of monks who do the exploiting of the specialities. Their *modus operandi* is to “get up” a speciality for a certain complaint, give it a name connecting it with their order, and then advertise it extensively. Some of their advertisements are “immoral” in the extreme, for they generally write a small pamphlet with a short tale to please their numerous clientèle, and, coming from “one in holy orders,” it is swallowed with gusto. Quite a lively competition is engaged in between the various orders, and so common has this trafficking become that little or no comment has been aroused. But familiarity breeds contempt, ’tis said, and two orders of monks (neither evidently doubting legal interference with their commerce) have just been disputing in the courts the right to a name for a speciality which one called “*Confiture de Saint Vincent de Paul*” and the other one copied. An order called “The Trappists” claimed the right, and by their insistence were rightly trapped, inasmuch as the law demands that no secret medicines shall be sold in public, that all specialities must bear their formula and be compounded by duly qualified individuals. Since the learned brotherhood failed to comply with the law in this little matter their case was quashed, and the doctors and chemists began to awaken to the fact that they had keen, impudent, and dangerous competitors in the field. The result was that both professions joined hands in a campaign against the commercial “brethren,” and are now making it generally lively for them. We shall no doubt soon hear of the nuns taking their turn, for they are likewise sinners in this respect. In fact, for some time past isolated instances have occurred in which chemists have complained against the practices of such and such a “sisterhood” and have gained the day, but no combined action has been taken such as that now entered upon to put down the sale of such rubbish as “*Pâte bienfaisante de Chantelle*” (for the toilet), “*Musculine*” (for jaded individuals), and “*Eucalyptine*” (for coughs, colds, etc.), to say nothing of various little contrivances of doubtful utility. If unchecked we may one day hear of them manufacturing serums, and so become competitors of the Institut Pasteur.

PHARMACY IN AUSTRALASIA.

(From Our Melbourne Correspondent.)

IT IS SOMEWHAT UNFORTUNATE that the two societies into which the New South Wales (or should I say Sydney?) pharmacists have split up—that is to say, the Pharmaceutical Society of New South Wales and the Registered Pharmacists' Society—should take such diametrically opposed views in connection with the Early Closing Bill at present before Parliament. It is scarcely edifying to find the latter forming a deputation to the Premier objecting to chemists being brought under the Act on any consideration, while the former pass motions approving of the principle involved and suggesting certain hours for adoption. In justice to the Registered Pharmacists Society, I must state that, while objecting to pharmacies being brought under the operation of the Act, they express themselves as quite willing to agree to any restriction limiting the hours of apprentices and assistants. So far as my information goes at present, I understand that the New South Wales chemists as a body are working for the adoption of the following clauses:—(1) That pharmacists' shops shall close not later than 9 o'clock on five days of the week, and not later than 11 o'clock on one day of the week; provided that pharmacists at any time may attend to urgent cases. (2) That pharmacists may open their shops on Sundays from 10 a.m. to 1 p.m., and from 7 p.m. to 9 p.m. (3) That no clause of the bill shall affect pharmacists.

DISPENSING CHARGES.—At a recent meeting of the Canterbury (N.Z.) Pharmaceutical Association the following report from a sub-committee in reference to "dispensing" charges was submitted and adopted. It may be of comparative interest to English pharmacists:—Mixtures, 2-oz., 1s. 6d.; 3-oz., 1s. 6d.; 4-oz., 3i dose, 2s.; 4-oz., ʒ ii dose, 1s. 6d.; 6-oz., 2s.; 8-oz., 2s. 6d.; 12-oz., 3s.; 15-oz., 3s. 6d. Powders—Single, 3d.; ½-do., 1s.; 1-do., 1s. 6d.; 2-do., 2s. 6d. Cachets—Single, 6d.; ½-do., 1s. 6d.; 1-do., 2s. 6d. Ointments—1-oz., 1s.; 2-oz., 1s. 6d.; 3-oz., 2s.; 4-oz., 2s. 6d. Pills and Tablets—½-do., alone, 1s.; with other medicine, 6d.; 1-do., 1s.; 2-do., 1s. 6d. Liniments, Bellad., Aconite, Chlorof., Iodine, Pot. Iodine, Opium and Compounds of these, 2-oz., 1s. 6d.; 3-oz., 2s.; 4-oz., 2s. 6d.; 6-oz., 3s.; 8-oz., 4s. Other Liniments—2-oz., 1s.; 3-oz., 1s. 6d.; 4-oz., 1s. 6d.; 6-oz., 2s.; 8-oz., 2s. 6d. Lotions, Gargles, Mouth-washes—3-oz., 1s. 6d.; 4-oz., 1s. 6d.; 6-oz., 2s.; 8-oz., 2s.; 12-oz., 2s. 6d.; 16-oz., 3s. Eye and Ear Drops—Minimum price, 1s.; 1-oz., 1s. 6d. Suppositories—½-do., 1s. 6d.; 1-do., 2s. 6d.

THE PROPOSAL TO HOLD A "RECIPROCIITY" CONFERENCE in Melbourne while the annual meeting of the Australasian Association for the Advancement of Science is taking place in January has not caught on with the two principal colonies—New South Wales and Victoria—and it is now very improbable that anything will come of it. As a matter of fact, the crux of the question lies between the two colonies mentioned; and as, notwithstanding the special negotiations entered into between them about two years ago, and which have since been kept more or less open, they still agree to differ, they see no benefit that would arise from the discussion of their differences at a general meeting.

THUS IT IS that, at the last meeting of the Pharmacy Board of Victoria, after consideration of correspondence with the New South Wales and Queensland Boards, it was resolved—"That the Pharmacy Board of New South Wales be referred to the letter of December 24, 1897, which expresses the views on the subject, and that a reply be sent to the Queensland Board, that in view of the improbability of anything definite being arrived at with New South Wales a conference would be useless."

AND THUS IT IS ALSO that even the *Australasian Journal of Pharmacy*, which may almost be said to have given birth to the federal idea as relating to pharmacy, and has, at least during the past thirteen years, nurtured it with all the solicitude of a parent, arrives at a similar conclusion. In an editorial in its December number, the *Australasian Journal of Pharmacy* refers to the first conference held on the subject in Melbourne in 1886, and after recounting the various resolutions arrived at during that meeting, adds:—"It will be seen from the foregoing that we were apparently justified in congratulating ourselves on the prospect of an early realisation of the grand object in view—the pharmaceutical federation of Australia. 'Pharmacists are now committed to the task,' we then wrote, 'and we have every confidence as to the final results.' We were sadly mistaken. During the thirteen years that have since elapsed the colonies whose delegates were then so enthusiastic in the cause of uniformity and federation have been drifting further apart than ever, and what might be considered a compact entered into on their behalf has been deliberately broken in one or more particular by every colony which has since obtained pharmacy legislation. As witness the subsequent legislation of South Australia, 1891; New South Wales, 1897; and New Zealand, 1898, in all of which the agreement as to apprenticeship was ignored. West Australia was not represented at the conference, but her Act (1894) does not provide for a curriculum." To sum the whole matter up, the *Australasian Journal of Pharmacy* concludes that, apart from the expenditure which the proposed conference would involve, its practical utility, in view of past experience, and more especially in view of the unbending attitude of New South Wales and Victoria in connection with the comparatively small differences existing between them, appears more than problematical. "Undoubtedly," it adds, "a great responsibility rests on the two colonies named, for were they to agree to a common platform a conference might in that case be not only successful, but practically unnecessary."

AT THE DECEMBER MEETING of the Pharmaceutical Society of Australasia a letter was received from the Honorary Secretary of the Australasian Association for the Advancement of Science, asking that someone should be nominated to represent the Society on the General Council. Naturally, the choice fell on their energetic Secretary (Mr. Shillinglaw, Registrar of the Pharmacy Board), than whom no one is more able to give the Council valuable advice and assistance during their forthcoming meeting.

PHARMACY IN SOUTH AUSTRALIA has suffered a severe loss by the death of Mr. W. J. Main, President of the Pharmacy Board. Mr. Main—a native of the colony, by the way—was among the first to recognise the need for pharmaceutical legislation and association, and it was at a meeting convened by him in 1885, and greatly through his influence, that a resolution was carried founding the Pharmaceutical Society of South Australia, a considerable number being in favour of having simply a trade association. Undertaking the duties of Hon. Secretary, he was subsequently elected President of the Society, and later on President of the Pharmacy Board, which office he filled until his death, and in which he rendered conspicuous service to the cause of pharmacy in its educational and broadest aspects.

THE ELECTION OF MEMBERS of the Pharmacy Board of South Australia for the next term of office was held on December 18, when, in addition to the old members, three new candidates (Messrs. Glover, Stubbs, and Williams) came to the post. Of the latter, only Mr. Glover proved successful, the death of Mr. Main affording him his opportunity. The new Board will therefore be constituted as follows:—Messrs. John White, Robert Hutton, Joseph Parker, J. J. H. Young, Howard Whitbread, C. S. Hill, and E. G. Glover.

EXTRACTS FROM CONSULAR REPORTS.

THE MANUFACTURE OF FERRO-CHROME is stated to be one of the specialities of the Boucan (France) iron foundries. The article is exported in small barrels, and according to a recent report about 40 to 50 tons is annually shipped to Great Britain, whilst the demand from Germany amounts to 500 tons. A ton of 1,000 kilos. is said to be worth about £40.

THE DECIMAL AND METRIC SYSTEMS OF WEIGHTS AND MEASURES are reported to be in use all over Brazil, and are employed throughout the tariff. Weights are always calculated in kilos. Measures vary according to the article, some being in English yards, others in metres, and others in Portuguese varas. When the English system is adopted in invoicing, it is stated in a report on matters of commercial intelligence relating to Brazil, to be generally advantageous to give equivalents in the decimal system for custom-house work and other purposes.

"SLEEPING SICKNESS," OR "DOENÇA DE SOMNA," is a malady which is reported to be responsible for the deaths of more natives in the districts of the Lower Congo (South-West Africa) than any other of the many ills to which African flesh is heir. So far it has defied the medical knowledge or missionary skill brought to its treatment, and it is expected that if European medicine cannot find a remedy entire districts of South-West Africa will be either stripped of their present inhabitants or kept in a perpetual state of under population. A medical man at Cabinda is said to be engaged in trying to inoculate two tame monkeys with the virus of the disease by hypodermic injections of the blood of persons suffering from it, his hope being to ultimately establish by inoculation a cure for the malady so communicated. It is suggested that the School of Tropical Medicine, lately established in Liverpool, should find in a study of sleeping sickness a work of as great importance to the future of Africa as in anything that malarial fevers may offer to special research.

WHEN ONCE ATTACKED BY SLEEPING SICKNESS, ultimate recovery is stated to be unknown. The disease has been attributed by some to a too prevalent use of food-stuffs prepared from manioe or cassava root (*Manihot utilissima*)—the staple food of the Lower Congo country—but this surmise has not been verified. Others attribute it to bad water. The remedies tried have varied from frequent hot baths to strong doses of arsenic and violent movement. Of these, that of brisk movement, some continual occupation of mind and body, and change of scene, are said to have produced the most lasting effect. The disease is stated to be highly contagious, so much so that in the native Christian communities, situated in the "land of death" area of the Lower Congo, it has now become established usage to provide each communicant with a separate vessel in which to partake of the Sacramental wine.

MANY OF THE QUALIFICATIONS OF GENUINE INDIARUBBER are said to be possessed by a substance produced by the oxidation of linseed oil, with the addition of prepared jute refuse, or similar hitherto worthless textile refuse. This substance is reported to be capable of being utilised in various ways and of being manufactured into various articles hitherto made of indiarubber.

A CURIOUS METHOD OF COLLECTING RUBBER is mentioned by Consul Casement in a recent report on the trade and commerce of Angola. Referring to the uses made by the wild people of the Balolo tribe of the rubber-giving vines, he states that during a journey through a forest country it was noticed that some of the drumsticks used for striking the hollow section of a tree-trunk were covered with knobs of hardened rubber. How coagulation

had been brought about was not ascertained, but the method of collection was said to be simplicity itself. The native simply smeared his naked body over with the milk as it exuded from the cut creeper, and after a certain exposure to sun and air this was then worked off with the fingers into more or less sticky masses.

TO PREVENT THE DESTRUCTION of rubber-giving plants by hasty and avaricious collectors, the Government of the Congo State has issued a decree, ordaining that each firm exploiting rubber from its territories shall plant a certain number of fresh trees in proportion to its shipments of that article. In addition to this, the Government has itself caused fresh varieties of rubber plants to be imported, and is, through its agents, paying attention to their distribution and cultivation. Among such plants may be mentioned the *Ficus elastica*, the Ceará or *Manihot glaziovii*, and the *Hevea brasiliensis*, which furnishes the celebrated Pará rubber of Brazil.

THE RUTHLESS DESTRUCTION by the natives of rubber-yielding trees in German East Africa has brought about a great diminution in the amount of rubber exported. A few years ago rubber was exported from Mikindani to the extent of about five hundred bags a month in the season, but, according to a recent report, owing to the cause already mentioned, the export has fallen off to about forty or fifty bags a month. The natives are now only allowed to tap the trees by incisions some way up, and it is hoped that by thus preventing the cutting down of the trees the export will revive considerably during the next five years or so.

THE RISE IN THE PRICE OF QUININE AND CINCHONA BARK in the beginning of 1899, led to an enquiry by the Government Botanical Department of Jamaica into the present condition of the cinchona plantations, and the practicability of manufacturing quinine locally, as in India. The result of the enquiry appears to show that it is doubtful, unless prices rise still further, whether bark can be harvested for sale, or quinine manufactured in Jamaica, as a source of profit.

THE NECESSITY FOR RETRENCHMENT in public departments in Jamaica has led to various economies being effected in the several establishments during last year. In the medical establishment consequent on the transfer of the medical attendant at the Lepers' Home to Port Royal as Health officer, and the retirement, etc., of a few district medical officers, their successors were appointed at smaller salaries. Another economy was effected by the appointment of Mr. F. Watts, Government Chemist at Antigua, as Government Analytical and Agricultural Chemist in Jamaica, succession to the late Mr. Bowrey, under an arrangement by which his services were made available to the Jamaica Agricultural Society, and the public as well as the Government, at less cost to public revenue.

THE CULTIVATION OF TOBACCO in Spain is forbidden by law, although, as Mr. H. Harrison, Commercial Attaché to Her Majesty's Embassy at Madrid points out, judging from the small quantities grown in many gardens, it appears that it might be made an important industry. According to the regulations by which the sole right of sale and manufacture of tobacco in Spain is held by the Bank of Spain in the form of a monopoly, the cultivation of tobacco is prohibited both in Spain and the Balearic Islands. The tobacco monopoly is required to make experiments in cultivation during three years in different parts of Spain, and these experiments are being carried out, but whatever the result, Mr. Harrison is of opinion that it is most improbable that the cultivation of tobacco will be allowed during the lease of the present monopoly, which extends for twenty-five years from August 30, 1896.

THE IMPORTATION OF DRUGS AND CHEMICALS into Spain is a trade of some importance, the following being the values of the imports during the last three years:—Simple drugs, 1896, £598,000, 1897, £610,000, 1898, £395,000; colours, dyes and varnishes, £458,000, £405,000, £388,000; chemical and pharmaceutical products, £935,000, £1,067,000, £1,054,000; wax, soap, etc., £270,000, £269,000, £250,000; perfumery, £55,000, £55,500, £41,000. The total values for the three years, were £2,317,000, £2,407,000, and £2,129,000 respectively. Of general chemical and pharmaceutical products the largest supply is imported from France, Great Britain coming next, followed by Italy and Germany.

THE EXPORT OF DRUGS AND CHEMICALS from Spain for the three years (1896, 1897, 1898) shows little variation, the following being the values of the principal classes exported:—Simple drugs, 1896, £152,000; 1897, £308,000; 1898, £291,000; salt, £153,000, £142,000, £131,000; chemical products, £221,000, £229,000, £261,000; wax, soap, etc., £304,000, £248,000, £193,000; perfumery, £25,000, £26,000, £14,000. The total values for the three years were £857,000, £954,000, and £891,000 respectively.

DENTAL NOTES.

PORCELAIN INLAY WORK FOR IRREGULAR CAVITIES is on its trial before the dental profession, and will no doubt, for obvious reasons, become one of the future methods of repairing the ravages of dental caries. In theory nothing could be more simple or beautiful, but in practice it is found that there are many little difficulties to overcome, and it is doubtful if it will in the future be extensively used except by expert operators. One of the difficulties is the obtaining of a perfect impression of approximal cavities where, from overcrowding or other causes, it is impossible to get as wide a separation as desired necessarily in this position, where the labial and lingual walls are left intact; the separation must at least be a little wider than the depth of the cavity. In such cases (where platinum or platinised gold foil is not used as in the Jenkins system) wax for taking the impression will be found unworkable. A better plan is to use softened King's crown composition dipped in French chalk, finishing off nearly flush with the edges of the cavity; place a very thin separating file (serrated side) over the compo., just sufficiently warmed to cause it to adhere, being careful not to injure the impression of the cavity edges; harden with ethyl chloride spray, and the impression can be withdrawn without injury.

IN CASES OF SUPERIOR PROTRUSION with the lower incisors biting against the gums, before attempting to retract the upper teeth, Mr. Mattheson, who described his method of treatment at a recent meeting of the British Dental Association, inserts an upper plate for the lower incisors to bite against, thickening it as occasion requires. The models shown illustrated the fact that the incisors were pressed downwards into their sockets rather than that the level of the molars and bicuspid were raised. Mr. Mattheson also explained his way of replacing a porcelain face on a crown. The pivot holes in the backing were made into one slot and the sides freely bevelled, a new porcelain front adjusted and fine fitted, with the pins bent so as to slightly diverge. Phosphate cement smeared over the back of the porcelain, then squeezed home, the surplus cement removed, and the slot filled up with amalgam. As was pointed out, the thicker the gold backing is the better, and in cases of close bite the method would not be so good.

NERVANIN IS A NEW LOCAL ANÆSTHETIC derived from orthoform, and said to be but one-tenth as toxic as cocaine. For extraction of teeth a 5 per cent. solution is employed. No sterilising agent need be added, as nervanin in 1 per cent. solution prevents bacterial growth, and, according to an account by Dr. Kyner in *Items of*

Interest, it will produce a deeper and more prolonged anæsthesia than either cocaine or eucaïne B. The anæsthetic effect is continuous for a number of hours after operating.

TO RELIEVE TOOTHACHE from an inflamed pulp, introduce into the cavity a plug of cotton wool steeped in an alcoholic solution of orthoform. The pain instantly disappears. Being absolutely non-toxic, it makes a simple remedy which the patient can apply without danger.—*Southern Dental Journal*.

DENTAL STUDENTS have their attention directed by Mr. W. A. Maggs, in the *British Medical Journal*, to the fact that, on and after January 1, 1900, a dental or medical student will be required, before registration by the General Medical Council, to produce a certificate of having passed the first class College of Preceptors Examination (or its equivalent), whereas until the above-named date the second-class certificate will suffice. It is probable, he continues, that a large number of men now registered as dental students only, with the lesser certificates, may subsequently desire to take medical qualifications, and the question is, Will the first-class certificate be demanded by the Council, or will the dental student registered before January 1, 1900, be exempted? Mr. Maggs has interviewed the Registrar of the General Medical Council, who has promised to lay the matter before the Educational Committee at an early date. But, in order to avoid any difficulty arising, he advises all dental students registered with second-class certificates, and who intend entering a medical school during this year, to take out a course of chemistry from October at one of the institutions recognised throughout the Kingdom, and forthwith to become registered as medical students. Apart from the consideration of medical registration, a course of chemistry is necessary for the dental licence, and the instruction and examination in this subject are best taken during pupilage.

WHEN USING THE NAPKIN in filling an upper molar or bicuspid an excellent way to hold it in position and to free the left hand is to pass the napkin across the tooth just at the back of the one to be operated on, and place a clamp over it, holding it to the tooth, then place a roll of bibulous paper between the gum and cheek. This liberates the left hand, and very much facilitates the operation.

RELIEF OF TOOTHACHE FROM INFLAMED PULP.—Introduce into the cavity a plug of cotton wool steeped in an alcoholic solution of orthoform. The pain disappears for a considerable time. Being non-toxic it is a simple remedy which even the patient can apply without danger.

A SUBSTITUTE FOR THE DIAMOND DISK.—Dr. Roberts, in the *International Dental Journal*, states that a small disk of thin copper, used with water or oil, will cut as perfectly as a diamond disk and even more quickly.

TO KEEP A PARTIAL LOWER COMBINATION PLATE from crawling when being swaged, Mr. C. Rippon, in the *Journal of the British Dental Association*, recommends that after having roughly swaged the plate into position drill a hole through the plate and a considerable depth into the die, then drive an ordinary tack, cut off the head; thus you have the plate nailed to the die. If necessary, two or three tacks can be used. The holes are easily filled up by forcing in a piece of wire and soldering with fine solder.

BORDER OF CAVITIES.—Any practical hint that enables the dentist to obtain a perfectly smooth and polished border to cavities previous to inserting any filling material is of the greatest interest to every dentist, for all experienced men know how much of their success depends upon this point. Dr. Greystone, in *Items*, states that he

uses an ordinary fine-cut plug, finishing bur of suitable size, dipped in water, then in carborundum powder, using it in the usual way, dipping it in the water and carborundum powder as often as necessary. He uses half-worn-out burs, and says it is a faster method than using diamond burs.

POWDERED BORAX added, in sparing amount, to cement mixture will cause the latter to set quickly and produce a hard and tenacious cement.

SILVER LACTATE is strongly recommended by many practitioners as one of the best germicides to use in the treatment of pyorrhea alveolaris, also for any septic or suppurating condition around teeth. It can be used up to 20 per cent. without causing pain.

TO REMOVE TEETH FROM A RUBBER PLATE without danger of cracking or etching the teeth, boil the plate in glycerin in a porcelain pan till it smokes, and the teeth will come away clean and free from discoloration. Put them back in the glycerin till cold to anneal them, and when cool wash in water—they will be as bright as new and free from grease. When cold bottle glycerin for future use.—*Ohio Dental Journal*.

WHEN USING VAPOCAINE in a cavity, tie a piece of rubber dam over to prevent evaporation, and it will be found that the obtunding effects are far deeper than if put loosely into the cavity.

COMBINATION FILLING.—Dr. Spooner, in *Items of Interest* tells how he makes a combination filling with alloy and osteo without the use of mercury. He writes: "The alloy is first mixed with the liquid, so as to ensure that the metal becomes thoroughly coated with the liquid, next mix the zinc powder with the wet alloy, working it up thoroughly into a tolerably stiff mass. The mass hardens quickly, so it has to be handled rapidly. Sometimes I put a softer mix into the cavity, following with the stiffer one. In this way adhesion is got with the first and strength with the last. A surplus is put in, while an instrument, dipped in the powder, can be used to contour the filling to the edges."

ANTISEPTIC VARNISH.—Canada balsam, deprived of its volatile turpentine by evaporation over a water bath, then dissolved in ether, with about 10 per cent. of creosote added, makes an excellent antiseptic varnish for lining cavities previous to inserting stopping. The cavity should be carefully dried out with warm air, so as to allow the varnish to penetrate deeply into the tubuli of the dentine.

THE USE OF CARBOLIC ACID.—An article by Dr. Oscar H. Allis in the *Polyclinic* on the use of carbolic acid, full strength, is of interest to dentists. He says the use of carbolic acid of full strength upon flesh tissues, raw surfaces, etc., causes the formation of a protective albuminate, a condition which makes further absorption impossible. The same takes place when the strong acid is applied to a raw-burned surface. It is not claimed that an aqueous dilution is safe when applied extensively to raw surfaces; on the contrary, the more dilute the more dangerous. He goes so far as to state that excess of strong acid in a cavity, such as an abscess cavity, or upon exposed tissue, as a burn, or a fresh wound, does no harm; while excess of a dilute solution if left in a cavity, or used over an extensive raw surface, will be promptly followed by dangerous, if not fatal, toxic effects.

TO HOLD A DAM out of the way when it is applied to the upper front teeth and secured with a holder, draw it between the bicuspid on each side with a silk ligature, allowing the thread to pass from side to side. This will effectually hold the dam up in the mouth and out of the way.—Dr. CATELING.

WHERE THE EDGE OF CERVICAL CAVITIES extends far under the gum, and it is found impossible to carry the rubber over the edge and retain it with a silk ligature, binding wire will prove of great use. It can be placed around and the ends twisted with a pair of pliers, then bent and pushed with a blunt instrument into position, carrying the rubber dam with it.

PHOTOGRAPHIC NOTES.

REDUCING ACTION OF PERSALTS.—For some years now chemists have been paying considerable attention to the subject of photography and photographic chemicals, and now hardly a month passes but what we have some new discovery or investigation of an old subject, the main principles of which have been but poorly comprehended, or buried in empiricism. The latest announcement that has been made is one by MM. Lumière and Seyewetz, the well-known chemists of Lumière Frères, of Lyons, who have probably the largest dry-plate factory on the Continent. They have been examining the reducing action of certain metallic persalts on the negative image with the hope of finding a satisfactory one-solution reducer, free from the staining and unequal action of the most generally used reducer, first suggested by Howard Farmer, a mixture of potassium ferridcyanide and sodium thio-sulphate (hypo). They point out that ferric, manganic, titanous, and mercuric will nearly all of them act as reducers, but that there are certain disadvantages which they find can be entirely obviated by the use of ceric sulphate.

CERIC SULPHATE is a commercial salt which can be obtained without any difficulty, and although there is a slight precipitate when dissolved in water, this may be totally avoided by the addition of a small quantity of sulphuric acid, and this has no action on the gelatin of the film, and it will keep almost indefinitely. Further, the solution may be used in any concentration, the rapidity of its action being solely dependent on its strength, and no irregularity of action nor stain can be detected, and it is therefore quite suitable for bromide prints. The best strength for a stock solution is 10 per cent., and this should be made with distilled water, to which 4 per cent. sulphuric acid has been added. Such a solution may be diluted with water to any extent, without the precipitation of any basic salt. When used of 5 per cent. strength, that is, the above solution diluted with an equal volume of water, a reducer is obtained which, like ammonium persulphate, attacks the denser portions of the negatives first, whilst a 1 or 2 per cent. acts slowly and evenly over the whole negative.

MERCURIC IODIDE INTENSIFIER.—Some little time back the same chemists suggested a modification of the well-known mercuric iodide intensifier, which is also useful, and it has but two disadvantages, one that the solution itself is sensitive to light and must therefore be kept in the dark, and the other that the final image partially consists of silver iodide, and this is sensitive to light also, and the negative gradually bleaches by the conversion of the metallic, mercuric and silver iodide into a complex double salt of mercurous and silver iodides, but this bleaching may be entirely obviated by treating the intensified negative with a developer, old or once used. Lumière's improvement is in the substitution of anhydrous sodium sulphate for sodium thiosulphate (hypo) as a solvent for the mercuric iodide, and this may be prepared as a stock solution as follows:—

Anhydrous sodium sulphate	40 Gm.
Mercuric iodide	4 Gm.
Distilled water	to 100 C.c.

For use, dilute one part of this solution with three parts of water. The negative should be washed for five minutes in running water and then immersed in the solution. Intensification may be

Stopped at any stage by merely washing, and the dilute solution may be used over and over again till exhausted.

SENSITISING POSTCARDS.—Considerable interest is still being taken in those solutions which can be used for sensitising post cards, linen or other fabrics, without any preliminary preparation; the latest formula is:—

Silver nitrate	3 Gm.
Distilled water	10 C.c.
Uranium nitrate	30 Gm.
Alcohol	100 C.c.

This solution must of course be kept in the dark, and should be applied to the paper or other material by a camel's hair brush somewhat freely, and then allowed to dry, and be exposed under a negative in the usual way, then rinse in water and fix. Ironing the pictures thus obtained with a moderately hot flat iron somewhat improves the colour.

PHOTOGRAPHIC PATTERN CARDS.—Although photography has been considered as one of the minor discoveries of the fast-dying century it promises in the near future to take a much more prominent part in some of our industries than it has hitherto done and the latest application of it is for the preparation of the pattern cards which are used for weaving in the Jacquard loom. It has been customary hitherto for artists to draw their designs and for these then to be spaced out on a particular kind of paper by hand. An Austrian photographer has, however, discovered a very simple method by means of which any picture or design may be "spaced" or "squared" in a few hours, and this not only in two but any number of colours. He has even produced woven photographs in natural colours by this method, though they were not absolutely perfect.

THE PICTURE OR DESIGN to be reproduced in fabric is first of all photographed in the ordinary way, and from the negatives thus obtained transparencies on glass are made. These are then projected by means of an electric light and a lens on to a perforated plate in contact with a sensitive surface, such as a dry plate or bromide paper. The lens is fitted with different shaped stops, some round, some slits, others square, or in the shape of the ordinary numerals. The result is a design broken up into small squares, dots, longitudinal or numeral figures, which, with a key, form the pattern card for the weaver. Recently this ingenious inventor produced in six hours the pattern-cards for a portrait of the Austrian Emperor which would have taken the ordinary pattern-cutter working by hand at least nine months. It is stated that at the Paris Exhibition the invention will be shown in operation, but many of the leading English, French, and German weavers have seen it in operation, and are enthusiastic over the results.

INTERFERENCE COLOURS.—An extremely interesting communication has been made on behalf of M. Vallut to the Académie des Sciences by Professor Kippmann, who was the discoverer of the photography in natural colours by the interference method, and it is to the effect that if an ordinary negative be exposed to the vapour of nitric acid so that the silver image be converted into the nitrate and then to sulphuretted hydrogen the silver is deposited in a black state, but in very thin layers which give rise to interference colours, which at first sight appear to be distributed haphazard; but, on careful examination, it would be seen that there really was some sort of distribution of the colours, according to those of the original subject, and it was possible to distinctly trace the blue of the sky, the green of the trees, etc. This is a promising field, not only for speculation, but for experiment.

SECRET PREPARATIONS are decidedly on the increase in photography, and one or two firms are doing a very good thing by putting up special developers, etc. For a one-solution developer,

capable of being used both for plates and papers, that will keep well and stain neither fingers nor films, the following should satisfy most requirements:—

Sodium sulphite	300 Gm.
Potassium carbonate.....	600 Gm.
Distilled water (hot).....	1,000 C.c.
Adurol.....	60 Gm.

For use dilute the above with from 10 to 15 parts of water.

Adurol is bromohydroquinone, which is formed by the substitution of one molecule of bromine for a molecule of hydrogen in hydroquinone, and although subject of a patent adurol can be very easily made by adding to hydroquinone dissolved in benzole the necessary quantity of bromine, also dissolved in benzole.

POWDERS FOR PHOTOGRAPHIC DEVELOPERS.—(1) *Pyrogallol developer.*—Pyrogallol, 0.3 Gm.; sodium sulphite, 1.2 Gm.; sodium carbonate, 1.2 Gm. (2) *Hydroquinone developer.*—Hydroquinone, 0.6 Gm.; sodium sulphite, 3.4 Gm.; potassium bromide, 0.3 Gm.; sodium carbonate, 7 Gm. (3) *Eikonogen developer.*—Eikonogen, 1.1 Gm.; sodium sulphite, 2.4 Gm.; potassium carbonate, 1.5 Gm. The powders are wrapped in parchment paper, and then in black paper. For use 1 powder is dissolved in 60 C.c. water.—*Oesterr Zeits für Pharm.*, 53, '975.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The PRESIDENT, Mr. F. W. Gamble, occupied the chair at a meeting of this Association, held at 73, Newman Street, W., on Thursday, February 15, when Mr. W. A. KNIGHT delivered a lecture on

INSECTS WHICH INFEST CRUDE DRUGS,
the substance of which is printed at page 186.

The PRESIDENT, in thanking Mr. Knight for his lecture, said it was difficult in dealing with any subject of interest to chemists, to touch upon new ground, but the lecturer had hit upon what was practically a new subject, and had displayed much originality in his manner of treatment. At the outset he showed that he was an educationalist in that he advocated that zoology should be taken up by pharmacists, not only as an interesting study, but because it would tend to their profit. The President then complimented Mr. Knight on the manner in which he had dealt with his subject and on the excellence of his illustrations. Mr. Knight had mentioned carbon bisulphide as a destroying agent; he (the President) should have thought that chloroform was more destructive.

Mr. C. J. STROTHER, referring to the remark of the President as to the originality of the subject matter of the lecture, recalled the fact that on one occasion he had himself addressed the Association on the subject. His paper dealt principally with the insects infesting linseed meal, and he pointed out that, inasmuch as they were not destroyed by a temperature of 90 degrees, in applying a poultice to an open wound there was a certain amount of danger that the insects in the meal would cause trouble unless it was subjected to a temperature sufficiently high to destroy them. Mr. Stark, he believed, also read a paper on the subject, but neither went into it so thoroughly as Mr. Knight had done that night. With regard to the use of chloroform in destroying insects in drugs; he had known instances where it had been tried and had failed in its purpose.

Several members followed with suggestions for preserving drugs from the attacks of insects, Mr. Moore mentioning formic aldehyde, while Mr. Morley Taylor thought cyanide vapour would answer the purpose well. Mr. Peck and one or two others stated that they had employed chloroform as a means of destroying insect pests with but indifferent success.

Mr. KNIGHT, in reply, said he had found a few drops of carbon bisulphide perfect as a destroying agent except for the egg state, and with a little knowledge of zoology one knew how long it would

take for the eggs to develop into the larva stage, when the operation could be repeated. With regard to chloroform, he had found it extremely difficult to get rid of the odour when a weak solution of 1 in 400 only was used, and as it would take a stronger solution than that to kill insects, it would take longer to volatilise. That objection also applied to cyanide of potassium; neither were to be compared with carbon bisulphide in that respect. Owing to its powerful reducing properties, formic aldehyde was also to be avoided. Mr. Knight then referred to the study of zoology, and said he was certainly of opinion that it should be included in the syllabus of the Pharmaceutical Society. Some knowledge of the subject was at present necessary in the Major syllabus in respect to the microscopic structure of animal materia medica. He had to thank Mr. Kirkland for the drawings which had illustrated the lecture, and also Mr. E. M. Holmes, Curator of the Pharmaceutical Society's museums, for some of the specimens exhibited of drugs infested with insects. He had always found that Mr. Holmes was willing to help anyone who undertook original work, and he seemed to know something about everything.

A hearty vote of thanks was then accorded to Mr. Knight, and the meeting terminated.

NORTH-EAST LANCASHIRE CHEMISTS' ASSOCIATION.

The annual dinner of the North-East Lancashire Chemists' Association was held on February 15, at the White Bull Hotel, Blackburn. Mr. Councillor CRITCHLEY (President) occupied the chair, and Mr. Councillor Shorrocks the vice-chair, and there was a capital attendance, in spite of the terrible inclemency of the weather.

Mr. J. RYMER YOUNG (member of the Pharmaceutical Council) proposed the toast of

THE NORTH-EAST LANCASHIRE CHEMISTS' ASSOCIATION.

He said he would leave questions of pharmaceutical politics to his friend, Mr. Newsholme, who was the chief mate of the good old-fashioned ship the Pharmaceutical Society—a craft perhaps not quite equipped with all the most modern appliances, but one of the good old copper-bottomed sort that would weather the present as well as other storms. Of both the gentlemen on his right (Mr. Newsholme and Dr. Symes) he would say that no two gentlemen could more profoundly appreciate the miserable position which pharmacists occupied in the country, or would do more to extricate them from the wretched position to which he had alluded. When one thought of the appalling apathy that pervaded the pharmaceutical atmosphere at large, it was refreshing to find that there were scattered over the surface of Great Britain associations like the N.-E.L.C.A., consisting of men who had emphatic views and the courage and ability to express them, and enthusiastic men willing to leave their business for days in order to give attention to matters of vital interest to their fellow chemists. But there was sometimes danger that enthusiasm would outstrip discretion, although he freely confessed that he would rather have open, direct, and straightforward opposition than be hampered with the wretched apathy and indifference which is the besetting sin of the pharmaceutical community. He did not think that the Council of the Pharmaceutical Society always received the consideration it deserved. The Council could not be regarded as a body of delegates. He was perfectly sure that neither Mr. Gifford nor anybody else would like to see that: intelligent men could not be got to submit to such a position. But there were broad lines of policy, the main features of which every member of the Pharmaceutical Council might be expected to observe in regard to the interests of the trade and in seeing that the Pharmacy Act of 1868 was carried out. In view of the fact that there are twenty-one members on the Pharmaceutical Council it went without saying that there would be many differences of opinion, and sometimes their views were treated with some degree

of impatience. He had frequently expressed his own views in the columns of the official journal, and he was pleased to think that they were held by the North-East Lancashire Association. But all the members do not think alike on all matters; and when they noticed how each section of the Council was represented by a different trade journal, they must come to the conclusion that it was a difficult thing indeed to bring them all over to the same view. Although every member of the Pharmaceutical Council was equally desirous of ameliorating the condition of things, the moment the question how that was to be done was approached almost twenty-one different methods were disclosed. In conclusion, he wished continued prosperity to the N.-E.L.C.A., and hoped it would be still more useful and a still greater power in the land. He would remind them that the elections were coming on, and there was no reason why North-East Lancashire should not elect a member of its own.

Mr. Councillor SHORROCK, in reply, said he had every confidence in the Pharmaceutical Council, and believed that the members were conscientious in their work. If they in North-East Lancashire, however, could stir up the spirit of discussion and bring about a measure which would put pharmacists on a better footing they would only be doing their duty, and he hoped other local associations would do the same thing.

Mr. EDWARD EVANS, jun., J.P. (Liverpool), proposed
PHARMACY.

He remarked that, commercially, pharmacy was not altogether inviting, if one were to judge by the announcements in the trade papers of the "wills of deceased chemists." They heard of millionaires in almost every trade, but they had never yet heard of a millionaire druggist; although for that matter he did not know that the amassing of a great fortune was everything in this life. The social position of the chemist had undoubtedly greatly improved during the last forty or fifty years, and for that they had to thank the much-maligned Pharmaceutical Society. To-day, however, pharmacy was going through a critical time. He had means of knowing some of the troubles and anxieties the trade was suffering from just now, but he was optimistic enough to believe that they would come through all right. He was not quite sure that the bringing of these matters before Parliament would be much to the benefit of the trade, because there was a possibility of misunderstanding upon matters that might be detrimental. One thing was certain, that the chemists must never allow the idea to get abroad that they looked to legislation to enable them to make their customers pay more than they now paid the retail trader. A chemist, however, was entitled to a certain amount of protection, just as a doctor or a lawyer was; but, given that, he believed the business could be made pleasant and profitable. He wished success to pharmacy with all its just rights, brought about, if not by legislation, by consolidation and union, such as that exemplified in the North-East Lancashire Chemists' Association.

Mr. HEATON (Burnley) responded. He thought professional pharmacy had been strangled by apathy. Commercially, they were hampered by little "stores" which were springing up all around, and they were not under such restrictions as chemists as to qualified assistants. The great difficulty chemists now experienced in getting qualified assistants called for a reform in the method and cost of examinations.

Mr. R. LORD GIFFORD proposed the toast of
THE PHARMACEUTICAL SOCIETY.

He said the Committee had honoured him with the responsibility of expressing its feelings towards the Society at a time when affairs were at such a critical stage, when they were in at the death, or the salvation, of their legal rights. The policy of a Society must depend upon the dominating influence, and the old paternal influence still prevailed which all along had taken their money and allowed them to run wild. There could not be any improvement until the great body, by sheer insistence, altered the character of

the ruling influence. The Pharmaceutical Society was on paper perfectly democratic, but in practice intolerably oligarchic, ruled and regulated by obsolete methods, by impossible people—altogether out of touch with the constituency and ignorant of the spirit of the times. The Pharmacy Act of 1868 was not acceptable to the Pharmaceutical Society, which was imbued with aspirations of high pharmacy, and that idea had been preserved ever since. That had been the curse of pharmacy—that inability on the part of the dominating influence on the Council to see that governments look beyond the needs of sections to the requirements of the whole people; even now the official journal was used to bolster up that fallacy, and had used every discreditable means to push the “pre '68” policy and to suppress the real opinion of practically every chemist on the Register. The Pharmacy Act of 1868 established the principle of qualification, and, in the interests of the public, put the sale of poisons outside the operations of free trade, confining their distribution to properly qualified persons. Chemists had omitted to keep intact the principle of the Act, with the result that the edifice, however insignificant, was now falling about their ears. Had the Council insisted upon the retention of those principles that the association of the chemist with responsibility would have induced a real practice of pharmacy? It was by such natural evolution that they must look for a settlement of the irritating problems of chemists prescribing and doctors dispensing. What was needed for natural development to take place was that qualification must (1) be recognisable and (2) not negotiable. In regard to the organisation of the drug trade, his Association asked why the stagnant Pharmaceutical Society did not make effective Mr. Newsholme's scheme for increasing the membership and power of the Society, which it professed to approve? If the Society lifted its finger it could bring within its fold at once the great majority of registered chemists, and it had only itself to thank if it was stated that the dominating traditional element did not want them, but only just guineas enough plus the examination fees. The administration of the Pharmacy Acts had been, and still was, inept, ineffective, and incompetent. Lastly, his Committee protested that it was shameful their own Journal should distort, manipulate, manufacture, and misrepresent opinions in the way it did.* An official organ should reflect accurately the views of the members; it could not with propriety do the questionable things which private enterprise might do. Its primary duty was to insist that the views of any considerable section of members were stated with clearness. He proposed the Pharmaceutical Society in harmony with its constitution.

Mr. G. T. W. NEWSHOLME, in response, said that Mr. Gifford was nothing if not outspoken. He did not blame him for that—indeed, it might be better if other men copied him in that respect. He had spoken of the Pharmaceutical Council being “oligarchic.” That was a word which they had heard a great deal about lately, and it reminded him somewhat of “that blessed word Mesopotamia.” But whether the Pharmaceutical Council was democratic or oligarchic it was what the chemists of the country made it. Members could vote as they pleased, and if the North-East Lancashire chemists were not satisfied with the Council they should alter it. The Bill read in the House of Commons two days before was on similar lines to the Bill introduced into the Lords last session. One of the most important clauses affecting registered chemists proposed to give limited companies the right to call themselves by chemists' titles provided the companies had qualified individuals in their employ. That was a monstrous thing: the qualification for which they had worked was to be bartered away to a limited company. Was it reasonable that a limited company should be allowed to do

* While on this occasion Mr. Gifford is accorded the publicity to which he considers his effusions are entitled, he requires to be reminded that he abuses his privilege and the considerate indulgence he has received. The infamous statements he makes concerning this Journal are so utterly untrue that they must recoil upon himself and upon the Association in whose name he professed to speak.—[Editor, *Ph. Journ.*]

this; and would it not be equally fair that any individual should be able to do the same? In reference to that matter the Council were not united, but he thought it would be the Council's duty to do all it could to oppose the Bill unless chemists were included with medical men, dentists, and midwives. Surely they had some claim to professional knowledge and ability? It had been said over and over again that chemists were traders. He admitted the fact, but they were not upon the same level as ordinary grocers. They claimed to be professional men because they were, or ought to be, responsible for every article that went out of their shops. They did not want to be elevated above their proper station by calling themselves professional men, but enormous sums of money had been spent on their education to fit them for their position and for the protection of the public. It was not that chemists would benefit very much, even if the companies were not allowed to carry on their business; he did not think that would be any great advantage to them. The Pharmaceutical Council—either present or past—was not to be blamed for the position chemists were now in, nor did he think that another Pharmacy Act was required. The Act of 1868 was good enough now and for all time if chemists would be loyal to themselves and to the Society. They must not forget that companies could not carry on if qualified men did not sell themselves. It was very unfortunate that the evil had grown to such an extent, but he believed that if an effort was made they could defeat the proposal of the Companies Bill. He thought they ought to go further and get a penal clause inserted to prevent a chemist covering any company. With the chemists of the country properly organised, he was of opinion that there would be no need to fear limited companies or anybody else. Every man had to do his duty to himself, and could not expect to be protected solely by the Pharmaceutical Society. They could not expect Government to protect trade interests. If better times were coming it depended upon chemists being loyal to themselves and their craft, otherwise it was no use looking to the Pharmaceutical Society.

Dr. SYMES remarked that they were told that the Pharmaceutical Council did not attempt what it ought to, and he felt that taunt a little. Eight or nine years ago he moved, and not for the first time, that carbolic acid should be placed on the Poisons Schedule, and every member of the Council on that occasion voted with him. The resolution was sent to the Privy Council, and they knew what became of it. The same resolution had again been passed by the Pharmaceutical Council some months ago, and the Privy Council had told them that the matter was under consideration. Did they think that in the face of such experience it was fair to blame the Council? He maintained that the accidental deaths which were happening through the drinking of carbolic acid were largely to be laid at the door of the Privy Council. Two conditions were at the bottom of their troubles—first, the madness on the part of the public to get things cheap; that pervaded all classes. If the turnover of the chemist was four or five times larger than what it now was their profits would still be unsatisfactory, but when the turnover was small the diminution in their profits was felt very much more severely. Then they were suffering from the medical profession dispensing their own medicines. There was also the “cutter,” who, whether individual or store, had no regard for his fellow, but went into the business solely for what he could make. There was also the great evil of the qualified man who was willing to sell his services and become a hireling to an unqualified employer. It was the accumulation of such things that was acting prejudicially towards them. If they asked him for the remedy he would say he was there to learn it, for if they succeeded in preventing limited companies carrying on their business they would not be free from difficulties. Other toasts followed, the toast of

THE MEDICAL PROFESSION

being replied to by Dr. CUNLIFFE and Dr. POLLARD. The former speaker deprecated the position taken up by the *Practitioner* and

the *Pharmaceutical Journal* on the question of the moment—[The reference is presumably to the suggestion of Mr. Malcolm Morris, that "would-be reformers should reform their manners" (see *P. J.*, February 3, page 106).—Ed. *P. J.*]—and urged that it was particularly desirable that the opinions of all should be known, irrespective of their position in medicine or pharmacy. It was advisable that the work of educating people up to the present situation should be vigorously proceeded with. One effect of this policy was that their own local Medical Society had recently, after a full discussion, unanimously passed a resolution of sympathy with qualified chemists and pledged itself to support them actively in the protection of their titles and practice.

GLASGOW CHEMISTS' AND DRUGGISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.

The weekly meeting of this Association was held on the 16th inst., when Mr. J. P. GILMOUR occupied the chair, and Mr. JOHN LOTHIAN, Ph.C., lectured on

Urine Analysis.

At the outset the lecturer claimed that analytical work in reference to this subject was peculiarly suitable for the pharmacist, medical men with whom he had discussed the matter freely conceding as much.

In the healthy subject there was an average excretion of 50 oz. per diem. Normal urine had a specific gravity of 1.015 to 1.025, and should be of a pale straw colour. When freshly passed the urine was said to have an aromatic odour, but this was difficult to detect. It contained about 4 per cent. of solid matter. The normal organic constituents were creatine, creatinine, and uric acid, while the inorganic salts were mainly sodium and calcium in combination with phosphoric and uric acids, the acid reaction being due to monosodium phosphate. The most important abnormal or pathogenic constituents of urine were albumen and glucose. Of the many qualitative tests for the former the most convenient and trustworthy were:—(1) Boiling and subsequent acidulation with acetic acid, (2) the contact test with nitric acid, and (3) the reaction with freshly-prepared metaphosphoric acid.

Having given demonstrations of each of these tests, the lecturer went on to deal with the qualitative tests for glucose. As in the case of albumen, a host of reagents had been proposed, but Fehling's Solution was still *facile princeps*. No doubt substances like creatinine had a slight reducing effect on Fehling's Solution, but there was practically no danger of mistaking this for the presence of dextrose in pathological quantity. Albumen if present or H₂S should first be removed before using Fehling.

Acetone was best identified by distilling the urine and applying the iodoform test to the distillate. Blood was easily detected by the ozonic ether and guaiacum test, mutual reduction of the hydrogen peroxide and oxyhæmoglobin taking place. There was also the spectroscopic test, the absorption spectra of oxyhæmoglobin and hæmoglobin being characteristic; but this was not so accessible to the ordinary pharmacist. As regards the bile pigments and acids, Pettenkofer's test answered well.

The quantitative determination of glucose, urea and uric acid was next dealt with. The precipitation method for glucose with Fehling's Solution had all the disadvantages of precipitation methods, and was only roughly proximate unless conducted with very great care. Pavy's ammonio cupric test was both expeditious and effective, but the evolution of NH₃ fumes was objectionable, especially in a shop. He had found Gerrard's cyano-cupric test convenient and accurate; a little practice, however, was necessary. The best way was to make a rough preliminary determination, to get an idea of the quantity of glucose present, and then to do two very careful determinations. It was essential that the same degree of dilution be maintained. For these operations the burette was indispensable, and he would strongly advise students to keep their

burettes after the Minor was passed, as it was an instrument of wide and varied usefulness. The polarimetric test for glucose was probably too technical for general use, and it had the drawback that if the urine contained lævogyre substances it would counteract the dextro rotation of the glucose. Proceeding to speak of ureametric analysis, Mr. Lothian gave a demonstration with Gerrard's ureameter, and concluded with a reference to the separation of uric acid and the relation of the latter to theobromine and caffeine.

The separation of urinary deposits was next performed by means of the centrifuge, and at the close of the lecture emission and absorption spectra were shown by means of a fine spectroscope, the property of the lecturer.

The CHAIRMAN having expressed on behalf of the Association its deep indebtedness to Mr. Lothian for his lecture, commented upon the well authenticated but little known fact that a diabetic urine may have as low a specific gravity as 1.010 or 1.015. The tests for blood in urine were all conclusive enough, but not even the spectroscopic test was distinctive for human blood, although scores of novelists and detective story writers would have us believe that the medical jurist, by simply turning his searchlight on a suspected blood-stain, can tell that it is the sanguinary fluid of a red-haired Irishman, six feet high. If any of his hearers wanted to cover himself with glory he had only to discover a differential test for human blood. Reference had been made to the medicinal treatment of diabete mellitus. Speaking from his personal experience of hospital practice, he found that although there had been active experimentation with other agents—*e.g.*, nitrate of uranium—the tendency always was to go back to codeine. He had found Pavy's method for determining glucose most serviceable and exact. The mention of the polarimetric determination of glucose reminded him that some years ago Dr. Dawson Turner, of Edinburgh, had made a research as to the electrical conductivity of morbid urines, which showed that in certain renal and urinary diseases an electrical diagnostic might be determined. However, this method seemed to be merely tentative and academic. The synthetic affinities of uric acid with alkaloids, and the alkaloidal character of ptomaines and toxines, would probably lead to remarkable discoveries in the near future. They had an earnest of this in the separation of antitoxines.

Mr. J. P. TAYLOR proposed a vote of thanks to the lecturer, and considered that Mr. Lothian had been very happy in his choice of a subject, as it was one in which every pharmacist ought to be interested.

Mr. LOTHIAN, in the course of a brief reply, suggested that the low specific gravity of some diabetic urine was probably due to the excessive amount voided by the patient. Pavy's process was undoubtedly one of the best, as the whole process was carried out in an atmosphere of NH₃, so that there was no possibility of atmospheric oxidation. In Gerrard's method the final determinations should be smartly performed to avoid oxidation.

CHEMICAL SOCIETY.

At a special meeting held on Thursday, February 8, Sir HENRY ROSCOE occupying the chair, the

Victor Meyer Memorial Lecture

was delivered by the President, Professor T. E. THORPE, F.R.S. Professor Thorpe said that as a friend of nearly thirty years' standing, and as one who had worked with him literally side by side under the directorship of Bunsen, he had taken upon himself the duty of placing on record the Society's appreciation of the remarkable services rendered by Meyer to the science he cultivated with such assiduity and success. He was born in Berlin, the son of a calico manufacturer, and there was nothing in his home life to incline him to the study of chemistry; rather, the environment of his youth was of a literary nature, his mother being a woman of considerable intellectual power. He himself wished to be an actor,

and in that calling would no doubt have succeeded; his gift of ready speech, affable manner and humour made it always a pleasure to hear him. At Heidelberg there existed a small chemical society, with which he became associated, and about the same time he became interested in a series of lectures given by Hofmann. When barely seventeen years of age he took up chemistry with Bunsen, who was struck with his capabilities. Bunsen employed him in his private laboratory, where he worked extensively on water analyses, profiting greatly, as everyone must who carefully followed Bunsen's laborious methods. In 1868 he left Bunsen and entered Baeyer's laboratory in Berlin, afterwards becoming assistant to Fehling at the Stuttgart Polytechnic. Here he carried out researches upon the di-substituted benzene derivatives, notably on isophthalic acid. His great work on orientation led him to conclusions that, except in the case of the hydroxy benzenes, have not since been materially altered. It was noteworthy that he even touched upon the constitution of camphor. When only twenty-four years of age he succeeded Wislicenus as director of the chemical laboratory at Zürich. On the remark being made at his appointment that he was very young, he wittily replied that he should endeavour to repair the fault day by day. During the thirteen years that he remained there he brought himself to the foremost rank of contemporary investigators. His famous method of determining vapour densities, devised in 1877, is too well known to need comment. Among his important works may be mentioned a study of the chemical nature of chloral hydrate, the discovery of nitro-compounds of the aliphatic hydrocarbons, and their constitution. But perhaps his most important discovery was that of the oximes. They led to his investigating a great number of ketones, and it is probably not too much to say that stereo-chemistry took its rise from the discovery of oximes. Fruitful of ideas, he was never at a loss for an experiment, but Meyer's genius was of a different kind to that of his master, Bunsen. Bunsen considered his problem and weighed it with such care that when his apparatus or method was given to the world it left no room for improvement. In 1879 he announced, together with his assistant, Carl Meyer (not a relative), the phenomenon of dissociation. Such was his energy and enthusiasm, and his influence on those about him, that the Zürich laboratory during his stay there gave no less than 130 papers and memoirs to chemical literature, and it was said by Carl Meyer that he was compelled to work so hard, although only by the fascinating influence of his master, that fits of depression came to him, almost driving him to suicide. His lectures were always made interesting and lucid, while his delivery was easy and natural. Great care was bestowed on the lecture experiments. On one occasion the indophenin reaction in benzene failed, although, as was customary, it had been tried with success immediately before the lecture. It was found that his assistant had substituted benzene prepared from benzoic acid in the lecture for coal tar benzene. This led directly to the discovery of thiophene, and a new branch was added to organic chemistry hardly less extensive than that of benzene itself. Pyrochemical problems always interested him, and he expressed the belief that a new chemistry, with undreamt-of discoveries, would arise when vessels were obtained capable of bearing temperatures at which meter could no longer exist and oxyhydrogen gas became an unflammable mixture. He was one of the first in Germany to recognise the value of Raoult's method of determining molecular weights. On the death of Hübner he was called to Göttingen, and in 1888 to Heidelberg, as successor to Bunsen, the Nestor of chemistry, who himself said that no one was better fitted than his former pupil and assistant to take his place. In 1892 he announced with Wachter the existence of iodoso compounds, the study of which led him to the discovery of the remarkable iodonium compounds. The formation and electrolysis of ethereal salts of aromatic acids occupied him from 1894 up to the year of his death. During the last few years of his life his health suffered severely from the over-active energy of his younger days. Insomnia afflicted him heavily, and his memory, formerly so clear that it had few parallels,

became very weak. He died, at the age of forty-nine years, on August 8, 1897, his merits being recognised in every country where science has penetrated. Among the distinctions conferred upon him by this country may be mentioned the Davy medal of the Royal Society.

Professor DEWAR, at the request of the Chairman, rose to propose a vote of thanks to the President, who had admirably carried out the task of giving a faithful picture of the life and work of Victor Meyer. He had done an imperial service to chemistry, and our action would be appreciated beyond the sea. Professor ARMSTRONG seconded the vote of thanks.

The PRESIDENT, in acknowledging the vote of thanks, announced that at the anniversary meeting of the Society, on March 29, the Chairman, Sir Henry Roscoe, would deliver a lecture on the life and work of Bunsen.

At a meeting, held on Thursday, February 15, the PRESIDENT, Professor T. E. Thorpe, F.R.S., in the chair, a paper by Edward Divers and Musataka Ogawa on

AMMONIUM AMIDO-SULPHITE

was read by Dr. DIVERS. No important work has been done on the interaction of ammonia and sulphur dioxide in the dry condition for sixty years. The authors have taken up the subject, and find that when sulphur dioxide is passed into a solution of ammonia in alcohol-free ether, kept cold by a freezing mixture two volumes of ammonia react with one volume of sulphur dioxide and a substance is at once precipitated, to which the authors have assigned the name of ammonium amido-sulphite, its properties indicating that it is a sulphuryl compound—

and not a thionyl compound—

Hitherto the text-books have always stated that dry ammonia and sulphur dioxide interact in the proportion of equal volumes, and in fact, unless the containing vessel be well cooled, the product of reaction has the composition NH_3SO_2 , but the authors have shown that this compound is produced by the action of heat on ammonium amido-sulphite with the loss of a molecule of ammonia, hence the true nature of the reaction between the two gases must be represented as involving two molecules of ammonia to one of sulphur dioxide.

Another paper by the same authors on
PRODUCTS OF HEATING AMMONIUM SULPHITES, THIOSULPHATES,
AND TRITHIONATE,
was read describing the properties of the substances formed. The work is being continued.

A note was also communicated on

THE COLOUR OF ALKALI NITRITES,
showing that the yellow colour was a property of the pure substance, even in the solid condition.

A short discussion, in which Mr. C. E. GROVES, Mr. BAKER, and Dr. SCOTT joined.

A paper by Edward J. Russell and Norman Smith on

THE COMBINATION OF SULPHUR DIOXIDE AND OXYGEN,
was given by Mr. RUSSELL. The authors have carried out experiments to determine the amount of combination of these gases in the presence of certain metallic oxides due to surface action of the latter. No sulphur trioxide was ever found unless an absorption of sulphur dioxide by the metallic oxide took place and manganese peroxide which absorbs no sulphur dioxide alone, produced no combination. The experiments and apparatus were also described

which had been used to determine the amount of combination between these gases in the presence of platinised pumice heated to 400°—450°. The platinised pumice was dried by passing dry hot air over it continuously for three weeks; sulphur dioxide was then admitted, and the contraction observed. In spite of the difficulty of obtaining perfectly dry platinised pumice the results clearly indicated that in the absence of moisture sulphur dioxide and oxygen do not combine in the presence of platinised pumice.

Congratulations to the authors were expressed by Mr. GROVES and Dr. BAKER, and another note was given by Mr. RUSSELL on

THE ESTIMATION OF GASES CONTAINING SULPHUR.

Except in the case of sulphur dioxide absorption methods are unsatisfactory for estimating hydrogen sulphide, carbonyl sulphide, and carbon disulphide in gaseous mixtures; it is better to explode with oxygen. When hydrogen sulphide is exploded with oxygen the reaction—

is accompanied by the formation of sulphur trioxide, yet accurate results may be obtained by introducing equations furnished by the diminutions observed.

A paper by William Jackson Pope and S. Peachey on

OPTICALLY ACTIVE TIN COMPOUNDS

was read by Mr. POPE. Up to now no compounds of tin have been prepared having four different groups attached to the tin atom, but this has now been successfully accomplished.

The authors started with tri-methyl tin iodide— $\text{Sn}(\text{CH}_3)_3\text{I}$.

By the action of zinc ethyl the following reaction easily takes place:—

The resulting tin compound is then treated with iodine, and dimethyl ethyl tin iodide is produced.

This substance is now acted upon with zinc propyl, and in this way methyl-ethyl-propyl tin iodide is obtained. It is an oil of unpleasant odour, which reacts readily with silver dextro-camphor sulphonate, giving a compound that may be represented by

in which it is seen that the tin atom is asymmetric.

The molecular rotation of the dextro-camphor sulphate ion is 95°, while the molecular rotation of the tin compound is found to be 51°, the difference being due to the optical activity of the tin base.

By careful decomposition with potassium iodide in the cold methyl-ethyl-propyl tin iodide was regenerated from the sulphonate, and was found to have a molecular rotation in ether of $[\alpha]_D 23^\circ$.

This iodide racemises with extreme ease, and it is only by keeping it at a low temperature that it can be preserved. Concluding, Mr. Pope drew attention to the fact that tin belongs to the carbon group in the periodic system, and stated that as lead follows after in the same group he hoped to be able to obtain similar results with it also.

The PRESIDENT congratulated the authors on their achievement, the importance of which he said it was impossible to exaggerate, and hoped that they would be able to communicate to the Society a similar result upon lead.

ROYAL INSTITUTION.

On Friday evening, February 2, a discourse was given by Signor MARCONI, before a crowded audience, on recent developments of

Wireless Telegraphy.

During the past year elaborate experiments have been made, in order to test the system of wireless telegraphy for all sorts of purposes. It has been proved that by means of poles 150 feet high messages may be sent from one station to another a distance of eighty-five miles. It is necessary that the transmitting and receiving station should be fitted with a pole sufficiently high to counteract the curvature of the earth's surface. In the case of transmission from cliff to cliff, or hill to hill, the elevation may often be high enough to enable the operators to dispense with poles. This extension of the distance over which messages can be sent has been largely brought about by means of a new induction coil.

Communication has now been daily kept up between the installations at the South Foreland and the Goodwin lightship, showing conclusively that the system is both certain and trustworthy in operation. Daily messages are sent by the men on board the lightship to relatives on shore, and in five instances serious loss of life and property has been averted by a prompt call for aid by means of wireless telegraphic messages. In one instance the salvage value was £52,588, a sum that would equip enough stations to set the system in operation all round our coasts ten times over. It is to be hoped that before long the Trinity House authorities will be able to provide the money for this enterprise, as it will enable our coastguards and lifeboatmen to avert huge loss of life and property.

In the recent

NAVAL MANŒUVRES

the system was severely tested in the B fleet, on board the flagship *Alexandria* and the cruisers *Juno* and *Europa*. These vessels were able to send messages to and fro when out of sight, with great advantage to the Admiral of the fleet. It was found that the *Europa* and the *Juno* were able to maintain communication at a distance of sixty nautical miles. The maximum distance through which messages were sent was seventy-four nautical miles.

The use of a new transmitter and a new transformer contributed largely to the success of the trials, and give promise of even greater possibilities in the future. At the autumn meeting of the British Association at Dover last year it was found that the large masses of rock at Dover did not interfere with the operations by ether wave telegraphy. At the International Yacht Race, in October last, wireless telegraphy was used to great advantage. As Signor Marconi was returning on board the *St. Paul* he was requested to signal the station at the Needles, in order to obtain the latest war news. This was done at a distance of sixty-six nautical miles, the *St. Paul* at the time going at a speed of twenty knots. The news was printed on board in the form of a paper which was called the *Transatlantic Times*. At the same time the passengers sent messages to their homes; thus the time may not be far distant when voyagers will be able to maintain communications *en route* with the land they have left and the land to which they are journeying. Wireless telegraphy is now being severely tested in South Africa

IN ACTUAL WARFARE.

Towards the end of last year, at the tardy request of the War Office, Mr. Bullock and five assistants went to South Africa. They were intended only for the base and the main railroads, but the officers on the spot desired their presence also at the front. Owing to lack of balloons, kites, and poles the first operations, conducted in December, were not satisfactory. Eventually, however, through the exertions of Major Baden-Powell and Captain Kennedy, kites

and poles were obtained which were sufficiently suitable to be of use. Stations were fitted up at De Aar, Orange River, Modder River, Enslin, and Belmont. Messages were sent from De Aar to Orange River, a distance of about seventy miles; and for general use portable installations were set up on service wagons. These preparations will, it is to be hoped, prove of extreme value, should the field telegraph lines be cut by the enemy. Indeed, it is regrettable that Kimberley, Ladysmith, and Mafeking were not in possession of the apparatus before their investment. Two of Mr. Bullock's assistants volunteered to make their way through the Boer lines into Kimberley, but the military authorities considered the attempt too risky. Mr. Bullock is now with General Buller in Natal.

A report was circulated recently that the iron in the hills in South Africa was the cause of the partial failure of the apparatus. This is incorrect, since iron has no more effect on the messages than any other metal. During the Naval Manœuvres messages were constantly being dispatched through a fleet of thirty ironclads.

Towards the end of last year a consignment of apparatus consigned to the Boers was intercepted. It was found to be imperfect and unworkable, and proved to have been made in Germany. It is unlikely that the Boers have in their possession any apparatus in working order, as Signor Marconi himself has not allowed any apparatus to leave his works that might be intended for Boer use.

There is reason to believe that during the present year still more astonishing progress will be made in ether wave telegraphy.

A discourse was given on Friday, February 9, by Professor J. REYNOLDS GREEN, Sc.D., F.R.S., on:—

Symbiosis and Symbiotic Fermentation.

There are various degrees of completeness of relationship in known cases of symbiosis. True symbiosis is always associated with reciprocity; where reciprocity does not exist, *e.g.*, in *Azolla*, *Anthoceros*, *Cycas*, and *Gunnera*, the term commensalism is applied; in either of these plants a seaweed may shelter and so live more easily, but the seaweed does not confer any known benefit on the plant that harbours it.

True symbiosis is frequently met with in plants of the Corollifloræ, especially in the natural orders, Scrophulariaceæ and Santalaceæ. *Thesium linophyllum*, a plant which grows on grasses, was formerly, like many others, called a parasite, but since there is a mutual benefit arising from the partnership it is now regarded as a case of symbiosis.

The mistletoe grows freely on the poplar and the apple, but is now seldom found on the oak. The seed of the mistletoe plant is carried by birds; on germinating, the roots penetrate through the bark of the tree, and put forth seekers at right angles, which branch freely among the softer tissues of the trunk. The mistletoe is always associated with the Druids, who are said to have used silver knives to sever it from the oak on which it grew. Possibly these ancient priests were so successful in cutting it that it explains why the plant is so seldom found nowadays on the oak.

This is a good case of symbiosis. Both plants are green in summer, absorb carbon dioxide from the atmosphere, and manufacture sugar. In the autumn the host plant loses its leaves, but the mistletoe is evergreen, and continues the work of elaborating food materials throughout the winter, to the advantage both of itself and its host.

In some of the higher plants—*e.g.*, the rhododendron and some of the Cupuliferæ—the roots are covered with a dense feltwork of the mycelium of a fungus, which is developed in the absence of root-hairs, and provides for the absorption of nourishment.

The lichens show an even more complete alliance—a fungus and an alga in close symbiotic relationship. As a rule, the alga is

surrounded by the fungal filaments. The fungus condenses aqueous vapour from the air, which dissolves debris and quasi-organic matter, to be worked up by the fungus. The alga, by virtue of its chlorophyll, decomposes carbon dioxide and builds up from it and the various foods at hand the necessary materials for the life of the dual organism. The alga, growing inside the fungus, develops larger cells and is more vigorous than when it lives alone.

Many leguminous plants—*e.g.*, pea, bean, clover—show an interesting relationship between a flowering plant and a fungus or bacterium. It is now well known that the atmosphere is the source of the nitrogen from which such plants build up the necessary proteid. These plants when fully developed contain more nitrogen than they could possibly obtain from the soil. This has been established as a case of symbiosis. If one of the tubercles that are found on the roots of these plants be cut across it may be seen that a fungus enters the tip of a root-hair, which consequently swells enormously, and eventually passes into the tissues of the root. It there branches, and breaks up into small bodies of various shapes. These are known as bacteroids, and are responsible for the intake of atmospheric nitrogen. If a leguminous plant be cultivated in a soil that has been sterilised by heat the amount of nitrogen absorbed diminishes, whereas such a culture, if treated with an aqueous extract of soil, gives on analysis the extra amount of nitrogen that is normally found in leguminous plants. It is not yet definitely known when and how the nitrogen is fixed, but it has been suggested by recent workers that it takes place in the tubular structures that grow down the root-hairs. As these tubes are not always present the subject is still under investigation.

There are certain bacteria which, together with schizomycetes, induce symbiotic fermentation, but in these cases a mutual benefit is not well seen at present. Undoubtedly there is a power possessed by the joint organism in a direction which the constituents do not possess. In putrefaction there are many organisms present; some attack the organic matter directly; some attack the products; others could be dispensed with. In one well-known case there are three so-called nitrifying bacteria which work together: one decomposes proteid, with production of ammonia; the ammonia is converted into nitrous acid by a second bacterium; while the third converts the nitrous acid to nitric acid.

The drink known as kefir, which is so popular in the Caucasus, is produced by three organisms, which act on the milk of goats. The ginger-beer plant furnishes another example of symbiotic fermentation, the organisms being *Saccharomyces pyriformis* and *Bacillus vermiformis*. In Madagascar a disease of the sugar-cane has been traced to some organisms which also act jointly.

GLYCERIN IN NEPHROLITHIASIS.—By giving doses of 1 to 4 ounces by weight of glycerin, taken in one dose between meals, A. Hermann has obtained good results in certain cases of nephrolithiasis. A certain amount of pain in the kidneys was noticeable after taking the dose, but was not generally severe; this was sometimes followed by the passing of a calculus. Much mucus and pus were generally present in the urine excreted. The anodyne and stone-expelling properties of glycerin appear to be due more to its lubricating properties on the urinary passages than to any solvent action on uric acid. In no case was any toxic effect produced by the largest dose of glycerin, but, in some instances, headache or diarrhoea was complained of. To obviate these, the smaller dose should be first employed. In the treatment of 115 cases by this method, it proved efficacious in 60 per cent., in fifteen cases concretions were passed and improvement followed, in twenty-nine cases concretions passed without bringing about improvement, and in twenty-five cases improvement only was observed without the passage of any concretions.—*Med. Chron.* [3], 2, 235.

NOTICES OF BOOKS AND OTHER PUBLICATIONS.

'A MANUAL OF SURGERY,' by Charles Stonham, F.R.C.S., Eng. In three vols., 7s. 6d., 7s. 6d., 10s. 6d. net. (Macmillan and Co., London.)—This is a comprehensive and essentially practical work, giving a succinct account of modern surgical pathology, diagnosis, and treatment. The work covers the whole field of modern surgery, and is arranged in such a systematic and concise manner as to make it an easy and rapid work of reference for practitioners and students. The author has wisely divided the work into three volumes—Vol. 1, General Surgery; Vol. 2, Injuries; Vol. 3, Regional Surgery. Each volume is carefully indexed and profusely illustrated, there being about four hundred and fifty illustrations throughout the work, many of which are original. The whole work is quite in keeping with Mr. Stonham's high reputation as a surgeon and teacher, and the publisher's name is a sufficient guarantee of the style in which the volumes are produced.

'THE STORY OF LIFE'S MECHANISM,' by H. W. Conn. Pp. 219, with 50 illustrations. Price 1s. (London: George Newnes, Limited.)—The living body is here described as a machine, with the object of explaining the trend of recent biological science and of the advances made toward the solution of the problem of life. The story is related in a most interesting manner, and one can only marvel that the publisher is able to produce such a work at the price.

'PHOTOGRAPHY AT HOME,' being No. 8 of the *Photo-Miniature*. Price 6d. (London: Dawbarn and Ward, Ltd.)—The monthly magazine of photographic information known as the *Photo-Miniature* is a very high-class production, and should meet with a wide circulation among those who take up photography as more than a mere passing amusement. Each number of the publication is complete in itself, one single subject being dealt with therein, and the idea of devoting one number to hints on photography at home should commend itself to many.

'OUR PATENT LAWS,' by James Keith, C.E. Pp. 20. (London and Woking: Unwin Brothers.)—This is a reprint of an article on the subject of British patent laws, which was originally published ten years ago, with the object of helping to secure much-needed reforms in the Patent Office regulations. An article on "American competition" is now added.

'MATRICULATION DIRECTORY' for January, 1900. Pp. 142. (London: University Correspondence College.)—Everyone who has any idea of attempting to secure a university degree should make a point of writing for a copy of this extremely useful guide, which is sent free on application. Information is given respecting the choice of text-books, as well as solutions of examination papers which have been set at past examinations.

'TERPENELESS ESSENTIAL OILS,' by Ernest J. Parry, B.Sc. Pp. 20. (Pimor, Germany: Heinrich Haensel.)—This is a report on a well-known brand of terpeneless essential oils, interesting particulars regarding which are given at some length. The terpeneless oils of lemon, orange, lavender, caraway, pimento, and angelica are dealt with.

'GOLDEN RULES OF PHYSIOLOGY,' by I. W. Hall, M.B., Ch.B., and J. A. Menzies, M.D., C.M. Pp. 80. Price 1s. (Bristol: John Wright and Co.)—The sixth booklet in the "Golden Rules" Series is intended for the use of students who have already attended lectures on physiology and read a text-book, prior to entering for examination. It is hoped that such students will find it a stimulant, both to memory and to thought. An alphabetical arrangement has been adopted to facilitate reference.

Obituary.

DITTMAR.—On February 1, William Dittmar, managing director of the well-known firm, the Chemische Fabrik auf Actien vorm E. Schering, Berlin. Aged 48. Mr. Dittmar was well and favourably known in English chemical manufacturing circles, and has frequently occupied the chair at meetings of chemical manufacturers in this country. He would shortly have celebrated his twenty-fifth anniversary in the position he held in the factory, which he entered in October, 1875, after having for several years been with Mr. E. de Haen, of List. The loss to Messrs. Schering of such an eminent and influential leader will be felt very much, and his memory held in universal esteem.

ELLIOT.—On February 16, John Elliot, Chemist and Druggist, Hyde Hill, Berwick-upon-Tweed. Aged 84. Mr. Elliot was the oldest tradesman in the town, having been in business there about sixty years. He was born at Temple, near Dalkeith, where his father was forester to Lord Dunglass, and after a hard struggle in his early days he saved sufficient money to enable him to attend Edinburgh University. In 1840 he commenced business in Berwick with a capital of about £7. Twenty years later he was involved in a law suit with a Border farmer, who alleged that a number of his sheep had been poisoned by Mr. Elliot's sheep-dip, the action costing some £22,000. In spite of this loss he prospered, and became the owner of considerable property, being engaged in several other occupations in addition to that of chemist and druggist. Mr. Elliot was the oldest office-bearer of Wallace Green Presbyterian Church, Berwick. Last year Mr. Elliot and Mrs. Elliot, who is over 90 years of age, celebrated their golden wedding.

FRANCIS.—On February 9, at Hertford, Sarah Inglesby, widow of George Bagget Francis. Aged 72.

JOHNSTONE.—On February 6, James Johnstone, Chemist and Druggist, Carlisle. Aged 30.

RICH.—On February 15, George B. O. Rich, Chemist and Druggist, Mile End Road, London, E. Aged 56.

RUST.—On February 15, James Rust, Chemist and Druggist, Thaxted, Essex. Aged 58.

NEW REMEDIES.

GLAUCIUM LUTEUM IN GLYCOSURIA.—Marpmann some time back (*P. J.* [4], 8, 91) drew attention to the value of the extract of *Glaucium luteum* in the treatment of diabetes. Helt confirms this statement, and finds that after fourteen days of treatment with this drug, the blood of the patient becomes richer in hæmoglobin, and the number of the red corpuscles is increased in a degree which is not attained by treatment with iron. The dose is a teaspoonful of the fluid extract in the evening, or morning and evening, with beer or water. After three weeks of treatment the amount of sugar excreted is reduced, and, in many cases, disappears.—*Pharm. Post*, 32, 346, after *Südd. Apoth. Ztg.*

TROPACOCAINE FOR OPTICAL ANESTHESIA.—R. Hilbert states that the hydrochloride of tropacocaine is preferable to the same salt of cocaine for use in ophthalmic work. Although it rapidly produces a strong anæsthesia, it is absolutely free from irritant action; it acts as a slight antiseptic, it is more stable in solution, does not affect the arterial pressure, and does not dilate the pupil. At the same time, it is less toxic than cocaine. The solution employed consists of tropacocaine hydrochloride, 50 centigrammes; sodium chloride, 10 centigrammes; distilled water, 10 Gms.—*Nouv. Rem.*, 15, 554.

[E. Merck has shown (*P. J.* [4], 8, 431) that a similar but even weaker solution of the same ingredients remained perfectly stable for eighteen months.—*Ed. P. J.*]

THE STUDENTS' COLUMNS.

THE MATERIA MEDICA OF THE PHARMACOPŒIA.

Belladonnæ Radix.

BELLADONNA ROOT is obtained from *Atropa belladonna*, Linn. (N. O. Solanaceæ), usually from plants cultivated in England or Germany. The stout, branching tap-root is collected in the autumn when about three or four years old, and carefully dried. Both old and exhausted roots are excluded by the official description. The medicinal properties of the root are the same as those of the leaves; the root is used in the preparation of Atropine, Extractum Belladonnæ Liquidum, and, indirectly, of Emplastrum Belladonnæ, Extractum Belladonnæ Alcoholicum, Linimentum Belladonnæ, Suppositoria Belladonnæ, Tinctura Belladonnæ, and Unguentum Belladonnæ

BELLADONNÆ RADIX.—A, transverse section of upper part of root; B, transverse section of young root; C, portion of young root, natural size.

CHARACTERS.—Belladonna root of good quality occurs in nearly cylindrical pieces, varying in diameter from 10 to 20 Mm., and in length from 15 to 30 Cm. or more. It is of a pale greyish-brown colour externally, finely wrinkled or striated longitudinally, and often marked with short transverse scars like liquorice and marsh-mallow roots. It differs from those, however, by frequently having a powdery or mealy surface, owing to the thin epidermis being easily abraded, and starchy matter beneath becoming detached. The transverse fracture also is short, and not at all fibrous, while the interior of the root is whitish, owing to the presence of small compound starch-grains in the parenchymatous cells of both bark and wood. Other cells are filled with numerous, very minute, sandy crystals of calcium oxalate, both those and the muller-shaped starch-grains being revealed under the microscope. A transverse section of a young root exhibits a greyish non-fibrous bark, separated by a dark cambium layer from the whitish wood, to which it adheres closely; near the cambium ring the wood contains numerous scattered dark groups of large porous vessels and fibres, which are seldom arranged in more than an indistinctly radiate manner, except near the crown of the root, where it passes imperceptibly into the rhizome and one or more rings of radiate yellowish wood may be found, as well as an evident pith.

NOTES.—The distinctive characters of belladonna root of good quality are its firm, plump appearance; the short, mealy fracture; the dark cambium line, and the manner in which the vessels and fibres are distributed. In badly dried roots the transverse fracture often appears brownish, hard, and resinous, and the epidermis is not easily abraded. Old roots are deficient in alkaloid, and should not be used; they are woody, and exhibit a prominently radiate structure. Roots collected in spring are also deficient in alkaloid; they contain sugar, and but little starch, their

outer surface is shrunken, and their interior dark-coloured and

BELLADONNÆ RADIX.—Transverse section of the woody portion showing (K) cells containing sandy crystals, (pr) parenchyma filled with starch, (sp) fibrovascular bundle, (ms) medullary rays. After Vogl.

spongy. Several roots may be mistaken for that of belladonna. That of elecampane contains oil glands, and the groups of vessels are inconspicuous; small pieces of scammony root have a very characteristic structure; marshmallow root has a fibrous bark, and radiate wood, in which scattered groups of vessels are not visible; liquorice root is yellowish internally, and possesses a characteristic sweet taste. The chief constituents of belladonna root are the alkaloid hyoscyamine and its isomer atropine. The fluorescent principle— β -methyl- α -esculetin or chrysotropic acid is also present, whilst traces of scopolamine may be found, and belladonnine and apoatropine appear to be formed in the course of isolating the more important bases. The total alkaloid present varies, as a rule, between 0.4 and 0.6 per cent., but as much as 1.0 per cent. has been found. The plant is most active when about four years old, and wild specimens are somewhat richer in alkaloid than cultivated ones.

Benzoinum.

BENZOIN is a balsamic resin obtained from *Styrax benzoin* Dryand. (N.O. Styraceæ), and probably other species of *Styrax*. The only tree definitely known to produce the resin is indigenous to Java and Sumatra, and yields the variety known as Sumatra benzoin. As the tree does not at any period of its development contain special secreting cells or ducts, the resin is probably a purely pathological product, the formation of which may be induced by injury to the bark of the tree, such as is caused by the benzoin collectors hacking it with an axe. The parenchymatous cells of the medullary rays appear to become resinified first; the contents and walls of the cells of the bast parenchyma and wood are attacked next. The fluid resin exudes from the incisions in the bark or accumulates between the bark and the trunk, and gradually hardens. When quite firm the benzoin is collected and sold to Chinese traders, who soften it, by the aid of heat, and pack it in oblong boxes, together with a varying proportion of vegetable debris, and exported from the west coast of Sumatra (Padang). Siam benzoin, which is a much superior article, is collected from an unknown species of *Styrax*, growing in the province of Luang Prabang, on the Mekong River. Other varieties are the non-official Penang and Palembang benzoin, both of which are collected in the south-east districts of Sumatra. Preference should be given to Siam benzoin for making pharmaceutical preparations, as the Sumatra variety rarely answers the B.P. requirements. Benzoin possesses expectorant, styptic and anti-septic properties; it is used for preparing Acidum Benzoicum, Adeps Benzoatus, Tinctura Benzoini Composita, and Unguentum Cetacci

CHARACTERS.—Siam benzoin may occur in flat or curved (concavo-convex) tears, or in masses. The tears vary considerably in size, but rarely exceed 5 Cm. in length and 12 Mm. in thickness. The shape of the curved pieces is due to the resin accumulating between the bark and trunk of the tree. The tears are brittle but soften when warmed and, when further heated, give off fumes of benzoic acid. They are opaque and milky-white internally, but they are usually covered with a coating of yellowish or reddish-brown resin, which increases in thickness with age, probably as the result of chemical changes brought about by oxidation. Block Siam benzoin consists of small tears, more or less closely cemented together by a glassy reddish-brown, transparent or translucent resin, the proportion of which increases with age. Siam benzoin is characterised by its agreeable odour, recalling that of vanilla, and is almost entirely soluble in solution of potassium hydroxide, or in 5 parts of 90 per cent. alcohol, yielding only about 1 to 2.5 per cent. of insoluble residue, and not more than 1.5 per cent. of ash. Sumatra benzoin occurs only in masses consisting of white tears imbedded in a dull reddish-brown or greyish-brown opaque resin, and having an odour recalling that of storax. It is soluble in 90 per cent. alcohol, to the extent of 70 to 80 per cent. only, but should not yield more than 1.5 per cent. of ash. Penang benzoin also has the storax odour, and is sometimes called Sumatra, but it is easily distinguished by its fused and glassy appearance when fractured. Palembang benzoin is a mixture of resin and woody matter, and is probably of similar origin to Penang benzoin.

NOTES.—The distinctive characters of Siam benzoin are the bold tears and vanilla-like odour; of Sumatra benzoin, the dull appearance of the resin in which the tears are imbedded, the storax-like odour, and the presence of cinnamic acid. Siam benzoin is said to contain no cinnamic acid, but about 38 per cent. of benzoic acid, partly free, and the remainder combined with the two alcohols—benzo-resinol and sia-resinotannol—of which the resin mainly consists; it also contains 0.15 per cent. of vanillin, and 0.3 per cent. of an oily, aromatic liquid—probably an ester of benzoic acid. Sumatra benzoin yields about 18 per cent. of benzoic acid, and 20 per cent. of cinnamic acid, both of which are partly free and partly combined with two alcohols—benzo-resinol and resinotannol; it also contains 1 per cent. of vanillin, and traces of benzaldehyde, styrol, styracin, phenyl-propyl cinnamate, etc., all of which tend to modify its odour. The presence of cinnamic acid is indicated by the evolution of benzaldehyde (bitter almond odour) when a little powdered Sumatra benzoin is boiled in acidulated solution of potassium permanganate.

Buchu Folia.

BUCHU LEAVES, the "short buchu" of commerce, are obtained from *Barosma betulina*, Bart. and Wendl. (N.O. Rutaceæ), a small shrubby plant which is indigenous to Cape Colony. They are collected while the plant is flowering and fruiting, then dried, and

SECTION OF BUCHU LEAF, showing the sub-epidermal mucilaginous cells swollen in water. After Planchon and Collin.

exported from Cape Town. The leaves possess tonic, stomachic, diuretic, and diaphoretic properties; they are used for preparing Infusum Buchu and Tinctura Buchu.

CHARACTERS.—Buchu leaves are roundish (rhomboid-obovate) in shape, from 12 to 20 Mm. long, pale green or yellowish-green in colour, rigid and brittle when dry, but cartilaginous when moist. The surface of the leaves is free from hairs (glabrous), finely

LOWER EPIDERMIS, showing crystals of hesperidin and sphaeraphides. After Planchon and Collin.

wrinkled below, and with small wart-like prominences above owing to the elevation of the epidermis by subjacent oil-glands. The margin shows numerous minute sharp teeth (denticulate), and the apex is blunt and recurved. On examination with a lens, by transmitted light, numerous oil-glands are distinctly visible, especially near the margin of the leaves, one being situated near the base of each indentation. A transverse section of a leaf exhibits an epidermis of five or six-sided tabular cells, containing yellow amorphous masses or spherocrystals of hesperidin; the thick, inner walls of those cells are rich in mucilage, and swell in the presence of water. The odour of buchu, which is particularly marked when the leaves

LEAVES, natural size, and tips of same, enlarged. (A) *Barosma betulina*; (B) *B. crenulata*; (C) *B. serratifolia*; (D) *Empleurum serrulatum*.

are crushed, is reminiscent of a mixture of peppermint and black currant; the strong and aromatic taste is due to the presence of a volatile oil.

NOTES.—The distinctive characters of buchu leaves are their roundish shape and recurved apex, the distribution of the oil-glands, and the characteristic odour and taste. Bearberry leaves are spoon-shaped, rounded at the apex, and destitute of oil-glands. The leaves of *Empleurum serrulatum* and of other varieties of buchu differ from those of *B. betulina* in shape, margin, distribution of oil-glands, absence of diosphenol, etc. Buchu leaves should yield about 1.45 per cent. of volatile oil, containing about 30 per cent. of the crystalline substance—diosphenol—which is probably the most important constituent of the drug. Other constituents of the leaves are the mucilage and hesperidin, a yellow crystalline substance which forms the spherocrystals, but has no marked physiological action.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

PHOTOGRAPHS OF BRITISH PLANTS.

J. C. Shenstone exhibited at a recent meeting of the Linnean Society a collection of seven hundred photographs of British flowering plants, to show what could be accomplished by means of the camera in the direction of botanical illustration. He contended that photography was the only means by which the lines and masses of our flowering plants, as truly characteristic as the less subtle characters by means of which botanists group and arrange plants into orders, genera, and species, could be readily reproduced. He explained the various technical processes and apparatus necessary for successful plant photography, and alluded to the difficulties inseparable from the photography of plants in their natural habitats, etc. His remarks were illustrated by means of lantern slides.

APIGENIN, APIIN, AND VITEXIN.

A. G. Perkin points out that, by the action of nitric acid on apigenin under varied conditions, four nitro-derivatives have been obtained: mononitro-apigenin, $C_{15}H_9O_5(NO)_2$, orange-yellow needles, m. p. about 302° , somewhat soluble in alcohol; trinitro-apigenin (a), $C_{15}H_7O_5(NO_2)_3$, yellow needles, m. p. about 296° ; trinitro-apigenin (b), yellow needles, m. p. $245-246^\circ$, and tetranitro-apigenin, $C_{15}H_6O_5(NO_2)_4$, almost colourless needles, m. p. $243-244^\circ$. With the exception of the first mentioned, all dissolve with difficulty in the usual solvents. In preparing the mononitro-compound, dinitro-*p*-hydroxybenzoic acid was obtained as a decomposition product, a further proof that apigenin does not contain a catechol group (*Trans. Chem. Soc.*, 1897, **71**, 805). Tetranitro-apigenin appears to be identical with the compound, $C_{15}H_6O_5(NO_2)_4$, obtained from vitexin (*Trans. Chem. Soc.*, 1898, **73**, 1026), and as the decomposition products of both colouring matters are identical, vitexin must be a derivative of apigenin. The formulæ $C_{21}H_{20}O_{10}$ and $C_{21}H_{19}O_{10}(C_2H_3O)_7$ are now assigned to vitexin and acetylvitexin, and it is suggested that vitexin is a stable glucoside of apigenin, and that a like constitution may also apply to scoparin (*Proc. Chem. Soc.*, 1899, **15**, 123), which, according to this view, is a glucoside of a luteolin monomethyl ether. Apiin, $C_{27}H_{32}O_{16}$, the glucoside of apigenin occurring in *Apium petroselinum*, is not converted by dilute nitric acid into nitro-apigenin, but into nitro-apigetrin, $C_{21}H_{21}O_{11}NO_2$, a yellow, crystalline powder very sparingly soluble in the usual solvents. This is the nitro-compound of a new glucoside, apigetrin, which differs from apigenin in containing but one sugar group. By prolonged digestion with dilute hydrochloric acid, it yields the above mononitro-apigenin.—*Pr. c. Chem. Soc.*, **16**, 44.

CONVERSION OF PHENOLIC ACETATES INTO BENZOATES.

F. Bodroux finds that phenyl acetate may be converted, almost quantitatively, into benzoate, at ordinary temperatures, by the action of benzoyl chloride and zinc dust. Benzoyl chloride, 15 Gm., is introduced into a capacious flask, and a few Gm. of zinc dust added. The mixture gradually develops heat, and in a few minutes violent reaction takes place, with the abundant evolution of hydrochloric acid. When reaction ceases, the product solidifies in a few hours into a crystalline mass of impure phenyl benzoate. This solidification may be hastened by agitating with a dilute solution of potash. Recrystallised from dilute alcohol, phenyl benzoate separates out in large prismatic crystals, melting at $69^\circ C$. The same reaction may be obtained with the acetic esters of thymol, and of paracresol, but beta-naphthol acetate does not undergo the same conversion.—*Bull. Soc. Chim.*, **23**, 54.

NEW SALINE INJECTION MATERIAL.

By employing a minute quantity of sodium saccharate as an ingredient in saline injection solutions, A. Schiekling finds that the value of the injection is greatly increased, since that salt combines with the free carbon dioxide of the blood, being converted into sodium carbonate and sugar. The toxic gas is thus eliminated, as the course of the natural physiological process. The proportion used is 0.03 per cent. of sodium saccharate, and 0.7 per cent. of sodium chloride. With this injection fluid, good results were obtained even where the ordinary physiological salt solution had failed, and no deleterious effects were observed to follow its employment. Care was taken that the sodium saccharate was pure, containing neither free sodium hydrate nor free sugar.—*B.M.J. Epit.* 1, 1900, 19, after *Therap. Monats.*

CUPRENE, A NEW HYDROCARBON.

By passing a current of pure acetylene gas over reduced copper or bright copper filings, in a tube heated at first to about $180^\circ C$, after a time the metal is observed to swell, and eventually to entirely fill the tube; if a little of this substance be spread in a thin layer in a tube and again heated to $170-250^\circ C$ in a current of acetylene, a further great increase of volume takes place, a yellow bulky solid is formed, consisting of matted filaments, resembling amadou in appearance. This is the new hydrocarbon, which, according to Paul Sabatier and J. B. Senderens, has the empirical formula C_7H_8 , and has been named cuprene. It is practically non-volatile, decomposes above $400^\circ C$, yielding empyreumatic products, and leaving a solid carbonaceous residue. Cuprene is insoluble in all solvents; sulphuric acid is without action upon it in the cold, nitric acid slowly attacks it, forming nitro-compounds.—*Comp. rend.*, **130**, 250.

COLOURING PRINCIPLES OF TANNIN MATTERS.

A. G. Perkin states that the colouring matter of the leaves of *Arctostaphylos uva-ursi* (bearberry) and *Hæmatoxylon campechianum* (logwood) is quercetin, which is accompanied by a second substance, probably myricetin, to which the green colour of its alkaline solutions are due. Gallotannic acid occurs in some quantity in the latter leaves. The leaves of *Rhus metopium* contain gallotannin, myricetin, and a trace of quercetin, but the stem of this plant, unlike *R. cotinus*, and *R. rhodanthema* is devoid of colouring matter. The sparing solubilities of acetylmyricetin and dibromoquercetin have been employed for the separation of myricetin and quercetin. The leaves of *Robinia pseudacacia* contain a feeble colouring matter, acacetin, $C_{16}H_{12}O_5$, which yields an acetyl derivative, $C_{16}H_{10}O_5(C_2H_3O)_2$, colourless needles, m. p. $195-198^\circ$, and on fusion with alkali phloroglucinol, *p*-hydroxybenzoic acid, and a trace of protocatechuic acid. Acacetin contains one methoxyl group, on removal of which a colouring matter, $C_{15}H_{10}O_5$, results, having the reactions of apigenin. It is thus probably an apigenin monomethyl ether. The leaves of *Myrica gale* and *Coriaria myrtifolia* contain respectively myricetin and quercetin. Although a relationship frequently exists between the tannin and the colouring matters of the same plant (*Trans. Chem. Soc.*, 1897, **71**, 1138), there is no rule on this point, for exceptions are somewhat numerous.—*Proc. Chem. Soc.*, **16**, 45.

NOMENCLATURE OF EGG ALBUMINS.

A. Panormof finds that the number of different albumins contained in the eggs of birds is considerable. He therefore proposes to distinguish these by a definite system of nomenclature, the name being derived from that of the animal, while the suffixes "in," "inin," and "inidin," indicate respectively the albumins insoluble, sparingly soluble, or readily soluble in ammonium sulphate solutions. Thus, pigeons' eggs contain an insoluble amorphous albumin "columbin," and sparingly soluble crystalline albumin "columbinin."—*Bull. Soc. Chim.*, **24**, 93, after *Journ. Soc. Physiol. Chim.*

THE TANNIN VALUE OF MALABAR KINO.

BY DAVID HOOPER.

Among the exudations belonging to the class of kinos, the most important is that obtained from *Pterocarpus marsupium*, a tree more abundant than anywhere else in the Malabar district of the Madras Presidency. Its value depends upon its comparative purity and its great solubility in water and in alcohol, and, for these reasons, the drug has for several years held a place of honour in the British and other Pharmacopœias. The astringency of kino is universally acknowledged, and kino-tannic acid has been shown to be the principal ingredient, but there is an absence in chemical and pharmaceutical works of experimental data having for their object the standardisation of the commercial drug and its preparations.

The only recent attempts to determine the tannic acid in kino were performed by Messrs. Will and Branch.* The results were obtained by a potassium permanganate process, which is now almost entirely superseded; and the absence of any reference to the amount of water in the samples is an important omission in the paper. At any rate the figures, representing one half the drug as tannic acid, have not been confirmed, and are not in accord with my experience of its composition.

In Southall's 'Materia Medica,' edited by Mr. John Barclay, the percentage of kino-tannic acid is returned at from 70 to 75 per cent., but it is not clear from the context whether these proportions include gallic acid, kinoic acid and pectin.

The subject attracted my attention more than two years ago when a decoction of the bark of *Pterocarpus marsupium* was sent from Coorg for its valuation as a tan liquor. The solid matter of the red coloured decoction consisted almost entirely of pure tannic acid. Following up the inquiry, a specimen of the bark of the tree was obtained from a reliable source, and this was submitted to examination. The powdered air-dried bark yielded to water, at 60° C., 7 per cent. of extract. This was a low proportion, but on treating it with hide powder the percentage of tannin was found to be 77.1.

When kino exudes from the tree it is a thick red liquid of such a strength that 100 C.c. affords 50 Gm. of dry kino. During the process of evaporation the drug breaks up into the peculiar angular fragments by which it is known in commerce. The hide powder process was used in the determination of the following nine samples of kino. They were all collected by Forest officers, and although not all from Malabar, they were obtained from the official botanical source.

	Water.	Tannin.	Non-tannins.	In-soluble.	Ash.	Tannin in Dry Substance.
1	15.3	79.1	4.1	—	1.5	93.2
2	14.6	82.4	1.6	0.4	1.0	96.5
3	14.9	78.4	4.6	1.0	1.1	92.1
4	15.7	79.0	3.8	—	1.5	93.7
5	14.7	79.5	4.2	—	1.6	93.2
6	15.7	79.6	1.1	1.3	2.3	94.4
7	13.5	76.4	4.0	4.0	2.1	88.3
8	15.1	70.0	11.5	1.5	1.9	82.4
9	12.2	70.4	10.6	5.1	1.7	80.2

The astringent character of Malabar kino is very marked according to these results. Eliminating the last three, which were derived from the Central Provinces, and collected as an experiment, the yield of tannic acid in the dry substance is over 90 per cent.

The only quantitative test for kino in the present British Pharmacopœia, that not less than 80 per cent. should be soluble in boiling water, is quite consistent with the above results. The 80 per cent. of extractive matter, together with 15 per cent. of water natural to the kino, would leave a margin of 5 per cent. for insoluble impurities.

* *Chemist and Druggist*, July 9, 1898, p. 57.

The above tests were made on fresh specimens of dried juice, and it is probable that this accounts for the superiority of the products just reported upon. The gelatinisation of tincture of kino is supposed to be due to a molecular alteration of the tannic acid, whereby it becomes insoluble in diluted alcohol.

An insoluble tannin is similarly liable to form in the kino on prolonged storage or exposure in a dry state.

THE MATERIA MEDICA OF THE SOCIETY'S MUSEUM.*

BY E. M. HOLMES, F.L.S.,

Curator of the Pharmaceutical Society's Museum.

SENNA LEAVES.

Cassia acutifolia, Del.—The specimens in the Museum represent to some extent the history of the drug in English commerce during the last fifty years. In 1842 the quality of the drug was so inferior, and it was so frequently adulterated with argel leaves, that a protest was made by Mr. Jacob Bell (*Pharm. Journ.* [1], 2, p. 63, and as a result of Dr. Christison's experiments (which showed that argel leaves caused griping without being purgative) the use of Alexandrian senna was almost given up in Edinburgh, the Tinnevely being substituted. A threat to boycott the Alexandrian drug by refusing to purchase it led to an improvement in the quality which, with a few intermissions, has continued to the present day, the senna being now sorted to a certain extent before leaving the Egyptian ports of shipment.

The Museum specimens consist of:—(1) Alexandrian senna as imported in 1842, of very inferior quality, containing discoloured leaves, leafstalks, pods, argel leaves, dirt, etc. (2) Alexandrian senna of 1899 importation. (3) Ditto, with the dust removed, or "Dust out." (4) Ditto, with the small and broken leaves removed by sifting or screening. (5) Ditto, "Hand-picked," consisting of the finest leaves. The hand-picking is usually done at home by the children of the employes at the wholesale houses. The term "Elect" is sometimes applied to the finest samples of the drug after one or more siftings into leaves of different sizes, but which have not been hand-picked. (6) Small senna removed from No. 4. (7) Argel leaves, argel flowers, and pods removed from No. 1. The argel leaves are now rarely or only at long intervals found in Alexandrian senna, and the pods and flowers not at all. The leaves appear to be added at an Egyptian central depôt for the purpose of giving the senna a better odour, since they are bitter, not purgative, and do not cheapen the senna, *P.J.* [1] 8, p. 400; 9, p. 25-31; [2] 10, p. 196. The argel leaves are easily recognised by their minutely wrinkled surface and the equal base of the leaf, senna leaves being always unequal at the base and having more prominent lateral veins than the argel leaves, and being thinner in texture. Of the other so-called adulterants none practically occur. Specimens of each, viz., *Tephrosia apollinea*, *Colutea arborescens*, *Coriaria myrtifolia*, and *Globularia alypum* are to be found in the Reference Museum and in the Society's Herbarium. *Globularia alypum* is said to have appeared once in Germany as a substitute as "Wild Senna." *Pharm. Journ.* [1] 16, p. 426. The leaves of *Colutea* and *Coriaria* have never been noticed in senna in this country, and *Tephrosia apollinea* has only been found as an extremely rare accidental mixture to the extent perhaps of a leaflet or two in 1lb. of senna. The histological differences of all these leaves are given in the *Pharm. Journ.* [4] 2, p. 481-484, by E. Latour. The relative value of the different grades of Alexandrian senna is as follows:—The sifted and "elect" senna are about twice the value of the crude drug, and the hand-picked three-and-a-half to four times its value. The siftings, or small senna, is worth about half the value of the crude drug. Judging from the prices, the powdered drug is probably made from the sifted drug or from the siftings, according to price. (8) Senna pods. The use of senna pods, although well known to the Arabian and mediæval physicians, who preferred them

to the leaves ('Pharmacographia,' 2nd ed., p. 217), has only been revived of late years (*Lancet*, July 27, 1889, p. 164). The infusion is said to be milder in odour and flavour and slower in its action, but equally effective, *Pharm. Journ.* [3] 20, pp. 164, 281, 394.

According to the Consul at Suakin senna is there sorted into picked leaves, broken leaves, and pods. The pods are exported chiefly to Trieste, and are used for imparting a gloss to silk fabrics. Although the senna plant grows wild freely all over the Eastern Soudan, the best quality comes from near Rowayyah, and inferior kinds from Sinkat and Erkoweit, *Pharm. Journ.* [3] 24, p. 10.

CASSIA ANGUSTIFOLIA, Vahl.—This plant yields the cultivated or Tinnevelly senna, the Bombay or East Indian senna, and the Arabian, Mecca, or Aden senna, although sometimes the last name is given to the leaflets of another species, *C. holosericea*.

The specimens in the Museum consist of:—(1) East Indian senna from Dr. Pereira's collection, consisting of leafstalks, leaflets, and discoloured leaflets; it is a very inferior drug. (2) Tinnevelly "hand-picked," consisting of the finest leaflets of the cultivated plant, free from seed, stalks, and discoloured leaflets. (3) "Aden senna, small," imported in 1898, of excellent quality, resembling Tinnevelly, but consisting of smaller and narrower leaflets, free from stalks and discoloured leaflets. (4) Pods. Besides these, which are all commercial specimens, there are in the Reference Museum, (5) a specimen of Arabian senna, containing stalks and pods and discoloured leaflets, from Aden, presented by D. Vaughan, and of (6) Somali or African senna, resembling Bombay senna in the longer leaflets, green and discoloured, and leafstalks. The hairs are said to be more numerous and the epidermal cells smaller in Alexandrian than in E. Indian senna, and the stomata round in the Alexandrian but oval in the E. Indian senna, *Pharm. Journ.* [4] 5, p. 5. Usually four to six grades of Tinnevelly senna are kept by wholesale druggists, differing in value according to size, colour, freedom from leaflets, etc.; they are obtained by sifting the leaves through sieves of different meshes.

CASSIA HOLOCERICEA, Fresenius.—The leaflets of this species, which are shorter, smaller, and more obtuse, and much more hairy than those of Alexandrian senna, have occasionally been met with in Arabian and Alexandrian senna, but in March, 1892, were offered in London in a separate bale, with Mecca senna, but fetched only a nominal price. Mr. J. Moss, however, experimented with them, and found them equally effectual with the Alexandrian drug, but that they did not produce griping, *Pharm. Journ.* [3] 22, p. 874.

CASSIA OBOVATA.—The leaflets of this species were at one time mixed with the Alexandrian senna, and were official in the British Pharmacopœia in 1867, but do not now occur in it. They are occasionally offered in the London market. The specimens in the Museum include: (1) Leaflets imported as Suez senna in 1899. (2) Senegal senna, from Dr. Pereira's collection. (3) Cultivated senna from Barcelona. The leaflets vary considerably in size in these specimens, the Senegal senna having leaflets nearly twice, and the Barcelona nearly four times as large as the Suez senna. The leaflets of *Cassia obovata* have the reputation of being less active than those of *C. acutifolia*. In powder they can be recognised by the papillose cells of the lower epidermis, *Pharm. Journ.* [4], 9, pp. 470-478. Other specimens of this species from Cape Colony, Porto Rico, and from Madras occur in the Reference Museum. It is interesting as being stated to be the original senna introduced by the Arabs into Europe, and cultivated in the sixteenth century in Italy, France, and Spain. The only other species in the museum, of senna used as a purgative, is the *Cassia marilandica*, a specimen of which is in the collection of the United States materia medica in the Reference Museum. The leaves of this species are not unlike those of *C. obovata*, but are thinner, and are characterised by the upper epidermis having no stomata, epidermal cells with sinuous walls, and by the absence of hairs, *Pharm. Journ.* [4] 2, p. 484, Fig. 17.

THE RARER COPAIBA BALSAMS AND MECCA BALSAM.*

BY K. DIETERICH.

Angostura, Bahia, Cartagena, Maracaibo, Maturin, East Indian (Gurjun), Para, West African (Illurin), and Mecca balsams have been examined. The method of analysis adopted was as follows:—

(1) *Determination of acid number.*—1 Gm. of balsam is dissolved in 30 C.c. strong alcohol and titrated with semi-normal alcoholic potash with phenol-phthalein as indicator. The number of C.c. semi-normal KOH \times 28 = acid number.

(2) *Determination of saponification number.*—1 Gm. of balsam is treated in a flask with 20 C.c. semi-normal alcoholic potash and 50 C.c. petroleum ether (boiling point, 60-70° C). This is allowed to stand for 24 hours at ordinary temperatures and then titrated, after dilution with strong alcohol (not with water), with semi-normal H₂SO₄, phenol-phthalein being the indicator used. The number of C.c. semi-normal KOH used up \times 28 = saponification number.

(3) *The ester number* is obtained by subtracting the acid number from the saponification number.

The following are the results obtained:—

ANGOSTURA BALSAM, three samples.

	(1)	(2)	(3)
Acid number	{ 79.52 80.70	{ 75.87 76.32	{ 83.00 83.50
Ester ,,	{ 16.24 17.38	{ 16.07 16.19	{ 8.36 7.84
Saponification number	{ 95.76 98.08	{ 91.94 92.51	{ 91.36 91.44

BAHIA BALSAM, TWO SAMPLES.—The first was undoubtedly pure, the second probably adulterated.

	(1)		(2)	
Acid number	64.19	64.25	81.09	81.27
Ester ,,	1.76	2.60	5.08	6.05
Saponification number	65.95	66.85	86.17	87.23

CARTAGENA BALSAM, three samples.

	(1)		(2)		(3)	
Acid number	49.00	49.4	62.30	62.67	87.75	88.23
Ester ,,	56.20	57.17	41.15	40.90	4.55	4.67
Saponification number	105.20	106.57	105.45	103.57	92.30	92.90

MARACAIBO BALSAM, two normal samples and one (3) five years old.

* From the *Pharmaceutische Centralhalle*, 40, 311. Abstract.

MECCA BALSAM.—Two samples were examined, the first pure and fresh, the second old and resinified, smelling of turpentine.

	(1)		(2)	
Acid number.....	39.84	39.96	60.77	61.37
Ester „	101.10	101.39	81.90	82.66
Saponification number..	140.94	141.35	144.67	145.03

The first balsam was a very thin fluid of very pleasant odour, and clear yellow colour, the second was a cloudy, thick fluid, and had an unpleasant turpentine odour.

COMMERCIAL CALCIUM LACTOPHOSPHATE.

BY THOS. S. BARRIE.

Lactophosphate of calcium is usually obtained in lumpy masses somewhat resembling a very coarsely granulated effervescent citrate. It is very acid, hygroscopic and dissolves partially in water leaving a more or less abundant residue. In the course of certain experimental work it became necessary to examine carefully the sample in stock, and afterwards two other samples were obtained and examined also. A qualitative examination was first made, when each sample was found to be a mixture of calcium phosphate, calcium lactate, and free lactic acid. The free acid only dissolved part of the phosphate, the remainder of the phosphate constituting the residue already referred to. That the acidity was due to lactic acid was proved by extracting same with ether and allowing the latter to spontaneously evaporate. The residue was oily in appearance, was acid to taste, dissolved readily in water and gave odour of aldehyde when treated with potassium permanganate.

The quantitative examination included the following, viz.:—Determination of acidity reckoned as lactic acid; determination of total calcium phosphate; determination of total calcium oxide; determination of hygroscopic water.

The free acid was determined by normal soda solution, with and without the removal of the insoluble phosphate. Concordant results were obtained in both cases. The total calcium phosphate was determined by standard solution of uranium nitrate. It was at first considered necessary to separate the calcium phosphate from the other substances present; but, as a result of many experiments, it was seen that very closely agreeing figures could be obtained without separation at all. The total calcium oxide was determined by precipitation as oxalate from acetic acid solution and titration of the well-washed oxalate with normal potassium permanganate. The hygroscopic water was determined by exposing in a desiccator over sulphuric acid for forty-eight hours. In the accompanying table the percentage of calcium lactate is shown. This value was obtained by subtracting from the total calcium oxide the amount in combination as phosphate and calculating the remainder into calcium lactate. The third sample was received wrapped in paper only, and was kept in the desiccator some days before examination.

COLOUR-TEST FOR SAFFRON.—Cæsar and Loretz advocate as a test for saffron that 0.3 Gm., macerated with 300 C.c. of water for several hours, should give a solution, which, when diluted 1:1,000 should give a distinct colour. This test requires a greater tinctorial power than that of the Ph. G.—*Pharm. Cent.*, 40, 611.

A PRESCRIPTION RECORD.*

BY R. J. WESTERMAYR.

I submit a sample page, reduced in size, of my prescription record, that my system may be readily understood in its simplicity. I have used it now for four years and would not do without it; it has served its purpose admirably, and every day attests over again its manifold practical value.

Annual Number.	Date.	Number of Prescription.	Name of Physician.	Nature of Prescription.	Prescriptionist's Initial.	Value.	Total Value to Date.	
7046	Jan. 1	47344	Miles.	Salve.	W.	45	\$2113.80	
47	"	23	Bard.	Mixture.	W.	35		
48	"	24	Lyon.	Eye drops.	W.	25		
49	"	23444	Miles.	Suppos.	R.	50		
50	"	25	Lathrop.	Liniment.	R.	45		
51	"	26	"	Pills.	R.	25		
52	"	27	"	Wash.	R.	50		
53	"	28	"	Ear drops.	W.	25		
54	"	41340	Morrow.	Paint.	W.	20		
55	"	41342	"	Plaster.	W.	25		
56	"	41341	"	Tablet.	W.	50		
57	Jan. 2	29	Martin.	Capsules.	B.	50		
58	"	30	"	Inhalant.	L.	25		4.70
								\$2118.50

On January 1 of every year I begin an annual record of prescriptions, giving each prescription, whether original or refilled, its "annual" number apart from the regular prescription number which it of course bears, as do all prescriptions. These "annual" numbers are put in the first column of my record, as will be seen by referring to the accompanying illustration; the date goes in the second column; the regular prescription number in the third; the name of the physician in the fourth; the nature of the prescription—that is, whether liniment, eye drops, or pills—in the fifth; the initial of the compounder in the sixth; the price in the seventh; and the total daily prescription receipts in the last. Whenever a prescription is compounded, whether for the first or successive time, it is *always* registered in this manner. It takes but a minute, and is of the greatest value.

Among other things, this record shows you at a glance how many prescriptions you have prepared since the first of the year up to date. By comparing this number with the number compounded during the same time the year before, you can tell at once whether your prescription business is falling off or increasing. You can tell how the business of the two years compares in money values. You can tell, if you choose, what the relation is between original and refill prescriptions.

Should a customer want a prescription repeated, but does not remember its number or the date of its compounding, he can generally give at least some idea regarding the price, the doctor's name, the approximate time, and whether liniment, pills, salve, or eye drops. With this aid the chances are that you will locate the prescription by running over the record; if not at the first trial, then almost surely at a second one. I know from my long experience that I lose but very few prescriptions from being unable to locate them.

Then, too, the data as to prescriptionist's identity, the price, etc., etc., are often useful when the price is in dispute or when any one of a number of other things may be in question. This furnishes an absolute record of every detail concerning not only original prescriptions, but every refilled prescription as well.

At first sight the system may look complex, and perhaps it may seem that it consumes considerable time; but upon adoption it

* From the *Bulletin of Pharmacy*.

will be found most simple indeed, and to consume no time worthy of mention.

For this record I use an ordinary single-entry account book, simply making one extra column by drawing the upright line between "number of prescription" and "name of physician."

PRACTICAL NOTES AND FORMULÆ.

Ointment for Gonorrhœa.

Cacao butter, 100; yellow wax, 2 to 6; silver nitrate, 5; balsam of Peru, 2; mix. To be used on a metal sound; four applications are often sufficient to effect a cure.—*Formulary of Bull. Gen. de Therap.*

Steresol and Adhesol.

Steresol is a varnish composed of shellac, 270; benzoin, 10; balsam of tolu, 10; phenol, 100; oil of cinnamon, 6; saccharin, 6; alcohol, 90 per cent., to produce 1,000 fluid parts. It is used as an antiseptic dressing for the skin or the mucous membrane. Adhesol is less viscous, and contains alpha-naphthol in place of phenol. It is composed of copal resin, 35; benzoin, 3; alpha-naphthol, 0.3; balsam of tolu, 3; oil of thyme, 2; ether, 100.—*Formulary of Bull. Gen. de Therap.*

Grafting Wax.

Melt together resin, 3, and beeswax, 1. For use remelt in a glue-pot, the water jacket of which will retain it in a workable consistence for a considerable time, and, at the same time, prevent it from being overheated to a point dangerous to the scions. For hot climates, the proportion of resin should be increased to 4 to 1 of wax.—T. Tidmarsh in *Gard. Chron.* [3], 26, 420.

Remedy for Apple Tree Canker.

A strong solution of cupric sulphate, 1:50, sprayed from a knapsack machine on the affected trees in the autumn will destroy the canker fungus (*Nectria ditissima*) in its conidia and spore stage. The spray should be directed for some time on the affected parts, and should be repeated once or twice during the winter. A warm spray of sulphate of iron, 1:10, would also be of value if applied in the autumn and winter. It would at the same time remove lichens and mosses, which harbour fungi and insects, and injuriously affect the trees.—*Garden*, 56, 440.

Palatable Quinine Mixture for Children.

W. J. Greanelle finds the following mixture readily taken by children:—(1) Quinine hydrochloride, 5-10 gr.; alcohol, 1 fluid drachm. (2) Oil of cinnamon, oil of anise, of each 30-40 minims; magnesia, *q.s.*, water, 1 fl. ounce. Rub down together, let stand for some hours and filter. Mix 1 and 2 and add simple syrup, 3 fl. ounces; carmine or cochineal solution, 5 drops. Dose, one to two drachms.—*Pediat.*, 8, 560.

Florida Water.

Lavender oil, 7.5 Gm.; Lemon oil, 7.5 Gm.; Bergamot oil, 7.5 Gm.; Neroli oil, 3.75 Gm.; Clove oil, 3.75 Gm.; Rose oil, 6 drops; Melissa oil, 1.8 Gm.; are dissolved in alcohol (90 per cent.), 880 Gm.; allowed to stand for some time, then filtered through magnesia after addition of distilled water, 180 Gm.—*Pharm. Post*, 32, 721.

Formalin Mouth Wash.

Formalin (4 per cent.), 25, is dissolved in alcohol (90 per cent.), 500; tincture of benzoin, 100; tincture of myrrh, 25; peppermint oil, 1.5; anise oil, 1; cinnamon oil, 0.5; powdered cochineal, 1, are added, the last being rubbed down with spirit. The mixture, after standing for 1 to 2 days, with frequent shaking, is filtered. For use, one tablespoonful is added to a medium-sized glass of water.—*Pharm. Post*, 32, 721.

NOTES ON QUININE,

WITH A BRIEF HISTORY OF THE BARKS FROM WHICH IT IS DERIVED.*

BY H. A. MARTIN.

The precise period and manner of the discovery of the therapeutic power of cinchona bark are enveloped in mystery. No undoubted proofs have been handed down to show that the aborigines of South America had any acquaintance with the medicinal properties of the bark, as even to-day they do not look upon cinchona bark with a favourable eye, although they adhere tenaciously to their traditional customs.

The modes of discovery of its remedial power are of a very fabulous character. One told by Geoffrey (1855) is that an Indian was cured of an ague by drinking at a pool into which some cinchona trees had fallen; another, related by Condamine (a French explorer), is that the Indians observed that the American lions, when ill with ague, eat the cinchona bark! Lions are not found, however, in the cinchona forests, though the puma has been met 15,000 feet above sea level. A third, mentioned by Humboldt, and considered to be less improbable, is that the Jesuits accidentally discovered the bitterness of the bark, and tried an infusion of it in tertian ague.

Although Peru was discovered in 1513, and submitted to the Spanish yoke by the middle of the century, no mention has been found of the febrifuge bark with which the name of the country is connected earlier than the commencement of the seventeenth century.

Humboldt (1807) declares that at Loxa (founded by the Spaniards in 1546) the natives would rather die than have recourse to what they consider so dangerous a remedy, although it seems probable, nevertheless, that they were aware of its virtues, but would not impart that knowledge to their conquerors, whom they looked upon with dislike and suspicion.

About the year 1638 the wife of the Viceroy of Peru, Luis Gerónimo Fernandez de Cabrera y Bobadilla, fourth Count of Chinchon, having been attacked with fever, the corregidor of Loxa, Don Juan Lopez Canizares, sent a packet of powdered bark to her physician, Juan de Vega, assuring him of its efficacy in the treatment of "tertiana." The remedy was tried, and fully bore out its reputation, and the Countess Ana was cured. Upon her recovery she caused to be collected large quantities of the bark, which she brought to Spain with her, and gave away to those sick of fever upon her husband's estate. It thus came to be called Countess's powder (Pulvo de la Condessa, or Pulvis Comitissæ), and was long known to druggists and in commerce under this name.

The introduction of Peruvian bark into Europe is stated to be about 1640—that is, about the time that Countess Chinchon returned to Spain—but Sebastian Badus gives an extract from a letter of a Spanish physician, D. Joseph Villerobel, from which it appears that it was imported into Spain in 1632, though no trial was made of it until 1639.

Chifflet, physician to the Archduke Leopold of Austria in 1653, says, "Among the wonders of the day many reckon the tree growing in the kingdom of Peru, which the Spaniards call Palo de Calenturas—*i.e.*, *Lignum febrium*. Its virtues reside chiefly in the bark, which is known as 'China Febris,' and which, taken in powder, drives off the febrile symptoms." He further states that during the last few years the bark has been imported into Spain, and from thence sent to the Jesuit Cardinal de Lugo at Rome. From this it acquired the names of Jesuits' bark, Pulvis Patrum, Pulvis Cardinalis de Lago, etc., as these worthy fathers used to distribute it to the poor in Cardinal de Lugo's palace.

The drug began to be known in England about 1655, so says Sir G. Baker, in a paper published in the Medical Transactions of the College of Physicians of London, 1785.

The *Mercurius Politicus*, one of the earliest English newspapers, contains in several of its numbers for 1658 (which are to be found

* Read at a meeting of the Chemists' Assistants' Association, on February 8, 1900 (see *ante*, p. 167).

in the British Museum), a year remarkable for the prevalence in England of an epidemic, intermittent fever advertisements offering for sale "the excellent powder by the name of Jesuits' Powder," brought over by James Thomson, merchant, of Antwerp.

Dr. Robert Talbor, afterwards Sir Robert Talbor, was one who powerfully contributed to the diffusion of the new medicine, but he by no means intimates his method of cure depended upon the use of the bark; no doubt he was wise, as he kept his remedy a secret. His reputation increasing, in 1678 he was appointed physician-in-ordinary to Charles II., and in 1679, the King being ill of tertian fever at Windsor, Dr. Talbor cured him by his secret remedy. He acquired similar favour in France, and Louis XIV., having purchased his secret for 2,000 louis d'or, a large pension, and a title, ordered the publication of his method of cure, which appeared accordingly by Nicholas de Blegny, surgeon to the King. This was immediately translated into English under the title of "The English Remedy, or Talbor's Wonderful Secret for Curing of Agues and Fevers," and was known in France as such.

From that time Peruvian bark seems to have been recognised as the most efficacious remedy for intermittent fevers, although previously to that bitter controversy had taken place as to its value in fevers, one Dr. Colmenero, a Professor of the University of Salamanca, declaring that ninety sudden deaths had been caused by its use in Madrid alone.

It first appeared in the London Pharmacopœia of 1677 under the name of Cortex Peruannus.

In memory of the great service to humanity performed by the Countess of Chinchon, Linnæus in 1742 named the genus which yields Peruvian bark, "cinchona," but, unfortunately, the great botanist was misinformed as to the exact spelling of her name whom he desired to honour, and spelt it "cinchona," omitting the first "h." It was still more unlucky that Linnæus died before the error was pointed out and corrected.

The variety which cured the Countess was Linnæus's *C. officinalis*.

SOURCE.

The British Pharmacopœia gives quinine as the sulphate of an alkaloid obtained from the bark of various species of cinchona and remijia.

I will first deal with cuprea bark. Messrs. Howards and Sons, to whom I am greatly indebted, both for information and the kind loan of specimens exhibited, told me that fifteen years ago cuprea was imported, but when the bark from the East Indies began to come in freely the price dropped, and it no longer pays to import cuprea; furthermore, it contains a very low percentage of quinine, and no manufacturer would think of using it for quinine-making; and the cupreine which it does contain is of no commercial value. Cupreine is, however, of scientific interest, because it is the only chemical compound from which quinine is believed to have been prepared.

Of cinchona barks there are about thirty-six species, but only half furnish commercial barks. These were obtained from South America, their native home, but no idea of cultivating them out of that country was thought of until the forests looked like being exterminated by the reckless system of bark cutting; in various localities many of the trees were entirely destroyed. The idea of cultivating them was introduced by Ruiz in 1792; by Fée, in Strasburg, 1826; by Fritze, in Java, 1837; and by Miquel in 1846, and many other Dutch botanists and chemists. Royle, in 1839, pointed out the suitability of various parts of India, particularly the Neilgherry Hills, and argued indefatigably in favour of the introduction of the tree. It was not until 1852 that an impulse was given to the project of cinchona planting, when in a report addressed to the East India Company, he pointed out that the Government of India were then spending more than £7,000 a year for cinchona bark, in addition to about £25,000 for quinine.

The Dutch were the first to make important attempts at cinchona cultivations, and under the auspices of the Colonial Minister, Pahud

(Governor-General of the Dutch East Indies), a botanist was despatched to Peru to obtain seeds and plants. The mission was successful, but the plants reached Java in a very unsatisfactory condition, and therefore did not approach expectations, as by unforeseen circumstances only 167 were reared out of the 400 specimens brought from South America.

A variety of cinchona was named Pahudianha by Howard for the zeal shown by the Colonial Minister, but, unfortunately, this variety is not of much value.

Mr. Markham, though not a professed botanist, but having a knowledge of the country and people, the languages of both Spanish and Quichua, and possessed of all the zeal, intelligence, and forethought for such an expedition, offered his services to the British Government, which were accepted; and he, with the assistance of four others—Richard Spruce, G. J. Pritchett, John Weir, and Robt. Cross—started from Islay in March, 1860, to procure seeds and plants. (A Mr. Ledger also started very soon after, independently, and to this latter gentleman we are indebted for the most valuable variety of cinchona bark.) After passing through many vicissitudes of difficulty and danger, such as the hostile attitude of the inhabitants, jealousy of governments, insalubrious climate, and want of roads, these four succeeded in bringing or sending plants to their respective destination—viz., India. The first district tried was the Neilgherry Hills, and so rapid was the propagation that in September, 1866, there were more than one and a half millions of cinchona plants on the Neilgherry Hills alone.

Ceylon also took up the cultivation of the bark tree, and great success was obtained—so much so that Ceylon bark was put on the market, but for some reason or other no great amount of it is now to be found on the market.

The plantations of Java, started in 1854 by Hasskarl, succeeded under Junghuhn's management extensively, and have continued to do so ever since. It is rather significant that Java, whose first attempt at cinchona cultivation was nearly a failure, is now at the present time the largest bark-producing district.

The cultivation of cinchona has also been carried out at a great many other places, but not to any considerable extent.

The bark used by manufacturers for the preparation of quinine is the *Cinchona calisaya* var. *Ledgeriana*, which contains more crystallisable quinine than any other.

Mr. Markham, in his valuable history on Cinchona, says:—"This variety was named after a Mr. Ledger, who collected the seeds of this valuable variety from South America, and who thereby enriched the value of both the Indian and East India plantations, but, strange to say, the financial expenditure entailed upon procuring these seeds far exceeded the sum obtained by their sale, and consequently he lost heavily. I twice endeavoured to obtain him a suitable recompense from the Government of India, but in both cases I was refused. It is unnecessary that I should give further expression to the indignation I feel at the injustice with which *those* (he referred to his other assistants as well) have been treated who have done an inestimable service to mankind." "If," he goes on to say, "the people of England, and still more the people of India, are contented that this should be the requital for such service, there is nothing more to be said."

In addition to this Ledger's calisaya from Java, there is some calisaya occasionally comes into the market from South America, whilst *Ledgeriana officinalis* and *succirubra* are still imported from Ceylon and India, though in very much smaller quantities than was the case a few years ago.

The Ledgerian calisaya variety yields from 9 to 10.5 per cent. quinine, with 10½ and 11½ per cent. of total alkaloids.

The official cinchona *succirubra* yields about 5 to 6 per cent. total alkaloids, half of that being quinine; it is however the best bark for yielding the greatest amount of total alkaloids—that is quinine, quinidine, cinchonine, and cinchonidine.

A report of the Indian Government, 1892-3, is very interesting. It states that nearly all of the existing trees are of the pure quinine-

yielding variety—viz., Ledger's calisaya, which shows a vast difference to the time when first introduced, as at that time succirubra was cultivated, not for the sake of its quinine, but to provide a cheap febrifuge for the people. The report also stated that when all the red bark trees were used up only Ledger variety would be cultivated. The produce of the factories in Bengal and Madras for the year was 6,980lb. of febrifuge and 10,175lb. quinine sulphate. The quinine produced, it goes on to say, is now sold to public institutions and Government offices at one rupee per oz., whilst the febrifuge is sold at ten annas per oz.

Eight hundred and thirty-five thousand doses of quinine were put up during the year, each containing five grains, each dose bearing simple instructions in one of the vernacular languages. They are put up in the gaol department, and issued to local postmasters, who for a small commission retail them to the public at one pice (one farthing) per dose.

The harvest of bark was 423,000lb. during 1892-93.

The effect of cultivation upon the cinchona alkaloids is very interesting, and at the same time very extraordinary, sometimes doubling and trebling the quantity; they are increased by the processes of mossaing, coppicing, or shaving.

I will just touch upon them briefly.

MOSSING.—This process was introduced by Mr. McIvor in 1863, and consists of cutting strips of the bark from the tree (eight years old) alternately—and laying in the open places thus caused damp moss—binding the same to the tree by means of some fibre. Not only does this increase the amount of alkaloids, but also increases the quantity of bark also. The object is to exclude light and air, which seems to favour the growth. It is repeated in from six to twenty months and goes on until the tree has reached its maximum yield, which is in about eight to twelve years' time.

COPPICING.—This consists of cutting down trees either close to the ground, or within a short distance of it, and of allowing one or more of the crop of shoots which rises from the stumps to grow, they in their turn being cut down together or one by one. This was introduced in 1866, but is not so favourable as the mossaing process.

SHAVING.—This process, known as Neven's, has been carried out in Ceylon, and is done by spokeshaves, simply shaving the outer bark away only.

First shaving yielded equal to 1.96 per cent. quin. sulph.

First renewal „ „ „ 5.76 „ „ „

Second renewal „ „ „ 7.05 „ „ „

There is more cinchonidine, however, increased with the quinine in this instance.

DISCOVERY OF QUININE AND OTHER ALKALOIDS.

It was not until the beginning of the present century (1810) that Gomez, of Lisbon, first succeeded in obtaining active principles of cinchona. He treated an alcoholic extract of the bark with water, added caustic potash, and crystallised the precipitate from alcohol. The basic properties of the substance thus obtained, which he named *Cinchonino*, were observed in the laboratory of Phénard by Houton Labillardiere, and communicated to Pelletier and Caventou. Shortly before that time Sertürner had asserted the existence of organic alkalis, and the French chemists, guided by that brilliant discovery, were enabled to show that the cinchonino of Gomez belonged to the same class of substances. Pelletier and Caventou, however, speedily pointed out that it consisted of two distinct alkaloids, one of which they named *Quinine* and the other *Cinchonine*. These worthy chemists in 1827 were awarded by the Institut de France the Montyon prize of 10,000 francs for their discovery of 1820.

Quinidine was discovered by Henry and Delondre in 1833 and *Cinchonidine* in 1847 by Winckler; whilst *Quinamine* was not discovered until 1872, by Hesse.

In 1802 Sequin concluded that as the active principle of cinchona was precipitated by infusion of nutgalls, it must be gelatin, and therefore proposed the use of, and employed, clarified glue as a febrifuge in intermittents!

(To be continued.)

BRITISH PHARMACOPEIA, 1898. INDIAN AND COLONIAL ADDENDUM.*

INDIAN SECTION.

13. **EMBELIA.**—Both *E. ribes* and *E. robusta* occur in commerce mixed, and they both contain the active principle (embelic acid) according to the investigations of Warden. The suggestion, therefore, to use both in making the preparations of the drug is good. We recommend the simple powder—pulvis embelice—in doses of 1 to 4 drachms as a valuable anthelmintic against tapeworm. We are preparing a liquid extract, but our report on its efficacy must be postponed.

14. **EXACUM.**—We agree that *E. tetragonum* (N.W. and C. India), *E. bicolor* (Nilgiris, S. India), *Andrographis* (plains all over India), *E. pedunculatum* (plains all over India up to 3,000 feet), and *Swertia corymbosa* (Nilgiris, S. India), and *Swertia affinis* (hills in Vizagapatam), may be used interchangeably, according to locality and convenience. Except *Andrographis*, they all belong to the Gentian family.

(Note.—We sent for a supply of *Swertia affinis* (Clarke), syn. *Ophelia elegans* (Wight), from the Vizagapatam district (Jeypore Zemindary), and we obtained a specimen which is practically indistinguishable from the official *Swertia chiretta*. A sample will be sent to you next mail if possible.)

[To provide for the suggested interchangeableness has been found to be difficult. Moreover, the Pharmacopœia Committee has been advised on good authority that simple bitters, indigenous to India, are sufficiently represented by the official *chiretta* and the *andrographis* of the Draft Addendum. Will the Madras reporters please further advise?]

15. **GOSSYPII RADICIS CORTEX** is official in the United States Pharmacopœia, and has a great reputation in America as an emmenagogue. Dymock alludes to it as “an undoubted emmenagogue.” Strength, 2 ounces of root bark to 1 pint of boiling water, the whole boiled down to one-half. We have made inquiries, but the fresh active plant will not be available for some months. We shall then get preparations made and submit results in a subsequent communication.

[The plant is said to be common in India and Ceylon. Bidie says “Ergot often deteriorates in the tropics.”]

16. **JASMINUM.**—The fresh flowers are undoubtedly lactifuge when applied locally in appropriate cases. We cannot at present mention any preparations as advisable, but recommend the official recognition of the fresh flowers. (Note.—A description of the flowers will follow next mail.) The flowers are available in March to May. We shall prepare a juice, and perhaps other compounds, and obtain further information regarding the plant.

17. **KALADANA.**—All medical men of standing here have experience of this drug. It is very commonly used by natives as a purge. We agree that the best preparation is the compound powder, prepared in a similar way to that of jalap, with ginger and cream of tartar, as in the Indian Pharmacopœia. The proportions to be the same. The resin, “Pharbitisin,” and the tincture are also very active, and may be officially recognised; the resin in doses of 5 to 8 grains, and the tincture $\frac{1}{2}$ to 1 fluid drachm. The tincture should have the same strength, namely, 4 ozs. of powdered seeds to 1 pint of alcohol (70 per cent.). The extract of the Indian Pharmacopœia may, as Dr. Bidie says, degenerate, as it is really a mixture of an alcoholic and an aqueous extract, and may therefore be excluded, considering the efficacy of the other preparations.

[The official recognition of kaladana (*Ipomœa hederacea*) was strongly recommended by Dr. Bidie.]

18. **MUDAR.**—The official name, for the reasons stated, should be “*Calotropis*.” It has lately been under investigation, but the results are not yet officially announced. The drug is an old and

* Concluded from page 189. The notes within brackets are by the Editor of the Indian and Colonial Addendum, Dr. John Attfield.

well-established one in reputation, and its tonic and emetic properties are well known. The powdered root-bark is an alterative tonic in 3 to 10 grain doses, and emetic in 30 to 60 grain. A tincture was investigated by the Indian Drugs Committee, and was found to possess the same properties as the powder. Its strength is 2 ounces to the pint, and its dose $\frac{1}{2}$ to 1 fluid drachm.

[Bidie, Van Dort, and other authorities in India and Ceylon are in favour of the official recognition of *Calotropis*.]

19. MYLABRIS has been in use in Indian Government Medical Stores in making preparations similar to those of cantharides, whose place it practically takes in the manufacture of emplastrum at all events, the most universally used of cantharides preparations in this country. The *Mylabris cichorli* is the beetle in most use, and we recommend its being made the official one, and not the *Mylabris phalerata*. The name mylabris should of course be applied to all preparations made from the Indian beetle, the word cantharides being restricted to compounds actually made therewith. On account of the similarity between the two beetles, similar preparations of the Indian one may be officially recognised with similar strength.

[South African authorities desire the official recognition of *Mylabris bifasciata*.]

20. MYROBALANUM.—The fruit is extremely common: besides being aperient in action, it possesses an astringent principle, and we think some doubt would arise regarding the exact effect of a decoction administered internally. Results might differ. Natives use the drug as a purgative, but in combination with other purgatives. The two ointments are the preparations to which we attach most importance, one with opium, the other without, as in the Indian Pharmacopœia.

[In India and Ceylon this drug appears to possess close pharmacological resemblance to rhubarb, and to be both as useful and as indefinite in regard to active principle.]

21. OLEUM AJOWAN.—We agree that this volatile oil has a special value of its own. The drug (chiefly the fruit) is in universal use throughout South India as a carminative in all bowel complaints, such as diarrhoea, colic, cholera, etc. It has a great reputation for producing a feeling of warmth and exhilaration and relieving the sinking and fainting feeling which accompanies bowel disorders.

[All authorities in India and Ceylon appear to be agreed regarding the usefulness of this oil.]

22. OLEUM GRAMINIS CITRATI.—As a stimulant carminative this oil may be officially recognised for its own merits.

[Bidie and Van Dort state that it is largely produced and used for medicinal purposes in Ceylon. Indian authorities appear to be agreed as to its value.]

23. SAMADERA is widely distributed on the West Coast, Malabar, and Ceylon, but it probably is not sufficiently readily attainable in the various bazaars in the Presidency to warrant its official recognition for the present. In this connection please see note at end on *Azadirachta* (the Neem Tree).

[Van Dort states that the root-bark is used in Ceylon. *Samadera* is not strongly recommended by any of the authorities in India and Ceylon.]

24. SAPPAN contains a fair amount of tannic and gallic acids, and it has been used in Government depôts for some years instead of logwood. It is very widely distributed, and we think a decoction similarly made to that of *hæmatoxyli lignum* might be officially recognised.

[Van Dort speaks favourably of sappan, and states that it is largely exported from Ceylon.]

25. SWERTIA—*Vide supra*, No. 14, *Exacum*. ["Not represented in our Ceylon flora."—Van Dort.]

26. THUS INDICUM.—We have no special knowledge of this substance. The emplastrum *piciis* is little used in this country. Later we propose experimenting with a local substance "gondah-

birozah," which is said to yield a useful equivalent of Burgundy pitch. The Bombay Medical Stores manufacture it, and we shall refer to them subsequently.

[The pharmacy of this so-called Indian frankincense, "Gunda Barosa," according to Bidie, would seem at present to be insufficiently definite to warrant the official recognition of it as an Indian equivalent of *Thus americanum*.]

27. TINOSPORA.—A very old-established drug. The root and stem should be collected in the hot season when the bitter principle is most abundant. The tincture should be made in the same way as that of *calumba*, strength 4 ounces to the pint. The strength of the infusion should be 1 in 10. The liquor *concentratus* might be officially recognised if the results of our present experiments will stand the tests detailed in the preface to the British Pharmacopœia of 1893, p. xvii.

[Van Dort states that the plant is very common in the central and southern provinces of Ceylon, and that as a drug it is very popular in fever and dyspepsia.]

28. TODDALIA.—Also a well-known drug with a considerable reputation as an aromatic tonic, comparable to *cusparia*. The tincture is made in the ordinary way—strength, $2\frac{1}{2}$ ounces to the pint; infusion, 1 in 10 of boiling water, and straining. With regard to the liquor *concentratus*, the same remark applies as in No. 27. We are conducting experiments, some of the preparations already being under observation.

[Van Dort states that in Ceylon *toddalia* is very abundant, and is very commonly used as a bitter tonic.]

29.—TYLOPHORA is a very abundant plant, and of well-established reputation as the equivalent of *ipecacuanha*. It is emetic, diaphoretic, and anti-dysenteric. Kirkpatrick's evidence on this point is pretty well conclusive. With regard to the preparations, we find we must for the present confine ourselves to recommending that the powder [of the leaf, *Ed.*] alone should be officially recognised. Later, we hope to submit results of experiments showing whether any liquid preparation has the active principle of the drug.

[All medical authorities in India and Ceylon agree that this drug is worthy of official recognition.]

30. VALERIANA INDICA.—As far as we can make sure, this Indian valerian possesses the same strength in volatile oil and valerianic acid as the *Valeriana officinalis* of the British Pharmacopœia. An ammoniated tincture of the strength of 4 ounces to the pint, and prepared like the official tincture, may be officially recognised.

[All Indian authorities appear to be agreed respecting the desirability of official recognition of this drug. Perhaps the Madras Committee will be good enough to forward a botanical and general description.]

Appendix.

The Madras Committee considers that in any list of Indian drugs which it is in contemplation to recognise officially, the following should find a place:—*Azadirachta indica* (the common neem tree), *Alstonia scholaris*, and *Gynocarpia odorata*. These are indeed of much greater repute than many of those already detailed. In what way they were originally omitted from our 1894 report I have now forgotten. That report made no pretence of finality, and the committee anticipated further references and investigations before it could be looked upon as a settled list of representative well-known native Indian drugs.

(a) *Azadirachta indica* is of considerable repute among the natives of South India, who utilise every part of the tree for medicinal purposes. As being of greatest value it is the bark of the wood we recommend to be official. It is a bitter tonic and has excellent properties similar to those of quassia. Natives indeed make neem cups, like we make quassia cups, in which they pour water for producing a stomachic drink. We shall experiment as before with a liquor *concentratus*. The tincture and the infusion

should be official, of the same strength and mode of preparation as quassia.

(b) *Alstonia scholaris*.—A well-known astringent tonic of much value. A tincture and infusion should be official:—Tincture, 2½ ounces to the pint, and infusion, ½ ounce to 10 fluid ounces. Drachm and ounce doses respectively. Same remark applies with regard to the liquor concentratus as before.

(c) *Gynocardia odorata*.—The seeds of this yield chaulmoogra oil of very well-known value in leprosy. It is administered both internally and externally. The evidence regarding its utility is considerable. Most medical men who are engaged in treating lepers place considerable trust in this oil. It is alterative also in other chronic skin diseases and in tubercular eruptions. The ointment might be official (Indian Pharmacopœia), its composition being, the oil 1 part, hard paraffin 4 parts, soft paraffin 5 parts. The oil itself might be made official, not the seeds. "Oleum Gynocardiaë." The oil is given in doses of 4 minims, increased gradually to from ½ to 1 fluid drachm.

RESPECTING ACACIE GUMMI.

1A.—*Anogeissus latifolia* (Wall) is a gum-yielding tree of considerable repute. The gum is said to be double the strength of gum acacia in viscosity. It would make an admirable equivalent for the official gum acacia in making mucilages. The tree occurs throughout India except north of the Ganges. The gum may be obtained in any quantity, nearly free from admixture with other gums and from adulteration. It occurs as clear white or straw-coloured elongated tears, adhering into masses sometimes honey-coloured, and is gathered from outside of the bark of the larger branches of the trunk. It has a glassy fracture, and is quite transparent internally and free from cracks. With water it forms a nearly colourless mucilage, quite colourless in the case of the finer qualities of the gum. It possesses a faint characteristic odour. We recommend the official recognition of this gum as a strong equivalent of gum acacia. Preparation, mucilago gummi indici, 2 ozs. of gum, in small pieces; rapidly rinse with a little distilled water; dissolve in 6 fluid ozs. of distilled water in a closed vessel; strain.

[In the Addendum Report, page 8, the question was raised as to the sufficiency of this one gum alone for official galenical use in India. Bidie says that this is the best of all the Indian gums for pharmaceutical purposes. It is similarly commended in Pharmacographia Indica. Unlike other Indian gums, it appears to be collected and sold in the unmixed condition.]

TESTING TOLU BALSAM.—Gehe and Co. point out that the requirement of the German Pharmacopœia, that this balsam should be hard, gives rise to a great deal of adulteration with colophony. They find also that, as a rule, about 25 per cent. of the balsam is soluble in carbon disulphide, and though others have reported to have found as much as 80 per cent. soluble, they doubt if these samples were pure. They advocate the inclusion of the following characters in the forthcoming New German Pharmacopœia: "The resinous balsam of *Toluifera balsamum* is a brownish yellow or brownish red viscous or hard mass, transparent in thin layers, with an aromatic odour, and pleasant, sharp, somewhat acrid taste. It is soluble in chloroform and in rectified spirit; also in caustic potash solution, diluted with four volumes of water. Carbon disulphide dissolves not more than 30 per cent. on heating for half-an-hour at 30-35° C. The residue, after evaporation of the CS₂, should give a blood-red-colour with sulphuric acid."—*Pharm. Central.*, 40,269. [The value of carbon disulphide as a solvent for cinnamic acid in testing this balsam was pointed out by J. O. Braithwaite in 1895, and has been confirmed by Spilsbury and Joyce. See *P. J.* [4], 10, 93. See *P. J.*, [4], 1, 145, and [4], 307.]

FACTS AND FANCIES.

BY AN ORDINARY PHARMACIST.

A Healthy Expression of Opinion.

The letter by Mr. John Taylor, of Bolton, in last week's Journal has redirected my attention to the superlatively excellent paper by that healthy-minded pharmacist, which appeared in the issue of the previous week. There was a freshness about that production, which should appeal particularly to those of us who feel bored to death by the continual repetition of the stale arguments which find so much favour with the shrieking, hysterical individuals who seem to imagine that the inscription of one's name on the Register of Chemists and Druggists ought to assure the possession of a kind of divine right. Granted that the registered chemist has had to work hard to attain his peculiar position, and that in so doing he has been compelled to expend much energy, time, and money; but what has he done more than many professional men who have not half the chance of self-protection he has, and have to wait a much longer time than he before they can expect to secure any adequate return for the much greater outlay upon their education and professional training? As a tradesman the pharmacist is better protected at the present moment than anyone else who depends to any extent upon buying and selling for the means of livelihood; on the professional side he is quite as well protected as medical men and dentists, and if he can only secure the absolute restriction of his statutory titles to duly qualified individuals he will have improved upon their position. To all who are despondent and also inclined to reflect despairingly upon the future of pharmacy I would commend a careful and sympathetic perusal of Mr. Taylor's decidedly healthy expression of opinion. He is no idealist; but, on the other hand, he is not afflicted with the hopeless pessimism which troubles so many in our ranks to-day, who are less disposed to help themselves than to wait upon a special providence in the shape of an unwilling Government.

The Government Position.

For that, as it happens, is the position at the present moment. To those who are capable of reading with understanding—to say nothing of ability to read between the lines—the first and second paragraphs in last week's "Political Gossip" should sound the knell of the hope, based on desire, which has urged that nothing but a direct appeal to an all-benevolent Government is required to insure the speedy putting up of the shutters at every establishment where the business of a chemist and druggist is carried on by a company of unqualified persons. We now learn, in the first place, that Mr. Ritchie, the Minister in charge of the Companies Bill, is inclined to resent the inclusion in that measure of any clauses dealing with pharmacy, medicine, dentistry, or midwifery. He thinks, and I agree with him in that respect, that questions concerning professional qualification should be dealt with in measures specially promoted to regulate professional practice. Inasmuch, however, as the pharmacy and medical clauses have found place in the Companies Bill and, to some limited extent, have begun to seem at home there, the President of the Board of Trade is not unwilling to proceed with them so long as he is not unduly worried with regard to the matters to which they refer. That is to say, Mr. Ritchie, while objecting, on principle, to the regulation of pharmacy, medicine, etc., by means of a Bill originally intended only to safeguard the interests of shareholders in limited companies, is prepared to submit to the retention of the two clauses which particularly interest pharmacists on condition that he is not pressed to amend them in any way. But he declines to entertain the idea of suppressing company trading in pharmacy, and insists that there can be no more menace to the safety of the community in a company pharmacy, if regulated as proposed, than in the branch establishment of a registered chemist who runs a dozen shops.

The Evil of the Branch Shop.

In so doing, it seems to me—and must seem to many other pharmacists—Mr. Ritchie has struck at the root of most of the evil which has come upon pharmacy in these latter days. The so-called “widow’s clause” has been blamed for much; but it has not been responsible for all the difficulties that have interposed themselves in the path of pharmaceutical progress. The branch shop is undoubtedly the curse of the drug trade and, even if in charge of a duly registered manager or assistant, it is then only less mischievous than under other circumstances. Someone has recently pointed out that a professional qualification cannot be divided—that is to say, the holder of the qualification cannot, at one and the same time, be exercising a proper supervision over the conduct of affairs at more than one place of business. How much greater, then, must be the difficulty of supervising the business carried on at six or a dozen different establishments? So far as strictly professional duties are concerned the thing is a physical impossibility, whatever may be done in connection with purely trading concerns. In fact, it could not be regarded as an unreasonable thing if Parliament were to insist that no professional qualification should be permitted to cover the exercise of the functions of the profession in question unless the actual holder of the qualification were present and controlling the operations carried on. Pharmacists, therefore, who prefer to dissipate their energy or diffuse their qualification over more than one place of business need not be greatly surprised if, after regulating company pharmacy, the Government should next turn its attention to the stricter regulation of what I and other pharmacists are accustomed to regard as the only legitimate pharmacy. The idea will doubtless not commend itself to some; but the risk that it may be realised before long is not small, and the obvious moral is that there must be a closing together of our ranks to repel the present attack, otherwise we may shortly have to fight much nearer home, on ground not of our own choosing.

Awaiting the Word of Command.

As a matter of fact, I have a strong conviction that the pharmacists of Great Britain are spoiling for a fight. They have talked and listened about an unchanged and apparently unchangeable subject until they are tired of talking and listening. Signs of the prevailing restlessness may be perceived in the recent decision of the Executive Committee of the Federation of Local Pharmaceutical Associations—by the way, why not call it the Chemists’ Federation?—to issue a statement of reasons why the pharmacy clause in the Companies Bill should be opposed. I think it is rather unfortunate that the Federation officials could not see their way to recommend the local associations to plump for such an amendment of the clause as would prohibit the use of chemists’ titles by companies and also restrict to duly qualified individuals the compounding and dispensing—if not the sale—of poisons, but the too painfully manifest lack of agreement on the subject which prevails in pharmaceutical circles generally cannot fail to be reflected in all our representative bodies. I make bold, however, to advise everyone who finds it in his power to act on the initiative of the Federation, to have no scruples about the matter, but to bring what pressure he can to bear upon his representative in Parliament, in the hope that the latter may be persuaded to do what is right and fair for pharmacy and leave us to work out our own salvation—as we must in any case set about doing in the immediate future. It will be preferable to reform our own affairs rather than have them reformed compulsorily on cut and dried lines laid down by unsympathetic souls who know naught of the progress of pharmacy and care less. But if we desire to cry “Hands off!” we must be prepared to follow up that defiance with vigorous action, and none will rejoice more than I to see such action taken. Meanwhile it is well to note that Mr. Balfour has stated that further consideration of the Companies Bill may be expected before Easter, and that we are already in Lent!

LETTERS TO THE EDITOR.

The Federation and the Council Election.

The comments of “An Ordinary Pharmacist” and Mr. Hyslop upon my remarks at Stoke appear to require a disclaimer from me of any intention to propose that this Federation should take upon itself the work of a caucus. For general information I may mention that at the meeting of the Executive Committee held last week no action in any way connected with the election of members of Council was proposed or even discussed. If the matter were of sufficient general interest I could explain what I had in mind, as a possible course to suggest in certain circumstances, but I was careful to state that what I did say was personal and not on behalf of the Federation. Every member of the Executive Committee realises that his position requires that he should not endeavour to carry out his own personal views or the views of a section, but that the business of the Federation should be conducted in accordance with the wishes of the Associations which constitute the organisation.

Liverpool, February 27, 1900.

JOHN SMITH,

Chairman of the Federation.

The Society’s Examinations.

I am following with interest the correspondence relating to the examinations, and hope the discussion will continue for some time. I have been much struck with Mr. J. Rutherford Hill’s paper in last week’s Journal on the “Statutory Functions of the Pharmacist,” especially with the fact that “the Society was the first to provide a laboratory course of instruction in practical chemistry,” and I heartily endorse his statement “that we ought to develop this side of our Charter rights and, by a suitable examination, grant a certificate that would be recognised as fitting the holder thereof to fill any State appointment as a trained chemist or public analyst.” This naturally raises the question, “What is the object of our examinations?” Is it simply to qualify a body of men to dispense and retail scheduled poisons, or is it to produce men thoroughly proficient in chemistry, physics, and botany, both theoretical and practical, to say nothing of the special subjects of materia medica and pharmacy? If the former, then the Minor is amply sufficient; if the latter, then I am afraid nothing short of a two or three years’ curriculum will be sufficient; but it seems to me absurd to compel every chemist’s assistant to become a scientific pharmacist. There would therefore appear to be room for two grades—those who wish to be simply trading pharmacists and those who wish to become scientific pharmacists. At present the candidate who passes the Major gets little satisfaction for his trouble. I can well remember when I had passed my Major examination, after six months’ hard study, my father’s opinion was that he did not think it worth the trouble, worry, and expense, seeing that it neither fitted me for an analyst’s post, nor conferred any degree or other advantage beyond the purely educational, and that is the reason why so few go forward to it. I am of opinion that the Society should examine for and grant the legal or qualifying certificate, but that it should be necessary for those who wish to take a higher qualification to produce evidence that they have studied for three years at some university or college, of which time part can, of course, have been employed in preparing for the qualifying examination; also that a degree in pharmacy be granted by the universities, equivalent to B.Sc., fitting the holder to undertake analysis of food and drugs, or to act as a skilled chemist in the preparation of the finer chemicals. Now that “commercial education” is being taken up by the universities, it is surely time that pharmacists, through their Society, affiliated themselves with the universities unless they are content to see all the finer work pass entirely out of their hands.

February 21, 1900.

“BETTER LATE THAN NEVER.” (22/51)

Wanted, A Chemists' Club.

In support of Mr. C. E. Pickering's letter in last week's issue, I wish to express hearty approval of the idea of a Chemists' Club. Why cannot we, as chemists, unite and make this matter a success? We are, I believe, in most matters pertaining to aggressive lines very much behind. From a trade standpoint we are not to be compared with our neighbour the energetic, enterprising draper or grocer—or, from a *professional* point, we make no social strides like the lawyer or doctor. In fact, we are all an enigma in commerce and society. By all means let us have a Chemists' Club worthy of the name, and decidedly let us avoid any trashy or quack advertisements being plastered on the walls or even allow any cases of so-called pharmaceutical products taking up any valuable space. Their presence only reminds us of the "shop." I strongly advocate a good-class club on thoroughly good lines. But when country chemists come to town, don't you "Cockneys" look them up and down as if they were some curiosities; yea, botanical monstrosities. Take them by the hand, and to them show all good things they want to see and know. After all, we are but brother "pills," heir to all diseases of flesh and ills.

Newport (Mon.), February 26, 1900.

BENSON HARRIES.

Chemists and the Companies Bill.

I wrote a four-page letter last week to Major Rasch, the M.P. for this division, asking him to oppose the second clause in the Companies Bill now before Parliament, and the enclosed brief reply came to hand this morning.

Grays, Essex, February 27, 1900.

A. DYSON.

[ENCLOSURE.]

"House of Commons,

"February 26, 1900.

"MY DEAR SIR,—I have yours to hand; also from Mr. Guy. I fancy the clause may be strongly opposed.

"F. C. RASCH."

Suggested Standards for Drugs.

I have read with great interest Mr. Moor's able paper, and also your paragraph on the above subject in this week's Journal. In common with my neighbour chemists I have recently received a visit from some official of the Camberwell Vestry, who informed me that the B.P. is the legal standard, and, therefore, I should be liable to prosecution if I supplied him with any article that did not comply with the B.P. requirements. He particularly mentioned camphorated oil and pure magnesia. Now, I contend that unless B.P. preparations are asked for, the retailer is at liberty to use his own judgment in what he sells; it is only right and necessary that the B.P. should be regarded as a standard for dispensing, in order to promote uniformity and, thereby, avoid confusion, which doubtless is the intention of the Medical Council. The weights and measures have been legalised by Act of Parliament, therefore the same rule should apply to the B.P. It is quite time the Pharmaceutical Council took the matter in hand, and I would suggest circularising the different vestries so as to put an end to ignorant officials' intimidation and prosecutions, which cause a great deal of vexation and annoyance, in addition to the expense to the parties concerned. Moreover, a representation coming from a public body would be considered, whereas individual protests are simply treated with contempt.

East Dulwich, S.E., February 26, 1900.

F. W. SANDY.

Strychnine Hydrochloride and Potassium Arsenate.

Referring to my paper on "Strychnine Hydrochloride and Potassium Arsenate," at page 184 of the Journal, permit me to make a slight addition and correction which, owing to the exigencies of a special issue, you did not receive in time for last week. After "crystallisation" in line 13, insert "3.805 Gm. of powdered crystals, heated

for an hour to near 300° C., cooled in a desiccator and weighed, had lost 0.399 Gm., equal to 10.5 per cent., showing reduction to metarsenate $KAsO_3$, which requires a difference of 10 per cent.; and this confirms Mr. Lothian's result." Under characters and tests "1 per cent. when heated to 300° F." should be "0.1 per cent."

Edinburgh, February 26, 1900.

J. RUTHERFORD HILL.

Spiritus Ammoniae Aromaticus.

It has apparently escaped the attention of Mr. White and others who were present at the Evening Meeting on February 13, that the strength of the test solution of barium chloride now official differs from that of the '85 B.P. in being slightly stronger, as it contains *one* part by weight in ten parts by volume, instead of *one* part and ten parts by volume of water as formerly. (B.P., 1885, p. 482.) Therefore a slight increase has been made, not only in the quantity but also in the strength of the solution.

Newcastle-on-Tyne, February 23, 1900.

F. R. DUDDERIDGE.

Re "Many Mickles."

Let Mr. C. Edward Sage take Solomon's advice, and "with all his getting, get understanding," to know a proverb and the interpretation, or the easier advice to "drink water from his own cistern," for the Scots' well is evidently too strong for his constitution. Using an unknown tongue is wandering in a dark wood, and he has fallen, not among thieves, but along with a goodly company of his fellow countrymen, and it is only we—Scots who cannot see a joke—that see the joke in "Many mickles make a muckle." How he interprets mickle, or how it is a trite saying I know not. This I do know, that mickle means not little, but much or big, and muckle is synonymous with it; hence "many mickles" only make a "muck," not a muckle. It is a ridiculous and nonsensical saying which was made in England for the use of Englishmen, and, like the use of goff for golf, is given the go-by in Scotland with the laugh of derision. Truly if a little knowledge is dangerous, a little ignorance proves a veritable fly in the ointment, but he teaches best who himself is willing to be taught, and I hope Mr. C. Edward Sage will take it not amiss to be told how to do better and speak sense. "Giff-gaff maks guid friens," which being interpreted means that the interchange of gifts cementeth friendship.

Edinburgh, February 24, 1900.

"SCOTS WHA HAE" (22/4).

* * * Mr. Sage will doubtless accept the above reproof in a spirit of due humility—realising forcibly, as he now must, the danger of meddling with unknown tongues, and the enormity of quoting uncouth dialects.—[Ed., P.J.]

Uragoga Ipecacuanha.

Inquiries having been addressed to me concerning the plant which is indicated by the above name in the MS. of the new German Pharmacopœia, it would seem that there is doubt as to the plant intended, whether Brazilian or Carthagena or some other ipecacuanha. It may be useful, therefore, to explain that it is only another name for *Cephaelis ipecacuanha*, Rich., or *Psychotria ipecacuanha*, Stokes. It affords an instance of the difficulties that arise when a definite system of nomenclature is not universally adopted. It has been agreed by most botanists that the priority of names should date from the year of publication of the first edition of the 'Species Plantarum' of Linnæus, *i.e.*, 1753, as being by far the most convenient date. A few botanists, however, prefer the earlier date of the first edition of the 'Genera Plantarum' of Linnæus, *i.e.*, 1737. The name Uragoga was apparently founded as a generic name by Linnæus on the ipecacuanha of Marggraf. In 1759 Linnæus described the genus *Psychotria*, and this being the earliest date after 1753, ipecacuanha is now placed in that genus, in the 'Kew Index,' in the British Pharmacopœia, and is used by most botanists, the name being earlier than *Cephaelis*, which was given by Stokes in 1788. But Professor Baillon, of Paris, preferred to go back to an earlier date—*viz.*, that of the 'Genera Plantarum' of Linnæus in 1737, and revived the genus *Uragoga*, naming the plant *Uragoga ipecacuanha*.

But it may be hoped, that although this name appears in the MS. of the German Pharmacopœia that it will not be allowed to appear in the final proof. Uniformity and the endeavour to lessen difficulties was the cardinal principal of Linnaeus' work, and it is contrary to the teaching of the great botanist to sacrifice clearness to what may be regarded as pedantry.

London, February 26, 1900.

E. M. HOLMES.

ANSWERS TO QUERIES.

Special Notice.—Scientific, technical, legal, and general information required by readers of the *Pharmaceutical Journal* will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured. Not more than six plants should be sent for recognition at one time.

MAPONITE (W. B.—38/31).—We are unable to inform you what is the composition of the substance.

CACAO BUTTER SUPPOSITORIES (C. F. J.—39/22).—You should be able to procure them from any firm of wholesale druggists.

GUIDE TO THE PRELIMINARY EXAMINATION (C. B. M.—39/24).—The book you mention is published at 42, Cannon Street, E.C.

ADULTERANT OF HYDRASTIS (S. J. L.—39/15).—It is the rhizome of *Asarum canadense*, L. (N.O. Aristolochiaceæ), Canada snake root.

PREPARATION OF ARSENIC (A. S.—39/12).—If the preparation contains arsenic it must be dealt with in accordance with Part 1 of the Poisons Schedule.

ELECTRIC BATHS (F. H. R.—39/18).—We are not acquainted with any, but you might get what you require at the Camden Turkish Baths, 11a, Kentish Town Road, N.W.

GLYCERINUM ACIDI BORICI (S. J. L.—39/16).—The combination of the boric acid and glycerin is not completed until the water is removed by evaporation to the extent described in the monograph.

ASSAY OF TINCTURE OF OPIUM (S. J. L.—39/14).—It would certainly appear from your results that the allowance for solids was too large. Why not write a note on the subject suitable for publication in our columns?

PRESCRIPTION DIFFICULTY (B. G. K. C.—37/25).—The prescription you send is a bad one. The lime soap is not soluble or miscible with the water subsequently added, and always separates in lumps, whatever order of mixing is adopted.

MECHANICAL SHAKER (S. J. L.—39/17).—It must be a question for yourself to decide whether you need one or not. The instrument to which you refer was made by Messrs. Baird and Tatlock, London, but you can obtain a similar article from any dealers in chemical apparatus.

INACCURATE SCALES (J. T.—39/21).—You are liable to a fine if you have in your possession any unjust weights, measures, scales, etc., and we should advise you to send the inaccurate scales to be adjusted and restamped. It is a good plan to have all scales re-adjusted every year.

ELIXIR SENECIO (J. P. S.—39/20).—A fluid extract of senecio has been used in medicine, and there is a homœopathic tincture, but we cannot find any published formula for an elixir. Have you

applied to Messrs. Parke, Davis and Co., 21, North Audley Street, London, W.?

SOLUTION OF LACTIC ACID (W. E. M.—38/23).—We think the prescriber intended a 5 per cent. of pure lactic acid—not the Acidum Lacticum of the Pharmacopœia. The density of such a solution would differ only slightly from that of water, so that no serious variation would result from making the percentage by weight or measure. The ambiguity, however, still remains, and is chiefly due to the fact that the prescriber himself seldom understands the true meaning of his prescription and the various interpretations which may be applied to it.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

Members of the Pharmaceutical Society must address all communications with reference to the transmission of the Journal, to the Secretary, 17, Bloomsbury Square, London, W.C.

LONDON: SATURDAY, MARCH 3, 1900.

CHEMISTS AND THE COMPANIES BILL.

THE Federation of Local Pharmaceutical Associations has prepared for the instruction of members of Parliament a statement of reasons for amending Clause 2 of the Companies Bill (see p. 243). The reasons given are practically identical with those suggested to our readers in last week's Journal (see p. 200), but they are prefaced by a concise explanation of the existing position and, in conclusion, it is urged that—while companies should not be allowed to use chemists' titles—persons without a competent practical knowledge of a chemist's business should not be permitted to exercise any control over the compounding, dispensing, and even retailing of poisons. Last, but not least, the attention of the recipient of the statement is directed to it in a forcibly worded letter which is intended to be signed by the sender—either the president of a local association, a local secretary of the Pharmaceutical Society, or any individual chemist. In that letter it is pointed out that the Pharmacy Act, 1868, which at present regulates the business, is admittedly defective in many respects, but that the registered chemists of Great Britain—whilst fully prepared to assist in any reasonable revision of the Statute, preferably by means of a Bill amending the Pharmacy Act—are strongly of opinion that the amendment now proposed by the Government is both unjust to them and of such a nature as inevitably to compromise the public safety. With the object, therefore, of preventing an injustice and of averting what—in the judgment of those best fitted to form an opinion on the subject—would be nothing less than a public calamity, the attention of members of Parliament is directed to the accompanying statement, and they are invited to do their utmost to secure the substitution of a modified clause in place of Clause 2 of the Companies Bill.

Copies of the letter are being sent, we understand, to every local pharmaceutical association and local secretary in Great Britain with a request that it may be signed and despatched to the members of Parliament for the respective districts. Copies of two modified clauses are also being sent and it is suggested, by the Executive Committee of the Federation, that one of those clauses should be adopted and members of Parliament be requested to do their utmost to secure the substitution of the selected clause in place of Clause 2 of the Companies

Bill. With regard to the two suggested clauses, it may be stated that one summarises the policy of the "no surrender" party, whilst the other combines the views of those who are willing to acquiesce, so far, in the proposal of the Government as to allow companies to carry on the business of a chemist and druggist, provided that such business is controlled by a qualified directorate and conducted in every shop by a legally qualified person. Thus, suggested Clause 2 (A) provides that:—

2 (A). No company may use the description of a pharmaceutical chemist, or chemist and druggist, or any other title implying registration under the Pharmacy Act, 1868; and no company may carry on the profession or business of compounding, dispensing, or retailing poisons; and if any company contravenes this enactment it shall be liable, on summary conviction, to a fine not exceeding five pounds for every day during which the contravention happens.

The effect of this clause would be to protect both titles and practice to an extent that would not be possible by simply including registered chemists in Clause 3 of the Companies Bill, for Clause 3—relating to medicine, surgery, and dentistry—is designed only to restrict practice and does not protect titles. This draft clause, therefore, may be strongly commended to the attention of registered chemists, and if some eight or ten thousand of them were to send copies of the Federation statement, with Clause 2 (A) included, to their parliamentary representatives, a powerful effect should be produced.

It would have been well if the Executive Committee of the Federation could have seen its way to avoid putting forward the second suggested clause, as the effect of having two distinct, and to some extent conflicting, policies advocated by registered chemists must be in great measure unsatisfactory. For in Clause 2 (B) the principle of legally qualified ownership is definitely abandoned, and it is provided that—

2 (B). No company may carry on the business of retailing, dispensing, or compounding poisons, unless the business is controlled by directors, each of whom is registered under the Pharmacy Act, 1868, and unless such business is conducted, in each place where it is carried on, by an individual qualified in accordance with that Act, whose name is conspicuously posted outside the premises and printed upon all labels used in the business; and no company may use the description of a pharmaceutical chemist or chemist and druggist, or any other title implying registration under the Pharmacy Act, 1868; and if any company contravenes this enactment it shall be liable, on summary conviction, to a fine not exceeding five pounds for every day during which the contravention happens.

But the main principle—*i.e.*, the restriction of chemists' titles to individuals registered under the Pharmacy Act, 1868—is supported by both the suggested clauses and, though 2 (A) and 2 (B) are diametrically opposed with regard to the qualification of the proprietor of the business, both would have the effect of preventing the exercise of control over the compounding, dispensing, or retailing of poisons by incompetent and legally unqualified persons.

ANNOTATIONS.

THE COUNCIL ELECTION is sufficiently near for the pharmaceutical electorate to begin thinking about the choice of suitable candidates to contest the seven vacancies created by virtue of the Pharmacy Acts Amendment Act of 1898, and it is highly desirable that each elector should become conversant with the salient points of the bye-law regulating the election. Any member of the Society who is entitled to vote—that is to say, any person on the current roll of membership, not being an honorary or a corresponding member—has the privilege of nominating another member for the office of councillor or auditor. Those who desire to exercise this privilege must, not later than the eighteenth day of March, give to the Secretary a signed notice stating the name and the address of the person or persons it is desired to nominate, and must send the same so that it may reach the Secretary on or before the date above specified. No form of nomination is required, and there is no restriction as to the number of members a duly qualified nominator may put forward as candidates. Within two days after the date fixed for the close of nominations the Secretary has to communicate with each candidate, inquiring whether he or she (for it is quite legitimate for lady members to be nominated) will accept office if elected, and in default of a written reply being received before the end of the month of March, intimating readiness to accept office if elected, such nominees will be deemed unwilling and ineligible to stand for the election. The net result of those formalities is reported to the Council at its April meeting, and a list of candidates willing to undertake the duties of representation is thus obtained, from which, in due course, voting papers are prepared. The process of reforming the Council, at any rate to the extent of one-third of its membership, is thus by no means a complicated one. All that is necessary is first to catch your candidate, and then see that he is duly nominated before March 18. Fate, the Secretary, and the electors, will do the rest.

OF THE RETIRING MEMBERS OF COUNCIL, all of whom are eligible for re-election, the addresses of two only are found in London, one each in Scotland and Wales, and three in the North of England. Altogether, at the present moment, eight members of the Council hail from the metropolitan district, and no other resides nearer to London than Salisbury, Birmingham, or Norwich. It is somewhat absurd, therefore, to find a Scottish member of the Society writing to a trade paper which can have no legitimate interest in the matter, to assert that "most of the men who sit on the Council at the present time are London men, or men not far from London." More than that, his statement is untrue, and its publication is hardly likely to improve the chances of any Scottish candidates at the approaching election. It is well known that the total strength of the Society in Scotland will not alone suffice to return a single member of Council, but at the present time the members of the Society are content to be represented by two Scotchmen. If, however, candidates from any particular district are to be opposed because they reside or carry on business in that district, Scotland may fare much worse than London at the approaching Council election and, on that principle, it is even conceivable that Scotland might, sooner or later, be left without a direct representative at all.

BUT EVERY MEMBER OF COUNCIL represents the whole of Great Britain, and not any particular town or district; so long as the best men available are elected, it is quite immaterial whence they come. It would be well, perhaps, if a much larger proportion of the members of the Society could be prevailed upon to offer their services to their fellow-members. Indeed, no better system could be contrived for educating chemists regarding their duties and responsibilities than to compel them to take a fair share in the work of organisation and administration. But it is greatly to be feared that difficulty would be experienced in finding sufficient new

candidates annually to replace the seven retiring members, assuming that to be considered desirable by any important section of the constituency. Rumour has it that an attempt is to be made this year to run seven candidates, whose chief qualification shall be that they have never previously served on the Council; but if that can be done once, how many times can the experiment be repeated? As a matter of fact, there is too great a disinclination on the part of members of the Society to take a proper share in the work of administration, and, though it would be a matter for general congratulation if seven new and suitable candidates could be induced to stand for election in May next, it seems too much to expect that to happen every year. Moreover, bearing in mind the results of previous elections, it will be surprising if so many as two of the retiring members of Council are rejected this year after offering themselves for re-election.

THE REFERENCE TO THE WHEELDON CASE in last week's Journal (see p. 200) was not quite accurate, the decision in that case being attributed to the House of Lords instead of the Court of Queen's Bench. But, inasmuch as leave to appeal was refused by Justice Hawkins—speaking on behalf of Baron Pollock and himself—and as no further steps were taken, the judgment in the case was as final in its effects as a decision of the House of Lords would have been. It is interesting at this juncture to recall the fact that, in the opinion of Baron Pollock and Justice Hawkins, the intention of the Legislature was expressly to provide against the business of a chemist and druggist being left in charge of an unqualified person, by insisting upon one uniform qualification for every person who should sell poisons, whether on his own account or for any other person. It was considered by those judges that the object of the Legislature would be defeated if the selection of an assistant who was to be entrusted with the sale of poisons were left to the discretion of the employer, without regard to any qualification. Of course, the fact that an assistant is legally qualified does not relieve the employer of his civil liability to any person injured by the neglect of the assistant; but, so far as the provisions of Section 15 of the Pharmacy Act are concerned, an assistant who sells poison—having been held by the House of Lords to be the person actually responsible under the Pharmacy Act—would be liable to a penalty for an offence under that Section. If, however, the transaction were personally supervised by an employer who is a registered chemist, the entire responsibility, under Section 15, would then fall upon the employer. So far as limited companies are concerned, they are at present quite outside the operation of Section 15, and, consequently, not responsible for offences under that section committed by their managers or assistants, whether legally qualified or not. In the event of Clause 2 of the Companies Bill becoming law as it stands that position would not be altered; it would still be physically impossible for companies to supervise the acts of their managers or assistants, and the protection afforded to the public would thus be much less in the case of companies employing qualified managers or assistants than in the case of individual keepers of open shop for the sale of poisons. That would be especially marked in cases of neglect to conform with Regulation 3 for the dispensing and selling of poisons.

"CHEMISTS' ADULTERATION" is the heading of an editorial note in this week's *Medical Press*; but the case under the Sale of Food and Drugs Acts which has attracted the attention of the writer of the note is only one more instance of the ignorance or unfairness of that organ towards chemists. The case is reported at page 241 of this week's Journal, and the defendant, as there stated, is not a registered chemist. Further, the inaccurate writer on the staff of our contemporary may do well to note that the British Pharmacopœia is not a good standard for the purity of drugs; it may also be suggested to him that the fact of an offence being committed by a person who is not a chemist hardly justifies the publication of baseless innuendoes against those who are properly described by that title. But it was ever thus in the *Medical Press*.

A NEW USE FOR THE TOAST is seen by the *Preston Herald* in Mr. Gifford's curious and inaccurate speech (see *ante*, p. 217) at the annual dinner of the North-East Lancashire Chemists' Association, recently held at Blackburn; but we fail to see, as does a writer in that journal, that "a revolution will be effected by the same event in that conception which holds that public dinners are invariably succeeded by benignant proposals and endorsements in those who partake of them." The bulwark of conventionality has undoubtedly been broken down in many ways in recent years, but untruthful assertions are not likely to supplant correct statements of fact, or even compliments, in our day. The Preston oracle is of opinion that "a little more candour, and less humbug, would disperse a good deal of that somnolency which prevails at many business functions of this kind, and cause them to be regarded more with the idea of pleasure than a duty to be performed," but the utterance of falsehoods hardly comes within the definition of "candour," whilst "humbug" is surely an imposition under fair pretences, such as were manifested by the erratic speaker whom the *Preston Herald* seems so anxious to honour. Let us have more candour by all means, so long as the truth is not masked; on the other hand, a little transparent humbug is preferable to gross impertinence and utter lack of decency in public speech.

THE STAMPING OR MARKING OF GLASS MEASURES was brought up for consideration by a deputation from the Corporation of the City of London, which waited upon the President of the Board of Trade a few days ago, complaint being especially made of the competition which appears to go on among local authorities. It was pointed out that under the Act of 1878 there was a special schedule of charges, and it was expressly enacted that those should be the charges, "and no others, and no discount shall be allowed," but certain authorities, more particularly in Northumberland, have allowed discounts where the stamping took place upon the manufacturer's own premises. That was found to militate considerably against the trade of London, and the London County Council considered it expedient, with a view of keeping the trade to London, that it should enter into competition, and it did so by reducing the charge from 1s. to 6d. The Board of Trade, however, intimated to the County Council that it was illegal to charge only one-half of the statutory fee. The County Council then agreed to revert to the old charge, but shortly after determined to make no charge at all, but instead to charge 4½d. per dozen on glass measures for unpacking and repacking. That, the Corporation contended, was an evasion of the Act, but the County Council could not be got to obey the Act strictly, the principle assigned therefor being that it was absolutely necessary in order to keep the trade to London and to enable the Council properly to compete with other authorities. It was now urged that for the protection of British industry it would be far better not to have such a system, because foreigners were able to import their glass measures and get them stamped by the County Council merely at the cost of this packing charge, whereas if they had to pay the statutory fee the British manufacturer would undoubtedly be able to hold his own. The number of glass measures brought to the City to be stamped had dwindled down very much, so the grievance was a very substantial one to the Corporation. It was therefore earnestly hoped that the Government would, by an amending Act or otherwise, secure uniformity of practice and of fees throughout the United Kingdom. Mr. Ritchie, in reply, said there was no doubt that it was a very unsatisfactory and a very inconvenient thing that within the area of London there should be two different scales of fees, because, after all, it came to that. He should not like to say whether the position of the County Council was legal or otherwise, but there was certainly something more to be said for the County Council's present position than if it had charged a reduced fee. If the contention of the City was right there was no necessity for new legislation on the subject. If some general Bill on weights and measures were required in the

public interest it might be comparatively easy to put this question of the stamping of glass measures into such a Bill; but he was not aware that there was any such public demand, and, therefore, he could not undertake any legislation on the subject. However, he would address a communication to the London County Council, drawing attention to the representations made to him by the City authorities.

THE NATIVE DRUG PLANTS OF THE UNITED STATES involve the expenditure of millions of dollars annually in their collection, but, according to the United States Secretary of Agriculture, the commercial extermination of some of the most useful species is already threatened. He states that the Pan-American Medical Congress has recently submitted to him a proposition to co-operate with the Department of Agriculture in a technical and statistical investigation and classification of American drug plants. By accepting that proposal, it is thought the cordial assistance of an influential association of learned physicians will be secured in a research of which the need has long been felt. As quoted by the *British Medical Journal*, the Secretary of Agriculture, in urging the appropriation of ten thousand dollars to enable his Department to co-operate in this investigation, asserts that encouragement will thus be given to each of the other American nations—all of which are represented in the Pan-American Medical Congress—to proceed with a similar investigation of their own medical flora, whilst furnishing a basis for the remunerative employment of much land and many people, and stimulating the great growth and growing trade in drugs between the countries of North America and South America.

THE BRITISH PHARMACEUTICAL CONFERENCE GENERAL COMMITTEE for the London meeting now includes the names of eighty-one gentlemen, and the Hon. Secretary to the local Executive Committee asks us to state that he will be glad to receive the names of any others who are willing to join the General Committee. He also sends a first list of subscriptions (see p. 236) to the B.P.C. Entertainment Fund, the total of which now exceeds two hundred and sixty pounds. Those who have not yet intimated the amount of their subscriptions are asked to communicate with the Hon. Secretary, Mr. William Warren, 24, Russell Street, Covent Garden, W.C.

THE POISONING CASES AT CRUMPSALL WORKHOUSE, particulars concerning which were published in the *Pharmaceutical Journal* for December 30 last, have been reported upon by the Visiting Committee of the Crumpsall workhouse. It is stated that there appears to be no doubt that the fatality arose from a mistake having been made by one of the dispensers when refilling a bottle labelled spirit of nitrous ether, that having, through an inadvertence, been filled from a stock jar containing a preparation of strychnine. At the same time, the committee is satisfied that existing arrangements for the dispensing of medicines for the sick inmates are such as are calculated, with the exercise of reasonable care, to prevent the occurrence of such mistakes as that alluded to, and it is stated that no serious mistake of the kind has been known to have occurred before at the workhouse. A sub-committee has, however, made a thorough investigation into the existing arrangements at the dispensary, and suggests that special cupboards be set apart for storing bottles containing poisons, and that two dispensers be required to be present when dealing with poisons intended for patients. An inspector of the Local Government Board, who was present at the meeting at which the foregoing report was presented, said that he went to Crumpsall workhouse shortly after the occurrence referred to. As a result of inquiries he made, he was satisfied that great care had always been taken to prevent accidents taking place. It seemed to him absolutely inexplicable how such a blunder could have been made. Ultimately, the report and suggestions were adopted by the Manchester Board of Guardians.

POLITICAL GOSSIP.

THE GOVERNMENT is continually being questioned as to its intentions, and no dilatory lover could be more pestered by an anxious parent than the Leader of the House is by impatient or suspicious M.P.'s. Mr. J. Bryce (S. Aberdeen) and Sir J. Brummer (Northwich) jointly and severally invited Mr. Balfour, on Friday, the 23rd ult., to reveal the Ministerial plan of campaign in reference to the Companies Bill, and the response to that invitation is highly satisfactory in so far as it shows that the official intentions towards the question of company reform are perfectly honourable. In fact the Government honestly proposes to proceed with the Bill at the earliest favourable opportunity, and hopes to take the second reading before Easter. Furthermore, endeavours will be made to give at least three days' notice of the date on which that stage will be taken—a graceful acknowledgment of the importance of the subject and of the wide interest felt in the proposed amendment of company law. Whilst few will share Mr. Balfour's optimistic estimate of parliamentary progress, all chemists will agree that it is essential no more time should be wasted in minutely differentiating the merits of rival schemes of pharmaceutical salvation; the leaders and the led should, in fact, now emerge from the self-generated "company" fog which has enveloped them for so long, and set about the serious work of defensive preparation.

TOO MANY COOKS, especially when they are all active and zealous, may be depended upon to effectually spoil any meal, and similarly there is some fear that pharmacy may suffer in Parliament through the gratuitous meddling of a number of pharmaceutical chefs whose zeal is more to be commended than their judgment. It is not a very exhilarating thing when interviewing a member in the Lobby to find that the apostle of how not to do it has already captured that member and supplied him with arguments which are plausible and specious enough to render his mind unreceptive to higher considerations. Most abominably active, too, are these same apostles—just as the bandsman with an ill-tuned cornet always possesses abnormal lung power—and their effect upon the average M.P. is distressing. What with journalistic circulars, Federation circulars, and independent missives from individual chemists; members are being made sick of the pharmaceutical aspect of the Company question, and by the time the Pharmaceutical Council makes up its mind to put its political influence into operation the House will most likely have become quite lethargic and indifferent to the subject. Perhaps this is not realised by chemists and druggists as it should be; if it were, there would not be such a feverish anxiety to be active at all costs, irrespective of eventualities. Petitions for alteration of the Companies Bill are likely to be favourite methods of letting off political steam. One has already been received from Bolton, and as petitioning is a comparatively harmless form of relief it may be commended to the attention of those who feel they must do something or burst.

THE BOARD OF EDUCATION created by last Session's Board of Education Act is to be assisted in its work by a Consultative Committee, the functions of which were prescribed by the Act, and some anxiety is being manifested by educationalists as the time for constituting the Committee draws near whether the right men will be appointed. On behalf of the member for Oxford University (Sir W. Anson) a question was put to Sir J. Gorst on the 23rd asking whether universities and other bodies concerned in teaching would be invited to nominate persons for appointment on the Committee. The Vice-President of the Council seemed quite shocked at the idea of utilising the accumulated experience of respectable teaching bodies in such a direction, and answered

with a curt "No." He further stated that the Committee would be constituted by an Order in Council which would also provide for the appointment of subsequent members. Sir William Anson also elicited that regulations or terms of reference under which the advisory duties of the Committee are to be discharged will not be submitted to the criticism of the House. The Order in Council constituting the body will alone be open to observation during its month's stay on the Table. There is no chance of the "tail wagging the dog" here, for it is evident that the Committee is to be kept well under, and will only be required to advise when it is asked to do so, and then strictly on the particular matter referred to it. Mr. Yoxall (Nottingham) has tried his hand at drawing Sir John, but failed to get more than an assurance that suitable persons would be chosen.

DEPARTMENTAL ENLIGHTENMENT is a rare thing to meet with, and should be noted whenever found; hence, the Medical Department of the Admiralty deserves some commendation. In the course of his speech introducing the naval estimates, Mr. Goschen is reported to have said that hitherto medical officers had to supply their own instruments, and, as a consequence, these instruments and drugs, which are so essential for the welfare of the sailors, have not been carried in sufficient quantities. The Medical Department has thought it to be a duty to change that condition of affairs; hence some increase in the amounts asked for on account of *personnel*. We know that a very reasonable attitude prevails also at the Admiralty in reference to the status of Naval dispensers, and the old disposition to regard them as rather inferior to good stokers has almost entirely died out. Sir Walter Foster gave in his testimony to the intelligent working of the department, and praise from Sir Walter is praise indeed, when medical matters are involved.

ENGLISH NEWS.

IMPERIAL COLLEGE OF CHEMISTRY.—The students attending this College visited the South Metropolitan Gas Works, on February 14, the party being conducted throughout by Mr. Duckham, assistant engineer, who described the various processes most graphically. The distillation of the coal by the old and new variety of retorts was of great educational interest; the charging and drawing processes being accomplished by compressed air in the one case, and gravitation in the other. The gas passes from the retorts up the ascension pipes into the hydraulic main, where a large amount of the tar and ammonia contained in the crude gas is caught. From these mains the gas passes into the condensers, where it cools, and thence it is pumped by the exhausters through the purifying plant, which consists of:—1. "Livesey" washers, which take out the remainder of the tar and soluble impurities; 2. Tower scrubbers which remove the remainder of the ammonia from the gas. 3. Purifiers, three, charged with lime, removing the carbon dioxide and sulphur, whilst the two charged with oxide of iron remove the sulphuretted hydrogen from the gas. All of the ammoniacal liquor is converted into sulphate of ammonia, and the sulphur recovered by means of "Claus" sulphur kilns. The making of Prussian blue having been studied, the students presented Mr. Duckham with a handsome silver card case. Mr. Frederick Davis proposed a vote of thanks, and the proceedings then terminated.

SOUTH LONDON SCHOOL OF PHARMACY.—On Monday, February 26, the staff and present students of this school dined together in the Empire Hall of the Trocadero Restaurant, having been invited thereto by Dr. Muter on the occasion of his birthday and to celebrate the thirty-second anniversary of the school. In giving the usual loyal and patriotic toasts reference was made to the fact that several of the students had gone to the Front as Imperial Yeomen and in the Hospital Corps. Dr. Muter's health was pro-

posed by the Rev. S. Bache Harris, Vicar of Kennington. During the evening a presentation of a gold waistcoat-pocket card case was made to Dr. Muter as a souvenir of the occasion, and, after the toasts, a smoking concert was given by the musical students.

SHEFFIELD COLLEGE OF PHARMACY.—On Shrove Tuesday the students of this school, by kind permission of Colonel J. Bingham, J.P., visited the works of Messrs. Walker and Hall, electro-plate manufacturers. The manufacture of spoons, forks, soup ladles, dish covers, carvers, tea and coffee pots, were shown in detail. The electro-depositing of copper, silver, and gold, the electricity generated by specially constructed dynamos. Some real ivy leaves and berries were silver-plated, as well as some real lace for ornamental purposes. The embossing and chasing of presentation cups, etc., by skilled artisans were much admired. In the afternoon the Handsworth nurseries were visited. The choice selection of orchids was much in evidence, several varieties being explained by the superintendent. The croton, fern, and azalea houses next received attention. The whole day's outing proved most instructive.

NORTHAMPTON CHEMISTS' ASSOCIATION.—At a recent meeting of the Northampton chemists, the initial steps were taken to form a chemists' association for the town and district, and after the business was concluded Mr. Mayger, the senior chemist of the town, very kindly invited his brother chemists to a dinner. This took place on February 22, when over twenty chemists and assistants partook of a most excellent repast. Mr. Mayger expressed regret that two or three gentlemen were unable to be present through illness, amongst the number being the energetic local secretary—Mr. John Bingley, Mr. G. C. Druce, M.A., of Oxford, spoke of the pleasure it afforded him of being present; being an old Northampton chemist, and having a great affection for the old town, he was always glad to renew acquaintance with his friends there. The usual toasts were proposed and honoured, that of the Queen being most enthusiastically received. Speeches and songs followed, and a most enjoyable evening was spent.

NORTH-EAST LANCASHIRE CHEMISTS' ASSOCIATION.—A meeting of the Executive Committee of the North-East Lancashire Chemists' Association was held at the "White Bull" Hotel, Blackburn, on Friday night last, Councillor Critchley presiding. The recommendations of the Federation in the matter of the Companies Bill were considered, and it was resolved not to entertain any other policy than that represented by the Federation's first resolution.—Councillor Shorrock, Mr. Wells, and the Secretary were appointed a deputation to wait upon Sir Harry Hornby, Bart., M.P., Sir William Coddington, Bart., M.P., and Mr. J. Rutherford, M.P., to request their support in the direction indicated. Messrs. J. Booth and Percy Bean were afterwards added to the deputation, and it was stated that an interview with Sir Harry Hornby had already been arranged.—Mr. Wells, referring to the Association's agitation in favour of making operative the Act of 1868, said the time had evidently arrived when the reactionary forces would prove too strong for them, and they must either give up the struggle or put their backs against the wall for a more determined fight. The latter alternative meant that they must run a candidate of their own for election on the Pharmaceutical Council, and he moved that a general meeting of the members be called for March 6, with a view to inviting Mr. R. Lord Gifford, their secretary, to consent to nomination.—Mr. W. Holt seconded the motion. He remarked that at their recent dinner one of the members of the Council said he did not see why the Association should not have a representative on the Council, while another said it was within their power to make the Council what they required it to be. Another reason, and a stronger one to his mind, was that it would be a pity to allow the persevering and painstaking work of Mr. Gifford to fail of its effect.—The proposition was supported by Councillor Shorrock and others, and carried with enthusiasm.

NORTH OF ENGLAND SCHOOL OF CHEMISTRY AND PHARMACY, NEWCASTLE-ON-TYNE.—On Tuesday evening, February 20, the past and present students of this school met in Simpson's Café for a social gathering, also to give a send-off supper to one of the late students, Mr. J. T. Hogarth, who recently qualified from the school, and has volunteered for active service with the 1st V.B. Northumberland Fusiliers. The Principal of the School, Mr. F. R. Dudderidge, occupied the chair. After supper a purse of gold was presented to Mr. Hogarth, on behalf of the students, by Mr. G. F. Merson, former principal of the School, who in suitable terms wished Private Hogarth God-speed and a safe return. The remainder of the evening was devoted to music and recitations, the following gentlemen contributing:—Songs by Messrs. Dudderidge, J. Duncan, and McPhail; violon solos by Messrs. J. G. Duncan and Stevens, a recitation by Mr. Shadforth, and a 'cello solo by Mr. J. S. Hill; Messrs. J. Duncan and Hill also taking the place of accompanists. A very enthusiastic and enjoyable evening was appropriately ended by the singing of the National Anthem.

QUOTING FROM WHOLESALE DRUG LISTS.—At a recent meeting of the Brecon Board of Guardians a letter was received from a local firm of chemists, Messrs. Meredith and Stanton, who forwarded the wholesale price list of Messrs. Hodgkinson, Clarke, and Ward, in response to Board's advertisement for the supply of drugs for the workhouse. Messrs. Meredith and Stanton pointed out that it was difficult to submit samples, but they were prepared to charge the Union according to the figures on the price list, and the quality of the drugs supplied would, they added, be the highest.—The Clerk said that what was sent was their wholesale drug list. The firm said they were prepared to accept wholesale prices.—It was pointed out that carriage would be saved in this way.—The Rev. W. Williams, one of the members, remarked: I have had some experience in the matter of tenders. I have had it from a chemist in the town that the wholesale price list which chemists send out is no guide whatever to the actual cost. The discounts are so large to the retail dealer that you can form no idea of the actual cost.—Another gentleman inquired whether the prices submitted were subject to a further discount!—Mr. George, one of the other members, asked how it was to be expected that a firm could pay rates and taxes if they supplied the Union at a loss of the carriage. The Board wanted the penny and the cake.—Eventually the tender of Messrs. Meredith and Stanton was accepted.

SALE OF CAMPHORATED OIL.—At Lambeth Police-court on Thursday, February 22, Thomas Tyrrell, described as a chemist, of Southampton Street, Camberwell [The name Thomas Tyrrell does not appear on the Register of Chemists and Druggists, 1900.—Ed. P.J.], was summoned, at the instance of the Camberwell Vestry, for selling camphorated oil which was not of the nature, substance, and quality of the article demanded by the purchaser, inasmuch as it was certified by Dr. Frank Teed, the public analyst, that it contained 80 per cent. of mineral oil, whereas the British Pharmacopœia required that camphorated oil should be made in the proportion of one ounce of camphor dissolved in four fluid ounces of olive oil. Dr. Teed also stated that the proportion of camphor was about 2 per cent. below the mark.—For the defence it was stated that the defendant kept two kinds of camphorated oil, one for retailing, and the other for use in rheumatic liniment. They both stood on the same shelf, and the defendant, who was old and near-sighted, served the inspector from the wrong bottle.—Mr. Hopkins regarded the case as a bad one, and ordered the defendant to pay a penalty of £20 and costs.—At Worksop Police-court on Wednesday, February 21, Richard Chambers, was charged with selling camphorated oil which was not in accordance with the British Pharmacopœia.—Inspector Crabtree, who proved the case, stated that he had pur-

chased the whole of the camphorated oil the defendant had in stock, and he thought the defendant was not so responsible as the wholesale house that supplied the oil.—Defendant's wife stated that the traveller for the firm from which the oil was purchased had visited her on his ordinary journey a few days prior to the case coming before the Court, when he stated that the oil supplied was not up to the requisite strength. Other customers had been notified of this, and oil had been returned, but they had omitted to notify her.—The Bench fined the defendant £1, and expressed the hope, in the interests of the public, that defendant would sue the wholesale firm in the County Court for damages sustained, the inspector having promised to give evidence.—At Swadlincote Police-court on Tuesday, February 20, Samuel Kirby, grocer, Overseal, was fined £1 1s., including costs, for selling camphorated oil containing 35 per cent. of mineral oil. The Chairman stated that the Bench did not think defendant had wilfully broken the law, and pointed out that he had his remedy against the wholesale dealer.

SALE OF OLIVE OIL.—Ernest Scruby, grocer, Minster, was fined £4 by the Ramsgate magistrates on Tuesday, February 20, for supplying cottonseed oil when olive oil was asked for.—Defendant pleaded that he had purchased the stock-in-trade of the shop in bulk, and did not know whether the oil was olive oil or not.—The Bench informed him that it was his business to know.—The Police Superintendent stated that the county police had received orders to take frequent samples of oil, there having been numerous complaints as to the oil sold as "olive."

OVERDOSE OF CHLORODYNE.—On Monday, February 19, the Wigan Borough Coroner held an inquiry touching the death of a woman named Sarah Crook. The deceased had been in the habit of taking chlorodyne, and on the previous day she was found in a comatose condition, having taken an overdose. A verdict of "Death by misadventure" was returned.

POISONING BY PRUSSIC ACID.—An inquest was held at Nottingham on Friday, February 23, with respect to the death of Fred Lumby, chemist and druggist and sub-postmaster, at 46, Arkwright Street, Nottingham.—Evidence was given to the effect that deceased had been unwell for some time past, and had been worried about the post-office business. On the previous Tuesday night he had no sleep, and on Wednesday morning complained of his head and chest. Later the same day he was found in his bedroom suffering from prussic acid poisoning.—The jury returned a verdict of "Death from prussic acid poisoning," but were of opinion that there was not sufficient evidence to show the circumstances under which it was administered.

OVERDOSE OF COCAINE.—An inquest was held at Dalton Parva on Friday, February 23, touching the death of Edith Walker (22), wife of John William Walker, farmer, who died suddenly on Tuesday, February 20. The husband stated that deceased had been in the habit of taking cocaine for some time past. About 3 o'clock on Tuesday morning he heard a noise, and found her on the bedroom floor insensible. He sent for Dr. Knight, but she died about 3.30 a.m. There was a paper labelled cocaine on a stool near the bed, and it had apparently been purchased at Rotherham.—Dr. Henry Ernest Knight, surgeon, said about two years ago deceased complained of toothache, and he prescribed cocaine. He had no idea she had taken any since. He saw her the previous Monday afternoon, and she was then well and cheerful.—The jury returned a verdict that death was due to an overdose of cocaine, administered by herself without felonious intention.

SCOTTISH NEWS.

THE EDUCATIONAL INSTITUTE PRELIMINARY EXAMINATIONS.—In connection with the reference in last week's Journal to the alterations which take place after July in the registration of pharmaceutical students, it is of some interest to notice that the Educational Institute of Scotland has already begun to move in the direction of providing facilities for earning the necessary certificates. In the new 'Calendar,' just issued, intimation is made that arrangements are in progress for conducting the general knowledge examinations for the certificates required by the Pharmaceutical Society. What is proposed is that pharmaceutical students will be admitted to the Medical Preliminary Examinations under exactly the same conditions and on the same terms as medical students, and certificates will be granted stating what subjects they have been successful in passing. The fee for the examination is one pound, and candidates may take the whole six subjects at one time or as many as they may wish to take. Hitherto the Institute Medical Preliminary Examinations have only been held in Edinburgh and Glasgow, but it is intended to have centres in Aberdeen, Dundee, and Dumfries, so that the whole country will be embraced. The first examination after July will be held in September of this year, English and Latin on September 18, arithmetic and algebra on September 19, and Euclid and French (or German) on September 20. The syllabus gives the following particulars:—English: Including dictation, composition, parsing, and derivation. Shorthand is accepted as an alternative to questions in derivation. Latin: Grammar, translation into English from Cæsar de Bello Gallico, Book IV., and Virgil, Æneid, Book VI., lines 1-402: and translation of passages from authors not specified; and composition in Latin. French (or German): Including grammar, translation from English into French (or German), and French (or German) into English. No authors are specified in modern languages. Arithmetic: The common rules and vulgar and decimal fractions. Algebra: Up to and including simple equations. Euclid. Books I.—III., with deductions. Full particulars of the examinations will be advertised in due course.

GLASGOW CHEMISTS' AND DRUGGISTS' ASSISTANTS', AND APPRENTICES' ASSOCIATION.—This Association held a highly successful smoking concert in its rooms, 100, West Regent Street, on Friday, February 23. Mr. J. P. Taylor made an efficient Chairman, and an exceptionally bright programme of songs, musical selections, etc., was rendered with ability and acceptance. Owing to the indisposition of Dr. Coull, of Edinburgh, it was announced that his lecture on "Stereo-Chemistry," due on March 2, would be postponed until March 9 or later.

IRISH NEWS.

PHARMACEUTICAL SOCIETY OF IRELAND.—At an evening meeting held at 67, Lower Mount Street, Dublin, on Monday, when Mr. J. Smith occupied the chair, a lecture was delivered by Mr. J. N. Laird, B.A., Trinity College, on "Some facts about the Distribution of Plants." The lecture was illustrated by a number of beautiful limelight views, and the lantern was worked by Mr. E. H. Hanley, B.A., a friend of the lecturer. Mr. Laird, having introduced the subject of his discourse in a few well-chosen words, referred to the geographical and geological distribution of plants and to the mechanical methods made use of plants in aiding growth. He explained some of the principles which governed such distribution, and referred at some length to the depression of land caused by human structures, submerged forests, and coral islands, and instanced a number of cases in connection therewith. Stratified and volcanic rocks, and their respective functions in the distribution of plants, were spoken about, and the principles of change of organisms due to physical surroundings commented on. The theory of the survival of the fittest was instanced by the struggle

for existence which was continually going on in the animal and plant world. Plant distribution was best studied in islands, there being a restricted area and definite boundaries, with a much smaller number of species and genera than in continents. Their peculiar species and groups were well defined and limited in range. Their relation to other lands was often simple, and they exhibited certain influences on the forms of life which continents did not show, and were altogether simpler than the continental species. The study of island plant life was accordingly preferable to continents. Oceanic islands and continental islands were differentiated, and the total absence of warm-blooded animals on the former commented on. Ancient continental islands and mammals came next under notice. The lecturer carried his hearers through the Azores, and said of 480 phanerogams and ferns extant 440 were found in Europe. Forty other species were of a peculiar kind, but were allied to the European species. The dispersal of seed was next referred to, and the speaker showed how a single seed could populate an entire island. Seeds could be carried enormous distances by the agency of wind, birds, sea-water, etc. The seeds of oats, capsicum and potato grew after a hundred days' immersion in water. Most of them, however, sank after a few days' immersion. Of twenty-two land birds in the Azores one half of them were fruit eaters. The transmission of seeds on birds' feet and in excreta was referred to. Six and three-quarter ounces of mud on the edge of a pond, being carefully treated under glass, gave 537 plants. The composition of Azorean plants was compared. Forty-five had pappus or winged seeds, sixty-five had very minute seed, thirty had fleshy fruits such as were greedily eaten by birds, and eighty-four were glumaceous plants, all of which were well adapted for wind and water. There were no trees or shrubs in the Azores with large or heavy fruits. Such trees as the oak, chestnut, hazel, etc., were unknown. The Galapagos were next described, and the flora thereof dwelt upon for some time. The lecture, which occupied about two hours, was throughout of an interesting and instructive nature, and at its conclusion a hearty vote of thanks was accorded to the lecturer.

FOREIGN NEWS.

DARK RAYS DESTROY BACTERIA.—It appears to be well proved that the rays of the ultra-violet end of the spectrum—the chemical rays—have the property of destroying bacteria, also that they may produce inflammation of the skin and penetrate it. These facts are likely to prove of great importance in medicine. Dr. Finsen, a Danish physician, concluded some time ago that the skin inflammation in small-pox was due to increased sensitiveness to the chemical rays, and on excluding these rays by placing the patient in red light, he greatly diminished this painful effect. Sunburn and X-ray burns seem to be due to a concentration of the actinic rays. Dr. Finsen has now taken advantage of the bactericidal property, and in cases of skin diseases due to microbes, instead of excluding the chemical rays, he concentrates and cools them by a special instrument. His experiments thus far have been chiefly applied to lupus, with which he has had such success that any failure throws doubts on the diagnosis, about three hundred and fifty cases having been treated.

AN ILLEGAL DRUG.—Monsieur P—, analytical chemist, has just had a "mauvais quart d'heure" with the judges of the Tenth Correctional Chamber, who convinced him (or at least made the attempt) that a specialty called "Stéréol," whose base was alum, and which was destined to form antiseptic solutions, was illegal, since he was exercising pharmacy. He declared upon his prospectus that "Stéréol" was capable of destroying other germs than microbes, and might fill equally as well the prescriptions of Malthus as those of Pasteur. In his defence he argued in vain that the use of his tablets constituted a measure of hygienic precaution and not medication. Failure to bring the judges to his way of thinking cost him 500 francs.

FEDERATION OF LOCAL PHARMACEUTICAL ASSOCIATIONS.

A meeting of the Executive was held at Law's Hotel, Surrey Street, London, W.C., on Monday, February 19, at 10 a.m., when all were present. Messrs. J. SMITH (Liverpool), Chairman, Currie (Glasgow), Thompson (Birmingham), Peck (Cambridge), and Jas. Cocks (Plymouth), Hon. Secretary and Treasurer.

Suggestions for Discussion, etc.

It was decided that the following recommendations regarding subjects for discussion, etc., should be forwarded to local associations and local secretaries of the Pharmaceutical Society:—

(1) Oppose Clause 2 of the Government Companies Bill adopt one of the two following resolutions, and interview members of Parliament, soliciting their support, furnishing copies of printed reasons at the same time:—

(A) To protect chemists' titles, and make it illegal for companies of unregistered persons to keep open shop for selling poisons, as in the case of individuals.

(B) To protect chemists' titles, insist that drug companies should have a qualified directorate, and that the business shall be conducted by a qualified person, whose name shall be conspicuously posted over the shop or place of business.

(2) Discuss the disadvantages of ordering in prescriptions B.P. preparations under fancy names, with the view of pointing out the same to local medical men.

(3) Discuss the advisability of approaching the Poor Law authorities, that in filling future vacancies for dispensers under their control, candidates holding the qualifying examination of the Pharmaceutical Society only should be eligible.

(4) Discuss, and forward to the Secretary of the Federation, as to whether chemists should be included in any future Bill introduced into Parliament dealing with the regulation of hours of business in retail shops.
