DIVISION OF NAVAL INTELLIGENCE, NAVY DEPARTMENT

CONFIDENTIAL

JAPANESE ELECTRONICS

"Japanese Electronics" is the first of several replacement supplements to Section 8, Technical Studies, PHOTOGRAPHIC INTERPRETATION HANDBOOK-UNITED STATES FORCES, dated April 1944. Other studies of Section 8 are under revision and will be issued to complete and replace entire section.

Four distinct types of electronics installations are represented in this supplement: Radar, Communications, Direction Finding, and Navigational Aids. Only major characteristics, usages and graphic appearances of these are included. For further and detailed information refer to (1) "JAPANESE ELECTRONICS," Photographic Intelligence Center - Report 1, OPNAV 16 VP101, January 1945; and (2) "TECHNICAL DATA ON JAPANESE RADIO AND RADAR EQUIPMENT," Naval Research Laboratory Report #RA3A215B.

Certain examples of German Electronics are included because of probable availability of German equipment and methods for Japanese use.

GLOSSARY

- DIPOLE** Center fed rod or wire antenna, usually elevated.
- UNIPOLE** End fed pole, rod or wire antenna, usually vertical and grounded. (Also called MONOPOLE)
- KILOCYCLE** 1000 cycles. (In electronics, used to indicate frequency in kilocycles per second)
- MEGACYCLE** 1,000,000 cycles. (In electronics, used to indicate frequency in megacycles per second).
- FREQUENCY (KCS)** = $\frac{300,000}{\text{Wave length (meters)}}$ (Velocity of light in Kilometers per second)

STANDARD FREQUENCY TABLE

SHF -- Super High Frequency	3000-30000 Mcs. ("microwave")
UHF -- Ultra High Frequency	300-3000 Mcs.
VHF -- Very High Frequency	30-300 Mcs.
HF -- High Frequency	3-30 Mcs.
MF -- Medium Frequency	300-3000 Kcs. (0.3-3 Mcs.)
LF -- Low Frequency	30-300 Kcs. (0.03-0.3 Mcs.)
VLF -- Very Low Frequency	10-30 Kcs. (0.01-0.03 Mcs.)

RADAR SUMMARY

DEFINITION

Radar is an electronic device which emits a continuous stream of pulses of radio waves at extremely high frequencies (70 to 30,000 mcs) which are reflected back from a dense obstruction and presented on a cathode ray tube to record position and range of that obstruction in a visual manner.

USES

Present known uses of Japanese Radar include air search, surface search, fire control and searchlight control.

INTERPRETATION FEATURES

Land Based Search Radar:

Location: High points in mountainous areas.

Sites often near seacoasts.

Characteristics:

- Isolated ground scar and connecting road.
- Antenna (size, shape, shadow).

- Generator building usually associated.
 - May be found as multiple installations.
- Land Based AA Fire Control:
- Location: Associated with Heavy Batteries.
- Characteristics: (Information incomplete but following may be expected):
- Installation usually found within 600' from fire control center of battery.
 - May be in revetment or in circular cleared area.
 - Complete Radar may consist of one unit, or transmitter and receiver may be separated.

USE OF FREQUENCY DATA

Frequency bands listed in table below may be utilized for positive identification of radar types through collaboration with the local Electronics officer.

TABLE OF IMPORTANT JAPANESE RADAR TYPES

	POPULAR NAME	JAPANESE DESIGNATION	ANTENNA	FREQUENCY IN MCS.	USE	REMARKS
LAND BASED SEARCH	GUADALCANAL TYPE	MARK I, MODEL 1	26'x18'	97-103	A.W.	FIRST FOUND ON GUADALCANAL
	"ATTU TYPE"	MARK I, MODEL 1 MODIFICATION 1	28'x14'x2 1/3'	97-103	A.W.	'BOX' TYPE ANTENNA
	"MOBILE MATTRESS"	MARK I, MODEL 2	14'x7'x1 2/3'	187-205	A.W.	OFTEN FOUND EMLACED IN A REVETMENT
	"MARK VI PORTABLE"	AIR MARK VI "SPECIAL"	7' YAGI DIPOLES MOUNTED ON COLLAPSIBLE TRIPOD	140-160	A.W.	PORTABLE ADAPTATION OF AIR-BORNE SET
	"LADDER TYPE"	MARK I, MODEL 3	STACK OF 3 1/2 FT. OR 7 FT. DIPOLES	140-160	A.W.	SET MAY BE LAND-BASED OR SHIP-BORNE
	"WEWAK YAGI"	"YA" OR MARK B	2 HORIZONTAL ROWS OF YAGI DIPOLES ON A MAST	60-80	A.W.	TRANSPORTABLE PHOTOGRAPHED AT WEWAK 1943. INCREASING USE.
	"CHI"	"CHI" OR MARK 229	SIMILAR TO WEWAK YAGI	60-80	A.W.	FIXED TRANSMITTER T. AND R. ARE AT SEPARATE LOCATIONS. INCREASING USE.
SHIP-BORNE	"SHIP MATTRESS"	MARK 2, MODEL 1	14'x7'x1 2/3' (SIMILAR TO MOBILE MATTRESS)	187-205	A.W. S.W.	SAME AS MOBILE MATTRESS WITH A DIFFERENT ANTENNA MOUNT.
	"2-HORN TYPE"	MARK 2, MODEL 2	2 ELECTRO-MAGNETIC HORNS APPROX. 3' LONG	3000	S.W.	HORNS MAY BE IN TURNABLE. RECEIVER IS HIGHER THAN TRANSMITTER.
	"3-HORN TYPE"	MARK 2, MODEL 2 MODIFICATION 2	3 ELECTRO-MAGNETIC HORNS APPROX. 3' LONG	3000	S.F.C. S.W.	RECEIVER HORN IS REPLACED BY DOUBLE HORN ATTACHMENT
	"PARABALOID"	MARK 2, MODEL 3	PROBABLY PARABALOID	520	S.W. A.W. A.A.F.C.	(CAPTURED DOCUMENTS ONLY)
AIR BORNE		AIR MARK VI MODEL 4	VARIOUS: YAGI, DIPOLES, ARRAYS	140-160	A.S.V. A.I.	FIRST USED IN BETTY. NOW IN ALL TYPES OF PLANES WITH VARIOUS ANTENNA DESIGNS
FIRE AND SEARCHLIGHT CONTROL		MARK IV, MODEL 1 (S-3)	MATTRESS 25 3/4'x6'x4'	200	A.A.F.C. A.W.	ADAPTATION OF OUR SCR 268
		MARK IV, MODEL 2 (ALSO MODIF. 2)	PROBABLY MATTRESS	200	A.A.F.C. A.W.	SMALLER AND IMPROVED MK IV, MODEL 1 (CAPTURED DOCUMENTS ONLY)
		MARK IV, MODEL 3	4 YAGIS ON S/L 1 YAGI ON S/L CONTROLLER	200	A.A.F.C. S.L.C.	SIMILAR TO BRITISH "SLC" BUT TRANSMITTING ANTENNA SEPARATED
		MARK "TA", MODEL 1	4 YAGIS WITH TRANS. ANTENNA ATTACHED ABOVE	200	A.A.F.C.	(CAPTURED DOCUMENTS ONLY)
		MARK "TA", MODEL 2	5 YAGIS - EACH WITH REFLECTOR	200	A.A.F.C. A.W.	(CAPTURED DOCUMENTS ONLY)
		MARK "TA", MODEL 3	ELABORATE ANTENNAE SYSTEM T/R SEPARATED	75	A.A.F.C.	ADAPTATION OF BRITISH "GL" MARK 2 (CAPTURED DOCUMENTS ONLY)

15 MARCH 1945

LAND BASED - FIXED

VERTICAL VIEW

ANTENNA 26' x 18'

LOCATION High points and near sea-coast.

USE Early warning.

COMMENTS Oldest type. Still in use. Usually flat roof. Antenna and shack rotate on turntable. 100 MCS. (MK1, MODEL 1).

GUADALCANAL TYPE

LAND BASED - FIXED

VERTICAL VIEW

ANTENNA 28' x 14' x 2 1/3'

LOCATION High points and near sea-coast.

USE Early warning

COMMENTS Improved Guadalcanal Type. Box screen. Usually pitched roof. Antenna and shack rotate on turntable. 100 MCS. (MK1, MODEL 1, Modification 1).

A T T U T Y P E

LAND BASED - MOBILE

VERTICAL VIEW

ANTENNA 14' x 7' x 1 2/3'

LOCATION Often on high points and near seacoast.

USE Early warning.

COMMENTS Although mobile, this is often set in fixed emplacements sometimes in addition to other fixed types. 200 MCS. (MK1, MODEL 2).

MOBILE MATTRESS

LAND BASED - PORTABLE

VERTICAL VIEW

ANTENNA 7' x 7'

LOCATION Near airfields, etc.

USE Short range early warning.

COMMENTS Portable adaptation of airborne set (MK 6, MOD-EL 4). Difficult to interpret. 150 MCS.

MARK 6 PORTABLE

LAND BASED AND SHIP BORNE

ANTENNA Stack of 7' or 3 1/2' dipoles on mast.

LOCATION Land - Various; ships.

USE Early warning.

COMMENTS Stack of dipoles main identifying characteristic (resembles a ladder). On land, - sometimes on observation tower. On SHIP, - adapted to fit any existing masts. 150 MCS. (MK1, MODEL 3).

L A D D E R T Y P E

LAND BASED - PORTABLE OR FIXED

VERTICAL VIEW

ANTENNA Array of horizontal dipoles on mast.

LOCATION Land - Various.

USE Early warning

COMMENTS Same types have separated transmitting antenna. Mast supporting. Tent often used to cover ladder equipment and operations. 70 MCS. (MK 229 etc.)

WEWAK TYPE OR "CHI"

SHIP BORNE SEARCH

ANTENNA 14' x 7' x 1 2/3'

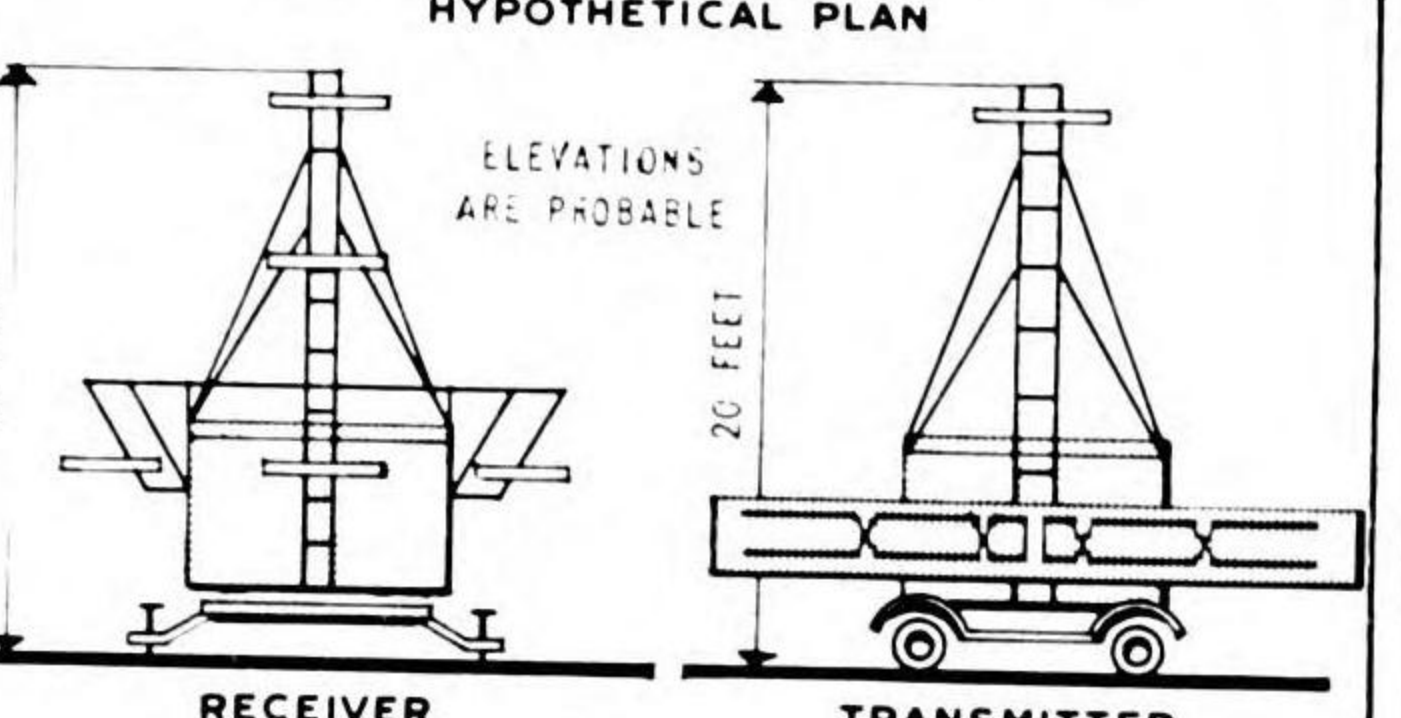

LOCATION SHIPS, - on mast or super-structure.

USE Early warning.

COMMENTS Essentially the same Radar as the land-based Mobile Mattress but has different designation. 200 MCS. (MK2, MODEL 1).

COMMUNICATIONS SUMMARY

The field of Radio Communications involves transfer of intelligence from one point to another and includes all installations from the portable high frequency station to the large multi-frequency military and pre-war station.

The interpreter is concerned primarily with fixed land based stations. Determination of the capacities and ranges of these stations involves analysis of mast types, mast heights and mast patterns.

MAST TYPES

MAST PATTERNS

MAST-FREQUENCY RELATIONSHIP (FIXED INSTALLATIONS)

	FREQUENCY	NO. MASTS	MAST HEIGHT	FREQUENCY IN MEGACYCLES PER SEC.	WAVE LENGTH	USUAL OPERATING RANGE
STICK MASTS	*VERY HIGH (LINE OF SIGHT)	1	GERMAN DECIMETRE STATIONS HAVE 160' MASTS	30 TO 300 MCS (50 TO 100 LIKELY)	10 TO 1 METER	75 MILES
	HIGH	1 TO 3	WHIP ANTENNAE OR VERY SMALL STICK MASTS	3 TO 30 MCS	100 TO 10 METERS	200 OR 8000 MILES
	MEDIUM**	2 OR MORE	50' TO 75'	0.3 TO 3 MCS	1000 TO 100 METERS	500 MILES
LATTICE MASTS	MEDIUM**	2 OR MORE	60' TO 100'	0.3 TO 3 MCS (300 TO 3000 KCS.)	1000 TO 100 METERS	500 MILES
	LOW	2 OR MORE	100' TO 500' (125' TO 300' MOST LIKELY)	0.03 TO 0.3 MCS (30 TO 300 KCS)	10,000 TO 1000 METERS	1000 MILES
	VERY LOW	3 OR MORE	400' TO 800' STICK OR LATTICE	10 TO 30 KCS	30,000 TO 10,000 METERS	5000 MILES

* Although there are many types of V.H.F. antennae in connection with portable, mobile, and airborne equipment, no fixed Japanese installations have been seen as

yet which operate at such high frequency.

** Most used for land based communication stations.

TECHNICAL STUDIES D.F. SUMMARY

DIRECTION FINDING SUMMARY

DIRECTION FINDERS: Operate on received radio signals and indicate their direction of arrival. Direction Finding is utilized primarily as a navigational aid by the Japanese but is also used for intelligence purposes.

- (c) Semi Portable:
 - High Frequency
 - Four small stick masts (poles) arranged in square.
 - Diagonal distance between poles approx. 18'.
 - Small operator's tower (7' x 7' approx.) in center of square.
 - Difficult to interpret from aerial photos

CHARACTERISTICS OF D. F. TYPES MOST USED BY JAPANESE

I ADCOCK: Four vertical antennae arranged in square pattern, diagonals oriented N-S, E-W.

2 LOOP: Medium Frequency rotating loop, (3' in diam.) housed in 11' - 12' square building. Similar to shipborne units.

- (a) Housed:
 - High Frequency
 - Antennae (dipoles) enclosed in square building, (23' x 23' roof plan).
 - Antennae located in corners of building.
 - Station may consist of one or more housed Adcocks.
 - Most D. F. centers have 3 housed Adcocks arranged in a triangle or on a straight line.

GENERAL NOTES ON JAPANESE D. F.

1. Located near airfields (and other locations).
2. Site is well cleared, fairly level and high.
3. Pattern of roads and paths connecting installations usually visible.
4. Radio communications station (reporting station) is always associated.
5. High and medium frequency set-ups are usually present in combination at important D. F. centers.
6. A Japanese D. F. center usually consists of:
 - (a) 1, 2, or 3 HF Installations or
 - (b) 1 or 2 MF Installations or
 - (c) Combinations of high and medium frequency up to a usual maximum of three high and two medium.

- (b) Open:
 - Medium Frequency
 - Four stick masts (unipoles) arranged in square pattern.
 - Small hut in center, approx. 20' square.
 - Strongly visible diagonal lines connecting antennae.
 - Diagonal distance between unipoles approx. 100'.

TABLE OF FREQUENCIES

FREQUENCY	UNIPOLE OR (DIPOLE) DIAGONAL SPACING	UNIPOLE (OR DIPOLE) HEIGHT	WAVE LENGTH IN METERS	FREQUENCY IN MEGACYCLES PER SEC.
HIGH ("HOUSED ADCOCK")	20' TO 30' (MOST ARE 25')	15' TO 25'	100 TO 10 M	3 TO 30 MCS.
MEDIUM ("OPEN ADCOCK")	90' TO 150' (MOST ARE 100')	50' TO 75'	1000 TO 100 M	0.1 TO 3 MCS.

TECHNICAL STUDIES

JAPANESE SEARCHLIGHTS

CONFIDENTIAL
15 MARCH 1945

1. M. 1933 150 cm. SEARCHLIGHT

This 150 cm searchlight, either mobile or fixed is the most commonly encountered Japanese AA light. The canvas cover often imparts a white tone on photographs.

2. M. 1930 SMALL SOUND LOCATOR

Used with the 150 cm searchlight, this sound locator was the only detector until the recent advent of radar control. A comparator (electrical remote control) is used with the sound locator.

3. MK. IV, MOD 3 RECEIVING ANTENNA

Captured photograph of the MK. IV, Mod. 3 radar receiver. The receiving antenna consists of 4 Yagis mounted on a 110 cm. searchlight.

4. MK. IV, MOD 3 TRANSMITTING ANTENNA

Captured photograph of the MK. IV, Mod. 3 radar transmitter. The rotating mount consists of Yagi antennae, radar equipment, and operator's seat. This equipment was captured in the Mariana and Palau Islands.

CIRCULAR REVETMENT

PLAN

DIMENSIONS Interior diameter: 8' to 35', 30 diameter most common.

LOCATION Clearings, open waterfront areas, ridges, near heavy AA.

REMARKS The most common type of searchlight emplacement.

DOUBLE WALL REVETMENT

PLAN

DIMENSIONS Outer walk: 35' diameter, inner space: 15' diameter.

LOCATION Clearings, promontories, near heavy AA.

REMARKS Designed for manual operation of the 150 cm. light with extended hand control.

CIRCULAR SOUND LOCATOR REVETMENT

PLAN

DIMENSIONS 35' diameter (inner rim)

LOCATION Generally within 100' to 150' of circular or double wall searchlight revetments.

REMARKS Concave cross section for acoustical efficiency.

CONFIDENTIAL
15 MARCH 1945

TECHNICAL STUDIES

JAPANESE SEARCHLIGHTS

CIRCULAR PLATFORM

DIMENSIONS 12' diameter.

LOCATION Island perimeters, near heavy AA - especially 127 mm.

REMARKS Prefabricated steel construction. Generator equipment may be housed under the platform.

PLAN

RECTANGULAR PLATFORM

DIMENSIONS 10' x 12' or 12' x 12'

LOCATION Island perimeters, near heavy AA - especially 127 mm.

REMARKS Reinforced concrete or wooden frame. May house generator equipment.

PLAN

RAISED REVETMENT

DIMENSIONS Revetment diameter: 12' to 15', outermost diameter: 40' to 50'.

LOCATION Flat areas, island perimeters, ridges, near heavy AA.

REMARKS Earth or sand bag construction. May house generator equipment.

PLAN

98 cm. TRUCK MOUNTED LIGHT

DIMENSIONS Length: 19'.

LOCATION Complete mobility.

REMARKS Easily concealed or camouflaged. Self-contained source of electricity.

PLAN

GENERATOR TRUCK

DIMENSIONS Length: 18'.

LOCATION Near any type of searchlight emplacement.

REMARKS Commonly emplaced in rectangular revetments, roadside excavations.

NAVIGATIONAL AIDS SUMMARY

CONFIDENTIAL
15 MARCH 1945

NAVIGATIONAL AIDS SUMMARY

Navigational aids are electronics installations that transmit signals for position finding purposes. Known Japanese installations transmit one or more radio beams for guiding mobile units, such as ships or planes, to target or home base. These include radio range stations, communi-

cations stations, single radiating lattice masts, portable beam transmitters, and various ship navigational aids. In addition, the Japanese use Direction Finders as aids to navigation. These are treated separately in this supplement.

RADIO RANGE STATIONS FOR AIRCRAFT

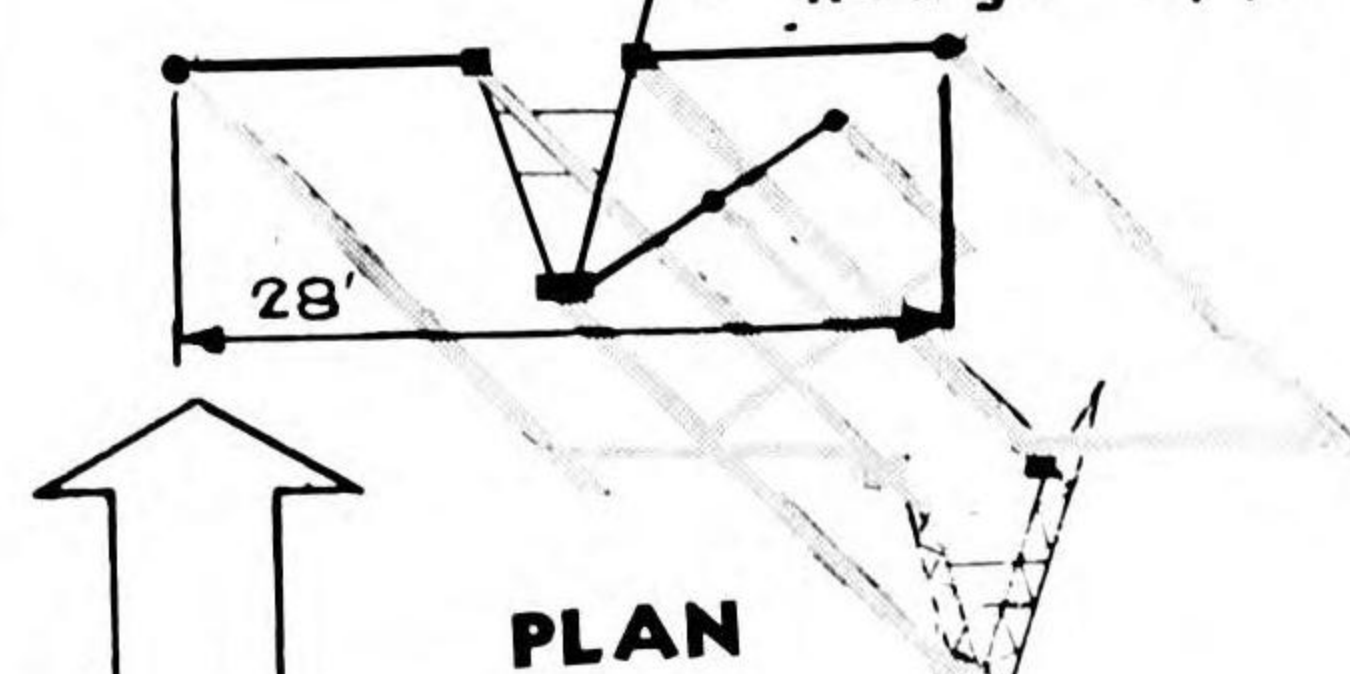

- Five lattice masts, 200' ± High
- Capable of transmitting one or several beams to any point of compass.
- Range 200 - 400 miles.

R. F. - 1/1000

NAVIGATIONAL AIDS FOR SHIPS

- Two types observed to date:
- KISKA
 - Poor design
 - Operates at 60-70 Mcs.
 - Range approx. 100 miles.

FOREWORD

Purpose of Report:

1. To compile a pictorial reference on Japanese Electronics installations.
2. To develop Photographic Interpretation techniques for extracting needed information on Electronics from aerial photographs.
3. To present coordinated Electronics information in combination with Photographic Interpretation data in order to supply maximum intelligence on enemy installations.

Additional looseleaf pages will be issued to holders of this report at such times as important new information becomes available.

INTRODUCTION

GLOSSARY

Collectors	Antennae used in connection with D. F.
Echo	A radar pulse returned to its source by reflection from a solid surface.
Dipole	Pole or rod antennae fed at middle of pole or rod.
Ground clutter	Signals on a radar indicator caused by reflections of transmitted pulses from land or cultural features.
Indicator	The radar scope or screen on which signals are visually presented.
Kilocycle	1000 cycles.
Lobe	A definite beam of radiation emitted by a radar antenna.
Lobe switching	Method of electrical operation in certain fire control radars for getting fix on plane.
Mast	Term used for vertical member which supports antennae used in connection with radio installations. Stick mast - Single trunk made of wood or steel and may be guyed. Lattice mast - Mast designed of several members, assembled in a criss-cross pattern for height and strength. Usually of steel but may be wood.
Megacycle	1,000,000 cycles (or 1000 kilocycles).
Permanent echoes	(See ground clutter).
Propagation	The manner in which radar waves travel along the earth.
Pulse	Radiation (of radar waves) emitted in short burst.
Radiating mast	Metal mast which acts as antenna in itself.
Range marks	Linearly spaced marks on the indicator for estimating the ranges of targets.
Refraction	Bending of a radar beam by air strata of differing densities.
Scope	(See Indicator).
Sensing Antenna	Central antenna used with an Adcock D. F.
Trace	Line of light on the indicator caused by the oscillating spot.
Unipole	Pole or rod antennae element fed at end of pole or rod.
Frequency (Kcs) =	$\frac{\text{Speed of light (meters)}}{\text{Wave length (meters)}}$

GENERAL

It was found necessary in creating a report of this type, to make numerous interpretations in widely separated areas throughout the world. In some few cases, conclusions drawn are not in complete agreement with other reports on the same installations.

In most cases methods of reasoning and assumptions on which the interpretations were based are set forth in the various section of this report.

It is the announced aim of the study to create, record and disseminate an "interpretation approach" and techniques for locating and classifying Japanese Electronics installations.

It follows, then, that the study may serve the Armed Forces best if it is (1) accurate, (2) clearly catalogued and indexed, and (3) represents a common language for use of interpretation and electronics officers.

It is requested, therefore, that any differences of opinion, errors found or additional information be directed to the Photographic Interpretation Center. Additions and corrections will be made in looseleaf form and forwarded immediately for inclusion in all copies of this report.

CONFIDENTIAL

INTRODUCTION

JAPANESE ELECTRONICS

Prepared November 1944, replaces "Japanese Radio-Radar and Related installations" (P.I.C. No. 2 - 5/6/8/9/-K-1/44) and is a revised and enlarged edition of the latter. (Certain examples of German Electronics are included because of German equipment and technicians available for Japanese use.)

For further and detailed information on Japanese electronics equipment see Naval Research Laboratory Report #RA3A215B entitled: "Technical Data on Japanese Radio and Radar Equipment."

This report deals mainly with four distinct types of electronics installations. The interpreter should clearly understand the exact functions of each.

RADAR

(Radio Detecting and Ranging)

1. Transmits and receives.
2. Provides early warning of approaching aircraft and surface vessels.
3. Used in connection with gunfire to give accuracy of range and deflection (called "Fire Control" type).
4. May be used for Navigational purposes.

COMMUNICATIONS

("Radio")

1. Transmits and receives spoken word or code.

DIRECTION FINDERS

(Receives Radio Signals)

1. Detects radio and records range and direction.
2. Aid to Navigation - It is believed this is a primary use of Japanese installations.

NAVIGATIONAL AIDS

(Navigational Beam)

1. Transmits radio signals creating a "beam" for guiding ships and planes to home base or to bombing target.

Tendencies towards standardization are an inevitable outgrowth of development, especially in the electronics field. Because of this, the interpreter's job with respect to newly covered installations becomes easier in direct proportion to his familiarity with the old or captured installations.

It is with this purpose in mind that a large number of photographic examples of known installations are included and an attempt made to group them in a logical manner, reflecting their use in waging war.

Frequencies are given in connection with all installations, to enable the interpreter to check his visual interpretation against frequency data obtained from radio signals picked up from any particular area.

CONFIDENTIAL

SCALE

In order to establish a more realistic yardstick of the possibilities of electronics interpretation, the following table of photographic scales is prepared.

The first column represents the smallest scale at which the object may usually be recognized.

The second column suggests a scale at which a good detailed interpretation can usually be made.

It is assumed that good quality prints are available and that the interpreter knows what he is looking for.

RADAR	RECOGNITION	DETAIL
Fixed types	1/10000	1/5000
Mobile types	1/8000	1/5000
Fire Control	1/5000	1/2000
COMMUNICATIONS		
Lattice masts	1/15000	1/8000
Stick masts	1/10000	1/5000
DIRECTION FINDERS		
Open Adcock	1/18000	1/11000
Housed Adcock	1/15000	1/10000
Portable or unusual types	1/8000	1/5000
NAVIGATIONAL AIDS		
Vary considerably in size and type.		

FREQUENCIES

RADAR	VHF, UHF, SHF (30-30000 Mcs.)
COMMUNICATIONS	VLF, LF, MF, HF, VHF (0.01-30 Mcs.)
DIRECTION FINDERS	MF, HF (0.3-30 Mcs.)
NAVIGATIONAL AIDS	LF, MF, HF, VHF (0.03-300 Mcs.)

In general: low frequencies indicate long ranges; high frequencies indicate short ranges. This is true of all types of electronics shown.

STANDARD FREQUENCY TABLE

SHF -- Super High Frequency	3000-30000 Mcs. ("microwave")
UHF -- Ultra High Frequency	300-3000 Mcs.
VHF -- Very High Frequency	30-300 Mcs.
HF -- High Frequency	3-30 Mcs.
MF -- Medium Frequency	300-3000 Kcs. (0.3-3 Mcs.)
LF -- Low Frequency	30-300 Kcs. (0.03-0.3 Mcs.)
VLF -- Very Low Frequency	10-30 Kcs. (0.01-0.03 Mcs.)
D. F. --	Direction Finder.

SECTION-1

1.01 - 1.99

RADAR

CONFIDENTIAL

In an effort to eliminate confusion with respect to Japanese Radar Designations, the following table is included. In cases where popular names have developed, the popular name is used for page headings.

JAPANESE RADAR DESIGNATIONS

POPULAR NAME	JAPANESE TEMPORARY DESIGNATION	JAPANESE ABBREVIATED DESIGNATION
"Guadalcanal" type	Mark 1, Model 1	Mark 11
"Attu" type	Mark 1, Model 1, Modification 1	Mark 11
"Mobile Mattress"	Mark 1, Model 2	Mark 12
"Mark 6 Portable"	Air Mark 6 "Special"	?
"Mark 13 Portable"	Mark 1, Model 3	Mark 13
"Wewak Yagi"	"YA"	Mark B ?
"Chi"	"Chi"	Mark 229
"Ship Mattress"	Mark 2, Model 1	?
Ship "2-Horn" type	Mark 2, Model 2	Mark 51
Ship "3-Horn" type	Mark 2, Model 2 Modification 2	Mark 61
"Parabaloid"	Mark 2, Model 3	Mark 52

_____	Mark "TA", Model 2	?
_____	Mark "TA", Model 3	?

RADAR SUMMARY

In principle, all Radar systems are alike, although individual installations may vary widely in physical aspects as well as tactical use. Examples of land based, airborne, and ship mount radar are shown and discussed in this section.

Simply stated Radar is an electronic device which emits continuous stream of radio waves of extremely high frequencies (70 to 30,000 Mcs.) which, when reflected back from a dense obstruction in their path, are received and presented on a cathode ray tube to record position and range of that obstruction in a visual manner.

Each installation both transmits and receives.

Radar will not penetrate land forms, buildings, ships and planes, and, therefore records them by reflection. Generally, Radar will penetrate clouds and foliage, however, rain-laden dense cumulus clouds may be picked up, as may be dense forest.

Radar waves travel in a straight line except for atmospheric refraction which bends the beam earthwards, and which is important beyond the 20 mile range. Very little is known as yet concerning the exact effects of refraction (called "propagation"). However, it is considered reasonable, in order to plot radar waves as a straight line, to regard the earth as being $\frac{4}{3}$ of its actual diameter when calculating the effect of curvature of the earth on radar "shadows" under "standard" weather conditions.

LAND BASED SEARCH RADAR

The Japanese often locate search radar on high points in mountainous areas, and on a high concrete base in low flat areas. This enables the radar to search greater ranges close to the earth's surface. Radar sites are very often near the seacoast.

When two Radars are used in close proximity it is likely to be for the following reasons:

1. One may search while the other tracks objective.
2. Two may be required to complete coverage of all required sectors of search.
3. The additional set may be erected as a supplementary installation in the event of damage or malfunctioning of the first set.

It is important that interpreters learn to associate the graphic appearance and sizes of Radar types with their known frequency band, for as information on signals received is usually available, it is possible to make a positive and exact identification in this way.

INTERPRETATION FEATURES

1. Size and shape of screen.
2. Blast wall sometimes present (example: Kiska).

CONFIDENTIAL

3. Often mounted on high concrete base, particularly low coral islands (example: Makin).
4. Generator building often visible (example: Marcus).
5. May be found as twin installation (example: Kiska).
6. Site will be free from dense obstructions in area of required coverage.

REPORTING ON SEARCH RADAR

In Photographic Interpretation reports on radar installations, the following information is desirable :

1. Exact location and elevation above sea level.
2. Probable area of search (nearby obstructions etc.).
3. Height of screen above ground.
4. Generator Building location - if visible.
5. Size and shape of screen (note particularly if parabolic or horn.)
6. Operation of screen.
 - (a) fixed
 - (b) rotates
 - (c) elevates
 - (d) tips upward
7. Design of base for screen.
8. Probable use of installation.
9. Type of radar - if known.
10. Frequency, Pulse Length, Pulse Frequency.

RANGE

Ranges of Radar equipment cannot be cited in exact figures due to variations caused by weather conditions, size of objective, radar operators skill etc. However, rough ranges are given in connection with each type in the following pages.

The concern of the Japanese with respect to Radar and its development and use is expressed in the following excerpt from a captured Japanese notebook, probably written from a class lecture early in 1944.

"The value of radar (in firing action) is tremendous. We must quickly marshal its full capabilities since it is the very essence of the present war of science. Great advantages can be gained by progress in radar. Those responsible for meeting the present war situation in its tactical phases must examine the essential elements and endeavor to obtain maximum efficiency in both men and equipment in the Imperial Navy. A glance at the present condition of the fleet reveals that the ships of those with an active interest (TN: in radar) are well-equipped in all essential details and the accuracy of some of the equipment has exceeded all expectations. On the other hand there are many who lack confidence in its use and feel that radar is a white elephant on their hands. We must strive all the more for the perfection of radar by further research and training."

RADAR

SUMMARY (CONT.)

TABLE OF IMPORTANT JAPANESE RADAR TYPES

A.S.V. - AIRPLANE SEARCH FOR SURFACE CRAFT
A.I. --- AIRBORNE INTERCEPT

NOTE: IN ADDITION TO THE ABOVE, GERMAN RADAR TYPES MAY BE FOUND IN USE IN JAPANESE CONTROLLED AREAS.

RADAR SUMMARY

The following diagrams were prepared by the Special Devices Division of the Bureau of Aeronautics, Navy Department, for use in connection with terrain models and special R.P.D. equipment.

They are included here because they constitute a rapid way of estimating enemy radar coverage, with or without the use of terrain models.

Charts, prepared by Gen. Hq., S.W.P.A., are available for plotting Japanese Radar coverage and propagation according to type of Radar and number of A/C in formation.

Curvature can be neglected within 20 miles of the radar site, and outside of that range relatively few curvature computations are required. These computations fall into two simple classes:

CASE 1: OPEN SEA BETWEEN RADAR AND OBJECT. In this case no shadow will be present on the flat model. Referring to diagram, if "h" is greater than the height above sea level of the terrain at "P", no ground echo will appear on the radar.

HOW TO USE NOMOGRAPH

Pass a ruler through the points on the two vertical lines representing known quantities, and read off the solution at the intersection of the third line with the ruler.

Example: If the radar is at 1250 feet, the shadow height at 200 miles is found by lining up the ruler with "d" = 1250 and "R" = 200. The ruler will then pass through "h" = 11,250 feet, which is the solution.

RADAR SUMMARY

CASE 2: SHADOW CAST BY A TERRAIN FEATURE IN THE FOREGROUND. In this case the shadow edge at a point "P" will be raised by earth curvature by an amount which depends on the range of "P" and the distance between "P" and the feature which casts the shadow. Referring to page 42, if the amount which the mountain at "P" protrudes above the shadow edge on the flat model is less than the computed "h", the effect of curvature will be to remove the mountain from the beam.

Whenever a hill is found to disappear into shadow as a result of curvature computations, a shadow cannot be cast by this hill on objects still more distant. Should such a problem arise, elevate the hill with a pencil or any convenient object to the computed shadow edge, and use the new shadow (cast on the more distant object by the pencil) as the basis for making a case 2 computation.

Note: In rare cases, it may be difficult to decide whether case 1 or case 2 applies. In such circumstances apply both, and take the higher of the two computed shadows.

$h = 1/2 RD$

R = RANGE OF "P" FROM RADAR.
D = DISTANCE FROM "P" TO "Q".
h = ADDITIONAL SHADOW-HEIGHT AT "P" DUE TO CURVATURE.

Example: Suppose the distant point "P" is at a range of 200 miles, and the object casting a shadow on "P" is at a distance of 150 miles from "P". Passing the ruler through "R" = 200 and "D" = 150, the answer "h" = 15,000 feet will appear at the intersection of the ruler and the center scale.

RADAR GUAD. TYPE

The first captured Japanese Radar, found on Guadalcanal, is shown on this page.

The antenna is five "elements" (half-wave dipoles) wide. Each section is 2 dipoles high. Polarization is horizontal (i.e. The dipoles lie horizontally rather than vertically). The screen is backed with chicken wire type mesh. This equipment has a frequency of 96.5 to 103 Mcs. It is primarily for early warning of aircraft approach and gives range and bearing with a maximum range of 50 to 60 miles for high-flying aircraft. The antenna rotates with the shack to which it is attached but does not elevate. The shack is motor-driven. The screen framework and shack are of wood construction.

Drawing of Guadalcanal type screen with steel framework, which typifies all later models.

LOCATION	GUADALCANAL
TYPE	(MARK I, MODEL I) "GUADALCANAL"
ANTENNA	26' x 18'
FREQUENCY	100 MCS
P.R.F.	880 - 1200 PULSE 12 - 30
MAXIMUM RANGE	60 N. MI.

CONFIDENTIAL

GUADALCANAL, SOLOMONS

RADAR

GUAD. TYPE (CONT.)

KISKA, ALEUTIANS (R.F. - 1 1200)

ABOVE: note strong screen shadows. Generator building not present, power coming from a removed source. Revetment 1 foot high and 32 feet in diameter. Distance between screens is 130 feet.

KISKA, ALEUTIANS (R.F. - 173600)

The Guadalcanal type radar is now constructed as shown on this page, with a metal screen framework.

Both localities afford examples of twin installations, where one set may be used for search while the other tracks a specific target.

Screen is 28 feet wide and 18 feet high. Control shack, which rotates with screen, is 10' x 10' with an additional small square projection on side opposite screen.

LOCATION KISKA

 ANTENNA 26' x 18'
 FREQUENCY 100 MCS
 P.R.F. 880 - 1200 PULSE 12 - 30
 MAXIMUM RANGE 75 N. MI.

On this page are shown three more localities having Guadalcanal type Radar, similar to those at Kiska and Kwajalein. On coral islands the required height for installation is sometimes obtained by mounting set atop existing buildings. Note particularly the small square appendage on back of control shack.

RADAR

GUAD. TYPE (CONT.)

(R.F. - 1/9000)

MARCUS

(R.F. - 1/4000)

LOCATION MARCUS
 TYPE (MARK I, MODEL I) "GUADALCANAL"
 ANTENNA 26' x 18'
 FREQUENCY 100 MCS
 P.R.F. 880 - 1200 PULSE 12 - 30
 MAXIMUM RANGE 75 N. MI.

The above twin Radar installation at Marcus is located near the D. F. Station. The generator building is centrally located and is approximately 12 feet square.

In this case, one Radar may be used for search while the other tracks.

(R.F. - 1/3000)

LOCATION NAURU
 TYPE (MARK I, MODEL I) "GUADALCANAL"
 ANTENNA 26' x 18'
 FREQUENCY 100 MCS
 P.R.F. 880 - 1200 PULSE 12 - 30
 MAXIMUM RANGE 75 N. MI.

This installation at Nauru was once thought to have had a parabolic screen. However, it is now believed that the equipment functions in a similar manner and at the same frequency as the "Guadalcanal" type.

Previously, this set was shown as an example of a separate type of Japanese Radar, called "Nauru type". However in light of present information it seems more fitting to include it under Guadalcanal type.

This submarine photo of Shikoku, Japan, shows the faint outlines of a screen which is probably the Guadalcanal type radar. Identification cannot usually be based on such meager information, however. (Below)

SHIKOKU, JAPAN

LOCATION RABAUL
 TYPE (MARK I, MODEL I) "GUADALCANAL"
 ANTENNA 26' x 18'
 FREQUENCY 100 MCS
 P.R.F. 880 - 1200 PULSE 12 - 30
 MAXIMUM RANGE 75 N. MI.

At the present date it is more likely that the Mobile Mattress, Attu, and other new types will be found in greater numbers than the Guadalcanal type.

The Stereo oblique to the left is a remarkably clear example of the "Guadalcanal" type. Note the projection of rows of dipoles from the front of the screen, which is two-dimensional and does not have a box-like character such as may be observed in "Attu" type shown on other pages later in this section. The flat roof on the control shack is characteristic of the Guadalcanal type. Note also that clearing of surrounding vegetation is not necessary for operation of this Radar.

RADAR

GUAD. TYPE (CONT.)

The Kuku Point Radar is apparently a slightly different version of the Guadalcanal type. The bend as shown in the artist's drawing is approximately 25 degrees from a straight line. The low revetment suggests Kiska installations but is much smaller in diameter.

LOCATION KUKU PT., WAKE
 TYPE (MARK I, MODEL I) "GUADALCANAL"

 MAXIMUM RANGE 75 N. MI.

RADAR

ATTU TYPE

This radar, hereafter called the "Attu" type, was in an unassembled state when first found at Attu, Aleutians.

Electrically, it is very similar to the Guadalcanal type but is, in general, an improved modification. As of November 1944, it is still being used by the Japanese to a considerable extent in all areas.

The most important identification factor, the box screen, is not present in these photos. Spotting of radar positions in aerial photos is largely dependent on screens and screen shadows. Below are shown drawings reconstructing the "Attu" type radar, shown on this and several following pages.

ATTU, ALEUTIANS

ATTU, ALEUTIANS

(R.F. - 1/8000)

The first example found of the Attu type Radar was still in the process of construction. These views will illustrate the extreme difficulty of spotting radar without its best identifying characteristic -- the screen. Shown below is a well camouflaged generator house, also very difficult to detect in aerial photos.

MAKIN, GILBERTS

ABOVE: Radar on South Coast. Concrete base is 8 feet high.

The two Radar installations on Makin are of the same design as at Tarawa and were installed in October 1943. The control shacks rotate with the screens on steel turntables to afford complete search coverage.

The high concrete bases afford greater range for surface search.

RADAR

MOBILE MATTRESS

A later, and apparently more efficient, Radar type is the "Mobile Mattress" or "Mark I, Model II". The Radar operates at 200 mcs. and is identified by a small screen (14' x 7') mounted on a Japanese standard army trailer (type 94).

This Radar is being used more and more for land-based search, either alone or in conjunction with older types. It is frequently seen mounted in emplacements, suggestive of a permanent siting.

Below are reconstructed drawings made from photos of the Kwajalein set.

The shack, antennae, revolving mount and trailer may be separated for shipping purposes.

SHACK AND SCREEN ROTATE ON TURNTABLE

MARK 6 PORTABLE

ABOVE AND LEFT COLUMN: This portable Radar ("Mark 6 Portable") is an adaptation of the same set used in aircraft for search (Mark 6, Model 4), and its characteristics are believed to be similar to the original airborne model. When in operation, the Radar gear, shown at lower left, rests on the lower shelf and the whole is supported by a collapsible tripod. The dipoles are approximately 7 feet long. This set was found on Guam.

RIGHT COLUMN: The "Mark 13 Portable", (temporary designation Mark 1, Model 3) is believed to be essentially the same set as the "Mark 6 Portable" with certain modifications including higher power and greater range. The mode of construction at the site may vary considerable with this Radar. The above ground shot shows improvised antenna at Saipan. At Goerango Point, Morotai, the antenna, all equipment and control shack were mounted on a tower 30 feet in height. Note that in both cases, however, the antenna consists of a stack of dipoles.

WEWAK TYPE

WEWAK TYPE

WEWAK TYPE

Information on the exact designations, characteristics and use of the 70 megacycle Radars are not entirely clear at this time. However, they may be reasonably broken down into two main subdivisions:

(1) A transportable (possibly mobile) type which was first seen at Wewak in 1943 and which has been called the "Wewak" type or "Ya".

(2) A type which may be transportable but entails the use of a separated small non-directional transmitter which is fixed (often attached to the trunk of a tree under the foliage). This type is known as "Chi" or Mark 229.

TYPE ("YA")	"WEWAK"
ANTENNA	20' x 7' x 4'
FREQUENCY	70 MCS
P.R.F. 750 PULSE	25 - 35
MAXIMUM RANGE	125 N. MI.

The best recognition feature for the 70 megacycle Radars is the 20' array set on top of a pole. Rough dimensions are as follows: Overall length of row of dipoles - 20'; length of dipoles - 7'; vertical separation between rows of dipoles - 7'; overall height above ground - 25'. The entire shaft and dipoles rotate.

This equipment has the greatest range of most known Japanese Radars now in production and undoubtedly enjoys wide usage in certain areas for early warning purposes. It possesses the advantages of being transportable and is easily camouflaged.

TYPE (MK 229)	"CHI"
ANTENNA	20' x 7 1/4' x
FREQUENCY	70 MCS

SHOKAKU CV

NAVAL TENDER

There are two basic Radar types in use by the Japanese Navy afloat at the present time. One is a 200 Mcs. search Radar with a mattress type antenna, the other is a 3000 Mcs. Radar for surface search and surface fire control, using electromagnetic horns. (A 150 mcs. Search Radar has been reported)

Search Radar has been photographed many times on Japanese naval vessels and is usually located at the highest point of the ship, except on aircraft carriers, where there are two sets. This search Radar is Mark 2, Model 1 or "Ship Mattress" and is designed primarily for early warning against planes.

TAIHO CV

"A" - Two Mark 2, Model 1 antennae, one mounted forward and the other abaft the island of the CV "Taiho", new Japanese carrier.

"B" - Two Medium Frequency Loop Type Direction Finders.

"C" - Mark 2, Model 1 antenna mounted on top of the island superstructure of the CV Shokaku. (See left)

The "Ship Mattress" or Mark 2, Model 1 antenna (see drawing below) is thought to be almost identical to that of the "Mobile Mattress", a land based Radar. This type is believed to be the most widely used, at present, for shipborne air warning equipment.

SHIP MATTRESS ANTENNA

CV TAIHO, DETAIL OF ISLAND

RADAR

SHIP BORNE TYPES

Drawings of the Electromagnetic horn antennae of the Mark 2, Model 2 Radar are shown on this page.

The Japanese have met with many difficulties in the early development of this "micro-wave" set. Nevertheless, it is now believed to be functioning in a satisfactory manner. P.O.W.'s have reported that it is now used widely throughout the fleet with good results. In that the information on which these drawings were based (lower right) is now over a year old, changes in appearance are quite possible.

However, the configuration will undoubtedly consist of horns similar to the drawings shown on this page. The horn dimensions and the design of the turntable may vary somewhat.

Excerpt from a captured Japanese notebook, probably written from class lecture early in 1944, presents the Japanese problem in Naval Radar. The lecturer is discussing the use and development of Mark 2 Model 1, "Ship Mattress" Radar.

"However it was immediately apparent that it would be difficult to use the set for fire control since this would require range and bearing accuracy beyond the scope of a set designed primarily as a warning device. Nevertheless, the exigencies of war demanded that this set be used for other purposes than those of a mere warning device. Since the set was to be used for fire control, the improvement of range and bearing accuracy was given top priority and the present supplementary equipment was placed in trial production. With the addition of this equipment, the expected results were obtained, but though its sensitivity was enough for a set designed primarily as a warning device, it was still not accurate enough for effective fire control making fullest use of measurement data. It is hoped that great improvements in performance may be expected with the early production of radar designed solely for fire control. (ED: Probably Mk. 2, Model 2, Modif. 12)

But in the present stage of the war we must get the most out of our present equipment, and not vainly discuss the possibilities for the future. Various methods of dealing with this problem are now under study."

Recent P.O.W. information indicates that many types of Naval Vessels are now equipped with Mark 2, Model 2 and modifications. Knowledge of the present status and performance of the equipment is still somewhat hazy, but interpreters should examine all ships for presence of electro-magnetic horns.

In most vessels, the likely location for the horns is near the top of the foremast or forward superstructure. On aircraft carriers, they will be high on the island and on subs, close to the conning tower.

It should be kept in mind that Mark 2, Model 2, with modifications or attachments, may be used either for surface search or surface fire control. It is believed that the fire control function requires three horns. The Mark 2, Model 2 set is known as a "micro-wave" Radar, designed for sensitive readings and accurate plotting of surface craft and not for great range.

All information on this page is taken from P.O.W. and captured document sources.

AIR BORNE TYPES

EMILY

EMILY, large Japanese Patrol Bomber, has a linear array in the forward part of the hull.

All plane types probably contain the same Radar equipment, designated as "Mark VI, Model 4", and operating at 150 mcs., with range of approximately 75 nautical miles.

Japanese Airborne Radar antennae can often be detected from aerial photographs. The Japanese probably have but one airborne model in wide use at present (MARK VI, MODEL 4), but a variety of types and locations of antennae are used. This is a search Radar.

Antennae may be a Yagi, dipole, or linear array, and may be located in the nose, leading edge of wing, or side of fuselage.

Undoubtedly, several other types will be forthcoming soon, particularly for use in night fighters.

BETTY, Japanese Medium Bomber, was the first to use Airborne Radar. The antennae consists of a nose Yagi and a small "H" shaped arrangement on the side of the fuselage.

RADAR

FIRE CONTROL (MK. IV, MOD. 3)

Japanese land-based Fire Control Radar is now coming into general use. Although information is sketchy and incomplete as to the types that may be most used, facts and pictures which are now available are shown and discussed on these pages. At this time there are apparently three basic trends in Japanese Fire and Searchlight Control Radar:

(1) Models based on British "SLC" (Yagi antennae mounted on a searchlight, which was probably captured on Singapore).

(2) Models based on the United States SCR268, probably captured on the Philippines.

(3) Models based on British GL, Mark 2, which uses separated transmitter and receiver installations with elaborate arrays.

In addition to these general types, the possibility of the Japanese developing a copy of the German Wurzburg for land-based fire control must be kept in mind.

The Japanese designation of the installation shown on this page is "Mark IV, Model 3". It is a 200 mcs Radar consisting of two parts: (1) The Transmitter (mounted on a searchlight controller), which supports one row of Yagi antennae on an elevated cross arm. The whole mount, including antenna and operator's seat, rotates, and the antenna tips up and down. Radar equipment is on either side of the operator.

(2) The Receiving antenna, consisting of 4 Yagis mounted on a type 96 110 cm. searchlight. (See below, right.) It is lobe switched at 25 per second. Note that searchlight shown here is mounted on a hut.

The pictures shown here are of the first fire control equipment captured in the Pacific war, and indicate an adaptation of the British S.L.C. In these examples, it will be noted that the transmitting and receiving antennae were on separate mounts at separate locations.

TRANSMITTER MOUNT

RADAR

(MK. TA., MOD. I) FIRE CONTROL

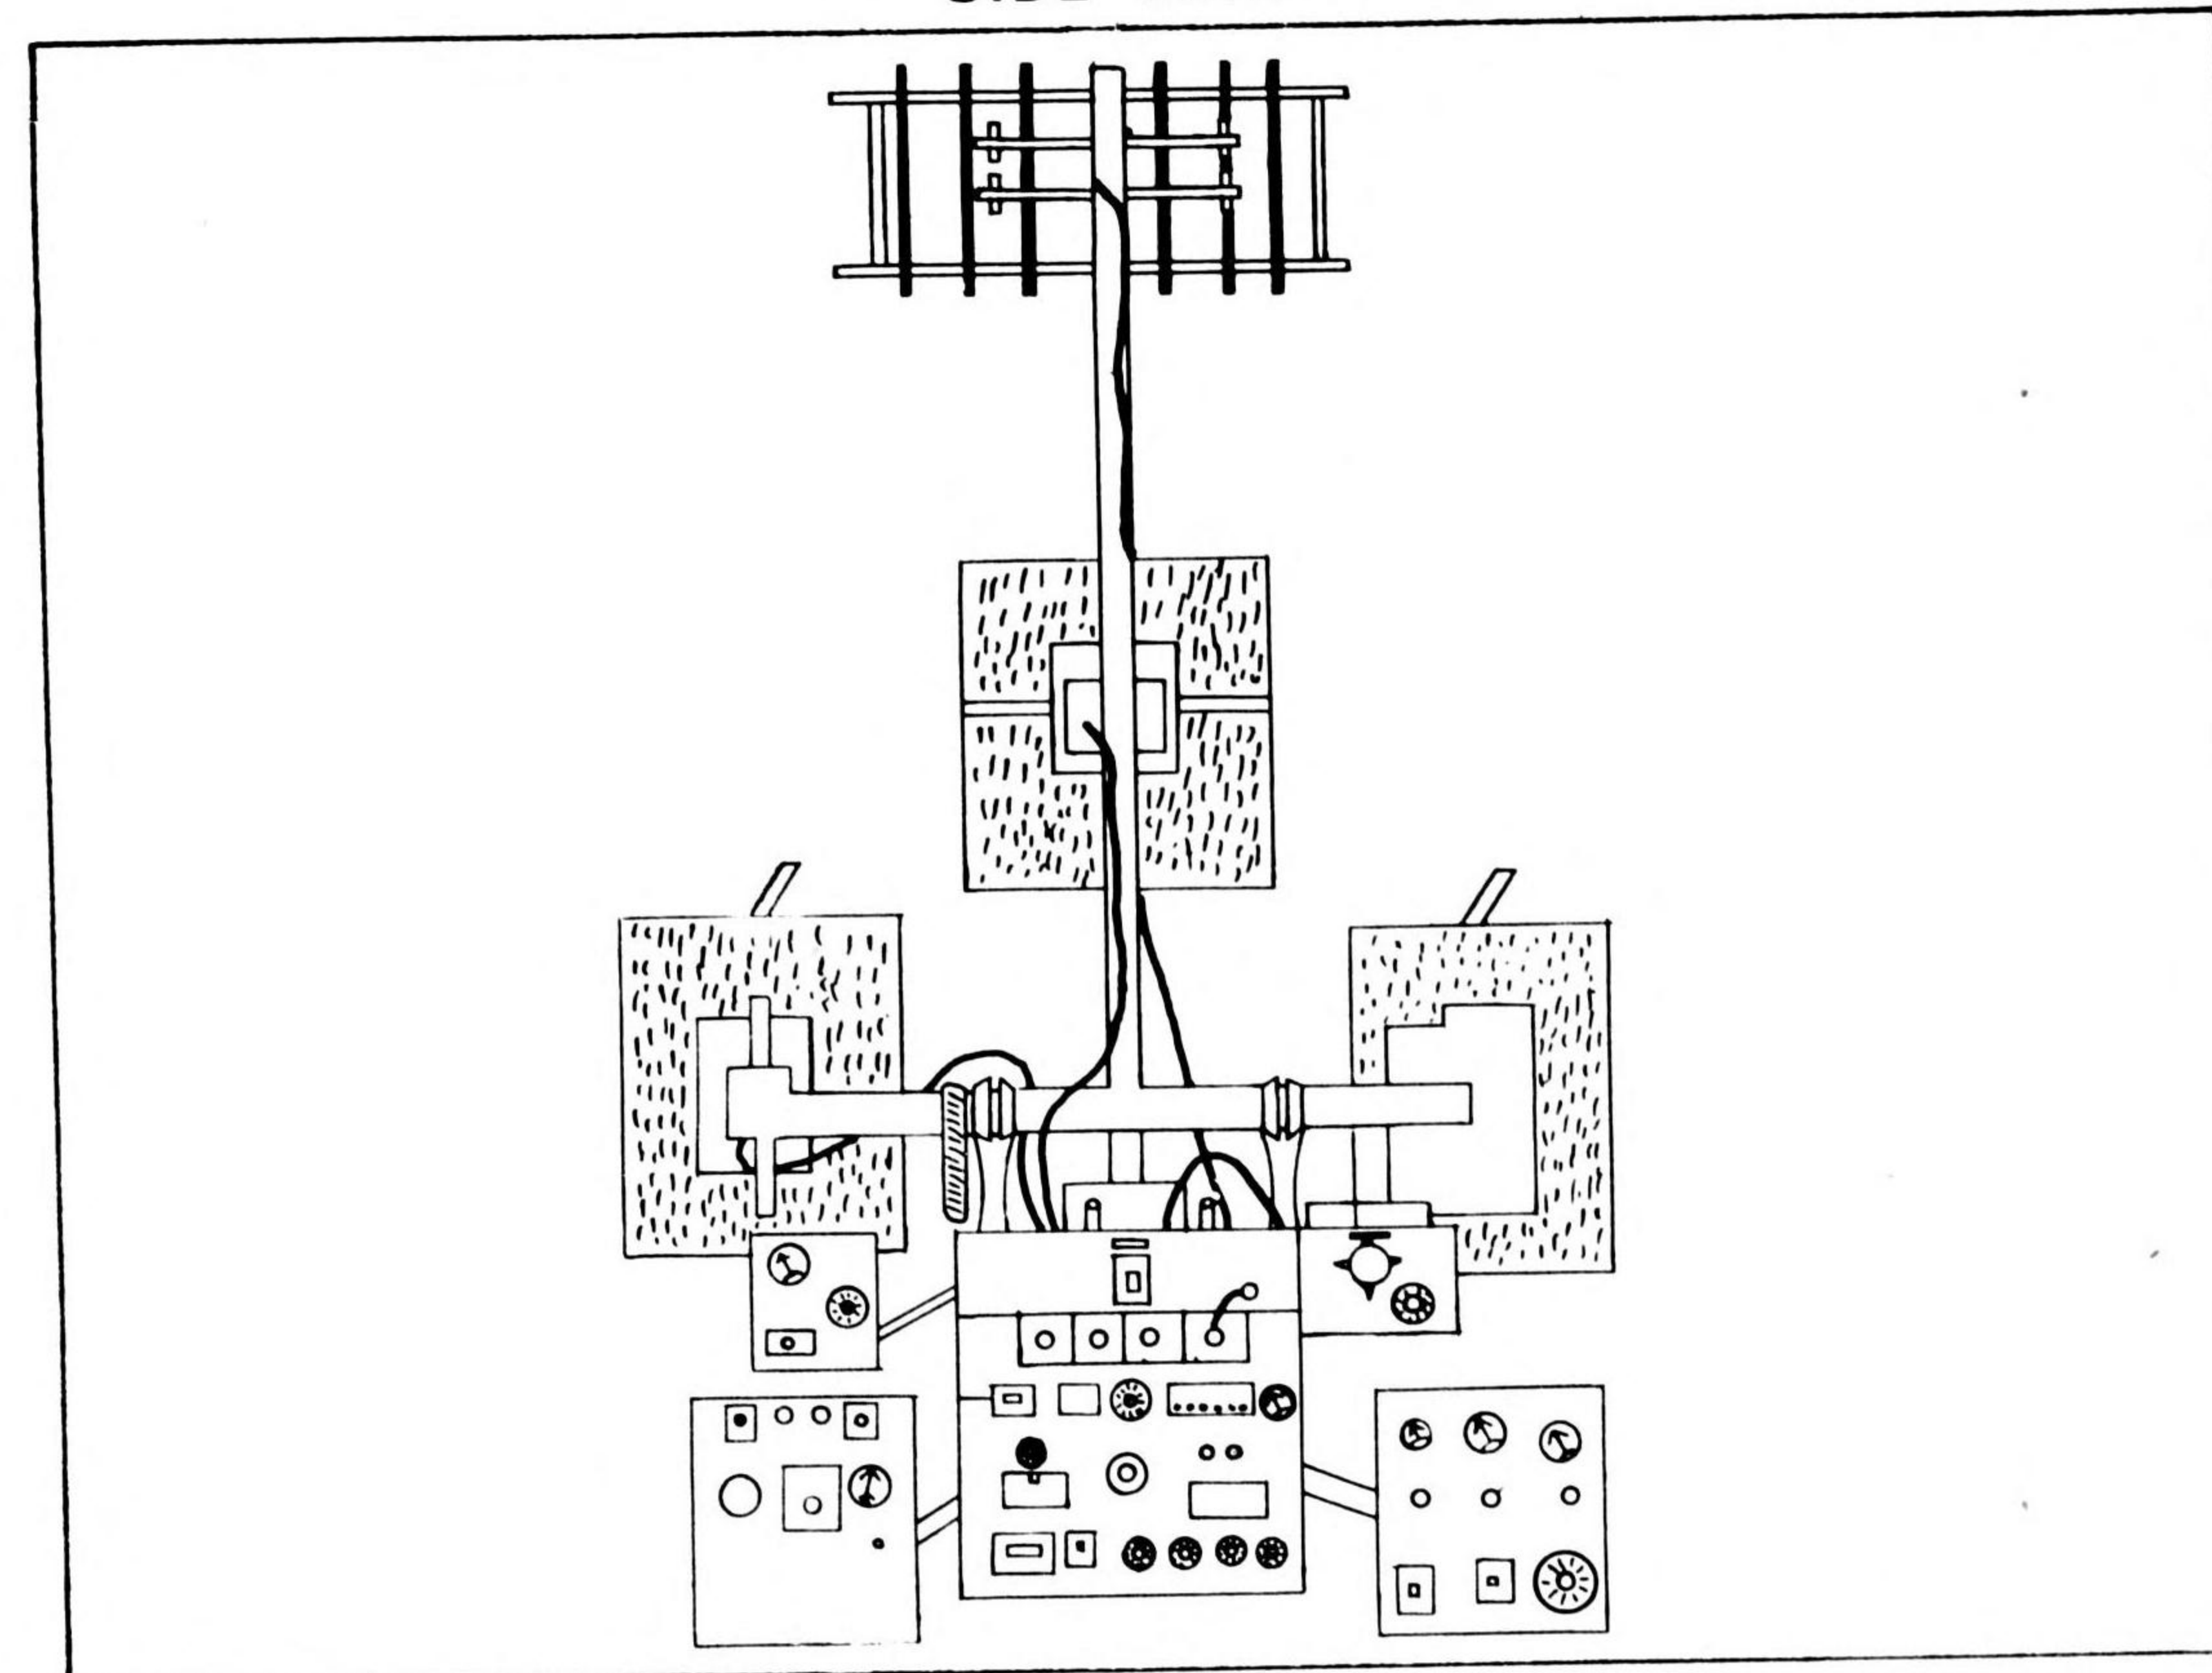

It is thought that the Mark "TA", Model 1 A/A Fire Control Radar operates in a similar manner, basically, to the Mark IV, Model 3 which is shown on the previous page.

However, in this case, the transmitting antenna is mounted above the four receiving Yagis, on the same piece of equipment. Also, the mount is believed to be of special design and not a searchlight or searchlight controller. The frequency of this set is 200 mcs. as are most of the Japanese Fire Control Radars at this stage of development.

Most of the information on this page was taken from notes and sketches of a Japanese non-commissioned officer, which were made during training. The sketches leave much to be desired in clarity of drawing. Nevertheless, a rough estimate of size yields the following dimensions: front view 8 - 10 feet wide; side view 12 - 15 feet high. The whole installation rotates, and the vertical shaft appears to tip back at point A.

SIDE VIEW

FRONT VIEW

LOCATION A/A OR S/L
TYPE MARK "TA", MODEL 1
ANTENNA YAGI S
FREQUENCY 200 MCS
P.R.F. PULSE 3

Captured documents have referred to a Mark "TA", Model 2, Fire and Searchlight Control Radar, but very little is known about this set except for the following data: Frequency - 200 Mc., PRF - 1000 Cps., Pulse - 2 microseconds, Range accuracy - 100 yards. It is listed as being designed for A/A Fire Control and Air Warning.

The antennae (5 YAGI S) are thought to be mounted on a searchlight in a manner similar to the British S.L.C., in which case both the transmitting and receiving antennae are mounted together. This is in contrast to the separated design of the Mark IV, Model 3.

A photo of the British S.L.C. (A/A, No. 2, Mark VI) is shown here for reference.

BRITISH S.L.C. (A/A, NO. 2, MK 6)

RADAR

FIRE CONTROL (MK. TA., MOD. 3)

The Mark "TA", Model 3 Fire Control Radar is believed to be radically different from Model 1 and 2 of the "TA" series.

The prototype of this set is probably the British GL Mark 2 which was captured in Malaya.

Most of the present information on this Radar is taken from a captured notebook which was translated and analyzed by Gen. Hq., S. W. P. A.

This model is a Low Frequency (75 mcs.) Fire Control Radar which uses a transmitter with a five element Sterba array set close to the ground with a single dipole 20 feet above and a separated receiver which has 6 dispersed dipoles. There may be 80 to 150 feet separation between transmitting and receiving equipment.

A feature of this set which should be of distinct interest to interpreters is the fact that it requires an extensive cleared area around the transmitter, and it is thought by some that a slight (swale-like) depression provides the best siting for its functions as a Fire Control Radar. At any rate, the ground must be clear of trees for a radius of 200 feet or more and should be accurately graded close to the receiver.

Sketches of the probable appearance of the Japanese Transmitter and Receiver as indicated from captured document sources, are shown here, as well as ground photos of the original British equipment from which they are believed to have been copied or adapted.

TRANSMITTER

RADAR

(MK. IV, MOD. I) FIRE CONTROL

The Japanese adaptation of our SCR 268 Fire Control Radar was first captured on Peleliu and is believed to be the same set referred to in captured documents as "Mark IV, Model 1," and sometimes as "S-3".

The Mark IV, Model 1 (shown on this page) is a Fire Control Radar which operates at a frequency of 200 mcs. This set is not well adapted to mass production for wide use. Captured documents refer to a "Mark IV, Model 2" and a "Mark IV, Model 2, Modification 2" which may indicate that future use of a smaller improved model or models of this Radar, designed for mass production, can be expected.

The "Mark IV, Model 1" type (or types) will function better when sited in a cleared graded area.

SIDE VIEW

There are three antenna bays mounted on a 25 3/4-foot long horizontal beam which in turn is mounted on top of the large frame which supports all the various units of the radar. The beam is about 9 feet above ground base. All antenna elements reflectors, radiators, and directors are lengths of 1/4 inch copper tubing mounted by means of ceramic insulators on wooden frames which are fastened to the cross beam.

RADAR

SUPPLEMENTARY MATERIAL (FIRE CONTROL)

FIRE AND SEARCHLIGHT CONTROL RADAR

Here, under the heading, "Supplementary Material", is shown a collection of stereograms of interest to the photographic interpreter when checking on new patterns in aerial photographs which suggest Fire Control Radar.

Conservatively, all of the installations should be referred to as being "suspicious" if not "probable". However, it must be borne in mind that none have been positively identified.

To review the Fire Control Radar situation at the close of 1944, the following trends and types are believed to be in use or in production:

British "SL" Types	British "GL" Types	United States SCR 268 Types
1. Mark IV, Model 3	1. Mark "TA", Model 3	1. Mark IV, Model 1 (S-3)
2. Mark "TA", Model 1		2. Mark IV, Model 2
3. Mark "TA", Model 2		3. Mark IV, Model 2, Mod. 2

In addition to those listed above, the German Wurzburg should be watched for, as well as other Japanese types which have been reported, but on which little information is available at this time.

Fire Control Radar interpretation is also a part of gun interpretation, and an understanding of the equipment and functions of anti-aircraft fire control centers and guns is helpful to identification. (See P. I. C. Publication #3: "Japanese Anti-aircraft and Coastal Defense Guns")

Certain specific forms and patterns have been observed repeatedly in pictures taken over Japanese-controlled territory, which have created

suspicious as to the presence of Fire Control Radar. In each case the forms in question are found close to heavy A/A and are sited fairly well for the functions of Fire Control Radar. It is believed, further, that such forms and patterns do not represent other known functions of A/A fire control such as directors, visual range finders, sound locators, searchlights, etc.

In general, these forms and patterns may be classified as follows:

1. A circular cleared area, often with a saucer-shaped depression, with a diameter of from 150' to 200'.
2. A 22' diameter cylindrical form, about 10' high (possibly with a conical roof) out of the center of which extends a vertical shaft supporting a cross-arm (antennae?). The whole is frequently enclosed in a low revetment of 50' diameter.
3. A small circular revetment, enclosing "something", from which a buried cable is observed running to the fire control center (to the director?) and thence to the heavy A/A guns.

It must be borne in mind that A/A Fire Control Radar need not be sited on the highest point of land, but often will be found in low flat areas, wide valleys, and frequently on the same level or lower than the heavy A/A guns.

When searchlight revetments are found accompanied by another circular revetment, and not in the immediate vicinity of heavy A/A batteries, the extra revetment is likely to contain either Searchlight Control Radar or a Sound Locator.

UNIDENTIFIED

(R.F. - 1/16170)

UNIDENTIFIED

(R.F. - 1/16170)

UNIDENTIFIED

(R.F. - 1/16170)

ABOVE:

The cylindrical form is similar in shape and dimensions to the standard concrete water cistern, i. e., 20-22 feet in diameter and approximately 10 to 12 feet in height. The revetment is about 50 feet inside diameter. A definite shadow, presumably from a horizontal cross arm erected on top of this structure, looks very much like antennae and causes speculation on the possibilities of the installation enclosing Fire Control Radar. Each of these installations is in association with two 6-gun heavy A/A batteries marked "A".

"A" - HEAVY A/A GUNS (127 MM?)

"B" - FIRE CONTROL CENTER

Encircled forms are saucer-shaped and are 150 feet in diameter. The sides of the saucer are built up above grade. The lowest part of the saucer is probably on grade or slightly below. A shadow from a vertical shaft is seen in the left emplacement.

SUSPECTED MARK IV, MODEL 3

"A" - HEAVY A/A BATTERY

"B" - FIRE CONTROL CENTER

"C" - BURIED CABLE

The encircled emplacements above are believed to contain Fire Control Radar equipment, possibly Mk. IV, Mod. 3. (If only one emplacement is in use, Mk. "TA", Mod. 1 or 2 would be likely.) Note underground cable leading to Fire Control Center, a distance of 550', and thence to each heavy A/A gun position.

CONFIDENTIAL

RADAR

SUPPLEMENTARY MATERIAL (FIRE CONTROL)

The Mark "TA", Model 3 Fire Control Radar, which is an adaptation of the British GL, Mark 2, has been the most frequently identified model up to the present, particularly on Honshu. This is partially due to the ease of recognition of this particular type. Three examples which are believed to contain Mark "TA", Model 3 are included on this page.

Two Searchlight Stations with accompanying Sound Locator revetments are included here for comparative purposes.

PROBABLE MARK "TA", MODEL 3

(R.F. - 1/9000±)

"A" - RECEIVER; "B" - TRANSMITTER; "C" - SUSPECTED D. F.

PROBABLE MARK "TA", MODEL 3

(R.F. - 1/9000±)

"A" - RECEIVER; "B" - TRANSMITTER- "C" - SEARCHLIGHT

The two stereograms shown above are good examples of Mark "TA", Model 3. Fire Control Radar set up with heavy A/A gun batteries.

The circular clearings around the transmitter are about 200' in diameter and are carefully graded. (The inner circular clearing in lower stereogram is 100' in diameter.) Cable lines run between the transmitter and the Receiver and from the Receiver to the Director (in the Fire Control Center). Receiver is usually 500' - 600' from the Fire Control Center.

All guns shown are 75 millimeter except the hexagonal battery in lower stereogram which is probably composed of 120 millimeter guns.

SEARCHLIGHT

(R.F. - 1/9000±)

"A" - SEARCHLIGHT; "B" - SOUND LOCATOR; "C" - BARRACKS BUILDING FOR SEARCHLIGHT CREW; "D" - HIGH TENSION POWER LINES.

SEARCHLIGHT

(R.F. - 1/9000±)

"A" - SEARCHLIGHT; "B" - SOUND LOCATOR; "C" - BARRACKS BUILDING FOR SEARCHLIGHT CREW.

The two stereograms shown above are of Searchlight Stations with Sound Locator control. These are included for comparison with Radar Fire Control emplacements. Although these are fairly typical examples of Sound Locator revetments, it would be difficult to ascertain, at this scale, if the Sound Locator apparatus were replaced by Radar Searchlight Control.

SUSPECTED MARK "TA", MODEL 3

(R.F. - 1/9000)

"A" - RECEIVER; "B" - TRANSMITTER.

In this stereo, the form that resembles a buried fuel tank is apparently surmounted by a Mark "TA", Model 3 Receiver. The A/A battery appears to be composed of 75 mm. guns. This is a smaller group of guns than is usually found with Radar Fire Control of this type.

Several other examples of Mark "TA", Model 3 have been found recently (in addition to those shown in this book). At the present time, it has been identified more frequently than any other type - but this may be partially due to the fact that it offers the most obvious identifying characteristics.

SUPPLEMENTARY MATERIAL (SEARCH)

CHICHI JIMA, BONIN IS.

(R.F. - 1/5500)

CHICHI JIMA, BONIN IS.

(R.F. - 1/6000)

Two radar sites on Chichi Jima show a standardization of associated structures which may prove helpful for interpretation at scales too small to clearly identify the Radar itself.

"A" - MARK I, MODEL I RADAR.

"B" - OBSERVATION PLATFORM ON TOP OF BUILDING.

"C" - PROBABLE BARRACKS BUILDING.

Radio Station at "D" is 700 feet from Radar, and is not related.

CONFIDENTIAL

DARIEN, MANCHURIA

(R.F. - 1/13000)

Unidentified installation at Darien, Manchuria, which is thought to be a long range Early Warning Coastal Radar similar to the German "Large Hoarding". The screen is 90 feet long by 30-35 feet high, set atop a hill in such a manner as to command the harbor and its approaches.

Signals have been reported from this general area which tend to support this interpretation. Larger scale pictures are necessary for final identification.

EARLY WARNING STATION

(R.F. - 1/13500)

A Japanese Coastal Early Warning Station, above, in the Philippines, is sited in a similar manner to many German examples. Station includes, two Radars - an "Attu" type and a "Chi" type.

GUADALCANAL TYPE - SAIPAN

ATTU TYPE - TINIAN

Views of badly damaged Radars captured on Tinian and Saipan illustrate the fact that both the Guadalcanal Type and the Attu Type Radars are still in use in the same general area.

Both of these radars were clearly visible in pre-invasion vertical coverage.

RADAR (GERMAN)

SUMMARY

Examples of German Radar are included here to cover the possibility that the Japanese may have access to German equipment and technicians.

The Germans employ several types of land based installations covering the functions of Air Search, Fire Control, and Coast Watching.

These types are quite well standardized and are much more efficient apparatus than those the Japanese are known to have.

There is now some photographic evidence of German Radar equipment in use by the Japanese. Also, it is known that many other types of German electronics equipment are being used.

The following table represents the latest list of German Radar types with salient information concerning each.

GERMAN LAND BASED RADAR TYPES

NAME	SIZE OF SCREEN*	TOP OF SCREEN ABOVE GROUND	FREQUENCY	RANGE IN NAUTICAL MILES	USE	PAGE NO.

LIMBER FREYA

POLE FREYA

Drawings of all of the basic German Radar types are included on this page. Best known popular names are used for the designation of each type. It will be noted that these designs are quite well standardized for each particular use, and identification is easier because of this fact.

In most cases, this German equipment is superior to that now in use by the Japanese. A constant watch for German type designs of Radar in Japanese held territory is therefore in order.

LARGE HOARDING

GIRDER CHIMNEY

RADAR (GERMAN) FREYA

The Limber Freya is one of the earliest types of German equipment, developed for air search or early warning. The Pole Freya is a later mechanical development, but the electrical performance is much the same. Both types may or may not support the I.F.F. array. The operating cabin is 7' square.

The high blast wall is a characteristic of Freya installations. This Pole Freya is minus the I.F.F. The Pole type is assembled from a number of small parts, thus making it more suitable for air transport.

Practical range of Limber Freya is 75 Naut. miles. Practical range of Pole Freya is 100 Naut. miles. Frequency is 116 - 146 Mcs.

POLE FREYA

The encircled object appears to be a portable voice carrying light beam signal device which, although of German design, is also in use by Japanese. Its range is approximately 8 miles and it cannot be jammed or intercepted successfully.

POLE FREYA WITH I.F.F.

RADAR (GERMAN) CHIMNEY

On this page are shown two types of Chimney Radar- the Girder type and the Cylindrical type.

The Girder type consists of a triangular or square (in transverse section) girder mast rising out of a short steel column, which is in turn, fitted to a socket on the ground. The radar equipment is in the cabin at the bottom. Steel guy wires secured at the top, assist in supporting. The screen is 19½' wide by 97½' high. Practical range is 110 Nautical Miles.

Frequency is 120 - 130 Mcs.

The Cylindrical type has a large partly buried concrete casemate, at one end of which is set up a hollow steel cylinder, 130 feet high and 8 feet in diameter surmounted by a crane arm for hoisting frames into position. The screen varies in width somewhat but is likely to be about 60 feet, usually by 97 1/2 feet high.

Both types rotate, are capable of long range reporting, and operate at the same frequency of 120-130 Mcs.

Practical range is 160 Nautical Miles.

Frequency is 120 - 130 Mcs.

RADAR (GERMAN) COASTWATCHER

There are two types of German Coastwatcher Radar, the "Gema Coastwatcher" and the "Large Coastwatcher".

The Gema Coastwatcher, shown on this page, is used for detection of ships approaching the coast and for securing range and bearing for fire of coast defense guns.

The aerial is similar to Freya and is 20 feet wide by 8 feet high. The whole apparatus rotates in azimuth.

The aerial is always mounted on limbers, but may be sited on the ground or on top of a building such as the octagonal tower shown on this page. Range varies with the elevation of the set above sea level. It is 20 Naut. Miles at 250 feet A. S. L. Frequency is 370 - 390 mcs.

GEMA COASTWATCHER

(R.F. - 1/11000±)

On this page is shown the "Large Coastwatcher" as well as other views of the "Gema Coastwatcher".

The Large Coastwatcher is a late addition to the list of German Radar, and at the time of the Normandy invasion, little was known in detail concerning its characteristics.

The aerial or screen is nearly square in shape, being 35 feet wide by 34 feet high. The screen and cabin rotate in azimuth.

Its main purpose is the detection of ships.

Practical range of Large Coastwatcher is 60 - 75 nautical miles

Frequency is 70 - 90 mcs.

LARGE COASTWATCHER

LARGE COASTWATCHER

LARGE COASTWATCHER

RADAR (GERMAN) HOARDING

The "Hoarding" apparatus (sometimes called "Mammut") is for long range aircraft reporting, measuring range and bearing. The screen is fixed and is not capable of rotation. Searching is achieved by electrical swinging of the beam. The Large Hoarding consists of a screen 98 feet long by 36½ feet high, looking very much like a billboard. Four heavy vertical girders set in concrete bases give support to the screen. The screen usually consists of two fixed broad-side arrays, one attached to each side of the vertical girders.

Practical range of Large Hoarding is 100 - 115 Nautical Miles. Frequency is 120 - 130 Mcs.

LARGE HOARDING (R.F. - 1/11000)

LARGE HOARDING

LARGE HOARDING

LARGE HOARDING (R.F. - 1/10000)

LARGE HOARDING (R.F. - 1/5700)

LARGE HOARDING

A very recent type of German Radar is the Small Hoarding. This apparatus is probably also for coastwatching, and bears a strong similarity to the Large Hoarding, although smaller.

The screen is 63 ¾ feet long by 44 ¾ feet high and is supported by three vertical girders set in concrete bases. The two outside bases are larger than the middle one.

At the top of the vertical girders runs a horizontal rail or bar, which is probably used for hoisting screen into place.

SMALL HOARDING

BASE OF SMALL HOARDING (R.F. - 1/11000±)

SMALL HOARDING (R.F. - 1/9000±)

RADAR (GERMAN) SMALL WURZBURG

The "Small Wurzburg" or "Bowlfire" was first designed in 1936, and is one of the most efficient Radars. It is primarily for A.A. fire control but has been used for A/C reporting, searchlight control, and as a standby for Ground Control of A/C. In general, it is a mobile Kadar, mounted on a four-wheeled trailer with outriggers for levelling. Some sets are emplaced, however, and the wheels removed.

Search is by mechanical rotation of the apparatus for bearing and by elevation of the reflector bowl for height measurement.

The diameter of the paraboloid reflector is 10 feet, the top of which is but 12½ feet above the ground. A cupboard, housing the radar equipment, and an operators seat are attached to the rear and side of the reflector.

There are several types of Small Wurzburgs; among them Types "A", "C", and "D" are most used and are quite similar. Type "D" is found with limber mounting and may be without wheels or even set in concrete.

For transport, the paraboloid can be split, by hinges, and turned down in two halves. (See below)

WITH BOWL TURNED DOWN

RIGHT: Type F.M.G. 41-T is a modification of the Small Wurzburg which incorporates a scoop-like form for cutting out ground echoes.

The practical range of the Small Wurzburg is not more than 25 nautical miles but it has a high degree of accuracy for Fire Control purposes.

RADAR (GERMAN)

GIANT WURZBURG

The Giant Wurzburg is a fixed (non-mobile) Radar for measuring range, bearing and height of target aircraft. The whole equipment rotates in azimuth, and the paraboloid tips upward for height finding. Its principal use is for Ground Control Intercept, but some are used for ship-watching.

The basket type metal paraboloid has a diameter of 24 feet.

The large cabin (16' x 10' x 8 1/2' high) rotates with the screen on a turntable which is, in turn, set on a concrete base. In upright position, the top rim of the paraboloid is 27 feet above the ground. An I.F.F. array, consisting of two pairs of dipoles, is located at the top of the paraboloid rim.

The Giant Wurzburg has been used in great numbers throughout German occupied Europe as a multi-purpose Radar. Practical range of the Giant Wurzburg is 40 N. Mi. Frequency is 470-580 Mcs.

RADAR (GERMAN) COMBINATIONS

Most German Radar stations, excepting some Hoarding and Chimney sites and a few Ship Watching sites, are provided with several pieces of equipment.

The most common station, the Coastal Early Warning Station, usually has two Freyas and one or two Wurzburgs. The Freyas are in circular emplacements.

The typical G.C.I. station has two Giant Wurzburgs, one Freya, and occasionally a Small Wurzburg.

Ship watching stations have one Coastwatcher and a Small or Giant Wurzburg.

ALLIED STANDARD FREQUENCY TABLE

SUPER HIGH FREQUENCY (MICRO-WAVE)	3000 - 30,000 Mcs.
ULTRA HIGH FREQUENCY	300 - 3,000 Mcs.
VERY HIGH FREQUENCY	30 - 300 Mcs.
HIGH FREQUENCY	3 - 30 Mcs.
MEDIUM FREQUENCY	0.3 - 3 Mcs. (300-3000 Kcs.)
LOW FREQUENCY	0.03 - 0.3 Mcs. (30-300 Kcs.)
VERY LOW FREQUENCY	0.01 - 0.03 Mcs. (10-30 Kcs.)

Frequency bands of Radio Communications Stations do not fall exactly into the breakdown listed above. Also, it is impossible to determine exact frequencies by means of photographic interpretation alone.

To prevent confusion, the following system is used in this report:

If it is thought that the frequency band of a station overlaps the divisions listed in the standard breakdown, the dominant frequency will dictate the frequency band as called for in the above table.

For example, if a transmitter will operate from 300 to 600 Kcs., it will be called "Medium Frequency" for purposes of classification because 3/4 of this frequency band of 400 Kcs. (or 300 Kcs.) falls into the standard "Medium Frequency" division.

Many standardized Japanese Communication Centers, utilizing three 75 foot high steel lattice masts, are believed to fall in this category. They may be more exactly referred to as being fairly powerful Low-Medium Frequency stations with reliable ranges of greater than 500 miles.

When a station is catalogued as being of a certain frequency, the classification also presumes the possibility of another transmitter being present, operating at higher frequencies. However, the general classification of the station is still derived by an estimate of its dominant lowest frequency.

CONFIDENTIAL

COMMUNICATIONS SUMMARY

Radio communication plays a very important part in the Japanese military system and has been developed to a great extent, both in quality and quantity. German technical skills are known to have contributed to the former, and for years the Japanese themselves have been building an elaborate communications network throughout their widely dispersed empire.

The problem of interpreting radio communications installations correctly and precisely is more complex than with other electronics equipment, even though the installation may often be catalogued as "radio" at a glance.

Apparently conscious of their "Achilles heel" of communication, the Japanese have followed a policy of duplication of installations, multi-frequency setups, camouflage, well protected power plants etc. A typical coral atoll, for example, will contain three or four large stations operating over hundreds of miles, and countless small stations, difficult to spot on aerial photographs.

In addition to these are well made semi-portable and portable transmitters and receivers, & hand-held walky-talkies. Also, weather stations, communications auxiliary to D. F. installations, and Radio ships.

PHILIPPINES

This U.S. station in the Philippines is more powerful than is likely to be found in most Japanese controlled areas. At the present time the mast at the far left is missing. However, the enemy is thought to be using the two remaining masts in connection with a station now operated by them. These are called "lattice masts" and are 600' high, with a spread at the base of 125' or more. Masts of Japanese design, found to date, are usually not over 350' in height.

COMMUNICATIONS

SUMMARY (CONT.)

In this section an attempt has been made to treat more exactly than heretofore, the interpretation of fixed radio installations, based solely on features that can be seen by the Photographic Interpreter.

In that antennae can seldom be seen on aerial photos, masts are of primary importance in interpreting radio communications. In vertical photos mast location, type and height can often be determined by the shadows they cast on the ground.

KISKA

(R.F. - 1/2000)

ABOVE: In this view of a 3 mast Kiska station, the masts would not be visible were it not for the shadows cast by them.

The masts usually surround, or are close to the transmitting building.

RIGHT: Antennae and lines supporting masts are barely visible here at an elevation of 100 feet. Few pictures afford this amount of detail, however.

BORAM, NEW GUINEA

KISKA

(R.F. - 1/2000)

ABOVE: This 2 mast Kiska station contains 75' spliced wooden masts and smaller power line poles crossing diagonally at lower left of picture.

KISKA

ABOVE: Low oblique of masts and poles. This spliced mast design is usually 75' high and is a favorite of the Japanese.

COMMUNICATIONS SUMMARY (CONT.)

On this page are shown examples of the various mast designs in use by the Japanese. Shadow patterns are indicated to stress the importance of this method of interpretation.

WHIP MASTS

There are many other types and locations in connection with portable, mobile, ship and aircraft equipment, which are usually impossible to interpret adequately in small scale vertical photography.

STICK MASTS

Below are shown six designs of stick masts found in Japanese areas. With the exception of S-1 and S-2 these are generally between 50 feet and 75 feet in height. S-5 and S-6 are usually 75' high. With good photography it is often possible to determine exact design, even at fairly small scale.

CONFIDENTIAL

LATTICE MASTS

A great variety of designs occurs in lattice type masts. They are usually of steel construction with prefabricated members. The following diagrams show certain basic types which are frequently found with enemy installations.

L-1, L-2, and L-3 are more typical of occidental design, and often indicate pre-war broadcast stations.

Lattice masts may range in height from 60 feet to 600 feet with the majority falling between 75 feet and 300 feet.

PLATFORMS

Lattice masts with Japanese military radio stations usually have platforms as indicated below. L-5 is likely to be found in threes and is normally 75 feet high.

COMMUNICATIONS

SUMMARY (CONT.)

MAST PATTERNS

Patterns in vertical photographs are important insofar as they indicate directional capacities and probable use. Certain directional patterns of masts indicate Direction Finding or Navigational Aids, which removes the installation from the category of communications.

A single mast is non-directional.

Note: Dotted lines are to show form of pattern and do not necessarily represent location of antennae. Arrow indicates direction(s) of radio "beam".

Patterns #1, #2, and #3 represent non-directional Radio Communications. Although it may be possible to achieve directivity from these patterns, particularly #1, they are much more likely to be used for non-directional communications and constitute the most frequently found patterns for communication stations.

Pattern #4 usually represents a non-directional array for a powerful transmitter. However, it can be directional (on long or short axis) if spaced and fed for that purpose.

Pattern #5 can represent directional high frequency transmission, if masts are spaced close together ($\frac{1}{2}$ wave length).

6

7

Patterns #6 and #7 are examples of arrangements that are likely to create difficulties in interpretation:

#6, with a diagonal dimension of approximately 600 feet is likely to be a radio range station capable of sending a navigational beam in any prescribed direction. This is not a communications pattern.

#7 is either a communication station pattern or a direction finder pattern.

- (a) If Communications, the size will be a clue. The diagonal dimension will then be from several hundred to two thousand feet. Large auxiliary buildings, housing transmitter, power house, offices and personnel quarters will be visible.
- (b) If a Direction Finder, the diagonal dimension will be approximately 100 feet. In Japanese design there is likely to be a small shack in the exact center of the pattern, but this is not absolutely necessary. Diagonal underground cables are usually visible.

8

Pattern #8 represents a communications station which may be directional as shown by arrow.

9

10

Pattern #9 used singly or repeated may indicate a navigational aid, either for ships or aircraft. Such an arrangement is also used for intercept purposes; for directional communication, 2 masts may be at point of "V".

Pattern #10 indicates directional communications and is called a "rhombic" pattern. It usually occurs in multiple units, radiating from a central point. Such a pattern is used with HF or VHF transmitting gear or may support receiving antenna.

COMMUNICATIONS SUMMARY (CONT.)

MAST HEIGHTS

Heights of masts are the best indication of the frequency and range of the radio installation. This is true because it is desirable to raise the antennae, and, thus, the feed wire which transmits, as far off the ground as possible for best operation. By relating the height to the number and type of mast, it is possible to estimate the station capacity by fairly logical means.

IN GENERAL

High Mast = low frequency = long wave = long range
Low Mast = high frequency = short wave = short range

The following table will be helpful in estimating frequencies and ranges from masts visible on aerial photographs.

JAPANESE RADIO COMMUNICATIONS, MAST-FREQUENCY RELATIONSHIP
FIXED INSTALLATIONS

	FREQUENCY	NO. MASTS	MAST HEIGHT	FREQUENCY IN MEGACYCLES PER SEC.	WAVE LENGTH	*** USUAL OPERATING RANGE
STICK MASTS	*VERY HIGH (LINE OF SIGHT)	1	GERMAN DECIMETRE STATIONS HAVE 160' MASTS	30 TO 300 MCS (50 TO 100 LIKELY)	10 TO 1 METER	75 MILES
	HIGH	1 TO 3	WHIP ANTENNAE OR VERY SMALL STICK MASTS	3 TO 30 MCS	100 TO 10 METERS	****200 MILES
	MEDIUM**	2 OR MORE	50' TO 75'	0.3 TO 3 MCS	1000 TO 100 METERS	500 MILES
LATTICE MASTS	MEDIUM**	2 OR MORE	60' TO 100'	0.3 TO 3 MCS (300 TO 3000 KCS.)	1000 TO 100 METERS	500 MILES
	LOW	2 OR MORE	100' TO 500' (125' TO 300' MOST LIKELY)	0.03 TO 0.3 MCS (30 TO 300 KCS)	10,000 TO 1000 METERS	1000 MILES
	VERY LOW	3 OR MORE	400' TO 800' STICK OR LATTICE	10 TO 30 KCS	30,000 TO 10,000 METERS	5000 MILES

* Although there are many types of V.H.F. antennae in connection with portable, mobile, and airborne equipment, no fixed Japanese installations have been seen as yet which operate at such high frequency.

** Most used for land based communication stations.

*** Very rough figures, dependent on many factors.

****When utilizing sky waves, H.F. can transmit over long distances (beyond

1000 miles) on any height of mast.

Estimates of frequency in the following pages are based on the lowest frequency, and auxiliary higher frequency transmitters should be presumed to be present.

Rule of thumb method to determine wave length: Approximate wave length (in meters) 4 x mast height (in meters).

RANGE

1. Some factors which affect range are transmitter power, time of day, weather, time of year, sun spots, and receiver sensitivity.
2. A single steel lattice mast may sometimes be used as a radiating mast and its range would be less than normally expected of its height because of electrical difficulties in transmitting in this manner. In this case the station must operate on a limited fixed frequency and cannot be directional.
3. Many masts imply many channels of communication and do not necessarily mean added range.
4. Siting of masts on or near water gives added range.

SPACING

Spacing between masts in communications is not very important electrically, as is the case in Direction Finding and Navigational Beam installations.

However, due to the mechanical difficulties of supporting antennae in long spans, it can be assumed that the longer the span (or distance between masts) the more powerful the transmitter, for it would not be economically wise to build equipment in excess of the needs of the power of the transmitter.

By this reasoning, for example, a spacing of 500-600 feet would imply that a low frequency transmitter of considerable power were present.

COMMUNICATIONS

SUMMARY (CONT.)

BASES

Bases of lattice masts consist of three or four legs, set in square blocks of concrete which often show up clearly in aerial photos. (Occasionally the concrete bases of stick masts are visible)

It is quite possible to determine, very roughly, the height of the lattice mast by the distance between legs at the base. (this table for Japanese masts only).

Distance between legs.	Height of Mast.
10 - 20	60' to 75'
20 - 30	75' to 125'
30 - 45	125' to 200'
45 - 65	200' to 300'

However, it is recommended that shadow or parallax measurements be used to determine height wherever possible.

PLATFORMS

Most Japanese lattice masts of recent design incorporate a relatively elaborate system of platforms near the top, triangular and rectangular in shape, ranging in size from 25 square feet to 125 square feet in floor area.

These platforms occur singly and in twos and threes. In a three mast station, identical platforms are found in each of the three masts.

NAMUR

PALAU

PROBABLE USES

- Observation. In many cases no other observation towers are present.
- Warning devices. Note siren in photo. (left above)
- Light Beacons.
- Visual Signals - The Japanese now possess, in addition to the usual blinker light signaling systems, equipment of German design which can send blinker or voice and may use infra-red light. The range is approximately eight miles and is not vulnerable to the usual jamming methods.
- Antennae. It is possible but not determined by ground information, that certain platforms on low and medium frequency masts may contain high or very high frequency whip antennae or dipoles.

TRANSMITTERS

- The transmitter is the most vital installation in a communications set-up and is usually found within 300 feet of the masts. It is possible that the communications office may be separated from the transmitter but the latter will be near the masts nevertheless. Generally they are grouped together, however. (See "Communications Centers").
- Range increases as the square root of the increase in transmitter power. Example: 4 times the power = 2 times the range.

With this in mind, it can be readily seen that tremendous additional power must be used to establish reliable communications beyond the range for which the station was designed.

"A" - Antenna, "B" - Insulators, "C" - Feed

MEDIUM FREQUENCY TRANSMITTER

Receiving stations are often found some distance away from transmitting stations, and have their own masts and antennae.

PHOTOGRAPHIC INTERPRETATION REPORTS

In writing reports on Radio communication installations, it is desirable to mention the following:

- Probable frequency of station.
- Probable use of station.
Example: (a) Communication Center
(b) Weather Station etc.
- Probable geographic area of range.
(a) Important geographic connecting points (for medium frequency stations, particularly).
(b) Other known stations within range.
(c) Directional capabilities, if any.
- Pattern of masts, especially if installation suggests a possible Direction Finder or Navigational Aid.
- Location of transmitter and generator buildings.

COMMUNICATIONS

HIGH FREQUENCY

3 MAST-HIGH FREQUENCY

ABOVE: Ground to plane communication. Japanese High Frequency aircraft band is approximately 5 to 10 Mcs. High Frequency Radio Communication is not used by the Japanese for large land based stations except as a supplementary transmission. It is used as follows, (except for long range sky wave of approx. 10 mcs.)

- (a) Near airports for communication with pilots in the air or on the runway
- (b) Small well-hidden stations for short distance communications between commands
- (c) Semi-portable, portable, mobile, and walky-talky sets for the ground troops, A/A batteries etc.

All of these types are extremely difficult to pick up on aerial photographs.

Mast arrangement may assume a variety of forms but is likely to be made up of small, flimsy wooden stick masts or whip antennae.

2 MAST-HIGH FREQUENCY

LEFT: Probable High Frequency Field Radio Station with transmitter and receiver housed in tents. This type of station may be interpreted with good photography at scales of 1/10000 or less.

Insufficient information is available on the use of Very High Frequency (V.H.F.) fixed installations by the Japanese. No transmitters of this frequency have been captured. V.H.F. can be used for portable transmitters, aircraft communications, and point to point communications over short distances (up to 75 miles). The German "Decimeter Stations" (which are 30 miles apart) are an example of the latter use.

SINGLE MAST-HIGH FREQUENCY (R.F. - 1/7500)

ABOVE: Another example of ground to aircraft communication. This may be a type of stick mast or whip antennae carrying High Frequency messages for use of control tower at airport. Radio operates at 3-30 Mcs. This mast may be called a "whip antennae".

WHIP ANTENNAE - HIGH FREQUENCY (R.F. - 1/2500)

ABOVE: Stereogram and sketch of whip antennae mounted on top of warehouse building. Such a station is often impossible to spot in aerial photographs, except when coverage is unusually low and photos are good. High Frequency transmitters are normally used for Communications over distances of less than 200 miles.

COMMUNICATIONS

MEDIUM FREQUENCY

Most Japanese communication stations fall in the Medium Frequency band (0.3 to 3 Mcs.). These stations take on many forms. The typical military communications center with a somewhat standardized concrete building and three 75 feet high lattice masts is already familiar to interpreters. Examples of these are shown under "Communication Centers".

In addition, a less standardized use of spliced stick masts with associated buildings of various designs and adaptations, is widely employed for medium frequency antennae in advanced areas.

Some stations, classified as "Medium Frequency" on these pages, probably overlap into the "Low Frequency" band. International standard breakdown and nomenclature is used for classifications throughout this report.

On this page are shown two Medium Frequency Communications Stations utilizing stick masts.

JALUIT: Masts over 100 feet high and 425 feet apart are excessive for Medium Frequency. However, it is unlikely that Low Frequency antennae would be carried on this type of stick mast. It is quite possible that this station will include the upper part of the Low Frequency band, as well as lower part of the Medium Frequency.

ARAIDO: Three Medium Frequency stick masts, 60 feet high, arranged in a near isosceles triangle pattern.

In the more built up land areas captured by the Japanese and on Japan itself will be found many peacetime broadcast stations operating in the medium frequency band as well as stations associated with airfields and industry. All of this latter group are likely to employ lattice masts.

In this section, many examples of various types are shown and salient information and dimensions, as may be obtained from aerial photographs, are presented. Ground information is not yet available on most of the installations shown, so it is best not to regard any specific interpretation as the final word, but, rather, to utilize the benefits of a reference collection and an interpretation approach.

ARAIDO, KURILES

(R.F. - 1/200)

JALUIT, MARSHALLS

(R.F. - 1/4250)

RIGHT:
"A" - 100' stick masts.
"B" - observation tower.

JALUIT, MARSHALLS

(R.F. - 1/6750)

COMMUNICATIONS

MEDIUM FREQUENCY (CONT.)

JALUIT, MARSHALLS

Medium Frequency Station at Jaluit has two lattice towers, approximately 75 feet high, spaced 350 feet apart.

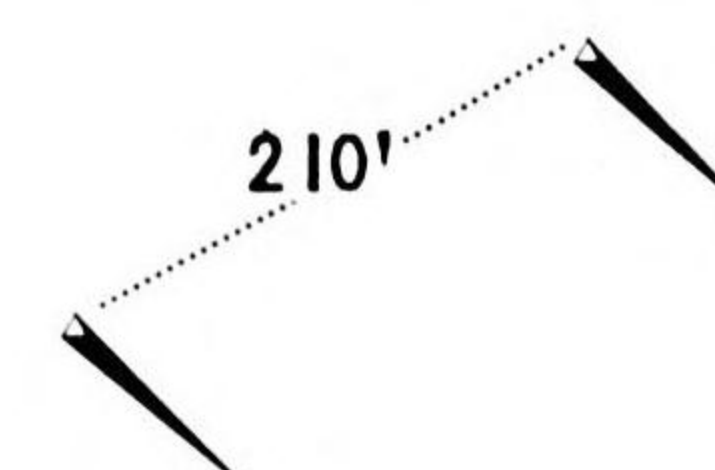

JALUIT, MARSHALLS

Three masts, of steel lattice design with platform, are L-6 type.

The transmitter is probably at "A"; the power is probably at "B".

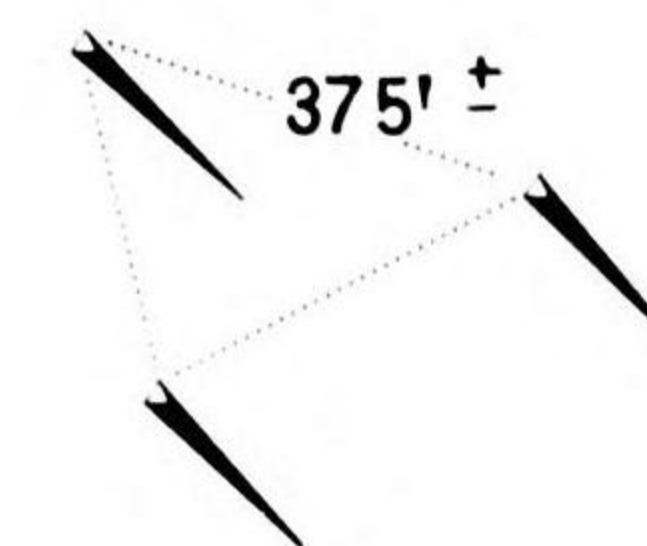

JALUIT, MARSHALLS

PALAU

Steel lattice masts at Palau, approximately 75 feet high, are for Medium Frequency Communications. Water siting offers better ground. Type L-6.

HOKKAIDO, JAPAN (BIHORO)

HOKKAIDO, JAPAN (CHITOSE)

The two examples above (Bihero and Chitose) show Medium Frequency lattice masts in connection with Japanese industrial plants and airfields. Masts are type L-6.

Lattice masts (A) are 100 feet or less in height, which indicates probable Medium Frequency - but fairly powerful stations.

COMMUNICATIONS

MEDIUM FREQUENCY (CONT.)

PALAU

(R.F. - 1/11000)

Probable Medium Frequency lattice masts, type L-6. This arrangement is unusual in that the towers do not appear to be related to a transmitter building for convenient direct feed wire connection. Note power or telephone line at "A". This is a border-line example and could be Low Frequency or a powerful Medium Frequency Station.

PONAPE, CAROLINES

(R.F. - 1/4500)

Medium Frequency station with three type S-5 stick masts. Transmitting building is at center of three masts. Power is at "A" (Note proximity of water cooling building). Building at top is a barracks. A station of this size frequently has lattice masts.

BURMA

(R.F. - 1/5500)

Existing trees might be used effectively to camouflage a radio installation. In this example palms appear to be used as masts for support of Medium Frequency antennae.

WAKE

Stereo-oblique of Medium Frequency station with 60' type S-1 stick masts. Transmitter appears to be buried.

COMMUNICATIONS

MEDIUM FREQUENCY (CONT.)

(R.F. - 174300)

PIGEEYATTO, MALOELAP, MARSHALLS

ABOVE: The station on Maloelap is introduced here as a typical example of the standard Medium Frequency communications building and arrangements of mast as shown in "Communications Center" section. This design is a favorite of the Japanese throughout their island bases. The lattice masts are usually 75 feet high arranged in an equilateral triangular pattern with 150 to 300 feet sides.

"A" - Two of the three 75' high lattice masts.

"B" - Platform and signal light.

PIGEEYATTO, MALOELAP, MARSHALLS

PIGEEYATTO, MALOELAP, MARSHALLS

JALUIT, MARSHALLS

Medium Frequency communications center at Jaluit, which is similar to Maloelap.

COMMUNICATIONS

LOW FREQUENCY

The stations shown here under "Low Frequency" include "Very Low Frequency" and some that may be unusually powerful "Medium Frequency" stations, which would have added range.

Irrespective of exact determination of frequency, which is often very difficult, it is important to refer to installations such as shown on these particular pages as powerful, long range stations in the lower frequency band.

The most powerful Communications Stations are likely to be Low Frequency and are more often found in the Inner Empire, and in other well-populated conquered areas.

KOROR, PALAU

View of Koror Radio Station taken in 1926. At this time the station operated on several frequencies, including low, and could communicate with Japan. The masts are 300 feet high and arranged in a square pattern, 800 feet on a side.

KOROR, PALAU

Same station at Koror taken July 1944. This installation is also included under Navigational Aids because its pattern and dimensions indicate such a capacity in addition to communications.

TAKAO, FORMOSA

Low Frequency lattice masts adjacent to Provincial Office Bldg., Takao, Formosa.

TAKAO, FORMOSA

(R.F. - 1/16400)

The Hozan Station at Takao is one of the largest and most powerful in Japanese possession. The five lattice masts are 350 feet or more in height. The cross-shaped building appears to be a recently constructed transmitting and administration center. The heavily revetted building probably houses the main transmitter, which may include Low Frequency. Masts are spaced 800'-1000'. The circular and radial patterns seem to be a result of tuning houses which are set up on the outside diameter. These houses are 15 feet square and are arranged in groups of threes (in equilateral triangles); they number 54 in all.

TAKAO, FORMOSA

(R.F. - 1/16400)

Another probable Low Frequency Station at Takao. Two lattice masts are 125 feet high; two are 90 feet high. Transmitter is in large central building.

Takao has several high powered Radio Communication Stations.

COMMUNICATIONS

LOW FREQUENCY (CONT.)

BANKOK, THAILAND (R.F. - 1/17700)

Low Frequency station at Bangkok with 225 foot high lattice masts. Transmitter building has dark tone on roof.

BABELTHUAP, PALAU (R.F. - 1/7500)

SAIGON, F. I. C.

Powerful Low Frequency or Very Low Frequency station under construction at Saigon, French Indo China. This arrangement of high stick

LEFT: Six lattice masts and three stick masts support Low Frequency antennae at this large station on Palau. (See page 2.17) The numerous small stick masts that are present do not show up in this vertical. Cross-shaped building is probably housing for one or more transmitters. All masts shown are between 150 feet and 225 feet in height.

(R.F. - 1/13500)

masts apparently erected for supporting triatics, is a typically French design. (Note Bourges Station under "German").

YAP

YAP

"A" - 125 FEET HIGH - LATTICE MASTS.
 "B" - TRANSMISSION LINES.
 "C" - 60 FEET HIGH SPLICED WOOD STICK MAST.

This station at Yap is probably Low Frequency. The masts are in a triangular pattern with the large, three-storied building in the center (probably housing for transmitter).

COMMUNICATIONS

LOW FREQUENCY (CONT.)

TOKYO, JAPAN

Three lattice masts of a pre-war Low Frequency Station in Tokyo. These masts are about 250 feet high and arranged in an equilateral triangle with 500 to 600 foot sides.

PARAMUSHIRO

(R.F. - 1/9000)

Night photo of station at Surabachi Wan, on the east coast of Paramushiro. The masts, two lattice and two stick, are arranged in a "T" form with the bottom of the "T" pointing toward Tokyo. This station may be directional.

CHICHI JIMA, BONIN IS.

Multi-mast Low Frequency Station at northern end of Chichi Jima. Note effect of hilly topography on design of lattice masts. Note also the seaplane base.

KOWLOON, CHINA

(R.F. - 1/1000)

Pre-war British broadcast station at Kowloon, near Hong Kong, now being operated by the Japanese.

PESCADORES IS.

(R.F. - 1/15200)

Medium or Low Frequency Station. Two lattice masts, 100 feet or more in height, are supporting the antennae. This installation appears to be of fairly recent construction.

YOSAMI, HONSHU, JAPAN

The Yosami station is a Japanese pre-war communications center and broadcasting station.

COMMUNICATIONS

LOW FREQUENCY (CONT.)

CAVITE, PHILIPPINES

Above and to the right are views of a Very Low Frequency military station, constructed by the U. S. at Cavite. Although there are now but two masts left of the original three, the Japs appear to have reconstructed and are now using this station.

The masts are 600 feet high, which is taller than any masts of Japanese design yet discovered outside of Japan proper.

KWAJALEIN

Two lattice masts, 210 feet high, used by the Japanese at Kwajalein. One was damaged during U. S. occupation of the island. The two lattice masts were spaced 500 feet apart.

KWAJALEIN

"A" - 210' LATTICE MAST

"B" - SITE OF 210' LATTICE MAST DAMAGED DURING OCCUPATION BY U. S. FORCES.

COMMUNICATIONS COMBINATIONS

The following two pages of "combinations" are included to make comparisons between the appearance of masts of different types, heights and frequencies.

SAIPAN, MARIANAS

(R.F. - 1/5000)

"A" - FOUR 100 LATTICE MASTS.

"B" - TWO 50 STICK MASTS.

SAIPAN, MARIANAS

(R.F. - 1/5000)

"A" - TWO 125' LATTICE MASTS. "B" - THREE 60' STICK MASTS

When topography is very rough, or when the sun is high at the time of photography, it is difficult to estimate the height of masts.

The two stations above at Saipan probably include Low, Medium, and High Frequency transmitters.

In the lower picture, the three closely spaced stick masts in line are unusual. No report has been received on this from the field, however.

WAKE

(R.F. - 1/2200)

WAKE

"A" - TWO 60' STICK MASTS

"B" - THREE 35' STICK MASTS

"C" - RECEIVING ANTENNAE AND/OR POWER LINES

The above views, when compared, show the value of obliques for picking up detail sometimes missed in vertical coverage. This is a poor example of the capabilities of this method.

Low altitude stereo-obliques, simultaneously exposed, would have great value in electronics interpretation.

(R.F. - 1/14800)

TAIHOKU, FORMOSA

"A" - THREE 200' LATTICE MASTS.

"B" - TWO 75'-100' STEEL STICK MASTS.

"C" - TRANSMITTER PROBABLY IN THIS BUILDING.

COMMUNICATIONS COMBINATIONS (CONT.)

KWAJALEIN

"A" - TWO 210' LATTICE MASTS. "B" - SIXTEEN 60'-75' SPLICED WOOD STICK MASTS.
This station is now in Allied possession. One lattice mast was damaged during occupation.

OKINAWA

(R.F. - 1/7500)

Combined Low Frequency radio communications and weather station at Naha, Okinawa.

GARANBI POINT, FORMOSA

(R.F. - 1/2000)

"A" - HIGH FREQUENCY D. F. TOWER. "B" and "C" - MEDIUM FREQUENCY COMMUNICATION STATION
Two Medium Frequency Communications Stations in Formosa, spaced 1200 yards apart. One serves as a reporting station for a D. F. aid to navigation.

BABELTHUAP, PALAU

"A" - THREE 200' LATTICE MASTS "B" - THREE 150' STEEL STICK MASTS

This is a section of a very large multi-channel Communications Center shown elsewhere in this section. This pattern appears to be directional.

BABELTHUAP, PALAU

JALUIT, MARSHALLS

"A" - THREE 75' LATTICE MASTS "B" - SHIP'S COMMUNICATION ANTENNAE

In the background, can be seen a typical Japanese Military Communications Center with standard concrete building.

COMMUNICATIONS COMMUNICATION CENTERS

The Japanese have standardized a type of Medium Frequency Communication Center design to such an extent that it is easily recognized, even with very small scale photography. This particular design has been found in about fifteen different localities to date.

The arrangement consists of three 60'-75' Lattice Masts laid out in an equilateral triangular pattern with the communications building in the center of the pattern.

The Communications Building is of modern looking concrete design with flat roof slabs and parapets. It is usually two stories in height and embodies an asymmetrical disposition of roof terraces.

This building houses the transmitter, generators, and storage batteries. In addition are communication offices, living quarters and storage.

Throughout the Pacific Islands, 20' diameter cisterns (usually three in number) are clustered near the building. Other smaller auxiliary buildings include water cooling tanks (probably for the water-cooled Diesel engines used for generating power), and a concrete oil storage building.

Other types of Communication Centers are also taken up in this section.

All pictures on this page are of a station at Taroa, Maloelap, Marshalls, showing most of the features mentioned. The masts here are spaced 175 feet apart and support the now familiar platforms. These masts are slightly different from the majority used with this type of station in that they are but 60 feet high. The platforms are triangular in shape.

(R.F. - 1/4000)

PIGEEYATTO, MALOELAP

CONFIDENTIAL

COMMUNICATIONS COMMUNICATION CENTERS (CONT.)

ENNUBIRR, KWAJALEIN, MARSHALLS

The pictures and plans on this page are of a Medium Frequency Communications Center on Ennubirr Island, Kwajalein Atoll, Marshall Islands.

Apparently, the sole military use of this particular island was radio communication, and the "Standard" buildings and arrangement were employed.

ENNUBIRR

(R.F. - 1/10000)

This installation has three lattice towers, 75 feet high, which are spaced 350 feet apart. This indicates that it is a fairly powerful station in the Medium Frequency band (.3 to 3 mcs.) and probably has a reliable range of 500 to 800 miles when operating under normal conditions.

The Ennubirr Station is one of several communication stations at Kwajalein, which are mostly High and Medium Frequency, with one probable Low Frequency.

CONFIDENTIAL

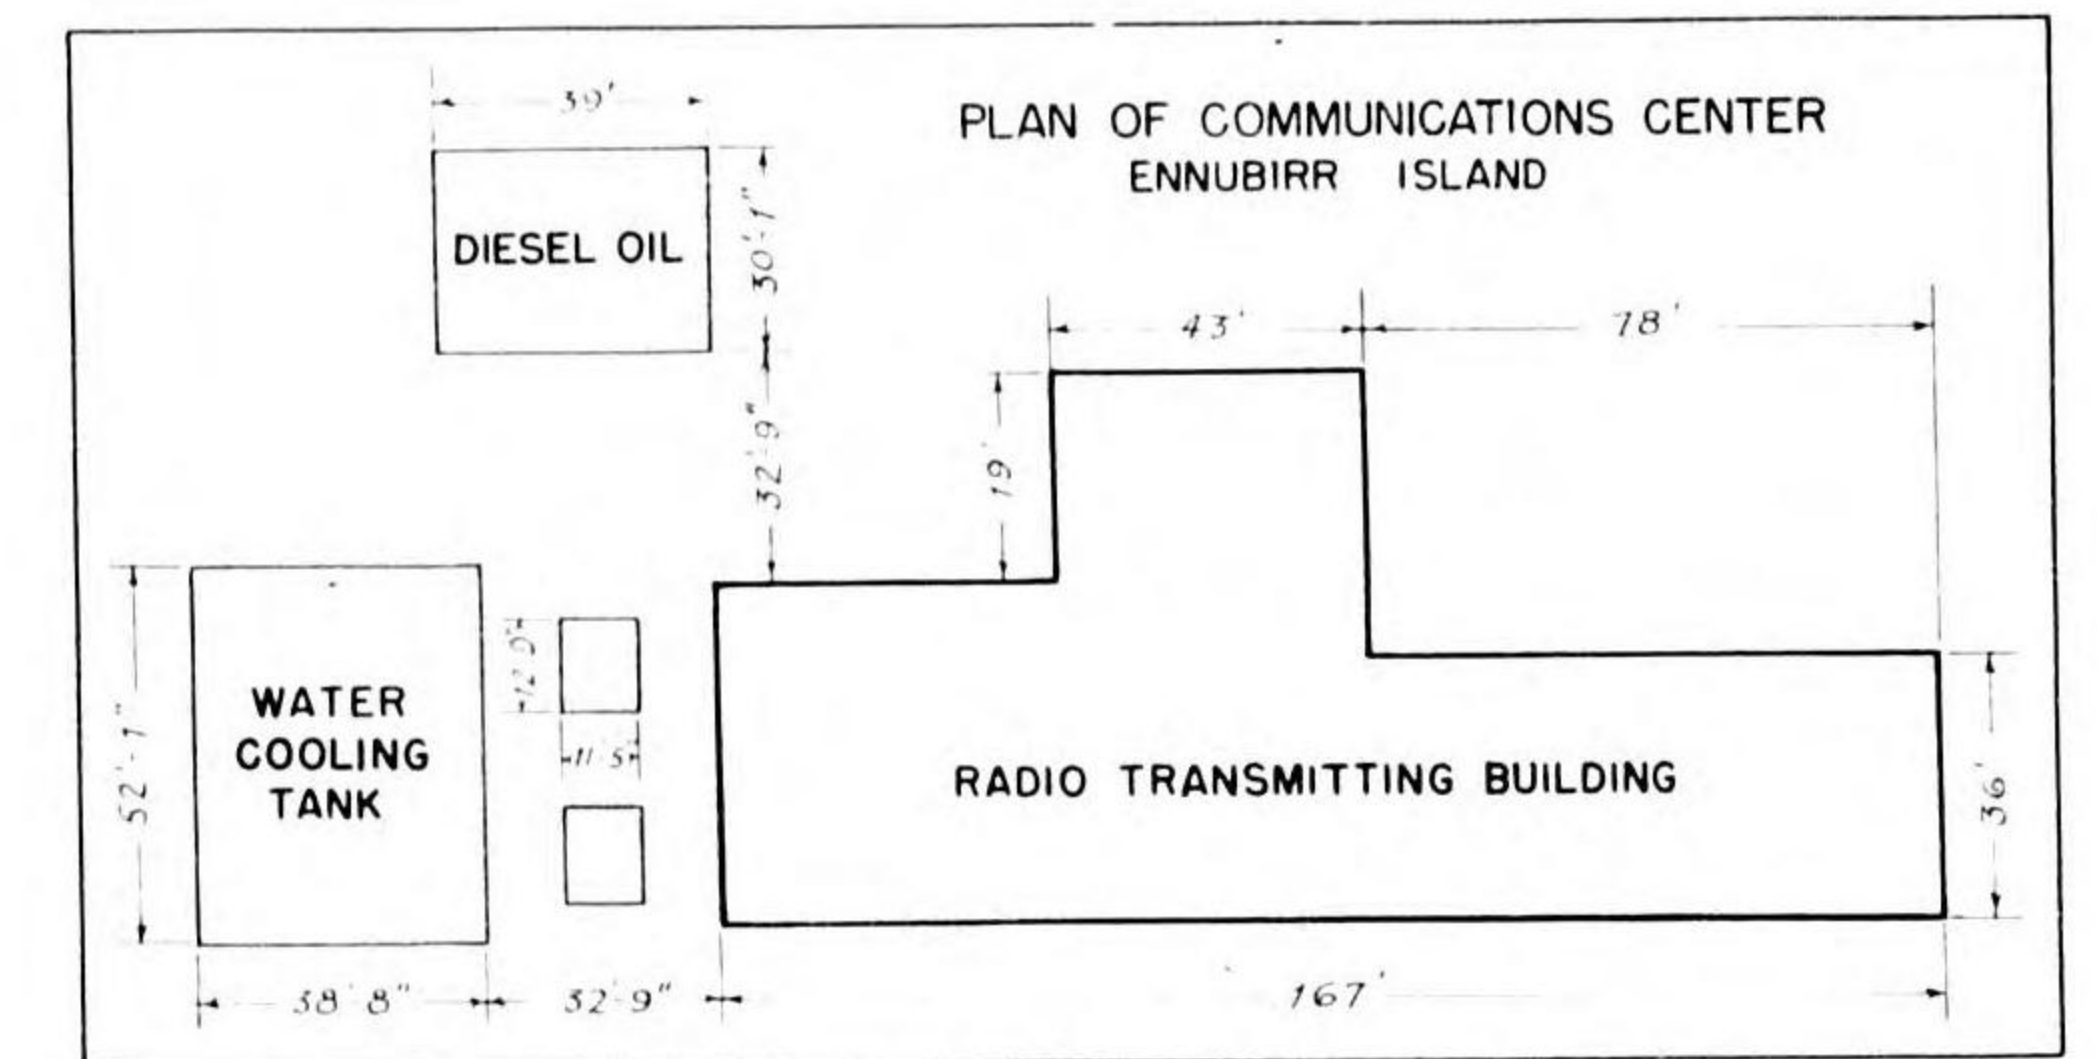

ENNUBIRR

The buildings are as follows: main concrete communications building, concrete oil storage building and three 20 foot diameter concrete cisterns. A long pier for transportation and supplies was necessary because of the shallow water over the coral reefs. This is evidently the only means of access to the island.

ENNUBIRR

From these examples it can be more forcibly realized the extent to which the Japanese have developed a Military Communication network throughout their empire. Ample and reliable communication facilities, throughout widely dispersed areas and involving great expanses of water, are an imperative need of the Japanese military machine hence their great reliance on radio.

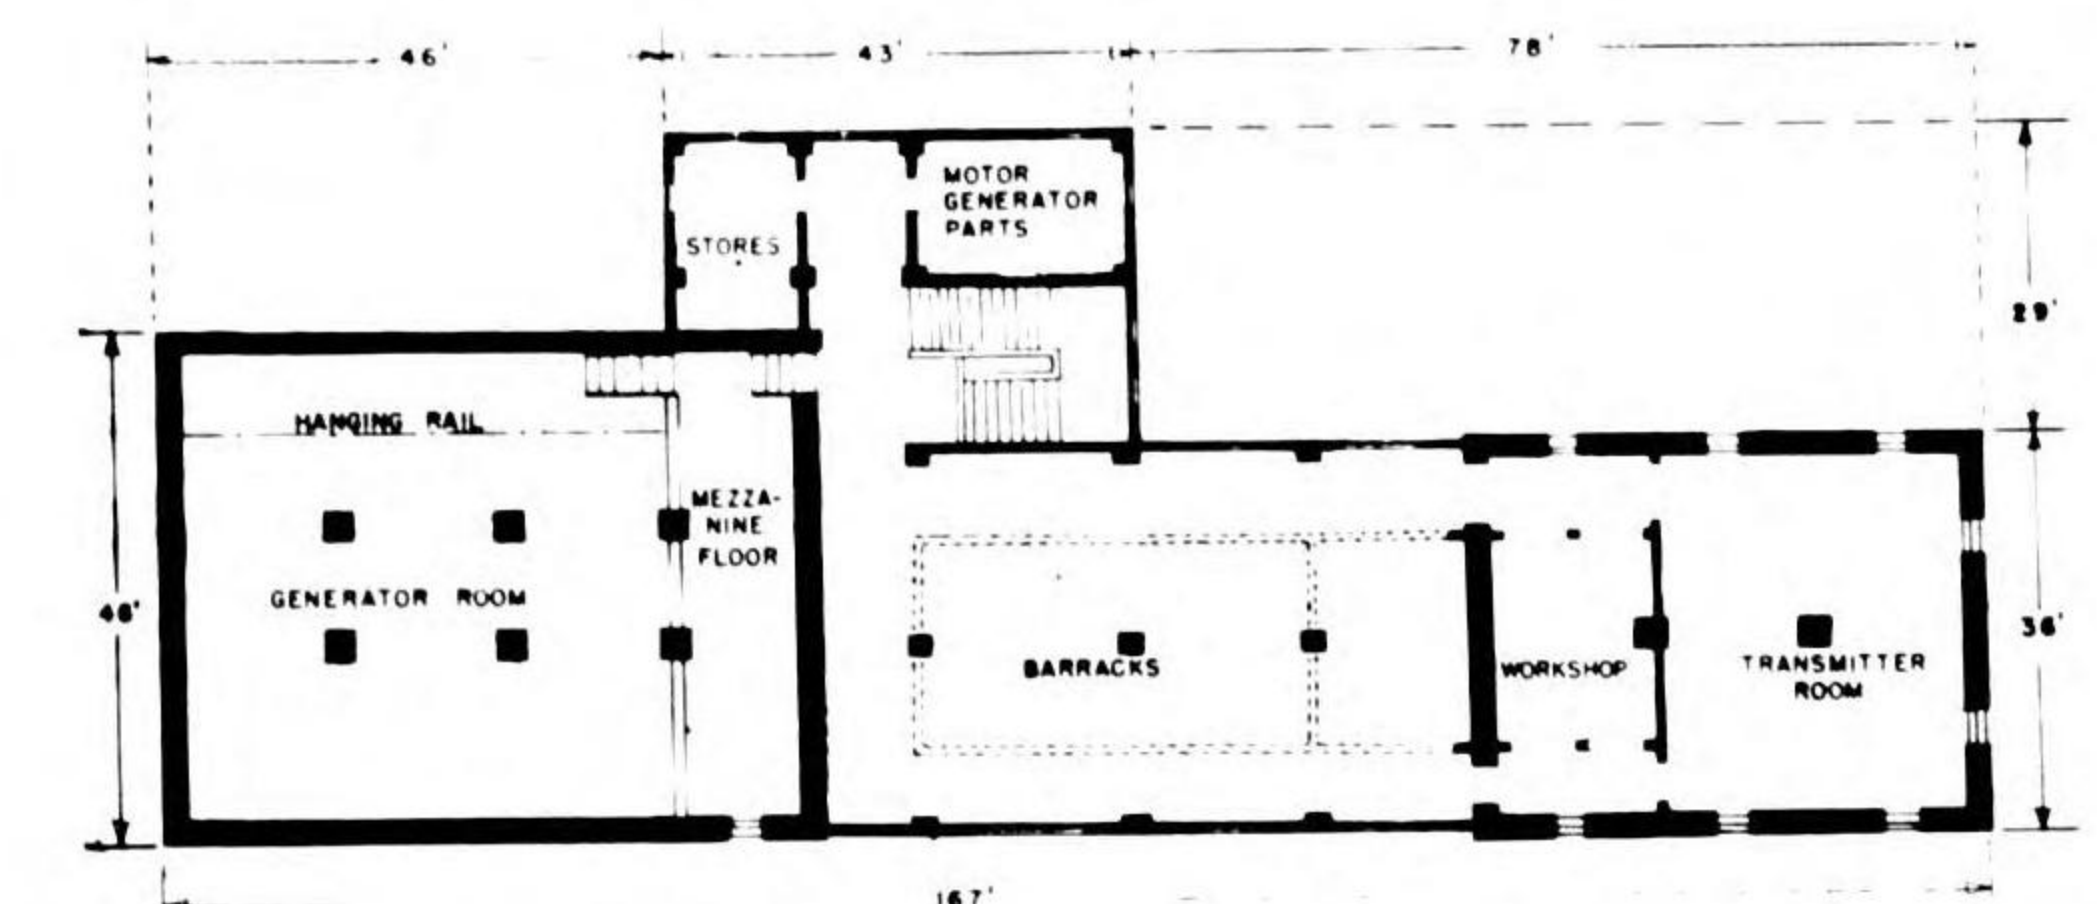

PLOT PLAN OF ENNUBIRR

The two small rectangles between the transmitting building and the water cooling building may represent exhausts for the Diesel engines. Water cooling tank buildings are built of wood with pitched roof and monitor. Oil storage buildings are usually concrete with flat roofs.

FIRST FLOOR PLAN

SECOND FLOOR PLAN

The first floor contains most of the services, engines and heavy equipment. The structure is heavy and well-built of reinforced concrete. The second floor contains most of the electrical equipment (such as the transmitter, which is most vulnerable and difficult to replace), and also barracks for the crew. The generator room ceiling is two stories in height.

COMMUNICATIONS

COMMUNICATION CENTERS (CONT.)

CONCRETE - 25' x 35'

ABOVE: Two examples of bomb proof communications and command posts. These are quite small as compared with the concrete Communications Center Buildings. The design of heavy reinforced concrete

CONCRETE - 14' x 60'

varies considerably. The transmitters in these posts are probably high and medium frequency and are used in connection with ground troops and A. A. and C. D. batteries.

ENTRANCE

Entrance to completed vault is shown here. Eight feet of coral backfill has been placed on top of vault which is 18 feet wide by 50 feet long (outside dimensions). Concrete is 2½ feet thick.

Exterior view of buried concrete barrel vault Communications Center at Guam, designed mainly for local ground force communication while under attack. These types are extremely hard to locate on aerial photos and are strongly resistant to bomb damage. Note camouflage during construction.

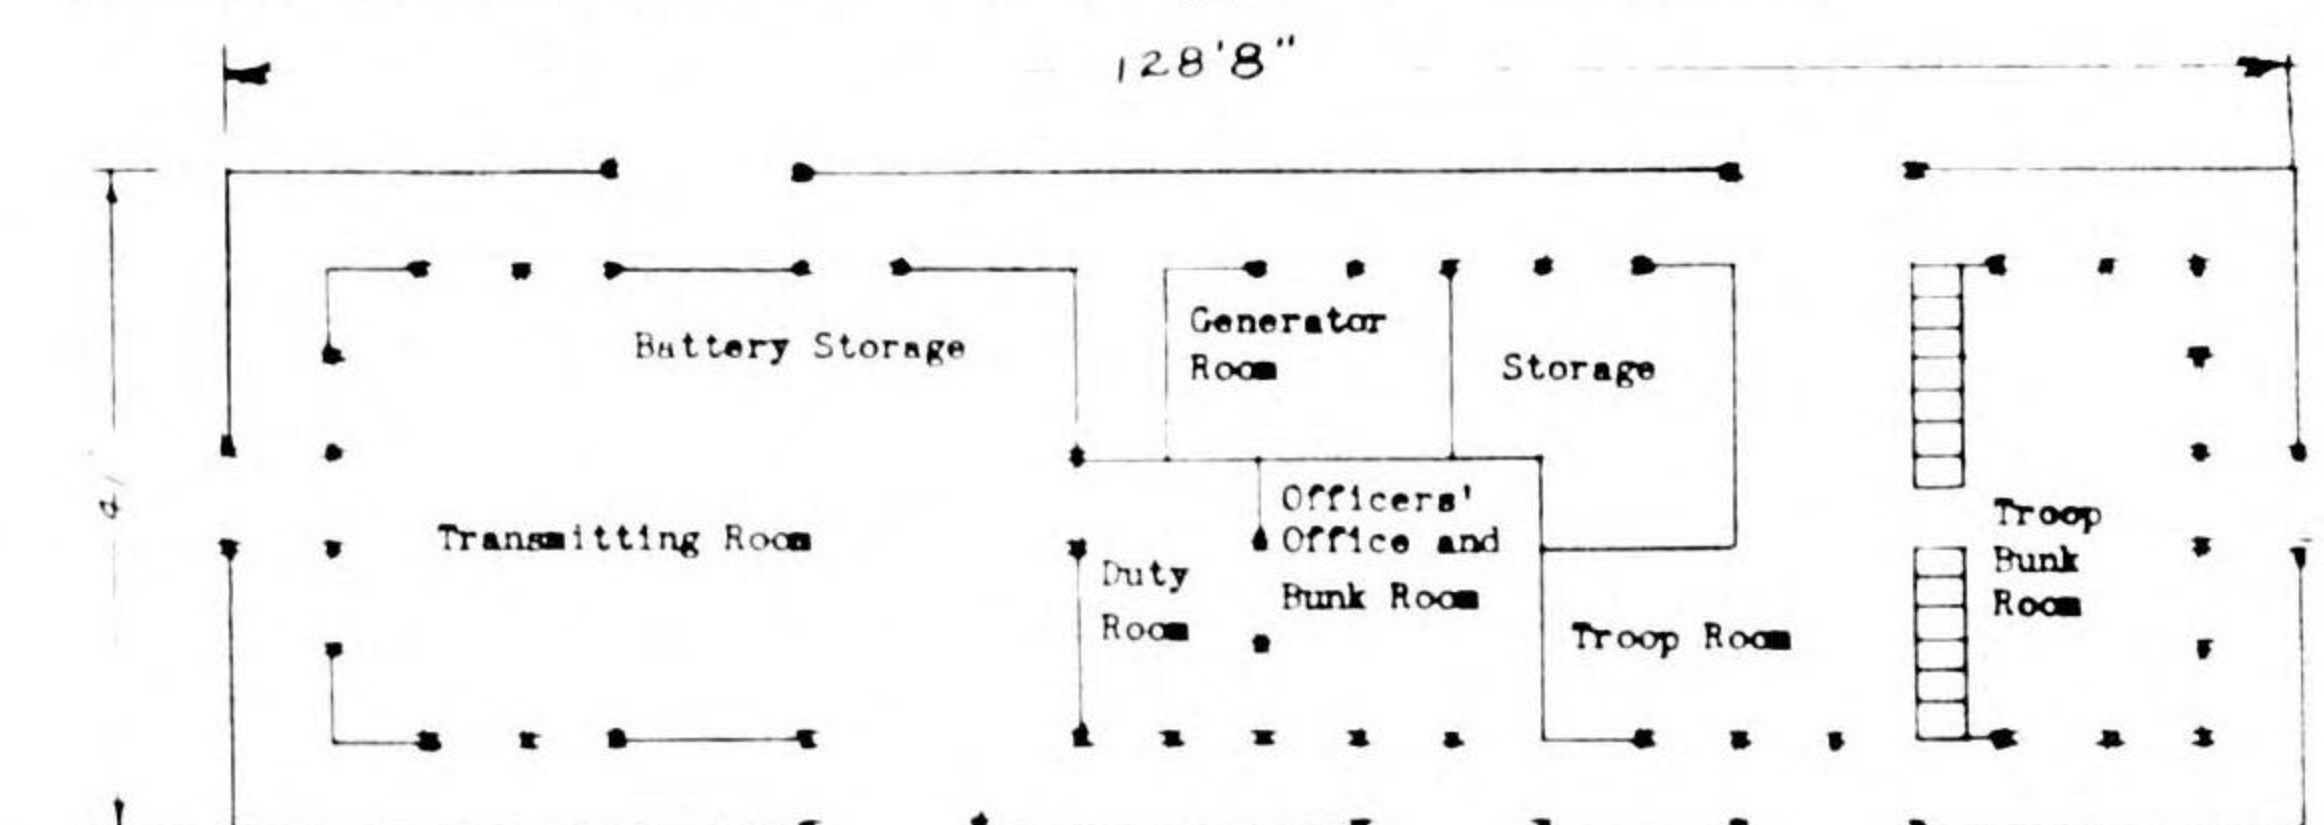

GUAM

Interior view of concrete vault shown at bottom of page. Inside dimensions are 13' x 45'.

GUAM

Transmitter in small buried communications center. Observation of tracks and presence of antenna masts are clues to this type of station.

PLAN

ELEVATION

The standard Japanese prefabricated barracks building is used as a communications center in several instances. When radio masts are visible near barracks buildings, there is a good chance that the barracks nearest to them contains the transmitter. Transmitting rooms are invariably at the end of a building, and on the second floor, if a two story structure.

COMMUNICATIONS

COMMUNICATION CENTERS (CONT.)

FRONT VIEW

PLAN-FIRST FLOOR

PLAN-SECOND FLOOR

Another type of communications center which is apparently a development of the prefabricated barracks building. This structure is two-storied, with the transmitter on the second floor.

The design of Communication Center, at the southwest tip of Dublon Island, is curiously jumbled and makeshift for a station that is apparently quite powerful.

High and Medium Frequency transmitters are likely to be present, the latter with fairly good range. The tallest stick masts are 100 feet high; the spliced wood stick masts are about 60 feet.

FAR RIGHT: This Center, on the north side of Dublon town, utilizes three typical 125 foot lattice masts with platforms and an informal arrangement of stick and spliced wood stick masts. There is very likely a low frequency transmitter present in connection with the lattice masts.

All of the pictures on this page are examples of the use of prefabricated barracks-type buildings in connection with Communication Centers. Most are one story in height and are 38 feet wide, including roof overhang.

S. W. DUBLON, TRUK

S. W. DUBLON, TRUK

This communication center at Truk is a multi-channel station operating at various frequencies including long range, medium or low frequency. The informal, jumbled nature of the group is not very typical of the larger stations.

DUBLON TOWN, TRUK

COMMUNICATIONS WEATHER STATIONS

Japanese military Weather Stations are fairly easily recognized in small scale photography by the following features:

1. 50'-60' steel (sometimes wood) tower containing wind instruments for recording speed and direction and/or low wooden platform constructed on top of roof of main building.
2. Three small white-painted instrument houses, usually in line. These are roughly 3' to 5' square - but show up very plainly because of their pure white color.
3. If near water, may have tide gauge house.
4. Main building for transmitting, offices, quarters, etc.
5. Other buildings present are likely to be barracks, generator building, oil storage and water storage.
6. Two spliced wood stick masts supporting antennae for reporting station.

BELOW: This weather station at Yap is unusual in that four stick masts are used for communications. In most stations, only the two spliced masts are present.

COMMUNICATIONS

GERMAN

German Radio practice differs in many ways from the Japanese, and examples are shown on these two pages to illustrate this fact.

Most German radio is likely to be in the High or Very High Frequency bands, although Medium Frequency is used also. Very few Low Frequency stations are found, however.

A collection of tall, (300 feet high) lattice masts is likely to mean a powerful short wave transmitter, rather than Low Frequency as would be the case in Japanese stations.

The Germans also employ point to point relay stations at V.H.F. (Decimeter Stations) and High Frequency directional layouts.

DECIMETER STATION

DECIMETER STATION

The above German Decimeter Station is near Le Havre, France. This equipment, widely used for German point to point communications, is Very High Frequency. The stations are spaced 30 miles apart and have masts 160 feet high.

GERMAN

POWERFUL SHORT WAVE

Giant short wave High Frequency transmitter, Zeesen. There are 10 masts 350 feet high. When high lattice masts are used in German radio, it is likely to indicate powerful High Frequency transmission. In Japanese-held territory, however, such masts would be likely to represent Low Frequency.

FIELD RADIO

(R.F. - 1/9000±)

This German field radio station is similar to certain Japanese headquarters stations.

BROADCAST STATION

(R.F. - 1/10000±)

This station is a commercial station. Note German type lattice masts.

DENMARK

(R.F. - 1/2500 - no parallax)

These masts are approximately 350 feet high, spaced 250 feet apart, and indicate a powerful shortwave transmitter.

WEATHER STATION, SPITZBERGEN

COMMUNICATIONS

GERMAN (CONT.)

BOURGES, FRANCE

Two very large stations under construction at Bourges.

Station "A" consists of 4 masts 800 feet high, insulated at base and guyed to concrete deadmen. The square pattern is $\frac{1}{4}$ mile on a side.

Station "B" consists of two lattice masts 350 feet high spaced 480 feet apart. Small stick masts, irregularly spaced, are present also, and may constitute an earth device.

These stations probably will operate on many different frequencies and will have great range. Station "A" is of French radio design; a similar type installation may be seen at Saigon, French Indo China.

VALHERMIEL, FRANCE

View of German type High Frequency masts with some stick masts of a directional Rhombic layout in the background. This station also has Medium Frequency masts (not shown).

Antennae on High Frequency masts are probably in a vertical position.

GERMANY

(R.F. - 1/10000)

Probable Medium Frequency Communication Station at an aircraft plant in Germany. The small square building probably contains the transmitter.

ROANNES CHANCEY, FRANCE

Directional Rhombic layout in France. This pattern may be used for highly directional transmitting and receiving of communications. It is a common Radio Intercept pattern.

UNION OF SOVIET SOCIALIST REPUBLICS

The primary use of Japanese land-based Direction Finding Stations is for air navigation purposes.

The pilot who wishes to know his position sends a continuous signal on his short wave plane radio (most are between 5 and 10 mcs). The operators of the ground station or stations (in this case High Frequency D.F. Towers), take azimuthal readings of the signal and notify a radio reporting station of the plane's position. The radio station relays position and instructions to the pilot.

According to a captured document, the average error is less than 50 nautical miles at ranges between 300 and 700 nautical miles. The time consumed is 30 minutes or less.

Although the Japanese have D.F. equipment in planes also, and have built several radio range stations, apparently considerable reliance is placed on ground D.F. Stations for air navigation.

NOTE:
These stations were located solely through photographic interpretation.
This list, prepared in October 1944, is, obviously, incomplete. It is hoped that interpreters in the various field units will keep the map up to date by including any missing stations known to them and make such information available to the proper authorities.

DIRECTION FINDING SUMMARY

Direction finders are RECEIVERS of radio signals. They are equipped to determine the direction from which such radio signals are being sent. D.F.ing is possible on any transmitting equipment operating in the same frequency band as the D.F. receiver.

D.F. STATION AT TRUK

D.F. installations are used on aircraft and on naval vessels as well as on land. This section, however, deals primarily with fixed land installations. D.F. is often used by the Japanese as an aid to aerial navigation in addition to its use for intelligence purposes. In such cases the customary procedure is as follows:

When Japanese pilots desire bearings from these stations, they hold down on the key sending a continuous signal on which an azimuth reading is taken by the D.F. operator. The bearing is then transmitted to the pilot via a radio communications station which is usually found near a D.F. installation.

TYPES OF D.F.

There are two basic types of direction finders - the loop and the Adcock. Although the loop method is used on aircraft and ships, the majority of Japanese land based D.F. stations photographed to date operate on the Adcock system.

ADCOCK

The Japanese style Adcock, in simplest form, may be described in this manner: Four vertical members arranged in a square, with the receiver in the center, and with diagonal electrical connections between the center and all four vertical members, called collectors (may be dipoles or unipoles).

This arrangement is augmented by a central sensing antennae (frequently not visible but which determines the direction of the signal after the line of bearing has been established.)

Example: When the unipoles determine the signal to be on 10° - 190° line the central sensing antennae indicates whether the signal is coming from 10° or from 190° .

This type may also be referred to as "fixed Adcock" in that the unipoles or dipoles do not rotate. It may be either completely housed or the collectors may be exposed.

As in Radio Communications, D.F. is catalogued by frequency. The common types are in the High and Medium frequency ranges.

TABLE OF FREQUENCIES

FREQUENCY	UNIPOLE OR (DIPOLE) DIAGONAL SPACING	UNIPOLE (OR DIPOLE) HEIGHT	WAVE LENGTH IN METERS	FREQUENCY IN MEGACYCLES PER SEC.
HIGH ("HOUSED ADCOCK")	20' TO 30' (MOST ARE 25')	15' TO 25'	100 TO 10 M	3 TO 30 MCS.
MEDIUM ("OPEN ADCOCK")	90' TO 150' (MOST ARE 100')	50' TO 75'	1000 TO 100 M	0.1 TO 3 MCS.

DIRECTION FINDING SUMMARY (CONT.)

HIGH FREQUENCY ADCOCK

The Japanese usually construct the high frequency Adcock in a house which encloses the dipoles within its walls, one set of dipoles being in each corner.

This installation which is called "Housed Adcock" has been standardized to some extent in use throughout the Pacific islands.

PATTERNS

Although found in ones, twos, and threes, most stations have three Housed Adcocks arranged in a triangle or on a straight line. Arrangements vary to such an extent that identification cannot be based on pattern.

The type most often found is identified best by the following key dimensions: Plan view - 23' x 23' (including roof overhang). Interior - 20' x 20'.

Height - 32' (from ground to eave)

Buttresses - 5' spread at base

* (Note: Hereafter, this type of station will be called a "Housed Adcock" or "High Frequency D.F. tower".)

RIGHT: Front view of High Frequency D.F. Receiver. Connections with dipoles are made at the top of instrument which is surmounted by the central sensing antennae. Goniometers are used to determine direction instead of rotating the dipoles which are fixed in the corners of the building.

BELOW: High Frequency D.F. tower at Kwajalein. The receiver, dipoles, and operator's table are all enclosed within the walls of this structure. The buttresses, for some unknown reason, are usually present on D.F. towers.

KWAJALEIN

KWAJALEIN

JAPANESE HIGH FREQUENCY D.F. RECEIVER

MEDIUM FREQUENCY ADCOCK

Most Japanese Medium Frequency Adcock D.F. stations ("Open Adcock") may be identified by the following keys:

1. Four stick masts (unipoles) arranged in a square pattern.
2. Small hut in center approximately 20 feet square.
3. Strongly visible diagonal lines (cables) connecting unipoles.
4. Diagonal distance between unipoles is approximately 100 feet.
5. 12 Square concrete blocks 3' x 3' anchoring guy wires.

The Medium Frequency Adcock operates in a similar manner to the High Frequency, the main difference being the greater distance between vertical antennae elements which is necessary for efficient medium frequency reception.

The four stick masts found with this installation are called unipoles, electrical connections being made by means of buried feeds leading from each pole to the central hut or shack.

DIRECTION FINDING

SUMMARY (CONT.)

IWO JIMA

IWO JIMA

(R. F. - 177500)

"A" - TYPE 1 HIGH FREQUENCY D.F. TOWER

"B" - D.F. CENTER WITH MEDIUM FREQUENCY RADIO REPORTING STATION

BELOW, LEFT: Two Direction Finding towers at Pagan. The height of the left tower is 32 feet (from ground to eave) while the right tower is about 22 feet high. The short tower design is not used to a great extent, and is thought to house a Naval type Medium Frequency loop D.F. equipment.

BELOW, RIGHT: Medium Frequency loop type D.F. antennae used on Japanese naval vessels.

PAGAN, MARIANAS

DIRECTION FINDER ON D. D.

BELOW: The drawing below was made from a High Frequency D.F. tower at Tarawa. It is not a typical design in that it is higher than any others seen to date. However, it is thought that the basic principles of the interior design are characteristic of most Japanese High Frequency D.F. towers.

As can be seen from this diagram, each D.F. tower requires an operator.

DIRECTION FINDING

SUMMARY (CONT.)

On this page are shown eight D.F. tower designs in use by the Japanese. Types "1", "2", "3", "4", and "5" are thought to enclose High Frequency Adcocks. These structures are 20' square by 30'-32' high.

Types "6", "7", and "8" are thought to enclose Medium Frequency rotating loop D.F. (similar to naval type). The loop type may be used in a structure with a floor plan of less area than High Frequency fixed Adcock. A 12 foot square plan would allow sufficient space. The best clue, however is in the

height of the structure. 18-20 feet of height is sufficient for a loop type, but is not considered enough for a High Frequency fixed Adcock.

Elaborate buttress systems characterize many of these designs. The towers are capable of withstanding abnormally high winds.

The towers shown were reconstructed from aerial photographs and not to be regarded as examples of detailed accuracy - but merely key information for identification purposes.

CONFIDENTIAL

DIRECTION FINDING HIGH FREQUENCY

MAJURO

This D.F. setup, when captured on Darritt Island, Majuro, had been abandoned before equipment was installed in the buildings. However, due to the fact that no damage resulted from the occupation, these provide a good opportunity for studying the architectural details of the most recent D.F. building design. Note the finished appearance of the Structures, in which even the buttresses are sheathed with clapboards. This is type "5".

MAJURO

MAJURO

(R. F. - 1/17000)

Above: "A" = High Frequency D.F., "B" - Probable Generator Building

Below are close ups of the two structures erected on Darritt. The one at the left was designed to house the High Frequency D.F. equipment. The building at the right is a standard type, seen usually with large D.F. centers and is thought to be a generator building. However, it may contain a D.F. receiver. This, however, has not been determined from ground information as yet. Approximate dimensions are length -38', width 32', height 22'.

MAJURO

(R. F. - 1/2200)

The above Stereogram shows quite clearly the important identification characteristics of the High Frequency D.F. tower. The hipped roof is 23' to 24' square (including overhang). Height, from ground to eave is 32'. The buttresses, spreading 6' at the base are clearly visible here.

MAJURO

High Frequency D.F. tower

Note that there is but one floor above the ground floor.

MAJURO

Unidentified. Probable Generator Building
This structure was empty when our troops took over Majuro.

DIRECTION FINDING HIGH FREQUENCY (CONT.)

JALUIT, MARSHALLS

Type "5" similar to Majuro tower but without window sun shades. Roof is hipped and measures 23' x 23' in plan, including overhang.

SAIPAN, MARIANAS

(R.F. - 1/6000)

- "A" - High Frequency D.F.
- "B" - D.F. Center
- "C" - Probable Generator Building

A High Frequency D.F. Station on Saipan. Complete with D.F. center and large (probable) generator building. It is more usual to find one or two Medium Frequency installations, in addition to the High Frequency towers, with this size station. Contents of "C" have not been reported as yet.

(R.F. - 1/3500)

JALUIT, MARSHALLS

Vertical view of all three towers in the Jaluit Direction Finding Station. Note the "in line" pattern, road connection to all towers and probable generator building at left.

ULALU, TRUK

Type "4" tower with pitched roof and wooden sun shades. Note that road or path is always visible at operative stations.

TINIAN, MARIANAS (R.F. - 1/2200)

Type "4" tower with hipped roof and wooden sun shades. The pattern on the roof presents an unusual appearance in this view.

VUNAKANAU, RABAUL

Type "4" High Frequency D.F. tower with hipped roof at Rabaul. This is one of three which are used.

DIRECTION FINDING HIGH FREQUENCY (CONT.)

WAKE

Tower on Wake, Type "1", was one of the earliest examples found of Japanese High Frequency D.F. towers. Note the absence of buttresses.

MILLE, MARSHALLS

(R.F. - 1/2600)

This installation at Mille is unusual in construction. The four rows of buttress type braced on each side have not been seen elsewhere. Apparently, construction was not complete when these pictures were taken.

ITUABA, TISSARD BANK

(R.F. - 1/4700)

It is difficult to determine the exact design of these towers due to the unusual shadow pattern. This equilateral triangle pattern is often found. Distance between towers is 350'.

WOTJE, GILBERTS

"A" - High Frequency D.F. tower
"B"-Probable Medium Frequency tower (loop type)

PALAU

"A" - High Frequency D.F. tower
"B"-Probable Medium Frequency tower (loop type)

PAGAN, MARIANAS

"A" - High Frequency D.F. tower
"B" Probable Medium Frequency tower (loop type)

These examples, at Wotje, Palau, and Pagan, illustrate a lower design of tower which is occasionally found with the 32' high standard tower. These low towers are approximately 22

feet high, from ground to roof eave, and probably enclose Medium Frequency loop type D.F. apparatus operating best between 100 and 2000 Kcs.

DIRECTION FINDING HIGH FREQUENCY (CONT.)

YUNCHENG, CHINA

(R.F. - 1/13000)

The installation shown above appears, at first glance, to resemble a fuel storage tank emplacement. However, upon closer examination, it is found to be a structure which resembles a typical D.F. tower, surrounded by a dike for protection against flood water.

NAURU

(R.F. - 1/5000)

Type "3" D.F. tower. Note single corner buttresses.

HANKOW, CHINA

(R.F. - 1/13000)

Probable High Frequency D.F. tower set in a square enclosure which appears to be a protective dike.

"A" - End of runway.

"B" - Unidentified tower, possibly High or Very High Frequency D.F.

CHICHI JIMA, BONIN IS.

"A" - Six high frequency D.F. towers

"B" - One Medium Frequency D.F.

This is one of the very few examples of a group of more than three D.F. towers on the same site. Normally, if more than three towers are used on an airfield, they are widely separated.
