H. P. MOSHER, M.D.
ROBERT B. OSGOOD, M.D.
STEPHEN RUSHMORE, M.D.
HENRY R. STEDMAN, M.D.
PERCY G. STILES, M.D.
JOHN J. THOMAS, M.D.
PAUL THORNDIKE, M.D.
S. B. WOLBACH, M.D.

INDEX TO VOLUME CLXXVII.

AUTHORS.

A

- Amsden, H. H.** Hemorrhage following tonsillectomy, 594.
- Anocovs, J. M.** Diagnosis of focal sepsis, 319.
- Anderson, V. V.** A comparative study of feeble-mindedness and psychopathic personality among offenders in court, 210; The immoral woman as seen in court, a preliminary report, 899.
- Alexander, H. L.** Observations at the Peter Bent Brigham Hospital on cases of pneumonia in relation to types of pneumococci and the serum treatment of Type 1 cases, 874.
- Armstrong, Donald B.** Community health and tuberculosis demonstration at Framingham, 660.

B

- Babcock, H. L.** Some observations on the Barany test as applied to aviators, 840.
- Bailey, Karl R., Sinek, Francis H., and Castleman, Philip.** A year's work with the Wassermann test, in the Boston Health Department laboratory, with special reference to doubtful reactions, 180.
- Barnes, George Edward.** The rationale of neuroasthenia and of disturbances of arterial tension, 643; The etiology of disturbances of the heart beat, 588.
- Burringer, B. S.** Radium treatment of bladder and prostatic carcinoma, 444.
- Bartlett, P. Chaille, and Graves, John B., 2nd.** Progress in tuberculosis: a collective abstract of important articles published during the year 1916, p. 27.
- Beet, George, and Simmons, C. C.** Hodgkin's disease: a report on the cases observed at the Collis P. Huntington Memorial Hospital from April, 1913, to July, 1916, with special reference to treatment with radium and the x-ray, 819.
- Billings, Bernice M.** What becomes of the discharged convalescents?, 664.
- Bine, Rene.** Botulismus: report of two fatal cases, 559.
- Blake, Mabelle B.** The defective girl who is immoral, 492.
- Boardman, William P.** Syphilis in internal medicine, 72.
- Boon, William F.** The treatment of gastric hyperacidity and hypersecretion, 469.
- Bosworth, A. W., and Bowditch, H. I.** Studies of infant feeding. viii. The mineral constituents (ash) of milk, 248; Studies of infant feeding, ix, 864.
- Bowditch, H. I., and Bosworth, A. W.** Studies of infant feeding. vi. The mineral constituents (ash) of milk, 248; Studies of infant feeding, ix, 864.
- Bowditch, Vincent Y.** Introductory remarks by the president, 653.
- Boven, John F.** Report on dermatology, 154.
- Bowman, John G.** The standardization of hospitals, 283.
- Brackett, E. G., and New, Way Snaag.** Treatment of old ununited fracture of the neck of the femur by transplantation of the head of the femur to the trochanter, 351.
- Bradley, R. M.** Health insurance and the medical profession—from the financial and administrative point of view, 698.
- Bradley, Theodore J.** A study of some percentage solutions, 843.
- Burns, Walter L.** The founding of the Berkshire District Medical Society, Massachusetts, in the first period of the existence of the Massachusetts Medical Society, 720.

C

- Capps, Joseph A.** Efficiency tests applied to the attending and house physicians at the Cook County Hospital, Chicago, 286.
- Caro, Helma.** Intestinal adhesions and peritoneal bands in epileptics, 208.
- Carstens, C. C.** What it means to have non-committed feeble-minded in the community, 487.
- Castleman, Philip, Sinek, Francis H., and Bailey, Karl R.** A year's work with the Wassermann test, in the Boston Health Department laboratory, with special reference to doubtful reactions, 180.
- Chadwick, Henry D., and Morgan, Roy.** Diagnosis of tuberculosis in children, 138.
- Chase, Richard R.** Treatment of the visceroprotic, 290.
- Christman, Henry A.** The significance of arrhythmias and systolic murmurs in relation to cardiac efficiency, 750.
- Clark, L. Pierce.** The diagnostic importance of recognizing the absence of the epileptic make-up in states simulating idiopathic epilepsy, 915.
- Clark, W. Irving.** The adjustment of physical defectives to employment, 578.
- Cline, Samuel.** Thoracophagus: an unusual cause of dystocia. Report of a Case, 661.

- Cobb, Cereus.** Some medical practice among the New England Indians and early settlers, 97.
- Cochrane, Robert C.** The technic of abdominal Cesarean section, and a report of sixty cases, 419.
- Codman, E. A.** Uniformity of hospital morbidity reports, 279.
- Cohn, Alfred E.** The basis of certain changes in the electrocardiogram, 752.
- Conlon, Frank A.** Essential shrinking of the conjunctiva occurring in acute and chronic pemphigus, with a report of two cases, 206.
- Cotting, William F., and Cotton, Frederic J.** A brief report of cases of fracture of the skull and spine, from the fourth surgical service, Boston City Hospital, 519.
- Cotting, William F., Shortell, Joseph H., and Leary, Timothy.** The treatment of wounds with normal (beef) serum. Studies in serum therapy, vi, 622.
- Cotton, Frederic J., and Cotting, William F.** A brief report of cases of fracture of the skull and spine, from the fourth surgical service, Boston City Hospital, 519.
- Cones, William Pearce.** Fracture of the cuboid bone, 117.
- Couriney, J. W.** The temperature as a valuable guide to diagnosis, prognosis and surgical treatment in cranio-cerebral traumatism, 611.
- Cronin, Herbert J.** The establishment of a first-aid hospital in industry, 580.
- Crown, John.** Foreign bodies in the eye, 435.
- Curtis, Francis George.** What should constitute reportable tuberculosis, 141.
- Cutter, Raymond W.** Physical examination of factory employees: two thousand consecutive cases and the defects found, 627.

D

- Dann, Harold W.** The meningeal syndrome and other sources of error in pyelitis, 702.
- Davis, Michael M., Jr.** Relations of prenatal and post-natal work, 294.
- DeNormandie, Robert L.** Hemorrhage: accidental, inevitable, post-partum, 391.
- Donoghue, P. D.** Mesothorium and combination methods in the treatment of cancer, 365.
- Downing, Andrew F.** The medical profession and social progress, 237.
- Duane, William.** Methods of preparing and using radioactive substances in the treatment of malignant disease, and of estimating suitable dosages, 787.
- Duane, William, and Greenough, Robert B.** Report of results of radium treatment at the Collis P. Huntington Memorial Hospital by the Cancer Commission of Harvard University, 359.
- Dunbar, Frank H., and Leary, Timothy.** The preparation of beef serum for use. Studies in serum therapy, iii, 617.
- Dunbar, Frank H., Leary, Timothy, and Watson, John W.** Anaphylactic reactions to normal sera. Studies in serum therapy, iv, 618.
- Dunham, F. L.** Biologic analysis in the study of true epilepsy, 105.
- Dunlap, A. M.** The Chinese barber and his use of aural instruments, 438.

E

- Eaton, David L.** The bearings of industry on medical practice, 575.
- Eisenstadt, Daniel N., and Shultz, Oscar T.** Ascending lymphogenous renal infection, 10.
- Ellot, Charles W.** The future of medicine, 631.
- Elwyn, H.** Basic principles in the symptomatology of Bright's disease, 251.
- Emerson, Francis P.** Changing methods and advances in the treatment of progressive deafness from chronic secretory otitis media, 583.
- Encubuske, Cines Julius.** Orthoarteriotomy (a new form of pharmacodynamic energy): the biochemical explanation of its action, together with a contribution to the interpretation of its physiological mechanism, 799.

F

- Faxon, Nathaniel W.** The country doctor and the hospital, 107.
- Freeman, G. H.** Address, 632.
- French, Rippl W.** Clinical data of gall-bladder disease, 151.
- Fulton, Frank Taylor.** Acute carditis, 756.

G

- Gardner, Edwin D.** A case of Henoch's purpura, 118; Cholecyst-duodenal fistula, 523.
- George, A., and Leonard, R. D.** The roentgen diagnosis of the pathological gall-bladder, 376.

- Gray, Horace, and Gray, K. M.** Normal weight, 894, 714, 715, 828, 837, 925.
- Gregg, Donald.** The differentiation of psychotic from neurotic conditions, 904.
- Gilma, Herbert Z.** Observations on the treatment of myelocytic leukemia by radium, 686.
- Goodine, Harold I.** Paralysis or dementia precox, 324.
- Greenough, Robert H., and Dunne, William.** Report of results of radium treatment at the Collis P. Huntington Memorial Hospital by the Cancer Commission of Harvard University, 353.

H

- Harnier, Torr Wagner.** Spina bifida and allied malformations: based on an operative experience of 34 cases, 353; Tendon suture, 808.
- Harrington, Thomas F.** Occupational diseases in Massachusetts, 153; Industrial benzol poisoning in Massachusetts, 293; Tri-nitro-toluene poisoning in Massachusetts, 838; Anthrax as an occupational disease in Massachusetts, 867.
- Harris, Carl Thorburn, and Nissen, H. A.** A series of fractured skulls from the surgical records of the Boston City Hospital, 1902-1917, 870.
- Hartwell, John B.** An analysis of 133 fractures of the spine treated at the Massachusetts General Hospital, 31; Indications for laminectomy in fracture of the spine, with case symptoms, p. 513.
- Hawes, John B., 2nd.** Definitions and diagnostic standards in the diagnosis of pulmonary tuberculosis in adults, 145; Pulmonary puzzles, 912.
- Hawes, John B., and Barrett, P. Collins.** Progress in tuberculosis: a collective abstract of important articles published during the year 1916, 537.
- Henderson, F. F.** Dislocations of the shoulder, with a few complications, 550.
- Hill, Lewis Webb.** A review of the literature of the last nine years on the nephritis of infancy and childhood, 313.
- Hillard, Curtis M.** Tuberculosis in dairy cattle, 654.
- Hodskins, Morgan H.** Body types in epileptics, 87.

J

- Johnson, W. L.** A physician's impressions of Florida, 647.

K

- Kelley, Eugene H.** County tuberculosis hospitals: report of progress, 64.
- Kellings, Foster S.** Chronic valvular heart disease in pregnancy and labor, 398.
- Kelso, Robert W.** Feeble-mindedness as an element in poverty, 854.
- Koukoff, M. J.** A long umbilical cord, causing three loops around the neck, 560.

L

- Leary, Timothy.** The use of normal blood serum, particularly with reference to the treatment of wounds. Studies in serum therapy, II, 611.
- Leary, Timothy, and Dunbar, Frank H.** The preparation of blood serum for use. Studies in serum therapy, III, 617.
- Leary, Timothy, Dunbar, Frank H., and Watson, John W.** Anaphylactic reactions to normal sera. Studies in serum therapy, IV, 618.
- Leary, Timothy, Shortell, Joseph H., and Cutting, William F., 2nd.** The treatment of wounds with normal (beef) serum. Studies in serum therapy, VI, 622.
- Leland, George A., and Bailey, E. H.** Report of a pythritic treatment of carcinoma of cervix at the Huntington Hospital for period of four years, 891.
- Leonard, H. H., and George, A. W.** The roentgen diagnosis of the pathological gall-bladder, 375.
- Lowrey, Lawson G.** A case of pernicious anemia in a pythitic treated with anvarsan, 52; The mastiehe and potassium permanganate tests applied to the cerebrospinal fluid of the insane, 115.
- Lawrey, Lawson G., and Smith, C. E.** On the use of the Emanuel-Cutting mastiehe test in examining spinal fluid from psychopathic subjects, 557.
- Lyman, David H.** When is the diagnosis of tuberculosis without positive sputum justified?, 155.
- Lord, Frederick T.** The newer methods of diagnostic technic, 309.
- Lo-Ing, Louisa P.** Starting health habits in childhood, as illustrated by a recent experiment, 659.
- Lawman, G. L.** Results of further study in leg rotation, 410.

M

- Mackentz, John E.** Surgical treatment of laryngeal cancer, 110.
- McCarthy, Francis P.** A case of streptococcal meningitis successfully treated with normal (human) serum. Studies in serum therapy, V, 621.
- McGaiden, Francis H.** The urethrin content of the feces as a measure of rate of blood destruction, 907.

- McIntosh, Herbert.** Technic and interpretation of dental roentgenograms, 84.
- Milner, W. J.** Fractures of the base of the skull at Massachusetts General Hospital, 518.
- Morgan, Roy, and Chadwick, Henry D.** Diagnosis of tuberculosis in children, 128.
- Morse, Mary Elizabeth, and Tryon, Geneva.** An epidemic of dysentery at the Boston State Hospital, due to a member of the paratyphoid-entertidis group, 173, 218, 255.
- Moylan, Berkeley.** Wounds of the knee joint, 717.
- Mulready, Edwin.** The activities of a labor department, 576.

N

- Nevy, Way Sung, and Brackett, E. G.** Treatment of old ununited fracture of the neck of the femur by transplantation of the head of the femur to the trochanter, 351.
- Nichols, Charles H.** Indications for operation on traumatic head cases, 508.
- Nissen, Harry Archibald, and Harris, C. T.** A series of fractured skulls from the surgical records of the Boston City Hospital, 1902-1917, 870.

O

- Olmsted, J. M. D., and Wodehouse, R. P.** Preparation of animal food proteins for anaphylactic tests, 85.
- Ovsholzer, Alfred.** The cerebrospinal fluid in aneurysmal meningitis. Report of 103 cases, 480.
- Osaka, H.** Study of the operative treatment of osteoarthritis of the hip joint, 679.

P

- Penbody, Francis H.** Report on the treatment of myelogenous leukemia with radium, 873.
- Phineuf, L. E.** Unusually large hydrosalpinx: report of a case, 879.
- Phillips, Arthur R.** X-ray therapy in tinea tonsurans (chronic), 880.
- Porter, W. T.** Further observations on shock at the front, 326.
- Prenn, Joseph.** The use of the hemostat in tonsil operation, 816.

R

- Reed, J. Marlon.** Lymphocytosis: a clinical study from group diagnosis, 691.
- Richards, George L.** Hearing tests from a practical standpoint, 213.
- Ringer, Paul H.** Some Notes on Artificial Pneumothorax, 50.
- Risley, Edward Hammond.** The modern treatment of burns, with especial reference to severe burns and to the use of ambrine and its substitutes, 343.
- Risley, Edward H., and Leland, G. A., Jr.** Report of treatment of carcinoma of cervix at the Huntington Hospital for period of four years, 891.
- Rushmore, Stephen.** Progress in gynecology, 726.

S

- Sever, James Warren.** The value of diagnosis in back lesions, 857.
- Scheppegrell, William.** The classification of hay-fever pollens from a biological standpoint, 42.
- Shortell, Joseph H., Cutting, William F., and Leary, Timothy.** The treatment of wounds with normal (beef) serum. Studies in serum therapy, VI, 622.
- Shultz, Oscar T., and Eisenhardt, Daniel N.** Ascending lymphogenous renal infection, 10.
- Simmons, Channing C.** A report of service with the First Harvard Surgical Unit serving at a British base hospital, with the end-results of the cases one year later. The follow-up system, 275.
- Simmons, Channing C., and Benedict, George.** Hodgkin's disease: a report on the cases observed at the Collis P. Huntington Memorial Hospital from April, 1913, to July, 1916, with special reference to treatment with radium and the x-ray, 819.
- Slack, Francis H., Castleman, Philip, and Bailey, Karl R.** A year's work with the Wassermann test, in the Boston Health Department laboratory, with special reference to doubtful reactions, 180.
- Smith, Curtis E., and Lawrey, Lawson G.** On the use of the Emanuel-Cutting mastiehe test in examining spinal fluid from psychopathic subjects, 557.
- Smith, Curtis E., and Solomon, H. C.** Bruck's Serological test for syphilis: a report of 400 cases compared with the Wassermann reaction, 321.
- Smith, Richard M.** The danger to children from tuberculosis in cattle.
- Solomon, H. C., and Smith, Curtis E.** Bruck's serological test for syphilis: a report of 400 cases compared with the Wassermann reaction, 321.
- Stiles, P. G.** Recent progress in physiology, II, 876.
- Stokes, William Royal, and Stoozer, H. W.** The use of the precipitin test for the detection of human blood in criminal trials, 65.

- Stone, Seymour H.** Annual report of the Massachusetts Anti-Tuberculosis League—1917, 667.
- Stoacr, H. W., and Stokes, William Royal.** The use of the precipitin test for the detection of human blood in criminal trials, 65.
- Swift, Walter H.** Speech correction—a new medical study and a new educational movement, 811.
- T**
- Thompson, Herbert E.** A case of brain tumor showing extensive destruction, with few diagnostic symptoms, 592.
- Titus, Raymond S.** Bleeding in pregnancy, 413.
- Torrance, Gaston.** Colic surgery, with report of 28 cases operated upon, with one death, 790.
- Tracy, Edward A.** A method of testing the vasomotor reflexes of the skin and of recording the same, 810.
- Tryon, Geneva, and Morse, Mary Elizabeth.** An epidemic of dysentery at the Boston State Hospital, due to a member of the paratyphoid-enteritidis group, 173, 216, 255.
- Twitcheil, G. P.** The management of labor, 419.

U

- Ulrich, Helmut.** A comparison of several methods of specific arial treatment of acute anterior poliomyelitis, 78.

W

- Watson, John W., Leary, Timothy, and Dosbar, Frank H.** Anaphylactic reactions to normal sera. Studies in serum therapy, iv, 618.
- Wentworth, Mark H.** Intestinal stasis, 548.
- West, F. O.** A study of the urines of picric acid workers, 171.
- White, Franklin W.** The etiology and pathology of perforating gastric and duodenal ulcers, 555.
- Williams, Frankwood E.** Dr. Samuel G. Howe and the beginning of work for the feeble-minded in Massachusetts, 481.
- Williams, Horatio B.** The method of electrocardiography and the electrocardiogram in health, 719.
- Woodbury, William H.** The Peterham plan, 834.
- Wodehouse, H. P., and Olmsted, J. M. D.** Preparation of animal food proteins for anaphylactic tests, 85.
- Wohl, M. G.** Carcinoma of the umbilicus, 442.
- Woodbury, Malcolm S.** The vegetative nervous system from the clinical viewpoint, 695.
- Wright, Harold W.** The significance of persistent pain and other symptoms referred to the peripheral nerves, 287.

Y

- Vale, Caroline A.** A plea for the instruction and after-school care of the feeble-minded deaf, 490.

SUBJECTS.

A

- Alcohol** and human metabolism, 918.
- American Doctors.** welcome to, 55.
- American Medical** casualties in France, 709; Units, 63.
- American Occupation** of British field hospitals, 55.
- American Public Health Association,** war meeting of the, 300.
- American Urological Association,** New England branch of the, meeting in Boston, March 13, 1917, 451.
- Animal Food Proteins.** preparation of, for anaphylactic tests, R. P. Wodehouse and J. M. D. Olmsted, 85.
- Anemia,** treatment of pernicious, especially by transfusion and splenectomy, George R. Minot, M.D.; and Roger I. Lee, M.D., 76.
- Annual Report** of the Massachusetts Anti-Tuberculosis League—1917, Seymour H. Stone, 667.
- Anthrax** as an occupational disease in Massachusetts, Thomas F. Harrington, M.D., 867.
- Anthrax** in Massachusetts for the current year, 785.
- Antiseptics,** the position of, 329.
- Anti-Tuberculosis Associations,** war activities for, 855.
- Army Medical Corps,** preparations of United States, in Mexico, 35.
- Arrhythmias,** the significance of, and systolic murmurs in relation to cardiac efficiency, Henry A. Christian, M.D., 750.
- Artrial Tension,** the rationale of neurasthenia and of disturbances of, George Edward Barnes, A.B., M.D., 543.
- Artificial Pneumothorax,** some notes on, Paul H. Ringer, A.B., M.D., 50.
- Ascending Lymphogenous Renal Infection,** Daniel N. Eisenrath, A.B., M.D., and Oscar T. Shultz, A.B., M.D., 10.
- Ayres, Edward A., M.D.,** obituary, 888.

B

- Bacteriology** at the front, 308.
- Back Lesions,** the value of diagnosis in, James Warren Seaver, M.D., 357.
- Barany Tests,** some observations on the, as applied to aviators, H. L. Babcock, M.D., 840.
- Base Hospital,** a report of service with the First Harvard Surgical Unit serving at a British, with the end-results of the cases one year later, Channing C. Simmons, M.D., 1.
- Benzol Poisoning,** industrial, in Massachusetts, Thomas F. Harrington, M.D., 203.
- Berkshire District Medical Society,** the founding of the, with notes on the first period of the existence of the Massachusetts Medical Society, Walter L. Burrage, M.D., 720.
- Biologic Analysis** in the study of true epilepsy, F. L. Dunham, M.D., 105.
- Blood Destruction,** the urobilin content of the feces as a measure of rate of, Francis H. McCrudden, M.D., 907.
- Blood Serum,** the preparation of, for use; studies in serum therapy, iii, Timothy Leary, M.D., and Frank H. Dunbar, M.D., 617; The use of normal, particularly with reference to the treatment of wounds; studies in serum therapy, ii, Timothy Leary, M.D., 611.
- Hook Reviews.** Eye, ear, nose and throat, Howard C. Ballenger and A. G. Whippner, 775.
- Focal infection, Frank Billings, 739.

- A treatise on regional surgery, edited by John F. Binnie, M.D., 881.
- Cerebellar abscess,** Isidore Friesner and Alfred Braun, 775.
- The diagnosis and treatment** of heart disease, E. H. Brockbank, 739.
- A compend of human physiology.** Albert P. Brubaker, 124.
- The growth of medicine** from the earliest times to about 1800, Albert H. Buck, 422.
- A text-book of first aid and emergency treatment.** A. C. Burnham, 634.
- Cornell University Medical College,** studies from the department of physiology, 422.
- Crann,** an adaptive mechanism, George W. Crile, 595.
- Localization by x-rays and stereocopy,** Sir James Mackenzie Davidson, 739.
- The influence of joy,** George Van Ness Dearborn, 422.
- Case histories** in obstetrics, Robert L. De Normandie, 18.
- Diseases of the stomach,** Max Elnhorn, 124.
- Anatomical names,** Albert C. Eyleshymer and Daniel M. Schoemaker, 197.
- First-aid to the injured and sick;** an advanced ambulance handbook, F. J. Warwick and A. C. Tunstall, 624.
- An index of differential diagnosis,** Herbert French, 124.
- State Board questions and answers,** R. Max Goeppe, 18.
- A chart of food values,** Paul W. Goldsbury, 775.
- Diseases of the genito-urinary organs and the kidneys,** Robert H. Greene and Harlow Brooks, 226.
- Organism and environment** as illustrated by the physiology of breathing, John S. Haldane, 377.
- A text-book of practical therapeutics,** Hobart Amory Hare, 594.
- Progressive medicine,** Hobart Amory Hare and Leighton H. Appleman, 261.
- Abnormalities of myocardial function,** T. Stuart Hart, 236.
- An introduction to neurology,** C. Judson Herrick, 226.
- The starvation (Allen) treatment** of diabetes, with a series of graduated diets, Lewis Webb Hill and Rena S. Eckman, 87.
- The institutional care of the insane** in the United States and Canada, edited by Henry M. Hurd, 669.
- The Basle anatomical nomenclature,** E. B. Jamieson, 124.
- The treatment of war wounds,** W. W. Keen, 813.
- Diseases of the stomach, intestines and pancreas,** Robert C. Kemp, 124.
- Health in the camp,** H. R. Kenwood, 669.
- Health and disease,** their determining factors, Roger I. Lee, 297.
- Clinical and laboratory technic,** H. L. McNeil, 669.
- The medical clinics of Chicago,** 123.
- The medical clinics of Chicago,** 456.
- The pathology and differential diagnosis** of infectious diseases of animals, Veranus Alva Moore, 595.
- Traumatic surgery,** John J. Moorhead, 159.
- General surgery,** Albert J. Ochsner, 197.
- Pulmonary tuberculosis;** a handbook for students, Edward G. Ochs, 708.
- The epidemic of poliomyelitis** in New York City.

- in 1916, based on the official reports of the bureaus of the department of health, 87.
- Clinical tuberculosis, Francis Marion Pottenger, 297.
- Social diagnosis, Mary E. Richmond, 17.
- Modern medicine and some modern remedies, Thomas Bodley Scott, 706.
- Obstetrics, normal and operative, Georges Peaslee Shears, 818.
- Manual of chemistry, W. Simon and Daniel Base, 466.
- Who is insane?, Stephen Smith, 297.
- Dr. Lyman Spedding, M.D., Spalding, 705.
- A manual of pharmacology, Torald Solmann, 18.
- The adolescent period, Louis Starr, 706.
- Food for the worker, Frances Stern and Gertrude T. Spitz, 634.

A REPORT OF A SERVICE WITH THE FIRST HARVARD SURGICAL UNIT SERVING AT A BRITISH BASE HOSPITAL, WITH THE END-RESULTS OF THE CASES ONE YEAR LATER.

By CHANNING C. SIMMONS, M.D., BOSTON,

Assistant Visiting Surgeon, Massachusetts General Hospital; Assistant in Surgery, Harvard Medical School.

THE following is a report of the cases coming under my care at the 22d General Hospital during my service with the first Harvard Unit serving with the British Army in France. The service was short—from August 16 to October 2, 1915—practically seven weeks. As major I was responsible for five tent wards representing about one-third of the surgical cases. These wards held 139 beds which were increased towards the end of the service to 187, but at no time were they all filled. A medical officer, ranking as captain or lieutenant, was in charge of each ward and did the greater part of the routine work,—Drs. Bachman, Goodwin, Reardon, Steinberg and Stookey, and to them credit is due for any success the service may have had.

Although called a base hospital, we were not supposed to keep cases that had not a reasonable chance to recover in three or four weeks, consequently most of the interesting cases were sent to England after a few days' stay, depending on their condition and the demand for beds. The less seriously wounded remained in the hos-

pital longest. During the Loos drive all cases, mild and severe, were sent to England as soon as they could be moved to make room. Cases were received at the hospital in from twelve hours to several days after injury, the average time being two to four days. Occasionally men wounded in the morning would arrive the same night. Cases received more than 48 hours after injury were usually serious and had been kept at the clearing station until in a proper condition to be moved. The impression was that a man, after he had once been removed from the field, received extremely good care and attention.

I have delayed publishing a report of the service till this time as I wished to determine the results in some of the more serious cases. The home address of all patients was obtained with this in view, and also the address of a relative or friend. Letters were sent November 1, 1916, a year after the injury, to 87 of the more seriously wounded, including all cases of compound fracture, all head, lung, and abdominal wounds, most of the cases that had had infection with the gas bacillus, and certain of the cases that had serious wounds of the soft parts. Replies have been received from 59. Few of the replies are of great scientific value, but all are extremely interesting, as the British Tommy is a prolific writer. With hardly an exception the men, although maimed for life, are happy and cheerful, and have even tried to enlist again and been refused. Certain of the figures given are not absolutely accurate but the errors are slight and relatively unimportant.

There were 310 patients admitted to my wards during the service, divided as follows:

Wounds	238
Civil injuries and diseases	45
Injuries, not wounds, due to military service	28

WOUNDS.

The wounds varied from the slightest scratch to severe multiple injuries, compound fractures, etc. During the September offensive about Loos practically every wound, no matter how trivial, was sent back to the Base Hospitals and it was not unusual at that time to have a patient admitted one day with, for instance, a slight abrasion of the scalp, and discharged the next. In the ordinary trench fighting the wounds were more serious, as slight injuries were attended to at the Clearing Hospitals. The wounds during this drive were chiefly bullet wounds, while those received in trench fighting were usually from fragments of high explosive shells. It is difficult to determine what type of missile caused a given wound, for although the patient has definite ideas on the subject, he often does not know. As far as can be determined, the wounds were as follows:

Rifle bullet	95
Shrapnel bullet	8
Shell casing	118
Hand or rifle grenade	17
Wounded by own grenades	2
Wounded by English bullets	2
Self-inflicted (?)	1

WOUNDS BY REGIONS.

Head and face	46
Body (back)	41
Body (front)	19
Right upper extremity	35
Left upper extremity	62
Right lower extremity	40
Left lower extremity	35

The left upper extremity, including the shoulder, was more often the seat of injury than the head and face, although the steel helmet was not in use at this time. This part of the body is most often wounded as in trench fighting it is the most exposed, the left hand and arm protecting the face. Thus there were 17 wounds of the left hand and only four of the right. The wound was more often on the back than on the front of the body, due probably to the position of the men in the trenches. Fifty cases, 22%, presented multiple wounds. In 13 they were of one part of the body only, while in 37 they were widely scattered. Most of these were shell wounds, but some were caused by bullets, one man having rifle bullets in his foot, arm, and chest. A certain number had in-and-out wounds of different portions of the body caused by the same bullet, as, for example, in-and-out wounds of the soft parts of both thighs, both buttocks, etc.

Severity. Some idea of the severity of the wounds may be obtained by the disposal of the case. Cases were discharged to Convalescent

Camp, Base Detail, or to England (hospital ship). If sent to the Camp they remained there for a short time and then rejoined their commands, and no case requiring a dressing could be discharged in this manner. Discharged to Base Detail implied that the patient was considered fit for light duty. Cases sent to England were usually seriously wounded, but I have divided this last group into the severe and slight wounds, which under ordinary circumstances would have stayed in the hospital a short time and been discharged to the Convalescent Camp, but which during the Loos drive were sent to England at once to free the beds. This last and the first two groups would be able to return to their commands in a short time.

DISCHARGES.

Convalescent camp	72
Base detail	12
Dead	3
Transferred medical	3
Sent to England	
severely wounded	70
slightly wounded	38
Remaining in wards	40

Thus in 122 cases, or 51%, the wounds were comparatively slight and the man returned to his command in a short time. A larger percentage than this returned to active service, as many seriously wounded and sent to England permanently recovered, and also all cases remaining in the wards at the end of the service are classed as permanently disabled, which they were not. It is interesting to note that of the 22 cases seriously wounded, from whom I had letters and who had returned to active service, 10 have been wounded again or killed.

OPERATIONS.

There were 113 operations done on the service, of which there are records in the operating room, but many minor ones were done in the wards. Of these, 29 were done by me and 84 by the medical officers. During the drive many minor cases were sent directly to England without having foreign bodies removed. The average case seen was one of minor surgery,—the removal of a foreign body, opening an abscess, etc. On the other hand, certain cases, brain and abdominal wounds, compound fractures, and cases with a gas bacillus infection, for example, are the most major surgery, and require the best judgment possible, only to be acquired by experience with that type of case.

There were two cases admitted, both shell wounds, that had had a traumatic amputation of the left hand. Two amputations were performed on the service, both for gas gangrene and both compound fractures. The English army surgeon is more inclined to amputate in compound fracture than the American, who is much more conservative. Whether or not in war times this had been proved to be the most efficient treatment and enables the man to become

a wage-earner sooner, I do not know. My personal feeling is to save everything possible, and it was discouraging to learn that a limb, saved with difficulty, was amputated soon after the patient was transferred to England. Three cases of compound fracture that were doing well at the time of transfer, had the limb amputated later. From the letters received from these patients, describing their condition, I do not think an American surgeon would have considered amputation.

MORTALITY.

There was a mortality of three cases, but a fourth case, a fracture of the dorsal spine, was sent to England and probably died soon after. It is to be inferred from this that most of the serious cases were treated at the Clearing Hospitals, and that the mortally wounded usually die in a few days. It would also seem that any cases living 5 to 7 days have a very good chance of ultimate recovery.

CASE 73. Shell wound. Compound fracture of skull, penetrating wound of lung with hemothorax, multiple wounds of back and right arm with gas bacillus infection. Died two days after admission. Autopsy.

CASE 10. Shell wound of groin with division of the femoral artery. Patient moribund when admitted and died in a few hours of hemorrhage and shock.

CASE 221. Shell wound of leg with compound fracture of fibula, bullet wound and compound fracture of humerus, pneumonia. Patient lay between the trenches in the rain for 36 hours before being brought in. Gas gangrene of leg. Amputation. Death three days later.

SEPSIS.

Most of the wounds were infected and practically all were treated as septic. This was particularly the case with the shell wounds. The fragments invariably carried in pieces of dirty clothing, and it was the rule to explore every case and remove the foreign body and, more important, the cloth. We found that in jagged shell wounds caused by a "side swipe" with a large fragment of shell and in which there was no penetration, time could be saved in healing by excising the sloughing edges and base of the wound, and doing a secondary suture. Something was always gained, although slight sepsis was to be expected. Bullet wounds were less apt to be followed by sepsis, and a certain number of both in-and-out and penetrating wounds remained clean and healed rapidly.

Infection with a bacillus of the gas-forming group is the thing to be dreaded, but the bacillus is not as virulent as the one commonly met with in this country. In some cases where a positive culture was obtained, there were no constitutional symptoms. Clinically, the short, thick forms appeared to be more virulent than the

long, thin forms that at times appeared in chains. Credit should be given to Dr. F. R. Frazer for his careful bacteriological work under very adverse conditions. There were 25 cases of gas bacillus infection on the service, with two deaths, but in neither of these did the infection alone cause the fatal result. Full bacteriological reports were obtained in 15, while the other 10 cases were seen during the rush, and the diagnosis was only clinical or made from smears, but cannot be doubted. The wounds were caused by shell fragments in 12 cases and bullets in 13, but 10 of these latter were compound fractures. The appearance of the wounds was characteristic. The limb was swollen, the tissues necrotic and exuding a thin watery pus filled with fine air bubbles. The odor is unmistakable. But three of the cases presented subcutaneous emphysema. Probably the other cases were operated upon before it developed.

The cultures from the wounds resembled cultures from feces. I have more or less detailed reports of cultures from 35 wounds infected with gas bacillus that were made in the hospital. One is given which is typical of them all.

CASE 87. Compound fracture fibula. Multiple wounds of both arms (shell).

Sept. 8. Smear, no organisms. Culture (agar). Gram-negative bacillus (colon?) and a Gram-positive bacillus resembling gas bacillus. Anaerobic agar, sterile. Anaerobic litmus milk, sterile.

Sept. 9. Smear, streptococci and Gram-positive and negative bacilli. Culture (agar) staphylococci and streptococci. Anaerobic agar, Gram-negative bacillus. Anaerobic litmus milk, acid, clotted, gas formation, and gas bacillus present.

Sept. 10. Second culture. Smear, diplococci. Culture (agar) streptococci. Anaerobic agar, sterile, 24 hours. Anaerobic litmus milk, acid, clotted, gas formation, and gas bacillus present.

For the determination of the presence of the gas bacillus only, Dr. Frazer made the culture in boiling milk. Bacteria, except the spores of the gas bacillus, were killed by the heat, but the spores of the gas bacillus withstood the temperature for the short time it took the milk to cool.

Cultures were taken from a series of 15 ordinary wounds when the patients were admitted. The wounds were cleaned, and healed the way slightly septic wounds ordinarily do. Three had, however, a pure culture of gas bacilli, although clinically they showed no signs of it. One case, a severe wound of the arm, complained a week after admission of soreness in a finger. Examination showed a shell fragment one-half inch in diameter which had been overlooked. It was removed and the wound healed promptly although culture showed a pure culture of gas bacillus.

Most wounds infected with the gas bacillus were thoroughly cleaned out, all dead tissue cut away, and packed wide open. Peroxide of hydrogen dressings were used or, when possible, a constant irrigation of hyperchlorous acid.

TETANUS.

There were no cases of tetanus, although the wounds were very dirty. As a routine, all cases were given anti-tetanic serum at the front, but occasionally a case was overlooked. On admission all cases were questioned as to whether they had received the serum, and if not it was immediately given. Eleven cases had more or less serum sickness coming on from five to twenty days after its administration. These varied from transient urticaria to severe prostration with high fever lasting three or four days. There were two cases of giant urticaria.

WOUNDS OF THE LUNG.

There were 11 cases of wounds of the lungs with one death (wound complicated by a compound fracture of the skull), and no cases of empyema. Four were caused by a rifle ball, one by a shrapnel ball, and six by shell fragments. Four, three rifle bullet and the shrapnel bullet wound, were in-and-out wounds, and in five a piece of shell was in the lung. Two cases were fracture of the lung without penetration. The cases reached the hospital in from one to five days after the injury, the average time being two and one-half days. Constitutional symptoms were comparatively slight in all and the temperature and pulse were only slightly elevated, returning to normal in a few days in all but one case. Cough was present only six times, the sputum being bloody in five cases and mucoid in one.

The physical signs were the same in eight of the cases. There was evidence of hemothorax above which was consolidated or compressed lung, but with a small area of normal respiration at the apex. Two cases, both with profuse bloody sputum, had no hemothorax at entrance, one and one and one-half days after injury. Examination showed coarse, moist râles only, but one case developed hemothorax five days later,—an in-and-out bullet wound. The other case, a fracture without penetration, never had an effusion.

No case developed empyema, although on account of the persistent temperature it was suspected in one. A tap revealed only bloody fluid, which clotted on being withdrawn. Culture was sterile. The case complicated by fractured skull died and an autopsy was obtained. The pleural cavity contained two litres of bloody fluid. The lung was collapsed and showed a few areas of consolidation. It was necessary to place the organ under the fluoroscope before the missile, a piece of casing one-fourth inch in diameter, could be found. Although no accurate analysis of the fluid was made, it appeared to be about one-third blood and two-thirds serum.

Two cases had wounds of other portions of the body, and one pneumonia of the unwounded lung.

The end-results are known in nine of the eleven cases. One died. Four of the other eight

are back on active service and one has been wounded again. Two of these were fracture without penetration, and in two a shell fragment was in the lung. Only two of these men had a hemothorax and one of them has spit up blood twice since the injury and has some shortness of breath. The fifth case, an in-and-out bullet wound with hemothorax and subcutaneous emphysema, has no symptoms. He also had a bullet wound of both legs.

Two other cases are working at a base,—an in-and-out wound, and a shell wound. Both had a hemothorax and both now complain of some shortness of breath. One has had "pleurisy" within a few months, and the other says that a recent x-ray shows some consolidation.

The other two cases have been discharged as unfit for service. Both have shortness of breath and both say that a recent examination of the lung showed that it "was not normal." One, a miner, can work only three days a week.

ABDOMINAL WOUNDS.

There were only three cases of abdominal wounds, two of which had been operated upon at the Clearing Hospital and were convalescent when admitted. All recovered. In one the abdominal cavity had been opened in the groin by a large shell fragment. This man at present has no abdominal symptoms, but is incapacitated as he also had a traumatic amputation of the left hand. One case had multiple bullet wounds of the intestine, which had been sutured at the front. He also had a compound fracture of both bones of the forearm and pneumonia. In the third case a shrapnel ball had entered the buttocks. He was admitted 36 hours after injury with a history of suppression of urine for that length of time. X-ray showed the ball in the pelvis. Suprapubic cystostomy was done and the ball found loose in the bladder. There was considerable sloughing of tissues from extravasation of urine, but recovery was otherwise uneventful. The man reports a year later that for some time he had incontinence and occasionally passed blood but is now well. He has been working in a bank for the past four months.

SKULL AND SPINE.

Eight cases. There were six cases of fracture of the skull. Two were slight depressed fractures of the vertex without symptoms. The depression was elevated. Three had a compound fracture of the frontal bone, one of whom died. In the other two there was an extensive injury to the upper jaw and face with the loss of an eye. There were no cerebral symptoms in either. Both of these men have been heard from and both are now working. They sent me their photographs, and the cosmetic result is good considering the injury. It was necessary to do two plastic operations on one case.

The sixth case had a small piece of shell in the brain in the parietal region and a brain

abseess. The fragment was removed and the abseess drained with the perforated metal tube suggested by Sargent. At discharge this patient was aphasic and had paresis of the face and arm. A letter from his mother states that he was in the hospital for some time, and several pieces of shell were removed from the scalp. His aphasia and paresis evidently cleared up as he was discharged to base duty, but recently he has lost his speech again.

Spine. Two cases. One case, now dead, had a fracture of the dorsal spine with complete paralysis (shrapnel ball). The other case had a fracture of the spinous processes of the first four dorsal vertebrae without symptoms. He is now on active service, but not in the trenches, as carrying a pack hurts his back.

PERIPHERAL NERVES.

There were but two cases of injury to the peripheral nerves recognized, one a paralysis of the recurrent laryngeal nerve following a wound of the neck, and the other a paralysis of the ulnar nerve in an extensive septic wound of the forearm. It was thought at the time that, owing to the hurry and the fact that most of our efforts were spent in combating sepsis, nerve injuries were overlooked, and this has proved to be the case. Five cases of compound fracture report by letter to have some nerve injury. In two of the six cases of fracture of the shaft of the humerus heard from, there is musculospiral paralysis. Both have been operated upon and in one, function has returned. The radial nerve was divided in two instances, but the disability is slight and both men are back on active service. There is one case of paralysis of the median and ulnar nerve in an extensively comminuted fracture of both bones of the forearm. This man has little use of his hand, but prefers it to an artificial one.

JAWS.

Contrary to the usual experience, there was a relatively small proportion of fractures of the jaws. There are only two cases, both upper jaws, and both complicated by fracture of the skull. Both have been heard from, and, considering the injury, the cosmetic results are good. Both are self-supporting.

COMPOUND FRACTURE.

A year ago I reported the compound fractures coming under my care (BOSTON MEDICAL AND SURGICAL JOURNAL, Feb. 17, 1916) and will, therefore, consider only the results. There were 61 cases of compound fracture, or over 25% of all cases. Of these, 45 were of the long bones. Several points have been brought out by the letters.

Of the 45 cases, the end-results are known in 34. Two died. In thirteen of the cases from one to seven operations were done after their return to England for the removal of fragments of dead bone. Five cases had an injury to a peripheral nerve which was overlooked when the patient was under treatment in France, and two had had a plastic operation on the musculospiral nerve with one success. There was only one case of non-union. This was a patient with a fracture of both bones of the leg. This was plated, but the plate was later removed.

Three cases had an amputation performed after their transfer (see amputations). The cases are as follows:

CASE 141. Sept. 26, 1915. Bullet wounds of the forearm, chest, and ankle, with fracture of a rib and the lower end of the tibia into the joint. Three bullets removed. Little comminution and no displacement of the fragments. The wounds of the arm and chest healed rapidly. After his return to England he had several operations for the removal

COMPOUND FRACTURES.

HUMERUS	TOTAL CASES	CASES HEARD FROM	OTHER OPERATIONS	RESULTS
Head	2	2		1 perfect, 1 dead (see fracture fibula).
Shaft	7	5	3	1 perfect, 4 with stiff elbow.
Lower end	3	3	1 Amputation	2 with musculospiral paralysis. 1 perfect (a crack only), 1 stiff elbow, 1 amputated in England.
RADIUS				stiff elbow.
Head	1	1		
Shaft	2	2		1 perfect, 1 amputation (gas gangrene).
Lower end	3	3		3 perfect.
BOTH BONES				
FOREARM	3	2		1 perfect, 1 ulna and median paralysis.
METACARPALS	10	6	2	3 perfect, 3 some use of hand.
FEMUR	4	2	1	Both sinuses, 2 in, shortening. Walk with cane. (gas infection. A question of hip joint amputation in one case.)
BOTH BONES, LEG	2	1	1	Non-union.
TIBIA	3	3	3	2 amputated in England, 1 has a sinus, but walks with cane.
FIBULA	2	2		1 amputation for gas gangrene,—death, 1 perfect.
METATARSALS	2	2	1	1 perfect, 1 walks with cane.

of fragments of dead bone about the ankle and the opening of abscesses. Leg amputated in February, 1916.

CASE 218. Sept. 28, 1915. Compound, badly comminuted fracture of the lower end of the tibia, extending into the joint. Rifle bullet in head of astragalus. Bullet removed. After transfer had many operations for fragments of dead bone, but wound healed in the spring of 1916, leaving the ankle stiff. In October, 1916, another abscess formed, and the leg was amputated in November, 1916, over a year from the time of injury.

CASE 225. Sept. 28, 1916. In-and-out bullet wound which practically destroyed the elbow joint. Gas bacillus infection. At discharge the wounds were granulating well and the motions of the hand were good. The arm was amputated ten days after his transfer to England.

JOINTS.

There was only one case of a wound of a joint other than those occurring in compound fractures, or of the carpus or tarsus. In this case a small shell fragment was removed from the knee joint 24 hours after injury. The joint was washed out with salt solution and closed without drainage. The joint remained clean, although the superficial wound was infected. The man is back on active service, but the knee swells at times after violent exercise.

WOUNDS OF THE SOFT PARTS.

The following is a brief analysis of the wounds of the soft parts. These figures, as others, are not absolutely accurate, as cases wounded in two places, as the arm and leg, have usually been counted twice, while others have already been considered under other headings.

Shell wounds (no foreign body).....	61
Shell wounds (foreign body).....	59
Bullet wounds (no foreign body).....	50
Bullet wounds (foreign body).....	8
Shrapnel ball.....	1

The shell wounds, where there was no foreign body, were usually cuts with large fragments of casing. The bullet wounds were usually in-and-out wounds, but some were gutter wounds.

Head and scalp. 25 cases (other than fractures). All slight wounds. Most were caused by shells bursting near the patient, and the fragments either peppering the scalp or making slight cuts. A few were gutter wounds, which cut the scalp without injuring the bone. It was in this type of wound that excision and secondary suture gave the best results. Some idea of the severity of the wounds may be had by studying the discharges. 23 of the 25 patients were sent to the Convalescent Camp, or to Base Detail, well. Two were sent to England, to give more beds.

Neck. 6 cases. Five shell and one in-and-out bullet wound. The wounds were all slight with one exception,—a man with a small wound, recurrent laryngeal paralysis and pneumonia.

Body. Back 21, front 4. These were similar to all wounds of the soft parts, and the chief interest lies in the frequency with which the wound was on the back. The buttocks were proportionately commonly wounded,—6 cases. Most of the wounds were slight, 19 of the cases being well or practically so when last seen. Four were severe, one having a shrapnel ball pass through the back from the left shoulder to the right kidney, where it lodged without causing damage. Another case had a gas bacillus infection involving the ischio-rectal fossa.

Shoulder. 20 cases, 13 shell wounds and 7 bullet wounds. Of the latter, 4 were in-and-out wounds and 1 was a gutter wound. All were slight flesh wounds. In one case a shell fragment entered under the acromial end of the clavicle and was found, with the x-ray, in the mediastinum. Although it is difficult to see how the lung escaped injury, there were no symptoms referable to that organ. The man is now, one year later, on active service.

Arm. 19 cases, 12 bullet and 7 shell wounds. 7 were multiple. There were 3 moderately severe wounds, 1 being infected by a gas bacillus. This man, however, returned to active service, and has since been wounded again. I believe all the cases returned to active service.

Forearm. 19 cases, 9 bullet and 10 shell wounds. In the 9 bullet wounds, 8 were in-and-out or abrasions only, while in the other the bullet lodged against the ulna without fracturing it. In 7 of the shell wounds fragments were removed.

Hand. 15 cases, 2 bullet and 13 shell wounds. In two of the latter, only, was it necessary to remove a foreign body. The wounds were often severe as regards permanent disability, as several had one or more tendons severed or joints opened. One man had the tendons of the four fingers severed. Tendon suture was done 48 hours after the injury was received, and, although the wounds went septic, he writes a year later he has perfect use of his hand and is still in the service, but stationed at a base.

Thigh. 25 cases, 12 bullet and 13 shell wounds. Many of the bullet wounds were in-and-out, while in 11 of the shell wounds it was necessary to remove foreign bodies. Three wounds were infected by a gas bacillus.

Leg. 20 cases, 12 shell and 8 bullet wounds, of which 7 were in-and-out. Four of the wounds were severe.

Foot. 5 cases. All slight wounds, but the disability was relatively great. All would eventually permanently recover.

Burns. 2 cases. Both were of the face and hands, and were superficial. One was caused by the premature explosion of an English fire bomb, and the other by the explosion of a German grenade from which the man was attempting to make a souvenir.

INJURIES DUE TO SERVICE.

Twenty-eight cases. The injuries in this

group, although not properly wounds, were due directly or indirectly to military service. There were 6 cases of fracture, 8 of minor sepsis, and 14 of sprains, etc.

Six of the cases, three fractures, were caused by horses or mules, and one, a fracture of both bones of the leg, by an automobile. Six cases were injured by being buried in earth or sand bags by the explosion of a shell. Most of these were minor injuries, but two were severe sacro-iliac strain. Several of these "buried cases" presented a peculiar mental condition, best described as having "lost their nerve," although the injury was comparatively slight.

The other injuries were caused by falling into shell holes, falling over a trench, entrenching, etc.

There were eight cases of minor sepsis, all trivial, several due to the conditions under which the men lived in the trenches.

<i>Fractures</i>	Metacarpal, rib, clavicle, nose, fibula, both bones of leg.	
<i>Minor sepsis</i>	Eight cases.	
<i>Sprains, etc.</i>	Sprained ankle	3
	Synovitis knee	3
	Dislocated semilunar cartilage	1
	Abrasions	3
	Sacro-iliac strain	3
	Tuberculosis hip	1

CASES OF CIVIL SURGERY.

Forty-five cases.

There were five cases of sprains or fracture, three being due to football; and two, dislocated semilunar cartilages of the knee, had had trouble for years, and should never have been accepted in the army.

Minor sepsis. Many of these, such as four cases of multiple boils, were probably due to the conditions in the trenches.

Abdominal cases. Eleven cases. There were two cases of appendicitis, one of an abdominal sinus following appendectomy eight years before, and eight cases of hernia. Hernia is common. Three of the cases, two inguinal and one ventral, had been operated upon previously, and were recurrent. One case had had a hernia for years, which had not bothered him until he entered the army one month before. This man also had thrombosis of the ophthalmic vein, and should not have been passed by the examining surgeon. Three cases of hernia were operated upon and five were not. It is impossible to force a man to be operated upon if he does not wish it, and all patients have to be given the choice of a truss or an operation. A certain number choose a truss, as it means they will not be called upon to do active work, but he put at clerical work at the base.

Genito-urinary diseases. Five cases. There were two cases of acute epididymitis, one of syphilis, one of phimosis, and one of varicocele. Venereal diseases were uncommon, owing partly

to the fact that they were all sent to a special venereal hospital.

Medical cases. Three medical cases were admitted to the wards,—a case of malaria, contracted in India, a case of diabetes, and one of pulmonary tuberculosis. These cases were transferred to the medical service. Several other cases that presented wounds were transferred to other departments, such as the dental, ear, or nose and throat, after the wounds had healed.

Varicose veins (3 cases). Hemorrhoids (10 cases). The three cases of varicose veins were not severe, and two I am inclined to think exaggerated the symptoms in order to get a rest. The hemorrhoid cases were probably due to the conditions in the trenches, and constipation, which was almost universal. Five were cases of many years' duration which had recurred, and five had had no trouble until they had been on active service. Six were operated upon and four refused, probably for the same reason the herniae refused,—they knew they would be put to work at the base and not be sent back to the front.

FIG. 1. Case 28. Compound fracture of the radius and ulna with division of the brachial artery at the bend of the elbow with gas bacillus infection. The arm is much swollen as far as the shoulder.

FIG. 2. Case 28 after operation. (See Fig. 1.) Multiple incisions have been made in the arm and forearm and large wicks, wet with hydrogen peroxide, passed from one wound to the other. Amputation was performed the following day for gangrene. The man is now well but almost destitute as he is unable to obtain work.

FIG. 3. Case 77. Multiple shell wounds of the back and compound fracture of the right humerus, with gas bacillus infection of all wounds. Foreign bodies removed and wounds drained. A year later patient reports that he has a useful arm but with some deformity. He is at present serving as an army cook.

FIG. 5. Case 31. In-and-out wound of the forearm four days old. No disability. This man was discharged well five days later.

FIG. 4. Case 27. In-and-out wound of both buttocks, the arrow indicating the course of the bullet. The wound of entrance is hardly visible while the second wound of exit is quite large. The discoloration of the skin is due to iodine.

FIG. 6. Case 48. Multiple shell wounds of scalp with one fragment in the brain and brain abscess. Fragment removed and abscess drained with Sargent perforated metal tube. At discharge patient has a small brain hernia and paresis of the hand and face. A year later his mother wrote that he had been doing some work around a camp, but that he had recently lost his speech.

FIG. 7. Case 41. In-and-out, in-and-out wound of the face, made by a bullet. Note the comparatively small wound of entrance and large wound of exit. A salivary fistula persisted for some time, but the wounds were all healed in four weeks.

FIG. 8. Case 32. Cutter bullet wound of the scalp without injury to the skull. The arrow indicates direction of the bullet. Excision of wound with secondary suture followed by rapid healing. This man was killed later by the explosion of a German mine.

FIG. 9. Case 86. Compound fracture of the frontal bone and upper jaw with destruction of the eye. The wound extended into the mouth. No cerebral symptoms. A plastic operation to repair the cheek was done.

FIG. 10. Case 86. (See Fig. 9.) One year after injury. Two plastic operations were done after the patient returned to England. The man is working as a gardener.

ASCENDING LYMPHOGENOUS RENAL INFECTION.*

By DANIEL N. EISENDRATH, A.B., M.D., CHICAGO,
AND
OSCAR T. SCHULTZ, A.B., M.D., CHICAGO.

[From the Morris Institute for Medical Research of the Michael Reese Hospital.]

WE have attempted to study the route of infection of the kidney which takes place in an ascending direction along the interstitial lymphatics of the ureter. A preliminary report of our work was published early in the present year¹ and the complete results of our experiments will be published shortly.²

We have felt for some time that the older view of infectious ascending from the bladder to the

kidneys along the lumen of the ureter must be abandoned, except in cases of complete obstruction of the ureters. The work of Sakata, Bauer-eisen, and Kumita has shown that there is a direct and very intimate connection between the lymphatics of the bladder and those of the ureter and of the latter with those of the renal pelvis and kidney parenchyma. The work of Kumita especially has demonstrated the presence of a network of lymphatics in close relation to the blood vessels within the kidney. This network within the kidney communicates again with the lymphatics of the fatty capsule of the kidney (Fig. 1). In all previous experiments the ureter was either ligated and the organism injected above the point of ligation or the ureter was severed and reimplanted into the intestine. We believe that the ligation method produces a complete obstruction seldom found clinically, while the objection to the reimplantation method

* Read at a meeting of the New England Branch of the American Urological Association, Nov. 28, 1916.

FIG. 1.

is that the action of the ureteral sphincter is nullified, and that the opportunity for entrance of organisms into the lymphatics of the end ends of the ureters allows pathologic changes to occur with such intensity that it is difficult to trace the paths of the infection.

Technic.

The organisms employed were *Bacillus coli*, *Staphylococcus aureus* and *Bacillus proteus*. We attempted to imitate conditions found clinically in cases of ascending renal infection in the human being, by making an emulsion of sterile salt solution and scrapings of four agar slant cultures of the organisms. This emulsion was then injected into the bladders of female animals (dogs and rabbits) through a sterile silver cannula of very narrow caliber. The external genitalia were first thoroughly cleansed and some of the urine obtained for cultures so as to determine whether any infection was present before the emulsion of the bacteria was injected. The animals having been anaesthetized with ether, every precaution was taken to avoid any injury to the mucosa of the bladder and urethra. A minimum degree of force was used in injecting the emulsion.

Our animals were killed at varying intervals with strychnine and cultures were immediately made from the heart's blood, from both kidneys and from the bladder. For microscopic study the urinary tract with the surrounding connective tissue was removed *en masse*. Areas from different portions of the bladder were first taken, then the entire ureter was divided into segments. The lowest segment included the uretero-vesical junction and the highest, the junction of the ureter and renal pelvis. Between these two, the ureter was divided into four segments.

The kidney sections were taken so as to include in one set the areas where the finer divisions of the renal pelvis receive the papillae and in another set as much as possible of the medulla and cortex in a single section. All tissues were imbedded in paraffin, cut serially and stained with hematoxylin and eosin. The various segments of the ureters were cut longitudinally in serial sections, so that one could follow the paths of the infection continuously from the bladder upward into the ureter and along the walls of this structure into the parenchyma of the kidney. We cannot emphasize too strongly the great value of longitudinal serial sections in following the evidences of infection along the lymphatics of the ureter.

In two series of experiments carried out according to this technic, just outlined, a total of thirty-seven animals were used. Of these, eleven were rabbits and twenty-six were dogs. Of the eleven rabbits, six showed involvement of the ureter, five of the pelvis, and six of the kidney. The pathogenic organism injected was recovered from the bladder five times; from the kidney twice.

Of the twenty-six dogs used, twenty-one showed ureteral involvement, sixteen pelvic involvement, and thirteen, lesions of the kidney. The organism injected was recovered from the bladder twelve times and from the kidney five times. Seven dogs were examined by the same method as controls. One of these showed the same type of lesion in the ureter and pelvis.

Microscopic Changes.

Five days after the introduction of the bacteria into the bladder the urinary tract is the seat of a well-marked sub-acute inflammatory reaction, which is chiefly infiltrative in character. The change is most marked in the sub-epithelial tissues of the lower end of the ureter, especially about the mouth of the latter, and in the tissues of the pelvis. At these situations the stroma is decidedly infiltrated with lymphocytes, the endothelium of the lymphatics is swollen and there are numerous foci of perivascular infiltration. The mucosa of the bladder is decidedly infiltrated and in the mucosa and sub-mucosa the lymphocytes are congregated about the vessels. The ureter, between its lower and upper ends, where the reaction is most pronounced, shows moderate paths of lymphoid infiltration of the stroma, epithelium and muscle with some perivascular localization. The same reaction is present in the interstitial stroma of the kidneys leading to the formation of lines or band-like areas of cellular infiltration. The epithelium of the entire tract is intact, except in a few places where it has been invaded by the lymphoid infiltration.

Examination of the serial sections of these areas shows that these foci are largest in the sub-epithelial tissue, indicating that they had their origin here and only secondarily invaded the deeper portion of the epithelial layer. The experiments of longer duration, as compared with the five-day experiments, show those progressive changes in the inflammatory reaction that are to be expected. The sub-epithelial stroma is proliferated throughout the urinary tract from the bladder to the renal pelvis. The older series are more proliferated than in the fifteen-day experiments. New blood vessels are present and the lymphatic endothelium is proliferated. The focal lymphoid infiltration may be present in the bladder mucosa, in the sub-epithelial tissues of the ureter and pelvis. In the pelvis the infiltration may be diffuse as well as focal. The lymphoid infiltration is most marked at the mouth of the ureter and in the pelvis along the middle third of the ureter there may be, scattered, small foci of perivascular infiltration in the tissues of the outer zone of the ureteral wall.

Comparison of the changes due to the three species of the bacterial organisms used shows in the dogs the most marked reaction after *B. coli* and the least marked after *Staphylococcus aureus*, with after *B. proteus* a reaction inter-

mediate between the other two. The findings are at variance with the usual statement that a pyogenic infection produces a most intense localization.

In the rabbits the same virulent reactions were obtained after *B. coli* and *B. proteus* as well as staphylococci. In the dogs in every case the reaction is characterized by the absence of polymorphonuclear leucocytosis; by diffuse or focal lymphoid infiltration in the early stage, of variable degree, depending upon the organisms; and by moderate proliferation of the sub-epithelial stroma and of the capillaries in the later stages. Always, even when the changes are slight, the endothelium of the lymphatics reacts by swelling and proliferation, which may continue to such a degree that individual lymphatics may become completely filled with large, irregular polyhedral cells. Common to all the experiments is the intact condition of the lining epithelium of the entire tract. In every case the uretero-vesical and the uretero-pelvic junctions show a greater degree of inflammatory reaction than does the rest of the tract.

DISCUSSION OF CLINICAL APPLICATIONS.

Our work shows that both motile and non-motile organisms are easily transported from the bladder to the kidneys by the lymphatic stream in the ureteral wall. This is not dependent upon the presence of any obstruction of the lower urinary tract, and it occurs even with intact uretero-vesical orifices. This would explain many of the cases of pyelitis and pyelonephritis which complicate a cystitis. When fever and chills occur during the course of an infection of the lower urinary tract, it is now generally accepted that this indicates an infection of the upper urinary tract, a pyelonephritis. Our experiments prove conclusively, we believe, that the path along which this infection travels is first in the bladder in the submucous and perivesical lymphatics, then by way of the lymphatics of the ureter (especially the submucous and peri-ureteral) to the submucous lymphatic vessels of the renal pelvis, and from here by continuity of the lymphatics directly into the network of intrarenal lymphatics, and then beyond this, into the perinephritic tissues (through the communication of the lymphatics of the cortex with those of the true and fatty capsule of the kidney).

Although difficult to prove experimentally, we believe that our work shows that the free anastomosis between the lymphatics of the broad ligament and those of the ureter makes it possible for infection to travel directly from the uterus and adnexa to the ureter, and from here to the renal pelvis of the kidney.

The intensity of the pyelitis in some of our dogs was out of all proportion to the ureteral changes. We believe that the same occurs clinically, and is explained by the slowing up of the lymphatic stream just before it communi-

cates with the lymphatic current within the kidney. We have observed the gradual lessening of the intensity of the reaction the longer the animals lived. This is due to the immunization of the animal toward further infection, unless the intra-vesical inoculation is constantly repeated. The same phenomenon is observed clinically. As the infection in the bladder decreases, the pyelitis improves in equal ratio. This explains why bladder irrigations and supra-pubic or perineal drainage cause a rapid improvement in conditions of urinary sepsis, especially in infected kidneys.

CONCLUSIONS.

1. Anatomical studies have demonstrated the presence of an anastomosing network of lymphatics in the wall of the bladder and of the ureter, communicating above with a similar lymphatic network in the renal pelvis and parenchyma. At its lower end this system communicates also with the lymphatics of the pelvic structures, in both the male and female.

2. Infections of the bladder or lower ureter may reach the renal pelvis or the kidney, either by way of the lumen of the urinary tract or by way of the mural lymphatics.

3. Experimental and clinical evidence indicates that almost complete obstruction to the free passage of urine is necessary for ascent of infection by way of the lumen of the urinary tract.

4. Experimentally we have shown that infection, set up by the simple introduction of bacteria into the bladder without injury or without obstruction, may pass upward by means of the interstitial lymphatics of the ureter.

5. The degree of involvement following the introduction of bacteria into the bladder depends upon the virulence of the organism and upon the susceptibility of the animal. The subsequent tissue reaction may remain limited to the bladder and ureter, it may pass upward to the tissues of the renal pelvis, or even the parenchyma of the kidney itself may become involved.

6. When the kidney tissue is involved in ascending infection brought about experimentally, as described, the path of travel is from the sub-epithelial tissues of the pelvis to the kidney by way of the inter-tubular and perivascular lymphatics.

7. From the kidney the perirenal tissues may become involved through the capsular lymphatics, which anastomose with those of the cortex.

8. The experimental evidence indicates that, in cases of pyelitis and pyelonephritis in the human, secondary to infection of the bladder, the lymphatics constitute the most important course of upward travel of the infection, especially in those cases where there is no hindrance to the urinary outflow.

9. Pyelitis and pyelonephritis, not secondary

to cystitis, may also be the result of lymphatic transport of infection from the pelvic organs in the male and female, and from the lower intestinal tract.

DISCUSSION.

DR. HUGH CABOT: This paper raises a very interesting group of questions which are important. I want to thank Dr. Eisendrath for giving us ample opportunity for going over his material in advance. It is certainly in that way that one gets down to the facts, where you can take a man's work and go over it at your leisure. When any one of us puts out work which is at variance with the work of previous observers he will not object to confirmation.

Dr. Eisendrath's method of producing all these infections is by the injection of organisms into the untraumatized bladder. That is a type of experimental work which has been done for years. There is an immense mass of evidence showing that infection of the bladder and the urinary tract cannot be produced by that method, and I submit that there is an inherent possibility of error at this point. There is clinical and an immense mass of experimental evidence tending to show that by the introduction of organisms into the bladder in the absence of obstruction, whether produced experimentally or existing pathologically, no infection has ever been demonstrated to take place, and I think it is certainly necessary that this work be confirmed and that evidence be produced by other experimenters that it is possible to produce inflammatory lesions of the urinary tract without the production either of trauma or obstruction.

In the production of an inflammatory lesion of the urinary tract such that the lesion can be demonstrated and in which the organisms are recovered from the urine at autopsy, it is necessary to show that in the cases where the organisms are recovered there shall be a lesion in that patient. For example, in Case 401, a dog infected with the colon bacillus, there were no lesions and yet the organism was recovered from the bladder. That is a case that requires explanation. Take also Case 429, a dog with the bacillus proteus. There were lesions in the ureter, pelvis and kidney, and no culture. In one case there are lesions and no growth, and in the other, growth and no lesions. Again, the length of time over which these organisms appear to be recoverable seems to me quite extraordinary.

It is acknowledged that the chronic colon bacillus lesion of the kidney is a pyelitis which connects with the urinary tract. That is the lesion typical of pyelitis and has been so recognized for years. The organisms persist because they grow in the urinary tract, either in the mucous membrane or, in the presence of obstruction, in the urine itself. The characteristic thing about Dr. Eisendrath's lesions is that they are not in contact with the urinary stream and we should not expect to find organisms in culture in the urine.

It is interesting, I think, to trace the cause, the natural history, as one might say, of a case of pyelitis. The early cases have been difficult to find. There is very little pathological material other than experimental material showing the exact nature of the colon bacillus infection, which later may termin-

ate fatally. Now those specimens, as far as I have known of them, have universally shown a pyelitis demonstrated by the organism in the mucous membrane and in infiltration of the mucous membrane, the process having settled there because that is a satisfactory medium for it, whereas the kidney itself is not a satisfactory medium. The organisms enter the kidney from above and infect it. They do not find a location favorable for growth and ultimately arrive at the mucous membrane and do find there a congenial condition, so there they remain. That is, as I believe, the typical cause of colon bacillus pyelitis.

Dr. Eisendrath says that this work shows the transference of organisms from the bladder up along the ureter to the kidney. I submit that no transference is shown. Perhaps he has slides which show organisms, but if so we have not seen them. It seems to me absolutely essential that if it is to be claimed, as he claims, that he has demonstrated the transference through the bladder to the kidney, the organism would be somewhere along the road. Organisms in these lesions must be shown if we are to believe that the organism and the lesion are fastened together.

I understood him to correlate the occurrence of fever and chills in a case of acute pyelitis subsequent to a cystitis with the passage of the organism along the lymphatics. One might suggest that fever and chills are commonly produced by the entrance of organisms into the blood stream, and the colon bacillus has been found in the circulation with great regularity. It is not safe to assume that fever and chills occurring in pyelitis are due to lymphatic infection. They certainly may reach the kidney through the blood stream.

Again, I think one does well to remember that the lymphatic systems of the ureter are exceedingly segmented. There is nothing, as far as I know, approaching a continuous chain of lymphatics for any considerable distance. They leave the region of the ureter and go to the lymph nodes. They must return back along the lymphatics from the nodes to the ureter. It is not a continuous performance, by any means. We must be prepared to assume that they leave the ureter and then see fit to return to the ureter in preference to staying where they are.

Again, we should do well to remember that where, as is shown here, there are areas of definite infiltration about the blood vessels, it does not follow that those are lesions of the lymphatics. We know, in fact, that lesions of the vein will produce that appearance about the vein involved, and that a perivascular infiltration does not by any means show it to be lymphatic and in some cases clearly does show it to be vascular in origin. Undoubtedly organisms leave the vein and reach the lymphatic, and *vice versa*, once having been in a lymphatic, very readily enter blood vessels. It may be readily interrupted at any point in its progress by direct entrance into the vein.

Then finally (and I trespass here slightly on the ground which Dr. Crabtree will cover), lymphatic infiltration is not characteristic of any inflammation known to be produced by the *Staphylococcus aureus*. It is quite at variance with human microscopic pathology, and is evidence of a chronic and not of an acute lesion.

We must hold that this is an interesting piece of work, that though it shows lesions in the peri-ureteral, peri-vesical and peri-pelvic structures,

there is a lack of evidence showing how these lesions are produced, and it has not been demonstrated that these lesions bear any relation to the bladder.

DR. E. GRANVILLE CRABTREE: Dr. Eisendrath very kindly brought on with him the pathological material on which this paper is based and left it with Dr. Cabot and myself over the period of the Yale-Harvard game. I have had an opportunity both to read the paper which you have just heard and to go over carefully the pathological material at my leisure.

The material is most interesting. Areas, such as you have seen pictured, of undoubtedly inflammatory nature are found beneath the pelvic mucosa and along the ureter. The infiltrations are almost invariably lymphocytic with, in some cases, a few leucocytes. The areas of infiltration are small with a striking absence of renal lesions of significance. I have failed to find any difference in the character of the lesion produced (pus cell or lymphocyte) when the lesion represents infections of 5-7 days—or that of many weeks. One must then believe that acute coccus infections produce what we must classify pathologically as chronic inflammation.

There are several facts which come to mind which require explanation before the theory of lymphatic infection of these kidneys can be accepted.

One of these points is, that inasmuch as you have to deal with lymph channels, when pus-producing organisms are used as infecting agents, suppurative changes of the regional glands are to be expected. Dr. Eisendrath does not mention whether or not he has noted it. Perhaps these changes exist and have not been noted.

That the *Staphylococcus aureus* in cases of recent infection produces the chronic type of inflammation in lymphogenous infections is possible, but pus cell changes in hematogenous infections is an inconsistency demanding explanation. That, it seems to me, is a condition which does not approximate the human kidney, which is the lesion we are endeavoring to explain.

Lymphatic involvement of the perivascular tissue, perineum and peritonium has been shown by many observers to result *quickly* in blood invasion. I do not believe the cultural evidence here presented excludes the blood stream.

Dr. Cabot has brought out a point which is paramount, *i. e.*, the demonstration of relation to the lesions here shown of the organism injected. I refer to staining of bacteria in the tissues.

There is still another point which I wish to mention, which has already been discussed by Dr. Cabot. That is, the absence of evidence of invasion of the urinary stream by the organism. There is some evidence produced to indicate the occurrence of small chronic inflammatory processes invading the mucosa, yet neither from a general involvement of the pelvic and ureteral mucosa, nor from the urine, is there evidence of a lesion similar to pyelitis in the human. This may explain the rather erratic cultural returns from kidney, ureter and bladder.

This work is noteworthy in that it has added one more gravestone to the ascending urogenous theory—a once popular and pernicious theory.

Dr. Eisendrath's work shows possibilities which, I think, can be developed. He has already determined to stop some of the leaks by further work. If the lymphatics are capable of causing renal infection, work along this line will be able to prove it.

We have spoken thus freely, not to appear in-

hospitable, but because Dr. Eisendrath asked us for a frank criticism of his work.

DR. JOHN CUNNINGHAM, JR.: I wish only to congratulate Dr. Eisendrath on the excellent piece of work he has done and thank him for bringing it to us for discussion. From the diversion of opinion expressed by others who have given special study to this subject it seems that all that the rest of us can do is to sit as a sort of jury and listen to the discussion of the subject by the two factions.

DR. G. G. SMITH: It seems to me that Dr. Eisendrath's paper does suggest the explanation of certain things which we see occur clinically. For instance, I remember a man who had a seminal vesiculitis in which the *Bacillus mucosus capsulatus* was the etiological factor, and during the course of treatment for that he developed a kidney infection on the same side. I catheterized his ureter to see what was happening, and I found the same organism coming from the kidney.

Of course, it may have been simply a coincidence. Things like that are unexplained by theory, but if Dr. Eisendrath can put his case on four legs so that it will run, I think that it will explain some of those things which, to my mind, have hitherto been unaccounted for.

DR. A. L. CHUTE: Dr. Eisendrath has given us the opportunity of listening to a very entertaining and suggestive paper. I agree with Dr. Smith that some such method of infection as the author has described will explain certain cases that we encounter, better than any other method of infection.

In regard to the question that has been brought up, as to whether or not an infection can travel along the lymphatics of the ureter, I had supposed that this point was pretty well settled some years ago by the work of Stewart and Sweet. It is true that in their experiments the infection entered the lymphatics through the cut end of the ureter and not through the mucous membrane of the bladder, as in Dr. Eisendrath's experiments, but I thought their work proved definitely that an infection could extend up the lymphatics of the ureter. In women, especially, there are infections that do not bear the imprint of the hematogenous infection; there are one-sided renal infections that follow infection of the bladder quite promptly. The element of back pressure is so very slight in women as to make it improbable that these infections are up the lumen of the ureter, though it would be useless to deny the possibility of this. The only other probable methods are by the organisms getting through the bladder mucosa either into the blood stream or into the lymphatics, and one-sided infection is too frequent in such cases to make it seem probable that the infection is always by the blood stream. The importance of the blood-borne infections of the kidney, I think we have all recognized and appreciated for a considerable number of years, but to the minds of many of us it does not satisfactorily account for all renal infections.

I want to thank Dr. Eisendrath for my pleasure in his paper.

DR. EISENDRATH (closing): I certainly thank the gentlemen very much for what they have said. I want to tell you the circumstances under which I am reading this paper here. When we put out our preliminary report it was very brief. It appeared

last January in the *Journal of the American Medical Association*, and at that time Dr. Cabot referred to the article and I wrote him about showing him some of my specimens. It is my experience that the only way you can get ahead is to present your argument, and that is the reason I left my specimens at the disposal purposely of Dr. Cabot and Dr. Crabtree in order that they should look at them and have a full opportunity, without being influenced by my presence, of judging for themselves.

They have pointed out some weak points. One of them is that we have not examined the regional lymph nodes, but personally I do not think that is as weak a point as it seems. I do not agree with Dr. Cabot and Dr. Crabtree in saying that the lymphatics are segmental. We know, for instance, that in the case of the common duct or of the cystic duct there is quite a long tube without any intercepting lymph nodes, though there are some at the neck of the gall-bladder and around the junction of the cystic ducts. Another reason why I do not think so is that in examining hundreds of sections we can find in these sections, layer by layer, from the bladder all the way up into the ureter, the areas of infiltration continuous. There is not a single interruption. There is not a single place, in looking at all the sections, of a segment of the ureter. Where you see any infiltration, that would indicate an extension from this sub-mucosa layer out in the peri-ureteral sheath. We are going to repeat a great many of our experiments, and we shall pay particular attention to the lymph nodes.

In regard to the question of lymphatic tissue, our attention was called very early to that by Dr. D. J. Davis, professor of pathology in the University of Illinois. He saw one or two of the sections and marked such areas with a question mark. I called it infiltration and submitted them to him, and he said "No. I think it is normal lymph node"; but ever since then we have guarded against judging anything of that kind. They have such a definite anatomical arrangement that they do not look in the least bit like those of lymphocytic infiltration.

In regard to lymphocytic infiltration, that might seem at first glance like a weak point. Yet we did not try to produce infections which would be so diffuse. In cases where we produced infections such as Stewart and Sweet did in their reimplanting they were so diffuse that it was hard to get such pictures as we have. I have had experience with them, and you cannot tell where an infection really started. That was why we tried to work with the organisms and really study the early stages.

I am not enough of a pathologist to be able to say that in the animals the lymphocytic infiltration is characteristic of sub-acute or chronic inflammation as compared to acute, but I am assured by those who are competent that this infiltration does not contradict the possibility of a sub-acute or low-grade infiltration.

Dr. Cabot mentioned the fact of no infection taking place through an intact bladder. Between the epithelial cells of the mucous membrane of the stomach there is a most intact network of lymphatics that runs around between the individual cells of the stomach. When we see such pictures in so many sections we begin to be greatly influenced to assume that infection takes place through this. We know that, for instance, organisms in the mouth

will attack an intact mucous membrane and drain into the region of the lymph nodes.

Now, he showed some apparently weak points in my case 401, 15-day experiment, not finding any microscopical indication and yet finding it in the bladder. There seems to be the same thing in the animals that takes place in the human, that is, there seem to be animals which you are not able to infect. There may be a special immunizing process in these animals. The older the animal was the less changes we saw, because the animals would seem to have this immunizing process and would show less reaction.

Dr. Cabot made the statement that the colon bacillus finds a congenial medium for its growth in the pelvis of the kidney and therefore it lodges there. That colon bacillus has to go through the tubules of the kidney. It is supposed to destroy the convoluted tubules and lodge down in the mucous membrane of the pelvis and find a nice place to lodge there. Does that seem rational? When you have as strong a stream as a urinary stream, drop by drop, is there chance for it to find a long enough time to lodge there? It seems to me rational to think that in these cases of ascending infection they go to the lymphatics and that they grow there lying underneath the mucous membrane and then wander through the epithelial cells into the pelvis. It seems to me that of the two mine seems mechanically the more reasonable proposition.

In regard to stains for the micro-organism, we tried very few stains and our technic was faulty, but Dr. Crabtree and Dr. William H. Smith showed me a beautiful method for staining, and we are going to apply it in our future experiments.

The question that Dr. Crabtree also mentioned, that the kidney was seldom involved, does not quite hold water. Out of our total of 11 rabbits there were 6 kidneys which showed changes, and from our total of 26 dogs there were 13 showing changes. That seems a pretty fair proportion, considering that we purposely did not want to produce virulent lesions, and yet in those we found cases where, with the ureter almost completely destroyed, there were changes in the kidney. I want to thank you all for allowing me to present this to you, and for your frank discussion, and I hope to be able to report progress. I am personally convinced that it explains the cases of pyelitis of pregnancy and puerperium and the pyelitis of children better than anything I know of.

Society Report.

MEETING OF NEW ENGLAND BRANCH OF THE AMERICAN UROLOGICAL ASSOCIATION.

HARVARD CLUB, BOSTON, NOV. 28, 1916.

PRESENTATION OF SPECIMENS, INSTRUMENTS, ETC., AND REPORT OF CASES.

DR. BENNETT OF ARABIA: I apologize for appearing before a medical society of this kind, because I am really simply a surgeon, and have been for ten years a medical missionary in Mesopotamia. It happens that out there we have a great many stones in the bladder, and I have a few specimens here.

Five years ago I brought home about 35 specimens, and left them at the University of Michigan.

I would say that now I gather very few, because we do most of them by lithotomy, except where the urethra is blocked.

These, I think, are interesting simply from the point of view of their size. Probably the Arabs allow them to grow more than the Americans do. These have all been sterilized so I will pass them around. There is one they attempted to crush. I have broken my lithotrite in attempting to crush a big stone like that. In this case the man died, and so did the owner of the second large one. These others I think were more successful. One was removed from a boy about five years of age. In fact, most of these stones were removed from children. I have removed stones from children of two or three years of age, while they were still at their mothers' breasts.

I have a theory that some of these stones are caused by the bilharzia worm. The life history of a bilharzia worm, as we have established it, is that the bilharzia enters perhaps through ingestion, but more probably through the skin of the feet, and the Arabs, who work in the rice and wheat fields, are up to their ankles in mud which is full of bilharzia worms. The poison of this bilharzia is really a sharp horn on its anterior end and probably enters the circulation that way and reaches the liver. There it is found in the portal veins and the mesenteric veins, but there the worm is not fully developed, and in the post mortem they are small. They are more fully developed when found in the bladder and rectum. It seems to have an affinity for the walls of the bladder and rectum, more especially for the bladder, and we have cases coming to us giving symptoms of difficult micturition with blood and mucus and some times chyluria. All this is, I think, probably the cause of a large number of cases of stone in the bladder. We get renal calculi, but they are very infrequent.

If you study the life history of the bilharzia you will find that the male worm has a central fold. This encloses the female worm, which is a long, slim worm, and this lies in that ventral fold and the ova are generated in the walls of the bladder and rectum. These passing out cause the irritation and the fungoid growths which are so common. I have seen great, large, mushy growths which project both from the rectum and from the different fistulae which are found through the perineum, and it is very difficult to heal them. In fact, I do not know that they can be healed unless possibly a change of climate is brought about.

Dr. F. B. LAND, BOSTON: The chief interest of this specimen of hypernephroma is that it illustrates the large size to which a malignant tumor of the kidney can grow without producing any cachexia. The patient's symptoms consisted of attacks of pain in the right side, with very slight hematuria, and he presented this very large mass.

On account of the absence of cachexia, I was inclined to think the mass might be a congenital cystic kidney, although ordinarily you can feel the separate cysts, and this was quite smooth. Dr. Cunningham, who saw the patient with me, thought it was a hypernephroma.

No catheterization of the ureters was done for psychic reasons. Several times he refused operation, and we were in great doubt as to whether we could get him to have it done at all.

The tumor, as you notice, was entirely beneath the kidney and pushed it far up beneath the liver so that the vessels ran upward and backward from the aorta and vena cava, necessitating very wide exposure. The usual long kidney incision was made, and then the lower end of it carried forward, splitting the abdominal muscles, up to and into the sheath of the rectus. This gave a beautiful exposure and there was no difficulty about removing the tumor. The left kidney was of normal appearance and there was no evidence of metastasis anywhere.

A DEVICE TO REPLACE THE RUBBER URINAL.

Dr. JOHN CUNNINGHAM, JR., BOSTON: I have here a simple device the use of which is to hold urine in the bladder when the bladder sphincter control is destroyed. This device takes the place of the rubber urinal, about the disagreeable features of which nothing need be said. This device compresses the urethra so that no urine may escape, whereby the bladder takes on its normal function as a reservoir. It does not disturb the circulation of the penis. It has been of much service in dilating contracted bladders by enabling the patients to hold the urine after the impulse to urinate has occurred. I have made use of it to hold fluid in the bladder in doing suprapubic prostatectomy.

INCONTINENCE CLAMP IN POSITION.

The device was first made for a patient upon whom I resected about one-third of the bladder and removed the prostate for carcinoma three years ago, in which patient the sphincter control was lost by the use of the actual cauterization. His bladder, when the device was first employed, could be distended only to three ounces. He now holds seven ounces. The device has taken the place of the rubber urinal in all cases of incontinence which have come under my care since that time. It is sold by Mr. Charles R. Bard.

A CASE OF TUMOR OF THE TESTICLE.

Dr. R. F. O'NEIL, BOSTON: This specimen which I present is one of the so-called mixed tumors of the testicle. It was removed in April of this year. The patient had had it for a year and a half. The specimen at the time of removal was very much larger than it is now, and was also accompanied by a cer-

tain amount of hydrocele. At that time there were no metastases to be made out, but the operation was undertaken simply to remove this very large mass, without the idea of effecting a cure. I saw him again a week ago and there was a very extensive recurrence in the pelvis and in the groin. He is now being treated by radium and the x-ray.

A CASE OF CALCULOUS PYONEPHROSIS.

I wish to show this kidney which I removed this morning from a man 40 years of age. He has had symptoms for about a year and a half, although the lesion must have been present for a much longer time. You see the calculus, while not very large, is situated at the uretero-pelvic outlet, blocking the ureter, and has resulted in the complete destruction of the kidney. This kidney was situated high up under the ribs and was removed with difficulty. During its removal the renal vein either was torn or slipped from the clamp and we had a very sharp hemorrhage, which, fortunately, we were able to control.

SOME UNUSUAL URETERAL CALCULI.

These three calculi were removed from the ureter of a young man of about 25. You notice they are smooth and triangular, resembling teeth. The points of interest in this case are the enormous dilatation of the ureter which was present, the very good function of the kidney and the comparative absence of symptoms, together with the normal cystoscopic appearances of the ureter. If you notice, one of the x-ray plates shows two of the shadows apparently low in the ureter with a third up in the kidney region. Another plate shows all three shadows low in the ureter. The third plate, of the ureter injected with argentide solution, shows the enormous dilatation of the ureter which was present. Of course this was suspected, but I did not expect to find it to such an extent, in view of the perfectly normal cystoscopic appearance of the ureteric orifice. At operation the ureter was found much thickened and dilated; it was opened above the pelvic brim and stones removed with forceps. Incision in the ureter closed with a double row of stitches. Wound healed by first intention, never was there any leakage. Examination of the calculi showed them to be calcic oxalate.

DR. LESLEY H. SPOONER, BOSTON: I wish to report on some bacteriological work which has been doing on renal tuberculosis.

Thanks to Dr. Chute and Dr. Crosbie, I received kidneys after operation *in toto*. They had not been mutilated for the sake of gross observation and for this reason I was enabled to get what I believe to be pure growth from these kidneys.

In all I have studied twelve kidneys, three of which were non-tuberculous and nine tuberculous, and I was able to grow in pure culture from six of them the tubercle bacillus. In three others no growth has appeared, although in some it is expected. In none of these nine tuberculous kidneys was I able to grow in any form any bacteria other than the tubercle bacillus. In the three non-tuberculous kidneys which were removed, two for stone and one for a septic process with a sinus, I grew pure cultures of pyogenic organisms. In two cases where the tubercle bacillus was later grown from the kidney, ureteral specimens showed no growth on ordinary culture media, but in both instances acid-fast bacilli were demonstrated microscopically. Strangely enough, from these cases I did grow from the blad-

der catheter specimens various organisms such as the staphylococcus and diphtheroids.

I advance as a tentative conclusion from this work that the tubercle bacillus may be grown in pure culture from many tuberculous kidneys; that in no instance were other organisms grown; and that tuberculous causation is due to the action of the tubercle bacillus alone. The bladder urine in cases of renal tuberculosis may contain other organisms, while that from the ureter does not seem to be contaminated. Sufficient work has not been done to make the last two statements with certainty, however, and further experiments are to be performed as soon as possible.

I will say one word as to the method of procedure. The kidneys were delivered to me without being opened, the ureters tied off and the kidneys wrapped in sterile gauze from the operating table. I got them within two or three hours after operation. They were opened on a flat surface and scarified immediately with a red hot plumber's soldering iron. All work was done with instruments which were heated to a red heat in the flame and then cooled in boiled water, so that there was no chance of contamination. There was no possibility of killing the organisms by transmitted heat, and yet there was every chance of getting the material in its natural state. A wide variety of aerobic and anaerobic culture media was employed. It was found that the tubercle bacillus in primary culture was more profuse upon Doret's egg media; but that secondary growth flourished readily upon glycerine agar. (Photographs of the cultures upon the latter shown.)

DISCUSSION OF DR. SPOONER'S REPORT.

DR. D. N. EISENDRATH, CHICAGO: This subject interests me greatly. I had been considerably interested in cases of so-called mixed infection with tubercle bacilli. I am just recalling a case which occurred last winter in a young man 20 years of age who had been sick only 10 days. His clinical symptoms were those of ordinary acute hematogenous infection. I cut down upon the kidney and found a cortical abscess, and had some pus sent down to the laboratory immediately. They found the Staphylococcus aureus in pure culture. We had not suspected tuberculosis because the temperature was not typical. The urine was clear, and I was very much surprised when the laboratory reported that in addition to the Staphylococcus aureus they found tubercle bacilli in large quantity.

We took out the kidney the following week and it confirmed the diagnosis of a mixed infection, the Staphylococcus aureus predominating.

Book Reviews.

Social Diagnosis. By MARY E. RICHMOND. New York: The Russell Sage Foundation. 1917.

THIS volume, based on the author's personal experience in charitable and social service, and issued as a publication of the Russell Sage Foundation, is intended as a textbook on social work in Canada. Its genesis and evolution are described in the preface. The text is divided into three parts, dealing, first, with the methods of

obtaining, compiling and studying social evidence; second, with the processes leading to social diagnosis; and third, with the variations in these processes necessitated in the study of certain special groups of cases. The second part, which constitutes one-half the volume, deals in detail with the methods and steps of investigating families and individuals and the use of different sources of information and control in dealing with them. The third part consists largely of detailed series of questions useful in approaching special types of cases. The book is an elaborate treatise on the technique of social investigation and, as such, should prove useful to all concerned in this form of activity.

State Board Questions and Answers. By R. MAX GOEPP, M.D. Fourth Edition, revised. Philadelphia and London: W. B. Saunders Company. 1917.

THE second edition of this useful work was reviewed in the issue of the JOURNAL for July 27, 1911 (Vol. clxv, p. 141); and the third edition in the issue of April 2, 1914 (Vol. clxx, p. 553). In this fourth edition considerable new material has been added, particularly with regard to the newer laboratory tests in the study of diseases of the kidneys and disturbances of metabolism. Additions have also been made in regard to the practical application of serologic tests in diagnosis and treatment. The text is brought to date by the gathering and synthesis of many new questions from state board examinations of recent years. The volume should continue its effective value for students and teachers concerned in the preparation for these examinations.

Case Histories in Obstetrics. By ROBERT L. DE-NORMANDIE, A.B., M.D., F.A.C.S. Second Edition. Boston: W. M. Leonard. 1917.

THE first edition of this volume in the Case History Series was reviewed in the issue of the JOURNAL for February 18, 1915 (Vol. clxxii, p. 365). In this second edition, several alterations have been made for the purpose, as the author states in his preface, of clarifying the meaning of the text, though it should not seem, from the excellent and detailed style of the original, that changes for this reason were necessary. The sections in which the most material alterations have been made are those on accidental hemorrhage, sepsis, pyelitis and scopolamine-morphine anesthesia. Some material has also been introduced on the use of nitrous oxide in obstetrics and further data are given on the subsequent history of some of the cases. These additions, representing the development of the subject in the author's experience, increase the already established value of his work as a contribution to the teaching and practice of obstetrics.

A Manual of Pharmacology, and its application to Therapeutics and Toxicology. By THORALD SOLLMANN, M.D., Professor of Pharmacology and Materia Medica, Western Reserve University, Cleveland, Ohio. Octavo of 901 pages, illustrated. Philadelphia and London: W. B. Saunders Company. 1917. Cloth, \$4.50 net.

The author's division of his monumental labors into a laboratory guide of pharmacology and a manual containing eight hundred and eighty-seven pages of text, including a bibliography, is to be heartily commended.

The manual possesses the greatest value for physicians, in that most of the ineffective drugs are frankly omitted or mentioned in a few lines of fine print, while the more important ones, which have been proved effective, by careful scientific observation, are given their deservedly prominent position. The author does not look with favor upon the conversion of the old term "cubic centimeters" to "milliliters" as recommended both by the United States and British pharmacopoeias.

The section devoted to prescription writing is simple, easily understood and in a brief perusal, with some study, ought to equip the student for correct prescription writing.

The section on ferments presents the modern view with regard to the inefficiency of the therapeutic use of digestive enzymes, as well as the ample destructive action of one upon another. The author also explodes the theory of the use of pancreatic preparations in diabetes which physicians have already looked on with suspicion, though they have had no absolute proof of their lack of efficiency.

The viburnums, too, long employed by the medical profession, have received their death warrant at his hands.

A remarkably able discussion of anaphylaxis is given on page three hundred and sixty-nine, which includes all of the modern views on this obscure subject.

The discussion of the action of digitalis on the heart in health and in disease brings light on many obscure activities of this drug, and will check not only its indiscriminate use, but particularly, its abuse in cardiac stenosis.

The section on the action of dilute hydrochloric and other aids on digestion and pyloric control, adds much to our present knowledge, correlating all of the discoveries made within the last few years.

Many a physician's firm reliance on certain drugs and preparations will receive a rude shock at the hands of this author, who confirms every statement of incredulity in their efficacy by the unquestioned proof of experimental investigation. On the whole, no work has appeared in recent years on which the physician may rely with greater security.

THE BOSTON Medical and Surgical Journal

Established in 1812

An independently owned Journal of Medicine and Surgery published weekly under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, JULY 5, 1917

TUBERCULOSIS IN THE ARMY.

The problem of tuberculosis, like many others at this time, takes on a new aspect under the conditions of war and military duty. The appalling spread of pulmonary tuberculosis among the French troops has created a grave problem of public health in France, and the large incidence of the disease in the Canadian army has caused no little concern to military and sanitary officers. Not a few alarmists have predicted the same wholesale infection and destruction of our own troops. On careful consideration of all the facts, however, it becomes clear that much of the disease in the French army was due to the fact that many of the men were already tuberculous when sent to the front. The terrible need for every man who could be mobilized, forbade any examination for more than obvious physical incapacity to carry a rifle. Thousands who in

any less haste would have been rejected were passed, to their own speedy breakdown. These, under the forced intimacy and hardship of trench life, became a menace to fellow troops. Some part of the Canadian problem had a similar basis in lack of thorough appreciation that military duty in the field requires a degree of physical health much greater than for active work in civil life. In the examinations made for enlistment in the National Guard in this country, and for the Reserve Officers Corps, this fact has not always been recognized.

The army authorities, appreciating both aspects of this problem, have determined on a scheme by which they hope to prevent, as far as possible, this wastage of men, both as troops and as civilians, and to avoid the future cost in pensions. They plan to have every man now in service in the army, the Reserve Officers' Camps, and the National Guard, as fast as called into federal service, reexamined by men trained in correct methods of physical examination, to eliminate cases of active or obvious pulmonary tuberculosis.

For this work they ask the volunteer services of experienced physicians, trained in careful chest work. These men are to be commissioned as lieutenants in the Medical Corps and receive pay as such. They will be sent to the various army posts and camps, as far as possible, in their immediate territory, to save cost of transportation and the delay of travel. In view of the special and restricted nature of the service, the rigidity of physical examination required for regular commissions will be remitted and the age limits extended.

That the best men possible may be secured, the service will be made temporary, and men accepting it may be released at the end of three months, though it is desired to have them serve longer. For these reasons of limited service, commissions will be given only as lieutenants, higher rank as due to age or professional standing not being possible.

The work is to be expedited by having an adequate group of such officers sent to each post and camp at once, by July 1, as far as possible. It is desired to examine the enlisted men in posts and the officers at reserve camps at once. Following this, the personnel of the National Guard next to be called into service will be reviewed, and the way cleared to the new national army as fast as it is selected and sworn in.

It is not expected that this will prevent all tuberculosis in our forces, but it is hoped to reduce greatly its development. No army could be raised if every latent or possible future case of tuberculosis were rejected. But by a careful reëxamination of the chests by men of experience it is hoped to hold down the incidence to a minimum.

The appreciation of the signs of an incipient case of tuberculosis is not yet the common possession of every physician, and the realization of the physical requirements to meet the strain of military service rarely part of the knowledge of the civilian practitioner. Through these two gates of ignorance pass the greater number of cases of tuberculosis in our army. To guard from the start the source of trouble, and to find at once the cases which have slipped past, before length of service even in camps of training, raises the question of "disability acquired in line of duty," and to prevent further acceptance of known cases of tuberculosis, is the great purpose of this work.

Its value in preventing serious ineffectiveness in the fighting ranks, in saving to useful civil, working power the incipient case which would otherwise suffer from the over-physical strain of war, and in reducing the future cost of pensions, is beyond estimation.

It is a service which should receive the heartiest support of the medical profession. Its success will depend on the type of men who respond to the call. It is a rare opportunity for those of exceptional skill and experience to give for a brief period the best of help. Many, who for reasons of duty or age, cannot follow their desires into the field in line or hospital, can here rejoice in a chance to serve usefully and wear the honor of their country's uniform.

MEDICAL NOTES.

HONORARY DEGREES TO PHYSICIANS.—At the commencements of the various American universities last month, several honorary degrees were conferred upon physicians as follows: At Yale the degree of Sc.D. was conferred on Dr. Theobald Smith, director of the department of animal pathology of the Rockefeller Institute. Dr. Smith and Dr. Charles H. Mayo, retiring president of the American Medical Association, also received the same degree from Princeton. At Bowdoin the honorary doctorate in science was conferred on Dr. Fred H. Albee of New York, who has recently returned from service at a base hospital in France.

HEALTH CONDITIONS IN SOUTH AMERICA.—Dr. Richard M. Pearee, professor of research medicine in the University of Pennsylvania, has returned from a tour of three months through Brazil, Argentina and Uruguay to make a study of the medical, hospital, educational and public health conditions in those countries in the interest of the International Health Board of the Rockefeller Foundation.

MEDICAL RESEARCH.—The General Education Board founded by John D. Rockefeller has donated a million dollars to Washington University, St. Louis, to be used in research in the subjects of surgery, medicine and pediatrics.

HEALTH REPORT, MONTCLAIR, N.J.—According to the recently published twenty-second report of the Board of Health of Montclair, N. J., the mortality rate for the past year was 10.56 per thousand inhabitants. The chief causes of death were organic diseases of the heart, pneumonia, cancer and tuberculosis. The deaths due to cancer represent an increase of 100% over those of fifteen years ago.

PREVALENCE OF DISEASE IN THE UNITED STATES.—The weekly report of the United States Public Health Service for June 1, 1917, states that during the month of April there were reported in Mississippi, 7222 cases of malaria, 961 of pellagra, 221 of smallpox, and 188 of typhoid fever. During the same period there were 206 cases of cerebro-spinal meningitis in Pennsylvania, 94 in Minnesota, 25 in Kansas and 14 in Indiana. There were 15 cases of poliomyelitis in Pennsylvania, 246 of smallpox in Minnesota and 89 of typhoid in Indiana. There were 496 cases of smallpox in Indiana and 303 of typhoid in Pennsylvania.

In the weekly report of June 8 it is further noted that during the first five months of 1917 there were 274 cases of cerebro-spinal meningitis in Minnesota with 113 deaths. There were eighty cases of the disease in Connecticut in April. During that month there were 445 cases of malaria in Virginia, 108 of pellagra in Alabama, 572 of smallpox in Arkansas and 74 of typhoid fever in Montana.

LONDON DEATH RATES IN APRIL.—Statistics recently published show that in April, 1917, the total death rate of London was 18.2 per thousand inhabitants living. Among the several districts and boroughs the highest rate was 22.3 in St. Paneras, a populous northern area, and the lowest was 13 in the financial district of the city.

PREVALENCE OF MENINGITIS.—The weekly report of the United States Public Health Service for June 15, 1917, states that during the month of April, 149 cases of cerebro-spinal meningitis were reported in Ohio. During the year 1916

there were 327 cases of this disease in New York, 162 in Pennsylvania, 152 in Ohio and 150 in Massachusetts.

WAR NOTES.

LONDON CHAPTER OF AMERICAN RED CROSS.—There has been formed in England a London Chapter of the American Red Cross. One of the first acts of the Chapter was to plan for the establishment of headquarters for American nurses in the war zone. The chairman, Mrs. Whitelaw Reid, said that it would be a home where nurses could go when on leave from their duties in France and where those passing to England from the United States would find accommodations.

GIFT OF FORD AMBULANCES.—The Ford Motor Company, in a meeting of its directors, voted to donate \$500,000 worth of Ford ambulances to the Red Cross.

AID TO RUSSIA.—The American Red Cross has arranged to send an American commission to Russia to work behind the battle front in the same way as the commissions work in France and Belgium. This will enable the Red Cross to send its supplies and relief corps to the Russian front.

APPOINTMENT TO WAR COUNCIL.—The appointment has been announced of Dr. Charles V. Chapin of Providence, R. I., to the War Council of the American Red Cross. The council consists of a commission of ten to advise on matters relating to the European War relief and army health. Simon Flexner of New York will be chairman of the commission, and Dr. Milton J. Rosenau will be another of its members.

PUBLIC HEALTH NURSES TO REMAIN AT HOME.—The Instructive District Nursing Association of Boston has drawn up resolutions to the effect that public health nurses are most needed at their posts at home, on the ground that the public health nurse is helping to conserve the most precious of national resources, human life, and is serving her country no less than the nurse at the front. These resolutions are indorsed by the Massachusetts Committee of Public Safety, the Massachusetts Commissioner of Public Health and the Executive Committee of the Massachusetts Committee of Directors of Visiting Nursing Associations.

ADDITIONAL EQUIPMENT FOR BASE HOSPITAL No. 5.—The additional workers asked for by Major Harvey Cushing of Base Hospital No. 5 have been recruited and will go to France as soon as possible. They include forty men, twenty nurses and five doctors.

APPOINTMENTS FOR SERVICE IN FRANCE.—The American Red Cross has appointed Dr. Alex-

ander Lambert of New York as medical adviser to the War Relief Commission of the Red Cross during the war. Dr. Tom A. Williams of Washington will go to France as neurologist in the French Service de Santé.

CALL OF THE MEDICAL DEPARTMENTS OF THE NATIONAL GUARD.—The officers and enlisted men of the medical corps of the National Guard units in New England have been called to the South to undergo three month' course in instruction at the medical department training camp at Fort Oglethorpe, Ga. There will also be sent a number of officers and enlisted men of the sanitary troops connected with the regiments already in Federal service to Fort Ethan Allen, Vt., for a similar course in instruction. The men chosen for the Oglethorpe camp were all picked out in Washington and the list forwarded to department headquarters and to the adjutants-general of the several states.

Massachusetts has fifteen officers and forty-six men; New Hampshire, five officers and thirteen men; Maine, two officers and four men; Connecticut, six officers and twenty-one men, and Rhode Island three officers and thirteen men. These men were mustered into the Federal service and were ordered to report at Fort Oglethorpe on June 25. The Massachusetts men will be under the command of Major George F. Keenan.

ENTERTAINMENT OF CHICAGO UNIT.—The Red Cross Base Hospital recruited from Chicago has been enthusiastically received and entertained in London. On one occasion Sir Thomas Lipton invited the unit to his country place. Among the guests were Dr. Richard P. Strong of Harvard and the Italian bacteriologist, Dr. Castellani, both of whom were associated with Sir Thomas Lipton in combating the typhus plague in Serbia. Dr. Strong addressed the company and spoke highly of the work inaugurated by Sir Thomas Lipton in Serbia and expressed appreciation of the aid given the American Red Cross.

FRENCH WAR CROSS TO AMERICAN.—Dr. George Dock, professor of medicine in the medical school of Washington University, has received the French war cross and has been mentioned for his service in moving wounded soldiers under heavy bombardment while engaged in the American Field Ambulance Service.

APPEAL FOR SURGICAL DRESSINGS FUND.—The Surgical Dressings Committee again appeal to the public for contributions to their work. The dressings prepared by the committee at the Peter Bent Brigham Hospital and its branches are done so well and are so much depended upon by many hospitals abroad that any decrease in

their supply would be a calamity in the present crisis.

An indication of the extent of the work of the committee (and the value of this work to the Allies) is found in its report of shipments in May, which amounted to 601 cases, containing 814,719 dressings. This was an increase of 181,431 dressings over March—the next highest month.

All subscriptions should be made payable to the Surgical Dressings Committee and forwarded to the Old Colony Trust Company, 17 Court street, Boston.

BERKSHIRE AMBULANCE UNIT.—The Berkshire Ambulance Corps of eighty-six men has been mustered into Federal service. The unit is led by Dr. R. J. Carpenter of North Adams and consists of twelve automobile ambulances furnished by the citizens of Berkshire County.

HOSPITAL SUPPLIES FOR THE FRENCH.—The New England branch of the American Fund for French Wounded has sent in the last month 194,533 surgical dressings to France. Besides these the shipments included 14,800 yards of surgical gauze, 1,020 pounds of absorbent cotton, 1,100 pounds of chloroform and ether, 1,500 yards of adhesive plaster, 2,737 yards of mosquito netting, 9,063 hospital garments, 12,114 towels, wash cloths and handkerchiefs and large quantities of many other useful and necessary articles. The Branch appeals for absorbent cotton and surgical gauze both of which are difficult to obtain in France and the need of which is most urgent.

COMMISSION TO STUDY BATTLE CONDITIONS.—A commission headed by Major Hugh-Hampton Young, M.R.C., director of the Brady Institute of Johns Hopkins Hospital has left this country for England to study medical necessities at the battle front and to take charge of the medical care of the American Army in France.

Dr. Young will be accompanied by Captain Louis C. Lehr, of Georgetown University, Captain Montague L. Boyd, of Emory College, Atlanta, and Lieutenant Howard L. Cecil, of the Brady Institute, Johns Hopkins Hospital.

SURGEONS IN TRAINING CAMP.—The following officers and men have been chosen by Colonel Frank P. Williams, surgeon-general of the National Guard of Massachusetts to attend a three months' training camp at Fort Oglethorpe, Ga. They are Lieutenant William H. Barrow, First Field Hospital Company; Captain James F. Coughal, Coast Artillery; Lieutenant Joseph H. Dunn, Coast Artillery; Lieutenant Gustave P. Grabfield, First Ambulance Company; Lieutenant Albert A. Horner, First Regiment Field Artillery; Lieutenant Herbert L. Johnson, Fifth Infantry; Major George F. Keenan, office chief surgeon; Lieutenant Eugene J. McCarthy,

Second Ambulance Company; Lieutenant Peter G. McKenna, First Ambulance Company; Lieutenant Harold F. Parker, Second Field Hospital Company; Lieutenant Ruel A. Pierce, First Field Hospital Company; Lieutenant James J. Rodger, Second Field Hospital Company; Lieutenant Edward B. Sheehan, Second Ambulance Company; Lieutenant Conrad Wesselhoeft, Fifth Infantry; Lieutenant James J. Walsh, Fifth Infantry.

AMERICAN UNITS IN FRANCE.—The American Red Cross units from St. Louis and Philadelphia, numbering in all about four hundred persons, have left England for France. Each unit will care for five hundred beds.

WAR RELIEF FUNDS.—On June 30 the totals of the principal New England war relief funds reached the following amounts:

French Wounded Fund	\$235,303.52
Armenian Fund	197,104.79
Serbian Fund	122,638.66
Surgical Dressings Fund	103,488.47
British Imperial Fund	101,737.59
Metropolitan Red Cross Fund	72,576.79
French Phthisis Fund	67,469.33
Italian Fund	42,549.37

BOSTON AND MASSACHUSETTS.

BROCKTON HEALTH CONDITIONS.—The Department of Public Health of the City of Brockton has recently issued its thirty-fifth annual report, which covers the year 1916. The mortality rate during this period was 11.92 and the infant mortality rate was 90.2. There were 1,541 births registered of which 70 were stillbirths. Deaths under a year totaled 138. Immediately upon receipt of the birth return, a circular and Baby Book are mailed to the mother in regard to necessity for reporting any redness, swelling or discharge from the eyes of the infant. Three baby clinics were maintained during the summer at Baby Hygiene stations where demonstrations and instructions were given by nurses and advice and treatment by doctors. The total attendance at these clinics was 752, which meant a total of individual babies of 247. Following the clinics the nurses visited the babies in their homes, and in all 696 visits were made.

NORTHEASTERN DENTAL SOCIETY.—The members of the Northeastern Dental Society held an outing at Baker's Island, near Salem, Mass., on June 20. A clambake and athletic events were the features of the occasion.

DENTAL ALUMNI ASSOCIATION.—The Harvard Dental Alumni Association held its forty-sixth annual meeting and dinner on May 22. The following officers were elected for the coming year: Dr. Frank T. Taylor, president; Dr. J. William O'Connell, secretary; Dr. John W. Estabrook, treasurer.

NEW ENGLAND NOTES.

POLIOMYELITIS IN VERMONT.—On June 28th, a total of 16 cases of poliomyelitis had developed in Vermont. Two cases were in Waitsfield, two in Barre and 12 in Montpelier. Three of the victims were children and the others were under twenty years of age. Two suspicious cases are being watched in Montpelier, where all public assemblies have been forbidden.

The Massachusetts Medical Society.

PROCEEDINGS OF THE SOCIETY.

First Day, June 12, 1917.

CLINICS and demonstrations were held during the morning at the principal hospitals of Boston. All of the exercises of the anniversary were held at the Copley-Plaza Hotel, Boston, beginning with the annual meeting of the Supervisors, June 12, at 11.30 a.m., in the foyer, followed by the annual meeting of the Council in the same room, at noon, 126 Councilors being present. Meetings of the Sections of Medicine, Surgery, Tuberculosis and Hospital Administration, the last being a new section this year, were held in the afternoon in the different rooms of the hotel; a detailed and corrected program of the meetings and the officers is to be found in the Boston Medical and Surgical Journal for June 7, 1917, Vol. clxxvi, pages 822-824.

The following officers of the sections were elected for the ensuing year by the sections:

Section of Medicine: *Chairman*, William H. Smith, Boston; *Secretary*, George R. Minot, Boston.

Section of Surgery: *Chairman*, John Homan, Boston; *Secretary*, Hilbert F. Day, Boston.

Section of Tuberculosis: *Chairman*, Walter G. Phippen, Salem; *Secretary*, John B. Hawes, 2d, Boston.

Section of Hospital Administration: *Chairman*, Homer Gage, Worcester; *Secretary*, Channing C. Simmons, Boston.

The Shattuck Lecture was delivered in the evening by Dr. David Cheever of Boston, who read the lecture prepared by Dr. Walter B. Cannon, George Higginson Professor of Physiology in the Harvard Medical School, Dr. Cannon being absent in the service of the country in the war. Subject: "The Physiological Factors Concerned in Surgical Shock."

Following the lecture there was a reception to the President and a concert and refreshments.

Second Day, June 13, 1917.

The Society met at the Copley-Plaza Hotel, Boston, for the exercises of the one hundred and thirty-sixth anniversary. The President, Dr. Samuel B. Woodward of Worcester, was in the chair and about a hundred Fellows were present

during the morning. The minutes of the last meeting were read and accepted. The Secretary announced that during the past year the Society had lost by death 53 Fellows, by resignation 24, by deprivation of the privileges of fellowship 61, total loss 138. The Society had gained 171 Fellows as follows: restoration by the Council 4, readmitted by the Censors 2, new Fellows 165, total net gain 33, making the membership of the Society, June 13, 1917, 3666.

Dr. G. P. Twitchell explained in detail the following amendments to Chapter V of the By-Laws, that had been submitted to the Council, October 4, 1916, by the Supervisors:

Page 17, Section 1 (*Board of Supervisors*), line 7, to follow the word "board," this sentence: He shall call special meetings at the request of five supervisors.

Same page, same section, third paragraph (*Diplomas of colleges not on list*), add at end of paragraph, deleting the period, the following: by the district secretary before an applicant is permitted to take an examination.

Same page, same section, last paragraph (*Examinations; when held*), second line, delete "at 2.00 p.m.,"; also next line, change the word "second" to "first" in the two places where it occurs.

Page 18, Section 2 (*How applications are made*), first line, substitute the word "fellowship" for the word "examination."

Same line, after the word "apply," insert the following: on blanks furnished for the purpose. . .

Same section, end of second line, delete the semicolon and add the following: at least one week before the date of a given examination.

Same page, Section 3 (*Duties of district secretaries*), second line, to follow the word "censors," add the following: shall furnish applicants with blanks adopted by the board of supervisors; they. . .

No objection being made to considering all the amendments *en bloc*, they were passed unanimously.

The Chairman read the following amendment to Chapter VI of the By-Laws that had been submitted to the Council February 7, 1917, by the Standing Committee on Membership and Finance:

That the fourth paragraph of Chapter VI, Section 4, be amended so that it shall read: He shall attend the meetings of the Committee on Membership and Finance, furnish the committee with such data on membership and finance as the committee may require, and shall make all investments and reinvestments of the Society's funds subject to the approval of this committee.

The Treasurer stated that he thought the amendment a desirable one and favored its passage, and it was passed with no negative votes, twenty-five Fellows being present.

Dr. Edsall introduced this preamble and these resolutions, and moved their adoption:

Whereas, Senate Joint Resolution No. 63 has been introduced into the Senate of the United States with a view of controlling certain sanitary conditions in this country incident to our state of war, and has been endorsed by the Council of National Defense and all its subsidiary organizations, including the Medical Corps of the Army and Navy, the Treasury Department of the United States, and the executive officers of forty-three State Boards and Departments of Health assembled in conference, therefore, be it

Resolved: That in the opinion of the Massachusetts Medical Society this Resolution should be speedily enacted into law as offering a practical means for joint administrative control by Federal, State and local authorities of sanitary conditions beyond the jurisdiction of the military authorities, arising in connection with the establishment of military camps, and for controlling other extraordinary conditions incidental to a state of war, and be it further

Resolved: That the President and Secretary of this Society be directed to transmit copies of this Resolution to the Senators and each of the Representatives in Congress from the Commonwealth of Massachusetts.

After some questions had been asked and answered the resolutions were adopted by a unanimous vote.

Dr. Cook presented the following resolutions and they were passed:

Resolved: That in the belief of the Massachusetts Medical Society the public health would be greatly benefited by the restoration of the regulations concerning venereal prophyllaxis that were abolished by the Secretary of the Navy, therefore it is

Resolved: That the Secretary of the Navy be urged to restore these regulations in the Navy, and that the Massachusetts Senators and Representatives in Congress be requested to cooperate in bringing this about.

The President announced the names of the committee of five he had appointed "to look into the matter of an academic chair of Military Medicine in this Commonwealth," in accordance with a resolution passed by the Council the previous day, as follows:

E. H. Bradford, *Chairman*, E. C. Streeter, A. N. Broughton, P. P. Johnson, P. E. Truesdale.

The President read the resolution that had

been passed at the annual meeting of the Council, placing the Society on record as in favor of prohibition for the duration of the war, and it was adopted unanimously, and another resolution, passed at the same time, namely, be it

Resolved: That the Massachusetts Medical Society emphatically urges its members, especially the younger men, to offer their services to the Medical Reserve Corps of the United States Army; and it was adopted.

Papers on Certain Aspects of the Hazards of Industry were read, according to the program as printed in the Boston Medical and Surgical Journal, June 7, 1917, except that Dr. Edsall summarized and included in his remarks the paper that was to have been read by Dr. Wade S. Wright, who had been called away in the service of the country. Discussion of all the papers was participated in by Dr. A. N. Broughton, Dr. J. J. Minot, Dr. Eugene J. McCarthy and Mr. Edwin Mulready. On motion by Dr. Albert Evans it was

Voted: That the Council be asked to appoint a special committee to work in cooperation with the State Board of Labor and Industries.

At noon the Annual Discourse was delivered by Dr. P. E. Truesdale of Fall River. Subject: "Military Medicine; a Means to Perpetuate Its Teaching in Massachusetts."

In the afternoon the Combined Sections of Medicine and Surgery met in the salon of the hotel and listened to six papers and discussions, as set forth in the program as printed in the Boston Medical and Surgical Journal for June 7, 1917.

The Annual Dinner was served in the ballroom in the evening to 690 Fellows and guests. Grace was said by the Rev. Austin S. Garver. The President made an address and also acted as anniversary chairman, introducing as speakers, the Hon. Calvin Coolidge, Lieutenant-Governor of Massachusetts; Major F. F. Simpson, of the Medical Board of the Council of National Defense; Major H. D. Arnold, of the Medical Officers Reserve Corps; Dr. A. J. McLaughlin, Health Commissioner of Massachusetts; the Rt. Rev. William Lawrence, Bishop of Massachusetts; and President A. Lawrence Lowell of Harvard.

Adjourned at 10.20 p.m.

WALTER L. BURRAGE,
Secretary.

DEATHS REPORTED FROM JUNE 7, 1916, TO JUNE 13, 1917.

Admitted.	Name.	Place of Death.	Date of Death.	Age.
1880	Abbott, Stephen Wendell	Waverley	Sept. 1, 1916	66
1808	Barrows, Sterling	Worthington	Aug. 16, 1916	36
1876	Bell, William Appleton	Somerville	Apr. 3, 1917	45
1872	Bloodlet, Albert George	Ware	Feb. 10, 1917	75
1881	Brown, Francis Henry	Boston	May 16, 1917	81

OFFICERS OF THE MASSACHUSETTS MEDICAL SOCIETY.

Chosen by the Council, June 12, 1917.

Samuel B. Woodward, Worcester, President.
George P. Twitchell, Greenfield, Vice-president.
Walter L. Burrage, Boston, Secretary.
Arthur K. Stone, Boston, Treasurer.
Edwin H. Brigham, Brookline, Librarian.

STANDING COMMITTEES.

Of Arrangements.—J. H. Young, J. L. Huntington, R. H. Miller, C. H. Lawrence, Jr., Donald Macomber, A. W. Reggio.

On Publications and Scientific Papers.—G. B. Shattuck, E. W. Taylor, R. B. Osgood, F. T. Lord, R. M. Green.

On Membership and Finance.—C. M. Green, A. Coolidge, Jr., Samuel Crowell, F. W. Taylor, Alfred Worcester.

On Ethics and Discipline.—J. A. Gage, J. W. Bartol, Henry Jackson, T. J. Robinson, David Cheever.

On Medical Education and Medical Diplomas.—H. C. Ernst, C. F. Painter, H. W. Newhall, J. F. Burnham, C. Frothingham, Jr.

On State and National Legislation.—S. B. Woodward, P. G. Wheatley, W. P. Bowers, W. H. Robey, Jr., J. S. Stone.

On Public Health.—E. H. Bigelow, W. I. Clark, Annie L. Hamilton, R. I. Lee, E. F. Cody.

PRESIDENTS OF DISTRICT MEDICAL SOCIETIES.

Vice-Presidents (*Ex-Officio*).

Arranged according to seniority of fellowship in the Massachusetts Medical Society.

G. T. Tuttle	Middlesex South
H. P. Vickery	Suffolk
W. P. Lawler	Middlesex North
N. K. Noyes	Plymouth
M. F. Fallon	Worcester
J. H. Ash	Norfolk South
E. G. Fosgate	Worcester North
A. G. Minshall	Hampshire
T. R. Healy	Essex North
H. A. Gale	Middlesex East
J. C. Pitta	Bristol South
W. H. Allen	Bristol North
P. P. Johnson	Essex South
E. S. Osborne	Barnstable
H. N. Howe	Franklin
A. C. Merrill	Berkshire
F. W. Sleeper	Norfolk
J. M. Birnie	Hampden

COUNCILORS, 1917-1918.

NOTE.—The initials M. N. C., following the name of a councilor, indicate that he is a member of the Nominating Committee. V.P. indicates that a member is a councilor by virtue of his office of president of a district society, and so vice-president of the general society. C. indicates that he is chairman of a Standing Committee. Ex-P. indicates ex-president.

BERKSHIRE.

A. P. Merrill, V.P., Pittsfield.
C. S. Chapin, Great Barrington.
Henry Colt, Pittsfield.
W. W. Jones, Housatonic.
J. W. Riley, M.N.C., North Adams.

BRISTOL NORTH.

W. H. Allen, V.P., Mansfield.
A. B. Goss, Taunton.
W. O. Hewitt, Attleborough.
F. A. Hubbard, M.N.C., Taunton.
S. D. Presbrey, Ex-P., Taunton.

BRISTOL SOUTH.

J. C. Pitta, V.P., New Bedford.
E. F. Cody, New Bedford.
C. F. Connor, M.N.C., New Bedford.
E. F. Curry, Fall River.
A. B. Cushman, South Dartmouth.
W. A. Dolan, Fall River.
R. W. Jackson, Fall River.
A. H. Mandell, New Bedford.

ESSEX NORTH.

T. R. Healy, V.P., Newburyport.
J. Q. Adams, Amesbury.
G. M. Atwood, Bradford.
R. V. Baketel, Methuen.
I. J. Clarke, Haverhill.
G. E. Kurth, Lawrence.
E. H. Noyes, Newburyport.
J. J. O'Sullivan, Lawrence.
F. W. Snow, M.N.C., Newburyport.

ESSEX SOUTH.

P. P. Johnson, V.P., Beverly.
C. H. Bangs, Lynn.
R. E. Bicknell, Swampscott.
N. P. Breed, Lynn.
D. J. Finegan, Gloucester.
H. K. Foster, Peabody.
W. T. Hopkins, Lynn.
J. B. Macdonald, Danvers (Hathorne).
P. P. Moore, Gloucester.
W. G. Phippen, Salem.
Emile Poirier, M.N.C., Salem.
H. E. Sears, Beverly.
R. E. Starn, Beverly.

FRANKLIN.

H. N. Howe, V.P., Greenfield.
G. P. Twitchell, M.N.C., Greenfield.
X. P. Wood, Northfield.

HAMPDEN.

J. M. Birnie, V.P., Springfield.
T. S. Bacon, Springfield.
E. P. Bagz, Jr., Holyoke.
J. J. Carroll, Holyoke.
L. D. Chapin, Springfield.
P. M. Cort, Springfield.
A. C. Eastman, Springfield.
R. A. Greene, Monson.
E. A. Knowlton, Holyoke.
L. E. Mannix, Chicopee.
R. B. Ober, Springfield.
A. G. Rice, Springfield.
G. L. Schadt, Springfield.
H. W. Van Allen, M.N.C., Springfield.

HAMPSHIRE.

A. G. Minshall, V.P., Northampton.
C. A. Byrne, Hatfield.
J. S. Hitchcock, M.N.C., Northampton.
F. H. Smith, Hadley.

MIDDLESEX EAST.

H. A. Gale, V.P., Winchester.
J. W. Heath, M.N.C., Wakefield.
E. S. Jack, Melrose.
W. H. Keleher, Woburn.
G. N. P. Moad, Winchester.

MIDDLESEX NORTH,

W. P. Lawler, V.P., Lowell.
 J. A. Gage, C., Lowell.
 A. R. Gardner, Lowell.
 W. B. Jackson, M.N.C., Lowell.
 J. H. Lambert, Lowell.
 G. O. Lavalée, Lowell.
 E. G. Livingston, Lowell.
 M. A. Tighe, Lowell.

MIDDLESEX SOUTH,

G. T. Tuttle, V.P., Waverley.
 E. S. Abbot, Waverley.
 H. T. Baldwin, Chestnut Hill.
 S. O. Baldwin, Framingham.
 F. E. Bateman, Somerville.
 E. H. Bigelow, C., Framingham.
 C. H. Cook, Natick.
 E. A. Darling, Cambridge.
 D. C. Dow, Cambridge.
 A. W. Dudley, Cambridge.
 John Duff, Charlestown.
 W. E. Fernald, Waverley.
 G. W. Gay, Ex-P., Chestnut Hill.
 C. M. Hutchinson, Cambridge.
 A. A. Jackson, Everett.
 Edward Mellus, Newton.
 C. E. Mongan, Somerville.
 C. E. Prior, Malden.
 W. A. Putnam, Cambridge.
 Godfrey Ryder, Malden.
 L. F. Sise, Medford.
 Joseph Stanton, Brighton.
 E. H. Stevens, M.N.C., Cambridge.
 F. R. Stubbs, Newton.
 Julia Tolman, Arlington.
 H. P. Walcott, Ex-P., Cambridge.
 C. T. Warner, Marlborough.
 G. W. Whiting, Somerville.
 Alfred Worcester, Waltham.
 J. H. Young, C., Newton.

NORFOLK,

F. W. Sleeper, V.P., Dorchester.
 J. W. Bail, Brookline.
 W. W. Barker, Dorchester.
 W. H. Bennett, Hyde Park.

WORCESTER.—M. F. Fallon, Worcester, President; W. L. Johnson, Uxbridge, Vice-President; E. L. Hunt, Worcester, Secretary; G. O. Ward, Worcester, Treasurer; G. C. Lincoln, Worcester, Librarian.

WORCESTER NORTH.—E. G. Fosgate, Ashburnham, President; A. H. Pierce, Leominster, Vice-President; C. H. Jennings, Fitchburg, Secretary; F. H. Thompson, Jr., Fitchburg, Treasurer; A. P. Mason, Fitchburg, Librarian.

LIST OF PRESIDENTS OF THE MASSACHUSETTS MEDICAL SOCIETY—1782-1917

*Edward Augustus Holyoke	1782-1784
*William Kneland	1784-1786
*Edward Augustus Holyoke	1786-1787
*Cotton Tufts	1787-1795
*Samuel Danforth	1795-1798
*Isaac Rand	1798-1804
*John Warren	1804-1815
*Joshua Fisher	1815-1823
*John Brooks	1823-1825
*James Jackson	1825-1832
*John Collins Warren	1832-1836
*George Cheyne Shattuck	1836-1840
* Rufus Wyman	1840-1842
*Jacob Bigelow	1842-1847
*Zadok Howe	1847-1848
*John Ware	1848-1852
*George Hayward	1852-1855
*Elsha Huntington	1855-1857
*Luther V Bell	1857-1859
*John Homans	1859-1862

*Josiah Bartlett	1862-1864
*Augustus Addison Gould	1864-1866
*Henry Coit Perkins	1866-1868
*Charles Gideon Putnam	1868-1870
*Samuel Augustus Flisk	1870-1872
*George Cheyne Shattuck	1872-1874
*Benjamin Eddy Cotting	1874-1876
*William Coggswell	1876-1878
*George Hinckley Lyman	1878-1880
*Henry Willard Williams	1880-1882
*Alfred Hosmer	1882-1884
*Charles Dudley Homans	1884-1886
*Thomas Hovey Gage	1886-1888
*David Williams Cheever	1888-1890
*Amos Howe Johnson	1890-1892
*James Clarke White	1892-1894
*Franklin Kittredge Paddock	1894-1896
Henry Pickering Walcott	1896-1898
*Edwin Bayard Harvey	1898-1900
*Frank Winthrop Draper	1900-1902
*George Ebenezer Francis	1902-1904
*Arthur Tracy Cabot	1904-1906
George Washington Gay	1906-1908
Silas Dean Presbrey	1908-1910
George Brune Shattuck	1910-1912
Walter Prentice Bowers	1912-1914
*Charles Francis Withington	1914-1916
Samuel Bayard Woodward	1916-

* Deceased.

THE MASSACHUSETTS MEDICAL SOCIETY.

FRANKLIN DISTRICT MEDICAL SOCIETY.—The next meeting of the Franklin District Medical Society will be held at the Mansion House, Greenfield, July 10, 1917, at 11.15 A.M.

PAPERS

The Management of Labor.
Dr. George P. Twitchell, Greenfield.
Ear Complications of Infectious Diseases, with Case Reports.
Dr. Frank A. Millett, Greenfield.

FRANK A. MILLETT, Secretary.

Miscellany.

APPOINTMENTS.

CALIFORNIA STATE BOARD OF HEALTH.—Professor Charles J. Kofoid, professor of zoölogy in the University of California, and his assistant, Professor W. W. Cort, have been appointed to the California State Board of Health. Provision has been made for the establishment of a biological laboratory for protozoological and helminthological work in conjunction with the Bureau of Communicable Diseases.

RECENT DEATHS.

FERDINAND A. STILLINGS, M.D., of Concord, N. H., died at his home on June 22nd. He was born in Lancaster, N. H., on March 30, 1849. He had served as surgeon-general on the staffs of Governors Hiram Tuttle and Frank W. Rollins and had been president of the New Hampshire Medical Society. He was a member of the American College of Surgeons and other medical societies.

LIEUT.-COL. GEORGE D. DESHON, U. S. A., chief surgeon on the staff of Brig.-Gen. Clarence R. Ed. died of the Department of the Northeast, died on June 24 in Brookline, Mass. Lieut.-Col. Deshon was born in 1865. He had medical degrees from Dartmouth, Bellevue Medical College and the University of Pennsylvania, and had served in the Cuban and Philippine campaigns and was a department surgeon to Gen. Edwards at Panama. He is survived by a widow and a son.

AN ANALYSIS OF 133 FRACTURES OF THE SPINE TREATED AT THE MASSACHUSETTS GENERAL HOSPITAL.

By JOHN B. HARTWELL, M.D., BOSTON.

The data upon which this report is based were obtained from the records of 133 patients who were treated for fracture of the spine at the Massachusetts General Hospital between January 1, 1900, and December 31, 1914. To the members of the staff* of the hospital under whose care the patients came, I am indebted for the opportunity of making this analysis.

The report deals with 7 women and 126 men, the majority of them in the prime of life, who met with accidents which resulted in fracture of the vertebrae alone, or in combination with other injuries,

AGES BY DECADES

10-19	7
20-29	37
30-39	40
40-49	26
Over 50	21
Age not noted	2

133

* The patients were under the care of the following present and past members of the staff: Dr. F. G. Balch, Dr. H. H. A. Beach (deceased), Dr. G. W. W. Brewster, Dr. W. A. Brooks, Dr. A. T. Cabot (deceased), Dr. Hugh Cabot, Dr. Farrar Cobb, Dr. E. A. Codman, Dr. W. M. Conant, Dr. Lincoln Davis, Dr. J. W. Elliott, Dr. R. B. Greenough, Dr. F. B. Harrington (deceased), Dr. J. B. Hartwell, Dr. John Homans, Dr. D. F. Jones, Dr. S. J. Mixer, Dr. W. J. Mixer, Dr. J. G. Mumford (deceased), Dr. F. T. Murphy, Dr. C. A. Porter, Dr. C. B. Porter (deceased), Dr. C. L. Scudder, Dr. M. H. Richardson (deceased), Dr. J. C. Warren, Dr. Hugh Williams.

and directly or indirectly caused death in 59 instances.

The type of accident which produced the injuries is shown in the following table:

Falls from a height	83
Jack knifed by falling weight	11
Jack knifed by low bridge	6
Jack knifed by cave-in	1
Jack knifed by diving	5
Jack knifed by football	1
Jack knifed by coasting	1 25
Collision with trains	8
Collision with automobile	1 9
Direct blows	7
Alighting from moving cars	2
No history obtained	7

133

A study of the histories of the accidents, as given by the patients, in this series allows no general conclusion to be drawn as to the mechanism of the fracture of the spine. There is no reasonable doubt that in the jack-knifing accidents the immediate cause of fracture was hyperflexion of the spine, and a similar factor may be assumed to have been the causative means in the 83 patients who fell from a height, but this cannot be proven from the accounts given by the injured themselves. Thus 22 stated that they landed on their head and shoulders, 4 on their shoulders, 10 flat on their back, 4 on their buttocks, and 4 on their feet, while 39 were unable to state how they landed; but of the 22 who landed on their head and shoulders, 8 stated that the fall rendered them unconscious for varying periods; 1 was walking in his sleep when the accident occurred, and 1 was so intoxicated

that the fact that he landed on his head was the only detail of the accident he could give. Similar discrepancies are found in the records of the remaining 22 patients who made positive statements as to the manner of landing.

The regions injured by the different types of accident are shown in the following table:

	INJURED REGION		
	CERVICAL	DORSAL	LUMBAR
Falls from a height	31	30 ¹	22
Jack knifed by falling weights ..	3 ²	5	3
Jack knifed by low bridge ..	3	2	1
Jack knifed by cave-in	0	1	0
Jack knifed by diving	4	1	0
Jack knifed by football accident ..	1	0	0
Jack knifed by coasting accident ..	0	1	0
Collision with trains	3	2	3
Collision with automobiles	0	0	1
Direct blows	0	5	2
Alighting from moving cars	0	1	1
No history obtained	4	3	0
	49	51	33

All told, this series contains:

Fracture in the cervical region	48
Fracture in the cervical and dorsal regions ..	1
Fracture in the dorsal region	50
Fracture in the dorsal and lumbar regions ..	1
Fracture in lumbar region	33
	133

Of 49 instances of fracture in the cervical region, there were broken singly or in combination:

1st vertebra	0
2d vertebra	1
3d vertebra	7
4th vertebra	14
5th vertebra	29
6th vertebra	19
7th vertebra	6
	76

62 of 76 fractures in the cervical region, suffered by 49 patients, involved the fourth, fifth and sixth vertebrae alone or in combination.

51 patients suffered fractures of the dorsal spine as follows:

1st vertebra	1	} 16
2d vertebra	3	
3d vertebra	7	
4th vertebra	5	} 13
5th vertebra	1	
6th vertebra	2	
7th vertebra	4	
8th vertebra	6	
9th vertebra	3	} 37
10th vertebra	9	
11th vertebra	8	
12th vertebra	17	
	66	

If the dorsal spine be divided into thirds, there were fractures of the bones of the upper third in 16 instances, of the middle third in 13

¹ 12th dorsal and 1st lumbar injured.
² 7th cervical and 1st dorsal injured.

instances, and of the lowest third in 37 instances, or more frequently than the other two segments combined.

34 patients presented fractures of the lumbar spine, as follows:

1st vertebra	20
2d vertebra	8
3d vertebra	1
4th vertebra	3
5th vertebra	4
Unspecified	4
	40

These tables confirm the accepted view that there are two regions of the spine especially likely to suffer fracture, the mid-cervical and the dorso-lumbar. In the former situation the fourth, fifth and sixth vertebrae are the vulnerable ones, and in the latter situation the tenth, eleventh and twelfth dorsal and first lumbar.

In this series, isolated fractures of the vertebral processes seem rare; only seven are recorded; five of transverse process, and one each of spinous process and articular process. As is to be expected, these process fractures all occurred in the lumbar region, where the transverse processes are long and slender, not short and thick, as in the cervical region, nor protected by fragile ribs, as in the dorsal region. The spinous processes in the lumbar region are, likewise, less protected than in either the cervical or dorsal segments of the spine, where the imbrication of the spinous processes allows any trauma to be borne by several, and not by an isolated process.

Process fractures in this series resulted from direct trauma, in contradistinction to the body fractures, a certain proportion of which are certainly, and the remainder presumably, dependent on indirect trauma.

In addition to compression fractures of the vertebral bodies and fractures of the vertebral processes, a review of the post-mortem records has shown three cases of fracture of the intervertebral discs, all in the cervical segment of the spine. For access to the necropsy records, the author is indebted to Dr. James Homer Wright, director of the clinico-pathological laboratory of the Massachusetts General Hospital.

In each of the cases the patients on entrance to the hospital had a complete motor and sensory paralysis below the segment of the cord opposite the fractured disc, with abolition of all reflexes, superficial and deep, and retention of urine and feces.

The autopsy protocols in these cases are given in full so far as they relate to the spine, since no text-books examined by the author make mention of isolated fracture of the intervertebral discs.

(1) "Viewed from in front, the third cervical disc is of slightly increased prominence. A V-shaped segment saved from the front of the column shows discs between third and fourth cervical, and fourth and fifth cervical torn apart and blood-stained. Spinous process of the

third cervical abnormally mobile and somewhat separated from that of the fourth cervical. Spinal cord opposite third and fourth cervical flattened and distinctly soft to touch."

(2) "Cervical spine from in front shows deformity at level of fourth and fifth segments, characterized by projection forward of the body of the fourth cervical from that of the fifth cervical. Dissection reveals rupture of the fourth disc and adjoining ligaments. From behind, the cervical segment of the spine at the level of the fourth cervical, fragmented. On laminectomy, cord at the level of fracture depressed and softened. Vertebral canal at level of the fourth intervertebral disc interrupted, the column discontinuous, evidently by rupture of the disc and by the ligaments of the spinous processes."

(3) "Laminae of fifth and sixth cervical vertebrae are separated from one another by an interval of about 1 cm., and through an opening just to the right of the spinous process, dura is apparent. No fracture of the laminae or spinous process is made out. On removing the cord the anterior surface of the spinal canal, at a point corresponding to the interval between the fifth and sixth cervical vertebrae, is bent backward to form an obtuse angle from the shoving forward of the cervical vertebrae above this point. On section through the cervical vertebrae, the disc between the fifth and sixth cervical is found disintegrated."

In 41 instances, or 30.8%, the spinal fracture was but one item of the injuries sustained by the patient, as recorded in the records. The nature of these complicating injuries is tabulated below:

	CERVI- CAL	DOR- SAL	LUM- BAR	TOTAL
Fractured skull	6	4	2	12
Fractured ribs	5	8	3	16
(Punctured lung	1	3	0	4)
Fractured sternum	0	1	2	3
Fractured upper extremity:				
Girdle	2	1	0	3
Arm	1	0	0	1
Forearm	3	3	1	7
Fractured lower extremity:				
Pelvis	0	0	2	2
Thigh	1	2	1	4
Leg	0	1	4	5
Ruptured viscera	1	1	0	2
Hemothorax	0	1	2	3
Ruptured brachial plexus ...	1	0	0	1
Extensive lacerations	0	3	2	5
	20	25	19	64

The injury most frequently complicating fracture in the cervical region was fractured skull, and a careful study of the records makes skull fracture probable in several instances where this injury is not specifically stated to have been present; in the dorsal region, fracture of the ribs is the most common injury; and complicating fractures of the lumbar spine, fractures of the lower extremity are most frequently

noted. Of the seven fractures of the lower extremity noted as complicating injury to the lumbar spine, four were compound fractures. Hemothorax is noted three times, but in no instance was it recognized clinically. Necropsy revealed the condition.

The records of 107 patients who entered the hospital within forty-eight hours of the receipt of their injury is made the basis of the symptomatology of spinal fracture. This 107 includes 40 fractures of the cervical spine, 38 fractures of the dorsal spine, and 29 fractures of the lumbar spine.

Shock is noted in 24 instances: 3 times in cervical fracture, 11 times in dorsal fracture, and 10 times in lumbar fracture. In every instance of shock in fracture of the cervical vertebrae, there were also noted other severe injuries, and this holds true in 10 of the 11 instances of fracture in the dorsal region, and 8 of the 10 fractures in the lumbar region.

The histories of the 3 patients who showed shock without demonstrable injuries other than fracture of the vertebrae are detailed, because in these there is a reasonable doubt that the injury described was the only injury suffered.

One patient is said to have fallen a distance of 20 feet, landing on her head and shoulders, and presented the classical picture of a complete transverse lesion of the cord at the level of the fifth dorsal segment. No note is made of her mental state other than she was in a state of "considerable shock." She responded "fairly well" to stimulation, and within twenty-four hours was subjected to laminectomy, and died almost immediately after the operation, respiration failing. No autopsy was permitted.

Of the patients with fracture of the lumbar spine, one fell thirty feet into a vessel hold and landed on his "right buttock and side." He was dazed but able to stand with great difficulty. There were no paralytic symptoms and all his reflexes were normal. Fracture of the transverse process of the fifth lumbar vertebra is the only injury recorded, but does not seem enough to account for shock. The other patient with lumbar fracture was crushed by a falling boiler. He was a man of twenty-five. When seen in the accident room, he was unconscious and in a state of shock. There was no loss of motor power of legs. He died in half an hour, but "fracture of the fourth and fifth lumbar" is the only note of the injury. There was no autopsy.

If these three cases can be excepted, no patient with fracture of the spine, uncomplicated by other demonstrable severe injuries, was recorded as in a condition of shock when first seen.

From the data here presented, shock is not to be expected in uncomplicated vertebral fractures, and the presence of shock is indicative of additional injuries.

Neurological signs presented by the patients are shown in the following table:

CERVICAL DORSAL LUMBAR

Complete motor and sensory paralysis, sphincteric retention and absence of reflexes, superficial and deep	13	12	5
Complete motor and sensory paralysis, with sphincteric retention and absence of all reflexes, superficial and deep except the plantar	8	3	0
Complete motor and sensory paralysis with sphincteric retention, but notes on reflexes unsatisfactory	3	2	0
Complete motor and sensory paralysis with retention with presence of deep or superficial reflexes on one or both sides ..	5	3	0
Incomplete motor or sensory paralysis, sphincteric retention and complete absence of deep and superficial reflexes	0	1	1
Incomplete motor or sensory paralysis, sphincteric retention and complete absence of deep and superficial reflexes, except plantar	0	0	1
Incomplete motor or sensory paralysis with sphincteric retention but with difference in reflexes on two sides	3	0	1
Incomplete motor or sensory paralysis with retention of urine and feces with normal reflexes	0	1	1
Incomplete motor or sensory paralysis with retention of urine and feces with exaggerated reflexes	1	0	0
Incomplete motor or sensory paralysis with retention of urine and feces, but notes on reflexes unsatisfactory	1	1	1
No motor or sensory paralysis and normal reflexes, but sphincteric disturbances present	0	2	4
No motor or sensory paralysis, but sphincteric disturbances present and no note on reflexes	0	1	1
No motor or sensory paralysis, no sphincteric disturbance, but reflexes changed from the normal—diminished	1	2	0
No motor or sensory paralysis, no sphincteric disturbance, and normal reflexes	0	1	0
No motor or sensory paralysis, no sphincteric disturbance, and no notes on reflexes	1	4	11
No motor or sensory paralysis, no sphincteric disturbance, but no notes on reflexes	1	2	0
No notes on paralysis or reflexes	3	3	3

If the presumptive signs of total transverse lesion of the cord are considered to be a total motor and sensory paralysis with abolition of all reflexes, deep and superficial, except the plantar,—below the injured segment,—and if the cases presenting complete paralysis and sphincteric disturbance but in which the record of the reflexes is not complete, be admitted as presenting signs of total destruction of the cord, there are 46, or 43%, of the cases which meet this definition, divided as follows: cervical, 24, or 60%; dorsal, 17, or 44.7%; lumbar, 5, or 17.24%.

Disturbance in sensation or motion, complete or incomplete, with paralyzed sphincters and reflexes present; normal, exaggerated, diminished, or unequal on two sides,—in other words, signs of cord injury, but not of complete destruction,—were present in 21 additional cases (19.6%), divided as follows: cervical, 10, or 25%; dorsal 6, or 15.8%; lumbar, 5, or 17.24%.

In 8, or 7.4%, of cases, sphincteric retention was the only symptom indicative of cord injury. This condition presented in 3, or 8%, of the dorsal cases, and 5, or 17.24%, of the lumbar fractures.

There remain a few cases who presented no neurological symptoms. Included in this number are 3 cases in which no note was made of reflexes, but in which there was no paralysis or sphincteric disturbance, and 9 cases, 3 in each region, in which no mention is made of paralysis or sphincteric disturbance or the condition of the reflexes: cervical, 6, or 15%; dorsal, 12, or 31.6%; lumbar, 14, or 48.3%; a total of 32, or 30%, of the cases.

Signs of severe cord injury were present in 67, or 62.6% of 107 patients seen within forty-eight hours of the receipt of the injury. In 46, or 43%, the signs on first examination pointed to a complete myelitis, and in 21, or 19.6%, the signs were of a partial cord destruction. Eight, or 7.4% of the cases, showed sphincteric disturbance of short duration, while 32, or 30%, presented no signs of medullary trauma. Roughly, two-thirds of the patients showed severe injury to the cord, and one-third presented slight or no signs of cord injury.

If the 3 regions of the spine be studied, the vast majority (85%) of fractures in the cervical region, and over half (59.4%) of the fractures in the dorsal region were accompanied by symptoms of serious damage to the cord, while two-thirds (65.5%) of fractures in the lumbar segment were accompanied by slight or no evidence of medullary trauma.

A fact of great importance is that, of the 67 patients who had signs of cord lesions, in 66 the onset of the paralysis was immediate, and in only 1 was it gradual.

Priapism was noted in 27 cases: cervical, 16; dorsal, 11; lumbar, 0; and with 3 exceptions (1 in the cervical and 2 in the dorsal region) in patients who presented signs of complete destruction of the cord. From these figures, therefore, the presence of priapism should be a bad prognostic sign.

Subjective pain at the site of fracture was conspicuous by the infrequency of its mention,—only 12 times in all; 3 times in fractures involving the cervical spine, 4 times in the dorsal segment and 5 times in the lumbar segment,—and the extent of the cord lesion had no apparent effect on the presence of pain; 6 had complete cord lesion, 2 incomplete cord lesions, and 4 no cord lesions.

Though conclusions based on small figures are

frequently erroneous, at least these figures suggest that the lower the site of the fracture the more likely is subjective pain to be prominent. In the present series it was present in 3 instances in 40 fractures in the cervical region, a percentage of 7; in 4 out of 38 in the dorsal region, 10%; and in 5 out of 29 in the lumbar region, or 17%.

The classical local signs of fracture of the long bones—swelling and ecchymosis, localized tenderness, deformity and crepitation—were applied to the present series.

Discoloration, swelling or contusion at the site of fracture are mentioned in 23 instances, or in 21.5% of the cases under consideration; 2 in the cervical region, 17 times in the dorsal region, and 4 times in the lumbar region.

Localized tenderness was noted in 67 instances, or in 62.6% of the cases: 22 times in the cervical region, 26 times in the dorsal region, and 19 times in the lumbar region.

Deformity was noted in 51 instances, or in 47.7% of the cases: in the cervical region 14 times, in the dorsal region 25 times, and in the lumbar region 12 times.

Crepitation: was noted in but 8 instances, 7.5%: twice in the cervical region and three each in the dorsal and lumbar regions.

Localized tenderness over the spinous processes of the fractured vertebrae, or just lateral to the spinous processes, is the subjective sign most frequently noted in this series of cases, and the frequency of this sign is underestimated in the figures quoted, for in 7 instances where contusion or hematoma are noted, no note is made of localized tenderness. Moreover, a number of patients were unconscious when the examination was made, and in these cases the presence of tenderness could not be determined. It is, without doubt, fair to venture a general statement that localized tenderness is present in every instance of fracture of the spine. And as a corollary to this, localized tenderness over the spine should always suggest the possibility of fracture.

Fifty-five patients in this series of 133 were given an x-ray examination, with the results shown in the following table:

	CERVICAL	DORSAL	LUMBAR
Patients examined	23	15	17
Fractures demonstrated	12	8	15
Negative	2	2	0
Questionable fracture	5	5	0
Unsatisfactory plates	2	0	1
Interpretation not recorded	2	0	1

Positive evidence of fracture was obtained in a little over one-half of the cervical and dorsal cases, but in the vast majority of the lumbar cases; included in the lumbar cases are 5 cases of fracture of transverse processes and 1 case of fracture of an articular process that, except for x-ray, would have gone unrecognized.

The 4 cases that were reported "negative" were clinically positive. One of the cervical

cases had signs of complete and one of incomplete crush of the cord. One of the dorsal cases had signs of a transverse myelitis, and was further proven by operation to have sustained a fracture. The second dorsal case may be open to some question, for the patient presented no neurological symptoms, and the crepitus that was felt on examination might have been crepitus transmitted from a fractured rib which he suffered. This is the only doubtful case in the whole series.

Recent experience has shown that an absolutely satisfactory plate is necessary to make a diagnosis of fracture of the spine, and oftentimes several exposures are necessary before such a plate is secured. And further, the usual antero-posterior views, though the plates be excellent, often do not clearly show a compression fracture that is unmistakable in a lateral view.

Except in the mid-dorsal region, where the scapulae are interposed, and in the low lumbar region, where in like manner the alae of the ilia are interposed, satisfactory lateral views have been obtained.

If repeated exposures had been made in all cases in the present series in which the plates were unsatisfactory, or in which, from the standpoint of the radiographer, the fracture was "questionable," or in which the x-ray and clinical findings were at variance, there can be no doubt that 100% positive findings would have resulted.

Lumbar puncture is not recorded as being done on any of the patients in this series, though it would seem, *a priori* that valuable evidence as to the condition of the cord might be acquired by this means. A study of the meagre data obtainable, however, indicates that conclusions as to the condition of the cord, drawn from the appearance of the cerebrospinal fluid, may be misleading. The character of the cerebrospinal fluid which escaped on opening the dura at operation, was noted in 8 instances: 5 times as bloody and 3 times as clear. All three of the patients whose cerebrospinal fluid was reported as clear presented the clinical signs of a complete transverse myelitis, and were operated upon within twenty-four hours after the receipt of their injury. In 2 of those cases the cord was not demonstrably injured, while in the third it appeared normal until incised, when cord mush was extruded. Two of the cases with bloody cerebrospinal fluid were operated upon within twenty-four hours of the receipt of the injury, one on the third day, one on the fourth day, and one on the fourteenth day after injury. In 4 cases the cord was found at operation to be completely severed, and in one instance no cord injury could be demonstrated, though the man showed clinical evidence of a severe, though not complete lesion of the cord. From these small figures, a bloody cerebrospinal fluid on lumbar puncture may indicate that the cord be lacer-

ated, but clear fluid does not exclude the possibility of severe trauma to the cord.

In this series 40 patients were subjected to operation, 38 to laminectomy and 2 to attempts to remove deformity by manipulation. Of the laminectomies, 11 were in the cervical region, 24 in the dorsal region, and 3 in the lumbar region.

The data obtained by a study of the records of the findings at operation are disappointingly incomplete, and from their study few conclusions can be drawn. In 38 laminectomies spinous processes are noted as fractured in 19 instances, laminae in 18 instances, and the posterior vertebral ligaments in but 2 instances. These figures suggest that in the mechanism of fracture the bodies are first crushed; if the causative flexion is continued the unyielding bony posterior arch yields to the force, before the elastic ligaments are finally ruptured.

Extradural hemorrhage was noted but twice, and then the blood extravasation was small. In one instance the dura is noted as "bruised," and in 2 instances as "lacerated." Subdural hemorrhage is noted twice, but the extent of the hemorrhage is not mentioned.

In 5 cases the dura was not opened. Of the 33 instances in which the dura was opened no note of the character of the cerebrospinal fluid is made in 25; in 5 instances it is noted as bloody and in 3 cases as clear.

The condition of the spinal cord itself is noted in 30 cases. In 12 instances it is noted as "crushed," once as "lacerated," once as "thinned," once as "slightly discolored." In 13 instances there was no demonstrable injury to the cord. In two instances the cord is noted as being "fairly normal in appearance" until it was incised, when in both instances, cord mush was extruded. In the 12 instances in which the cord was noted as crushed, in the one instance of "lacerated" cord, in the one instance of "thinned" cord and in the two instances where the cord appeared "fairly normal until incised," the clinical symptoms pointed to a transverse myelitis. The patient whose cord was "slightly discolored" was also paralyzed completely. Of the 13 instances in which there was no demonstrable injury to the cord, the symptoms pointed to complete destruction of the cord in 8 cases, and to partial destruction in 5 cases. In 2 cases where no lesion of the cord was demonstrated at the time of operation, autopsy proved acute traumatic softening.

These operative findings indicate that extradural and subdural hemorrhages, secondary to spinal fracture, are infrequent, and rarely large enough to account for compression symptoms. In none of the cases here reported could hemorrhage be considered a factor in the production of symptoms. Further, in not a single instance was bone pressure on the cord demonstrated.

Another interesting and significant point is

emphasized by the operative findings; that a fairer estimate of the amount of eord injury was possible through the clinical manifestations than by palpation and ocular inspection of the cord. Moreover, it is shown that eord lesions may be demonstrated by incising the cord, that otherwise would escape unrecognized.

The following comparison of the progress of the patients treated by conservative and operative methods was made, to determine what advantages operative measures offered, as shown in a small series of cases.

The comparison can be most fairly made if cases presenting evidence of injury in the same spinal segment be treated separately, and if only recently injured patients be included. The 107 patients who entered the hospital within 48 hours of the receipt of their fracture will, therefore, form the basis for comparison. These cases are distributed as follows:

	TREATED EXPECTANTLY	BY LAMINECTOMY
Cervical ...	38	27
Dorsal	38	17
Lumbar ...	22	19
		11
		21
		3

In the cervical region, 38 cases form the basis of comparison; of these, 27 were treated expectantly and 11 by laminectomy. Two patients with fracture in the cervical spine, who were seen within forty-eight hours of the receipt of their injury, have not been included in the figures. In these two cases attempts were made to reduce the evident deformity by manipulation—a practice which is now generally considered poor.

Among the 27 patients who were treated conservatively, 6 had injuries other than fractured spine—5 with signs of complete and one of incomplete destruction of the eord—and 21 suffered fracture of the cervical spine only; 11 with signs of a complete myelitis, 6 of a partial myelitis, while 4 had no signs pointing to injury of the cord.

Five of the 6 patients with injuries in addition to the spinal fracture were either unconscious or in profound shock when first seen in the accident room, and the sixth gave a history of unconsciousness following his fall; in other words, their general condition was such as to put operation out of the question. Three of the six died within twenty-four hours, one lived two days, one lived three days, whose signs pointed to a subtotal eord destruction, and the mother of the sixth patient took her from the hospital on the nineteenth day following her injury, that she might die at home. She had been delirious the last four days of her stay in the hospital, her temperature was ranging between 99 and 106, and it was a matter of but a short time till death should relieve her suffering.

Ten of the eleven patients with signs of complete myelitis, but no other accompanying injuries, died in the hospital,—four died inside

of twenty-four hours, one in 3 days, one in 5 days, one in 6 days, one at the end of a week, one after 15 days, and one after 16 days. The eleventh patient remained in the hospital 8 weeks, when he was transferred to another institution. Not one of the patients in this class showed even symptomatic improvement during their hospital stay.

But two of the 6 patients died who suffered a cervical fracture and had signs of cord injury, but not of complete severance of the cord. One died inside of 24 hours and one at the end of three weeks, though the three weeks he lived produced no improvement in his condition. The remaining 4 patients made definite improvement. They were able to use their arms and hands to some extent, though in no instance perfectly; could all walk unassisted though awkwardly, and two regained control of their sphincters. Since leaving the hospital one patient has made a complete functional recovery, and at the end of a year was working at his old position as brakeman on the railroad.

The first definite improvement in these cases, as noted in the records, began between four days and two weeks after entrance to the hospital. The hospital stay varied from three to eleven and a half weeks.

Each of the four patients who suffered fracture of the cervical vertebrae, but who presented no signs of cord injury, remained in the hospital three weeks. During this period no symptoms developed. Two of these four have been seen a year or more after their injury and are perfectly well.

Eleven patients were subjected to laminectomy, and none of them had received injuries other than fracture of the cervical spine. Nine of this number on the first examination showed signs pointing to a transverse myelitis, and two had signs of cord injury, but not of complete destruction.

Seven of the nine patients with signs of complete cord destruction were operated upon within twenty-four hours of the receipt of the injury. One patient died on the table, and one patient stopped breathing as the operation was about to begin, and artificial respiration was necessary for some time before operation could be done. Two patients died inside of twenty-four hours, two inside of forty-eight hours, and one at the end of five days, one at the end of two weeks, and one lived within a couple of weeks of a year. With the exception of the last case, which was reported by Mixer and Chase,* no patient showed improvement before death. The last-mentioned case on entrance presented all the signs of a transverse myelitis with complete motor and sensory paralysis below the fifth cervical segment, retention of urine and feces and absence of all reflexes, superficial and deep. Two days after the operation, tactile sensation had begun to return. In

a week tactile sensation was present over the arms, body and legs. Within two weeks the knee jerks and plantar reflexes had returned. Within a month motion had begun to return in arms and hands and legs. After eight months he was able to move himself about in a wheel chair, had moderate control over both sphincters and had some power in the muscles of his legs. The immediate cause of his death was a calculous nephritis. A post-mortem examination was made and sections of the cord at the site of the crush proved that the cord at this level had not been entirely disintegrated. One patient submitted to laminectomy on the fourth day following his injury. On recovering from ether he had great difficulty in breathing, but this passed off in twenty-four hours. During the three weeks following his operation that he remained in the hospital, no improvement in his condition was noted, and he finally died six weeks after his accident. One patient was operated upon six days after his accident. He remained in the hospital six weeks after his operation, but during this time he did not improve.

The two patients with signs of cord injury, but not of a complete crush, had laminectomy done, one on the third and one on the fifth day, but both died on the fourth day following their operation, without any evidence of lessening of the paralysis.

Summary of fractures in the cervical region: all six patients with injuries accompanying the spinal fracture died—five inside of a week. Ten of the eleven patients with fracture of the cervical vertebrae and no accompanying injuries, whose neurological signs pointed to a complete severance of the cord, died, the majority inside of two weeks, and none improved any before death. Four of the six patients with cord lesions, not complete, improved very markedly under conservative treatment, and four, who had no neurological symptoms on entrance, developed no symptoms during their stay in the hospital.

Of nine patients with fracture of the cervical spine and signs of complete severance of the cord, subjected to laminectomy, there was one operative death. Eight died in the hospital, the majority inside of two weeks, but a much smaller majority than in the same class treated conservatively. One patient only improved following the operation, and though his improvement was very great, the autopsy findings showed that the injury to his cord was not complete, and it is questionable whether like betterment had not taken place had no operation been done. Both patients with signs of a partial myelitis, who were operated upon, died inside of two weeks and showed no betterment following the operation.

In this small series of fractures in the cervical spine with signs of cord injury, the only benefit that was derived from operation was a

* Mixer and Chase: *Annals of Surgery*, 1904, Vol. xxxix, p. 495.

possible prolongation of a miserable existence in the patient with original signs of complete crush of the cord. That improvement does take place where the cord is not severed is shown by the progress of those patients treated conservatively. That laminectomy improves the chances for recovery is not shown in this small series of cases.

Thirty-eight fractures of the dorsal vertebrae were first seen within forty-eight hours of the receipt of injury, of which seventeen were treated conservatively and twenty-one subjected to laminectomy.

Nine of the seventeen treated conservatively had other injuries complicating the spinal fracture. Two had signs pointing to complete destruction of the cord, and both died,—one within twenty-four hours and the other within forty-eight hours of the accident. One patient, the victim of a cave-in that crushed his chest, producing a subcutaneous emphysema, as well as fracturing his dorsal spine, presented signs of subtotal cord destruction; some sensation remained in the flaccid legs, though all reflexes and sphincteric control were lost. During the seventeen weeks he remained in the hospital he improved symptomatically in that the original hyperesthesia of the skin lessened, and he acquired the power of moving certain muscles in his legs a bit, but he failed in that time to regain control of his sphincters, and no note of the return of reflexes is made in the records. Two patients were moribund when first seen, and examination to reveal the extent of cord injury was unwarranted. Four patients had no symptoms pointing to cord injury. Three of the four died inside of forty-eight hours, and in one case the vertebral lesion was discovered at autopsy. The remaining patient stayed in the hospital three and a half weeks, during which time no signs pointing to cord injury developed. Of eight patients who suffered vertebral fracture alone, two had signs of injury to the cord, but not of complete destruction, and made complete recoveries. Loss of sphincteric control and inequality of the knee jerks, persisting for four days, were the cord signs presented by one of these patients, and the other patient had urinary retention and loss of the abdominal and patellar reflexes on one side, though no motor nor sensory paralysis was notable. In ten days the sphincteric disturbance had passed. During the month he remained in the hospital no new symptoms developed. Six patients who had no signs of cord injury were kept in the hospital under observation from one to three weeks, during which time no pressure symptoms developed.

Only four of the twenty-one patients on whom laminectomy was done had injuries other than spinal fractures, three presenting signs of complete and one of incomplete myelitis. Two of the three complete myelitis cases had suffered broken ribs, and a third a double Colles'

fracture. All were operated upon within twenty-four hours of the accident. Two died, one in five and a half weeks and one in ten weeks. The third patient was alive a year after his discharge from the hospital, but he had not improved and was bedridden. The patient with a partial myelitis received fractures of both femora and fractured ribs, as well as a fracture of the spine, but on entrance no cord symptoms were noted. On the morning of the second day, in dressing his legs, it was found that sensation was absent. In the evening all power of motion had been lost. Laminectomy was done on the fourth day, and he died on the sixth, experiencing no benefit from the operation.

The remaining seventeen patients had no other injuries than the vertebral fracture. Thirteen on entrance showed signs of a complete transverse lesion of the cord, two of a partial injury to the cord, one had no medullary symptoms, and in one case the results of examination are not stated in the records. Eight patients with symptoms of complete crush of the cord and the one patient whose record is incomplete, were operated upon within twenty-four hours of the receipt of their injury. One death occurred on the operating table, one death an hour after reaching the ward, one died after seven weeks and one after four months. Four patients were unimproved on discharge from the hospital, one to four months after operation. One patient, who improved not at all during the five months succeeding his operation that he remained in the hospital, was reported to have improved symptomatically during the next six months in that "reflexes returned in both feet." In eighteen months from the date of injury he reports that he could distinguish between heat and cold in right foot and left thigh, but that he had no control over sphincters and had regained no motor power in the legs. One patient with symptoms of complete crush was operated upon forty-eight hours after his injury. Within two days motion was noted in the toes; within ten days the zone of anesthesia had fallen two inches and plantar reflexes were obtained, but there was no improvement in sphincteric control or motor power, and in the following two weeks no gain took place. He died during the ensuing year. Laminectomy was done on one patient on the fourth day, and he died four days after the operation; another patient submitted to operation on the fifth day and within two weeks of the operation his knee jerks had returned, but the following two months yielded nothing more. One patient developed delirium tremens the day after his injury, and operation was postponed for two weeks, but no improvement followed during the next two months.

Two patients were operated upon whose symptoms pointed to cord injury but not to complete crush. One patient on entrance presented a flaccid paralysis of both legs, with abolition of patellar and plantar reflexes, retention of

urine and feces, but sensation in the legs was not lost, though somewhat dulled. Laminectomy was done within twenty-four hours. In three days after the operation sensation in the legs was normal; in twelve days there was a slight power of motion in the left foot; in a month he could voluntarily control the right calf muscles; in six weeks he could turn in bed without help; in two and a half months he regained control of his bladder; in six months he could stand with support, but complete control of the muscles of his lower extremities had not been acquired. The second patient on entrance had a partial motor paralysis of the right leg and a hyperesthesia of the legs, with sphincteric retention, but reflexes unaltered from the normal. Operation was postponed, on account of poor general condition, for seven days, but in the meantime he had recovered control of his sphincters, and had regained the motor power in the right leg to a large extent. Progressive betterment continued after operation. Four weeks after the operation all symptoms referable to the cord had disappeared, and in six weeks after the operation he was discharged on crutches.

The patient who had no cord symptoms was subjected to laminectomy within twenty-four hours. He remained five weeks in the hospital and developed no neurological symptoms.

Summary of fractures in the dorsal region: As in the cervical region, fracture of the dorsal spine, accompanied by other injuries, is very fatal, whether the cord be apparently totally or incompletely destroyed. Seven of nine patients thus injured died within forty-eight hours of their accident. Two patients with dorsal fracture, uncomplicated by other injuries, had medullary symptoms, though not symptoms of complete severance of the cord, and made complete recoveries. Improvement began between four and ten days after the receipt of the injury. Six patients with fractures and no signs of cord injury developed no medullary symptoms during the period of hospital observation.

Operative treatment certainly shortened the lives of two patients among the twenty-one subjected to laminectomy,—one death on the table and one an hour following operation. With one exception, the accompanying injuries of those patients operated upon who received other injuries than the vertebral fracture, were less severe than among those treated conservatively, and though three of the four died, they lived longer than those who were treated by palliative methods. The fourth patient reaped no benefit from his operation. Thirteen patients with fracture of the dorsal spine with signs of transverso myelitis but no accompanying injuries, were the subjects of laminectomy. Six died, two immediately after, three within four months, and one inside of a year. Five showed no improvement during their hospital stay. One patient who died and two patients who were discharged from the hospital showed slight symptomatic im-

provement after operation, but did not regain lost function. Two patients with signs of incomplete cord injury, made marked progress. One of these patients had gained considerably before operation was done; and the gain in the other case was very slow and the rôle the laminectomy played is open to question.

The results of laminectomy in fractures of the dorsal spine, as in fractures of the cervical spine are no better than the results of conservative treatment, and in this series of dorsal fractures laminectomy resulted in two deaths. Such improvement as followed operation in these cases cannot be credited to the operation, since patients who were treated conservatively made equal gain. The indication for operation on the patient who had no cord symptoms is not clear, since four patients under similar circumstances, treated conservatively, developed no cord symptoms.

With fracture of the lumbar spine, nineteen patients were treated conservatively (patients who received simple process fractures have not been included in this number) and three treated by laminectomy.

Ten of the nineteen cases treated by conservative methods sustained other injuries than the spinal fracture. Two showed signs of complete crush of the cord, and both died—one inside of twenty-four hours and the other in three weeks; two others were moribund on entrance and died within a few hours, and examination to determine the extent of the cord injury was unwarranted. In six instances the spinal injury, associated with other injuries, was accompanied by signs of cord injury, but not complete destruction. Three of these patients died within twenty-four hours. In two instances the only sign of cord injury was loss of control of the sphincters, lasting in one case four days and in the other twelve days. In the sixth patient, who had suffered compound comminuted fracture of both legs, loss of sensation in the legs was first noted while changing the dressings. It was obviously impossible at this time to test for motor paralysis. She remained in the hospital four months, during which time she regained control of her sphincters. When her plasters were removed six weeks later, tactile sensation had returned in her legs, but there was considerable loss of motor power and loss of patellar reflexes. She was, however, able to get about on crutches. In the following two years there was no further gain.

Of nine patients with fracture of the lumbar spine, unaccompanied by other injuries, one patient presented signs of a complete transverse lesion of the cord, five presented cord symptoms, but not of a complete severance, and three had no signs pointing to medullary injury. The patient with the complete transverse myelitis remained but one day in the hospital, since operation was not advised. In two patients loss of control of sphincters for two or three days was

the only sign of cord involvement, and no other signs developed during the month each remained under observation in the wards. One patient on entrance had total loss of sensation below the knees on both sides, retention of urine, abolition of patellar and plantar reflexes, but retained slight motor power in both legs. In ten days sensation had returned almost completely in one leg, and the opposite foot alone was anesthetic. He was also able to flex and extend his legs, though there was no power over ankles or toes. In five and a half weeks he was able to pass his urine voluntarily, but there was no increase in muscle power. Another patient's cord symptoms consisted in numbness of the legs and unequal patellar reflexes. His bladder control was not affected. He developed delirium tremens on the second day. At the end of two weeks, when he was transferred to the psychopathic hospital, the numbness of the legs had been replaced by a hyperesthesia. No note was made on the reflexes on discharge. The last patient in this group had an anesthetic strip over the outer aspect of one leg. There was no noted paralysis and no bladder symptoms. At the end of a month he walked from the hospital, but no record is made as to the anesthetic zone at this time. Each of the three patients with lumbar fracture and no cord symptoms remained under observation for three weeks, and, since no signs referable to the cord had developed, was discharged.

Only three patients with fracture of the lumbar vertebrae were subjected to laminectomy. Each at the first examination presented a total motor and sensory paralysis below the injured cord segment, with retention of urine and feces, and loss of both superficial and deep reflexes. In two instances, operation was done within twenty-four hours. In one instance, two days after operation, there was a marked lessening of the extent of the zone of anesthesia and in three weeks slight power was present in the adductor group of muscles of one leg, but at the end of six months he had improved no more and was transferred to another institution. The other patient made no gain after operation, and died in eighteen days from a septic meningitis secondary to the operation. The third patient was operated upon four days after his injury, but in the following two months no betterment had resulted and he was transferred to another institution.

Summary of lumbar fractures: As in the two other segments of the spine, fractures in the lumbar region, accompanying other injuries, are generally fatal, and regardless of whether the cord lesion is complete or partial. Seven deaths within twenty-four hours and one death within three weeks among ten patients thus injured tell the story. Where there were no accompanying injuries the cord injuries associated with lumbar fractures are less severe than in the other two segments. Thus among nine patients treated conservatively, one

case only presented signs of a complete medullary lesion, and his hospital stay was too short to permit any statement to be made concerning him. All of the five patients with incomplete lesions of the cord made marked improvement, four of the five being practically normal on discharge. Three patients had no signs of cord injury on admission, and developed no signs while in the hospital.

Of three patients subjected to laminectomy, the operation must be held responsible for one life, death being due to a postoperative septic meningitis. In one instance following operation there was symptomatic improvement, and in one instance no betterment. The number of patients in this group who submitted to laminectomy is too small to allow any conclusions to be drawn.

Taken as a whole, the results of laminectomy in this series of fractures of the spine do not justify an argument in favor of operation, but on the contrary serve as a warning against radical surgical treatment. Four deaths to which operation directly contributed in thirty-five patients operated upon, is a high mortality. But six patients among the thirty-five made any improvement following operation, and in three of these cases the improvement was symptomatic only. Among the three who made decided improvement, in one case the gain had begun before operation was done, and in the two other cases it is perfectly reasonable to suppose that like improvement would have followed had no operation been done. Certainly operation is not justified unless it offers the patient a better chance for recovery than conservative treatment.

In this series of cases, with one exception, the onset of paralysis did not succeed the injury, but was the direct accompaniment of it. The paralysis was present before the effect of hemorrhage or edema or bone pressure could work on the cord. Furthermore the anatomy of the cord and its membranes differs markedly from that of the brain in that the brain lies closely apposed to its dura, whereas the cord hangs so loosely in its dural envelope that a very considerable hemorrhage may occur within the dural sheath and no compression of the cord result, and there is ample room for any swelling of the cord from secondary edema. Bone pressure following the causative accident must be rare, judging from the present series, for bone pressure was not demonstrated at operation in any of the patients subjected to laminectomy. If permanent bone pressure be present, it results from so great a dislocation of the vertebrae that the spinal canal is narrowed to limits smaller than the diameter of the cord, and in such instances, irreparable damage has been done before operation can be accomplished, and no gain should be expected.

Furthermore, Taylor's³ observations, that cord lesions occur at a distance from the level

³Taylor, E. W.: *Journal Boston Society of Medical Science*, 1908, Vol. III, p. 60.

opposite the site of fracture, seems to be given no weight by those authors who are enthusiastic proponents of routine laminectomy in cases of vertebral fractures with accompanying cord symptoms. In the series of cases under discussion, autopsies were performed on nineteen cases, and in three of this number areas of softening of the cord substance are described at a distance from the site of the original injury.

One instance with fracture of the fourth dorsal showed "region of softening about one centimeter in length at level of fourth dorsal, and another, somewhat larger, at level of ninth and tenth dorsal vertebrae. Serial sections one centimeter apart, show in regions of softening loss of structural markings and softening of substance of the cord almost to diffidence, the cord at these levels being grayish white and at these points but slightly diminished in size."

In another instance in which first and second lumbar vertebrae were fractured "the pia-*arachnoid* in mid-dorsal region for a distance of twelve centimeters below the cervical enlargement deeply blood stained. The consistency of the upper and lower levels of the cord natural; that of the thoracic segment a little diminished."

In the third instance the fifth cervical vertebra was injured. "The lower two-thirds of the cervical enlargement somewhat flattened and soft. Reflection of the dura shows no subdural hemorrhage. Section through the cervical enlargement yields pale, gray-red, pulpy semi-diffident material. Section through lower part of enlargement shows hemorrhage into the right ventral and left dorsal horns, with yellowish softening at centre of the areas. On cross section, dorsal segment at a point seven centimeters below the cervical enlargement is slightly softened, and on section shows a central area, grayish-red and semi-diffident. This condition limited to a region about one and five-tenths centimeters in length. On serial section, elsewhere normal."

In this small series of cases on which necropsy was done, sixteen per cent. showed cord lesions so remote from the site of injury that an ordinary laminectomy would completely fail to reveal them.

Several patients in this series, who originally presented signs of a complete transverse crush of the cord, improved to a greater or lesser degree, thereby proving that the cord had not been destroyed, and add to the accumulating evidence that the extent of the cord damage cannot be absolutely determined on first examination.

Laminectomy cannot be considered other than a major operation which carries a definite mortal risk with it, and the desperate condition of a patient does not warrant the surgeon in adding the risk of operation unless there is more than a visionary chance of bettering a hopeless condition. A major operation is not justified on the basis that it will do no harm,

and can conceivably, though improbably, do good.

From a study of the data here presented, the writer believes that laminectomy is absolutely contraindicated in patients in shock or who have received demonstrable injuries in addition to the spinal fracture and the cord injuries accompanying it; that laminectomy is contraindicated in patients with fracture of the cervical spine, whose respiration is embarrassed by paralysis of the intercostal muscles; that laminectomy is contraindicated in all patients whose paralysis accompanied the accident, and was noted immediately after accident; that laminectomy is contraindicated before the fourth day of convalescence, because where improvement takes place such improvement cannot be expected to manifest itself before the fourth day; that laminectomy is contraindicated in all patients who are improving under conservative treatment, and laminectomy cannot be expected to better conditions if improvement, once shown, comes to a standstill; laminectomy is contraindicated in patients whose vertebral fracture is unaccompanied by medullary symptoms.

Laminectomy is indicated in the rare cases of gradual onset of medullary symptoms, and in patients who, originally free from cord symptoms, begin to develop symptoms referable to the cord.

In conclusion, the study of this series of cases seems to warrant the following deductions: Fracture of vertebral bodies is generally caused by a hyperflexion of the spine first crushing the bodies; if the flexing force is continued the inelastic posterior arch gives way before the more elastic interspinous ligaments. Fracture of vertebral processes occurs in the lumbar region and results from direct trauma.

The mid-cervical and dorso-lumbar regions of the spine are most frequently injured.

Tenderness over the site of injury is the most frequent and reliable sign of vertebral fracture.

Shock is not common in vertebral fracture, regardless of the accompanying cord lesion, and the presence of shock is indicative of complicating injuries.

The presence of priapism is a bad prognostic sign.

Injury to the cord, where present, is an accompaniment of the spinal fracture in a very large majority of cases; not secondary to hemorrhage or edema or persisting bone pressure, which are of relatively rare occurrence.

Laminectomy in this series has been accompanied by a definite operative mortality, and operative treatment in the present series has not shown better results than conservative treatment. Laminectomy is contraindicated in all patients who have received injuries in addition to the spinal fracture, and in all patients with uncomplicated vertebral fracture, whose cord injury accompanied the fracture, until at least four days have passed—the minimum time for spontaneous improvement to manifest itself.

THE CLASSIFICATION OF HAY-FEVER POLLENS FROM A BIOLOGICAL STANDPOINT.

BY WILLIAM SCHEPPEGRELL, A.M., M.D., NEW ORLEANS.

President, American Hay-Fever Prevention Association; ex-President, American Academy of Ophthalmology and Oto-Laryngology; Chief of Hay-Fever Clinic, Charity Hospital, New Orleans.

THE knowledge of the exact pollens which cause hay-fever is important from an etiological as well as from a prophylactic and therapeutic standpoint. In the prevention of hay-fever, we must know the plants which produce the noxious pollens in order to eradicate them or prevent them from reaching their pollinating stage, and, where these measures are not feasible, to have the patient avoid localities infested with these pollens. This knowledge is equally necessary from a therapeutic standpoint, as the modern treatment of hay-fever gives special prominence to methods, the correct application of which requires the knowledge of the proper hay-fever pollens.

Hay-fever pollens are not deleterious to health *per se*, as the great majority of persons (99%) are not inconvenienced by them. Those suffering from hay-fever have a special susceptibility or lower resistance which modern methods attempt to correct by immunizing the patient against these pollens.

The usual method of testing the susceptibility of the patient by applying an extract of various pollens to the conjunctival sac or scarified skin is not scientifically correct, as the question is not whether a patient reacts to various pollens, but whether he is sensitive to the pollen to which he is exposed.

We have, for instance, found many persons in the East susceptible to the pollen of the Western mugwort (*Artemisia heterophylla*), but the therapeutic use of this extract, in spite of the patient's reaction, would not be indicated in New York or Pennsylvania, as this weed is found in the Pacific States and not in the Eastern or Southern States. In the same manner, many patients in California react to the pollen of the common rag-weed (*Ambrosia elatior*), but the use of this extract would not be advisable in California as the common ragweed is not found in that State.

The correct test of the patient's susceptibility, therefore, should be directed to the pollen to which he is exposed. This may easily be determined by the atmospheric-pollen plates and the information obtained from these should form the basis of applied pollen therapy.

ATMOSPHERIC-POLLEN PLATES.

The atmospheric-pollen plates are ordinary glass slides used for the microscope, the central square inch being covered with a uniform coat-

ing of glycerin. In localities in which the humidity causes too great liquefaction of the glycerin, we use a thin coating of boiled linseed oil.

When these plates are examined, we apply an ordinary thin glass cover, and place the slide on a mechanical stage, so that the whole field may be traversed. As the glycerin leaves a surface of uneven refraction, it is necessary to inject a solution that will correct this. We use the ordinary Lugol's solution of iodine and iodide of potash, which not only corrects the refraction, but simplifies the identification of the pollens.

All the grass (gramineae) pollens, on account of the high percentage of starch, are stained blue-black (Fig. 1) which easily distinguishes them from all the other pollens. The members of the Ambrosiaceae group, including the rag-weeds, marsh elders, gaernerias and cockle burs, are stained brown by the iodine, and are recognized by the spicules (Fig. 2). The amarantths (*Amaranthus spinosus*), chenopods (*Chenopodium anthelminticum*) and docks (*Rumex crispus*) have a medium percentage of starch, and are partly stained by the iodine. These pollens are spherical and smooth.

The wormwoods (*Artemisias*) are stained brown and are recognized by their three-lobed appearance when seen from the end; otherwise they appear ovoid with one of the lines of the lobes showing longitudinally (Fig. 3).

In our biological laboratory, where we have the photomicrographs of over two hundred pollens, their identification is not difficult. Ordinarily, however, the number of varieties of atmospheric-pollen appearing on the plates is not great, and it soon becomes easy to identify them.

While several varieties of pollen are usually found, the important pollen is distinguished by its great numbers (Fig. 4). The occasional appearance of a new pollen on the plates is not of any importance.

After the pollens have been identified and counted, they are estimated on the basis of the number per square centimeter for twenty-four hours. This number, which has a definite relation to the number of pollen per kiloliter of air,¹ is important in its bearing on the development of hay-fever and its severity. With most pollens, 25 per square centimeter indicates that there is sufficient pollen in the air to cause hay-fever in most subjects, and 100 that the number of pollens will cause attacks of considerable severity. In the case of the wormwoods (*Artemisias*) a much smaller number is sufficient to produce this effect.

The use of the atmospheric-pollen plates is as necessary in hay-fever as making a blood test in malaria. Its value was recently demonstrated in determining the cause of an outbreak of hay-fever in Austin, Texas. Our atmospheric pollen plates were exposed by Dr. S. N. Key, and sent to our biological laboratory. The ex-

amination of these (Fig. 18) showed that the air contained an average per kiloliter of 88 pollens of the mountain cedar (*Sabina sabinoida*), the biological test of which showed a marked hay-fever reaction. As the cedar has not, heretofore, to our knowledge, been identified with hay-fever, the importance of the atmospheric-pollen plates in such cases was clearly demonstrated.

WIND-POLLINATED PLANTS.

The etiology of hay-fever has been greatly simplified by the knowledge that only atmospheric-pollens are responsible for hay-fever, and that these are generated only by wind-pollinated plants.² This fact, which we have advocated for some years, has been confirmed during the past year by the records of our atmospheric-pollen plates, and by the results of our microscopic examinations of hay-fever secretions.

As bright colors and odors in flowers are intended to attract insects, these are never responsible for true hay-fever. Some of these, such as the goldenrod, sunflower, sneezeweed, etc., have toxic* pollens, but as these are not atmospheric they do not cause hay-fever except on direct inhalation. The wind-pollinated plants are devoid of all attractive colors or scent, and the "flowers" or florescence are often overlooked as such, as is the case of the rag-weeds, cockle burs, amarantids, wormwoods and grasses.

All pollens from anemophilous (wind-pollinated) plants are not responsible for hay-fever, as, for instance, the sedges, rushes, pines, and many other trees. All persons susceptible to hay-fever are not susceptible to the same pollens. Many persons, for instance, suffer during the spring from the grass pollens, and recover when the atmospheric-pollen plates show that these have disappeared. Shortly afterwards, when the rag-weed pollens appear in the air, the majority of these are free of hay-fever, in spite of the fact that the rag-weed pollens usually produce a more severe reaction.

On the other hand, persons susceptible to the rag-weed pollens usually appear to be without discomfort during the spring in spite of large numbers of grass pollens in the air, but quickly develop hay-fever when the rag-weed pollens appear.

In addition to these two forms of hay-fever, we have patients who are susceptible to both grass and rag-weed pollens, and these are the unfortunates who suffer during both periods of hay-fever.

There are also various degrees of reaction among the hay-fever pollens. The most active pollens that we have tested are the wormwoods (*Artemisia*) of the Pacific and Rocky Mountain States. The pollen of the California mugwort (*Artemisia heterophylla*), for instance, will cause a reaction ten times more severe than the

* Toxic in this connection refers to the positive reaction in hay-fever subjects. The existence of true toxins in these pollens is still being investigated.

common rag-weed. Next to the *Artemisias*, we have found the rag-weeds (*Ambrosias*) most active, the pollen of the grasses (*Gramineae*) being less active than the rag-weeds.

There are also many pollens which will produce a hay-fever reaction in susceptible persons only when inhaled in very large numbers or, in lesser numbers, when inhaled by patients already suffering from hay-fever. Among these plants are the chenopods or goose-foot (*Chenopodium anthelminticum*, Fig. 5, album, etc.), careless weeds (*Amaranthus spinosus*, Fig. 6), docks (*Rumex crispus*, Fig. 7, obtusifolius), Western water hemp (*Aenida tamaraseina*, Fig. 8), etc.

These plants cause hay-fever only when growing in sufficient numbers near the patient. If his residence is surrounded by such plants so as to cause a concentration of atmospheric-pollen, he may suffer considerably, but this is not the case when these weeds are at a distance of four or five city blocks. In the case of active pollens, such as the rag-weeds, this distance is not sufficient to protect the patient from their effect.

CLASSIFICATION OF HAY-FEVER PLANTS.

While the prevention of hay-fever by the eradication of the hay-fever weeds is of the highest importance, it will evidently be some time before this becomes sufficiently general to eliminate the question of treatment. While most cases of hay-fever are due to the pollen of noxious weeds, there is also a certain number of cases which are due to plants of practical use, as, for instance, rye and other grains, mountain cedar, etc. In view of this, treatment will probably continue to be an important consideration in hay-fever.

Among the various treatments which have been tried, pollen therapy has, thus far, given the most encouraging results. The number of plants, however, which may cause hay-fever is exceedingly large. Of the *Artemisias*, the most important hay-fever plant of the Pacific and Rocky Mountain States, there are about two hundred varieties. There are about fifteen varieties of rag-weed (*Ambrosias*), and as many of the marsh elders (*Ivas*) and cockle burs (*Xanthiums*), while of the grasses (*Gramineae*), there are several thousand varieties.

If the application of pollen therapy required the use of the extract of the same pollen to which the patient is sensitive, it would make this method clearly impracticable, especially as most patients respond to many different pollens.

We have conducted a careful series of investigations with a view of dividing all the most common hay-fever pollens into groups which should be morphologically alike, and the number of which should be as few as possible, in order to simplify the question of pollen therapy. Thus far, we have succeeded in reducing the number to four groups. Should we succeed in finding a pollen which would morphologically

NOTE. As the photomicrographs have different magnification, the effect is lost unless the scale is stated. This has been corrected to accord with the reduction in the cuts.

represent these four groups, it would still further simplify the application of pollen therapy.

The four groups into which we have divided the hay-fever pollens are the following: Ambrosiaceae, Gramineae, Artemisiae and Chenopodiaceae.

THE AMBROSIACEAE (RAG-WEED) GROUP.

An extended series of tests at our biological laboratory has shown that all the pollens of the Ambrosiaceae family have a marked resemblance both microscopically and in their hay-fever reactions. They vary only in size and they present the same reaction to the Lugol solution. While their hay-fever reaction vary somewhat in the different genera, their similarity in this is quite sufficient to enable us to classify them in a single group.

Principal among the Ambrosiaceae is the common rag-weed (*Ambrosia elatior*, Fig. 2) which is responsible for 85% of fall hay-fever in the Eastern and Southern States. It is spiculated and measures 15 microns in diameter. The giant rag-weed (*Ambrosia trifida*, Fig. 9), which replaces the common rag-weed in moist sections, and which, in the general appearance of the plant has not the slightest resemblance to the common rag-weed, has a pollen with the same hay-fever reaction and microscopically differing only in size (20 microns.) The Western rag-weed (*Ambrosia psilostachya*, Fig. 10) also has the same hay-fever reaction, and the pollen is similar except in its size (25 microns).

The Gaertneria, sometimes called "false rag-weed," also belongs to the Ambrosiaceae family. The pollen gives a hay-fever reaction similar to the common rag-weed, and the pollen resembles them so much (Fig. 11) that they are difficult to distinguish microscopically.

The marsh elder (*Ivas*) is also a genus of the Ambrosiaceae family, and gives a reaction similar to the rag-weeds, but less marked. The extract requires 20% more strength to produce a hay-fever reaction similar to that of the rag-weeds. The spicules also are less prominent but more numerous (Fig. 12). They equal the Ambrosias in the amount of pollen generated. The principal varieties in the Eastern and Southern States is the rough marsh elder (*Iva ciliata*), but this is not sufficiently common to be of great importance, except in certain moist localities. In the Pacific and Rocky Mountain States, however, we have found the small-flowered marsh elder (*Iva ciliata*) and burweed marsh elder (*Iva xanthiifolia*) important factors in hay-fever.

The cockle bur (*Xanthium*) also belongs to this family and resembles the other species in the microscopic appearance and biological reaction. The spicules, however, are even less prominent than in the *Ivas* and more numerous (Fig. 13). The reaction is also less marked, being about 70% of the strength of the rag-weed reactions.

This resemblance in the Ambrosiaceae family in their biological reaction is very important from a therapeutic standpoint. Our tests have shown that the large majority of persons susceptible to one member of the group is susceptible also to the other members, so that all of the Ambrosiaceae family can morphologically be classified into a single group. As these form the principal cause of fall hay-fever in the Eastern and Southern States, the practical application of this greatly simplifies the subject of pollen-therapy.

THE GRAMINEAE (GRASS) GROUP.

In the gramineae (grass) family we have also a similarity of reaction. As there are altogether nearly 5000 species of grasses, this is fortunate from the standpoint of pollen-therapy. In practically all the cases which we have tested, subjects sensitive to grass pollens are also sensitive to other members of the group. The pollens of all the grasses are relatively large (30 to 80 microns), spherical and are stained blue-black by Lugol solution on account of their high proportion of starch.

The varieties of grasses vary greatly in different localities, but their reaction varies only in degree. This includes also the cereals, such as corn, rye, wheat and oats. The pollens of these, however, are relatively large (corn, 80 microns, Fig. 14; wheat, Fig. 15, and rye, 40 microns) so that they are not responsible for hay-fever except within limited areas. The grasses with small pollen, such as Bermuda grass (*Capriola dactylon*), June grass (*Poa annua*, Fig. 1) are responsible for more cases than the grass with large pollen, such as foxtail grass (*Chaetochloa glauca*), bull grass (*Paspalum dilatatum*), cocksbur grass (*Panicum erus galli*, Fig. 16), etc., on account of their greater buoyancy, which enables them to traverse a large territory.

THE ARTEMISIA GROUP.

The wormwoods (*Artemisiae*) also bear a marked resemblance to one another in their microscopic appearance* and chemical and biological reactions. The three-lobed form is characteristic of all the *Artemisiae* which we have examined, viz.: mugwort (*Artemisia heterophylla*, Fig. 3), wormwood sage (*Artemisia frigida*), sagebrush (*Artemisia tridentata*, Fig. 17), absinth wormwood (*Artemisia absinthium*), dark-leaved mugwort (*Artemisia ludoviciana*), biennial wormwood (*Artemisia biennis*), California old man (*Artemisia californica*), Indian hair tonic (*Artemisia dracunculoides*), and bud-brush (*Artemisia spinescens*). The wormwoods (*Artemisiae*) are the most important hay-fever plants of the Pacific and Rocky Mountain States, and the hay-fever reaction of all the varieties which we have examined is marked, being ten

times more active than that of the rag-weeds (*Ambrosiae*).

THE CHENOPODIACEAE GROUP.

Among the plants which rank next to the *Ambrosiaceae*, *Artemisiae* and *Gramineae* are the members of the *amaranthaceae*, *chenopodiaceae* and *Rumex* families, which are both numerous in their varieties and general in their geographical distribution, over 50 of each having been described, most of them being typical hay-fever weeds and wind-pollinated.

The members of the *amaranthaceae*, *chenopodiaceae* and *rumex* generate pollens which are smooth and spherical, and having a general resemblance to one another. They also have a similar reaction to the Lugol solution, indicating a low percentage of starch. All the varieties tested give a mild hay-fever reaction and, with few exceptions, persons susceptible to one species react also to other members of the group.

The *chenopodiaceae* are a large family which includes, in addition to the true *chenopods*, several other varieties, such as the orache (*Atriplex*), the grease-weeds (*Sarcobatus*) and saltwort (*Salsola*). They all give a similar mild hay-fever reaction.

The branch of the *Amaranthaceae* family which has several members of interest in hay-fever is the *Aenida* or water-hemp. Some of these, as the Western water-hemp (*Aenida tamarascina*), generate a large amount of pollen. Most of these are limited to swamps and moist land. The reaction is similar to that of the *Amaranthus*, *Rumex* and *Chenopodium*, which they also resemble in the general appearance of the pollen.

While the members of this group give a mild hay-fever reaction, they are sometimes of importance by causing hay-fever at seasons when the grasses (*Gramineae*), rag-weeds (*Ambrosiae*) and wormwoods (*Artemisiae*) are not pollinating.

The similarity of the *Amaranthus*, *Chenopodia*, water-hemp and docks, both as regards the character of the hay-fever reaction and the individual susceptibility to these pollens, demonstrates a similarity in their toxic principle. The indications are, therefore, that a pollen extract of any of these pollens will be applicable to all the members of this group.

In addition to the members of these groups, there are local and special cases of hay-fever due to the pollen of plants not included in these. This is the case with the Western cottonwood (*Populus sargentii*), to which a number of persons are susceptible. Another is the pollen of the mountain cedar (*Sabina sabinoides*) found in certain parts of Texas. These pollens, for instance, bear no resemblance in their appearance, chemical or biologic reaction, or individual susceptibility. Such cases of hay-fever must, for the present, be given individual consideration.

* The only exception is the *Artemisia biennis* which has spiculated pollens but otherwise is similar in appearance and reaction.

The four groups which we have described, however, include most of the pollens that are responsible for hay-fever. As this investigation has been carefully conducted, we believe that it will not only simplify the subject of pollen-therapy, but also place it on a more scientific basis.

SUMMARY.

(1) The efficacy of pollen-therapy requires accuracy as regards the pollen to which the patient is sensitive.

(2) The test of a hay-fever subject should be directed to the pollens to which he is exposed.

(3) The atmospheric-pollen plates give definite information regarding atmospheric pollen in any locality, and should be used before testing the hay-fever reaction or applying pollen-therapy.

(4) While there are hundreds of varieties of hay-fever plants, carefully conducted tests have shown that the majority of these may morphologically be divided into four groups, the members of which are sufficiently alike in their chemical and biological reaction to warrant the same pollen-therapy.

SOME NOTES ON ARTIFICIAL PNEUMOTHORAX.*

BY PAUL H. RINGER, A.B., M.D., ASHEVILLE, N.C.

IN the course of this brief paper it is my purpose to avoid the stereotyped questions of indications for the induction of artificial pneumothorax and details of technic in its administration, and to devote my attention to stressing a few points that have impressed me in the course of four and a half years of constant use of the procedure.

Quantity of Gas to be Injected.

In the early days of my use of this method the temptation was almost irresistible, both at the first and at subsequent injections, to allow as much gas to flow in as the patient could tolerate; depending, as an indication for stopping the flow, upon marked positive manometric readings and upon the patient's statements of feeling "full" and dyspnoeic. Experience has shown the fallacy of this procedure. Now, more than 300 cc. are never injected at the first sitting (save when the gas is administered for stopping hemorrhage), no matter what the manometric readings may be, and at subsequent injections the gas is cut off when the water manometer shows a mean reading of zero, or, at most, plus 1 or 2 cm. This conservatism necessitates a few more injections per patient, but the displacement of the thoracic contents comes about far more gradually, and subjective and objective signs of discomfort and oppression are far less marked. Subcutaneous emphysema is also less frequent, and quiescent processes in the uncollapsed side are less apt to be awakened into renewed activity, as the strain is thrown more gradually upon the sound lung. Thus, from the standpoint of the patient's comfort, as well as from that of his welfare, I am convinced that conservatism with regard to the amount injected is most important.

meter shows a mean reading of zero, or, at most, plus 1 or 2 cm. This conservatism necessitates a few more injections per patient, but the displacement of the thoracic contents comes about far more gradually, and subjective and objective signs of discomfort and oppression are far less marked. Subcutaneous emphysema is also less frequent, and quiescent processes in the uncollapsed side are less apt to be awakened into renewed activity, as the strain is thrown more gradually upon the sound lung. Thus, from the standpoint of the patient's comfort, as well as from that of his welfare, I am convinced that conservatism with regard to the amount injected is most important.

These considerations must be disregarded when the gas is injected to compress the lung for the checking of profuse hemorrhage. Here an emergency is present and chances must be taken. I have injected as much as 1000 cc. at once to control bleeding. The brilliant results that I have obtained in bleeding cases have imbued me with great confidence in artificial pneumothorax as a hemostatic. The sudden strain thrown upon the opposite side is not necessarily damaging, for compression is to be maintained only for a length of time sufficient to permit of the formation of a firm clot at the site of bleeding—prompt and firm compression for from seven to fifteen days is necessary. Then no more gas is given and the compressed lung soon re-expands, for at that time absorption of gas is relatively rapid and pulmonary elasticity as yet unimpaired.

Pleural Effusions.

The question of the occurrence and management of pleural effusions on the compressed side is one that is the subject of much controversy. In my experience fluid has appeared in about 50% of the cases where collapse has been obtained. In some of these cases but an ounce or two of the fluid has been visible in the costophrenic sinns by means of the fluoroscope; in some the effusion has reached to the clavicle. At first sight it would seem that the appearance of fluid should be of benefit. The fluid does quite as well as the gas in holding the lung collapsed, its presence lessens the frequency of gas injections, and if there be enough, does away with them entirely. But the other side of the question must be considered. First, as regards the patient's comfort: many are greatly annoyed by the sloshing about of a quart or more of free fluid in the pleural cavity, the noise and mobilization of weight being noticed at every shifting of position. Some find the fluid very heavy, and so it often is—(in one case I removed six and one-half pounds of fluid from the right chest)—in left sided cases the weight of the fluid pressing upon the subjacent stomach causes distressing and intractable digestive disturbances. Second, as regards the patient's welfare: Were we sure that the fluid present

* Read before the Buncombe County Medical Society at Asheville, N. C., 1916.

would always remain wholly liquid and therefore be under control (*i. e.*, capable of removal at any time), the discomforts of the patient, if not too great, might be disregarded because of the obvious aid on the part of the fluid in maintaining a collapse. Unfortunately, the fluid remaining in the pleural cavity for many months not infrequently undergoes a change in consistency. It becomes thick and finally gelatinous. As soon as it has lost its limpidity we are, of course, powerless to remove it. Hence, the collapsed lung is beyond control. The gelatinous mass that sometimes results may, in time, become reabsorbed, but a great mass of thick, inelastic tissue between lung and parietal pleura remains, inhibiting the collapsed lung from any marked degree of expansion. Quite apart from the eventual desirability of allowing the collapsed lung to re-expand, it may at any moment become imperative to remove the compressing force because of renewed activity on the opposite side, and this necessity may arise even after the collapse has been maintained for over a year. In the presence of thick fluid or a gelatinous deposit, evacuation is impossible. Hence, I have made it a practice to remove promptly any considerable accumulation of fluid (by that I mean any amount reaching the 4th rib) and substituting gas for it either at the time the fluid is withdrawn or shortly afterwards. The fluid may re-collect in the pleural space. If this occurs, paracentesis is again performed. It may be necessary to tap even a third time. If after this, the fluid still re-collects, I keep the patient under weekly fluoroscopic examinations in order to demonstrate the limpidity of the fluid or to discover any signs of its becoming thickened, and tap from time to time, usually when the fluid reaches or over-tops the fourth rib.

Air Embolism.

The great danger at the initial injection of gas is that of air embolism. This occurrence is rare, but its great fatality makes it ever dreaded. In initial injections performed by myself in some fifty-five cases and witnessed in more than one hundred additional cases, I have not yet seen this phenomenon; despite this, I never approach a new case without the thought and dread of this occurrence. Air embolism may be brought about without any gas having been injected. When the needle is inserted, it may be pushed too far in and puncture the lung, tearing one of the vessels in the walls of the air alveoli, or going through the wall of a known or unsuspected cavity. Under such conditions, the laceration may be so situated that with each inspiration air from the lung is aspirated into the pulmonary vessels, air embolism resulting. This is by no means a fanciful theory, as deaths have been reported from air embolism and this mechanism of its causation demonstrated at necropsy. Avoidance, or at any rate lessening, of this danger can be brought about, first, by

having the field of operation the highest point of the chest; thus, if the mid-axillary region be chosen, a pillow or sand bag placed beneath the patient in such a manner as to make the field of operation convex, will serve the purpose; second, by inserting the needle very slowly and steadily through the chest wall until it is thought that the pleura is reached, and by not inserting the needle at a greater depth than 3 or 4 cm., though in patients with very thick chest walls this latter rule must be disregarded. Saugmann, of Denmark, is very insistent upon not inserting the needle too deeply, and uses a needle with an adjustable washer, or shoulder, which he fixes at 3 cm. from the point, so convinced is he that the distance from skin to pleura is never more. I have not used this type of needle.

Gas Pockets.

It is often possible to obtain only small pockets of gas varying in size from 50 cc. to 200 cc. each. All authorities advise continuing injections in these cases in the hope that the limiting adhesions will give way, the pockets coalesce and a collapse be obtained. In accordance with these precepts I have kept patiently at work, but my results have been disappointing, and I feel very dubious about ever getting a really satisfactory collapse unless from the start gas flows in with comparative ease. Not infrequently, fine, fresh, exquisitely painful adhesions are encountered that yield easily. In such cases success may come. But in those cases where typical pockets form, failure has been my lot.

Partial Collapse.

A word must be said relative to partial collapse. While, of course, brilliant results are to be obtained only from total collapse, yet partial collapse must not be looked at askance, as it is often the means of prolonging life, relieving symptoms and rendering the patient infinitely more comfortable. In cases where partial collapse, alone, is obtainable, it usually happens that the walls of cavities are not closely coapted, and consequently secretion from these walls continues. Hence, symptoms of cough and expectation will not wholly subside, a certain amount of absorption of toxic material will always take place, and gas injections in such cases must be indefinitely continued.

Duration of Collapse.

Duration of collapse in cases where a complete result has been obtained should be from eighteen to thirty-six months, preferably the latter. I am a great advocate of "let well enough alone," and when a case is wholly collapsed, the sound side standing the added strain well, no fluid present, and the patient practically free from symptoms, I am loath to advocate re-expansion under three years or more. We may think healing has taken place: we do not know.

Moreover, in the majority of cases when the pleural layers are again allowed to coapt, they adhere once and for all, the gas having acted in the nature of an irritant to the membrane, and further injections of gas are out of the question. This is not invariably the case, for Dr. James A. Miller, of New York, told me of two cases of his that had been allowed wholly to re-expand and with whom he had subsequently been able to resume gas. Such patients are, however, the exception.

A word or two as to the personal opinion of the writer on the question of artificial pneumothorax. I think I may characterize myself as a conservative enthusiast with regard to artificial pneumothorax, save in those cases where gas is administered for the control of hemorrhage, when I become an unreserved enthusiast. I know of no result in tuberculo-therapy more brilliant than the change wrought by the successful induction of pneumothorax. The return to health and the subsidence of symptoms are sometimes so rapid as to be almost uncanny. But again there is the other side of the picture. We see few bluer and more despondent patients than those upon whom pneumothorax has been tried without success. They feel that the last straw has snapped, and alas! in the vast majority of cases they are right. The method is usually tried on advanced cases or in those in whom there is going on a rapid dissemination from a relatively small primary focus. If collapse fails, we are left face to face with prolonged bed-rest, etc., all of which has probably already been resorted to before pneumothorax was attempted. Again, there are no sadder pictures than are presented by those unfortunates in whom pneumothorax has worked wonders and in whom those wonders fade away before our eyes with the awakening to activity of a previously quiescent focus in the good side. We take out the gas—the focus may quiet down—but the last condition is never as good as the first, and more often the patient goes steadily down hill. Judgment and more judgment is needed in the selection of cases. But few there are that will be wholly unilateral. Then the question presents itself, will the relatively sound lung hold? Some we know will not—that settles it—but the borderline case is hard indeed to decide. Experience, small injections and frequent and repeated stethoscopic examinations of the sound side are necessary to reach a satisfactory conclusion.

While the preceding paragraphs may sound skeptical and possibly pessimistic, it is not the intention of the writer to convey that impression, but merely to stress the point that, despite the wonders wrought in certain cases by the use of this method, the way is fraught with danger and many and many a time failure will be our lot. I do feel, however, that the induction of artificial pneumothorax in the treatment of pulmonary tuberculosis is a procedure that should be at the command of every man dealing largely

in pulmonary affections. In an analysis of thirty cases of my own recently reported before the North Carolina Medical Society I was able to report success in 23 per cent. and adding thereto three successful injections for hemorrhage, a total of 33 per cent. was attained. Surely this is enough, and far less than this should be enough, to warrant the use of the method which is, as far as I know, the only procedure at our command by which we can offer, to a certain number of advanced cases, a one-in-three chance of a return to health and working efficiency.

In conclusion, I would express my thanks to my friend and colleague, Dr. Charles L. Minor, of Asheville, for his great kindness and courtesy in allowing me the free and constant use of his excellent fluoroscopic apparatus, enabling me thus to keep my patients under far better observation than I should otherwise have been able to do.

Clinical Department.

A CASE OF PERNICIOUS ANEMIA IN A SYPHILITIC TREATED WITH SAL-VARSAN.*

By LAWSON G. LOWREY, A.M., M.D., BOSTON,

*Assistant in Neuropathology, Harvard Medical School,
Pathologist to Danvers State Hospital.*

PERNICIOUS anemia as a cause of mental disturbance is uncommon, at least in this hospital, forming only a small fraction of a per cent. of the admissions. The psychosis is usually in the form of a depression.

This case is, therefore, unusual in the form of the psychosis. In addition, there was an interesting diagnostic problem, and finally, the man had been treated with salvarsan within a few months prior to the development of the anemia.

It is not my intention to present a study of the cerebral pathology as such; that is reserved for use in another connection.

Male, age 37, admitted to Danvers October 27, 1914. Born in Germany, 1877. Family history not remarkable. "Spinal trouble" as a baby. Operated for inguinal hernia, 1896. Otherwise well. Meagre education. Has worked as cooper, tinsmith and baker, which occupation he has pursued for some years. In his youth well liked, jovial, easy going. Intoxicated three or four times a year for many years, increasing of late.

At 20 a chancre, with treatment "for some time." For five years past treated for chronic nephritis. In July, 1913, went to the Massachusetts General Hospital complaining of feeling weak, headaches and abdominal distress. Wassermann reaction blood serum strongly positive. X-ray of abdomen

* A contribution to the William Leonard Worcester Series of Danvers State Hospital Papers, presented November 19, 1915.

gave a picture diagnosed as adhesions in right upper quadrant, involving stomach and hepatic flexure. In August and September he was given four doses of .3 gm. salvarsan. In October, condition good. In November, complained of cough. X-ray diagnosis, phthisis with calcification. Physical; lungs negative. In June, 1914, Wassermann reaction blood serum positive. June and July, 2 doses salvarsan.

For ten years migraine attacks, increased in severity and frequency of late. Married in 1906. No children. No miscarriages. For about four years very nervous, aggressive, irritable, violent temper. For three years unable to work steadily, and for 17 months, no work. Wife twice left him in this period because of his attitude toward her. For the past year practically always in a fighting mood. Twice arrested for fighting and drunkenness. Two weeks before commitment, secreted a knife under his bed clothing. About this time delusions became prominent. Thought he was dying. Wanted to become a Catholic so could claim his wife in the next world. Prayed much. One night said to his wife, who was lying quietly in bed, "Why are you dancing, and why is the house shaking?" Complained of white pigeons hanging over him.

The next night he became violent, leaped through the glass in a door and ran amuck on the streets in his night clothes, with a milk bottle as a weapon. Taken by the police to a general hospital, he was committed here three days later.

Here he was constantly restless, talkative and noisy; disoriented in all spheres; hallucinated and deluded. He had visual and auditory hallucinations. Thought he had been murdered, his body sawed in two in the median line. Then thought he was a Jewish rabbi in a Jewish church. Thought they were making a rocking-chair out of his body. Much of his conversation was incoherent. Afraid of being poisoned. Thought his eyes had come out of his body. Marked impairment of memory. Sense of choking.

Physical examination:—An emaciated man with yellow skin (not jaundice). Heart enlarged; all sounds feeble. A presystolic murmur at the apex transmitted upward. Liver dullness extended three fingers below costal border. Liver not felt. Spleen not enlarged. Penile scar. Pupils equal, react sluggishly to light and accommodation. Slight edema of feet. Knee jerks increased. Shuffling gait. Positive Romberg. Suggestion of Babinski. Stereognostic sense unimpaired. Tactile appreciation normal.

Wassermann on blood serum negative; spinal fluid negative; albumen normal; globulin negative; cells 3; gold 00000 00000. Blood examination; hemoglobin 40%; red cells 680,000; white cells 7600. Eosinophiles 0.6%; polynuclear 66.6%; mononuclear 32.6%. Normoblasts and macrocytes were observed. There was poikilocytosis and polychromatophilia. Hemoglobin 35%; red cells 500,000; white cells 6500.

As he failed he became quieter. Diagnosis, November 12, 1914: At first thought to be paresis, and some thought so even with the normal fluid. Others, psychosis associated with pernicious anemia.

Autopsy No. 1773—Two hours post-mortem. Summary of the autopsy findings: skin yellow; inguinal adenitis; pupils equal, dilated; fat, deep yellow; adhesive pleuritis, right and left; blood fluid, very light red color; hypertrophy and dilatation of heart; mitral stenosis; aortic valve fibrosis;

"tiger lily" heart; active and healed (calcified) tuberculosis, both lungs; fatty kidneys, fibrosis; fatty liver.

Head:—Scalp not remarkable. Calvarium thickened in occipital region. Wide line of diploë. Dura thickened, silvery white, not adherent. The pia is very slightly thickened. Basal vessels not sclerotic. Brain wt. 1275 g. Pons and cerebellum, 160 g. Cerebellum firm. Floor of 4th ventricle smooth. Brain somewhat soft with "sticky" feel. Frontal atrophy. Brain very pale. Pia adherent.

With the exception of the slight changes in the pia, there is nothing in the gross brain findings to indicate paresis. Microscopic examination. Heart, kidneys, liver and adrenals show very marked fatty changes. There is a sub-acute tubular nephritis. The lungs show active and healed tuberculosis. A peribronchial lymph node also shows a cellular tubercle. Hypophysis, slight connective tissue increase in anterior lobe.

Nervous system: Ten areas of cortex, 2 of the cerebellum, 1 of the medulla and 3 of the cord show none of the classical findings of paresis. There is slight fibrous thickening of the leptomeninges. At one point between the cerebellar folia is a single small collection of round cells. Judging by the appearances in surrounding areas, these cells are migrated glia cells.

There are no degenerations by the Marchi and Weigert methods.

The most important diagnostic question involved here was whether or not the man was a parietic. Obviously, from the description, he was not.

However, there are other important points. Salvarsan has been used in the treatment of anemia, apparently without untoward effects. In this case pernicious anemia developed some time after treatment with salvarsan. Whether this relation is purely incidental is uncertain, although it probably is, in view of the large number of persons who have been treated with salvarsan.

Book Review.

Diseases of Children. A Manual for Students and Practitioners. By GEORGE M. TUTTLE, M.D., Clinical Professor of Pediatrics, Washington University Medical School, and PHELPS G. HURFORD, M.D., Pediatrician, St. Louis Lutheran Hospital. Third edition, thoroughly revised and enlarged. Illustrated with 47 engravings and 3 plates. Philadelphia and New York: Lea and Febiger. 1917.

This book, now in its third edition, is midway in size between the quizzic compend and the ordinary text-book. It is necessarily superficial, but on the whole little objection can be taken to the contents. It is hard to see, however, why anyone should care to use this book when there are so many fuller and better text-books available. The only place we see for it is among the students of the Washington University Medical School, at which the authors are instructors.

THE BOSTON Medical and Surgical Journal

Established in 1812

An independently owned Journal of Medicine and Surgery published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, JULY 12, 1917

EDITORS.

ROBERT M. GREEN, M.D., *Editor-in-Chief*,
GEORGE G. SMITH, M.D., *Assistant Editor*,
WALTER L. BURRAGE, M.D., *For the Massachusetts Medical Society*.

COMMITTEE OF CONSULTING EDITORS.

WALTER B. CANNON, M.D. ROGER I. LEE, M.D.,
HARVEY CUSHING, M.D. ALLAN J. McLAUGHLIN, M.D.,
DAVID L. EDSALL, M.D. ROBERT B. OSGOOD, M.D.,
REID HUNT, M.D. MILTON J. ROSENAU, M.D.,

ADVISORY COMMITTEE.

EDWARD C. STREETER, M.D., *Boston, Chairman*,
WALTER P. BOWERS, M.D., *Clinton*,
HOMER GAGE, M.D., *Worcester*,
JOEL E. GOLDTHWAIT, M.D., *Boston*,
LYMAN A. JONES, M.D., *North Adams*,
ROBERT B. OSGOOD, M.D., *Boston*,
HUGH WILLIAMS, M.D., *Boston*,
ALFRED WORCESTER, M.D., *Waltham*.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.50 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager*,

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

VOLUNTEERS FOR THE MEDICAL CORPS.

IN times of war, when untold sacrifice is demanded of many people, and all people feel, through one means or another, the unrelenting imposition of unusual and necessary demands upon them, the medical profession, trained as it is to instant response to other men's needs, should find itself a leader in volunteering to patriotic service. In the matter of enlistment in the Medical Corps, however, this has not proved the case. The medical departments of the Government, organized for peace conditions, must enormously increase their capacity before they will be able to cope with the military situation brought about by the present war. Their func-

tion in the army is to do three things,—examine recruits, look after the hygiene of the camp and care for the wounded. To do these things adequately for the army soon to be in training will require from 10,000 to 12,000 physicians, and the number of men enrolled is far below this requirement. The surgeons-general have not as yet been given full authority and means whereby to enter upon their duties, and until the ranks of the departments are filled, the authority and means can be of little use. The service is recruited solely by volunteers, and with the President ready to confer authority and Congress ready to provide the means, there is lacking only the spirit of service among the profession.

It is to the younger physicians that the appeal is principally directed. Men who graduate at this time can enter the Medical Corps directly. Men who have graduated and have had one year's hospital training and are younger than 32 years of age, can enter the Medical Corps of the Army. For the Medical Reserve Corps or the new Officers' Reserve Corps, there is need of men who have graduated in the last five years, especially those who have had hospital experience. The older men of the profession can do much toward encouraging and stimulating the young men, more especially those not yet firmly anchored by family ties, promptly to enlist in the Reserve Corps; or if their education and training have been sufficiently broad, they may join the regular Army or Navy. It is unquestionably true that the advantages offered by the Medical Department of the Army and Navy, both for patriotic service and for rapid promotion, have not been before, and will not soon again, be paralleled.

In another column of this issue of the JOURNAL we publish further information issued by the United States War Department regarding appointment in the Medical Reserve Corps of the United States Army. We publish also the personnel of the examining boards for the Medical Reserve Corps in New England and New York. Physicians intending to join the Reserve Corps may obtain the necessary blanks by writing to the surgeon-general of the United States Army at Washington; and when the applications have been made out, should forward them to the nearest chairman of the examining boards, who will make appointment for the applicant to appear for the examination.

AMERICAN OCCUPATION OF BRITISH FIELD HOSPITALS.

AFTER being royally welcomed and entertained by the enthusiastic English, the American hospital units for foreign service crossed the Channel and quietly took possession of six of the British field hospitals in France, thereby releasing the British staffs for duty near their fronts. The hospitals have been located on carefully selected sites and have been developed and perfected to a high degree of efficiency in their three years of existence. Some of the hospitals are made up of tented wards, accommodating forty to sixty beds each; others are constructed of a series of huts, and operating theatres lack nothing in the way of modern surgical equipment. Originally planned for 1040 beds each, most of the hospitals can care for 1400 beds in an emergency, and some have accommodated 2000 patients in a crisis.

The first of the American units to reach France was known as United States Base Hospital No. 4, and was organized in Cleveland by Dr. George W. Crile, with Major Gilchrist of the United States Army as commanding officer. This unit has taken over British General Hospital No. 9, "somewhere in France." United States Base Hospital No. 5, organized at Harvard University by Dr. Harvey Cushing, with Major R. U. Patterson as commanding officer, has taken over British General Hospital No. 11; United States Base Hospital No. 2 from the Presbyterian Hospital, New York, organized by Dr. George Brewer, with Major Lucius P. Hopewood commanding, has taken over British General Hospital No. 1; United States Base Hospital No. 21, organized in St. Louis by Dr. Frederick Murphy, with Major James D. Fife commanding, has taken over British General Hospital No. 12; United States Base Hospital No. 10, organized in Philadelphia, largely in the University of Pennsylvania, by Dr. Richard Harte, with Major M. A. Delaney commanding, has taken over British General Hospital No. 16; United States Base Hospital No. 12, organized in Chicago by Dr. Frederick Besley, with Major C. C. Collins commanding, has taken over British General Hospital No. 18, all of course being "somewhere in France." To these may be added the Harvard Unit, which for over a year has been in charge of British General Hospital No. 22.

Each unit has an organizing director who was a surgeon in civil practice but now takes command as a major in the United States Reserve. The commanding officer in each unit is a regular American Army surgeon while the subordinate members of the staffs are made up of Regular Army surgeons and doctors commis-

sioned from civil life. The nurses are all graduates from well-known training schools and the non-commissioned orderlies and privates were practically all taken from civil life. Each American hospital staff has also organized a mobile unit for service in the casualty clearing stations, just back of the firing lines, for emergency work during the first days of great battles.

WELCOME TO AMERICAN DOCTORS.

THE JOURNAL has received a letter from J. Y. W. MacAlister, secretary of the Royal Society of Medicine, inviting most cordially all American doctors who are passing through London to make use of the Society's rooms in Cavendish Square. This is in further expression of the hearty welcome which is waiting for American doctors who are crossing the ocean to help in the war. Dr. MacAlister's letter reads further as follows:

"During their stay on this side we offer them all the privileges of Fellowship gratuitously. We have the finest medical library in this country, and many comforts in the house which make it almost a Club, and nothing would please us better than to see it crowded with our American friends. I have communicated this to some of the leading doctors who have already arrived and gone to France."

Further invitation is extended to attend the meetings which are held for reading of papers, clinical demonstrations and for discussions.

A CANCER DECALOGUE.

IN another column of this issue of the JOURNAL (page 62) is published the "cancer decalogue," prepared by the standing committee on the control of cancer of the Massachusetts Medical Society. The attention of members of the Society and of all other physicians is directed to this important statement, whose publication in the JOURNAL will be repeated monthly, by request of the committee.

MEDICAL NOTES.

FOURTH OF JULY PREPAREDNESS.—In 1903, 415 persons in the United States developed lock-jaw (tetanus) following Fourth of July pistol and firecracker wounds. In 1908 there were 76 such cases with 55 deaths, and last year, so far as we can learn, there was only one case of lock-jaw due to this cause. Two factors have led to this gratifying decrease in this unnecessary loss of life, namely, safe and sane celebration of Independence Day, and the prompt use of tetanus antitoxin.

The antitoxin, while almost infallible as a preventive of lock-jaw, has had but little value, as ordinarily used, in fully developed cases. Inasmuch as the disease so often follows Fourth of July pistol and firecracker wounds, it is of the utmost importance to have tetanus antitoxin injected promptly after the injury.

The New York Department of Health has for some years supplied tetanus antitoxin free of charge, and on request will even send a trained physician to inject the remedy. Not a single case of lock-jaw has occurred in any of the cases promptly injected.

The attention of physician readers is again called to the treatment of developed cases of tetanus by means of spinal injections of tetanus antitoxin.

The prevalence of Fourth of July tetanus in the United States is shown in the following table:

1903	415 cases		
1904	105 cases		
1905	104 cases of which	87 died	
1906	89 cases of which	62 died,	10 in New York City
1907	73 cases of which	62 died,	5 in New York City
1908	76 cases of which	55 died,	6 in New York City
1909	150 cases of which	126 died,	7 in New York City
1910	72 cases of which	67 died,	4 in New York City
1911	18 cases of which	10 died,	3 in New York City
1912	7 cases of which	6 died,	2 in New York City
1913	4 cases of which	3 died,	2 in New York City
1914	6 cases of which	6 died,	3 in New York City
1915	4 cases of which	4 died,	3 in New York City
1916	1 case of which	1 died,	1 in New York City

PREVALENCE OF DISEASES IN THE UNITED STATES.—The weekly report of the United States Public Health Service for June 22, 1917, states that during the month of May there were forty-three cases of cerebro-spinal meningitis in Maryland, twenty-four in Wisconsin and twenty-four in Massachusetts. During the same period there were in Massachusetts nine cases of poliomyelitis, and seventy of typhoid fever. There were eighty-one cases of typhoid fever in Maryland and eighty-three in West Virginia. There were 158 cases of smallpox in Wisconsin.

The number of poliomyelitis cases in the United States reported thus far this year is exceptionally low. The total number reported in the entire country for the month of May was only nineteen. Massachusetts led with nine cases. During the first week in June there were six deaths, two in Massachusetts, three in New York and one in New Jersey. Three cases were reported from Ohio, three from New Jersey and one each from New Hampshire, Wisconsin and Missouri.

DECREASE IN MORTALITY FROM PELLAGRA IN 1916.—The experience of the Metropolitan Life Insurance Company, which has a large number of policy-holders in the section of the country where pellagra prevails, contains sidelights on the progress of this disease during recent years.

In recent years pellagra has very rapidly in-

creased in importance as a cause of death. In 1911, the number of deaths in the company's experience was only 277; in 1915 this number had increased to 650. During this period the rate had increased from 3.6 per hundred thousand exposed persons, to 6.7. In 1916 the number of deaths dropped to 368, and the rate to 3.6 per 100,000, exactly the same as in 1911.

The insurance company's statistics make possible a number of interesting deductions with reference to the characteristics of this disease. The very remarkable drop in the rate in 1916 appears to bear out the tentative conclusions of the Government experts who are now studying pellagra, namely, that the disease is not of infectious origin but is probably one of the so-called "deficiency" diseases induced by insufficient, poorly balanced dietaries. The year 1914 and the first half of 1915 were periods of depression in the cotton belt and this was reflected by higher pellagra rates. In the latter part of 1915, and in all of 1916, prosperity prevailed, and the industrial and agricultural communities of the South enjoyed a more abundant and varied ration. Future observation and experiment by Government authorities will probably definitely determine whether this explanation of the declining death rate of the disease is entirely satisfactory.

The disease is much more prevalent among the colored people than among the whites, and is much more frequent among females than among males. Thus, in the five-year period, 1911-1915, the rate among colored females was highest, 20.3 per 100,000; among the colored males it was 6.4; among the white females, 4.2; and among white males, the least of all, 1.7 per 100,000. It would be very interesting to learn why females in this country have, approximately, three times the pellagra mortality rate of males. Another interesting fact is that the incidence of the disease increases with age. There is no exception to this fact up to age 65. After 65, the rate remains fairly stationary.

Early reports for 1916 which have come from the health authorities of certain of the Southern states are in general agreement with the encouraging insurance figures referred to above. There is in effect good indication that the measures instituted by the U. S. Public Health Service, and the hypothesis upon which their work has been planned, are sound, and we may confidently expect that this comparatively new scourge will soon be under control.

WAR NOTES.

PREVENTION OF TUBERCULOSIS IN THE ARMY.—It is announced that Col. George E. Bushnell, commandant of the General Hospital, Fort Bayard, N. M., which is the government hospital for the care of tuberculous soldiers, has been ordered to Washington to institute measures designed to safeguard American troops against

contracting tuberculosis. Colonel Bushnell was born in Massachusetts in 1853, graduated from Yale in 1876 and Yale Medical School in 1880. He served through the Spanish War as a major chief surgeon and received his commission as colonel in 1911.

EMERGENCY HOSPITALS.—President Wilson has sent to Congress a recommendation by Secretary Daniels for an appropriation of \$2,200,000 to be used in building emergency hospitals. Temporary hospitals are nearing completion at Portsmouth, N. H., Philadelphia, Newport, Norfolk, Charleston, Pensacola and New Orleans and plans have been made for the erection of similar hospitals at New York, Annapolis, Jamestown, Quantico, Va., Key West, the Great Lakes, Mare Island and Puget Sound.

A DRAFT FOR ARMY DOCTORS.—The New York Committee for National Defense, in a report to the central council at Washington, has urged a system of drafting doctors for the medical corps of the Army. The failure to obtain, through volunteering, anywhere near the necessary number of surgeons, has resulted in an effort on the part of the Committee to urge a selective draft of all available physicians. The Committee states that of the 140,000 doctors in the United States, less than one-half are available and desirable for military purposes, and that the policy of allotting or urging physicians to volunteer indiscriminately in the great numbers needed as medical officers for the war, is sure to result in confusion, waste and failure. The draft, based upon special classification by census, would accomplish the desired result by bringing into the army those best fitted for its uses and by leaving at home the physicians needed by the community.

RE-EDUCATION OF CRIPPLED SOLDIERS.—A conference of ten representative physicians has laid before the Council of National Defense recommendations for the establishment of a system of re-education and rehabilitation for men who may be maimed or crippled in the war. The physicians who framed the report are Drs. James Bordley, Jr., Baltimore (ophthalmology); John Staige Davis, Baltimore (plastic surgery); C. R. Dooley, Pittsburgh (vocational education); S. I. Franz, Washington (neurophysiology); F. B. Gilbreth, Providence (management engineer); R. W. Lovett, Boston (orthopedic surgery); Harris P. Mosher, Boston (otology); T. H. Weisenburg, Philadelphia (neurology); W. A. White, Washington (psychiatry), and Edwin W. Ryerson, Chicago (orthopedic surgery).

A study of the situation has shown that of the whole number of maimed men, at least 80 per cent. can be trained to new occupations if their physical defects receive immediate treatment after they have left the army hospitals

and their training is given proper attention. From 70 to 80 per cent. of the wounded returned to Canada have needed reconstruction work. The conference recommends that a permanent commission be formed to lay plans for the proper organization of the work.

STANDARDIZATION OF MILITARY MEDICAL SUPPLIES.—The Council of National Defense has compiled a set of catalogues of staple medical and surgical supplies selected to meet war conditions and listed for the purpose of standardizing such supplies. In the opinion of the Committee it is highly desirable that wide publicity be given its work with regard to this standardization. The first catalogue issued under its supervision is Part I, covering surgical instruments, and this will be mailed gratis to all interested physicians and surgeons upon application to Major F. F. Simpson, M.O.R.C., Chief, of Medical Section, Council of National Defense, Washington, D. C. Other catalogues in preparation are:

1. Medicines, Disinfectants, Anaesthetics, Chemicals, etc.
2. Hospital Equipment and Supplies.
3. Laboratory Apparatus.
4. X-Ray Apparatus.
5. Dental Instruments and Supplies.

Such a standardization of supplies will result, it is expected, in insuring for the needs of the medical services of the Army and Navy, the Red Cross and civilian hospitals sufficient amounts of these supplies even under the abnormal conditions of war. The committee is assured, by thus selecting a minimum number of staple and essential articles, the maximum and economical production of such articles. It has been agreed by the manufacturers that their production shall be given precedence over other articles for similar purposes.

ASSISTANCE FOR TUBERCULOSIS IN FRANCE.—Dr. Livingston Farrand, president of the University of Colorado, and director of the mission to be sent by the Rockefeller Foundation to render aid in the control of tuberculosis in France, makes the following statement regarding the prevalence of the disease in that stricken country:

"The French death rate from tuberculosis is, roughly, twice that of America and three times that of England. Normally France has a high death rate and a low birth rate, and with the increase in tuberculosis brought about by the war it is evident that something must be done and without delay.

"It is estimated, say the reports to the Rockefeller Foundation, that in the three years of the war 150,000 soldiers have been discharged from the French Army because of active tuberculosis. Nor is this condition confined to the army. Refugees from the occupied districts of Northern France are breaking down in large numbers

and the French prisoners returned from Germany indicate a high percentage in that group.

"Since the war began, a special commission has been created to care for tuberculous soldiers. This work is of the greatest importance and must go on. It is doubtful, however, if at the end of this year there will be more than 10,000 or 12,000 beds available for tuberculous patients in the whole of France, and these will be occupied almost exclusively by soldiers.

"A conservative estimate would indicate that there are 500,000 cases of tuberculosis in the country. It is obvious that, whatever preventive measures can be laid down and followed out in the future, an immediate need is for hospital accommodations, and there is no more pathetic appeal to which the wealthy people of America could respond."

AMERICAN HOSPITALS IN ENGLAND.—The American Women's War Relief Fund, whose president is Lady Paget, has made arrangements that its two hospitals, one at Lancaster Gate, London, and the other at Paignton, be used for the care of American soldiers. Although established for the care of the British soldiers, with the entry of America in the war these American women in England wish these hospitals to be always open for such Americans as may need their services.

"Lady Paget has been foremost in her charity work since the outbreak of hostilities. She has gathered from America 3,500,000 socks and these, with tens of thousands of garments such as underwear, pajamas and shirts, have been sent to British fighting men in need of them. Lady Paget, personally, has raised in America and England \$1,250,000 for British wounded, \$175,000 for Russian wounded, \$160,000 for French wounded and \$125,000 for American hospitals in England.

Others associated with her in the American Women's War Relief Fund are Mrs. John Astor, vice-president, the Duchess of Marlborough, chairman, and Lady Lowther and Mrs. Harcourt, who are secretaries. The nine American women who make up the executive committee are headed by the wife of the American ambassador, Mrs. Page. Lady Randolph Churchill is chairman of the hospital committee, while the chairman of the economic committee is the Duchess of Marlborough."

HOSPITAL UNITS FOR NERVOUS AND MENTAL DISORDERS.—The National Committee for Mental Hygiene has created a subcommittee on furnishing hospital units for nervous and mental disorders to the United States Government, the project having been approved by Surgeon General W. C. Gorgas of the U. S. Army.

This subcommittee, of which Dr. Pearce Bailey of New York is chairman, is authorized to secure the services of alienists and neurologists to be commissioned in the Officers' Reserve Corps, Medical Section, and to serve in the

neuro-psychiatric units which are to be attached to the base and other hospitals of the military services of the United States. Further information will be given, and application forms sent to physicians qualified in this branch of medicine, on application by letter or in person to The National Committee for Mental Hygiene, 50 Union Square, New York City.

DEARTH OF BRITISH MEDICAL OFFICERS.—In the issue of the *Lancet* for June 2 appears the following paragraph relative to the dearth in the supply of medical officers for the British Army and the expectations entertained for the making up of this deficiency by American physicians.

"The Central American War Committee has been working steadily and at great pressure to meet the demands of the War Office for medical officers for the Army, and the position indicated in these columns some time ago as imminent has clearly been reached. In existing circumstances all the War Office demands cannot be met. The information that a large number of American medical men will shortly be available for service in France has been considered by many to promise an amelioration of the situation, but there is as yet no definite and official warrant for believing that the problem of an adequate supply of medical officers for the British Army will be solved in this way. Undoubtedly there are American medical men promptly available to serve for the time being with our Army or with the French Army, and probably more of the same gallant assistance will be forthcoming. Recognition of the qualifications of these American confrères by their Medical Association or statutory Colleges would enable them to be at once available for the armies at the Allied fronts. But these American doctors would probably have to be returned to the American Army when expeditionary forces begin to arrive from the United States. A temporary respite from acute trouble, however, might be gained through the employment of American doctors, and such respite would be valuable to this country where the supply of medical men has become so dangerously short. The subject is now under the discussion of the Central Medical War Committee. No one who is aware of the circumstances in which exemption is refused or obtained by our medical men of military condition can possibly suggest that the Central Medical War Committee takes other than a very high view of its responsibilities towards the Army. It has, however, an enormously important duty towards the civilian population in this country, and cannot be blind to it. So closely have the areas in England been scrutinized with a view to obtaining every medical officer for the Army, so intensive is the method of investigation and reinvestigation now being conducted, that it seems certain that should all this energy and self-sacrifice not bear sufficient fruit, the Army will have to economise

in the employment of medical men under some plan of redistribution or reorganization. There are already men being sent into the Army who can badly be spared by the State."

WOMEN'S MEDICAL UNIT.—The first unit of women physicians for foreign service has been organized. Dr. Florence N. Ward, a surgeon of San Francisco, is chairman of the organization and Dr. Cornelia C. Brant, dean of New York Medical College and Hospital for Women, is treasurer. The unit includes women surgeons from all parts of the United States.

WAR RELIEF FUNDS.—On July 7, the totals of the two principal New England war relief funds reached the following amounts:

French Wounded Fund	\$235,898.43
Surgical Dressings Fund	103,713.47

BOSTON AND MASSACHUSETTS.

WEEK'S DEATH RATE IN BOSTON.—During the week ending June 30, 1917, the number of deaths reported was 242, against 214 for the same period last year, with a rate of 16.34, against 14.86 last year. There were 37 deaths under one year of age, against 37 last year, and 66 deaths over 60 years of age, against 62 last year.

The number of cases of principal reportable diseases were: diphtheria, 65; scarlet fever, 32; measles, 183; whooping cough, 12; tuberculosis, 137.

Included in the above were the following cases of non-residents: diphtheria, 8; scarlet fever, 8; measles, 3; tuberculosis, 8.

Total deaths from these diseases were: diphtheria, 8; scarlet fever, 2; measles, 8; tuberculosis, 22.

Included in the above were the following deaths of non-residents: diphtheria, 1; scarlet fever, 1; tuberculosis, 1.

LONG ISLAND HOSPITAL GRADUATION OF NURSES.—On June 28, the training school of the Long Island Hospital graduated seventeen nurses. Chairman Thomas A. McQuade of the institution trustees administered the Florence Nightingale oath to the graduates, and Mrs. William McNamara of the National Civic Federation spoke on "Opportunities in Industry for Graduate Nurses."

INFANTILE PARALYSIS FUND.—The fund of the Harvard Infantile Paralysis Commission has now reached a total of \$13,919.95.

DEDICATION OF WINCHESTER HOSPITAL.—The newly erected Winchester (Mass.) Hospital, the cost of which was raised by popular subscription,

was dedicated on June 28 in the presence of more than one hundred and fifty people. The building contains sixty beds, eight private rooms and two sun rooms.

MASSACHUSETTS HEALTH DEPARTMENT AND ALCOHOL.—The recently issued May number of the Public Health Bulletin of the Massachusetts State Department of Health gives the following notice to the subject of alcohol.

Recently Dr. Haven Emerson, Commissioner of Health of the city of New York, has twice come to Boston, first to address a meeting called by the alcohol committee of the Associated Charities, and later, a group of doctors and their wives, in regard to the effects of alcoholic drink on the health of the community. The information given by Dr. Emerson and the opinions expressed by the doctors present as to the part played by alcohol as a cause of sickness and death seem to demand that the Departments of Health should give out such information on the subject as they possess, especially the results of the more recent scientific inquiries.

Health departments are not called on to discuss the use of alcohol from a moral or religious point of view, but in so far as it affects the health of individuals and of society at large, the community has a right to expect the doctors and the health departments to give the facts, together with sound and reliable opinions; to tell the truth, the whole truth and nothing but the truth.

It is quite as important that the public should be correctly informed as to the effects of alcohol as it is that they should know the facts about tuberculosis and syphilis.

The amount of alcohol in patent medicines should be generally known.

We know now that alcohol is not a stimulant, but is a depressant; that its excessive use frequently causes insanity; that used even in moderation it more or less impairs the nervous system so that impressions are less clear and actions less accurate, thus causing innumerable accidents to the individuals and other innocent persons.

Alcohol causes damage to the heart, kidneys and blood vessels, as well as to the stomach and liver. Owing to its effect on the germ plasma it often damages the unborn babe. It reduces the resistance to bacterial infection, thus rendering individuals more susceptible to tuberculosis and other infections. Regular drinkers have a decidedly smaller chance of recovering from pneumonia. These subjects may be taken up more in detail in later numbers of the Bulletin.

The more we know about disease the more clearly we see that preventive medicine is most important for human welfare; for suppose a part of the body has been impaired or destroyed by syphilis or alcohol,—such destruction might have been prevented, but usually cannot be repaired.

NEW ENGLAND NOTES.

FUND FOR CONCORD (N. H.) HOSPITAL.—By the will of the late Dr. Ferdinand A. Stillings of Concord, N. H., the Margaret Pillsbury Hospital of that city is to receive a fund, the income of which is to be used for the purchase of surgical instruments. Dr. Stillings' own instruments were given to the Woman's Memorial Hospital.

INFANTILE PARALYSIS IN VERMONT.—On June 29 the total number of cases reported in Vermont had reached twenty-four. All but one are in Washington County.

The Massachusetts Medical Society.

NOTES FROM THE DISTRICT SOCIETIES.

ESSEX SOUTH.—The Executive Committee of the Essex South Medical Society at the annual meeting of the Society, May 9, 1917, was authorized to outline a course of action for the Society to follow that would aid those of our number about to enter the Government Service and that would tend to conserve their practice.

The Committee, after carefully considering the question, desires to submit the following recommendations:

1. One-half of the entire amount collected from the practice of an absentee, with the exception of lodge work, shall be paid to some designated person, preferably a bank official, for distribution to the absentee's family. Whoever serves as treasurer shall keep an accurate record of all money received and an accurate list of those from whom the money comes. The treasurer may also collect to advantage all unpaid accounts. The secretary of the Society shall have access to the lists at all times.

2. Every physician should agree not to visit professionally any of absentee's patients for at least six months after his return, without his knowledge and consent.

3. Each city in the district should take action on the question and decide how best the local situation can be met. The Committee feel that all physicians, irrespective of society affiliations, should take part in any action taken. A committee will be asked in each city to bring the physicians together.

4. Any agreement made should be signed by all the physicians in each city. A copy of the agreement should be in every office and the local papers should print the agreement with the signers.

The Committee realize that the suggested arrangement can apply only to those in general

practice. It is suggested that those doing special work make an agreement among themselves. In case of doubt as to whom the patient belongs, the absentee should be given the benefit of the doubt.

Obituaries.

COLONEL GEORGE D. DESHON.

COL. GEORGE D. DESHON, chief medical officer on the staff of General Clarence R. Edwards, commander of the Department of the Northeast, died suddenly at his home in Brookline, Mass., on June 24. Col. Deshon, whose record for service during the Philippine and Cuban campaigns had established, in military circles, his reputation for a brilliant officer, was asked by General Pershing to take command of his medical staff in France, which position he was obliged to refuse because of ill health.

Col. Deshon was born in Brookline, August 5, 1864, and attended Dartmouth College. From there he entered West Point and, upon the completion of his course there, was appointed to the same regiment with General Edwards, the 23d Infantry, at Fort Wayne, Ind. Shortly after his marriage he resigned in 1890, and studied medicine at Bellevue Medical College and the University of Pennsylvania. He then re-entered the army as a surgeon and was given the rank of Major. He was sent to the Philippines and achieved distinction. On his return he was appointed commandant of the Army and Navy General Hospital at Hot Springs, Ark. Subsequently he served in different capacities until appointed superintendent of the Ancon U. S. Canal Hospital at Panama. Under his supervision, the eleven army canal posts were brought to as high a mark as any in the government. Upon the transfer of General Edwards to the new northeastern department, Col. Deshon was chosen to accompany him. On arriving at Boston, Col. Deshon was not well, and for about two weeks was at the Massachusetts General Hospital. He did not, however, fully recover his health before he was stricken with death.

Colonel Deshon was a member of the Army and Navy Club, Washington; the Psi Upsilon fraternity, the Society of Colonial Wars in the Commonwealth of Massachusetts, the Massachusetts Society of the War of 1812, Massachusetts Society of the Military and Naval Order of the Spanish War, Massachusetts Society of Sons of

the American Revolution and the Society of the Army of the Philippines.

He is survived by a widow and a son, Captain Deshon of the field artillery, who is at the present time on sick leave in California. Of Colonel Deshon, General Edwards said:

"He was a loyal and devoted friend, and the ideal soldier-doctor. I do not believe there was a man of higher character in the United States service than he. Although the strictest kind of a disciplinarian, he was the sort of man that men loved and honored. The loss to the service will be serious."

HERBERT MAXON KING, M.D.

DR. HERBERT MAXON KING, who for many years had been physician-in-chief at the Loomis Sanatorium, died there from tuberculosis on June 24. Dr. King was born in Adams, N. Y., on August 11, 1864. He was educated at Dartmouth College and entered the University of the City of New York as a medical student, receiving his degree of M.D. in 1886. After practising for four years in New York, he entered the Marine Hospital service. This he left in two years to go to Grand Rapids, Mich. He soon achieved distinction in his profession, and became a recognized authority in the diagnosis and treatment of all forms of respiratory disorders. In 1897 he visited Paris for the purpose of studying the methods of the French, and upon his return resumed practice in Grand Rapids. In 1902 he was chosen to the position at the Loomis Sanatorium, which he held until his death.

JOHN WILLIAM WATSON, M.D.

DR. JOHN WILLIAM WATSON, who died at the Deaconess Hospital, Brookline, Mass., of toxemia, following an operation for appendicitis, was born at Lawrence, Mass., July 8, 1870. His college preparatory course was at Phillips Exeter Academy, and he was graduated from Dartmouth College in 1893, and from the College of Physicians and Surgeons at Baltimore, Md., in 1900. He had an A.M. from Dartmouth through post-graduate work. He practised his profession at West Hartford, Vt., at Beverly, Mass., and at South Braintree, Mass. At the time of his death he was a member of the officers of instruction of the Tufts College Medical and Dental Schools and Assistant to the Medical Examiner of the Suffolk South District. He was a Fellow of the American Medical Association and of the Massachusetts Medical Society. He is survived by his widow, his foster daughter, his mother and one sister and a brother.

Miscellany.

TUBERCULOSIS AND ITS RELATION TO THE MOTHER'S AID LAW IN MASSACHUSETTS.*

THE Mother's Aid Law in Massachusetts went into effect September 1, 1913. By this law the State, through the State Board of Charity, pays a sum towards the support of children under 14 years of age in dependent families in which the father is dead or incapacitated.

During the first three years of the Mother's Aid Law,—September 1, 1913, to September 1, 1916,—a total of 5052 cases were aided. In 3663 cases, or 73%, the husbands had died, and in 1389, or 27%, the husbands were living, but incapacitated for various reasons.

Two studies have been made of those cases dependent because of the *death* of the husband. The first, a study of 300 cases, shows that 92 husbands died of tuberculosis. The second, a study of 500 cases, shows that 126 husbands died of tuberculosis. This means that 27% of the husbands in these 800 cases died of tuberculosis.

The above studies indicate the percentage aided because the husbands had *died* of tuberculosis. There are also many *living husbands* of women receiving Mother's Aid who are tubercular, cared for in sanatoria or at home under supervision of local boards of health. Of the total of 5052 cases there were 266 of the husbands living but unable to support their families because of tuberculosis.

If 27% of the 800 cases studied is the correct proportion of *deaths* from tuberculosis, for the entire 3663 cases, we find the total number of such deaths to be 989, and adding the 266 cases of tuberculosis among the *living* but incapacitated husbands, we have a total of 1255 cases receiving Mother's Aid because of tuberculosis, or 25% of all the 5052 cases.

According to the estimate made by a state official, the total cost to cities, towns and state of the 5052 cases for the three years has been not less than \$1,500,000. The proportion of this amount spent because of tuberculosis is, therefore, in the neighborhood of \$375,000.

Besides the tubercular husbands, deceased or incapacitated by reason of tuberculosis, many of the mothers of these families are pre-tubercular or arrested cases of tuberculosis, and many of the children of these families are tubercular.

The problem of tuberculosis, as seen by those who administer the Mother's Aid Law, includes, therefore, the large number of husbands who died in the prime of life, leaving dependent families to be supported out of public funds; a

* Statement based on a paper read by Mrs. Elizabeth F. McJonev, Supervisor, Mother's Aid, Massachusetts State Board of Charity, at the Massachusetts State Conference of Charities, Lowell, Mass., October 27, 1916.

large number of tubercular husbands cared for at public expense in sanatoria or at home through the overseers of the poor and boards of health, and many of whose families must be aided by public funds; and many women and children who are incapacitated for work, and therefore have to be supported by public funds.

CANCER DECALOGUE PREPARED BY
THE STANDING COMMITTEE ON THE
CONTROL OF CANCER OF THE MASSA-
CHUSETTS MEDICAL SOCIETY.

1. The classical signs of cancer are the signs of its inenrable stages. Do not wait for the classical signs.

2. Early cancer causes no pain. Its symptoms are not distinctive, but should arouse suspicion. Confirm or overthrow this suspicion immediately by a thorough examination and, if necessary, by operation. The advice "Do not trouble that lump unless it troubles you," has cost countless lives.

3. There is no sharp line between the benign and the malignant. Many benign new growths become malignant and should, therefore, be removed without delay. All specimens should be examined microscopically to confirm the clinical diagnosis.

4. Precancerous stage. Chronic irritation is a source of cancer. The site and the cause of any chronic irritation should be removed. All erosions, ulcerations, and indurations of a chronic character should be excised. They are likely to become cancer.

5. Early cancer is usually curable by radical operation. The early operation is the effective one. Do not perform less radical operations on favorable cases than you do on unfavorable ones. The chances for a permanent cure are proportionate to the extent of the first operation. Make wide dissections; incision into cancer tissue in the wound defeats the object of the operation and leads to certain local recurrence.

6. Late cancer is inenrable, though not always unrelievable. Radium, x-rays, ligation, cautery, or palliative operations may change distress to comfort and may even prolong life.

7. Cancer of the breast. All chronic lumps in the breast should be removed without delay. Benign tumors can be removed without mutilation. Examine all specimens microscopically. An immediate microscopical examination is desirable since, if positive, it permits a radical operation at the same sitting. A radical operation performed ten days after an exploration is almost never successful in curing cancer of the breast.

8. Cancer of the uterus. Any irregular flowing demands thorough investigation. Of-

fensive or even very slight serous flows are especially suspicious. Curette and examine microscopically. Amputate all eroded cervixes which do not yield promptly to treatment. Do not wait for a positive diagnosis.

9. Cancer of the digestive system is difficult of early diagnosis, and therefore unfavorable in prognosis. All persistent and recurring indigestions (more especially if attended by change of color and loss of weight) and any bleeding or offensive discharges demand prompt and thorough investigation. Do not wait for a positive diagnosis.

10. Cancer of the skin. Any warts, moles, or birthmarks which enlarge, change color, or become irritated should be removed promptly. They are likely to become cancer. Do not wait for a positive diagnosis.

INFORMATION REGARDING APPOINTMENT
IN THE MEDICAL RESERVE
CORPS OF THE UNITED STATES
ARMY.

APPLICANT must be a citizen of the United States, between 22 and 55 years of age; a graduate of a reputable medical school; must have qualified to practise medicine in some state; and must be in the active practice of his profession. "Active practice" includes those who specialize in eye, ear, nose and throat, dermatology, neurology, obstetrics, etc.

The Act June 3, 1916, creating the Medical Officers' Reserve Corps, provides that in time of peace only those of the grade of first lieutenant may be ordered to active duty, and this with their own consent, but in time of war the services of officers of all grades are at the disposal of the government.

PROCEDURE.

(a) Fill out personal application blank; write distinctly.

(b) Certify to the application before a notary public or other person authorized to administer oaths. This is essential.

(c) Secure letters of recommendation from two prominent citizens who know you; these may be from physicians. Attach these letters to the application.

(d) Write to the examining board most convenient to you and arrange to present yourself for examination at such time as may be mutually agreeable. Do this as soon as possible.

(e) When you report to the board for examination, present to it your application blank, properly filled out and certified to as indicated above, your testimonials, your state certificate

and, if of foreign birth, documentary evidence of your full citizenship.

EXAMINATION.

The examination is physical and professional. The minimum physical requirements are: (a) height, 5 feet, 4 inches; (b) weight, 120 pounds; (c) vision, 20/100 each eye entirely corrected by glasses—no organic disease.

The professional examination for the Reserve Corps is not severe; it is oral and practical in character, and in case of failure is supplemented by a written examination.

MEDICAL CORPS.

A physician may be commissioned in the Medical Corps of the Army, provided he is between 22 and 32 years of age (34 up to Jan. 1, 1918), a citizen of the United States and a graduate of a reputable medical college legally authorized to confer the degree of Doctor of Medicine. He must have had also at least one year's hospital training subsequent to graduation, including practical experience in the practice of medicine, surgery, and obstetrics, and will be expected to present evidence to that effect. Whether or not he is married has no effect on his eligibility to the Medical Corps. He must pass a preliminary examination and a final or qualifying examination in accordance with the rules and regulations, which may be obtained on application.

EXAMINING BOARDS FOR MEDICAL RESERVE CORPS.

The following is a list of medical boards as appointed up to June 5. The name and address of the chairman of the board only is given. It is presumed that applicants will select the board most accessible to themselves, even though this may mean a board in another state:

Connecticut: New Haven, Lieut. John W. Churchman, M.R.C.

Maine: Brunswick, Lieut. F. N. Whittier, M.R.C.; Bowdoin College; Ft. Williams, the Surgeon; Portland, Dr. William L. Cousins, 231 Woodford Street.

Massachusetts: Boston, Major Horace D. Arnold, M.R.C., Harvard University Graduate School of Medicine (President); Ft. Banks, the Surgeon; Springfield, Lieut. Charles F. Lynch, M.R.C., 387 Main Street.

New Hampshire: Hanover, Capt. Percy Bartlett, M.R.C.; Manchester, Capt. J. Franklin Robinson, M.R.C.; Nashua, Lieut. A. W. Shea, M.R.C.

New York: Albany, Major Henry L. M. Shaw, M.R.C., 361 State Street, President; Buffalo, Capt. Herbert A. Smith, M.R.C., 566 Delaware Avenue; Plattsburg, the Surgeon; New York, Major Henry C. Coe, M.R.C., Academy of Medicine, 17 W. 43d Street, President

(office hours, 3 to 5 p.m. every day except Saturday and Sunday); New York, Dr. Simon Flexner, 150 E. 61st Street; Rochester, Major John M. Swan, M.R.C., 457 Park Avenue; Syracuse, First Lieut. Brewster Donst, M.R.C., 641 Park Avenue.

Rhode Island: Newport, Lieut. Charles D. Easton, M.R.C., 36 Ayrault Street; Pawtucket, Capt. James L. Wheaton, 210 Main street; Providence, Major John W. Keefe, 262 Blackstone Building.

Vermont: Ft. Ethan Allen, the Surgeon.

THE AMERICAN MEDICAL UNITS.

In the issue of the *British Medical Journal* for May 26, 1917, appears the following account of the reception of the early medical units of the United States Army upon their arrival in England:

"The first element of the United States army to arrive in Europe is a medical unit, which reached a British port last week, and will leave for the war zone very shortly. The unit consists of 23 medical men, in addition to the major and adjutant, both of whom belonged previously to the United States regular army; 65 trained nurses, and 155 orderlies, as well as four lady stenographers and others serving in subsidiary capacities, including a drum and bugle corps. It was organized for Red Cross work by Dr. George W. Crile, professor of clinical surgery at the Western Reserve University, Cleveland (who has already gone to France), and it has been placed under the command of Major Henry L. Gilchrist, chief surgeon of the 11th Division (22,000 troops) of the United States Army. Major Gilchrist was serving on the Mexican border at the beginning of May, and was relieved in order to assume this new command. The order to go to Europe was received on May 3, and by May 6, 288 men had been examined and the 155 orderlies selected from this number and sworn in. During the same period, the organization, which had originally been voluntary, was made a part of the regular army; every officer, nurse, and orderly has signed on for three years in the regulars and four years in the reserve. All the medical men in the unit, apart from Major Gilchrist and Captain Tuttle, the adjutant, are connected with the Western Reserve University, and in addition to Dr. Crile, they include Major Hoover, professor of medicine; Captain Karlsen, professor of bacteriology; and Major Lower, of the Mount Sinai Hospital. Nearly all the professors of the medical faculty of the university are among the contingent. The nurses are mostly college women, many of them from wealthy families in the West, and 90% of the orderlies are also college graduates or undergraduates from the best universities of the

Middle West, principally Ohio. Had it been authorized, a thousand such could have been enlisted at once. The unit left Cleveland on May 6, arrived at an American port the following day, still in civilian clothes, and donned their khaki uniforms as soon as they were out of the harbor. Classes were started on board, and the men were schooled for ten hours a day. The future plans of the unit cannot, of course, be fully disclosed, but it can be said that they are immediately to take entire charge of one of the large base hospitals, consisting of 1000 beds, and its present staff is to be relieved and re-distributed. It is hoped to devote special study to shell shock cases. Major Gilchrist, who gave these particulars, added that six special units from Boston and other parts of the States, with twenty-three medical men attached to each unit, would be sent, and as the United States had an abundance of medical men—I in 699 of the population—he did not doubt that many more would be forthcoming. He had heard it stated that in all a thousand doctors would arrive within the next two months. On May 23, at Buckingham Palace, the King and Queen received the medical and nursing staff of the first American medical unit, whose official title is No. 4 Base Hospital, United States Army. Sir Alfred Keogh, G.C.B., Lieutenant-Colonel F. W. Begbie, R.A.M.C., and Miss E. H. Becher, Matron-in-Chief Q.A.I.M.N.S., were in attendance, and the American surgeons were presented to His Majesty by the United States Ambassador. The King, in a few gracious words, expressed his pleasure and satisfaction at meeting the first detachment of the American army which has reached our shores since their country resolved to take its part in the war; it was characteristic of the American nation that the first assistance rendered to the Allies should be in connection with the profession of healing. On the same day a second contingent, comprising 26 surgeons, 60 nurses, and 250 orderlies, arrived at a British port."

Correspondence.

A REMINISCENCE OF DR. HOLMES.

Mr. Editor:—

While recalling some old memoranda and anecdotes, I find some which I take the liberty of sending you as having a general as well as a personal medical interest.

Some years ago—perhaps some of your readers recollect the exact date—Mr. Reginald Harrison the well-known surgeon of Liverpool, whose genial and hospitable acquaintance many American physicians had previously made, paid a visit to Boston at the time of the meeting of the Massachusetts Medical Society. He was taken to the annual dinner and given a seat by the side of Dr. O. W. Holmes.

After the meeting he was walking down the street beside his friend, who will be recognized by the older members of the Dorchester Medical Club as the most amusing of raconteurs, and who reported his guest's experience as follows:

"Very clever fellow, that 'Olmes."

"Yes, he's so considered here."

"Written something, I think."

"Well, yes, quite a number of things."

"I must get something of his to carry home with me. Let's see, what's the title? 'Breakfast in Bed' wasn't it, or something of that sort?"

The account of American peculiarities of manner and customs as given in foreign works is apt to be amusing. The exact text of the following I have lost. I would give several copies of old text books in exchange if I could find it. It was supposed to be in illustration—or proof (?)—of the stimulating effect of a fish diet:

"At certain seasons of the year the Americans gather in large crowds upon the seashore to air their politics, theories, and to feast upon a species of oyster called the clam. When they have gorged themselves with this insidious comestible, they indulge in the wildest of delusions, fall a prey to the most worthless of demagogues and exhibit in a high degree the stimulating effect of a diet rich in phosphorus."

"The lean and cadaverous appearance of the Americans is due to the corn meal upon which they habitually feed."—Extract from an English text book on dietetics.

I am,

Very respectfully,

ROBERT T. EDES.

Springfield, Mass.

APPOINTMENTS.

HARVARD UNIVERSITY.—Dr. Roger I. Loe has been appointed to the administrative board.

Dr. Elliott P. Joslin has been made assistant professor of medicine.

LEO M. LEVI MEMORIAL HOSPITAL.—Dr. George L. Hoffman, formerly assistant to Professor W. Kolle, past director of the Institut zur Erforschung der Infektionskrankheiten in Bern, has been appointed director of the newly created department of medical research at the Leo M. Levi Memorial Hospital, Hot Springs, Ark.

UNIVERSITY OF VIRGINIA.—The following appointments have been made at the University: Dr. Theodore Hough, acting dean, has been made dean of the medical school; Dr. James A. Wardell has been appointed professor of pharmacology and materia medica; and Dr. John H. Neff, adjunct professor of genito-urinary surgery.

MARRIAGES.

Miss Anna F. Hurley and Dr. Frederick J. McVey were recently married in Dorchester, Mass. Dr. McVey is a graduate of Harvard Medical School and of the University of Vienna. He is associate professor of diseases of the ear, nose and throat at the College of Physicians and Surgeons.

RECENT DEATHS.

Dr. GEORGE A. WEBBER, a veterinarian, died at his home in Brookline on June 26. Dr. Webber was born in Cambridge in 1841, the son of Dr. A. C. Webber. He was educated at Harvard and practised his profession for many years in his native city. He was a member of the Ancient and Honorable Artillery Company.

AMORY CHAPIN, M.D., a retired physician, died at his home in Boston on June 27. He was born in Providence, R. I., and received his early education at St. Paul's School at Concord, N. H. He had long been a resident of Boston, but had not practised his profession for about twenty years. He is survived by his widow.

THE USE OF THE PRECIPITIN TEST FOR THE DETECTION OF HUMAN BLOOD IN CRIMINAL TRIALS.

By WM. ROYAL STOKES, M.D., BALTIMORE,

AND

H. W. STONER, M.D., BALTIMORE.*

[From the bacteriological laboratories of the state and city departments of health, Baltimore, Md.]

THE literature of American medicine contains only meagre accounts of the use of Uhlenhuth's precipitin test for the detection of human blood stains in criminal cases, and as each new case adds to the precedents so important in legal proceedings, we have thought it worth while to report our experience in several investigations. Before doing this, however, it is necessary to consider the work of Uhlenhuth and others in the development of this test.

The above-mentioned author published his first observation concerning precipitins in 1900,¹ but these referred only to the preparation of a precipitin for egg albumen.

The preparation of a precipitating serum for the detection of human blood was described a year² later, and his method at that time was carried out as follows:

Rabbits were injected with about 10 cc. of human defibrinated blood at intervals of from 6 to 8 days until 5 injections had been made.

* Recently deceased.

He then prepared a solution of 1-100 of human blood, and mixed 2 cc. of this solution with 2 cc. of a double normal (1.6%) salt solution in a test-tube with a diameter of 6 mm. He then added from 6 to 8 drops of the serum from the rabbit that had been previously injected with human blood, and he obtained a distinct cloudiness. He then used solutions of the serum from many animals, but found that his immune rabbit serum produced no reaction when added to these sera, nor would normal rabbit serum cause a cloudiness when added to the solution of human blood serum.

He then expressed the opinion that the reaction distinguishes human from other kinds of blood.

In a later communication Uhlenhuth³ announced that this test could be made with dried and even decomposed blood, and he⁴ followed this with an account of the use of his method in the detection of human blood stains in medico-legal cases, and the first step in this process consists in establishing the proof that the suspected material is really blood. This is necessary, since human semen, albuminous urine, and ascitic fluid will all give the precipitin test for human albumen.

Having proven the material to be blood by means of the well-known guaiacum test, the demonstration of hemin crystals, and spectroscopic examination, he next proceeds to apply the precipitin test in the following manner:

The suspected material is dissolved in normal salt solution so as to produce a solution which is not distinctly colored, but which foams when shaken. To 4 cc. of this fluid he adds 5 drops

of the humanized rabbit serum, and an almost instantaneous clouding ensues, which later settles to the bottom of the tube as a sediment. A control test made with a solution of sheep's blood or that of some other animal must remain perfectly clear, and the rabbit's serum should be so strong as to cause a cloudiness and sediment in a solution of known human serum at a dilution of 1-100. The humanized rabbit serum should be perfectly clear and if cloudy or opalescent it should not be used. The reaction should take place within one hour, and those reactions which take place only after several hours or even as late as 24 hours should not be considered as positive.

This test is, therefore, a reliable test for the detection of human serum, and having shown by previous tests that the suspected material is blood, the conclusion can be maintained that the material is human blood. One exception must be admitted, however, for the blood of some species of highly organized apes will give this same reaction with humanized serum. This fact is without significance in the usual forensic case.

In a number of medico-legal cases Uhlenhuth was able to obtain positive reactions for human blood with such articles as a blood-stained stick, sand, cotton, a coat and pair of trousers, and a hatchet.

The following results, also obtained by this observer, are condensed by Nuttall⁵ as follows:

"(6) Blood stain several years on linen, tested with anti-pig serum, gave a reaction; not so with anti-sheep, anti-horse, anti-human serum. Professor Beumer subsequently informed him that the stain was due to pig blood. (7) Dried blood (1897) acted similarly, also subsequently stated to be pig blood by Beumer. (8) Dried blood mixture (1899), reacted to both anti-pig and anti-sheep serum, diagnosis recognized as correct by Beumer, who, as in the other cases, supplied the specimens without letting Uhlenhuth know what they were until after he reported the result of his tests. (9) Blood-stain on paper found in puddle of blood on a road, reacted to anti-pig serum, a suspicion of murder being thus removed. (10) Blood-stains on penknife and handkerchief, medico-legal case, diagnosis human blood, subsequently confirmed by prisoner, who stabbed a man with a knife, explaining the spots on the handkerchief as due to his own nose having bled. (11) Blood-stains on trousers and shirt, sent from Landgericht Munich, and relating to a case of rape—diagnosis, human blood. (12) Shavings from a blood-stained box, same source as preceding, tests negative with anti-human, anti-sheep, and anti-horse serum, further tests not made, and subsequently discovered that the stains were due to roebuck blood. (13) Blood-stained waistcoat and trousers, the owner being suspected of having killed some sheep, tests negative with anti-sheep, positive with anti-fowl,

and it was subsequently proved that he had killed a fowl a day before the sheep-killing. (14) Blood-stained wood shavings from a floor, sent from Braunschweig in connection with a murder case; reaction with anti-human serum; murderer subsequently confirmed this. (15) Two samples of blood-stained cloth sent by Prof. Minoviei (Medico-legal Institute, Bucharest), and 11 other articles, all blood-stained, were correctly diagnosed as subsequently reported by Minoviei. (16) Blood-stained coat, tests negative with anti-human and anti-pig sera, subsequently proved to be roebuck blood-stains, medico-legal case at Marklissa. (17) Dried blood sent from Luxemburg, diagnosed human, subsequently proved to come from a suicide. The blood had been found in front of a house where the suicide lived, the body having been thrown into the Moselle (whence it was recovered) by his relatives, who wished to keep the fact hidden that the man had committed suicide. (18) Blood-stains on wool fragments from waistcoat and basket for carrying wood, diagnosed as human, confirmed by evidence in court. (19) Blood-stained trousers, diagnosis fowl blood. Prisoner suspected of stealing chickens, had claimed the spots to be due to rabbit blood; microscopic examination of the stains had, however, shown the presence of elliptical corpuscles. Comparative tests made with other avian bloods (goose, duck) showed the reaction to take place much more slowly and feebly with these bloods. (I doubt that such tests to distinguish avian bloods medico-legally can have much value, in view of my results, see p. 200.) The diagnosis confirmed in the course of the trial. (20) Three shirts and a handkerchief in connection with a murder, human blood proved to be spattered on two of the shirts. (21) Blood-stained trousers, shirt, stockings from a murder case at Strassburg Landgericht—diagnosis, human blood, the prisoner having claimed that the blood came from a cow which had knocked off a horn. (22) Blood-stains on numerous articles of clothing were diagnosed to be human and from sheep. It was subsequently proved in court that the man had committed a murder, also that he had slaughtered some sheep two weeks before the murder."

Extensive use has been made of the precipitin test in Calcutta by the Imperial Serologist, Lt.-Col. W. D. Sutherland.⁶ The numerous examinations made by him were instituted in connection with various types of murder, assault, robbery, house trespass, rape, suicide, and other crimes, and included 2,643 offenses or alleged offenses. Various substances such as wearing apparel, instruments, tools, weapons, earth, hair, head-gear, stones, wood, and other such things, were examined; in all, 6,566. He found 5,186 specimens blood-stained, 36 with non-mammalian blood, 4,352 with human blood, and 90 with other mammalian blood such as that of the ox, buffalo, sheep, goat, horse, cat and pig.

This author by means of these examinations was not only able to aid in the detection of crime, but was often able to refute false witness of man against his neighbor.

Fowls were used for immunization, and these were found very satisfactory. On the first day of treatment the fowls received 5 cc. of the serum in the right wing vein, on the 4th day 10 cc. in the left wing vein, and on the 10th day 10 cc. in the abdominal cavity. The immunized fowl was bled on the 22d or 23d day. In testing the suspected material a dilution of 1-1000 by means of the foam test in comparison with a similar known dilution of 1-1000 normal serum was used. The contact test with 2 drops of the precipitating serum in the taper tubes was carried out, and a zone of reaction, or a contact ring of cloudiness must appear within 20 minutes.

Sutherland believes that with this time limit and dilution human serum can be distinguished from apes' blood, since the latter, if reacting at all, will not appear until after 20 minutes have elapsed. He made many comparative tests with orang (*Simia satyrus*), hooluek, (*Hylobates niger*), siamang (*Hylobates syndactylus*), lungoor (*Semnopithecus mitratus*), simpai (*Semnopithecus melalophus*), macaque (*Macacus cynomolgus*), pig-tailed monkey (*Macacus nemestrinus*), slender loris (*Nycticebus tardigradus*) and rhesus monkey (*Macacus rhesus*), and human serum. The human reaction took place in five minutes, but when human precipitating serum was used with any of these monkey bloods the reaction was not visible until after the expiration of 20 minutes.

This article closes with a brief résumé of 50 typical criminal cases involving murder, assault, rape, cattle-maiming, riot and other offenses, in which justice was usually done to both the guilty and the innocent.

The work of Wassermann and Schütze⁷ was also important in emphasizing the usefulness of the precipitin test in forensic medicine. These investigators examined 23 specimens of blood by this method, and obtained a positive reaction only when humanized rabbit serum was used in connection with human blood.

They gave from 5 to 6 subcutaneous injections of 10 cc. of human serum to rabbits every 2 to 3 days, and bled the rabbit 6 days after the last injection. The suspected material was then dissolved in from 6 to 8 cc. of salt solution and divided into 2 portions. To the first portion 0.5 cc. of the immune precipitating serum was added and to the other a similar quantity of normal rabbit serum was added. This second portion acted as a control, and as additional controls hogs' and sheep's bloods were tested with the immune rabbit serum.

The tests are all incubated at 37° C. for one half to one hour, and only human blood will show a clouding and sediment.

They conclude that "the test for human

blood is specific for this blood except in the case of monkeys' blood, when it acts only after a longer time and in lesser degree."

The value of the precipitin test for human plasma protein depends upon its specificity for this particular substance, and its value is enhanced by the demonstration of a general principle applicable to all of the sub-phylum Vertebrata. This principle has been clearly established by Nuttall,⁸ who performed an extensive series of experiments bearing upon this subject. These experiments are explained in detail in his interesting book, but a brief reference to his results is necessary in order to show the specificity of the precipitin test.

This observer first injected rabbits with the serum of the animal selected for the specificity tests, the amounts varying between 4 and 10 cc. The injections were usually intraperitoneal and were given at intervals of from 3 to 6 days, from 5 to 10 injections being given.

The antiserum was then obtained from the animal by bleeding and stored until used.

In collecting the bloods from the many animals whose blood was to be tested he used filter paper, and these dried slips were placed in salt solution so as to make a dilution when the blood was dissolved of 1 to 100. About 0.05 of a cc. of the special antiserum was added to 1 cc. of the solution of the blood to be tested, and the formation of a sediment or precipitate was noted, if present, at the end of several hours.

Nuttall's first series of experiments was performed with anti-human serum mixed with the diluted serum of the various orders of the Mammalia, Aves, Reptilia, Amphibia, and Pisces, and his results showed two distinct reactions. A faint or medium clouding occurred in a percentage varying from 4 to 100 with all of the orders of the Mammalia except the Lemuroidea and the Monotremata. This he termed the mammalian reaction, which merely indicated a general relation of the orders of the class Mammalia to each other. None of the many tests made with the other classes of Craniata gave any clouding with the anti-human serum, so that these negative results also confirm the theory of a general relationship between the various members of the Mammalia.

A much more intimate relationship, however, was demonstrated between the various members of the order of Primates, the positive reactions being noted as marked clouding or a complete reaction with the formation of precipitate when human antiserum was used with solutions of these various bloods. All of the 34 human bloods of four races gave a complete reaction, and the highest family of the sub-order Anthroproidea gave a similar result. The Simiidae, including the gibbons, orangs, chimpanzees, and gorillas, therefore, gave the complete reaction towards anti-human serum in 100% of cases.

The Cercopithecidae, including the baboons

and macaques, gave 10% of complete reactions, and 8% of marked clouding, thus demonstrating a less intimate blood relationship with man than the higher family type just mentioned.

The next family, the Cebidae, gave only 23% of marked clouding, so that the howling monkeys, the squirrel monkeys, the tee tees, the spider monkeys, and the capuchin monkeys, are less nearly related to *Homo sapiens*, while the Hapalidae, or marmosets, cannot even claim a speaking acquaintance, since they gave only the less marked general mammalian reaction in 50% of cases.

These experiments are not only of general biological interest, as showing the blood-relationship among animals, but they become important from the medico-legal standpoint when we consider that the complete reaction even with such a strong anti-human serum as 1-100 occurs only with human blood of the two highest families of the anthropoids. This is especially so since dilutions of 1-1000 and 1-10,000 are used in medico-legal tests for human blood, and the reaction must be complete, consisting of a distinct sediment at the point of contact between the solution of blood and the antiserum.

The negative tests also enable the medico-legal expert to exclude the blood of the other members of the vertebrates, since 320 tests with avian blood, 49 tests with reptilian blood, 14 tests with amphibian blood, and 19 tests with piscine blood failed to give a precipitate or even a marked clouding with a dilution of 1-100 of anti-human serum.

The medico-legalist is often required to prove the presence of the blood of other animals, and the researches of Nuttall also prove that an antiserum made from the blood serum of one sub-order of the class Mammalia will give a complete reaction only when added to the serum of this same sub-order at a dilution of 1-100.

The anti-serum of the Simiidae and Cercopitheidae reacted completely only with the serum of their own sub-order, and various members of the order Carnivora reacted only according to the same rule. Anti-cat and anti-dog serum, therefore, would react completely only with their own serum and failed to react completely with any of the other sub-orders of the Carnivora, or with members of the other orders of the Mammalia.

Among the order Ungulata anti-pig, anti-ox, anti-sheep and anti-horse serum gave the same results, and many bird and reptile sera acted in a similar manner.

Whittier⁹ and Wood¹⁰ have both used the precipitin test in murder trials in this country with positive results.

DESCRIPTION OF METHOD USED.

The method which was used for the detection of human blood in the cases about to be described is that described by Müller,¹¹ and this method is based upon the formation of a pre-

cipitin in a dilution of the suspected blood when this is mixed with the blood serum of an animal that has been injected with the blood serum of a human being. The injections of human serum were first injected intravenously, later subcutaneously, and finally by the intraperitoneal method. When injecting large quantities of serum by the latter method, the method advised by Müller, known as the method of Uhlenhuth, was carried out. The hind legs of a rabbit are grasped by the left hand of an assistant, and the fore legs with his right hand, the head being held downwards. The intestines thus fall as far as possible into the upper portion of the abdominal cavity, and the needle of the syringe is then less liable to puncture the intestine when the injection is made.

Kolmer¹² describes several methods as applicable for obtaining a precipitating serum. Of course the blood serum obtained from any of these methods must be carefully tested as to its titer and not used until it has a titer at least as high as 1-20,000. If the injections recommended are not sufficient, other doses must be given, and the experience of most workers seems to indicate that the third method, known as the slow method, will give the best results. No hard and fast rules, however, can be laid down for the immunization of any particular animal, it being understood that rabbits are used in preparing this serum. The methods described by Kolmer are as follows:

"In preparing precipitins for the purpose of identifying blood-stains, whole blood may be injected. It is better, however, to use serum only, as the immune serum may be used in diagnosis, according to the method of complement-fixation, when the presence of hemolysin is not advisable.

Serum Precipitins (Intravenous Method).—First Method.—Three injections are given—of 5, 10, and 15 cc.—on each of three successive days, and the animals are bled twelve days after the last injection has been made.

Second method.—One injection of 30 cc. of serum may be given, and followed twelve days later by bleeding.

Third Method.—A slower method consists in giving the injections at intervals of a week. After the third dose a few cubic centimeters of blood are withdrawn from the ear, and the serum titrated, as rabbits are most prone to succumb after the third dose, and in many instances the serum is of such strength as to require no further immunization. The animals are bled one week after the last injection has been given.

Doses may be given as follows:

First dose:	10 c.c. serum intravenously
Second dose:	8 c.c. serum intravenously
Third dose:	5 c.c. serum intravenously
Fourth dose:	5 c.c. serum intravenously
Fifth dose:	3 c.c. serum intravenously

Fourth Method.—Rabbits may be immunized by making intraperitoneal injections after any of the foregoing methods, and with the same or slightly larger doses.

The following table is a record of the various injections made for immunizing the rabbit from which the immune serum was later taken to test for human blood."

RECORD OF INJECTIONS OF RABBITS.

Jan. 20, 1914	2.0 c.c.	Intravenous
" 24, "	9.4 c.c.	Subcutaneous
Feb. 3, "	9.5 c.c.	Intraperitoneal
" 7, "	10.7 c.c.	Intraperitoneal

" 19, "	19.0 c.c.	Intraperitoneal
Mar. 2, "	20.0 c.c.	Intraperitoneal
Hydrocele fluid		

After the above-mentioned amounts of human serum had been injected into the rabbit the animal was killed several days after the last dose, and the blood serum was obtained and filtered through a small Berkefeld filter. It is important to have the animal fast for about six hours before obtaining the serum in order to avoid the milky opalescence which often appears in a serum soon after feeding and which cannot be removed by filtration. The serum used for this test must be absolutely clear. The titration of the serum was then made in order to determine its potency, and this was carried out according to the directions of Müller, which are as follows: "Dilutions of 1-1000, 1-10,000, and 1-20,000, respectively, of the serum or blood against which the immune serum acts are first prepared with physiological salt solution (0.8 to 0.9 per cent.). To 2 cc. of each of these dilutions add 0.1 cc. of the immune serum, without shaking. In the 1-1000 dilution a distinct clouding should appear at once, or, at the most, after one or two minutes; and, after three to five minutes, the beginning of the reaction should be distinctly recognizable in the higher dilutions. The reaction should be fully complete after thirty minutes at the most, at room temperature.

The immune serum may be preserved in sterile, hermetically sealed glass tubes, after filtering through a sterile Berkefeld filter. The serum will be rendered free of bacteria in this way, provided the filter works properly. Care should be taken to avoid using cracked filters.

A safer way is to preserve the serum, unfiltered, by the use of 0.5 per cent. carbolic acid (1-10 volume of 5 per cent. carbolic acid solution) as a preservative.

A solution of the *unknown substance*. Physiological salt solution only should be used as a solvent and diluent for blood-stains, etc. The dilution should be about 1-1000. In the case of blood-spots this is not always easy to estimate. Uhlenhuth gives the following directions for obtaining the proper dilution:

1. The dilution should be almost completely colorless by transmitted light.

2. It should give only a slight cloud on heating with a few drops of nitric acid.

3. It must foam freely on shaking, in spite of the high dilution.

This solution also must be crystal clear, for which purpose filtration may be employed.

Test-tubes, 10 cm. long by 0.9-1 cm. wide. These must be absolutely clean.

A *test-tube rack*. The rack for 12 tubes devised by Uhlenhuth is very convenient. This has the holes for the tubes bevelled, and permits the test-tubes to hang suspended in the holes. Since the small test-tubes are often of unequal diameter, it is a good plan to select in advance tubes as nearly as possible of the same size. To avoid mixing the tubes, the holes in the rack may be numbered.

Physiological salt solution. Volumetric pipettes, 0.1 cc. graduated in 1-100's (the calibration extending to the point), and 1 cc. and 10 cc. in 1-10's.

Dried blood-clots from various species of animal to serve as controls. Dilutions approximating 1-1000 should be prepared of each of these in the same manner as the unknown substance.

Technic.—The following mixtures are set up in a series of test-tubes:

1. The test proper: 2 cc. unknown solution + 0.1 cc. immune serum.

2. Control: 2 cc. salt solution + 0.1 cc. immune serum.

3. Control: 2 cc. diluted blood of that species of animal whose blood is suspected to be present in the unknown solution + 0.1 cc. immune serum.

4. Control: 2 cc. unknown solution alone.

5. Control: 2 cc. diluted blood-serum of a different species of animal from that suspected to be present in the unknown solution + 0.1 cc. immune serum.

The addition of the immune serum to the various solutions is best made by placing the unknown solution into test-tubes first and then with a fine pipette adding the blood serum at the very bottom of the tube so that the solution of the suspected material or the control human blood is floated up over the surface of the serum. This produces a ring of the precipitum very much like the contact test which is made for albumen in urine by adding nitric acid to the bottom of the test-tube and floating the urine on the surface of the nitric acid. This contact ring somewhat resembles the ring of albumen precipitated in urine by the nitric acid contact test.

When the test proper and control No. 3 result positively, and all the others negatively, the presence of the blood or proteid of the species suspected in the unknown is established. If the result is negative, the species to which the unknown specimen belongs has to be determined with the aid of new antisera prepared

for each species, and employed in the manner above described.

No test is to be regarded as positive unless, as in the preliminary tests of the immune serum, the beginning of the reaction manifests itself within, at the most, one or two minutes after the addition of the immune serum as a faint, misty cloud at the bottom of the test-tube; and within five minutes, at room temperature, this must become a thick woolly cloud. At the end of another ten minutes a definite precipitate must have formed.

Any cloudiness which develops later than twenty minutes after the beginning of the reaction has no significance. It is to be noted further that the tubes *must not be shaken* during the performance of the test.

If the reaction is carried out as above described, no heterologous reactions occur. The clouding, in other words, is very strictly specific, as Nuttall has shown on the basis of 16,000 blood-tests. Only as between very closely related species—horse and ass, sheep and goats, dog and fox—can any doubt possibly arise. Beef blood and sheep's blood are readily distinguished.

The reaction can be obtained from blood in an advanced state of putrefaction, or from a clot which has been dried for a year.

DESCRIPTION OF CASES IN WHICH THE PRECIPITIN TEST WAS USED.

The first case in which the precipitin test for human blood was used was of the State of Maryland vs. Norman Mabel and James Parroway, which was tried in the circuit court for Cecil County on Wednesday, the 4th of March, 1914. The testimony showed that a brutal murder had been committed upon a well-known white citizen living near Salisbury in Wicomico County. In travelling from the country store to his home the victim was waylaid by the two negroes and struck over the head several times with a corn planter, the assault resulting in the death of this man. A great deal of blood flowed from the wounds of the head, and some of the garments of the suspected murderers were brought to the laboratory for examination. A spot of blood on a button of the left sleeve of the coat of one of the murderers was detected by means of the usual chemical and micro-chemical tests, and 0.4 of a milligram of the blood was scraped from the button and accurately diluted so as to make a dilution of 1-1000, 1-10,000 and 1-20,000. The first dilution was also used as a color comparison for the second test in which no accurate weighings could be made. A spot of blood was also detected on the overalls of one of the murderers, and this spot was cut out and soaked in 2 cc. of salt solution and then diluted to the color of the weighed solution from the button, which equalled a dilution of 1-1000. Other dilutions equalling 1-10,000 and 1-20,000 were then made from this original dilution.

The technic, as described above, was then carried out, including the control tests recommended, and the dilutions of 1-1000 of suspected human blood, as well as the controls, gave a distinct clouding within about two minutes and were distinct at the end of thirty minutes. The higher dilution of 1-10,000 showed a beginning precipitum in about five minutes and was well marked at the end of thirty minutes. The tests were made at the usual room temperature.

The murder was committed for the sake of robbery and about fifty dollars were taken from an envelope found in the inside coat pocket of the victim. His coat was extensively stained with blood, and the envelope addressed to him was found at a short distance from the site of the crime. Dilutions of 1-1000, 1-10,000 and 1-20,000, were made by soaking the blood-stained paper of the envelope in salt solution and comparing the lowest dilution by color to the weighed solution of dried blood of 1-1000. The dilution of 1-1000 and 1-10,000 gave a positive precipitin test, as described above.

In giving the testimony it was admitted that the test might be positive if the blood had been from some of the higher orders of apes, but with that exception the opinion was given that the test was positive for human blood. The finding of blood stains on the button of the coat and the overalls of one of the suspected criminals was considered as important evidence, and the man was convicted of murder and received a long term sentence, but was not hanged.

This murder had stirred up great feeling in the town of Salisbury and a mob attacked the jail and attempted to remove the prisoners. This attempt was thwarted, however, and the prisoners were removed to another county for safe keeping and trial.

While public opinion was still seething, a white woman living just outside of Salisbury reported to the police authorities that while alone in her house she had been attacked by a colored man, who had then made away with a few trifling articles, having not been able to find any money or valuables. Upon investigation the doorpost, the threshold of the door, a satchel and various other articles were found smeared with blood and the woman claimed that she had defended herself with a knife and had inflicted certain wounds upon the negro, who then escaped. It should be mentioned that the woman was married, that her husband was absent from home and had been used to leaving her in the house in a lonely part of the country upon various other occasions. The wood from the door, the blood-stained satchel, a blood-stained corn-cob, and a blood-stained knife were brought to the laboratory for examination, and the usual tests soon demonstrated the presence of blood upon all of these materials. Some of the blood, however, was dissolved in normal salt solution

and examined. Somewhat to our surprise it was found that a number of the shriveled corpuscles contained nuclei, and this was confirmed by stained specimens. It was thought probable that the blood might be from a chicken, and rabbits were immunized with chicken blood. When the blood serum of an immunized rabbit had attained a strength sufficient to produce a precipitin reaction in a dilution of 1-20,000 the blood from these various materials was tested in the usual dilutions of 1-1000, 1-10,000 and 1-20,000. They all gave a marked reaction with the blood serum of the rabbit immunized with chicken blood, and the opinion was then expressed that the blood did not come from a human being but was chicken blood.

There had been a great deal of excitement amongst the public concerning this second alleged criminal attack, but when the woman was confronted with the evidence she admitted that she had staged a murder in order to keep her husband at home, as she thought that such an experience might make him more apprehensive concerning her safety in the future.

No further attempts, therefore, were made to apprehend the criminal, the public excitement subsided, and the husband presumably no longer strayed from his own fireside.

In connection with the above cases we tested some other specimens of blood with the immune serum made from the chicken's blood. These specimens were taken from several different orders of the Aves, including the pigeon, goose and duck. When dried blood was used and the dilution by weight was made, all of these specimens gave strong reactions at a dilution of 1-1000. The specimen from the goose gave a moderate reaction in a dilution of 1-10,000 and those from the duck and pigeon gave a slight reaction with this dilution. When blood serum was used instead of the dried blood the dilution was of course four times as weak, as blood loses three-fourths of its weight in drying. In this case the chicken serum with its homologous serum gave a strong reaction at a dilution of 1-100 and a moderate reaction at a dilution of 1-1000, and this result was also obtained when turkey serum was tested. When duck serum was tested the reaction was strong at 1-100 and weak at 1-1000 and when duck and pigeon sera were used the reaction was moderate at 1-100 and weak at 1-1000. It can be seen from these experiments that there is a well marked group reaction present amongst these different orders of the Aves.

The third case in which the precipitin test was used was carried out by Mr. W. A. Gunther, Director of the Co-operative Laboratory of the State Department of Health in the first sanitary district at Cumberland, Md., and we are indebted to him for the following information:

On the evening of November 26, 1915, Watson Howell was killed, or committed suicide, in a

saloon located at Reynolds. The state claimed that Howell at six o'clock in the evening was perfectly sober and was found three hours later with a bullet hole in his head, and his face and head covered with bruises and abrasions. They also claimed that the body had been moved for some distance from the spot where it fell, and this was denied by two men present in the saloon at the time, who claimed that they were asleep at the time of the shooting, which awakened them. There was a smear of blood about six feet long on the floor at the place where the man's head was lying. Scrapings of the blood stains were taken one foot apart, and dilutions of antihuman serum from 1-1000 to 1-20,000 were used. The highest dilution which gave a positive reaction was 1-16,000. The possibility of the blood having come from anthropoid apes was admitted, but with this exception it was testified that the blood must have been of human origin. The testimony was admitted as evidence, but the accused was acquitted.

The data upon the last case were also furnished by Mr. Gunther. Tony Mino was accused of having stabbed Carmelo Manone on August 17 in the subway of the Western Maryland Railroad at Cumberland. The victim died within twenty-four hours, and the prisoner was soon captured by bloodhounds. A stiletto was found about fifty feet from the place of capture. The prisoner's coat and cap contained a number of spots which gave the usual tests for blood. The highest dilution at which a positive precipitin reaction was obtained with antihuman serum was 1-9000, but the statement was made that the blood was either that from a highly organized ape or from a human being. The prisoner was convicted and sentenced to eighteen years in the penitentiary.

CONCLUSIONS.

The precipitin test for the detection of human blood is highly specific, and the work of Nuttall shows that anti-human serum even in as low a dilution as 1-100 will cause a reaction only in the presence of human blood or that of certain higher types of apes. There is some difference in the dilutions which have been recommended by various workers, but the dilutions of 1-1000, 1-5000, and 1-10,000, as recommended by Kolmer¹³ would seem to be reliable indications of the presence of human blood or that of highly organized apes. This is usually satisfactory for use in criminal cases, but an occasion might arise in which it would be necessary to distinguish between monkey and human blood. For this reason it seems desirable that an accurate set of experiments should be performed in order to ascertain, if possible, a dilution of anti-human serum which is always positive for human blood and always negative for the blood of apes. It is true that Sutherland believes that the latter can be differentiated from human blood by the fact that the reaction

will not appear until after twenty minutes, but this should be confirmed and the conclusion would certainly be strengthened by invariable differences of dilution between human and ape's blood. Dried blood should be used for making such tests as it is practically always the only kind obtainable in criminal cases.

SYPHILIS IN INTERNAL MEDICINE.

BY WILLIAM P. BOARDMAN, M.D., BOSTON.

In order to emphasize its frequency, it may be well to call attention to some of the statistics in regard to the prevalence of syphilis in general. Whitney,¹ in San Francisco, found 6.9% of the patients attending the out-patient clinics of one hospital infected in a series of 7885 patients. Symmers,² in New York City, found syphilis in 6.5% of autopsies in a series of 4880 done at Bellevue. Of Whitney's cases, 21.8% were found in the medical clinic and 22.6% in the nerve clinic, so that nearly a half of the cases were affected with internal syphilis. I shall consider in this paper very briefly the facts concerning syphilis of the cardiovascular and renal systems, the respiratory system, and the digestive system.

HEART AND BLOOD VESSELS.

Symmers found aortitis in 56% of autopsies on syphilitics, or more than in any other organ of the body and a quarter of these showed involvement of the coronary arteries. Lenz³ states that 25% of syphilitic patients in large cities die of aortitis or myocarditis or their results as against three or four per cent. from general paresis. Brooks⁴ states that 60% of his luetic cases die from or with serious circulatory diseases, apparently of syphilitic origin. On the other hand, Herz,⁵ in 2000 cardiovascular cases in his private practice, where Wassermanns are not possible in many cases and where direct questions in regard to syphilitic infection were not made frequently for social reasons, found 15% showed probable syphilitic etiology.

In regard to the pathology, the lesions in the heart may be pericardial, myocardial, or endocardial, always starting around the arterioles.

Pericardial syphilis is usually fibrous, involving, in some cases, small patches and sometimes the whole sac. This may show scars later resembling the ordinary white patches and sometimes leaves an adherent pericardium. Pericarditis not infrequently is noted clinically in early syphilis, though usually it is not important. In the heart muscle Warthin⁶ has shown that spirochetes can be demonstrated, causing every variety of parenchymatous change and, also, which is more frequent in the late-acquired syphilis, interstitial changes, always starting about the coronary arterioles, either as an arteritis or a periarteritis and going on to a fibrosis. There may be true gummata of the heart wall, but these are rare. In endocardial inflammation due to syphilis the left ventricle and septum are more commonly involved than the valve cusps and, of the valves, the aortic is the one usually involved. Signs of mitral leak are more often due in these cases to a muscular insufficiency. In the large blood vessels, as the aorta, the disease begins around the terminations of the vasa vasorum and causes a mesarteritis and periarteritis with breaking up of the elastic tissue of the media and consequent weakening of the wall, which makes a starting-place for a dilatation. In the small vessels endarteritis and periarteritis are the lesions found, the former leading to sclerosis and obliteration of the vessels. The arteries most commonly involved are the cerebral, coronary and the aorta. The latter is usually affected in its ascending part, preferably about the sinuses of Valsalva, which means probable involvement of the aortic cusps and mouths of the coronaries secondarily. Grossly, the artery wall shows gelatinous, translucent-looking areas over the places where the intima is destroyed. Later lesions show wrinkling and puckering of the intima over the fibrous media, often in radiating lines. The cerebral arteries, and especially the circle of Willis, are very frequent seats of the periarterial changes, which cause miliary aneurysms.

The time of onset of the arterial and cardiac lesions may be very early. Brooks⁷ has notes of 24 cases in the secondary period, one before the appearance of the secondary rash. Three of these were fatal. Fordyce,⁸ also, has collected several fatal cases in this period and he is of the opinion that, in the secondary period, when the body is overrun with spirochetes, some are lodged here and form the nidus for lesions which usually do not appear, clinically, until years later, usually from 47 to 49 years of age. Stadler and others give the average as twenty years after infection.

In regard to symptoms, in the early cases, irregularity of no definite type, and rapidity of action on slight exertion or apprehension, are often seen in secondary syphilis. Pain and tenderness on deep pressure over the pericardium are common. Irregularity of force and rhythm of the pulse, but no rise of blood pressure, unless renal

or other complications ensue, are frequent. All these lesions are seen in other acute infectious diseases without organic changes in the cardiovascular system, but from a few of them that have come to autopsy Brooks and Fordyce are of the opinion that these slight signs may be the outward signs of beginning trouble. Systolic murmurs, also, are common at this period, 40% of secondary cases, according to Grossman.⁹ Some of these cases may become serious, as before stated, and the following is an example:—

Male, age 30. P. H. Attacks of acute rheumatism for past nine years, frequently following tonsillitis, but up to beginning of present illness never any cardiac signs or symptoms. Present illness. Two months ago sore throat and general malaise with severe pains in joints generally. One week later, typical intense syphilitic rash appeared with severe headaches and general glandular enlargement. Induration found along urethra about $\frac{3}{4}$ inch from meatus. Wassermann strongly positive. Two weeks ago, day following third injection of salvarsan and after patient had received four doses of mercury salicylate intramuscularly, patient had chills, cough and pain in chest. Condition grew worse and on admission had to-and-fro murmur all over precordia. Two days later precordial sound had disappeared and there were signs of fluid in the pericardium. Patient was dangerously ill with septic temperature, gallop rhythm, and pulse 140 to 150. Under treatment with mercury, however, the friction sounds reappeared and the signs of fluid gradually disappeared and in two months he was discharged showing nothing abnormal in the heart on physical examination. It is fair to say that the patient received the best of hygienic and medical care with the usual cardiac remedies, but I think that Dr. T. F. Leen, under whose care he was for the cardiac trouble, agrees that, without the aid of antisyphilitic remedies, the patient would have died.

Later in the disease, in the so-called tertiary period, substernal pressure and pain are the most frequent initial symptoms of trouble in the aorta or heart. But frequently the disease of the coronaries causes sudden blocking of the vessel, or an acute dilatation, or rupture of a previously weak myocardium occurs and sudden death ensues with practically no premonitory symptoms. If the cerebral arteries are affected, there may be sudden vertigo or confused mental state, or loss of function of speech, or a weakness of the arm or hand or one foot due to changes in the circulation. If this has been the cause, rather than a complete rupture of the vessel, the circulation is often restored with complete restoration of function. Such a case is the following:—

Male, age 29. Infection 10 years ago. Treated six weeks. Tertiary lesion of throat one year ago. At that time started treatment again and took four full doses of salvarsan and courses of mercury salicylate until March, after which he neglected treatment again. Sept. 16th, while at work as a club steward, sudden motor aphasia with weakness of right hand grasp. Under inunctions of mercury and iodide of potash prescribed by his family doc-

tor, Dr. W. A. Griffin, who had previously referred the case to me, he recovered absolutely and was back to work in two weeks.

The following is a case where there was a rupture of the artery:—

Male, age 25. Seen at the City Hospital out-patient department last May. Patient was an old case, having had a short course of treatment a couple of years before when he had a secondary rash. Came to the out-patient department on account of headaches, which appeared to be syphilitic from the story. He was given a prescription for inunctions of mercury. On his way home he stopped at the L. St. Bath House and while there dropped dead. At autopsy by the medical examiner, Dr. Leary, a haemorrhage, filling the ventricles and covering a large part of one side of the cortex, was found arising from a ruptured miliary aneurysm at the base of the brain, about 2 mm. in diameter.

The circle of Willis is such a complete anastomosis that if these arteries are slowly shut off there may be no symptoms or only transitory disturbance of function, as is shown post mortem where the basilar artery may be completely occluded without any history of disturbance during life. A sudden blocking of any of these arteries, on the other hand, is necessarily always fatal. Another thing to be remembered in these cerebral cases is the fact that the lesions may be multiple and, after the patient has had one attack, he may be liable to have another under sudden mental strain. In the cardiac and the aortic cases, as the lesions progress, the symptoms develop according to the particular part affected, and they differ in no way from the same lesions—myocarditis, angina pectoris, aortitis, with involvement of the aortic valves and consequent regurgitations, or aneurysm of the heart or aorta—due to other etiological factors than syphilis. Certain lesions, however, are more common in syphilis than as a result of other infectious diseases. Aneurysm of the arch of the aorta is almost invariably due to syphilis. Fordyce recalls but one instance where he could ascribe it to other causes. Other authors vary on this point, some claiming that around 80% are due to syphilis, while others maintain that an aneurysm of the arch is *prima facie* evidence of syphilis. In my own experience, I have not met with a definite aneurysm of the aortic arch, with a negative Wassermann reaction. A roughening of the aorta with practically no enlargement of the heart and very little, if any, general arteriosclerosis, is usually of syphilitic origin. Heart block is nearly always due to syphilitic interstitial or gummatous disease of the Bundle of His. Brooks found that 70% of his cases of heart syphilis coming to autopsy showed valvular lesions, mostly of the aortic valve, but fairly often the mitral was also involved. He did not see any case where the mitral was involved without the aortic, however. The symptoms which all writers connect particularly

with syphilis are tachycardia and irregularity of the heart, the latter being just "irregularly irregular," as Brooks describes it, without any type whatever. Pain under the sternum and substernal tenderness after slight exertion are also particularly common and usually denote coronary disease or myocardial dilatation. With the x-ray we generally find a broadened aortic arch, and sometimes one part of it is slightly more dilated than the rest. The heart shadow is also said to be broadened in many cases. In aneurysm of the arch due to syphilis, the heart shadow is also lengthened and Friedländer¹⁰ considers a characteristic point, that the aneurysm of syphilis pulsates more markedly and the shadow is not so intense as in that due to ordinary sclerosis not due to syphilis; but I should imagine that this comparative difference would be hard to make out, and not of much practical value. The Wassermann reaction is practically always strongly positive in an aggressive case of cardiac syphilis, but some of the older ones, which are not showing anything more than a murmur, with compensation complete, may give a negative.

The venous system, also, is occasionally involved in acquired syphilis, but only rarely. Fordyce notes syphilitic thrombosis of the veins of the lower extremities. Friedländer mentions that nodular and general inflammatory changes of the venous walls, which appear to leave the lumen partly occluded by consequent puckering, may occur in any veins of the body, but the portal veins and their branches are the ones chiefly affected. The lumen of the vein is puckered, and around the vein is a gray, moist, translucent appearance fading gradually into the liver tissue.

DIAGNOSIS.

In early syphilis if care is taken to listen to the heart and note the pulse frequently, the appearance of a soft mitral systolic with irregular heart action and, perhaps, some tachycardia and substernal oppression after exercise, probably do not always mean cardiac syphilis, but they may be warnings enough to make us spare the heart in that patient by hygienic measures. Brooks has shown us, too, that these may mean real cardiovascular disease is present. In later syphilis, the problem is more difficult, from the fact that only about 30% of cardiac cases give a history of previous syphilis in hospital cases and probably less in private practice. Often the patient, thinking that the cardiac symptoms are so long delayed after the primary lesion, never imagines the connection and, unless directly questioned about syphilis, will fail to mention that he ever had it; but more frequently, in my experience, the patient is absolutely ignorant of ever having had any such trouble. As I have already shown, the cardiac lesion is only what we might find due to any other cause, except that aneurysm of the aortic arch and

heart block are almost always syphilitic. The age of the patient, usually between 40 and 50, frequently younger, is a little under that of the ordinary arteriosclerotic. The history may reveal another acute infectious disease, such as acute rheumatism or scarlatina or typhoid as an etiological factor. Brooks and others say that a cardiac or aortic lesion, developing without other known cause and without fever, and especially if combined with a positive Wassermann reaction, in a middle-aged person is probably syphilitic. In those cases where the Wassermann reaction is negative, a provocative injection of mercury salicylate or of salvarsan may develop a positive reaction. If still in doubt, and the patient is not doing well under ordinary cardiac treatment, no harm can be done by giving him the benefit of the therapeutic test, and this is the most surely to be relied upon of all. Care must be exercised in the interpretation of the Wassermann reaction in these cases, for this only means that the patient has syphilis and not that the particular lesion in the heart is necessarily syphilitic. This brings up another very important point in the diagnosis, namely: other signs of past or present syphilis in the patient, such as tibial nodes, obscure bone or joint lesions, enlarged liver, etc. Several authors have called attention to the frequency of combined cardiac and nervous syphilis, especially tabes. Lesser¹¹ in 91 autopsies on tabetics found aortic aneurysm 18 times. Others place the frequency of combined cardiovascular syphilis and tabes as about 6 to 10% of tabetics. The cardiac lesion may be present before the onset of the tabes, but it is usually noted about four and a half to five years after the first tabetic symptom.

TREATMENT.

All writers at present call attention to the necessity of protecting the heart in early syphilis from sudden or severe strain, as one would do in any other acute infectious disease, in order to avoid later heart complications. Fortunately, the treatment of the earlier lesions is, usually, pretty thoroughly carried out, for then there are other and very obvious symptoms of syphilis which make the patient follow up the physician's instructions. But too much stress cannot be laid on the fact that the treatment of syphilis which is given must be intensive and prolonged. In these early cases, outside of hygienic measures such as rest, cardiac medications such as digitalis, etc., are not needed and are better not employed.

In the later cases, one often meets with a patient in whom a thorough course of ordinary cardiac treatment, with rest in bed and digitalis and other cardiac remedies, has failed to establish compensation and the condition is pretty discouraging. It is just in such cases as this that we often see the most satisfactory improvement follow a course of intensive anti-syphilitic

treatment. If there is no immediate urgency, it is safer to commence with mercury, preferably injections of the insoluble salicylate of mercury, which is given once every five days or a week into the muscle. Inunctions do better in some cases, using the strong 50% ointment or one of its less disagreeable substitutes. In a week or two we may start with the salvarsan, which is more permanent in its beneficial effects and seems to cause no more serious collapse in these cardiac cases than the neosalvarsan, though the immediate effects of the latter may be just as striking in the way of relieving symptoms. Salvarsan should be used with great caution in these cardiac cases, beginning with a very small dose and increasing only after the effects are well borne. Most especially in cardiac cases with disease of the myocardium and irregular heart action must one use great caution with the first dose of salvarsan. Brooks reports two cases of nearly fatal collapse following the initial dose of salvarsan and I have seen one in consultation with Dr. A. D. MacLennan where salvarsan, given at my suggestion, was followed by a fatal result in a little over twenty-four hours, in a case of heart block. It is fair to state, however, that in my case the patient was nearly in *extremis* when the salvarsan was given and it was administered only in the forlorn hope that something might be done for the patient and it was evident that it must be done quickly if the life of the patient could be saved at all. In another such case I would suggest salvarsan but in a dose of only 0.1 or 0.15 g. In cardiovascular cases it seems to be better to give the doses of salvarsan far apart, continuing the mercury in the meantime. There seems to be no doubt that mercury alone will cure many cases of cardiac syphilis, but the addition of salvarsan surely does it with more speed and relieves the symptoms more quickly. It is also true that salvarsan alone will cure many of the earlier cases and possibly a few of the later ones, but it is too early to know of the permanency of these cures and, in the few where salvarsan has been used alone, its effects do not appear to be nearly so lasting as when it is backed up with an intensive course of mercury. If the case does not seem to improve under one form of mercury, it sometimes is advantageous to change to another. Anders¹² and Brooks both mention cases that after a while seemed to do pretty well on mercury by mouth, though these are rather the exception. As regards the duration of treatment with mercury and salvarsan, it is hard to lay down any rules. One should try, if possible, to get a negative Wassermann reaction and continue the mercury at least one year after this is obtained. But a negative reaction is sometimes not obtained at all, and if, after a couple of years, the reaction is not altered from the original strong positive, it may be better to give up and merely give an annual or a semi-annual

course of mercury to make sure that the disease does not return, provided that the limit of improvement seems to have been already obtained clinically. Often the patient seems to have become immune to the effects of mercury and it is, therefore, better to give it to the limit of tolerance and then stop for a while before giving any more.

The ordinary treatment with usual cardiac remedies should be in no way neglected, although they often do not seem to accomplish such definite results in these as in ordinary cardiac cases from other causes. In regard to iodides, the present idea is that they do not act in a specific sense, but merely absorb the products of inflammation and exudation after the cause has been removed by mercury and arsenic. From this point of view it is advised not to use them at first, but only after considerable treatment with mercury and arsenic. They do not need to be pushed very high, five to fifteen grains t. i. d. doing apparently as well as the larger doses. When once commenced they should be continued until their maximum effect is obtained, if any improvement is noticed, otherwise for a few months.

Now in regard to the prognosis in these cases. Under ordinary treatment the duration of life is usually about two years after the onset of symptoms. On the other hand, unless too far advanced, one can almost surely promise a prolongation of life by the specific treatment. In the secondary cases, with very rare exceptions, one can promise a cure in practically every case, regardless of the apparent hopelessness in some cases. In tertiary cases the inability to repair the heart muscle and the artery walls makes a cure impossible where much serious damage has been done. Post mortem, in a well treated case, one finds a fibrosis of the heart muscle, or an occluded coronary artery surrounded by fibrosis, or, if there has been a true aneurysm, this persists; and the same is true regarding serious damage to the valves, but, under the microscope, no active foci which can be diagnosed as syphilis and no spirochetes pallidæ are found. Clinically the results compare very favorably with treated gummata of the bones and other places and one can never tell how much irretrievable damage has been done until a thorough course of treatment, both with anti-syphilitic and ordinary cardiac remedies, has been tried. Good effects are often astonishing. Cases, however, where through neglecting treatment the symptoms have relapsed, do not as a rule respond so readily a second time. Where combined anti-syphilitic and cardiac remedies fail, the downward course is usually pretty rapid.

SYPHILIS OF THE KIDNEYS.

Albuminuria in early syphilis is by no means rare, but a true nephritis is very uncommon. Stokes,¹³ in the last year, has described a typical case of the latter. Early syphilitic nephri-

tis comes on about the fifth month of the disease on the average, though it has been reported before the appearance of the secondary rash. The condition starts in rather suddenly and is distinguished by the very large amount of albumin, with marked anemia and oedema. But outside of some general weakness there is comparatively little disturbance of the general health. There is often rather rapid loss of weight. Fournier states that the cases go on, in about 30%, to uremia, but other authors do not find this so frequent. Most writers say that they generally get well under treatment, though Bradford has noted frequent relapses with albuminuria. The urine in these cases is slightly diminished and shows a very large amount of albumin, many hyaline and granular casts, occasional epithelial casts, occasional red blood corpuscles and leucocytes. Stengel¹⁴ and Austin have made a careful study of the double refractive bodies described by Munk in syphilitic nephritis and find that they are pretty constant in the parenchymatous, but rarely occur in the interstitial forms. As this early nephritis is of the former variety, the findings of these bodies are noted, but as they also are found in a fair percentage of nephritis due to other causes, their significance would hardly be considered as great. Spirochetæ pallidæ have been noted in the urine of one of these cases, but this was not from a catheterized specimen. In later syphilis, Squier,¹⁵ in 186 autopsies on syphilitics, found 125 with renal lesions, amyloid 36, and gummata 6. Chronic interstitial and chronic parenchymatous nephritis, chiefly the former, are also found. Pathologically, in syphilitic nephritis, the chief characteristic is marked endarteritis with thickening of the connective tissue of the kidney and capsule (Fordyce). Spirochetæ pallidæ have not been demonstrated in the kidney. The diagnosis rests on the presence of a nephritis with a history of syphilis or a positive Wassermann reaction and the presence of syphilis elsewhere. There are very few cases, however, in which we can make a positive diagnosis of syphilitic nephritis without recourse to the therapeutic test. Barach¹⁶ reports several cases in which the albumin has disappeared, even in cases where it has existed for three years or longer before treatment. I have seen two such cases where the albumin has disappeared under the use of salvarsan. In my opinion, some of those which do not react to anti-syphilitic treatment are really due to syphilis, directly or indirectly, but there is no way of proving this. The treatment is by salvarsan given cautiously and in small doses, followed by mercury and the iodides. The physiological dose of mercury and salvarsan must be learned by trial on the particular case, as Stokes has shown that the proper amount can easily be overstepped and an increase of the albuminuria and suppression of the urine, with a return of the œdema, are produced.

SYPHILIS OF THE RESPIRATORY SYSTEM.

Mucous patches of the trachea are seen and a bronchitis, occurring in early syphilis and responding quickly to anti-syphilitic treatment, is probably a similar process in the bronchi; but secondary lesions of the lung are unknown. Tertiary lesions of the trachea and bronchi (gummata of the submucous tissue) are not uncommon and may lead to ulceration or cicatricial stenosis. Tertiary syphilis of the lung is very rare, according to the pathologist, but not so uncommon, according to the clinician. Clayton¹⁷ has analyzed the cases and says that they can be grouped into three classes:— 1. Gummata, which may occur anywhere but are most frequently situated near the root of the lung, and especially of the right lung and in the middle lobe. Some authors claim that these may break down in the center and discharge into the bronchi leaving cavities, but surely the more common change is into fibrous tissue with broad bands extending out into the lung. 2. A so-called syphilitic pneumonia which consists of an infiltration that may extend over the entire lobe and in which the blood vessels are much thickened. 3. What is, apparently, a later process of the preceding, fibroid induration, which consists of a proliferation of connective tissue starting around the root and extending around the bronchi and blood vessels, or occurring as nodules of fibrous tissue in other parts of the lung until the whole lung may be involved. Clayton does not believe that a case of true syphilitic phthisis, meaning a progressive destructive disease with cavity formation, has been proved. Bronchiectatic cavities are fairly frequent in syphilis of the lung and this fact aids a little in the diagnosis when they are found by the x-ray. Symptomatically, there is little difference between this condition and tuberculous of the lung. The fever is not so common and the hæmoptysis is rather rare, though several cases are reported. Levin reports one where this was the first symptom. The emaciation is usually not so marked. The duration for several years with a rather extensive process in the lung, especially if it is around the root of the lung, yet the patient does not show marked emaciation or poor nourishment, is a rather characteristic picture, and especially so when combined with an absence of T. B. in the sputum on repeated examinations, and with a positive Wassermann and other signs of syphilis elsewhere. The treatment is that of syphilis anywhere, but, according to the cases reported, if the lesion has existed for a very long time, results of treatment are unsatisfactory.

SYPHILIS OF THE GASTRO-INTESTINAL SYSTEM.

Symmers, in nearly 5000 autopsies, in which there were 314 cases showing signs of syphilis, found only seven cases of gastro-intestinal syphilis, of which only one was a lesion of the stom-

ach, and he considers gastric syphilis as very rare. Smithies, in 7545 cases of gastro-intestinal affections, found 25 cases, or 0.34%, of gastric syphilis. Pathologically, syphilis of the stomach begins, according to Smithies, as a dense round-cell infiltration of the loose areolar tissue of the wall, frequently with endarteritis. This progresses by infiltrating the wall of the organ generally and causing a stiff, thickened wall, or it forms single or multiple gummata, which may ulcerate, or may form a large tumor which, if it goes on to cicatrization, may give an abnormal shape to the stomach or may cause a stenosis. Clinically, the patient may show only symptoms of chronic gastritis, but often there is a history resembling chronic ulcer of the stomach. Haematemesis is not an infrequent symptom in these cases and, in one case reported by Clark,¹⁹ it was the only symptom in a fatal case. Other cases resemble carcinoma of the stomach very closely. Smithies found the hydrochloric acid in these cases not diminished, but most authors consider achylia the rule. A palpable tumor frequently is felt. A rather curious fact in some of these cases is the persistence of a good appetite and less anemia and cachexia than one would expect from such an extensive process if it were due to carcinoma. Usually the loss of weight is only about twenty pounds, on an average, which is less than we would expect in advanced cancer of the stomach. X-ray shows only a tumor or ulcer or stenosis, which is not characteristic of syphilis. Usually the Wassermann reaction is strongly positive and Smithies considers that this is the only way that we can be sure of a diagnosis, but Einhorn and Eiselmann²⁰ report cases with a negative reaction. Three cases which I have seen had positive reactions and were clinically indistinguishable from cancer, so that the blood test was the only symptom which led to anti-syphilitic treatment, the effects of which were remarkably satisfactory in all three. The treatment is that of late syphilis anywhere, as these cases are almost always tertiary. In Smithies' 26 cases, the results generally were pretty satisfactory, though recurrences must be guarded against in giving a prognosis. Only four of his cases remain cured over a period of three years and three of the cases show no improvement whatever. In these latter cases it would seem as if there were some surgical condition present such as stenosis, or there may have been mistaken diagnosis. Hayem and Niles both report cases which were cured very quickly by anti-syphilitic treatment.

Syphilis of the intestines is rare, with nothing to characterize it as syphilitic. Symmers found one ulcer of the cecum in his series of autopsies and four cases of syphilitic stenosis of the rectum. The latter is more common in women. Another interesting lesion noted by Fordyce²¹ is a proctitis involving the surrounding tissue to such an extent that it resembled a tumor of the adjacent fascia.

SYPHILIS OF THE LIVER.

This is fairly frequent, occurring 142 times in 5088 autopsies done by Fordyce. Symmers in 314 autopsies on syphilids found the liver involved in 105 cases (33.4%). Nearly one half of these cases were the so-called hepar-lobatum which appears to be more common in negroes and in women. In this condition the liver is separated grossly into numerous small lobules by scars and bands formed of fibrous tissue caused by syphilitic inflammatory changes resulting in an over-production of connective tissue. The spleen often is enlarged, also, in these cases. Clinically they are, practically, indistinguishable from cirrhosis due to alcohol. Gumma of the liver also is a fairly frequent result of syphilis. Usually they are multiple and the most common site is under the capsule on the anterior surface, where they are easily palpable. Amyloid resulting from syphilis gives a large, smooth liver clinically and, in the presence of other lesions elsewhere, is fairly frequently recognized during life. Perihepatitis, with fibrous adhesions to all the neighboring organs, is still another variety of the results of late syphilis. This may go on, as in one of my own cases, to adhesions throughout the abdomen which are most intractable to any form of treatment. In early syphilis we have a lesion which has attracted considerable attention in the last few years, namely, a parenchymatous hepatitis, similar to the parenchymatous changes in the kidney in early syphilis. Michael²² has shown that they are true syphilitic changes and not due to pressure on the gall ducts, as was formerly maintained. This process may be very acute and go on rapidly to acute yellow atrophy and death, as in one of our cases at the Carney Hospital, or it may clear up with the formation of connective tissue and resulting cirrhosis. Clinically, the liver is enlarged and somewhat tender, but in the very acute cases the size is diminished. The jaundice is intense, the stools may or may not be clay colored, usually not, and the gastro-intestinal symptoms are usually mild, consisting of nausea and occasional vomiting, resulting probably from the icterus.

A good many cases have been reported in the last few years during or following treatment with salvarsan and neosalvarsan. At first these were supposed to be due to the toxic effects of the arsenic, but Milian²³ has shown pretty conclusively that they really are always syphilitic, corresponding to a Herxheimer reaction or to the nerve recurrences which were so much discussed a few years ago. They all improve with more mercury and salvarsan.

SYPHILIS OF THE SPLEEN.

During the secondary stage the spleen is very frequently enlarged, often accompanied by asthenia and fever. Later we find changes similar to those in the liver, namely: interstitial

splenitis, at first with an enlarged spleen and, later, as the contraction of the connective tissue goes on, a small spleen; amyloid spleen; also multiple gummata. Perisplenitis is rather more common than perihepatitis, though the two often are combined. Clark²⁴ has described a case, with splenomegaly and asthenia and anemia, which resembled a case of early Banti's disease, but which quickly cleared up under anti-syphilitic treatment.

SYPHILIS OF THE PANCREAS.

Warthin, after finding marked interstitial changes in the pancreas in seven autopsies on cases of diabetes in whom there were, also, syphilitic changes in the myocardium, made a further study of the pancreas in a large number of autopsies in cases of apparently latent syphilis and found no one of them showing a normal pancreas. All showed marked changes in the form of a diffuse or patchy fibrosis with active inflammatory foci, corresponding to the localization of the spirochetæ. This shows the necessity of investigating cases of diabetes thoroughly with reference to syphilis as a possible etiological factor. I have seen one case where the glycosuria cleared up quickly under anti-syphilitic treatment and several of these have been reported.

SYPHILITIC FEVER.

A few words about syphilitic fever do not seem to be out of place in a review of internal syphilis. A low grade of fever in early syphilis, generally at the outbreak of the rash or a little before it, is not uncommon. Fournier states that it occurs in about 20% of cases. The type may resemble that of rheumatic fever, especially when it is accompanied by pains in the bones and joints. Occasionally it simulates typhoid. This lasts only three or four days, and seldom goes above 100° F. Later, in the secondary stage, usually in combination with other complications, a more prolonged fever occasionally is observed which goes higher and lasts for some time. In tertiary syphilis there may be prolonged fever or short attacks of fever. These are especially noticed in syphilis of the liver. Febrile attacks in general paresis, from no apparent cause, are quite frequent. Kraus²⁵ maintains that these late fevers are due to the entrance of spirochetæ into the blood stream. Taussig²⁶ claims that they are due to the entrance into the blood stream of endotoxins and dead bacteria, analogous to the fevers seen after a dose of salvarsan.

A COMPARISON OF SEVERAL METHODS OF SPECIFIC EARLY TREATMENT OF ACUTE ANTERIOR POLIOMYELITIS.

BY HELMUTH ULRICH, M.D., BOSTON.

Research Associate in the Evans Memorial for Clinical Research and Preventive Medicine.

[From the Evans Memorial for Clinical Research and Preventive Medicine and the Haynes Memorial for Contagious Diseases, Boston.]

OF the cases of acute anterior poliomyelitis that came to the Haynes Memorial Hospital during the recent epidemic, 120 are included in this comparative study. They are divided into six groups: Group I was treated with three intraspinal injections of immune serum; Group II was treated similarly with normal serum; cases of Group III were injected with their own spinal fluids (autotherapy—Duncan); Group IV comprised cases on which the effect of simple withdrawal of spinal fluid was tested; Group V received no specific treatment; Group VI includes cases of which one was of doubtful diagnosis, one died of pneumonia, and the others were moribund on admission.

1. The use of immune serum followed the discovery by Flexner and Lewis¹ that experimental poliomyelitis in monkeys produced immunity against reinfection. This resistance was found by Römer and Joseph² to be due to immune substances in the monkey's blood.

This immune body has the power of neutralizing the virus of poliomyelitis *in vitro*. It was furthermore found³ that serum from recovered human cases possessed curative or, at least, prophylactic properties if injected into monkeys within twenty-four hours after they had received an injection of virus. The treated animals did not develop the disease, whereas the control animals did.

The first application of this experimental knowledge in the treatment of human cases was made by Netter,⁴ who treated thirty-two cases by intraspinal injection of the immune serum.

He gave usually eight successive daily injections and obtained his serum from cases who had recovered from the acute stage three weeks to many years previously. He feels that the serum is decidedly beneficial, especially if treatment is begun before the fourth day of the paralysis.

Sophian⁶ treated four cases and was favorably impressed with the results obtained. Wells⁹ reports 15 cases, some of which received the serum intraspinally, others intravenously, and still others intramuscularly. He gives his results as either death or "recovery," and feels that the serum has been beneficial, especially when given intravenously in large doses and followed by withdrawal of spinal fluid. Four deaths out of the fifteen cases, a percentage of 26.7, is hardly to be considered encouraging. At any rate, the number of cases is too small and is not controlled by untreated cases, so that no unassailable conclusions are possible.

Zingher⁷ feels that immune serum is useful, particularly when given in the preparalytic stage. He is not so sure, however, of the results obtained if the serum is applied after the development of paralysis, stating that "it is difficult to forecast. . . what the natural result of the disease would have been in these cases."

Amoss and Chesney⁸ report 26 cases in considerable detail. Twelve of them received immune serum after paralysis had developed, and fourteen were injected during the preparalytic stage. Of the twelve paralytic cases, one died ten hours after the serum injection, two showed extension of paralysis, and in the remainder the paralysis receded. The authors do not seem to be very enthusiastic over these results. Needless to say, a parallel series with similar results could easily be drawn up from untreated cases. The preparalytic cases will be discussed later.

LeBoutillier⁹ believes that immune serum therapy is productive of some good "if used on the first or second day of the acute paralytic stage in doses ranging from 5 to 15, or even 30 cc., either intraspinally, intravenously, or intramuscularly." The number of cases treated by him, and other information essential for a correct estimate of the value of his conclusions, are not given.

Roby¹⁰ gave intramuscular injections of coalescents' whole blood to one case and of normal blood to two cases. He frankly says that no conclusions can be drawn from so few cases.

2. *Normal serum*, either human or animal, is supposed to exert a beneficial effect by the excitation of a polynuclear leucocytosis in the spinal fluid. Sophian⁵ used horse serum in ten cases. He compares the results with those obtained in four cases receiving immune serum, and concludes that horse serum is at least as efficient as immune serum. No untreated controls are cited by him, so that, in spite of his small number of cases, he may have determined that horse serum and immune serum are equally

efficient, but he cannot be said to have proved the value of either. Place¹¹ reports having used horse serum, as well as salvarsanized and mercurialized sera at the Boston City Hospital, without apparent beneficial results. LeBoutillier,⁹ too, considers normal serum useless.

Zingher,⁷ on the other hand, recommends normal serum, although he considers it less valuable than immune serum.

3. The subcutaneous *re-injection of the patient's own spinal fluid* is recommended by Duneau,¹² and is based upon alleged good results obtained from the use of the method in the treatment of cerebrospinal meningitis.

4. Simple repeated *withdrawal of spinal fluid* to reduce pressure was advocated by Römer and also by Koplik. Wynkoop¹³ states that it is of immediate benefit before the onset of paralysis if the spinal fluid pressure is increased, and LeBoutillier⁹ claims that it will relieve pain in a large percentage of cases.

Aside from the methods used in this study, two others deserve mention, although I have no experience with them. One is the administration of hexamethylenamin or urotropin, recommended by Flexner¹⁴ as being the "only drug which has shown any useful degree of activity." Fraser,¹⁵ however, after treating 22 cases by giving 0.3 gm. urotropin 3-4 times daily, states that in "no instance did this treatment appear to cut short the acute stage, and in no instance was there evidence of more satisfactory or more rapid recovery in the paralyzed parts." This result is in accord with the fact that hexamethylenamin acts as a germicide in an acid medium only, as, for instance, the urine, whereas the spinal fluid and blood are alkaline in reaction. Lovett is quoted by Barber¹⁶ as reporting three children of one family. "The first child received no hexamethylenamin, the second had a little, and the third had large doses from the beginning. The first child was severely paralyzed from the waist down, the second had weakness of the legs and back for a few months, and the third had no muscular involvement." Barber remarks that after "such an observation, its use early in suspected cases seems highly desirable," which again demonstrates the pernicious influence of drawing conclusions from too meager data. LeBoutillier⁹ abandoned it as useless after trying it for two and a half months.

Another method of drug therapy is the administration of adrenalin or epinephrin, of which Meltzer¹⁷ is the chief advocate. This preparation is given intraspinally to reduce the peri-inflammatory edema and active hyperemia. Lewis¹⁸ reports 77 cases treated in this way with results that led him to recommend its use. To the reader of his article the cause of his optimism is not made clear. Hoyne and Cepelka¹⁹ used epinephrin chlorid in several early cases and noticed immediate improvement in some of them. This, however, "was seldom

permanent, but gradual improvement in some cases seemed to be more rapid." Place¹¹ reported using the drug without favorable results, and Le Boutillier⁹ considers his own results questionable, because it seemed to him impossible to have the solution reach the upper part of the cord if the lesion was high. Nevertheless, he recommends its use until a better method is found, and feels that in combination and alternation with immune serum, it is beneficial. If the drug is of use, it probably finds its sphere of usefulness in the prevention of fleeting paralysis, especially of the respiratory centers, due to simple hyperemic pressure, rather than in exerting an influence upon paralysis caused by direct affection of nerve cells.

The appended tables, giving a few important facts about the cases at the Haynes Memorial, need practically no explanation. The results are tabulated under the headings: died, not improved, slightly, moderately, or markedly improved. *Table I* contains 20 cases treated with "immune" serum. The amount of serum injected varied from 2.5 to 15 cc. per dose. The donors were individuals who had recovered from the acute stage of the disease two weeks to five years previously.

Table II shows 16 cases who received normal serum intraspinaly. The amount of serum injected varied from 0.5 to 13 cc. Polynucleosis, which is supposed to be the cause of any benefit derived from this procedure, was found in all cases after the serum injection, ranging from over 100 to between 4000 and 5000 per cmm. (Immune serum gave the same reaction.)

Table III comprises 20 cases treated with autotherapy. The spinal fluid was reinjected immediately after withdrawal. The site of the injection was the subcutaneous tissue over the seventh rib in the posterior axillary line. With the exception of an occasional larger dose (to 7 cc.) in some of the older patients and a few smaller doses (as low as 1 cc.), when the amount of fluid obtained was no larger, the dose was 5 cc.

Table IV contains 20 cases, each treated by three lumbar punctures at 24-hour intervals. The amount of fluid drawn per puncture varied from 0 to 30 cc.

Table V is made up of 28 cases, untreated except for general measures such as were accorded all others.

Table VI contains 14 cases, in one of which the diagnosis was doubtful, one died in three weeks of pneumonia, and the others died within 2 to 48 hours after admission.

The results recorded in these tables were nearly all observed at the end of six weeks, when most of the patients left the hospital. The immediate effects showed no apparent differences in the various series. A comparison of the results obtained shows, I think, that none of

the measures used had any favorable influence whatever upon the progress or outcome of a single case.

Whether or not treatment instituted before the appearance of paralytic symptoms is useful, remains to be determined. Flexner and Lewis³ were able to prevent the development of poliomyelitis in monkeys if they injected immune serum within 24 hours after the animals were infected. Since the incubation period averages eight days, it would seem that the time for effective serum treatment is long past when the first symptoms make their appearance. Furthermore, the mere failure of paralysis to develop after serum treatment can certainly not be adduced to prove the efficacy of this procedure, because many so-called abortive cases never develop paralysis and recover without treatment. It would be necessary to show that untreated cases go on to paralysis in greater numbers than do treated ones.

Zingher⁷ reports 54 preparalytic cases, treated with immune serum, of which only ten developed paralysis, whereas of twelve untreated cases, seven became paralytic. Opposed to this is a series of 24 preparalytic cases reported by Place,¹¹ sixteen of which were left untreated and eight got intraspinal "immune" serum. Three of the treated cases and only one of the untreated ones developed paralysis, showing that the serum treatment was certainly not capable of preventing this complication. Place stated that his series of cases was too small to serve as a basis for definite conclusions, and the same objection may be advanced against Zingher's twelve untreated cases. Zingher himself admits that it is not easy to state "how many of the patients treated with immune serum would have remained free from paralysis without serum treatment," and that the "results and the conclusions from any form of treatment in a disease which is so variable in symptomatology and in prognosis, both as to life and disability, must be given with reserve."

Of the fourteen cases treated in the preparalytic stage by Amoss and Chesney,⁶ two developed respiratory paralysis and died, two acquired partial paralysis of certain muscle groups, and ten recovered without paralysis. No controls are cited, so that the series is of little value, particularly in view of the better results observed by Place in his series of untreated preparalytics.

In conclusion, I would say that not only must the various measures employed in this study be looked upon as useless, at least after the onset of paralysis and under the conditions under which the investigation was carried out, but the manipulation of the sufferers necessarily attendant upon lumbar puncture causes great pain, and would seem to be permanently harmful in view of the great need of rest during the early stage of the disease.

TABLE I. TWENTY CASES TREATED WITH "JAIMI NE" SERUM.

TABULAR NUMBER	SERIAL NUMBER	NAME	AGE	PARALYSIS	AMOUNT INJECTED (cc.)			IMPROVEMENT

TECHNIC AND INTERPRETATION OF DENTAL ROENTGENOGRAMS.*

By HERBERT MCINTOSH, M.D., BOSTON.

DENTAL radiology is a special branch of the larger field of Roentgen diagnosis. For its successful pursuit it requires something of the special qualifications of the dentist—mechanical skill and deftness in working in contracted areas. There are difficulties which do not present themselves in other fields of x-ray diagnosis. A formidable difficulty, for instance, is the varying character of the surface against which the film is laid. Nothing varies more in different patients than the conformation of the palate against which the film must be laid when radiographing the teeth of the superior maxillary region. This necessitates a different position of the tube for each case, since it is necessary to avoid foreshortening or lengthening of the roentgenogram. As the problem of root canal fillings is one of great importance, and a never-failing source of anxiety to the dentist, it is necessary to furnish him correct data with regard to the size and direction of these canals. It can readily be seen that with roots foreshortened or lengthened the dentist may be misled, for instance, in determining the length of a root canal which, after several attempts at filling, may still remain unfilled.

A common source of error for the radiographer is to forget that the plane of the cheek is not exactly the plane of the tooth or the palate, though there is considerable correspondence between these planes in the skeleton. Where covered with muscle and other structures, these planes diverge somewhat more, though less than is commonly supposed. Where the plane of the film and that of the object to be radiographed diverge, the rule is to bisect the angle made by the plane of the film and that of the object, and so place the tube as to throw the rays at right angles to the bisecting line. The resulting radiograph represents the exact length of the object radiographed. Foreshortening and elongation of root canals are thus avoided.

A practical difficulty presents itself in the intolerance which many throats offer to the proper placing of the films. I have never found it necessary, however, to anesthetize the mouth and throat, patience and thoughtfulness usually enabling the operator to secure a satisfactory film.

I have never found film holders of any value whatever. The finger of the patient holds the film admirably in place, folds it into the desired position and keeps it there firmly. It is, of course, desirable that exposures should be brief to avoid movement resulting from breathing during the exposure. Movement obliterates the picture of the root canal, always of the greatest importance. Exposures lasting from three to

five seconds furnish excellent results. In my judgment the film should not be too rapid. Powerful generators and slow films produce the best results.

It is of great importance so to place the film in the mouth as to get a position well beyond the apices of the roots. Inflammation shows itself first generally at the foramen of the tooth.

In order to obtain fine detail in the dental film it is necessary to keep the vacuum in the tube low. As tubes tend with use to increase their resistance to the passage of the current, this is a consideration of the highest importance. High tubes produce a flat picture with little differentiation of detail. A dental roentgenogram is a miniature, and depends for its value upon accuracy and beauty of detail. A tube, therefore, with the best regulating device on the market and a rather fine focus will aid in securing the best results. The tube stand should furnish a small diaphragm and cylinder for dental roentgenography.

Plate pictures are of no value whatever in dental radiography, except under unusual conditions. The shadows are necessarily superimposed to a considerable extent, and distortion is unavoidable. They are, therefore, rarely employed in dental roentgenography.

Films should be mounted upon cardboard or celluloid of suitable size for filing in cabinets. Small view boxes for studying films by transmitted light can now be obtained from supply houses, and are convenient and serviceable.

A subject of much interest is stereoroentgenography of the teeth. To introduce the third dimension into a shadow picture is to separate the various levels, which otherwise lie upon a flat surface and furnish no data for determining their third dimension relation. For radiographs of other parts of the body this presents no great difficulty, since the plate being in a fixed position it is necessary only to change the position of the tube in order to get a second view. In the mouth, however, the film has to be withdrawn, and a second introduced in exactly the same position as the first without change of position of the head itself. This offers many practical difficulties, so that failure to secure satisfactory results is frequent. Successes are, however, possible, and when obtained very satisfactory. The relation of unerupted teeth, the position of roots and fillings and many other obscurities may be thus cleared up.

The discovery that so-called rheumatic conditions and other disturbances of metabolism may have their origin in focal infections at remote points in the body has directed attention to the teeth as one of the sources of these troubles, and the extensive roentgenography of the teeth, which has become a routine procedure with many physicians, makes the interpretation of dental films of very great importance. What is the significance of the dark areas so frequently found at

* Read before the New England Alumni Association of the New York City Medical College, April 18, 1917.

the roots of teeth? The healthy alveolus presents a mottled appearance due to the unequal deposit of lime salts. Where the alveolus has become unhealthy there is a dark area which entirely alters the picture. To what is this change due? We are always right in answering that it is due to absorption of the alveolar process. But we are not justified in answering always that it is due to the presence of pus. Here, I think, a serious error may arise, for while there may have been pus in the area at some time or other, it does not follow that there is pus now. Pus always produces absorption of the process, but if the infection has ceased, the destroyed area may show a dark spot on the film for perhaps a year or two years longer, until nature has infiltrated the tissues with the bony deposit.

Another error of interpretation may arise from the fact that the tissues through which the ray passes are of varying degrees of thickness, and produce occasionally dark areas which suggest an infective process. These occurring over the foramina of teeth may lead to errors of diagnosis. Thus the natural thinness of the lower edge of the mandible, the dark line of the inferior alveolar canal, the circular shadow of the mental foramen, the shadows above the floor of the antrum, and the dark areas above the superior incisors may mislead the untrained eye. Further confusion may result from the high lights produced by the edge of the zygomatic bone, sometimes simulating an unerupted tooth, and the coronoid process of the mandible appearing on the film just behind the third superior molar.

It is entirely probable that dark areas at the apices of teeth are, in many instances, due to the destructive effect upon the process resulting from arsenic employed in devitalizing pulps. A small quantity of arsenic runs out through the foramen, producing the same effect upon the alveolus as upon the pulp. This would mean necrosis, but without infection. On the other hand, a dark area at the apex of the root is undoubtedly due in many instances to an imperfect root canal filling. I hesitate to speak upon this subject because I recognize the extreme difficulty which confronts the dentist in the management of many of these cases of root canal fillings. Often the canal is twisted and curved, and many times so thread-like that it would seem impossible to carry a gutta percha point or other material to the foramen. And yet open and unfilled spaces are breeding-places for infective processes. No doubt in many instances these dark and infected areas are due to defective root canal fillings where there seem to be insuperable obstacles to the achievement of the end desired. Important as root canal filling is, there would seem to be ample justification for many failures, especially in the molar region.

In cases of pyorrhea alveolaris there can be no question as to the significance of these dark

areas. They are areas of infection due to diminished resistance of the alveolar process to the attack of the germs, which appear to be normally present at times in every mouth. The appearance which pyorrhea presents on the film is characteristic. It is not the apex that is here chiefly involved, but the whole process—the interdental spaces as well as the apices.

It is frequently possible to differentiate between an abscess and a necrotic condition of long standing by the shape of the dark area. An acute abscess is sharply marked off from the surrounding healthy tissue. A necrotic condition of long standing has ragged and irregular edges.

Enough has been said to point out the necessity for care in interpreting dental films. Dark areas are not always indicative of infection, nor do they in all cases point to the necessity for extraction, or even treatment. They ought to be considered in the light of all the facts which the intelligent radiographer can gather from a careful consideration of the case. Patients ought not to be lightly advised to submit to a complete extraction of their teeth. No artificial dentures can ever take the place of the teeth which nature has furnished, even if the latter are not perfect. Teeth may willingly be surrendered if they are undeniably the sources of infection, but the case ought to be fairly well made out before giving such counsel. Dental roentgenography may be regarded as a most valuable aid in reaching a final judgment upon a most important question. In reaching this judgment, skill in interpreting the film is quite as important as technic in taking it.

My purpose has been chiefly to warn against possibilities of error in the interpretation of dental films. I might add that an area of infection at the root of a tooth might coincide with a neuritis or an arthritis or a possible cachexia, and yet not be the cause of it. Here, as in the interpretation of dental films, a certain caution in reaching conclusions might well be exercised.

PREPARATION OF ANIMAL FOOD PROTEINS FOR ANAPHYLACTIC TESTS.*

BY R. P. WODEHOUSE AND J. M. D. OLMSTED, BOSTON.
[From the Medical Clinic of the Peter Bent Brigham Hospital, Boston.]

SINCE it is well known the proteins of some foods are frequently the cause of certain types of asthma and other anaphylactic diseases, and since by the application of the proteins from these foods by means of the skin test it is possible to determine the particular food which causes the disease, it is desirable to have for the skin test suitable preparations of all the foods that enter into the average diet. Such preparations must be in a form convenient to handle,

* These preparations were made for the "Studies on Bronchial Asthma" (Jour. Med. Res., 35, et seq.) at the Peter Bent Brigham Hospital, Boston.

and must also be as concentrated as possible, in order to make the tests certain. For preliminary tests, however, it is not necessary or even desirable to have the individual proteins, which occur in each of the foods, separated one from another. Otherwise, each food would have to be represented by three, four or often more individual proteins, thus greatly increasing the necessary number of tests to be made.

In order to produce the skin reaction, the proteins must be in a soluble form. Although many proteins become insoluble after being heated, this does not prevent the use of heat in making these preparations, because, as it has been shown, foods which ordinarily are eaten in a cooked condition give the skin test after being cooked for the table as well as or even better than when raw. Consequently, in making these preparations, from foods which are generally eaten in a cooked form, heat was applied in making the extracts. This, of course, entirely eliminated the heat coagulable proteins from these preparations unless they happened to be partly hydrolyzed by the cooking, in which case the products of hydrolysis would enter into the preparation.

No attempt was made to remove entirely other substances, because any lengthy process of purification would be liable to alter the nature of the proteins so that the preparations would not be the true anaphylactogenic representatives of the foods from which they were made.

It is necessary that preparations for this purpose should keep indefinitely, be convenient to handle and not be subject to putrefaction from air contaminations. For this reason they are dried and kept in the form of a powder.

For making these preparations the method used by the authors^{1, 2} in the preparation of vegetable food proteins was modified in such a way as to be adaptable to meat and fish, since it yields the proteins in a highly concentrated form, and the preparations made by it are anaphylactogenically representative of the foods in the form in which they are generally eaten.

In general the method is as follows. The material is ground very fine in a meat chopper and heated with approximately two volumes of water to 90° C. for one-half hour. The liquid is then strained off through cheesecloth and allowed to stand for a few days (using toluol as preservative); at the end of this time fats, if any, collect at the surface and are removed, the liquid is decanted from the sediment which usually settles out, and is filtered. Filtration is often slow and difficult on account of the gummy nature of the extracts. However, it is always possible to obtain eventually a clear or slightly opalescent filtrate. This filtrate is then exposed in large evaporating dishes upon the warm water bath before an electric fan until nearly dry (with chloroform as preservative). The result is usually a more or less hygroscopic gummy substance. This is then dissolved in as

small an amount of water as possible and added to three or four volumes of 95 per cent. alcohol. This always causes the formation of a gummy or even syrupy precipitate which, probably on account of the hygroscopic nature of the peptones contained in it, shows a great avidity for water. Dehydration, however, can be completed by boiling and triturating in absolute alcohol, acetone and ether. The thorough washing given in these reagents also serves to remove all fats, oils and waxes. In removing the proteins from the baths of alcohol, acetone and ether, centrifugation is used in preference to filtration, since the process can thus be completed in much less time and with much less exposure to the atmosphere. This is important on account of the extremely hygroscopic nature of most of these preparations which in the presence of alcohol or acetone take up water so freely that an exposure of a few minutes is sufficient to render them liquid again; in this regard the animal food proteins show strong contrast to the vegetable food proteins. After the last ether bath the protein is removed to a sulphuric acid desiccator and drying is completed *in vacuo*. The result is always a friable powder which is readily soluble in water or dilute alkali.

The animal foods which we have so far prepared by this method are the following:

Pork	Haddock	Mackerel
Beef	Cod	Lobster
Laub	Salmon	Oyster
Chicken	Halibut	Clam
		(long necked)

In making the preparation from oysters alone the general method was deviated from in that heat was not applied. The oysters were simply ground and macerated in cold water for several days (with toluol as preservative). This was deemed advisable, because oysters are eaten raw as often as cooked.

When chemical tests were applied to these preparations, it was found that all gave the ordinary protein color reactions. The biuret was always red or reddish, and the precipitation reactions such as are obtained with phosphomolybdic, phosphotungstic, trichloroacetic, picric acid, etc., indicated that in all cases the preparations consisted mainly of proteoses and peptones. No quantitative tests were made to determine the percentage of protein, but the qualitative tests showed that the proportion of protein in these preparations is very large.

This method of macerating the fish or meat in water, hot or cold, according to its nature, and precipitating the extract so obtained by alcohol, then thoroughly washing this precipitate in alcohol, and drying in absolute alcohol and ether, yields preparations which contain the protein in a form highly concentrated and representative of the food as it is generally used.

BODY TYPES IN EPILEPTICS.*

BY MORGAN B. HODSKINS, M.D., PALMER, MASS.,
Monson State Hospital.

I HAVE been much interested in the work of Dr. John Bryant and Dr. Joel E. Goldthwait in their study of body types and the relation of these types to disease, especially their possible relation to epilepsy.

Bryant divides the human family into three types: the carnivorous, the herbivorous and the normal. Goldthwait, in the Shattuck Lecture for 1915, described these types fully.

In the lecture just referred to, Goldthwait says, "The characteristics are equally apparent in childhood as in adult life." Therefore, the study was first undertaken on young patients, with the idea that they were better prospects for treatment. The oldest patient in this group was twenty-four years of age, the majority being between twelve and fifteen years of age.

There are one hundred and fifteen patients included in this study, which, on analysis, gave forty-seven carnivores, 40.8%; eight herbivores, 6%; and sixty normals, 52.1%.

The causes of the epilepsy in the carnivores, as determined by the clinical examination, are as follows:

Idiopathic, twenty-two; indigestion, seventeen; meningitis, four; diphtheria, two; hydrocephalus and alcohol poisoning, one each.

In the normal group the determined causes were: encephalitis, sixteen; meningitis, ten; cerebral hemorrhage, seven; birth injury, three; rachitis, six; blow on head, congenital syphilis, diphtheria, pneumonia and sunstroke, one each; measles, two; idiopathic, four; indigestion, seven.

On further analysis we find that, in the carnivorous group, 10% were due to organic causes, and in the normal group, 60%. In the carnivorous group we find six different factors to account for the onset in forty-seven cases. In the normals, thirteen factors account for sixty cases. Thirty-six per cent. of the carnivores and 48% of the normals had a hereditary tendency.

The average age at onset of the disease in the carnivorous group was 5.1 years, in the normals 2.85 years.

The group of eight herbivores was too small for profitable analysis.

Book Reviews.

The Epidemic of Poliomyelitis in New York City in 1916. Based on the Official Reports of the Bureaus of the Department of Health.

A monograph of four hundred pages which incorporates a series of extensive reports of the infantile paralysis epidemic of 1916 has been issued by the Department of Health of New York. Beginning with a historical sketch of the disease and proceeding with the record of the epidemic in this City, with a reference to the extent of its spread elsewhere in the United States, the report deals with every phase of the disease as seen by the Department of Health, in co-operation with other departments of City, State and Federal Government, and with many official and unofficial advisory groups and organizations. The data here presented will render possible the widest use of the observations of the officers of the Department of Health by those engaged in the study and practice of preventive medicine in general and this dreaded disease in particular.

The Starvation (Allen) Treatment of Diabetes, with a Series of Graduated Diets. By LEWIS WEBB HILL, M.D., AND RENA S. ECKMAN. Third Edition. Boston: W. M. Leonard, 1917.

THE first edition of this convenient manual of the newer treatment of diabetes was reviewed in the issue of the JOURNAL for October 7, 1915 (Vol. clxxiii, p. 551); and the second edition was reviewed in the issue for March 9, 1916 (Vol. clxxiv, p. 357). The appearance of this third edition within so short a time is evidence of the merited success with which the work has met.

The third edition has been generally revised and is increased by sixteen pages over the second. The diet lists and references have been rewritten and increased in number. The endeavor has been made to add such data as may increase the value of the book to physicians and patients. Particular attention is directed to the table presenting the analyses of diabetic foods done by the Connecticut Agricultural Experiment Station and exposing many of the foods, flours and meals advertised for diabetes as not only valueless but dangerous. The series of graduated diets has been completely revised and indexed; and in accordance with the latest advances in the knowledge of diabetes, most of these new diets contain less fat than there was in the old series, emphasizing the present belief in the important rôle played by a high fat intake in the production of acidosis. The book needs no introduction and may be expected to continue with increased efficiency its service to the profession.

Subscription Terms: \$5.00 per year, in advance, postage paid, for the United States. \$8.50 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, Manager,

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

A NEW THEORY OF DREAMS.

It has not been long since Dr. Freud startled the scientific world with his new system of psychology, in which the interpretation of dreams plays such a prominent part. Owing to the enthusiasm of the supporters of his dream theory and the ardency of its detractors, most physicians are quite well aware of its essentials. They are, briefly, that every dream is the representation of a repressed wish; that besides its actual manifest content, a dream has a latent content which must be discovered; that there are numerous psychic mechanisms at work in dreams,—repression, distortion, symbolism, condensation, etc. Besides Freud's original theory, some of his disciples and his followers have elaborated many variations of this. Thus Stekel sees death and bisexuality in every dream. Adler thinks it is a

representation of the individual's sense of inferiority, and Maeder holds that it has the function of indicating a solution of the conflict—in other words, of pointing out, in symbolic language, perhaps, the road out of the difficulty.

Just at this time it is instructive to hear the subject of dreams presented, not in order to make a violent attack upon the psychoanalytic school, but merely as an attempt to epitomize scientific knowledge. This has been done by Dr. Robert Armstrong-Jones, who gave the result of his studies in a recent address to the Abernethian Society as reported in the *Lancet* for November 25, 1916. After giving some attention to the historical aspect of the subject, he discusses the relation which dreams bear to the senses, finding that the majority of them relate to sight, and only a very small percentage of them to hearing, taste, and smell.

Dr. Armstrong-Jones considers that the characteristic feature of dreams, considering them as mental processes, is that the will is in abeyance, while cognition and feeling play prominent parts. These three factors, which he considers the *sine qua non* of mental processes, become dissociated then in dreams and the will refuses to act. This he holds in spite of the not uncommon assertion by certain persons that they can direct their dreams. Speaking briefly of the psychoanalytic dream theory, the lecturer held that the chief danger was in arbitrarily investing dreams with a ruling thought, such as sex, when in reality other instincts, such as fear, anger and hunger may just as commonly figure in them.

Dr. Armstrong-Jones believes that impressions and associations which had been discarded during our waking hours as not pertinent to our welfare, find their way into the sleeping life and by reason of the fact that they had been given no scrutiny during our waking hours present a vague, disconnected appearance. Thus the parts of the mind that have been occupied throughout the day with certain essential ideas are allowed to relax, these ideas are stored away, so to speak, and new ideas are brought forth, other sections of the brain come into play and allow the ponderous parts to rest.

PROFITING BY THE MISTAKES OF OUR ALLIES.

If the medical profession, in conducting its part in the present war, may learn from the mistakes of the English and French to their advantage, they must urge the matter of proper

selection of physicians for military service. Large numbers of doctors will be needed not only to care for our own troops, but to fill the vacancies left by the lack of forces among the Allies, not only on the western front but in Russia and other eastern points. To supply her army's needs, France depleted the staffs of her medical schools, her civilian hospitals and laboratories. Those who remained were insufficient to give proper training to the coming medical classes and to afford proper protection to the civilian population. England made the same mistake. She accepted all the physicians who volunteered for the army and later found her medical ranks thinned to an alarming extent. There is today in this country, roughly speaking, one doctor for every 700 of our population. In England there are large sections where there remains only one doctor for every 8000 population, and France is in a worse plight. Therefore, whether such a system is made into law or not, we must apply to the calling of our medical force the same principles that control the draft of the Army. Those that can be spared at home must go, those who are more useful at home should be kept there. Our great city hospitals must not be crippled, and at all costs we must preserve adequate faculties for our medical schools, and keep them in full operation, so that the ranks of medicine may always have recruits. Medical students should be exempt from draft and not accepted for volunteer service.

TRAINING IN MILITARY ROENTGENOLOGY.

A PLAN put forward by the Council of National Defense, for the establishment of schools in military roentgenology, was noted in the *JOURNAL* for May 17, 1917 (Vol. clxxvi, No. 20).

At that time a committee consisting of twenty-seven roentgenologists was appointed by the president of the American Roentgen Ray Society to provide means whereby instruction could be given to men desirous of entering the medical corps as roentgenologists. The duties of this committee were to canvass the country for a complete list of medical men available for military roentgenology, to establish schools in different geographical centers where uniform instruction could be obtained and to prepare a manual of military roentgenology. The work of organization has now been completed and

eight schools have been established. These are at Boston, New York, Baltimore, Richmond, Philadelphia, Kansas City, Mo., Los Angeles, and Chicago. The school in Boston opens on or about the twentieth of July. The course of study covers the practical application of roentgenology, with clinics at the hospitals, special work on localization of foreign bodies, military administration and the scientific study of apparatus. Major A. W. George is in charge. Members of the Medical Reserve Corps or those who prefer to receive commissions in the Medical Reserve Corps as military roentgenologists can, upon receiving their commissions, be assigned to one of these several schools of instruction, by application to the Surgeon-General's Office, Washington, D. C.

MEDICAL NOTES.

BRITISH BIRTHDAY HONORS FOR PHYSICIANS.—The list of British honors, recently conferred upon the occasion of the observance of the King's birthday, contains the names of a number of physicians. Among these Dr. Frederick Taylor, president of the Royal College of Physicians of London, and an active member of the Central War Committee, has been created a baronet. The honor of knighthood has been conferred on a number of physicians, notably Col. Robert Jones, C.B., A.M.S., inspector of military orthopedics, and Surgeon-General Eugène Fiset, long an officer on the permanent staff of the Canadian Army Medical Corps.

“He went with the first Canadian contingent to South Africa, serving throughout the war and being taken prisoner. For his services at Paardeberg he received the D.S.O. In 1905 he became Director-General of Medical Services, Canada, but in 1907 he took over the work of the deputy Minister of Militia during the illness of the incumbent of that office; after that minister's death he succeeded to the post, Sir Eugène Fiset's place as Director-General being taken by Surgeon-General Carleton Jones. Sir Eugène Fiset was largely responsible for the organization of the Canadian contingent sent to take part in the present war. The honour of knighthood is also conferred upon Sir Thomas Kennedy Dalziel, who is lecturer on Clinical Surgery in the University of Glasgow, and surgeon to the Western Infirmary; on Sir E. C. Stirling, C.M.G., professor of physiology in Adelaide University, at one time lecturer on the subject at St. George's Hospital, and a well-known authority on the anthropology of Central Australia; and on Sir Herbert Waterhouse, surgeon to Charing Cross Hospital and Dean of the school, who has recently returned after

serving for nearly a year with the Anglo-Russian hospitals in Russia. Of the military honours, the first to catch the eye is the promotion of Sir Arthur Sloggett, K.C.B., Director-General with the British armies in France, already C.M.G., to be K.C.M.G. The same honour is conferred upon Surgeon-General Tom Percy Woodhouse, C.B., who was the D.M.S. of the original expeditionary force, and now holds the onerous and exacting office of D.M.S. of the lines of communication; and upon Surgeon-General Francis Treherne, C.M.G., who was D.M.S. in Mesopotamia during the reorganization of the medical arrangements of the expeditionary force there. The other recipient of this honour is Colonel Robert Neil Campbell, C.B., I.M.S., who was in command of the Pavilion Military Hospital for Limbless Soldiers, Brighton. Lieutenant-Colonel P. J. Freyer, who is made K.C.B., retired from the Indian Medical Service some years ago, but has long been consulting surgeon to Queen Alexandra's Military Hospital, Millbank. Soon after the war began he became consulting surgeon to the Indian Hospitals at Brighton, and afterwards consulting surgeon to the Eastern Command, with charge of the county of Sussex. The same honour has been conferred on Colonel James Magill, A.M.S., who served with the Guards Camel Regiment during the Nile campaign of 1885, and was severely wounded at Abu Klea. He also served during the South African war."

MOVING PICTURES IN TEACHING.—The use of moving pictures in photographing surgical operations has been tried and proved successful. The proceedings of the annual meeting of the American Institute of Dental Teachers, held in January, 1917, records the use of moving pictures to teach dentistry. The Clinical Film Company of New York, who have been successful in making records of surgical operations for educational purposes, became interested in testing out the possibilities of motion pictures for use in the illustration of lectures in dental schools. Six reels were made and presented to the Association. Reel No. 1 showed a method of filling a cavity in the grinding surface of a molar tooth with a non-cohesive gold foil filling by the cylinder method and hand pressure. Reel No. 2 showed an operation for the removal of teeth under nitrous oxid anesthesia. Reel No. 3 showed a prophylactic treatment of dentures. No. 4 illustrated the removal of impacted third molars by two methods. No. 5 showed a root amputation under anesthesia and No. 6 illustrated the system of dental hygiene and prophylaxis employed in the Bridgeport, Conn., public schools. The demonstration was received with enthusiasm by the association.

LARGE CHARITABLE BEQUESTS.—By the will of the late Colonel Oliver H. Payne of New York, one of the largest owners of Standard Oil Stock,

the Lakeside Hospital of Cleveland, Ohio, is the recipient of a gift of \$1,000,000. St. Vincent's Charity Hospital of the same city receives \$200,000.

WAR NOTES.

DR. ALEXIS CARREL'S ARRIVAL.—The arrival in this country of Dr. Alexis Carrel is announced. Dr. Carrel reached New York on July 4 and will give valuable assistance to the establishing in this country of proper hospital facilities for the care of the wounded.

WAR RELIEF FUNDS.—On July 13 the totals of the principal New England war relief funds reached the following amounts:

French Wounded Fund	\$237,884.20
Armenian Fund	199,836.74
Permanent Blind Fund	117,686.05
French Orphanage Fund	115,091.99
Surgical Dressings Fund	105,173.47
Serbian Hospitals Fund	96,333.44
Italian Fund	42,643.42
La Fayette Fund	28,298.03
War Dogs' Fund	806.25

BOSTON AND MASSACHUSETTS.

WEEK'S DEATH RATE IN BOSTON.—During the week ending July 7, 1917, the number of deaths reported was 211 against 215 for the same period last year, with a rate of 14.25 against 14.74 last year. There were 29 deaths under one year of age, against 32 last year, and 65 deaths over 60 years of age against 57 last year.

The number of cases of principal reportable diseases were: diphtheria, 53; scarlet fever, 13; measles, 128; whooping cough, 11; tuberculosis, 55.

Included in the above were the following cases of non-residents: diphtheria, 5; tuberculosis, 13; whooping cough, 2.

Total deaths from these diseases were: diphtheria, 6; scarlet fever, 2; measles, 2; tuberculosis, 35.

Included in the above were the following cases of non-residents: diphtheria, 1; scarlet fever, 1; tuberculosis, 5.

SHARON SANATORIUM.—The extension of the work of the Sharon Sanatorium, to include the treatment of tuberculous children, is an endeavor worthy of this excellent institution and merits the loyal support of the public.

The Sharon Sanatorium was established twenty-six years ago, in 1891, for the treatment of tuberculosis arising in women of refinement and limited means. It was the first of its kind in New England; and the first to prove that tuberculosis could be successfully treated in low altitudes, not far from the sea, in a rough, changeable climate. It is now known throughout the United States as a pioneer and model institution. Its success, after a short time of experimentation, was such that several years later a State Sanatorium at Rutland, Massachusetts,

the first one of many such state institutions, was opened for the very poor.

As a fitting mark of its twenty-fifth anniversary, the Children's Pavilion was begun in 1916 for the treatment of tuberculous children under fourteen years of age, and this is now well under way on the Sanatorium grounds. It is to be an open-air school and sanatorium. The importance of early treatment of suspected tuberculosis in children cannot be overestimated. The officers of the Sanatorium are, therefore, exceedingly desirous that the benefit of their experience may be immediately made available to children, and are asking that money, not only for current expenses but for the endowment fund and the Children's Pavilion, may be provided in generous quantity. Checks and pledges may be mailed to any member of the following committee: Dr. Vincent Y. Bowditch, chairman, William T. Sedgwick, Dr. Joel E. Goldthwait, Mrs. Charles A. Porter, Nathaniel H. Stone, Mrs. Henry P. King and Jeremiah Smith, Jr.

NEW ENGLAND NOTES.

NEW ENGLAND TUBERCULOSIS CONFERENCE.—A conference on tuberculosis, to include all New England, will be held in Rutland, Vermont, on October 4th and 5th of this year. A committee of fifty in the New England states has been appointed to help make this conference a success. Local members of this Committee are as follows:

Dr. Edward O. Otis, Boston; Dr. Arthur K. Stone, Boston; Dr. Vincent Y. Bowditch, Boston; Dr. Allen J. McLaughlin, State Com. of Health, Boston; Mrs. Thomas Conant, Gloucester; Dr. Donald B. Armstrong, Framingham; Seymour H. Stone, Boston; Dr. John B. Hawes, 2nd, Boston; Miss Mary Van Zile, Beverly; Dr. Joseph H. Pratt, Boston; Dr. I. J. Clark, Haverhill; Dr. George L. Schadt, Springfield.

Many phases of the tuberculosis problem will be dealt with. Because of the relation of tuberculosis to the war the conference should attract many delegates from different parts of New England.

The Massachusetts Medical Society.

NOTES FROM THE DISTRICT SOCIETIES.

FRANKLIN.—The regular bi-monthly meeting of the Franklin District Medical Society was held at the Mansion House, Greenfield, on Tuesday morning, July 10, at 11.15 o'clock.

The following papers were read: "Management of Labor," by Dr. G. P. Twitchell; "Ear Complications of Infectious Diseases," with case reports, by Dr. F. A. Milette.

Dr. H. N. HOWE, *Pres.*,
Dr. F. A. MILETT, *Sec.*

Miscellany.

UNITED STATES VITAL STATISTICS IN 1915.

THE census bureau of the United States Department of Commerce has recently completed and issued a survey of birth and death rates in the United States in 1915, affording a basis of comparison with similar statistics in other countries.

"In the recently established birth-registration area of the United States—comprising the six New England States, New York, Pennsylvania, Michigan, Minnesota, and the District of Columbia, with an estimated population of 31,150,000, representing 31 per cent. of the total for the United States—776,304 infants were born alive in 1915, representing a birth rate of 24.9 per 1,000 of population. For every state in the registration area and for most of the cities there was a substantial excess of births over deaths, but this excess was most pronounced in those localities in which the proportion of foreign population is largest. The mortality rate of infants under 1 year of age averaged 100 per 1,000 births, ranging from 70 in Minnesota to 120 in Rhode Island, and, among places having 25,000 inhabitants or more, from 54 in Brookline and Malden, Mass., to 196 in Shenandoah, Pa. These are among the significant facts presented in a preliminary statement just made public by Director Sam. L. Rogers of the Bureau of the Census, Department of Commerce.

"This statement—giving, as it does, the first Federal statistics of births ever published—makes possible a comparison of birth rates in the registration area of the United States and in foreign countries, and throws light on such matters as the extent to which the populations of the states and cities in the birth-registration area are increasing through excess of births over deaths, the relation between the birth rate and the rate of infant mortality, the relation between the birth rate and the racial composition of the population, etc.

"The birth rate for the birth-registration area as a whole in 1915—24.9 per 1,000 population—exceeded the death rate for the same area—14 per 1,000—by 10.9 per 1,000, or nearly 78 per cent. That is to say, if the birth and death rates prevailing in that year were to remain unchanged, and if no migration were to take place to or from the area to which the figures relate, its population would increase annually by 10.9 per 1,000, or by nearly 1.1 per cent. The birth rates of the registration states ranged from 21.1 in Maine to 26.7 in Connecticut and Michigan; and the death rates ranged from 10.1 in Minnesota to 16.1 in New Hampshire. The highest death rate was thus much lower than the lowest birth rate. The greatest excess of births over deaths—14.4 per 1,000 population—appears for Minnesota, and the smallest—5.5 per 1,000—for Maine.

"The statistics cover 96 cities and towns having, at the last census, 25,000 inhabitants or more. Of these, there were only three—Kingston and Troy, N. Y., and Norristown, Pa.—in which the deaths exceeded the births in 1915, and in each case the excess was small, being greatest—1.1 per 1,000 population—for Troy.

"The cities showing the highest five birth rates are: Detroit, Mich., 37.9; Chicopee, Mass., 37.6; Niagara Falls, N. Y., 37.5; New Britain, Conn., 36.4; and Chelsea, Mass., 34.5. The death rates for these cities—15.7, 14.7, 16, 11, and 14.3, respectively—were, with the single exception of that for New Britain, higher than the average for the birth-registration area but were far below the maximum death rate shown for any city in the area—21.7, for Norristown, Pa.

"The lowest five birth rates appear for Brookline, Mass., 12.7; York, Pa., 17.5; Kalamazoo, Mich., 18.2; Kingston, N. Y., 18.5; and Troy, N. Y., 18.6. The death rates for the first-named two places were lower than the average for the registration area, and those for the first-named three were lower than the corresponding birth rates; but for Kingston and Troy the death rates—18.6 and 19.7, respectively—exceeded the birth rates.

"The relation between the birth rate and the constitution of the population in respect of race and nativity is of great interest. For the six cities in the registration area in which the colored population at the last census either numbered more than 10,000 or represented more than 10 per cent. of the total, separate figures are given for the white and colored races; and in all but one of these cities—Washington, D. C.—the birth rates shown for the colored population were lower than those for the whites. It is probable, however, that the registration of births is less nearly complete among colored than among white persons, and that therefore the rates shown for the former class are too low. The death rates for the colored population are higher, and in many cases much higher, than those for the whites.

"The birth statistics do not, of course, show the number of children per family, but some indication of the fecundity of the native and foreign elements of the population may be obtained from a comparison between the proportion which the number of foreign parents formed of the total number of white parents to whom children were born in 1915 and the proportion which foreign-born persons represented of the total white population in 1910. From such a comparison it appears that far more births occur annually to foreign-born parents, proportionally to their number, than to native parents. In Connecticut approximately 30 per cent. of the white population in 1910 was of foreign birth, but nearly 63 per cent. of the white parents to whom children were born in 1915 were reported as natives of foreign countries. The corresponding percentages for the other states

and the District of Columbia are as follows: Maine, 15 and 28; Massachusetts, 31 and 58; Michigan, 21 and 35; Minnesota, 26 and 33; New Hampshire, 22 and 44; New York, 30 and 56; Pennsylvania, 19 and 40; Rhode Island, 33 and 59; Vermont, 14 and 25; District of Columbia, 10 and 17.

"Thus, on the assumption that the proportions of native and foreign-born persons in the total white population did not change materially between 1910 and 1915, it appears that the birth rates for the foreign-born population in most of these states and in the District of Columbia are nearly or quite twice as high as the rates for the native and foreign elements combined, and that, on the other hand, the rates for the natives are considerably lower than those for the entire white population, being little more than half as high in the case of Connecticut and less than two-thirds as high in the case of Massachusetts. On the basis of these figures—which of course represent only an approximation to the facts—the excess of the birth rate among the foreign-born population over that among the natives ranges from about 40 per cent. in Minnesota to about 300 per cent. in Connecticut. It should be borne in mind, however, that the proportion of the population in the reproductive period of life is considerably greater for the foreign born than for the natives.

"The rate of infant mortality—that is, the number of deaths of infants under 1 year of age per 1,000 born alive—is of particular interest. This rate, for the registration area as a whole, was 100 in 1915. This is practically equivalent to saying that of every ten infants born alive, one died before reaching the age of 1 year.

"Among the ten states these rates ranged from 70 for Minnesota to 120 for Rhode Island; and among the 96 cities and towns it varied from 54 for Brookline and Malden, Mass., to 196 for Shenandoah, Pa. The maximum rate was thus nearly four times as high as the minimum.

"It might be expected that a high rate of infant mortality would accompany a high birth rate, but an examination of the figures fails to disclose any well-defined relationship of this character. Among the States, both the highest and the lowest infant-mortality rates—120 for Rhode Island and 70 for Minnesota—are found in connection with birth rates—23.1 and 24.5 per 1,000 population, respectively—which are below the average for the registration area; and, moreover, the birth rate in the State with the lowest infant mortality is higher than that in the State with the highest infant mortality.

"Among the cities and towns the lowest infant-mortality rate—54 per 1,000 births—is shown for both Brookline and Malden, Mass. The former place had the lowest birth rate—12.7 per 1,000 population—given for any city or town in the registration area, but the birth rate of the latter—23.5 per 1,000—was not far below the average for the area. The highest infant-

mortality rate—196 per 1,000 births, for Shenandoah, Pa.—is accompanied by a birth rate—32.7 per 1,000 population—which is far above the average, although considerably below the maximum. Of the ten cities in which the birth rates were highest, three show infant-mortality rates lower than the average, and of the ten places in which the birth rates were lowest, five show infant-mortality rates higher than the average.

“The statistics compared with foreign tables show that England, France, Belgium, Sweden and Switzerland before the war had a lower birth rate than the United States had in 1915. Countries with a higher rate were Germany, Austria, Russia, Italy, Spain, Denmark, Holland, Japan and Australia.”

COMMUNICABLE DISEASES IN MASSACHUSETTS IN 1916.

Dr. Eugene R. Kelley, director of the division of communicable diseases of the Massachusetts State Department of Health, has recently issued his annual report for the year 1916, dealing particularly with epidemics of infectious diseases during that year and in the preceding decennial.

“A compilation of the deaths caused by ten of the most prominent communicable and preventable diseases shows that during the year just passed there were slightly more than 9000, or 17 per cent. of all the deaths. Twenty years ago deaths from these same diseases amounted to 13,600, or 30 per cent. of the deaths from all causes, and at the same time the population of the State was about 1,250,000 less than it is today.

“Although the number of cases in certain diseases showed marked increases, the total number of cases in all diseases last year was 68,488, and in 1915 was 71,900. Among those showing great increases are infantile paralysis, which spread to 1793 more persons in 1916 than it did in 1915, measles with an increase of 3300, anthrax and trichinosis. Twenty cases of the latter were traced to an infested hog which one slaughtering house refused and which was later taken and sold to some Italians.

“Among the diseases which showed a decrease are diphtheria, which fell from 9282 to 7338 cases; ophthalmia, which decreased 900 cases; scarlet fever, several hundred, and typhoid fever, 673.

“Perhaps the one fact which pleases the health authorities more than anything else is the record made in the fight against typhoid fever. In the year just past the authorities predict that there will be not more than 170 deaths from the disease at the outside, while there were 246 deaths from that cause in 1915. This, Dr. Kelly believes, is a rate for the State which has never been approached before, and he is confident that no other State has ever equalled it. In 1915 the

rate per 100,000 population was 6.7, and in 1916 he predicts that it will not be much more than 5, and possibly less.

“A compilation of figures in regard to the infantile paralysis epidemic also shows some surprising facts. The little town of Dalton led the State in the number of cases in proportion to her population and had a rate of 433, based on a population of 100,000. Amesbury is the next with a rate of 268, Holyoke third with 188, North Adams fourth with 172.4, and Pittsfield fifth with 161.9. Worcester had the lowest rate with 14.4; Lowell was next lowest with 15.7, and New Bedford third from last with a rate of 16.9. Boston is seventeenth in the list with a rate of 64.4, and Cambridge sixteenth with a rate of 65.6. Fall River and Brockton are the only large cities of the State which had less than fifteen cases of the disease.

“In connection with this disease, the report declares that the district health officer system has been given a great test, for, with the exception of the cases in a few of the large cities, these officers saw every infantile paralysis sufferer in the State and even those suspected of having the disease. Their knowledge proved of great assistance to the local boards of health, and was responsible for the reasonable regulations which were put in force, rather than some very drastic steps which might have been taken.

“The deaths from measles in the year just past will run far beyond those caused by scarlet fever. It is estimated that there will not be many more than 117 from the latter, while there were 307 deaths from measles up to Nov. 1, or twice as many as in 1915. There were more whooping cough deaths, although less cases than in 1916.

“Speaking of outbreaks, the report states that there were two of anthrax in Woburn and Winchester during the past year, but that the United States Government has remodelled its protective regulations since that time on the representations of the Massachusetts Health Department. Two outbreaks of diphtheria occurred in institutions, but antitoxin was administered early and no deaths resulted. One small contact epidemic occurred in Amherst with a sub-epidemic traced to milk. Fitchburg had an epidemic which was prolonged throughout the year and there were nineteen other distinct ones.

“The largest scarlet fever outbreak took place in Quincy, where 187 cases of the disease resulted from unrecognized carriers. A small outbreak occurred in Clinton from milk. Two outbreaks of smallpox, both of them traced to a single source, occurred in Fitchburg and Lee and Great Barrington. Nine persons contracted the disease in the former and eighteen in the latter.

“There was only one typhoid epidemic of any consequence during the year, and that occurred in Lynn during the summer. In all 114 cases resulted, although the carrier was never discovered. Fall River also had a milk epidemic

of twenty-eight cases, and there were three other small outbreaks from milk in which the typhoid was traced to the dealer.

"The laboratory work of the health department has shown an increase of thirty-four per cent. over that of other years, and diagnosed chiefly diphtheria, typhoid and tuberculosis.

"The Health Department has been aided greatly by the secretary's office towards making the record of deaths more complete. That office was forced to reorganize its whole routine in order to accommodate the health department, and now the records are made up monthly, only a month behind, whereas before they were at least a year behind."

BOSTON VITAL STATISTICS IN 1916.

THE Boston Health Department has recently issued a provisional statement of the vital statistics of this city for the year 1916. During this year the total death rate of the city was 16.72 as compared with 16.06 in 1915, the lowest figure recorded. The increase was due to several epidemics of streptococcus throat infection, the epidemic of poliomyelitis, and the Summer Street bridge accident. Not all death reports for the year have yet been received, so that the figures are only approximate and subject to subsequent modification.

"The deaths for the year numbered 12,717, compared with 12,021 in 1915. Of the total for 1916, deaths of non-residents numbered 1795, compared with 1640 in 1915, and known deaths of Bostonians outside the city numbered 675, compared with 704 in 1915. Corrected for these two factors, the 1916 death rate per 1000 population is 15.25, compared with 14.81 in 1915."

The total number of deaths in 1916 showed an increase of 696 over the previous year.

"Non-residents dying in Boston account for some of this increase, as there were 155 more than last year. Each year more and more non-residents take advantage of our hospitals, these constituting 14 per cent. of our total deaths, and as these deaths must be figured in our death rate, it can be seen how our death rates are kept high. This feature is especially noticeable in the communicable diseases. Surrounding cities and towns send their cases here for treatment. Of the 26 deaths from typhoid fever, 7 of them were non-residents. Scarlet fever was much higher—almost 50 per cent., of 19 of the deaths being those of non-residents of Boston; diphtheria showed 52 of these non-residents.

"During the early part of the year, the outbreak of influenza and pneumonia was responsible for an increase of more than 200 deaths. To this increase may be added the increase of 164 deaths from poliomyelitis, and the unfortunate electric-car accident at South Boston, which caused 48 more.

"It is gratifying to note the decrease in the

number of deaths from typhoid fever, scarlet fever, diphtheria and whooping cough; the low number of deaths from typhoid fever and the typhoid fever death rate being the lowest ever attained in this city, and up to this writing the lowest ever reached by any large American city having more than 350,000 population.

"While the total number of deaths of children under one year was 10 more than in 1915, and the infant mortality rate was 105 per 1000 births reported against 104 last year, some significance must be placed on the fact that there were outbreaks of influenza, pneumonia, and anterior poliomyelitis, all at different periods during the year, resulting in a great number of deaths of infants under one year of age.

"Only on two other occasions since 1882 has there been a lower number of deaths of children under one year of age. In this connection it might be said that nurses of this department visited almost 15,000 babies, and made subsequent visits totalling about 75,000."

The total number of births reported in 1916 was 19,583 and the infant mortality rate was 105 per thousand births reported.

With reference to the West End Health Unit on Blossom Street, Dr. Mahoney says in his statement accompanying the report that: "On March 1, 1916, through the efforts of His Honor the Mayor, there was inaugurated in the West End section of the city a health unit which has since developed into a civic center as well. This was established for the purpose of getting in close touch with the people and determining what effect education of the people, through the co-operation of all health agencies in the district, would have on the prevention of disease and deaths amongst infants and children and adults in that congested area of the city.

"His Honor felt that the first place to start such an institution would be where the congestion was greatest and in a section that contained the greatest number of people per acre.

"The success of the Unit soon became apparent and wonderful results were accomplished for the people of the district during the hot summer of last year. Nurses, visitors and physicians kept constantly in touch with the people using the Unit as headquarters, and with the outbreak of poliomyelitis in the city the advantages of the Unit were shown to a still greater extent.

"The Unit seemed to be a Mecca for the afflicted and the worried, and the women and children came with their troubles, and oftentimes imaginary illnesses, only to be sent home with their fears allayed and themselves comforted. The physicians and nurses kept in close touch with the people during this outbreak, and the security that the people in the district felt in having such assistance about them did much to help them."

PREPARATIONS OF UNITED STATES ARMY MEDICAL CORPS IN MEXICO.

REPORT from San Antonio, Texas, on November 24, 1916, described in detail the preparation which, during the previous summer, had been made at the Mexican frontier by the United States Army Medical Corps, for the care of sick and wounded troops, in the possible event of actual hostilities with Mexico.

"Within the last five months the most complete medical organization known to the United States Army has been developed to care for the 15,000 State and regular troops stationed at Border points and in Mexico. The system includes five base hospitals, located at strategic points; eight camp hospitals, a cantonment hospital at Columbus, N. M., and twenty-six ambulance companies and forty-one field hospitals.

"The base and camp hospitals will accommodate 4600 patients and have medical and surgical facilities equal to the finest hospitals. Not more than half the beds have been occupied at any one time since the nation's militia strength was called into the Federal service.

"Back of this array is the potential organization. A hospital train of ten Pullman cars, capacity 250 patients, would transport patients from the camp to the base hospitals and from base hospitals to general military hospitals in various parts of the country, should a campaign in Mexico be undertaken. These larger institutions are the Walter Reed Hospital at Washington, D. C., the General Army and Navy Hospital at Hot Springs, Ark., and the Lettiman Hospital at San Francisco. About 1200 beds are vacant in the three hospitals at the present time.

"In addition, a number of army posts have been selected for transformation into general hospitals in case of emergency. This list includes Fort McPherson, at Atlanta; Fort Oglethorpe, also in Georgia; Fort Benjamin Harrison, Indianapolis, and other army stations where barracks are available for hospital purposes.

"The medical corps has complete equipment in storage for twenty evacuation hospitals and two base hospitals. An evacuation hospital takes care of 300 patients and a base hospital accommodates 500, so the total reserve equipment ready for use at a moment's notice is sufficient for 6000 men. Evacuation hospitals are entirely under canvas and are intended for use along an extended line of communication.

"The base hospitals now in service are located at Fort Sam Houston, Fort Bliss, Brownsville, Eagle Pass and Nogales. Serving feeders for these institutions are the camp hospitals located at the following points: Laredo, 120 beds; Del Rio, 75 beds; Marfa, 150 beds; Deming, 180 beds; Douglas, 300 beds; Llano Grande, 200 beds; McAllen, 150 beds; and Fort Clark, 150 beds.

"Last July when State troops began arriving at the Border the only army establishments for

the care of sick were the post hospitals at Fort Sam Houston and Fort Bliss, and much smaller places at Laredo and a few other border points. Practically the entire system of base and camp hospitals has been built since the call on the National Guard was made.

"As a result of the scientific methods adopted by the medical corps and the steps taken to insure absolute sanitation in border camps, the big command of regulars and militia has set a new health record. From May 1 to Oct 31, there were only 75 deaths from disease in the force of more than 150,000, and of this small number, only 21 deaths were due to infectious maladies.

"Typhoid fever was formerly the worst scourge of camp, but it has no place among the troops along the Mexican border. May 1, to Oct. 18, only 24 cases of typhoid developed and no deaths resulted from the disease. All of these cases were among the National Guard organizations, where in some cases the men were not inoculated with typhus serum until after regiments had come to the border. There was not a single case among the 42,000 troops of the regular army engaged in patrol duty and stationed in Mexico with General Pershing's command.

"In Spanish-American War days—over a period of eight months in 1898—among 147,000 regulars and volunteers, the typhoid epidemic reached the enormous total of 21,000 cases and there were 2192 deaths from the disease.

ANNUAL CONFERENCE, MASSACHUSETTS SOCIETY FOR MENTAL HYGIENE.

THE recent conference on feeble-mindedness, held by the Massachusetts Society for Mental Hygiene, was marked by a series of addresses of much value and interest. Chief among them may be mentioned the address by Dr. Guy G. Fernald on the results of mental examination of young adults at the Concord Reformatory. He stated, among other things, that forty-four per cent. of the inmates of that institution are sub-normal mentally and fifteen per cent. are feeble-minded. This statement is based on a study of 1107 individuals. Only forty per cent. he rates as normal and responsible, the other sixty per cent. are made up of psychopathies, epileptics, congenital syphilis, sex perverts, the insane and feeble-minded.

The group of feeble-minded, 15 per cent. of the whole, he feels should be segregated from the others. "Members of this group are demonstrably defective and of limited responsibility, and as such should not be sentenced to serve with the fully responsible," he said, "but should be committed to a specially adapted environment for indefinite custodial care and training, with a view to their return to society only when such return would not be a menace.

"Absolute physical separation of the group

is of vital importance, and preferably this should be in a farm colony of which the hospital and laboratory features are prominent. Until such segregation is made possible, work in the interest of the prisoner who is normal mentally is greatly handicapped."

Dr. Fernald urged, also, that psychiatric clinics be established in connection with the courts, so that offenders of this type may be committed to custodial care.

Speaking on what he termed practical methods for protection, education, supervision and segregation of the feeble-minded, Dr. Walter E. Fernald advocated the following plans: Long-continued scientific study and research of all phases of feeble-mindedness; governmental cognizance of all neglected and uncared for feeble-minded persons; continued census for the unfortunates; extra institutional supervision of all uncared-for defectives; special classes for the education on this subject in all cities and towns; mental clinics for diagnosis all over the State; mental examination of persons accused or convicted of crime and the education of lawyers, teachers, physicians and clergy as to the nature of feeble-mindedness.

Dr. Elizabeth A. Sullivan, resident physician at the Massachusetts Reformatory for Women at Sherborn, said that only 10 out of 234 women admitted to the institution were free of disease and possessed of adult intelligence. She urged the need of separating the feeble-minded from reformatories and said that 4000 of the feeble-minded women discharged from the Sherborn Reformatory should have been placed in a suitable institution instead of being set adrift in the world.

The problem from the point of view of the social worker was brought out by J. Prentice Murphy, general secretary of the Boston Children's Aid Society, who stated that annually about 300 unmarried mothers, or one-third of the whole number in the city, call upon that Society for aid, and that in a group of 250 feeble-minded mothers none could tell the name of her child's father. Some of these feeble-minded women have as many as six illegitimate children. Mr. Murphy advocated the separation of the mother from her baby and its care being entrusted to the State. Twenty charitable organizations in Boston have under their care 1600 persons who have been diagnosed as defective mentally.

Dr. V. V. Anderson, psychiatrist, Boston Municipal Court, in speaking on the subject of feeble-mindedness as seen in court, gave the following statistics:

"Not more than 10 per cent. of the offenders brought to the Boston Municipal Court are feeble-minded, but that 10 per cent. is most troublesome, mainly because society has not yet come to recognize its needs. Out of 100 cases 75 per cent. are not self-supporting, and 34 per cent. do not work at all. These 100 have a record of 1825 arrests and 735 sentences. The chances are

four to one that they will not conduct themselves normally for six months when placed on probation. It would have been more profitable for society to have recognized these cases earlier and segregated the 75 per cent. who have a mental level below 12 years of age."

SELF-CONTROL IN DIET.

In Southern California, several ages ago, the oil escaping from a small spring formed in a depression of the earth, a little pool. The lighter portions of the oil evaporated, leaving the sticky asphalt. From time to time the rains covered the surface of the pool with water, animals and birds came down to drink, sank into the asphalt and were imprisoned in this gigantic animal trap. The hungry wolves saw there before their eyes fresh animal food of every sort, from the enormous mastodon to the smallest bird. They, too, were drawn into the trap as were also the large sabre-toothed tigers which then roamed that vicinity. Today scientists are engaged in excavating the bones deposited there by indiscreet appetite.

The aim of civilization is to create inhibition, the quality which holds back and directs to useful purposes the natural appetites, preventing them from leading man into the pitfalls which beset over-indulgence. Hunger is the great stimulus of action, but when it is satisfied to satiety, sodden inactivity follows. If the natural appetite is allowed to dominate it leads to over-indulgence, and the unwary victim suddenly finds himself in a trap from which he cannot escape.

One of the great elements in maintaining health is the regulation of the bodily intake to meet the appetite. The man who works with his hands requires more food than the brain worker. The man who labors in the open air needs more nourishment than he who sits cooped in an office all day long. Give the sedentary worker the appetite of the day laborer and if that appetite be uncontrolled the body will become clogged with the poisonous products of its own manufacture, and physical deterioration will surely follow. It is just as bad to eat too much as it is to eat too little. To indulge the appetite to too great an extent is equally as pernicious as its constant repression. The best is to be found in an average course, neither over- nor under-indulgence, neither the following of the inelastic dietary nor the promiscuous and ill-considered use of foods. Many a so-called case of dyspepsia is nothing in the world but the rebellion of an overworked stomach, the remonstrance of a body which has been stuffed to repletion. A great deal has been accomplished in the reduction of infant mortality because we are able to control what infants may eat. Adults must for themselves exercise this as self-control. If this is done there will be a decline in our adult mortality rates and an increase in health and efficiency.

RECENT DEATHS.

BROOKS HUGHES WELLS, M.D., of New York City, died at the home of his sister in Southport, Conn. on July 6 of injuries received in being thrown from a bicycle. Dr. Wells was a captain in the Medical Reserve Corps and was well and favorably known as a surgeon. He was connected with various New York hospitals, including the Polyclinic. He was born in New Haven, Conn., in 1859. He is survived by his widow and four daughters.

MARRIAGES.

The marriage is announced of Miss Marguerite Mayberry of Pittsfield, Mass., and Dr. William Franklu Temple, Jr., of Boston. Dr. Temple graduated from the Harvard Medical School in 1911.

SOME MEDICAL PRACTICE AMONG THE NEW ENGLAND INDIANS AND EARLY SETTLERS.

By CAROLUS M. COBB, M.D., LYNN, MASS.

So far as I know we have no accurate observation and record of medical practice among the New England Indians, especially such as existed prior to their contact with the early settlers. There were good reasons for this: the early settlers were too busy trying to get a living, there were no trained scientific observers among them; medical practice even in England was almost wholly empirical at that time. The Pilgrims and Puritans were particularly free from incantations and the rites of magic in their medical practice for the reason that they had broken away from all those who would be led to attach importance to such agencies, although they had an abiding belief in a personal devil and in witches. Their medicine was the folk medicine of tradition and personal experience, consisting as it did largely of roots and herbs. It is very hard to tell, many times, how much they learned from the Indians and how much the Indians learned from them. We have two early books written about New England from which some idea of Indian medicine may be gained, Wood and Josselyn. Wood was a sort of press agent for New England and the reference to medical matters is only incidental, but Josselyn was a

good deal of a naturalist and something of a physician.

Before giving an account of the medical practice of the New England Indians it seems necessary to say just a word in regard to medical superstition among them. Payne remarks that "The belief that internal maladies due to no visible cause are the work of evil spirits is traceable in the earliest records of ancient medicine which we possess, and is found among uncivilized races in most parts of the world, as the accounts of travelers and investigators clearly prove. It is evident that we have here one of the most fundamental, perhaps the most universal conception of the origin of internal disease." This is a true picture of the New England Indian. He believed in evil spirits and did things to drive them away, but he had never been contaminated by Eastern magic, neither did he use the elaborate methods employed, in later times at any rate, among the Indians of the West. Wood describes their Pow Wow. He says they worship Ketan who is their good God, to him "they invoke for fair weather, for rain in time of drought, and for the recovery of their sick." After giving some of the tricks of which, he says, the Indians told him, he goes on to give an account of a Pow Wow. "An honest Gentleman related a story to me, being an eye witness of the same: A Pow Wow having a patient with the stump of some small tree run through his foot, being past the cure of his ordinary surgery, betook himself to his charms, and being willing to show his miracles before the English stranger, he wrapt a piece of cloth about

the foot of the lame man; upon that wrapping a Beaver skin, through which he laying his mouth to the Beaver skin, by his sucking charmes he brought out the stump, which he spat into a tray of water, returning the foot as whole as its fellow in a short time. The manner of their action in their conjuration is thus: The parties that are sick or lame being brought before them, the Pow Wow sitting down, the rest of the Indians giving attentive audience to his imprecations and invocations, and after the violent expression of many a hideous bellowing and groaning, he makes a stop, and then all the auditors with one voice utter a short Canto; which done, the Pow Wow still proceeds in his invocations, sometimes roaring like a Bear, other times groaning like a dying horse, foaming at the mouth like a chased bore, smiting on his naked breast and thighs with such violence, as if he were mad. Thus will he continue sometimes half a day, spending his lungs, sweating out his fat, and tormenting his body in this diabolical worship; sometimes the Devil for requital of their worship, recovers the party, to nuzzle them up in their devilish religion. In former time he was wont to carry away their wives and children, because he would drive them to these Mattens, to fetch them again to confirm their belief of this his much desired authority over them: but since the English frequented those parts, they daily fall from his colorus, relinquishing their former fopperies, and acknowledge our God to be supreme. They acknowledge the power of the Englishman's God, as they call him, because they could never yet have power by their conjurations to damnify the English either in body or goods; and besides, they say he is a good God that sends them so many things—so much good corn, so many cattle, temperate rains, fair seasons, which they likewise are the better for since the arrival of the English; the times and seasons being much altered in seven or eight years, free from lightning and thunder, long droughts, sudden and tempestuous dashes of rain, and lamentable cold winters."—"New England Prospect." Wood wrote this in 1633. Both Wood and Josselyn consider the country healthful. Wood especially took a very optimistic view. The climate seemed to impress him favorably in comparison with that of England, as did also the abundance of food. He explains the death rate among the new arrivals and claims it was not due to the climate. "It is observed by the Indians that every tenth year there is little or no winter, which hath been twice observed of the English; the year of the new Plymouth men's arrival was no Winter in comparison; and in the tenth year after likewise when the great company settled themselves in Massachusetts Bay, was a very mild season, little frost, and less snow, but clear serene weather, few North-West winds, which was a great mercy to the English coming over so rawly and uncomfotably provided, wanting all utensils and provisions, which belonged to

the well being of planters: and whereas many died at the beginning of plantations, it was not because the country was unhealthfull, but because their bodies were corrupted with sea-diet, which was naught, their Beef and Pork being tainted, their Butter and Cheese corrupted, their Fish rotten, and voyage long, by reason of cross Winds, so that winter approaching before they could get warm houses, and the searching sharpness of that purer climate, creeping in at the errannies of their crazed bodies, caused death and sickness; but their harms having taught future voyagers more wisdom, in shipping good provision for sea, and finding warm houses at landing." He seems to consider New England a health resort. "In New England both men and women keep their natural complexion; and as it is for the outward complexion, so it is for the inward constitution; not very many being troubled with inflammations, or such diseases as are increased by too much heat: and whereas I say, not very many, yet dare I not exclude any; for death being certain to all, in all nations there must be something tending to death of like certainty. The soundest bodies are mortal and subject to change, therefore fall into diseases, and from diseases to death. Now the two chief messengers of mortality, be feavers and Callentures; but they be easily helped, if taken in time, and as easily prevented of any that will not prove a mere fool of his body. For the common diseases of England, they be strangers to the English now in that strange land. To my knowledge I never knew any who had the Pox, Measels, Green-sickness, Head-aches, Stone, or Consumptions, etc. Many that have come infirm out of England, retain their old grievances still, and some that were long troubled with lingering diseases, as Coughs of the lungs, Consumption, etc., have been restored by that medicineable Climate to their former strength and health."

All through the early writings about New England we find the question of drinking water taken very seriously. It was one of the doubts about making a success of the undertaking. The people came very naturally to view the subject in this light, for they had drunk beer for many centuries in England. Rogers says that during the thirteenth, fourteenth, fifteenth, and sixteenth centuries fully one third of the cost of maintaining the family was for malt. Probably the lack of sugar had something to do with this use of malt. The Pilgrims began to experiment with water drinking soon after they reached Plymouth. Bradford says: "Monday, the 25th. being Christmas day, we began to drink water abroad. But at night the master caused us to have some beer; and so on board we had divers times now and then some beer, but on shore none at all." Wood, writing thirteen years after, thinks the water good but is a little doubtful about drinking it himself, and says "he dare not prefer it before good beer." For the country

it is as well watered as any land under the Sun, every family, or every two families, having a spring of sweet waters betwixt them, which is far different from the waters of England, being not so sharp, but of a fatter substance, and of a more jetty color (sparkling), it is thought there be no better water in the world, yet dare I not prefer it before good Beer, as some have done, but any man will choose it before bad Beer, Whey, or Buttermilk. Those that drink it be as healthful, fresh, and lusty, as they that drink beer." Both Wood and Josselyn seem quite taken with the physical perfections of the Indians.

"First of their Stature, most of them being between five or six foot high, straight bodied, strongly composed, smooth skinned, merry countenanced, of complexion something more swarthy than Spaniards, black haired, high foreheaded, black eyed, out-nosed, broad shouldered, brawny armed, long and slender handed, out breasted, small waisted, lank bellied, well thighed, flat kneed, handsome grown legs, and small feet: In a word, take them when the blood brisk in their veins, when the flesh is on their backs, and narrow in their bones, when they frolic in their antique deportments and Indian postures; and they are more amiable to behold (though only in Adams Livery) than many a compounded phantastick in the newest fashion. It may puzzle belief, to conceive how such lustie bodies should have their rise and daily supportment from so slender a fostering; their houses being mean, their lodging as homely, commons scant, their drink water and Nature their best clothing, in them the old proverb may well be verified: (Natura paucis contenta) for though this be their daily portion, they still are healthful and lusty. I have been in many places yet did I never see one that was born either in redundance or defect a monster, or any that sickness had deformed, or casualitie made decrepit, saving one that had a bleared eye, and another that had a wenne on his cheek. The reason is rendered why they grow so proportionable, and continue so long in their vigor (most of them being 50 before a wrinkled brow or gray hair bewray their age, is because they are not brought down with suppressing labor, vexed with annoying cares, or drowned in the excessive abuse of overflowing plenty, which oftentimes kills them more than want, as may appear in them. For when they change their bare Indian commons for the plenty of England's fuller diet, it is so contrary to their stomachs, that death of a desperate sickness immediately accrevs, which makes so few of them desirous to see England. Their swarthinness is the sun's livery, for they are born fair. Their smooth skins proceed from the often anointing of their bodies with the oil of fishes, and the fat of Eagles, with the grease of Raccoones, which they hold in summer, the best antidote to keep their skins from blistering with the scorching

Sun, and it is their best armour against the Musketoos, and the surest expeller of the hairy excrement, and stops the pores of their bodies against the nipping winters cold. . . If their fancy drive them to trade, they choose rather a good coarse blanket, through which they cannot see, interposing it between the sun and them; or a piece of broad cloth, which they use for a double end, making it a coat by day, and a covering by night; they love not to be imprisoned in our English fashion: they love their own dog-fashion better (of shaking their ears, and being ready in a moment) than to spend time in dressing them, though they may as well spare it as any man I know, having little else to do. But the chief reasons they render why they will not conform to our English apparel, are, because their women cannot wash them when they be soiled, and their means will not reach to buy new when they have done with their old; and they confidently believe, the English will not be so liberal as to furnish them upon gifture; therefore they had rather go naked than be lousie, and bring their bodies out of their old tune, making them more tender by a new acquired habit, which poverty would constrain them to leave." (Wood's "New England Prospect.") Josselyn was particularly struck with the Indian women.

THE INDIAN.

"The Men are somewhat Horse Faced, and generally Faucious, that is, without beards, but the women many of them have very good features, seldom without a Come to me, or Cos Amoris, in their Countenance, all of them black eyed, having even short teeth, and very white, their hair black, thick and long, broad breasted, handsome straight bodies, and slender, considering their constant loose habit. Their limbs cleanly, straight, and of a convenient stature, generally, as plump as Partridges and saving here and there one, of a modest deportment.

"Their Garments are a pair of sleeves of deer, or Moose skin drest, and drawn with lines of several colours into Asiatick Works, with Boskins of the same, and short Mantle of Trading Cloth, either Blew or Red, fastened with a knot under the chin, and girt about the middle with a Zone wrought with white and blew Beads into pretty Works: of these Beads they have Bracelets for their Neck and Arms, and Links to hang in their Ears, and a fair Table curiously made up with Beads likewise, to wear before their breast, their Hair they comb backward, and tie it up short with a Border, about two handfulls broad, wrought in Works as the other with their Beads." ("New England Rarities.")

Wood goes fully into their diet, and from his description one gathers the impression that it was turkey one day and feathers the next. "Some of their scullerie having dressed these homely eates, presents it to his guests, dishing it up in a rude manner, placing it on the verdent

carpet of the earth which Nature spreads them, without either trenchers, napkins, or knives, upon which their hunger-fawced stomachs impatient of delays, falls aboard without scrupling at unwashed hands, without bread, salt, or beer, lolling in the Turkish fashion, not ceasing till their full bellies leave nothing but empty platters: they seldom or never make bread of their Indian corn, but seeth it whole like beans, eating three or four cornes with a mouthful of fish or flesh, sometimes eating meat first, and corns after, filling in chinkes with their broth. In summer, when their corn is spent, Isquountersquashes is their best bread, a fruit like a young Pumpion. To say and to speak paradoxically, they be great eaters, and yet little meat men; when they visit our English, being invited to eat, they are very moderate, whether it be to show their manners, or for shamefastness, I know not; but at home they will eat till their bellies stand forth, ready to split with fullness; it being their fashion to eat all at some times, and nothing at all in two or three days, wise Providence being a stranger to their wilder ways: they be right infidels, neither caring for the morrow, or providing for their own families; but as all are fellows at foot-ball, so they all meet friends at the kettle, saving their wives, that dance a Spaniel-like attendance at their backs for their bony fragments. If their imperious occasions cause them to travel, the best of their victuals for their journey is Nocake (as they call it), which is nothing but Indian corn parched in the hot ashes; the ashes being sifted from it, it is afterward beaten to powder, and put into a long leathern bag, trussed at their back like a knapsack; out of which they take thrie three spoonefulls a day, dividing it into three meals. If it be in Winter, and Snow be on the ground, they can eat when they please, stopping Snow after their dusty victuals, which otherwise would feed them little better than a Tiburne halter. In Summer they must stay till they meet with a Spring or Brook, where they may have water to prevent the imminent danger of choaking. With this strange viaticum they will travel four or five days together, with loads fitter for Elephants than men."

Wood mentions the pestilence which carried off many Indians just previous to the landing of the Pilgrims. He still acts the press agent and claims that the Indians were a particularly healthy race. To quote again from the *New England Prospect*, "Although the Indians be of lusty and healthful bodies, not experimentally knowing the Catalogue of those health-wasting diseases which are incident to other countries, as Fevers, Pleurisies, Callentures, Agues, Obstructions, Consumption, Subfumigations, Convulsions, Apoplexies, Dropsies, Gouts, Stones, Toothaches, Pox, Measels, or the like, but spinne out the thread of their days to a fair length, numbering three-score, four-score, some a hun-

dred years, before the worlds universal sun-moner eite them to the craving Grave."

All the English who came in contact with sick Indians were impressed with their ceremonies to drive away the devil. Winslow went to Gardner's Neck in Swanzy to visit Massassowat and found him very sick; he says, "When we came thither, we found the house so full of men, as we could scarce get in, though they used their best diligence to make way for us. There were they in the midst of their charms for him, making such a hellish noise, as it distempred us that were all well, and therefore unlike to ease him that was sick. About him were six or eight women, who chafed his arms, legs, and thighs, to keep heat in him." Winslow gave him some conserve which he had brought, and cleaned his mouth and tongue, and Massassowat began to improve. They did not appear to know anything of sick nursing or sick diet. Roger Williams says of them, "When they are sick, their misery appears, that they have not but what sometimes they get from the English, a raisin or currant, or any physie, fruit, or spice, or any comfort more than their corn and water. In which bleeding ease, wanting all means of recovery or present refreshing, I have been constrained, to and beyond my power, to refresh them, and to save many of them from death, who I am confident perish many millions of them, in that mighty continent, for want of means."

My impression is that for slight ailments, and for wounds and bruises they used medicine so far as their limited knowledge and limited resources went, but if a patient became very sick they lost confidence in medicine and resorted to the superstitious practices which are common to all people of their grade of intelligence, i. e., they tried to drive away the devil by making noise enough so that he would prefer a quieter place. This may have had a hypnotic effect upon the patient even if it did not upon the devil.

From these quotations we get the impression that the use of remedies by the Indians was extremely limited; in fact, Wood mentions but one herb which was so used, snake weed for snake bite; and Mourt's relation mentions the use of medicines but does not go into details. As a matter of fact they did use quite a number of remedies and with quite as much sense as the settlers used theirs. We are indebted to John Josselyn for a description of many of their methods of treating diseases and wounds.

John Josselyn made two voyages to New England, the first in 1638, arriving in Boston harbor July 3d, and remaining with his brother at Black Point in the town of Scarborough, Me., till October 10 of the following year. His second voyage was made in 1663. He arrived at Nantasket the 27th of July, and soon proceeded to his brother's plantation, where he tells us he staid eight years, and got together the matter for his book.

The book was not intended for a treatise on medicine but rather as a work on natural history. For this reason there is no arrangement of diseases and remedies, but he puts down anything he has learned of medical practice when he describes the bird, beast, or plant which is attracting his attention at the time. Occasionally he gives a remarkable cure of which he has heard, but generally he confines himself to what he has seen. He says he has seen pond frogs a foot high, and that the Indians told him that back in the country there were frogs as large as a child a year old. Either the story, or the frog, seems pretty large, but Josselyn makes no comment. One curious fact is that he does not mention the Pow Wow or any medicine man among the Indians in "New England Rarities," but does mention them in his Voyages, but he describes what the common people did for their ailments.

I have gone through his books, "New England Rarities" and Voyages very carefully and have tried to arrange the diseases which he mentions and remedies which he says were used. So far as possible I have let him tell his own story.

Josselyn does not take so rosy a view of the New England climate as does Wood; he says, "The Sea Coasts are accounted wholsomest, the East and South Winds coming from the sea produceth warm weather, the Northwest coming over land causeth extremity of Cold, and many times strikes the Inhabitants, both English and Indian, with that sad Disease called there the Plague of the back, but with us Empiema." He evidently found more disease in New England than did Wood and the list as he gives it is what one would expect to find.

"THE MOST COMMON DISEASES IN NEW ENGLAND."

"The Black Pox, the Spotted Fever, the Gripping of the Guts, the Dropsie, and Sciatica are the killing Diseases of New England." ("New England Rarities.")

"In New England the Indians are afflicted with pestilent Fevers, Plague Black-pox, Consumption of the Lungs, Falling-sickness, Kings-evil, and Disease called by the Spaniard the Plague in the back, with us Empyema, their physicians are the Powaws, or Indian Priests who cure sometimes by charms and medicine, but in a general infection they seldom come amongst them, therefore they use their own remedies, which is sweating, etc. Their manner is when they have plague or small pox amongst them to cover their Wigwams with Bark so close that no Air can enter in, lining them (as I said before) within, and making a great fire they remain there in a stewing heat till they are in a top sweat, and then run out into the Sea or River, and presently after they are come into their Huttas again they either recover or give up the Ghost." (Josselyn's Voyages.) Josselyn's "Spotted Fever" and Wood's "Callentures" were undoubtedly typhus fever.

People living under primitive conditions are very liable to accidents and we find a full list of remedies to be used in such emergencies.

"WOUNDS."

Cod Fish.—"About their Fins you may find a kind of Lowse, which healeth a green cut in a short time."

White Hellebore.—"The Indians cure their wounds with it, anointing the wound first with Raccoon grease, or Wild Cat grease, and then strewing upon it the powder of the Roots."

Alder.—"An Indian Bruising and cutting of his knee with a fall, used no other remedy, than Alder Bark, chewed fasting and laid to it, which did soon heal it. For wounds and cuts make a strong decoction of Bark of Alder, pour it into the wound, and drink thereof."

Birch.—"White and black, the bark of the birch is used by the Indians, for bruised wounds and cuts, boiled very tender and stamp between two stones to a plaster, and the decoction thereof, poured into the wound."

Board Pine.—"It yields a very sovereign Turpentine for curing of desperate wounds. The Indians make use of the moss boiled in Spring Water, for Stabbs, pouring in the liquor, and applying the boiled moss well stamped or beaten between two stones."

"An Indian, whose knee was bruised with a fall, and the skin and flesh striped down to the middle of the Calf of his Leg cured himself with Water Lilly Roots boiled and stamped."

"Winter Green, the leaves are excellent Wound Herbs."

"Clounes all heal, of New England, is another wound Herb not inferior to ours, but rather beyond it."

The Larch Tree.—"The leaves and gum are both very good to heal wounds and cuts. I once cured a desperate bruise with a cut upon the knee-pan with an Unguent made with the Leaves of the Larch Tree, and Hogs Grease, but the gum is best."

Proud Flesh.—"To eat out proud flesh, they take a kind of earth Nut boiled and stamped and last of all, they apply to the sore the roots of water lilies boiled and stamped between two stones to a plaster."

INJURIES, BRUISES, SPRAINS.

"The Rattle Snake, they have leaf of Fat in their bellies, which is excellent to anoint frozen limbs, and for Aches and Bruises wondrous sovereign."

"An Indian whose thumb was swelled, and very much inflamed, and full of pain increasing and creeping along to the wrist, with little black spots under the thumb, against the nail, I cured it with this Umbellious Veneris Root and all, the yolk of an egg, and wheat flour."

"The root of the Humming Bird Tree, the Indians make use of it for aches, being bruised

between two stones, and laid to cold, but made (after the English manner) into an unguent with Hogs Greese, there is not a more sovereign remedy for bruises for what kind soever, and for Aches upon the Stroaks."

"The Raccoon, their Fat is excellent for bruises and Aches."

"Blew Flower-de-luce.—For Bruises of the Feet and Face."

"Sperma Ceti Oil.—Is admirable for Bruises and Aches."

"Sassafras.—The leaves of the same Tree are very good made into an ointment for bruises and dry blows."

BURNS AND SCALDS.

"Seal Oil.—It is very good for Scalds and Burns."

Pond Frogs.—"They are of a glistening brass colour and very fat, which is excellent for Burns and Scaldings, to take out the Fire, and heal them, leaving no scar."

Decoction of Alder Bark.—"Is also excellent to take fire out of a Burn or Scald."

"Birch Bark.—Boiled very tender and stamped between two stones to a plaister, and a decoction thereof—to take the fire out of burns and scalds."

"Tobacco.—There is not much of it planted in New England, the Indians make use of a small kind with short round leaves called Pooke. With a strong decoction of tobacco, they cure Burns and Scalds, boiling it in water, from a Quart to a Pint, then wash the sore therewith, and strew on the powder of dried tobacco."

"The New England Daisy, or Primrose, is very good for Burns and Scalds."

"And for Burning and Scalding, they first take out the fire with a strong decoction of Alder Bark, then they lay upon it a plaister of the Board Pine (bark) first boiled tender, then beaten to a plaister between two stones. One Christopher Luxe, a fisherman, having burnt his knee pan, was healed again by an Indian Webb, or wife, for so they call those women who have husbands. She first made a strong decoction of Alder Bark with which she took out the fire, by Imbrocation, or letting of it drop upon the sore, which would smoke notably with it, then she plastered it with the Bark of Board Pine, or Hemlock Tree, boiled soft and stamped between two stones, till it was as thin as brown paper, and of the same colour. She annointed the plaister with Soyles Oil, (Seal oil) and the Sore likewise, then she laid it on warm, and sometimes she made use of the bark of the Larch Tree."

"Water Plantane.—Called here Water suck-leaves. It is much used for Burns and Scalds."

INFLAMMATION.

"Fat of the pond frog.—Very good to take away any inflammation."

"Wood-binc.—Good for hot swelling of the

legs, fomenting with the decoction, and applying the Fecees in the form of a Cataplasme."

"An Indian Webb, her Foot being very much swelled and inflamed, asswaged the swelling, and took away the inflammation with our Garden or English Patience, the Roots roasted."

ABSCESS.

"Indian Wheat (wild rice).—It is hotter than our wheat and clammy, excellent in Cataplasms to ripen any swelling or impostume."

"The Indians break and heal their Swellings and Sores with it, boiling the inner Bark of young Hemlock very well, then knocking it between two stones to a plaster and anointing, or soaking it in Soyls Oil, they apply it to the Sore, it will break a Sore Swelling Speedily."

Josselyn mentions two cases of cancer which were cured: the first is an example in an English woman of the arsenic treatment; it also contains a curious little touch showing where prohibition Maine got its beer even in those days.

"I shall conclude this Section with a strange Cure effected upon a Drummer's Wife, much afflicted with a Wold in her Breast; the poor Woman lived with her Husband at a Town called by the Indians, Casco, but by the English, Farnmouth; where for some time she swaged the Pain of her Sore by bathing it with strong Malt Beer, which it would suck in greedily, as if some living Creature; (for it was brought from Boston, along the Coasts by Merchants.) she made use of Rhum, a strong Water drawn from Sugar Canes, with which it was lull'd asleep, at last, (to be rid of it altogether) she put a quantity of Arsnick to the Rhum, and bathing of it as formerly, she utterly destroyed it, and Cured herself; but her kind Husband, who sucked out the Poison as the Sore was healing, lost all his Teeth, but without further danger or inconvenience."

In the description of the next case it is very hard to tell just what disease he meant. Bailey's definition of scirrhus is "A hard immovable Swelling that resists the Touch, and is without Pain."

"An Indian dissolved a Scirrhus Tumour in the arm and hip, with a fomentation of Tobacco, applying afterwards the Herb stamped between two stones."

BRONCHITIS—SHORTNESS OF WIND—COLDS.

"Oak of Cappadocia, both much of a nature, but Oak of Hierusalem is stronger in operation, excellent for stuffing of the lungs upon colds, shortness of Wind, and Ptsiack, maladies that the natives are often troubled with: I helped several of the Indians with a drink made of two Gallons of Molasses wort, (for in that part of the country where I abode we made our beer of Molasses, Water, Bran, chips of Sassafras Root, and a little Wormwood well boiled), into which I put of Oak of Hierusalem, Catmint, Sowthistle, of

each one handful, of Enula Campana Root one Ounce, Liquorice scraped bruised and cut in pieces, one Ounce, Sassafras Root cut in thin chips, one Ounce, Anny-seed and sweet Fennel seed, of each one Spoonful bruised; boil these in a close Pot, upon a soft Fire to the Consumption of one Gallon, then take it off, and strain it gently, you may if you will boil the strained liquor with Sugar to a Syrup, then when it is Cold, put it in Glass Bottles, and take thereof three or four spoonfuls at a time, letting it run down your throat as leasurably as possible you can; do thus in the Morning, in the Afternoon, and at Night going to Bed."

Sumach, "The English used to Boil it and drink it for a cold, and so do the Indians, from whom the English had the Medicine."

PLAGUE OF THE BACK.

"The Firr Tree, or Pitch Tree, the tar is made of all sorts of pitch wood is an excellent thing to take away those desperate Stitches of the Sides, which perpetually afflicteth those poor people that are stricken with the Plague of the Back." Note.—"You must make a toast, or Cake, slit and dipt in the Tar, and bind it warm to the side."

CONSUMPTION.

"The Land Turtle, they are good for Physick and Consumptions, and some say the Morbus Callicus." (Syphilis.)

They seem to have had fewer remedies for fevers than their frequency and importance would seem to warrant. The use of a decoction of black birch bark for chills was, of course, an accidental discovery of the effect of salicylic acid. They undoubtedly used it much as we do aspirin.

FEVERS.

"Water-Mellon, it is often given to those sick of Fevers, and other hot diseases with good success."

"Bill Berries, two kinds, Black and sky coloured, which is more frequent. They are very good to allay the burning heat of fevers, and hot Agues, either in syrup or conserve."

Agues.—Black birch for chills. The Indians are said to have used a decoction of black birch bark for chills. (Tradition.)

"Ravens-Claw is admirable for Agues."

"Sassafras, or Ague Tree, the Root boiled in Beer is excellent to allay the hot rage of Fevers, being drunk."

By aches Josselyn evidently means acute and chronic rheumatism. Here are his remedies.

ACHES.

"The Wobble, For aches, our way, for they are sovereign for aches, is to make mummies of them, that is, to salt them well, and dry them in an earthen pot well glazed in an oven; or else,

which is the better way, to burn them under ground for a day or two, then quarter them and stew them in a stew-pan with a very little water."

"The Bear, their grease is very good for Aches and Cold Swellings, the Indians anoint themselves therewith from top to toe, which hardens them against the cold weather." "One Edward Andrews being Foxt, that is drunk, and falling backward across a Thought (Thwart) in a Shallop, or Fisher-boat and taking cold upon it, grew crooked, lame, and full of pain, was cured, lying one winter upon Bears Skins newly flead off, with some upon him, so that he sweat every night.

"A black Wolf's skin is worth a Beaver Skin among the Indians, being highly esteemed for helping old aches in old People, worn as a Coat."

"The Ounce, a wild cat, their grease is sovereign for all manner of Aches and shrunk Sineus."

White Hellebore.—"For Aches they scarify the grievated part, and anoint it with one of the foresaid Oils, (Raccoon or Wild Cat grease) then strew upon it the powder."

Dropsy was one of the deadly diseases which he mentions, but the remedies are very few, as they are today.

DROPSY.

Water Plantane.—"To draw water out of swelled Legs."

"Stone.—Likewise there is a stone found in their bellies (Cod fish) in a bladder against their navel, which being pulverized and drank in White-wine Posset or Ale, is a present Remedy for stone."

"Manaty.—There is a stone taken out of the head that is rare for the Stone and Collect. Their bones beat to a Powder and drank with convenient liquors, is a gallant Urin Provoking Medicine."

Scurvy was one of the most common diseases with the early settlers; it was one of the causes of the great sickness among the Pilgrims during the first winter. They knew that lemons and limes were good for the disease but they did not grow here and so they sought for other remedies, and the following are what they found.

SCURVY.

"Sea-tears, they grow upon the sea banks in abundance, they are good for Scurvy and Dropsie."

"The tops of Green Spruce Boughs boiled in Beer, and drunk, is assuredly one of the best Remedies for the Scurvy, restoring the Infected party in a short time."

"Cran Berry,—they are excellent against the scurvy."

Wood says that the danger of snake bite was not very great, and that he never heard of but

one man who lost his life in this way, still it was an 'ever-present fear to the settlers. The remedies were few but heroic.

SNAKE BITE.

"When any man is bitten by any of these creatures, the poison spreads so suddenly through the veins and so runs to the heart, that in one hour it causeth death, unless he hath the Antodote to expell the poison, which is a root called snakeweed, which much be champed, the spittle swallowed, and the root applied to the sore; this is present cure against that which would be present death without it: this weed is ranck poison, if it be taken by any man that is not bitted: whosoever is bitte by these snakes his flesh becomes as spotted as a Leaper until he be perfectly cured. It is reported that if the party live that is bitten, the snake will die, and if the party die, the snake will live." (Wood's "New England Prospect.")

"The Rattle Snake.—Their hearts swallowed fresh, is a good Antidote against their Venome, and their liver, the Gall taken out, bruised and applied to their Bitings is a present Remedy." ("New England Rarities.")

"Wind in the Stomach.—The skin of the Gripe drest with the down on, is good to wear upon the stomach for the pain and coldness of it."

"The Beaver, their solid Cods are much used in Physick: Our English women in this Country use the powder grated, as much as will lie upon a shilling in a draught of Fiol Wine, for wind in the Stomach and Belly, and venture many times in such cases to give it to Women with Child."

Teething necklace.—"The Indian Webbes make use of the broad teeth of the Fauns (Moose) to hang about their children's necks when they are breeding their Teeth. The tongue of a grown Moose, dried in the smoke after the Indian manner, is a dish for a Sagamore."

Menorrhagia.—"The Codfish, in the head of this fish is found a Stone, or rather a bone which being Pulverized and drank in any convenient liquor, will stop Women's overflowing Courses notably."

Codfish.—"Their livers and Sounds eaten is a good Medicine for to restore them that have melted their Grease."

Emetics.—"Blew Flower-de-luce; it is excellent to provoke Vomiting."

Love philtre.—"Dogstones, a kind of Satyrion, whereof there are several kinds groweth in our salt Marshes. I once took notice of a wanton Woman compounding the Solid Roots of this Plant with wine, for an Amorous Cup, which wrought the desired effect."

Film of the eyes.—"The Sheath Fish, which shell Calceined and Pulverized, is excellent to take off a Pin and Web, or any kind of Filme growing over the Eye."

Piles.—"Morse, or Sea Horse, having a great head, a wide jaw, armed with Tushes as white as Ivory, a body as big as a cow, proportioned like a Hog, of brownish bay, smooth skinned and impenetrable, they are frequent at the Isle of Sables, their teeth are worth eight Groats the Pound, the best Ivory being sold but for half the money. It is very good against Poison. As also for Cramp, made into rings. And a secret for the Piles, if a wise man have the ordering of it."

SCURVY SORES.

"Coals of Birch pulverized and wrought with the white of an egg to a salve, is a gallant remedy for dry scurvy sores upon the shins, and for bruised wounds and cuts."

SCIATICA.

"Spunk, an exerescence growing out of Black Birch, the Indians use it for Touchwood, and therewith they help the Sciatica, or Gout or the Hips, upon the Thigh, and upon certain Veins."

HERPES MILIARIS.

White Hellebore.—"The Root sliced thin and boiled in Vinegar, is very good against Herpes Miliaris."

SORE MOUTH AND FALLING OF THE PALATE.

"The decoction of blew eorn is good to wash sore mouths with.

"Hasel, for sore mouths, falling of the Pallat."

Filberd.—"Both with hairy husks upon the nuts, and setting hollow from the nut, and filled with a kind of water, of an astringent taste, it is very good for sore mouths, and falling of the Pallat, as is the whole green nut, before it comes to Kernel, burnt and pulverized."

SCALLED HEAD.

"Of the Moss that grows at the roots of the White Oak the Indians make a strong decoction, with which they help their Papouses or young Children's scalled Heads."

TO KEEP THE FEET WARM.

"Bastard Calamus Aromaticus, the English make use of the leaves, to keep their feet warm."

MOTHER FITS.

Seal oil.—"Some of it, being cast upon Coals, will bring Women out of the Mother Fits." (Hysteria, Eclampsia?)

TOOTHACHE.

"The Osprey, their beaks excell for the toothache, picking the Gums therewith until they bleed."

"The dogfish, upon whose Back grows a

Thorn two or three Inches long, that helps the Toothache, scarifying the Gums therewith."

"Hellibore.—The powder of the Root put into a hollow tooth, is good for the Tooth-ache."

EARACHE.

Oil of the red fox.—"Their fat liquified and put into ears easeth pain."—Josselyn's Voyages.

FALLING SICKNESS.

"The Indians tell of a tree that grows far up in the land, that is as big as an Oake, that will cure the falling-sickness infallibly, what part thereof they use, Bark, Wood, or fruit, I could never learn; they promised often to bring it to me, but did not."—Josselyn's Voyages.

INDIAN TURKISH BATH.

"This Hot-house is a kind of little Cell or Cave, six or eight foot over, round, made on the side of a hill (commonly by some Rivulet or Brooke) into this frequently the Men enter after they have exceedingly heated it with store of wood, laid upon an heape of stones in the middle. When they have taken out the fire, the stones keepe still a great heat: Ten, twelve, twenty more or less, enter at once starke naked, leaving their Coats, small breeches, (or aprons) at the doore, with one to keepe all: here doe they sit round these hot stones an houre or more, taking tobacco, discoursing and sweating together; which sweating they use for two ends: First, to cleanse their skin: Secondly, to purge their bodies which doubtless is a great meanes of preserving them, and recovering them from diseases, especially from the French disease, which by sweating and some potions, they perfectly and speedily cure: when they come forth (which is matter of admiration) I have seen them runne (Summer and Winter) into the brookes to coole them, without the least hurt."—Roger Williams' Key to the Indian language.

This seems to be a description of a primitive but effectual Turkish bath. This was used, evidently, as a general hygienic measure and not for the treatment of the serious diseases such as Josselyn describes.

DISEASES COMMON TO THE ENGLISH.

"The Diseases that the English are afflicted with, are the same that they have in England, with some proper to New England, griping of the belly (accompanied with Feaver and Ague) which turns to the bloody-flux, a common disease in the Country, which together with the small pox hath carried away abundance of their children."

"Also they are troubled with a disease in the mouth or throat which hath proved mortal to some in a very short time,* Quinsies, and Impostumations of the Almonds, with great distempers of cold."—Josselyn's Voyages.

* Was this diphtheria?

The Indians were great users of oil, both as an article of diet, and to anoint their bodies. They used any kind of oil they could get, rattlesnake oil, eagle oil, seal oil, raccoon and bear's grease, and they had an elaborate method of obtaining oil from white oak acorns.

The remedies used by the New England Indians were entirely different from those used by the Western and Southern Indians, i. e., each used the plants which were native to their locality. The medicine used by the Indians and early English are of no use today, but the study of this primitive folk medicine is of interest, not alone from an historical point of view, but as showing the origin of many methods in use among the people as well.

BIOLOGIC ANALYSIS IN THE STUDY OF TRUE EPILEPSY.

BY F. L. DUNHAM, M.D., BALTIMORE.

THE derivation of the word "epilepsy," from the Greek verb "to seize upon," describes no less clearly the onset of the condition itself than it characterizes the whimsicalities frequently adopted by writers in discussing its etiology. It would be difficult to choose a symptom-complex about which have been woven more fantastic hypotheses than that of epilepsy, the "Sacred Disease" of the Asclepiades, which Hippocrates characterized as no more sacred or mysterious than other ills whose nature appears to be above the level of human understanding. The tendency to justify an attitude of doubt respecting the cause of epilepsy has probably found encouragement in the superior endowment of many subjects of this disorder, who are reckoned among the world's geniuses. The more adequate adaptation to their social environment, secured in recent years to segregated groups of epileptics, has produced definite results in studying the causes and results of the disorder. At the same time the broader application of scientific method in experimentation has tended to dispel the unethical haze long surrounding the subject. Even the more recent psycho-analytical point of view, with its appeal to an obscure symbolism, has helped to develop a more thorough biologic analysis.

Whether true epilepsy is to be regarded as a simple neurosis, as a manifestation of organic disease with evidence of cerebral toxemia, or as an "unconscious striving, with its insistent urge in the fits, to return to the maternal intra-uterine life," analyses following biologic lines only are justified as a means toward the recognition of potential subjects. From this point of view, a logical procedure of investigation will follow out the hereditary factors revealed in family tendencies to instability, the course of embryonic development, the early reaction to primitive instincts, together with a complete

review of the social behavior of the subject. Until the facts of such an analysis are secured no amount of pathological detail can render practical service in the disposition of individual cases.

Although most modern students of the subject agree with Hippocrates in ascribing true epilepsy to tendencies following the laws of heredity and recognize its stimuli as intimately connected with the brain, various cases, with no known intrinsic factors, indicate that some epileptics owe their condition to extrinsic or environmental causes. Current procedure, moreover, corresponds with that of Hippocratic times in attributing the most satisfactory therapeutic results to food and hygienic regulation, "without minding purifications, spells, and all other illiberal practices of a like kind."

Believing that satisfactory studies of the subject, especially such as deal with its relation to social adaptation, can result only from prolonged observation of segregated groups of epileptics, the writer presents the following data obtained from two groups of ten subjects each, inmates during several years of a modern colony-home in central New England. The children were unselected, save with reference to the frequency of definitely typical seizures. An attempt was also made to secure only those subjects who had shown no marked indication of mental inferiority in infancy. The data for analysis were secured from the following examinations:

1. An anthropological examination.
2. An intelligence test (point-scale) checked by a second (Binet-Simon) test.
3. A complete physical examination, including an examination of the urine.
4. A Wassermann reaction.
5. An examination of the social history of the family, so far as possible through personal solicitation, otherwise by questionnaire.

The subjects were also studied in their customary environment, now playing or working in groups, at other times alone with an attendant. An attempt was made to place each child at his ease by engaging him in some task, thus minimizing the changed emotional reaction incident to any examination, with its resulting inaccuracies.

That true epilepsy is often the result of defective development, whose beginnings are laid down in the egg, was suggested by the Father of Medicine in an Aphorism to the effect that "epilepsy begins to be formed while the fetus is *in utero*." This conception of its ultimate causation is amply justified by the usual pathological findings, *i. e.*, a typical arrangement of the convolutions and microgyria, generally without microscopic defect in structure except of a secondary nature. Moreover, it tends to harmonize various obscure psychic manifestations, now frequently attributed to the vagaries of lower levels of consciousness, by rec-

ognizing in them the primitive, unconditional reflexes which, through morphologic defect in mechanism, have failed to reach biologic adjustment as exemplified in the conditional reflex. In general, it is true that defective forms of morphological development are due to alterations of the normal environmental stimuli rather than to defective hereditary constitution. Even though a tendency to the latter may be inherited, a normal environment may prevent their appearance. The differentiations of cleavage, which are the earliest expressions leading to the formation of cells qualitatively and quantitatively different, are from the first subjected to an extrinsic environment whose delicacy is inconceivable save through an appeal to the elaborate physicochemical reactions of the blood. The problem of development here presented seeks to determine, so far as possible, the origin and sequence of morphological differentiations, together with the extrinsic factors whose results are manifest in epilepsy. It is well recognized that the earlier stages in development are more easily influenced by environmental changes than are later ones. That these may result in profound departures from the normal adult structures, is clear when it is recalled that at this germinal period entire organic systems may be represented by a few cells merely. Almost all persistent alterations of embryonic structure occur during cleavage, and are due primarily to interference with the divisional apparatus of the cell. This seems to be explained by the fact that when chromosomes, centrosomes or differentiated portions of the cell-body are once distributed abnormally to the two daughter cells there is no possibility of bringing about a normal redistribution of these structures. Experiments with the eggs of lower animals indicate that various environmental changes cause abnormalities in the separation of daughter chromosomes and in their fusion to form daughter nuclei. Subjected to various abnormal stimuli such as pressure, electric currents, unusual thermal conditions, unnatural chemical solutions, changes are produced in the type of cleavage, in the orientation and structure of mitotic figures and induction of polyspermy, together with various abnormalities of the chromatin and chromosome content of the cells. It is generally held that the human ovum follows the same general course in development as the germ cells of lower animals. Setting aside, therefore, those cases of defect which may be traced to intrinsic or hereditary factors, clinical observations as well as experimental deductions would indicate that the extrinsic elements surrounding the human germ-cell in syphilitic or tuberculous mothers or those with abnormal physiological secretions are amply able to leave their imprint of potential defect upon the plastic structure of the embryo. Again, if it is held that the egg cytoplasm fixes the general type of de-

velopment, while the sperm acts primarily in contributing details such as are exemplified by mental peculiarities, it is evident that the father's contribution to the fertilized germ-cell might also induce defect. Various studies have shown that environmental agents, such as alcohol, profoundly modify the germ-cells. "Thus the external as well as the internal factors are to be considered, not only in individual or embryonic development, but also in heredity. Experiments demonstrate for mammals that either the spermatozoon or the ovum may be experimentally injured or modified in such a manner as not only to give rise to abnormal development in the resulting embryo, but the effects of the injury may be transmitted from generation to generation, until an affected line actually fades out through degeneracy and sterility as a result of the transmitted condition." This tendency among students of genetics to give a broader interpretation to the influence of environment is well expressed by Morgan in his experimental studies on *Drosophila*: "If we measure or weigh or classify any character shown by the individuals of a population, we find differences. We recognize that some of these are due to the varied experiences that the individuals have encountered in the course of their lives, *i.e.*, to their environment, but we also recognize that some of the differences may be due to individuals having different germ plasm."

The various factors here reported show conclusively that the prenatal environment of each of these individuals was modified sufficiently to induce, in any organism, profound structural changes. The objection may be raised, however, that this offers no explanation of the specific defect. Why epilepsy instead of idiocy or a monster? To this one can only reply that the various objective results of the process seem to differ in degree only. All cerebral disturbances presuppose some specific defect of organization. Idiocy and epilepsy are frequently synonymous, and the epileptic has many physical stigmata which are the hall marks of the monster. It is of interest to note in this connection that recent investigation points to the conclusion that the primary causes underlying the origin of monsters in man and other mammals are autogenous chemical modifications of the parental blood. Working with butyric acid and acetone, Werber concludes that all morphological deformities of sensory organs may be induced through the blastolytic action of the modified environment.

In the absence of precise experimental data revealing the exact nature of the epileptic predisposition, a biologic analysis is able to present results of practical application from the standpoint of social adjustment. It is possible, for instance, to answer the questions, so vital to one seeking explanation of suspicious conduct, "How early is it possible to recognize traits in-

dicative of ill-balance in a child?" Through what factors of behavior may latent epilepsy be anticipated? A partial answer, at least, is found in the data here presented.

Significant incidents of behavior as the child emerged from infancy are the following:

EARLY OBSERVATIONS OF INSTABILITY.

- Case A. Frequent slight "worm-fits," tantrums, bed-wetting, somnambulism. Teeth, palate and ears stigmatic.
- " B. Mentally retarded, somnambulism, speech defect. Ears stigmatic.
- " C. Tantrums, bed-wetting, precocious day dreaming.
- " D. Tantrums, somnambulism, bed-wetting, recurrent dreams.
- " E. Tantrums, rolling out of bed during sleep, bed-wetting. Ears stigmatic.
- " F. Early persistent masturbation, thumb-sucking, tantrums, always bumping head. Cerebral hemorrhage at birth. Teeth, ears and palate stigmatic.
- " G. Early stealing and lying with definite object in view, over-emotional, bed-wetting.
- " H. Bed-wetting, rolling out of bed during sleep. Various stigmata.
- " I. Highly emotional, bed-wetting, rolling out of bed during sleep, day dreamer. Various stigmata.
- " J. Highly precocious in studies, bed-wetting, rolling out of bed during sleep, night terrors.
- " K. Tantrums, "forgetful," spasms at time of teething.
- " L. Night terrors, recurrent dreams, somnambulism, rolling out of bed, speech defect. Ears stigmatic.
- " M. Night terrors, dreams, somnambulism, bed-wetting, poor adaption at play, talking "strangely."
- " N. Early mental retardation of marked degree, spasms after food.

Following is the numerical distribution of the factors brought out in analysis:

CHRONOLOGICAL AGE.		MENTAL AGE.	
YEARS	NUMBER	YEARS	NUMBER
7	2	3	2
8	2	5	4
9	1	6	1
10	1	7	3
11	3	8	3
12	3	9	4
13	2	10	1
14	1	11	1
15	1	13	1
16	1		
17	1		
22	1		
26	1		

INTELLIGENCE QUOTIENT	CLASSIFICATION (TERMAN)	NUMBER
100	Normal	3
90	Dull	2
70	Borderline	5
Below 70	Peeble-minded	10

EARLY MENTAL CONDITION AS SHOWN BY SCHOOL PROGRESS.

Backward	11
Normal	8
Precocious	1

PHYSIOLOGICAL DEVELOPMENT

Prepubescent	7
Pubescent	8
Mature	5

SEX.

Male	10
Female	10

RANGE

Teething began ...	3 mos. to 1 yr.
Walking began ...	9 mos. to 2 yrs.
Talking began ...	7 mos. to 2 yrs.

Neurotic traits:

Nocturnal enuresis	13
Rolling out of bed	7
Night terrors	3
Recurrent dreams	9
Somnambulism	6
Masturbation	7
Persistent thumb-sucking	1
Tantrums	6
Over-mischievous	5
Speech defect	3
Violent fears with excessive emotional reaction	9
Anomalous teeth	9
Stigmata palate	12
Stigmata ears	18
Absent lobe	2
Darwinian tubercle	3
Heavy, right-angular	7
Satyriform	2
Asymmetrical	3
Unrolled helix	1

Immediate family history of:*

Drink	1
Drugs	1
Insanity	1
Epilepsy	2
Spasms	2
Rheumatism	7
Tuberculosis	8
Severe recurrent headache	5
Cancer	3
Chorea	1
"Skin disease"	1†
"Sex offender, habitual (mother)	1
"Uncontrolled temper"	5

Remote hereditary history of mental defect:

Epilepsy (maternal sister)	1
Epilepsy (paternal grandfather)	1
Chronic headache (p. and m. sibs.)	4
Convulsions (maternal sister)	1

Illegitimate	1
Instrumental delivery	3
History of family quarrels during pregnancy	4‡

Wassermann reaction:

Positive	9
Doubtful	4
Negative	5§

* No family history obtained was free from one or more of the diseases indicated under "Family History."

† Offspring's Wassermann positive.

‡ Three of these at two months.

§ Of the latter, two were from highly neurotic families and one from a tuberculosis family.

Attacks attributed by parent to:

"Fright"	1
Traumatic causes	4
"Punishment"	1
Unknown causes	14

Attacks dated from:

Birth	2
Infancy	12
2 to 8 years	6

Aura (Seventeen able to give satisfactory response)

Referred to abdominal region	15
Referred to head	2
Intensive visual image	2
Headache following	5

Seizures

Nocturnal and diurnal	9
Nocturnal	2
Diurnal	9
Ability to abort attacks frequently ...	4

Although various measurements of interest from an anthropological standpoint were taken, only those relating to cranial size will be considered here. Following are the head measurements:

	MEAN	MEAN VARIATION
Length (glabella to occipital protuberance)	18.1 cm.	.7 cm.
Breadth (max. temporo-parietal)	14.3 "	.69 cm.
Height (inter-auricular line to bregma)	13.1 "	.665 cm.
Circumference	53.0 "	.22 cm.

These figures correspond to the average for normal children.

The physical examination relating to the incidence of general somatic disease showed no unusual disturbance in the circulatory or respiratory organs. Evidence of a rachitic tendency was seen in several but no definite history to this effect was obtainable. Two showed traces of albumen with no casts or other clinical symptoms of renal disease. In none was the thyroid palpable. Two had marked exophthalmos with no other clinical manifestation of disease. In a majority the faucial tonsils were hypertrophic but not sufficiently so to obstruct normal activity. The pharyngeal tonsil, or "adenoids," was present or had been present in all, markedly obstructing the breathing of several. The superficial and deep reflexes were exaggerated in all. Several had visual defects which had been adjusted. In somewhat more than half the number the teeth were remarkably well preserved. In none were there evidences of an active tubercular process. None showed morphological evidence of hereditary syphilis. Although one subject had suffered from an attack of anterior poliomyelitis there was no residuum.

The frequency of seizures is indicated in the following table:

I. MILD GROUP.

		PRESENT CONDITION
8-year-old girl	Frequent during infancy.	Only once in 6 years past. I.
13-year-old girl	Daily during childhood.	Only once in 2 or 3 weeks. I.
11-year-old boy	Frequent in infancy.	Once or twice monthly. N.
17-year-old girl	Daily in childhood.	Two or three monthly. I.
7-year-old girl	Frequent in infancy.	Once in two weeks. D.
26-year-old girl	Once in several months since infancy.	I.
11-year-old boy	Daily during childhood.	One every night. I.
22-year-old girl	Every two days during childhood.	Once monthly. I.
11-year-old boy	Every one or two weeks since birth.	D.
13-year-old girl	Once a month since infancy.	D.

II. SEVERE GROUP.

		PRESENT CONDITION
14-year-old boy	Since infancy many mild diurnal and one severe nocturnal.	D.
12-year-old girl	Frequent since 2 years old.	Daily now. Status with complete loss of consciousness for 30 hours. D.
7-year-old boy	Since infancy.	Scores of mild diurnal and 1 severe nocturnal. D.
12-year-old boy	Since infancy.	One severe weekly. D.
10-year-old boy	Since birth.	A score daily. D.
12-year-old boy	For past 2 years, only, 1 to 3 diurnal and 2 severe nocturnal.	D.
16-year-old girl	Since infancy.	One severe daily. I. (Often a month free.)
9-year-old boy	Since infancy.	Two or three diurnal and two nocturnal. I
8-year-old girl	Since infancy.	Ten diurnal and four nocturnal. D.
15-year-old boy	Since infancy.	1 to 4 diurnal; 6 to 25 nocturnal. D.
	I, Improved	8
	D, Deteriorating	11
	N, Unchanged	2

Following are the analyses of social behavior as exemplified in several of the protocols:

M. A. A low-grade, 8-yr.-old, moronic girl, physically overdeveloped. Over-active, inattentive, very approachable, laughing or grimacing constantly unless engaged at work or play. Easily interested in subjects for which the normal child is adapted. Delights in and discusses "movies." Makes bed under supervision and does simple housework. Untidy. No interest in clothes for herself but rather for her doll. A good mixer, an unusual mimic. A leader of other children. Initiates new situations, plays school, hospital and watches desquamation of doll ill with scarlet fever. Very mischievous, prevaricates but never steals. Generous. Had tantrums but now anticipation of punishment in bed causes temper to subside. Whimpers much. Will not be driven but may be reasoned with. Has been an excessive masturbator (several times daily) but shows much improvement through education. Does little school work, but thrives out of doors. Some violent fears, especially other children in spasms, yet so fascinated as to be riveted to the spot, screaming and kicking, eyes protruding, unable to move. Reactions to food and sleep normal. Few attacks now.

E. A. An attractive, delicate girl of 13, of normal intelligence. Highly emotional, weeping during examination but voluntarily returning for its completion. Adapts herself well to others. Fond of fairy tales but "detests love stories." Over-fond of babies. "Affectionate," loyal, but will not assert her own independence. Unjustly accused, she fails to clear herself but remains in silent, tearful mood. Various neurotic traits have been overcome voluntarily. Since sexual maturity a year ago seizures much less frequent. An excellent worker. Very eager to recover completely. Responsible, thoughtful of others, truthful, neat, very consistent, eating no meat in order to hasten re-

covery. Good student. Many dreams of being pursued, of wetting bed, or having to go home where environment is poor.

R. B. A boy whose chronological and mental age is 11 yrs. Head circumference of 56 cm. is in excess of normal. Cruel, obscene, tormentor, thief, tease; lies, swears and kills birds for fun. Does well in school though attention is poor. Fond of embroidery and sewing. No fears. Sullen, vindictive, not easily approached. Masturbates but no other neurotic traits. Reactions to food and sleep normal.

E. B. A coarse girl of 17 yrs., mentally 9 yrs. Reacts very slowly but a good worker. Over-emotional, fond of boys and thinks she may marry. Quarrelsome, impulsive, neat but cares little for clothes though has obsession for white teeth (hers are distinctly wolf-like). Various fears—the dark, animals, etc. Very fond of children.

M. K. A thin, spare girl of 26 yrs., mentally 9 yrs. Very loquacious. Obsessed by family troubles of many years ago. Extremely religious, praying much. A good worker, responsible. Severe temper, a residuum of early tantrums, which had been utilized in obtaining her desires. Various peculiar food reactions; is also a somnambulist. Always same aura: A visual image of a large, red moon slowly changing to an enormous deer with threatening antlers. As soon as this image runs into a hole a seizure begins. Sometimes long delayed.

E. T. A coarse, masculine girl of 22 yrs., mentally 9 yrs. Early history unknown. No neurotic traits now. Seizures infrequent but very severe. Hard worker, responsible, likes boys. Fond of detective stories only. Very religious. Sullen but tractable. Has overcome bad habits. Attention good.

If the behavior of an epileptic is analyzed his unusual conduct cannot be explained consistently and excused upon the ground that "all epileptics indicate a bad adaptation to their environment." From the very beginning of development his environment has been unfavorable, according to prevailing standards of conduct. Manifestly his adaptation to a normal environment is poor but his environment has never been normal. Owing to inability from the first to react to a normal instinctive life his reflex activities are in a primitive, unconditional state. Thus the various manifestations of the primal demands of nutrition, self-preservation and reproduction, unable to functionate in the normal manner, because of abnormal mechanisms, exhibit their rebellious disposition in the incident of the epileptic seizure with its attendant toxæmia and its train of anomalous phenomena. This fact is adequately shown in the table of neurotic traits prevailing in the present group of subjects, and may be traced in one form or another in each analysis of instinctive behavior. The fact that instincts in the epileptic operate precociously renders his conduct less deserving of censure. While the higher mental processes also may be developed precociously in a large number of cases, it is the method of response to the vegetative processes which must elucidate the mental endowment of these subjects. The relation of these instinctive reactions to the chief objective phenomenon—the seizure—is manifest in the frequent cessation of attacks following castration or after the advent of sexual maturity or, as in a case here reported, after indulgence in auto-erotic practices has become established. Again the instinct of self-preservation, with its emotional reaction of fear, is rarely well adjusted in epileptics. As an interesting coincidence may be cited two of the cases here reported, the first seizure following an intensive appeal to flight from pursuing enemies. The ease with which a seizure could be induced through the reaction of emotional stimuli characterized a large percentage of the subjects. The ability frequently to abort an attack following a definite aura, by an appeal to the digestive or nutritional apparatus, together with the remarkable frequency with which digestive phenomena usher in the premonitory phenomena, further illustrates instinctive tendencies in the evolution of the true seizure. The epileptic's failure to make a good social adjustment follows as a logical consequence of his biologic defects. Conduct results from the activity of emotions and impulses springing as natural growths from the primary instincts. As a result of the organization of these emotions, the sentiments develop,—systems of the utmost importance in the formation of character. Consequently the child having epilepsy, whose basic instincts and mechanisms are at fault, is deprived of these organized elements of the affective processes, into whose composition enter

the principal emotional dispositions of the instinctive life. The natural result of this defect is an unstable and incomplete social adjustment.

SUMMARY.

1. In the foregoing analysis an attempt is made to emphasize the importance of the more intensive, biologic examination of children—in this instance, those afflicted with true epilepsy.
2. An explanation of epileptic phenomena is sought in the reactions of noxious stimuli upon the germ cell, whose environmental maladjustment appears to induce abnormal, morphological differentiations in the embryo with the power of hereditary transmission of tendencies toward defect, to succeeding generations.
3. An analysis is made of various phenomena in the social, somatic and psychic behavior of twenty subjects suffering from true epilepsy. Attention is called to these as evidence of instinctive instability.
4. The recognized hypothesis that structural abnormalities are concerned in the production of epileptic seizures is accepted and the unconditional reflex is suggested as an element in their mode of functioning.

SURGICAL TREATMENT OF LARYNGEAL CANCER.

By JOHN E. MACKENTY, M.D., NEW YORK CITY.

In presenting this subject, only two procedures will be considered, viz., total laryngectomy and hemilaryngectomy. The attempt to remove malignant growths by intra-laryngeal methods, advanced as these now are, is to be condemned. The eradication of cancer by thyrotomy is an ideal method, conserving the normal breath-way and a varying degree of audible speech. But it is applicable only in the most incipient cases. It is conceivable that improved diagnostic skill on the part of the profession at large may bring these cases to operation at a stage sufficiently early to justify a more frequent use of thyrotomy. My experience with it has been discouraging, giving a large return of hopeless recurrences.

Recurrence after thyrotomy means increased malignancy and irreparable loss of time. I firmly believe that the surgeon is given but one chance to eradicate cancer, wherever situated.

In border-line cases the patient's feelings may determine between total and partial removal, some preferring even death to a voiceless existence. When in doubt and the choice of operation is left to the surgeon, the larynx should be split and its interior inspected, then partly or totally removed, as seems advisable.

The degree of malignancy, as determined by the history and appearance of the growth, must be taken into account. When any doubt exists as to the best procedure, I would strongly advocate the more radical one. If the growth approaches close to the median line in the anterior or posterior commissure, total laryngectomy is indicated. If the arytenoids be involved, a liberal portion of the anterior part of the mouth of the esophagus should be resected with the larynx.

In total laryngectomy, I prefer the one-stage operation for the following reasons. When a preliminary tracheotomy is done and the trachea surrounded with gauze to establish peritracheal adhesions, the object aimed at is to prevent extension of infection to the mediastinum. This possible good is out-balanced, in my opinion, by the fact that at the second stage we are forced to operate in a well-established septic field. Another objection is that a primary union between the skin and tracheal mucous membrane is seldom possible when the trachea has been mutilated and the surrounding tissues infected. A clean union here means that the patient may dispense with the tracheal cannula. To wall off the trachea at the first stage and to leave it closed, would, I believe, be a more logical procedure in the two-stage operation.

Many points of interest arise in laryngectomy which, owing to limited time, I may but touch upon.

I am often asked, what is the mental state of these patients after partial or total laryngectomy? Their acceptance of the new conditions under which they are forced to live has been to me a great surprise. Those who have escaped a recurrence, or who think they have escaped it, are extremely grateful and uniformly cheerful.

Several of my laryngectomies have developed a remarkable degree of speech. Two of them have acquired a whisper, conveying words at short range.

In what cases should the gland-bearing tissue of the neck be removed? Unless this is thoroughly done, it is worse than useless. By the removal of gland-bearing tissue, I mean that all the fat and fascia of the region should be taken away by a painstaking dissection, carried well backward into the posterior triangle and upward into the submaxillary region and downward to the clavicle.

When the arytenoids are involved, it is almost certain that the disease has entered the lymphatics of the neck, necessitating their removal. If the median line is encroached upon, the dissection must include both sides.

How much of the esophagus may be removed without damage to its function? In all cases I remove the anterior part of the mouth of the tube, the extent being determined by existing conditions. At least one inch downwards anterior and one third of its circumference has been resected in five cases, without producing subsequent stricture.

Primary union is the exception in total laryngectomy. The wound infection in all my cases began above at the pharyngeal closure, manifesting itself between the third or fourth day. Liberal opening with drainage prevents or retards its spreading downwards to the danger zone behind the tracheal stump. This retardation is an important factor in the prevention of mediastinal infection, giving the retro-tracheal region time to become walled off. Wound infection with sloughing may not, after all, be an unmitigated evil, since it may, by the eradication of disseminated cancer cells, tend to retard or prevent recurrences. It has, I believe, done so in two of my cases.

In no case have I failed to secure primary union in the subsequent plastic repair following even extensive destruction of the tissues. The most important point here is to delay operation until long after the suppurative stage has passed.

Shock, pneumonic sepsis and mediastinitis are the ever-present dangers of laryngectomy.

Shock. Very old and decrepit individuals should not be subjected to this operation. As short and light a general anesthesia as possible should be given. In selected cases, I would suggest the use of local anesthesia carried as far as can be done without pain, that is, to the skeletonization of the larynx and trachea, then light general anesthesia during the detachment of the larynx from the neck and the closure of the pharynx. The operation may then be finished under local anesthesia. Thus the ether period should not last more than twenty to thirty minutes.

Pneumonia—short and light general anesthesia—the prevention of the entrance of blood into trachea during operation and of wound drainage after operation, and the removal of tracheal secretions by suction, materially lessen the danger of pneumonia.

Sepsis. Diseased teeth and chronic sinusitis may be overlooked factors in the production of virulent septic wound infection in any case where the pharynx is opened. I strongly advocate the removal of diseased teeth at a period as long before the operation as possible.

The removal of tissue for diagnosis is to be avoided, if possible. Syphilis must be excluded.

Before describing the technic I shall ask your

permission to digress and point out what seem to me to be some of the important points in the management of laryngectomy.

1st. The operation should be so conducted as absolutely to prevent blood entering the trachea during the operation.

2d. Wound contamination from the open trachea and pharynx should be guarded against during the operation.

3d. In total laryngectomy two lines of drainage are indicated,—one just below the pharyngeal closure and the other just behind the tracheal stump, where it is secured to the skin. The latter is of prime importance, crossing, as it does, the direct path of mediastinal infection. In this situation, unprotected, weak iodoform gauze is used to promote adhesions. If the infection from above can be delayed a few days (and in all of my infected cases it has been so delayed), the danger zone behind the trachea is eliminated and a primary union between the trachea and skin promoted.

4th. A nourishing and properly balanced diet is essential from the start. The only means of accomplishing this is by the use of the feeding-tube, introduced into the esophagus through the nose and left in place until the wound is healed. In one case the patient was thus fed for two months without producing esophagitis.

5th. When infection occurs, strict attention to drainage is imperative. The dressings should be changed every two hours or oftener during the day and every three or four hours during the night. At each dressing a negative pressure pump is used to remove the pus and tenacious mucus and pharyngeal secretions from the wound.

6th. The total absence of lung complications in my cases was partly due, in my opinion, to the use of inter-tracheal suction applied through a small catheter, introduced as far down as the bifurcation. This is used as indicated by the amount of tracheal secretion at least every hour or two for a few days following the operation.

Two physiological principles underlie the expulsion of secretions from the trachea, namely, normal ciliary action and normal cough. By normal cough I mean the compression of air behind the closed glottis and its expulsion by a sudden release of this closure.

In the open trachea normal cough is impossible and, following operative traumatism, the ciliary action of the tracheal mucous membrane is at least temporarily in abeyance. Hence there is a tendency for secretions, much increased after laryngectomy, to enter the lungs, producing well-known consequences. On this argument I contend that intratracheal suction rests on a logical basis.

The operation for hemilaryngectomy is my own. Its radical departure from the accepted method of Gluck makes me put it forward with some hesitation. It has been done in six cases

with six surgical recoveries. In all but one the larynx remained sufficiently open for normal breathing. In one there was some contraction, causing slight dyspnoea on exertion, and audible breathing at all times.

The operation for total laryngectomy is essentially the accepted method of the one-stage operation, with some modification of my own in the technic and in the after-treatment.

OPERATION FOR HEMILARYNGECTOMY.

Operation. If it cannot be decided whether a thyrotomy or a hemilaryngectomy is to be done, the larynx should be first opened for inspection. Then, if hemilaryngectomy is elected, before proceeding further with the operation, the trachea is opened just above the sternal notch. Two separate incisions are made, one for the laryngectomy and another for the tracheotomy. The first incision begins well up under the chin and extends to a point just below the cricoid ring in the centre line. This is deepened until the thyrohyoid membrane, the thyroid and the cricoid cartilages are exposed. Care is taken not to separate the tissues laterally. The larynx is then opened in the center line, its interior cocaineized and inspected. Blunt hooks or retractors are used in order to avoid injury to the edges of the cartilage, especially on the healthy side.

A hemilaryngectomy being decided upon, the trachea is next opened as low as possible. The second incision is here made, over the end of the sternal notch and up to within one inch, or more, if possible, of the first incision. Care is taken that a liberal bridge of tissue is left between the two incisions. The trachea is opened and a large tracheal cannula inserted. Into this is fitted a rubber tube, eighteen inches long, through which the anesthetic is continued. Before inserting the tracheal cannula, two stout silk threads are passed through the edges of the tracheal incision, one on each side and laid one on each side of the neck. The wound is then closed fairly close up to the cannula. The object of the silk threads is to control the tracheal opening, in case the tube should get displaced or come out. Traction on these threads opens the trachea. This precaution I always take in low tracheotomies.

The larynx is again opened with blunt hooks or narrow retractors. The trachea is cocaineized and tightly packed with gauze. The skin, cervical fascia, and pre-tracheal muscles covering the diseased half of the larynx are carefully dissected away from the cartilage, taking care to keep them all in one flap and not to injure the inner surface, which is composed of the pre-tracheal fascia, as this surface is to form the new laryngeal wall. This flap is gently held away while the removal of half of the larynx proceeds. The thyrohyoid membrane is slit laterally and the trachea divided below the cricoid ring on the diseased side. A

large wad of iodoform gauze is packed into the pharynx to prevent contamination from that quarter. This is removed through the mouth when the operation is near completion. The loosened half of the larynx is now retracted, well away from the centre line. If the mucous membrane over the posterior commissure and arytenoid is healthy it is saved and lifted away from the cartilage beneath. This mucous membrane dissection is carried backwards over the posterior surface of the arytenoid and down towards, and sometimes into, the anterior aspect of the mouth of the esophagus. The diseased half of the larynx is now removed in the usual way, being careful to save the mucous membrane flap outlined above. All bleeding points are controlled by catching only the vessels and by tying with an 00 iodized catgut. Stress should be laid upon careful and non-traumatic hemostasis. I would here digress to say that the usual rough handling of tissues, so frequently seen in general surgery, is entirely out of place in this operation. Much in the ultimate result depends on gentleness. The next step in the operation is to endeavor to cover as much as possible of the raw surface left by the hemilaryngectomy with mucous membrane. The flap mentioned above is brought downward and inward. It may sometimes be further enlarged by splitting the mouth of the esophagus. A considerable part of the raw surface left by the removal of half of the larynx may thus be covered. Stitches of fine, iodized gut are placed so as to hold the flap in its new position, care being taken that tension is avoided. The tracheal packing is now removed and the trachea cleared of blood clot down to the cannula. A long, half inch, folded strip of vaselined gauze, thoroughly impregnated with bismuth, is packed into the trachea, filling it from the cannula to its open end. This strip should be folded back and forth in the trachea, so that its removal may be more easily accomplished, and it should be packed in tight and even. To prevent the lower end of the gauze from falling into the trachea and to facilitate tight packing, a drawing-string is run through the gauze, being attached to its lower end. When the packing is in place this string is drawn up, thus approximating the two ends of the gauze. This corks the trachea against secretions from above. The end of the strip is brought out at the lower end of the laryngeal incision. The larynx is packed loosely with a strip of iodoform gauze, the end of which is brought out at the same point as the tracheal packing. The gauze in the pharynx is removed through the mouth and the feeding-tube is inserted through the nose and directed into the esophagus.

Closure. The mesial edge of the pre-tracheal muscles (the under surface of the lateral flap) is now united to the mucous membrane of the healthy side of the larynx, along its anterior median aspect, using fine iodized gut. The

skin edges are united with silkworm gut. The wound is left open at its lower angle, wide enough to give drainage room for the gauze ends. Two provisional stitches are placed here to be tied after these strips are removed, thus entirely closing the larynx. A sheet of rubber tissue, covered on both sides with gauze, is glued by its edge with collodion to the neck, across the bridge of skin separating the two wounds. This attachment should extend laterally one-half way around the neck. Its object is to act as a barrier between the laryngeal wound and the tracheal cannula, keeping the drainage of the one away from the other. The quantity of drainage that comes from the laryngeal wound saturates several pads of gauze a day, and makes one feel that if only a fraction of it should find its way into the lung through an open trachea, pneumonia might well be the result. The bismuth in the trachea plug keeps it clean and odorless for days and with the vaseline effectually turns the drainage out towards the surface.

After-Treatment. There are a few points in the after-treatment on which I would lay emphasis.

Paramount, in this regard, is a liberal and supporting diet. Without the use of the esophageal tube it is impossible to give enough food to support these patients through the important early days of convalescence. The diet I prescribe is as follows: Oatmeal thoroughly cooked and strained, mixed with milk. To the above may be added milk-sugar and raw egg, and occasionally melted butter. Six ounces of this thick mixture are forced through the tube with a piston syringe every four hours, followed by four ounces of water. Fruit and vegetable juices are later added.

The esophageal tube may be retained for weeks without injury, providing it is washed out after each feeding, as stated above. If by accident it should come out and cannot be replaced, I would not hesitate to do a gastrotomy, so important do I consider liberal feeding. Rectal feeding, in my opinion, should not be relied upon. It is merely an effective way of pretending to do something.

In some cases tracheal and bronchial secretion is much increased. In one case, a diabetic, crusts and plugs of inspissated mucus formed in the trachea and primary bronchi and had to be removed with a bronchoscope and forceps twice a day, to obviate suffocation. A negative pressure pump is used to unload the trachea as often as indicated. Strong suction may do much injury to the mucous membrane and should be avoided.

The dressings need constant attention. They should be changed every few hours. The patient's position should be frequently shifted from side to side and from the recumbent to the reclining posture.

When the laryngeal drain should be removed

depends upon the amount of drainage. It should be kept in as long as the serous flow continues. In my limited experience this is from two to four days. I remove the tracheal plug later for the reason that the blood and serum which flow into the larynx when disturbed by the drainage removal is thus prevented from entering the trachea. The tracheal plug may remain from three to five days. The tracheal cannula should be removed just as soon as the new larynx is open for comfortable breathing. If there is much tracheal secretion, tracheal drainage is best served by keeping the cannula in and using suction.

OPERATION FOR TOTAL LARYNGECTOMY.

At the cancer age clean mouths are the exception. Carious teeth and Riggs' disease make this cavity a veritable cesspool into which our operative field must extend, and out of which must come almost unavoidable infection. Before operation this condition should be remedied as far as time will allow. Chronic sinusitis must be borne with since it would be quite impossible to correct it in the time given. Any effort in this direction would but change a chronic into an acute process, with added risk of wound contamination.

If the patient will submit, the preliminary part of the operation may be done under local anaesthesia, carried as far as the tolerance of the patient and the skill of the operator permit. When the larynx is filled with carcinoma and the breathing is obstructed, local anaesthesia obviates the danger of suffocation and of an emergency tracheotomy during the early stage of the operation. Such a tracheotomy would mutilate the tracheal stump, making the subsequent skin and tracheal union defective. It is quite possible to skeletonize the larynx and upper portion of the trachea without pain. At this point it is better, I believe, to begin the general anaesthetic rather than attempt the removal of the larynx by the local method, since gagging, vomiting and coughing hinder the surgical procedure and add another infective factor.

If scopolamine-morphine has been given, great care in the administering of the general anaesthetic must be taken to guard against respiratory failure. I am inclined to use as little as possible such noisy adjuncts as the insufflation anaesthesia apparatus which interferes with the close observation of the patient's respiration. The removal of the larynx and closing of the pharynx is done under light ether anaesthesia. The remaining steps of the operation are better done under local, with an occasional whiff of ether if needed.

When, owing to the extent of the disease, a block dissection of the neck is indicated, the procedure is as follows:

An incision from the chin to the sternal notch is made, including all the tissues down to the

deep fascia. From the upper end, extending laterally on one or both sides, a second incision is carried outward across the sternomastoid just under the mastoid process. The third incision begins at the lower end of the first one and is carried outward and downward, crossing the clavicle near its outer third. The object aimed at is to make the flap as wide at its base and as thick as possible. My experience with the rectangular flap, generally used, has been that the inner edge is prone to slough from lack of nutrition. Much time is often wasted in trying to save the sternomastoid muscle. It is my custom to remove it entirely, thus gaining an immediate and good exposure of the deep structures of the neck. It is detached below and with it all the underlying gland and lymphatic bearing tissues are removed *en masse*. The wound is packed with gauze and the removal of the larynx proceeded with.

When a block dissection is not indicated, the procedure is as follows:

The first incision, as described above, is made. From its upper end two incisions are carried laterally for about one inch. This wide opening on top gives better access to the work of closing the hypopharynx. In long, thin necks the lateral incisions may be dispensed with. The thyroid bridge is tied and cut. In three cases I have been obliged to remove a portion of the thyroid gland overlying the trachea. The larynx and trachea are skeletonized and the thyrohyoid membrane exposed. The greater wings of the thyroid cartilage are cut and left in position. All vessels are tied and the wound made perfectly dry. The trachea is cut across just below the ericoid cartilage, being careful to secure all bleeding points so that no blood enters the trachea. A rubber tube ten inches long and large enough to fit tightly is inserted into the trachea. Through this tube the anaesthesia is continued. The cleavage plane between the larynx and esophagus is now found and the larynx separated upwards as far up as is compatible with the extent of the growth. If the cancer extends backwards into the esophageal mouth, that portion of the latter lying in juxtaposition to the larynx must be removed. The larynx is allowed to drop back into position and the thyrohyoid membrane is cut across, opening the hypopharynx; a large piece of gauze, either of iodoform or wrung out of a one per cent. Dakin's solution, is crowded into the pharynx, filling it and the mouth. The larynx is removed, either taking or leaving the epiglottis. The hypopharynx is closed with two lines of chromic gut sutures. Before the first line is entirely closed the gauze is removed from the mouth and a feeding-tube of suitable sized rubber is passed through the nose and guided into the esophagus to a depth of five or six inches. I have seen persistent vomiting caused by inserting the tube too far. Two lines of drainage are indicated—

one just below the hypopharyngeal closure and the other behind the tracheal stump. They are inserted through stab wounds in the flaps. If a gland dissection has been done, a third drain is placed in the lower outer angle of the wound. The wound is then closed in layers with number two iodized gut, or it may be closed *en masse* with silver wires piercing the tissues deeply and clamped with large shot.

The tracheal stump is pulled forward and two retention sutures of silkworm gut or silver wire are passed around the third or fourth ring, using a sharply curved, stout needle. The ends of these are plunged through the tissues and brought out about one inch from the central incision on either side of the trachea. They are tied around a piece of gauze, sufficient tension being exerted to hold the stump forward. A cuff of mucous membrane is made at the tracheal end by removing the cartilage of the first ring. The subcutaneous fat is removed from the skin in the immediate vicinity of the stump to facilitate bringing the skin and mucous membrane together. Union is made with horsehair on the front and sides of the stump and with silkworm gut behind. Tension must be avoided in joining the skin and mucous membrane. A large cannula wound with iodoform gauze and smeared with vaseline is inserted into the trachea, fitting its caliber snugly—an eight inch square of rubber-dam perforated in the centre is snapped over the exposed end of the inner tube of the cannula. Behind this apron the wound is dressed in the usual way. The cannula inserted, as above described, effectively corks the trachea, preventing secretions from being coughed up over the tracheal skin union. The rubber apron catches all tracheal secretions and serves as a barrier between the end of the cannula and the wound of the neck.

After-Treatment. Feeding and the care of the tracheal secretions are set down under the after-treatment of hemilaryngectomy. As wound infection is the rule in total laryngectomy, its proper surgical management is, perhaps, the most difficult and most important part of our task. Infection begins, as a rule, at the hypopharyngeal closure. To delay too long in opening the upper part of the wound is a fatal error, since the virulence here encountered is high and the infection spreads rapidly. After the wound is opened the packing should be changed every two to four hours and the field cleared of secretions by suction. The continuous or intermittent use of hypertonic salt solution does much to promote exosmosis and thin the discharges. If the infection extends to the tracheal region constant attention on the part of the nurses and surgeon is required to prevent the inhalation of pus and its extension to the mediastinum. All burrowing pockets are carefully followed, frequently packed and cleansed by suction. Nowhere in the body, with the exception of the brain, is uncontrolled infec-

tion more serious than in the neck. Such success as has come to me in this work has been, I believe, due to the time and pains taken in the after-treatment, to the use of very little general anaesthesia, and to a constant effort towards the elimination of traumatism from the operative technic.

THE MASTICHE AND POTASSIUM PERMANGANATE TESTS APPLIED TO THE CEREBRO-SPINAL FLUID OF THE INSANE.*

By LAWSON G. LOWREY, A.M., M.D., BOSTON.

Assistant in Neuropathology, Harvard Medical School; Pathologist to Danvers State Hospital.

A. In the *Berliner Klinische Wochenschrift* for July 26, 1915, G. Emanuel describes a new colloidal reaction for use in examining cerebro-spinal fluid.

The technic is as follows: Dissolve 10 gms. mastiche in 100 cc. of alcohol. Filter. Take 1 cc. of the above stock solution and add to 9 cc. of alcohol. Insufflate rapidly into 40 cc. of distilled water. This is the reagent. It is a pearly gray, opalescent solution with a slight bluish tinge. One cc. of 1.25 per cent. sodium chloride solution will flake out 1 cc. of mastiche reagent. Set up 5 tubes. In the first put 1.5 cc. of the 1.25 per cent. sodium chloride solution: In the others, 1 cc. To the first tube add 0.5 cc. of spinal fluid. Mix. Transfer 1 cc. to the second test tube: mix; and so on for the first 4 tubes, throwing away 1 cc. from the fourth. The fifth is used as a control.

Now add 1 cc. of the mastiche reagent to each tube. A positive reaction is evinced by a prompt precipitation in all 5 tubes. The reading is made at the end of 12 hours. This occurs in paresis or other syphilitic nervous disorders. In 32 cases Emanuel found the test negative in all but the 14 syphilitic. One case of dementia praecox, 1 of traumatic neurosis, and 1 of hemorrhage gave faintly positive reactions, but not to be compared with the pronounced reaction of paresis.

On account of the simplicity of the test and the statement that it is as reliable as the gold reaction, it seemed worth while to try it in the laboratory. Fluids from 35 cases were examined, the test being controlled by the routine tests of this laboratory (Wassermann reaction, albumen and globulin content, cell count and gold reaction).

The dilutions were made, the reagent added and the tubes thoroughly shaken. They were then examined at the end of 5 minutes: after one to one and a half hours, and finally at the end of 18 hours. As a general rule no change or at most a very slight change occurs between the hour and the 18 hour observations.

In 3 cases, 10 tubes were set up; the 10th used as a control: the other 9 containing fluid

* A contribution to the William Leonard Worcester Series of Danvers State Hospital Papers, presented November 19, 1915.

dilutions of 1:2 to 1:512. In all 3 cases whether positive or negative the last 5 tubes precipitated—i. e., the amount of restraining (?) substance in these dilutions of the fluid was not sufficient to prevent precipitation.

Three general types of reaction may be recognized. In the first the completed test solution is "clear" (i. e., only slightly opalescent); in the second the solution is "cloudy" or opaque; in the third flocculent precipitation occurs, the supernatant fluid being clear.

The results of the test are given in the appended table (I) in which the fluids are arranged according to the gold reactions.

¹ Contaminated
² Bloody

Some contaminated and bloody fluids were purposely included in the series in order to determine what difference, if any, this would make. If there was any difference (which is not demonstrable) it was in the direction of rendering a positive reaction negative. Of 21 fluids in which the gold reaction was positive (all from cases of nervous syphilis) 9, or 43 per cent., did not give precipitation in any of the

test dilutions (except 1 in a 1:16 dilution). Seven gave "cloudy" solutions and 2 "clear" solutions. In both of the latter the 1:16 dilution was "cloudy." Among 13 cases not due to syphilis in which the gold test was negative, 2 gave positive mastiche tests and 2 others showed precipitation in the 1:16 dilution; in 4 cases all test dilutions were "clear" and in 5 more only the 4th showed "cloudiness" or precipitation. Two cases were "cloudy" in all test dilutions.

One interesting case is the following:

A male tabo-paretic had several times given a weakly positive gold reaction (tabetic type). Fluid removed from the lumbar region at autopsy gave the following gold reaction: 4-5-5-5-5-4-4-2-0-0. Fluid from the base of the brain gave: 5-5-5-5-5-5-4-2-1-0. The mastiche test gave at the end of an hour:

Cord: cl-p-p-p-p

Base: p-p-p-p-p

At the end of 18 hours all tubes in both tests were precipitated.

The significance of "clear" and "cloudy" solutions and of precipitation in the fourth tube is by no means certain. We cannot assume that cloudy solutions and precipitation in one tube are to be regarded as evidence of a positive test, since both changes occur in fluids which otherwise are negative. If we are to regard as positive only those cases in which precipitation occurs in all tubes it is evident that the percentage of positive tests in the group here reported is very low and that the test does not offer a very safe means of determining the presence of syphilis of the nervous system.

Considering the data in this light it seems obvious that the mastiche test is not a valuable addition to our diagnostic armamentarium. It obviously cannot do the work of the gold test and does not seem to add any information which cannot be obtained from other tests.

B. P. Boveri described the following test in *Riv. di Patol. Nerv. e Ment.* p. 280, 1914. To 1 cc. of spinal fluid add slowly down the side, 1 cc. of 1 per cent. potassium permanganate. In a normal fluid the contact zone shows no color change. Having observed the ring the fluids are mixed. If the fluid is pathological the mixture assumes a straw-yellow tint.

Reactions are classified as follows: strong reaction, change in less than 3 minutes; moderate reaction, change in 3 to 4 minutes; weak reaction, change in 5 to 6 minutes. Changes occurring after 6 minutes have no meaning.

The test is said to be best marked in myelitis; to be more sensitive than the Nonné and Nognchi, but not parallel with them, and not parallel with lymphocytosis.

I have not had opportunity to use the test in myelitis cases. My cases are of cerebral rather than cord diseases. This may perhaps explain the aberrant findings here recorded. At any

rate it does not appear that the test is of value in the examination of spinal fluid from the insane.

The ring test showed a reddish zone in only 1 case—in the others nothing. The first appearance of the shaken mixture was "transparent purple" in 3 cases; "opaque purple" in 17. The 3 cases eventually gave a transparent red-straw color (6 minutes; translucent red at the end of 2 minutes). All 3 of these fluids gave a positive Noguchi test and were from cases of paresis. The tests of the other 17 cases remained opaque purple in color throughout the time of observation. Of these, 8 gave a negative Noguchi test, 2 contained blood and 7 gave positive Noguchi test and were from cases of paresis.

From these data it seemed unnecessary to proceed further with the test.

CONCLUSIONS.

From the data presented dealing with the mastich test on 36 fluids; and the permanganate test on 20 fluids from insane persons, the conclusion is drawn that neither of these tests is of sufficient value to become a part of the routine examination of spinal fluids from the insane.

Clinical Department.

FRACTURE OF THE CUBOID BONE.

By WM. PEARCE COUES, M.D., BOSTON.

IN the last few years many isolated fractures of the tarsal bones have been brought to light by the increased use of radiographs in the diagnosis of obscure injuries of the foot. Isolated fracture of the cuboid is one of the most uncommon of these unusual fractures and receives scant mention in many modern treatises on fractures.

Present-day experience demands that particular attention should be given all foot injuries caused by indirect violence, where the force seems too slight to produce a fracture. These are often the cases where a radiograph is not taken, and the case treated as one of sprained ankle or sprained foot. Often the clinical symptoms of these cases of isolated fracture are so obscure that the most painstaking clinical examination may not be positive as to fracture, and a radiograph is indispensable for a correct diagnosis. This refers to the fractures from indirect violence without any appreciable displacement, and not to those crushing injuries, where the diagnosis of tarsal fracture is at once

apparent clinically, and the only question is how many and just what tarsal bones are fractured.

The shape and anatomic position of the cuboid bone make it extremely difficult to obtain many of the classic signs of fracture, when this bone is injured, and linear cracks and splits are produced without much or any displacement. Point tenderness and the situation of the ecchymosis will prove most valuable signs in the absence of more definite symptoms. The situation and character of the swelling may also serve to show, at least approximately, the site of the possible fracture.

Report of a case:

Walter C., a boy of 11 years, was seen at the surgical clinic of the Boston Dispensary, on April 21st, 1915. He had always been well, and had no previous fractures. On April 20th, he turned his left ankle sharply, while running. He immediately felt much pain in the foot, and was unable to walk afterwards without much disability. Examination showed a well-developed and nourished boy of 11 years. He was unable to put the left foot to the ground without much pain. There was a moderate amount of swelling over the dorsum of the left foot, and slight ecchymosis over the external border of the foot. There was no crepitus obtained, but there was considerable pain on pressure over the base of the 5th metatarsal bone. Posterior to this, in the cuboid region, there was exquisite pain on pressure. Extension of the little toe gave some pain in the foot, but not definite pain in the 5th metatarsal. The x-ray showed a linear crack through the cuboid, without displacement. A cast was applied to just below the knee, and the boy given crutches. May 15th the plaster was removed, and June 5th the boy was discharged well, all tenderness having disappeared, and the foot being used without pain or discomfort.

Le Dentu and Delbet¹ have given a most recent and full account of this fracture, and say that Plagemann found one case of cuboid fracture in 114 fractures of the foot. Immelmann, in studying 20 cuboid fractures found 12 isolated, and 8 associated with fracture of other bones of the tarsus. Tanton² remarks that the cuboid, the key to the plantar arch, is practically never fractured in indirect traumatism of the foot. He considers that these extremely uncommon cases of fracture by indirect violence are most often caused by a fall from a height, on the toes, with the foot in hyperextension. Also exceptionally, he thinks they may be caused by antero-posterior compression of the foot, the heel being fixed on the ground, with violent pressure being exerted on the toes. A third possibility is given, also,—forced pronation of the foot, with at the same time abduction of the forefoot.

In the case recorded above there was no history of a blow and, as is often the case, the patient was unable to say just how the ankle "turned." It would seem probable that the third manner of production of the fracture was the one responsible for its occurrence in this

case, a forced pronation, with abduction of the forefoot.

A number of rare anatomic variants may cause confusion in certain cases of cuboid fracture, even with good radiographs as an aid to diagnosis. Among these are the shell-like epiphysis at the base of the 5th metatarsal bone, which sometimes remains without bony union to the base of the metatarsal, and the vesalianum, or bone of Vesalius, at the base of the 5th metatarsal. Occasionally there is a secondary os calcis, a small bone between the scaphoid and cuboid, which may cause confusion, in question of cuboid fracture.

The possibilities of mistaken diagnosis which come to light in the study of only one rare tarsal fracture makes apparent the necessity of careful radiographic study of these injuries.

A CASE OF HENOCH'S PURPURA.

By EDWIN D. GARDNER, M.D., NEW BEDFORD, MASS.

THE following case of Henoch's purpura seems to me unusual and deserving of report:

M. C., 7-year-old school-girl. Mother has had pulmonary tuberculosis, apparently healed. Otherwise family history is negative. Past history: for the last year has complained 5 or 6 times of having colicky pain in the region of the umbilicus. Mother says that child would be out playing and would come home complaining of this pain and no other symptoms. Child would lie down for an hour or two and then would feel all right. Child has had a lot of colds and sore throats. Past history otherwise negative. Present illness: seven days ago child came in complaining of the same pain as described above. No nausea or vomiting. Bowels all right. No fever. This lasted for twenty-four hours. Three days ago complained of a sore throat. Her mother took her temperature and found it was 102° F. Child had headache and backache. In twelve hours the child said her throat was well and temperature was normal. About this time, however, she began to complain of the same abdominal pain as described above only more severe. At this time the family physician was called in, the pain continued and twelve hours later the child began to vomit. She vomited very frequently, ten or twelve times a day, the vomitus consisting of mucus streaked with bright red blood. The pain and vomiting continued until I saw her, when she said the pain was less and she was vomiting less frequently. The bowels were constipated but a good result was obtained by enema. No blood in the stools. No cough. No urinary symptoms. The physician said that since he had seen the child there had been no signs of trouble in the throat and no fever. He also said that the physical signs were the same now as they had been.

Physical examination: Temp. 99.4, pulse 90, respiration, 22. General examination negative, save the abdomen, which was level and tympanitic throughout. No masses or organs made out. No spasm or, if

any, very slight and in the right rectus. Moderate tenderness on deep pressure over McBurney's point and in region of umbilicus. No other tenderness. No jaundice. No herniae. No costo-vertebral tenderness. Reflexes normal. Rectal examination was negative, save for slight tenderness high up on right side. Urine clear—acid 1020, alb. 0. Sugar 0. Sediment—rare leucocyte and round cell. Many squamous cells. White count 20,000. Hemoglobin normal. I advised an operation for fear it was appendicitis. The appendix looked normal. In the ileum, about six inches from the ileo-caecal valve, was a soft, smooth mass that gave the feel of putty. It was reddish brown or purplish in color and seemed to be in the lumen of the intestine, as it could be milked along. It was about the size of an olive. It gave the appearance of a blood clot. There was a similar mass about two inches proximal to this. Exploration of the abdomen revealed nothing further. On opening the appendix it was found filled with blood clot. The mucous membrane was normal except that it seemed a little edematous. The patient was troubled for two or three days with bronchitis. No pain or vomiting. On the fourth day temperature rose to 101° F. Abdomen and wound negative and the bronchitis was considered the cause. On the fourth day there was considerable dark blood in the urine and stools. This continued for twenty-four hours and then disappeared. On the fifth day the left ear began to discharge pus and the temperature dropped to normal. The ear continued to discharge for two or three weeks. The child insisted that she had no carache at any time. The mother told me at that time that the child had had considerable trouble with her ears previously. Except for the ear the convalescence was normal, the wound healing by first intention and no return of pain or vomiting. Four weeks after the operation the family physician was called to see some spots on the child's legs. These were typical purpuric spots. She had them scattered over her body, but principally on her legs. They lasted about one week. Since that time, so far as I know, the child has been perfectly well.

I am indebted to Dr. Charles A. Pratt of New Bedford, who referred the case to me.

Society Reports.

NEW ENGLAND SOCIETY OF DERMATOLOGY AND SYPHILIS.

The seventh meeting was held at the Massachusetts General Hospital on February 14, 1917, with the President, Dr. Abner Post, in the chair.

The following cases were presented and discussed:

1. SEVERE BURN.

Presented by DR. THORNDIKE.

The patient was brought before the Society because of the perfect usefulness of her arm despite its extraordinary and extensive deformity. When four years old the right arm was burned and yet, notwithstanding the tremendous contraction, she has absolutely normal motion in all joints. There is no suggestion of keloid or hypertrophic scarring and the skin is very soft. There is, however, a suggestion of chronic eczema which accounts for

the infiltration of certain areas. The woman has followed the trade of dressmaker and has raised a family.

2. DERMATITIS VENENATA.

Presented by DR. THORNDIKE.

The patient was a blue print dipper and presented a dermatitis due to bichromate of potassium—the third instance observed by the speaker during the present winter. The other two cases were diffuse inflammatory lesions on the hands, while the present outbreak is strikingly limited to superficial ulcers on the fingers which the man uses in dipping his blue prints.

3. X-RAY PLATES OF OLD SYPHILIS.

Presented by DR. THORNDIKE.

During the winter the speaker has observed ten cases of syphilis of the leg bones, all of which have shown profound syphilitic lesions and have given negative laboratory findings.

In the plates shown both bones of the leg appear to be involved. The periosteum is greatly thickened and the "cuticle" layer is also affected. There is no suggestion of tuberculosis or of any traumatic lesions in the patient's history and no history of luetic infection could be elicited, but with the x-ray evidence and with the satisfactory therapeutic reaction obtained thus far, a diagnosis of syphilis should be made. The patient has a heart lesion, is a heavy drinker and also suffers from arteriosclerosis.

4. PEMPFIGUS OF TONGUE AND CHEEKS.

Presented by DR. C. M. SMITH.

The process has lasted two years and the lesions have thus far been limited to the mouth. Dr. A. Coolidge, laryngologist, agrees that the lesions are those of pemphigus and that the manner in which fresh outbreaks occur is distinctly in line with the usual course of oral pemphigus. The patient has been observed in two different outbreaks of distinct, vesicular lesions, one attack limited to the cheek and the other to the tongue. The lesions always begin as vesicles, and in the last attack a blood blister, about the size of a lead pencil end, developed and ruptured within a comparatively few hours, leaving a superficially eroded area which was still evident.

The patient has been seen at the Huntington Hospital where the condition was considered to be precancerous and a positive Wassermann was obtained. Since then four Wassermanns at various times and in various places have proved negative. The patient received six injections of salvarsan intravenously a year ago without any benefit at all to the tongue and the only medication that has afforded any relief is one exposure to radium. At no time has any eruption of the skin been noted by patient or by exhibitor.

5. NAEVUS VASCULARIS.

Presented by DR. OLIVER.

The patient has been shown at several previous meetings. The entire affected area has been exposed once to the Kromayer lamp and to radium. The improvement is especially noticeable around the eyes where the skin is thin and where she has

had fairly short Kromayer treatments. All exposures have been fairly short.

6. RECURRENT (?) ROSEOLA OF SYPHILIS.

Presented by DR. C. M. SMITH.

The patient illustrates two points very well—the multiform character of the eruption and the lesions on the tonsil. There is no known source of infection, there is no history of a primary lesion and there is no adenitis. The outbreak appeared two to three weeks ago. Standing at a distance and looking at the back and chest there is sufficient amount of superficial drying and scaling of the skin to suggest some of the ordinary dermatoses. The color of the eruption is very much deeper than one would expect in an eruption of such a short duration.

The chief reason for presenting the patient lies in the rather unusual appearance of scalliness which in certain lights or in certain angles raises the remote possibility of pityriasis rosea. A second reason is the interesting family history. For four months the husband has been working in one town while the patient has been staying in another.

7. MULTIPLE CANCER OF SKIN.

Presented by DR. TOWLE.

The family history is negative. The lesion on the right buttock appeared forty years ago, gradually increasing in size, crusting and ulcerating. Lately it has become slightly sensitive. Twenty-five to thirty years ago a group of papules appeared below the right breast with persistent scaling. Twenty years ago a lesion was excised in the O.P.D., but recurred almost at once. A "water blister" appeared under the left lid twenty-one years ago, was diagnosed as epithelioma and treated with the x-ray, and has not recurred. Fifteen years ago a lesion appeared on the left scapula similar to that on the right breast. Two years ago a lesion appeared over the right clavicle, crusting and spreading, with very tender edges. A few weeks ago a small papule appeared at the crest of the right ilium accompanied by slight itching but no tenderness. On the right buttock there is an oblong lesion, seven by three and a half cm., with strikingly distinct corners, with necrotic, yellowish, slightly moist base of unhealthy granulations, with distinct, slightly raised cicatricial edges and narrow cicatricial margin. This area is very sensitive. Over the middle of the right clavicle is a lesion, six and a half by one cm., which has a smooth, cicatrized base, small sero-purulent crusts and slightly elevated edges. Below the right breast, about mid-way from the nipple to the mid-axillary line, there is an irregularly outlined, oval lesion, seven by three and one half cm., composed of slightly raised erythema with papules superimposed and small purulent and hemorrhagic crusts. This lesion is not sensitive. There is a similar lesion, five by three and a half cm., over the upper left scapula. Papulation is more distinct here and the erythema rather brighter. Just below the crest of the left ilium is a lesion similar to that described above. Near the umbilicus is a small, pea-sized, indurated, erythematous papule.

Biopsies from lesions on the right clavicle, right thorax and right buttock:

Microscopical examination of sections from the right buttock, and right clavicle shows small anastomosing columns of small undifferentiated cells of the basal-cell type in an abundant fibrous stroma. These lines present the typical character of epidermoid carcinoma of the rodent ulcer type. In the sections from the right trunk, although the epithelium does not show any deep invasion, it is, however, very atypical in appearance and must be regarded with suspicion. Epidermoid carcinoma.

Dr. Towle raised the question of treatment.

Dr. Burns replied that this type of epithelioma was suitable for excision and falls well within the class described by Dr. Bowen as precancerous dermatosis in view of its great chronicity and ultimate epithelial degeneration. The woman was originally a patient of Dr. J. C. White and Dr. Bowen. Dr. Burns had observed several patients exhibiting exactly the same appearance, chronicity and evolution.

Dr. Blaisdell inquired as to a possibly factitious element present, as a number of the lesions were squarish and others showed straight boundary lines.

Dr. Towle did not believe so and added that the tendency in the lesions was always toward hypertrophy with eventual breaking down into ulcerations. A factitious element might, however, have been the starting-point of the lesions.

Dr. White did not think that self-mutilation was present in the patient because the lesions were so scattered, were all in inaccessible places, and had lasted so long.

8. ERYSIPELAS (?)

Presented by DR. TOWLE.

Seven days ago the patient went to bed with a chill, pain in the right groin, slight nausea, no vomiting, and slept badly. The next day the temperature was 104°F. The patient states that she subsequently felt pain spread down the inside of the thigh. The inguinal glands were swollen. On the third day redness appeared in about the mid-thigh, which was also swollen and hot. Later still the erythema spread to the lower leg. There was no history of injury.

Physical examination is negative except that from the ankle to the knee the skin is bright red, hot, pitting on pressure, and without markedly distinct border. The affected area is tender, particularly over the mid-calf. There are large inguinal glands on the right side. Treatment: ice packs, forced fluids, crude coal tar.

Dr. Towle questioned the propriety of making in this case a diagnosis of erysipelas. The process started in the groin and went downward, whereas in his opinion erysipelas always spreads upwards. The typical sharply defined border was also absent. He was inclined to think that the process was connected more with the lymph than with the cellular tissue and therefore that diagnostically it was not a true erysipelas.

Dr. Oliver stated that he was under the impression that erysipelas could travel in any direction.

Dr. White spoke of examples of the disease in which he had noted progression both up and down a limb—the so-called wandering type.

9. ECZEMA SEBORRHOICUM OF THE NOSE ON A SYPHILITIC SOIL.

Presented by DR. DIX.

The patient developed syphilis five years ago and was treated in the Long Island Hospital and has continued treatment more or less since and is now on "mixed" treatment. Recently an eruption broke out on the face, especially about the nose and left temple, but has now faded out a good deal. There seem to be some white, characteristic lesions around the nasal openings, in the hair and also (one or two) on the chin.

Dr. Cones was interested to see this woman as her daughter, a well grown girl, was now a patient in the surgical clinic of the Boston Dispensary with the remains of two circular ulcerations over the tibia which had cleared up in a week's time under Ung. hydrarg.

Dr. Smith rather doubted the specific nature of the present lesion. He was perfectly sure that much of the eruption now present on the scalp and right cheek was not luetic.

10. PITYRIASIS ROSEA (?)

Presented by DR. TOWLE.

Three months ago the patient complained of sore teeth, sore throat and headache. A rash appeared on the abdomen and later covered the entire body. The patient consulted her physician and was given four injections of salvarsan at weekly intervals. The rash began to fade after the second injection. The patient showed about a dozen discrete maculopapular lesions, pinhead to dime-sized, in places somewhat annular, scaling particularly about the periphery, yellowish gray in the center. The scales were not loosened from the center.

The question arose as to whether the eruption was a seborrhea, pityriasis rosea, or was due to salvarsan. Dr. Towle was inclined to the seborrheal theory.

11. BENIGN CYSTIC EPITHELIOMA.

Presented by DR. BURNS.

The condition began in childhood, and the lesions grew steadily and gradually grown in number and in size until today there are on the forehead, the left temple, the inter-eyebrow area, on the sides of the nose, and over the left malar region, single and grouped lesions, the size of a small pinhead to that of a good-sized pea. It seems as though one could follow the lesions from what would surely be called ordinarily a milium to the finished product, which is a glistening, whitish, smooth, dome-shaped, papulo-nodule. There is very little redness about them and there is no tendency toward angiomatous formation on their surface, so that a diagnosis of adenoma sebaceum seems doubtful. These lesions seem rather greasy and their greatest density is in each naso-labial fold. The man presents a striking picture. Biopsy made and the histologic diagnosis is benign cystic epithelioma. The lesions were first treated with radium but better results have since been obtained with fulguration.

12. LYMPHANGIOMA TUBEROSUM MULTIPLEX.

Presented by DR. BURNS.

The disease has been present for four years on the feet and one and a half years on the hands. The lesions consist of papules, pea-sized to half an inch in diameter, bluish-red in color, arranged in annular form. There is neither stippling nor striation and the lesions are dome-shaped rather than flat-topped. Those on the feet, especially on the bottom, have fairly heavy scales from friction (?) and are more or less confluent. There has been no remission of lesions since the start and the patient has had no symptoms from them. It will be noted that the distribution of the lesions is distinctly unusual. The diagnosis has been confirmed by the microscope. As to treatment, Dr. Burns stated that incision followed by attempts at destruction with caustics or even fire does not always suffice to eradicate the process, but in a number of cases of lymphangioma radium has been quite successful.

13. SYPHILIS.

Presented by DR. SMITH.

In March, 1912, a penile sore was observed but was apparently not followed by skin or throat trouble or hair manifestations. This chancre appeared four days after coitus and there was no previous acknowledged exposure. In December, 1915, thickening of shins developed, accompanied by a scaly, papular eruption over the arms and legs, and interstitial keratitis was present. The Wassermann was negative.

On Feb. 8, 1916, the Wassermann was weakly positive. On Aug. 19, 1916, the lesions on the legs were typically rupial. From August to December four 0.4 doses of diarsenol were administered.

At present the man's physical examination is negative except for his skin condition and impaired resonance in the right lung. On the trunk and extremities there are numerous oyster-shell-like lesions, about twenty on each arm, from two to four cm. in diameter and there are numerous smaller ones on the legs, varying from two to twenty millimeters in diameter and from five to ten millimeters in height.

14. LUPUS ERYTHEMATOSUS.

Presented by DR. OLIVER.

The patient shows numerous pea to dollar-sized areas of lupus erythematosus scattered over the greater part of his face. He has had much treatment, both public and private, including many freezings with CO₂ snow, none of which, although some were severe, have relieved the itching and irritation of the lesions.

The patient states that after the first treatment with the Kronmayer lamp (two millimeters—blue quartz screen), lasting half an hour, he got complete relief from itching and irritation and since then many areas have been treated and the patient is very enthusiastic over the results of these treatments. The appearance of the lesion treated three months ago is very good; there is no scaling and the color is almost normal. On the patches more recently treated there is still some erythema but no scaling. A patch on the right cheek, treated four days ago, shows a flat, drying bulla. A lesion treated yesterday shows a flat, unruptured bulla.

The ears have been treated with white light, at a distance of two inches, applied for about six minutes at a time and here also there is considerable improvement with lessening of scaling. The question is, is the improvement so far obtained to be permanent? Immediate results have been remarkably good.

15. NAEVUS VASCULARIS.

Presented by DR. OLIVER.

The child presents a naevus of the large cavernous type—great masses of vessels covering a large part of the right side of the forehead. When first seen she was sixteen months old and up to that time the right eye had never been opened, nor could it be opened, and her parents thought that there was no eye underneath. Two areas were frozen with CO₂ snow, twenty-five to thirty-five seconds each. Two months after this treatment the eye opened, and at the time of admission to the hospital (Feb. 7, 1917) the child showed an apparently normal eye with the lids separated half an inch and the swelling markedly decreased. At the present time the eye is closed, due to marked edema from a freeze three days ago.

16. NAEVUS PIGMENTOSUS.

Presented by DR. OLIVER.

The condition has existed since birth and, according to the patient, is increasing. She is now sixteen years old and shows innumerable, pin-head sized, hemorrhagic points on both lips, at the corners of the mouth, on the muco-cutaneous membrane and on the mucous membrane as well. Occasionally the lesions are confluent, the majority, however, are distinct. The general effect on the lips is that of a deep bluish tint superimposed on the normal red.

It is rather interesting to note that a few days previous to the birth of the patient her mother was sitting opposite a woman who was eating blueberries and asked for some, but was refused, and this refusal made quite a deep impression on the mother.

CHARLES J. WHITE, *Secretary.*

NEW ENGLAND SOCIETY OF DERMATOLOGY AND SYPHILIS.

The eighth meeting of the Society was held at the Boston City Hospital on Tuesday, April 17th, 1917, with the President, Dr. Abner Post, in the chair.

The following cases were presented and discussed:

1. GENERAL CUTANEOUS ACTINOMYCOSIS.

Presented by DR. BOARDMAN.

One month ago the man noticed a "sore" under the angle of the jaw. Two weeks ago a similar lesion developed on one finger, and the attending surgeon told the man he had paronychia. Today there are many large cutaneous nodules (up to the size of a hen's egg) noted on the trunk, arms, legs and serotum and new lesions are appearing from day to day. No nodule has broken down, but incision has revealed yellow granules which microscopically have

proved to be actinomycotic. Thorough examination with x-rays has failed to disclose a single internal focus of the disease.

The patient has recently been working in a diet kitchen, but up to 4½ years ago was a Greek agriculturist.

Dr. Boardman stated that a purely cutaneous infection of actinomycosis was almost unique.

2. HEMANGIOMA OF PALM.

Presented by Dr. THORNDIKE.

When first observed there was a purple-red, peazoid, dome-shaped, sessile growth in the middle of the palm of five weeks' duration. The nodule was treated with radium and the lesion shriveled up and the crust fell off leaving practically no scar.

Dr. White asked Dr. Thorndike if he had considered the possibility of granuloma pyogenicum. Dr. Thorndike said "No," because of the bloody nature and profuse hemorrhage of the lesion.

3. DERMATITIS SIMULATING PAGET'S DISEASE.

Presented by Dr. THORNDIKE.

The patient was forty-five years old, single, and still menstruating. When first seen the pathologic area had been present for three weeks and was limited to the left nipple and appeared as a unilateral, superficial, well-defined ulceration with crusts and a slightly indurated base; no itching, no surrounding eczematous condition. The patient has been under treatment for ten days and the ulceration has cleared up remarkably under Lassar's paste so that one must consider the condition merely as an excoriation with subsequent pyogenic infection.

4. RINGWORM OF THE SCALP.

Presented by Dr. OLIVER.

The patient, a twelve-year-old girl, developed ringworm of the scalp about five months previously. She was treated for a while with ointments and later the whole scalp was x-rayed, with resulting complete epilation. The hair has now grown again in a rather curious manner, for the affected areas have very much thicker hair than the other portions of the scalp.

Dr. Oliver thought that the increased blood supply due to the severity of the ringworm may have produced the localized increased growth of hair. Dr. Chace suggested that the x-ray did not penetrate so deeply in the affected areas on account of the scales and crusting. Dr. White felt that the increased growth of hair was possibly due to the application of external stimulating ointments to the affected areas before and after the x-ray treatment.

5. RINGWORM.

Presented by Dr. BOARDMAN.

The patient has been in this country three years and the process has existed two years, beginning on the right hand and later involving both feet. There is no history of contact with animals. Scrapings from the finger nails revealed ringworm spores and cultures have been grown. This type of ringworm is not so well known to the general practitioner as it should be and is usually diagnosed as eczema. A cure under such conditions is well nigh impossible. Treatment in the present case has consisted of maceration followed by scraping and the subse-

quent application of an ointment containing 20% ammoniated mercury. A normal nail is now appearing on one finger.

6. DERMATITIS HERPETIFORMIS.

Presented by Dr. OLIVER.

The disease has lasted six months and is now irregularly distributed over the face, especially the lower part, the clavicular regions, the neck, the arms, and somewhat on the lower extremities. The eruption is purely vesicular in type, usually grouped, and the areas vary in size from two to three vesicles a quarter of a centimeter in diameter to groups of vesicles two inches in diameter. Almost all areas have more or less surrounding erythema and many of them are confluent and show a distinct gyrate and annular tendency. The process does not itch, but a severe burning is present. Since the beginning there has been temporary improvement but never entire remission of the outbreak. There is no history of psychic shock in this woman of twenty-seven.

7. ICHTHYOSIS.

Presented by Dr. BOARDMAN.

A typical ichthyosis dating back to early childhood. When the patient came to the hospital there were marked eczematous changes, especially on the legs. Following treatment with salicylic acid and olive oil and thyroid extract there has been marked improvement. The pulse, however, was rapid at first.

Dr. White asked about the propriety of giving thyroid extract to a child with rapid pulse. Dr. Boardman replied that medical men were not opposed to giving the extract under such circumstances. Dr. Oliver said that he believed that the results one got from thyroid medication were due to stimulation of glands and that there was in these cases no natural deficiency of thyroid secretion. He expressed himself as very sceptical about any marked change in these cases following the use of thyroid. He considered that the pulse should be watched carefully during thyroid therapy.

8. PEMPHIGUS OF THE MOUTH.

Presented by Dr. POST.

The duration of the disease is sixteen months and the patient has never been free from lesions during this period. Sometimes there have been five or six bullae present but for much of the time only one or two. The lesions appear as blisters filled with clear or slightly necrotic fluid, last one week and break, leaving a red, very tender base. The mouth is particularly sensitive to acids. The teeth have been extracted on account of heart trouble rather than with a view to curing the mouth condition. The process is gradually growing worse and today there are lesions in the mouth, on the tongue, and on the inside of the cheeks.

9. WHITE NEGRO.

Presented by Dr. THORNDIKE.

A very remarkable case. Ten years ago this totally black negro began to lose the pigment from his black skin and was first seen at the hospital two

years later. He now shows complete loss of pigment. The only history given was that twenty-four hours after a cat scratch on the chest the pigment began to disappear and from that point has spread over the entire body. Dr. Thorndike, in the early days, tried to cause a loss of pigment by pricking an unaffected portion of the skin with a needle, but no depigmentation could be observed in consequence. Today, this hitherto black man stands free from pigment. Hair, eyes, skin and nails, all have shared in this extraordinary example of acquired albinism.

10. SYPHILITIC PERIOSTITIS.

Presented by DR. THORNDIKE.

Seven months ago the patient began to have exceedingly painful osteoepic pains. Radiographs showed a typical periostitis with a certain amount of sclerosis. The Wassermann test was triple positive. The man has received mercury and salvarsan and the pains in the arms have improved, but those in the legs have not improved, and the patient is acquiring a gradual, but steady, interference with motion in the elbow joint, and now cannot straighten out his arms. Since the patient has been under treatment, there has been an increase of four or five per cent. in loss of extension. The tibiae also show periostitis.

Dr. Post said that he was very much interested in the case on account of its obstinacy, but he believed that treatment had not been exhausted until iodides had been tried. This inability to straighten the arms was a subject about which the older syphilologists talked more or less. It was supposed to be due, sometimes, to difficulty with the bones and sometimes to the effect on the muscles of the upper arm so that they lost some of their sensibility.

11. LUPUS VULGARIS.

Presented by DR. OLIVER.

The patient, an Armenian man, had had the disease for seventeen years and had endured every imaginable treatment. Finally the disease had quieted down, but as the nose was almost wholly gone, a plastic operation was performed. This was a year ago, and now the patient returned with a recrudescence of the disease in the flap. What was to be done?

Dr. Oliver said that he would try the Kromayer lamp on some of the areas involved.

12. SYPHILIS AND JAUNDICE.

Presented by DR. BOARDMAN.

Primary lesion, secondary rash, sore throat, and general glandular enlargement were present. The woman was given mercury for a week and then salvarsan. After the last injection three weeks ago, jaundice began to appear and the patient was treated at home for a week or two with general dietetic measures and mercury, and "606" was omitted. She was then admitted to the hospital where the liver was found to be enlarged with a pretty intense jaundice. The patient now feels much better. Mercury was again administered followed by an injection of "606" the day before yesterday. Jaundice is no worse, although it has not improved yet, but the liver is growing smaller. A previous deafness has grown worse during the present conditions.

13. MALIGNANT ERYSIPELAS.

Presented by DR. THORNDIKE.

A case of erysipelas in an alcoholic woman which had been followed by necrosis and discharge of a large part of the pudenda and perineum. The affected area had been treated with chlorinated soda and allowed to slough off until granulation began to appear. The patient was then referred to the surgeon who had done a most successful plastic operation. Curiously enough the woman ran a normal temperature throughout the whole course of the disease.

14. MARKED VENOUS ENLARGEMENT.

Presented by DR. BOARDMAN.

The man presented very great venous enlargement of the legs and trunk without obvious cause.

15. PRECOCIOUS SYPHILIS.

Presented by DR. BOARDMAN.

The woman showed evidences of secondary syphilis, with general but proportionately very slight glandular enlargement. No primary lesion could be found. There were mucous patches in the throat, and very marked, almost rupial lesions in the scalp.

16. LICHEN PLANUS.

Presented by DR. OLIVER.

The man presented a perfect embroidery of circinate lesions made up of fine, perfectly distinct papules, none of which averaged larger than the size of a pinhead, on the corona glandis, foreskin, inside the cheeks and on the palms.

17. EPITHELIOMA OF THE TONGUE.

Presented by DR. THORNDIKE.

The patient was a woman. The growth started in the mouth near the frenum. There had been two operations, the last Nov. 8, 1916. Since then the growth has returned and now the whole tongue is involved.

CHARLES J. WHITE, *Secretary.*

Book Reviews.

The Medical Clinics of Chicago, January, 1917.
Philadelphia and London: W. B. Saunders Company.

In this number eleven clinicians take up a wide variety of topics. Of particular interest is an excellent summary of barium diagnosis by Dr. Case. A case of true amebic dysentery developing in Chicago is also briefly recorded. The other discussions conform to the general plan of previous numbers.

An Index of Differential Diagnosis. Edited by HERBERT FRENCH, M.A., M.D., OXON., F.R.C.P. Lond. Second Edition. New York: Wm. Wood & Company. 1917.

THIS second edition of a well-known work on the differential diagnosis of main symptoms by various writers has been thoroughly revised and has several new articles added. The elaborate index has been made even more complete and the illustrations nearly double in number. There are now thirty-seven colored plates and over three hundred text cuts. The work is a useful reference manual of symptomatology and should continue its popularity with the medical profession. The symptoms are arranged alphabetically, from Accentuation of Heart Sounds to Yellow Vision. The contributors are twenty-three distinguished members of the British profession.

Diseases of the Stomach, Intestines and Pancreas. By ROBERT COLEMAN KEMP, M.D. Third edition, revised, with 438 illustrations. Philadelphia and London: W. B. Saunders Company. 1917.

THE first edition of this book was reviewed in the issue of the JOURNAL for September 1, 1910 (Vol. clxiii, p. 370). This third edition is enlarged by a new special section on the radiography of gastric ulcer, cancer, duodenal ulcer and gall-bladder disease; by a chapter on Lane's kink, Jackson's membrane, duodenal dilatation, and incompetency of the ileocecal valve; and by a section on sub-infection and protein absorption in the part on chronic intestinal putrefaction. Particular attention is devoted to abdominal ptosis and its mechanical treatment, though it seems that this aspect of the subject is made unnecessarily complex. Its importance, however, is not exaggerated. Other important additions to this volume are on hypochlorhydria and the treatment of obesity. The work should retain the position of usefulness prognosticated for it in our first review and successfully maintained by preceding editions.

Diseases of the Stomach. A Textbook for Students and Practitioners. By MAX EINHORN, M.D., Professor of Medicine at the New York Post Graduate School and Visiting Physician at the German Hospital. Sixth revised and enlarged edition. New York: Wm. Wood & Company. 1917.

THE first edition of this standard textbook for practitioners and students was favorably reviewed in the issue of the JOURNAL for May 27, 1897 (Vol. exxxvi, p. 524); the fourth edition, in the issue of January 3, 1907 (Vol. clvi, p. 19); and the fifth, in the issue of May 2, 1912

(Vol. clxvi, p. 672). This sixth edition, intended to keep the work abreast of the progress of gastric pathology, continues to fulfill the useful promise of its predecessors. The number of illustrations has been increased from 112 to 128. Since the publication of the original edition, the knowledge of stomach diseases has become much more generalized among the medical profession. The author's work represents his life experience in the subject, which has contributed in no small degree to its development as a specialty of scientific medicine.

The Basle Anatomical Nomenclature. By E. B. JAMESON, M.D., M.B., Ch.B. Edin. New York: Macmillan Company. 1916.

THIS monograph is a convenient compilation, in parallel columns, of an alphabetical list of terms showing the old anatomical terminology, the Basle anatomical nomenclature and the suggested English equivalent. In his introduction, the author describes the adoption of the B.N.A. terminology in 1895 and its subsequent gradual spread through the scientific world. Hitherto the chief obstacle to the universal employment of the B.N.A. in this country has been the lack of a satisfactory and accessible list of English equivalents and the unwillingness or inability of most American medical students to employ the Latin terminology correctly. This work by a Scottish anatomist supplies in convenient and accessible form this need of a standard English nomenclature of anatomy. It fills a very definite want in the teaching of this subject, and should prove a distinct aid in the ultimate establishment of a rational anatomic nomenclature.

A Compend of Human Physiology. By ALBERT P. BRUBAKER, A.M., M.D. Philadelphia: P. Blakiston's Son & Co. 1917.

THIS compend is intended for use by medical students and is probably a very fair representative of this fast disappearing type of medical literature. That a course in physiology should be so constituted as to be aided by the material here presented is fortunately increasingly inconceivable. As a summary of current physiology the book maintains the old anatomical viewpoint, a rather large amount of space being devoted to presentations of structure prior to every discussion of function. It can therefore be of assistance in only very elementary types of teaching or preparation. The fact that it is impossible to present physico-chemical material in canned form without rendering it inordinately difficult, spells the certain elimination of the compend in physiology, and this example, with its conspicuous absence of such material, can only go the eventual way of other members of the same class.

THE BOSTON Medical and Surgical Journal

Established in 1812

An independently owned Journal of Medicine and Surgery published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, JULY 26, 1917

EDITORS.

ROBERT M. GREEN, M.D., *Editor-in-Chief.*

GEORGE G. SMITH, M.D., *Assistant Editor.*

WALTER L. BERRAGE, M.D. *For the Massachusetts Medical Society.*

COMMITTEE OF CONSULTING EDITORS.

WALTER B. CANNON, M.D.

ROGER I. LEE, M.D.

HARVEY CUSHING, M.D.

ALLAN J. McLAUGHLIN, M.D.

WALTER L. EBSALL, M.D.

ROBERT B. OSGOOD, M.D.

REID HUNT, M.D.

MILTON J. ROSENAL, M.D.

EDWARD C. STREETER, M.D.

ADVISORY COMMITTEE.

EDWARD C. STREETER, M.D., *Boston, Chairman.*

WALTER P. BOWERS, M.D., *Clinton.*

HOMER GAGE, M.D., *Worcester.*

JOEL E. GOLDENWALT, M.D., *Boston.*

LYMAN A. JONES, M.D., *Swampscott.*

ROBERT B. OSGOOD, M.D., *Boston.*

HUGH WILLIAMS, M.D., *Boston.*

ALFRED WORCESTER, M.D., *Waltham.*

Subscription Terms: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager,*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

THE CAMP IDEA IN TUBERCULOSIS.

THE value of the open-air school, both in the winter and in the summer months, for either the poorly developed or the tubercular child, has been amply justified by the results reported in Boston and in Chicago, and wherever else it was tried. Similar results have been accomplished, in the reclamation of the child exposed to tuberculosis, in the preventoria maintained in many places. Not only have these children become well and strong, but their scholastic attainments have approached well within the standards of normal children. Whether the open-air treatment is administered to children in the open-air schools or in the preventoria, or to adults in day camps, it is the open-air treatment that holds the greatest hope for recovery. For the well-marked active case, whether in children or in

adults, there is no other method of treatment but the outdoor method. During the active stages neither the child nor the adult can afford to engage in educative pursuits or in any occupation. But for the arrested case or for the child or adult that is on the mend, it is neither right nor desirable to withhold education or occupation. For the adult, suitable work prevents his ultimate pauperization and prevents him from being a burden to himself, his dependents, or to society. Otherwise his reclamation would be a mistake rather than a benefit. For the child, the absence of education during the formative period of his life would be to throw it hopelessly in the mentally backward class. It is to these classes that the day-camp idea is of the greatest benefit.

But unless the day camp is supplemented by the night camp, the value of this method of treatment must fail, for the patients must return to their homes at night, where conditions are the same as those which undoubtedly caused the original infection. These patients can again become sources of infection, and of greater degree than even much worse contact during the day. Moreover, the night camp would afford a place for the tubercular case that is allowed whole-day employment. None of the artificial open-air sleeping contrivances for use in the congested homes can quite equal the value of sleep entirely in the open air, under the same conditions as obtain in the day camps. This method of treatment for the arrested cases would prevent a great many of them from becoming reactivated after a short period of occupation, and would undoubtedly broaden the scope of occupations allowed these individuals. The night camp must be a graduation from the day camp, at least where both cannot be given. The ideal substitutes for the sanatorium climatic treatment, where this cannot be afforded, are the day and the night camps. Besides hurrying recovery and reducing the chances of secondary infections, the camp idea would afford more room for the well members of a tubercular family, in homes where room is usually at a premium.

THE ECONOMIC VALUES OF LIFE AND HEALTH.

NOT until the nation is made to face the enormous expense of maintaining the sick or of replacing the loss during warfare, does the money

value of the individual and the loss entailed by his illness or death strike the public forcibly. Yet the money loss from sickness and death in civil life parallels that during war. Unless the figures are actually viewed and analyzed no adequate conception can be had. When once these figures are borne in mind, there can be no cost of study, research or of actual preventive measures that can quite equal the cost in money of disease or death from preventable disease. Moreover, besides the mere saving of life or the prevention of disease, measures looking toward prevention prolong the span of life many years. It is estimated that modern preventive measures now awaiting public approval, in the way of adequate funds, can increase the span of life more than fifteen years. Indeed, the gradual scientific developments since the Dark Ages have raised the span of life from an average of twelve years to nearly fifty years at the present time. Even now the deaths from preventable causes in the United States are estimated at much over half a million. From 20 to 50% of the children under one year die before the expiration of that period. While such diseases as typhoid and tuberculosis have been much reduced by modern preventive measures, the rise in the incidence of degenerative diseases, such as are justly attributed to alcohol, syphilis, and generally high-pressure life and overspeeding, has been very abrupt of late; and what has been gained in the reduction of acute infectious diseases and other disease conditions is much overbalanced by degenerative diseases. In the former it is the general public that is responsible for the rise or fall, according as they withhold or furnish cooperation in preventive measures, but in the latter the fault lies in the individual, who will not become educated to the proper mode of living.

Professor Irving Fisher of Yale University has aroused considerable interest in this general topic by his computation of the money values of life and health. He estimates the value of a new-born child at nearly \$100. At twenty years, this infant's value is about \$4000. The money loss from each postponable death is about \$1700, and about 40% of all the deaths are postponable. The total money loss from preventable or postponable deaths is much over a billion dollars yearly. If the annual cost of illness is included, the loss annually is much over two billion dollars. The money value of the people of this nation—the human asset—is estimated at more

than twice the value of the physical wealth. Nevertheless, in the conservation of the latter asset an infinitely larger proportion of the public money is expended than is so grudgingly bestowed upon the conservation of life and health.

GRADUATE WORK IN FRANCE.

A MOVEMENT is on foot to restore to its true status French science and learning in America. For a generation past Germany has been the goal of the graduate student in search of further attainment in his chosen field and a degree in recognition of his study. That France has been equipped with equal educational facilities has not been taken into account, and few students have patronized her universities. The probable reason is found in the refusal of French Universities to open the majority of their courses to Americans and to confer on American students the desired degree. Within the few years past a committee was formed of Paris professors, instigated by a small band of American students, to endeavor to prevail upon the French Ministry of Education to remove these prohibitive regulations. They were successful to the extent that in all of the faculties of Paris, and possibly of all the fifteen other French universities, a French university degree is attainable by any qualified American student. His American degree (if from an institution of repute) will be accepted as equivalent to the corresponding French degree, qualifying him to become a candidate for the next higher degree.

It is now the endeavor of a society calling itself The Society for American Fellowships in French Universities, to bring to general attention the excellence of French institutions and their extensive facilities, and to foster in American students the desire to find in them the opportunity for further study, which they have been led to believe existed only in German universities. To this end, ten or more graduate fellowships are to be established for American students in French Universities, to be awarded competitively every year for ten years, beginning October, 1917; each fellowship to hold for two years, if desired. The Society has also published a book entitled "Science and Learning in France," aimed to set forth the status of French learning in the world of knowledge.

Following is a list of the Trustees of the Society as thus far formed:

New York, Charles A. Coffin (chairman of the General Electric Company), acting chairman; Henry S. Pritchett (president of the Carnegie Foundation for Teachers); Alexander C. Humphreys (president of the Stevens Institute of Technology); Dwight W. Morrow (of the firm of J. P. Morgan and Company); Thomas Thacher (president of the University Club of New York); Robert Bacon (former ambassador to France). Boston, Major Henry L. Higginson (of Lee, Higginson and Company, Bankers; member of the Harvard Corporation). Chicago, Charles L. Hutchinson (vice-president of the Corn Exchange National Bank; president of the Art Institute of Chicago); John V. Farwell (former president of the Commercial Club; member of the Yale Corporation). Cleveland, Myron T. Herrick (former ambassador to France). New Orleans, Charles P. Fenner (of the New Orleans Bar; Dean of the College of Law of Tulane University). St. Louis, Robert S. Brookings (president of the Board of Trustees of Washington University). St. Paul-Minneapolis, Charles W. Ames (president of the West Publishing Company).

MEDICAL NOTES.

MORTALITY RATES IN JAPAN.—The Department of Health of Tokyo, Japan, publishes the following statistics regarding its death rates for the year 1915. During that period there were 41,582 deaths, of which 21,403 were men and 20,159 were women. Tuberculosis caused the largest number of deaths—6635; diarrhea, 4206; pneumonia, 4206; Bright's and other forms of kidney disease, 2274; brain diseases, 2103; meningitis, 2714; and cancer, 1431.

NEW YORK HEALTH RATES.—According to the annual report of the Department of Health of New York City, the year 1916 was the most healthful in its history, for, despite the infantile paralysis epidemic, the death rate was 13.89 per thousand inhabitants. Child mortality was reduced to 93 infants in every thousand, as compared with 125 in 1910. There was a decrease in births for the year of 3592, due, it is believed, to a cessation of immigration and the low marriage rate of the previous year. The marriage rate of 1916, however, increased by about 4000. There were 4235 deaths due to violence, many of them among children, and most of these preventable.

WAR NOTES.

PHYSICIANS FOR FRENCH CHILDREN.—A commission of pediatricians, under the leadership of Dr. J. P. Sedgwick of the University of Minnesota, will go to France to organize treatment of French children who are suffering from shell-shock and diseases resulting from lack of care during the war. The commission grew out of a conference of the American Pediatric Association with Herbert C. Hoover and physicians who worked with Mr. Hoover in Belgium.

WAR HONOR FOR BOSTON PHYSICIAN.—President Poincaré of France has conferred upon Dr. Ralph R. Fitch of Boston the distinction of being made knight of the Legion of Honor. This is in recognition of his work in the Franco-American Hospital at St. Valery en Caux, France. Dr. Fitch, who is a graduate of the Boston Latin School, received his degree of M.D. from the Harvard Medical School in 1903. After serving in the Massachusetts General Hospital and the Children's Hospital, Dr. Fitch associated himself with Dr. Weigel of Rochester, N. Y., well known for his work with x-ray. In December, 1914, Dr. Fitch offered his services to the Allies and was sent to a hospital at Yvetot, France. In August, 1915, he established a hospital at St. Valery en Caux, and became its head physician.

AMOUNT OF RED CROSS WAR FUND.—It is reported that on July 16 the amount of the Red Cross War Fund had totalled \$118,021,370. Of this amount, Massachusetts contributed \$5,613,268; Maine, \$604,898; New Hampshire, \$375,341; Vermont, \$162,000; Rhode Island, \$896,923; and Connecticut, \$2,633,622.

RECRUITING OF MOTOR UNIT FOR FRANCE.—The Society of Automotive Engineers has planned to recruit a unit consisting of twenty truck drivers and ten mechanics with twenty helpers, for Red Cross service in France. All expenses will be provided, but recruits will be expected to serve without pay. The trucks will be used for transporting supplies from seaports to the devastated districts of France.

AMERICAN AMBULANCE IN GOVERNMENT SERVICE.—The American Ambulance at Neuilly has been formally turned over to the United States Government to be used as a Red Cross Hospital. The ambulance committee will be replaced by an officer of the American Army, and the staff of surgeons and nurses will continue as before, if they choose to offer their services.

ARRIVAL OF MASSACHUSETTS GENERAL HOSPITAL UNIT.—It is reported that the United States Army base hospital No. 6, organized at the Massachusetts General Hospital, sailed secretly from Boston on July 9, and arrived safely on July 21 at a port in England.

WAR RELIEF FUNDS.—On July 21 the totals of the principal New England war relief funds reached the following amounts:

Secours National Fund	\$321,465.22
French Wounded Fund	241,636.71
Armenian Fund	203,722.41
Permanent Blind Fund	119,503.50
Surgical Dressings Fund	111,366.00
Italian Fund	42,959.72

BOSTON AND MASSACHUSETTS.

WEEK'S DEATH RATE IN BOSTON.—During the week ending July 14, 1917, the number of deaths reported was 183, against 199 last year, with a rate of 12.36, against 13.65 last year. There were 35 deaths under one year of age, against 31 last year.

The number of cases of principal reportable diseases were: diphtheria, 53; scarlet fever, 23; measles, 93; whooping cough, 15; typhoid fever, 3; tuberculosis, 127.

Included in the above were the following cases of non-residents: diphtheria, 3; scarlet fever, 5; whooping cough, 1; typhoid fever, 1; tuberculosis, 4.

Total deaths from these diseases were: diphtheria, 1; measles, 3; typhoid fever, 1; tuberculosis, 24.

Included in the above were the following non-residents: diphtheria, 1; typhoid fever, 1; tuberculosis, 2.

PRIVATE WARD OF THE MASSACHUSETTS GENERAL HOSPITAL.—The new and luxurious private ward at the Massachusetts General Hospital is in operation and is meeting with deserved approbation.

It is a building of eight stories and of fire-proof construction throughout. It has accommodations for 102 patients. It is equipped with three general surgical operating rooms, an operating room especially designed for nose and throat cases, a large plaster room for orthopedic cases, and two clinical pathological laboratories. There are large balconies on the level of each floor and also a roof garden, to which patients' beds may be wheeled. Patients' rooms are connected with the electrocardiograph. There is a complete x-ray department in the building, which is under the direction of Dr. George W. Holmes.

The Trustees have decided to offer the use of this ward to a limited number of physicians not on the staff of the Hospital. They will be glad to extend the use of the ward for the treatment of cases of the same general character as the Massachusetts General Hospital has always accepted.

BOSTON BABY HYGIENE ASSOCIATION.—At the July meeting of the Baby Hygiene Association the director submitted a report showing that during the past six months 1744 new babies were treated, which is an increase of 368, or

26.7%, for a corresponding period last year. With the usual increase in August and September, a weekly registration of 2500 babies may be expected before the end of the year.

HEALTH REPORT OF WORCESTER, MASS.—The recently issued annual report of the Worcester (Mass.) Board of Health states that its death rate for the year ended December 31, 1916, was 16.80 per thousand. Excluding deaths at both State Hospitals, it is 14.75, and excluding non-residents it is 13.80. The birth rate per thousand was 28.80.

POLIOMYELITIS IN HAVERHILL AND GROVELAND.—Five cases of poliomyelitis in Haverhill, Mass., and one in Groveland, Mass., make a total of sixteen cases of the disease reported in Massachusetts in June, 1917.

NEW ENGLAND NOTES.

MAINE HEALTH COMMISSIONER.—Upon the organization of the health department of the State of Maine, based on the administration of Massachusetts and New York Departments of Health, Governor Milliken appointed Dr. Leverett D. Bristol of Boston as Health Commissioner. Dr. Bristol was born in Chicago, Ill., on June 2, 1880. He graduated from Wesleyan University in 1903 with the degree of S.B., and from Johns Hopkins University in 1907 with the degree of M.D. He subsequently became engaged in public health work in New York, Minnesota and North Dakota. About a year ago he entered the Harvard Medical School enrolling for the degree of Doctor of Public Health. During that time he has been doing research work for both the Massachusetts State Health Department and the Harvard Infantile Paralysis Commission. Dr. Bristol will take charge of reorganizing the health work of Maine as soon as his appointment is confirmed by the executive council.

The Massachusetts Medical Society.

NOTES FROM THE DISTRICT MEDICAL SOCIETIES.

HAMPSHIRE.—The regular meeting was held at Boyden's Restaurant, Northampton, July 11, 1917. Papers were read by Dr. E. E. Thomas on "Acidosis in Children"; and by Dr. O. W. Cobb of Easthampton on "Health in the Public Schools." The matter of the medical care of enlisted men's dependents, as advocated by the State Board of Health, was brought up by Dr. Miner of Ware, and referred to the committee on military affairs. Seven Fellows have already received commissions in the Medical Reserve Corps of the Army, and five others have made application.

Lt. J. D. Collins, Lt. W. J. Collins, and Lt.

J. F. Bowen are on active duty at Fort Benjamin Harrison, Indiana; Lt. H. B. Perry is stationed at Boston with the Department of the Northeast. Capt. E. C. Green, Lt. E. E. Thomas, and Lt. E. H. Hughes are awaiting orders.

E. E. THOMAS, M.D.,
District Correspondent.

Obituaries.

EMIL VON BEHRING.

ON the day following the birth of Paul Ehrlich was born another illustrious German, Emil von Behring, and it is interesting to note that the present year ends both their careers. Dr. Behring was born at Hansdorf in West Prussia, on March 15, 1854. After qualifying in medicine at Berlin, he entered the Army Medical Corps, and in 1888 was made lecturer at the Army Medical College in Berlin. When he was thirty-five years of age he became assistant at Koch's Institute for Infectious Diseases and for the next five years he accomplished those achievements of research in immunity which have made his name known the world over. Of his work during this time the *Lancet* says:

"Working alone on diphtheria toxin and in association with Kitasato on tetanus toxin, 'the possibility of successfully treating cases of acute infectious disease' became the theme of a research published in the *Deut. med. Wochens.* in December, 1890, entitled 'Über das Zustandekommen der Diphtherie-Immunität und der Tetanus-Immunität bei Tieren.' Clinical experience, accumulated largely by Heubner, confirmed these experimental results, and at an address on the Aims and Achievements of Serum-therapy at the Naturalists' Congress in Lübeck (1895) Behring was justified in saying: 'I have no fear that the thought which forms the basis of serum-therapy will ever disappear out of medicine.' He estimated the probable saving of 75 per cent. of the mortality from diphtheria in Germany, an annual credit of 45,000 human lives. For this work Behring shared with Roux the 25,000-fr. prize of the Paris Academy of Medicine and the 50,000-fr. prize of the Institute of France. In 1901 he received the Nobel prize for Medicine, and delivered an address in Stockholm on Serum-therapy, while his progress in the receipt of official recognition at home reached the highest level of Excellency in 1903."

In 1895, when he was forty-one years of age, he was appointed director of the Institute of Hygiene of Marburg and from this time on he achieved nothing further corresponding to the five years of successful scientific work at Berlin. He suffered from ill-health and from periods of depression. Becoming financially interested in the manufacture of antitoxic serum by the Farb-

werke Höchst, he was given large and admirably equipped laboratories in which to work, where he conducted researches involving 7,000,000 ounces of tubercle cultures. His results with bovine vaccine excited keen interest for a time, but do not appear to have survived the test of time and prolonged experience. Whatever the practical outcome of his experiments, he has had a profound influence on contemporary thought in regarding tuberculosis as a lifelong affection. He died from an attack of pneumonia on March 31, 1917.

WILHELM WINTERNITZ.

WILHELM WINTERNITZ, emeritus professor of medicine in the University of Vienna and called "the father of scientific hydrotherapy," died on February 22nd at the age of 82 years. The *Lancet*, in its obituary, says of him:

"From the time of his inaugural dissertation (1865) on 'The Rational Basis of Certain Hydrotherapeutic Measures' to the appearance, a few days before his death, of 'The Water-Cure and Natural Immunity,' Winternitz was constantly occupied in research on physical treatment. Many of his studies of the action of thermo-mechanical influences on the circulation and metabolism are now classical, as well as the long and bitter feud between himself and Liebermeister with regard to the bath treatment of infectious diseases. His idea of determining a blood-flux to particular organs and parts of the body was worked out in great detail long before Bier annexed the word 'hyperaemia.' Winternitz's belief in his own methods was very great, so that he imbued his patients with a like confidence, and he was for nearly half a century one of the busiest consultants in Vienna. But in spite of his great popularity he remained an inquirer and a research student to the last, intent on improving the field of medicine which he had so specially made his own."

OSWALDO CRUZ.

THE premature death of Dr. Oswaldo Cruz in Rio de Janeiro has ended the career of the most eminent of South American hygienists. Upon his appointment as Director of Public Health of Rio de Janeiro, Dr. Cruz began a most drastic and fearless campaign to improve the sanitary condition of the city. He had demolished whole quarters of the city which were beyond repair and rigorously isolated all cases of infectious disease. At one time his measures nearly precipitated a revolution against the Government, but the successful issue of his efforts at length won his countrymen's confidence, and he was unhampered by political influence. He organized campaigns against mosquitoes and was untiring in devising measures for the safeguarding of human life. In three years' time he has eliminated yellow fever and plague from the city. In

1908 he began a war against malaria and smallpox and met with great success. In 1900 he founded an institute of bacteriology and serum therapy to which in 1908 the grateful citizens gave his name. This institution has become one of the finest institutes of parasitology in the world. There Carlo Chagas discovered the cause of chronic infective thyroiditis and much other valuable research work has been done. The proceedings of the institute are issued each year in a volume printed in Portuguese and formerly in German, now in French.

Miscellany.

RESUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR JUNE, 1917.

GENERAL PREVALENCE.

Over ten thousand (10,302) cases of communicable diseases were reported during June, a decrease of more than one thousand compared with the cases reported in May. During June, 1916, there were 7,514 cases reported.

The diseases that show an increase over the cases reported last month are typhoid fever, pulmonary tuberculosis, cerebrospinal meningitis and poliomyelitis. Features of special interest are noted concerning the following diseases.

Anthrax.—There were eight cases of anthrax reported during June, making a total of thirty-two cases for the first six months of this year, which is the largest number of cases ever reported in the state for a like period. Six of the thirty-two cases were fatal.

Six of the June cases were in persons who handled hides. Of these, two worked in the beam house or soak room of a tannery and four worked at unloading hides at the wharves or freight rooms. The two remaining cases were workers in a brush factory, and received their infection from the hair which they handled.

Cerebrospinal Meningitis.—A total of thirty-six cases for June is an increase over the usual number reported for this month; in the corresponding month of previous years, there were twenty-one cases in 1916, seventeen in 1915, and nineteen cases in 1914.

For the first six months of this year, there have been one hundred and twelve cases of this disease reported throughout the state. For the same period in 1916, there were eighty-eight cases reported. For several months this disease has been unusually prevalent in and about the cities of Boston, Pittsfield and Lowell. During June, Springfield and the adjoining city, Chicopee, also reported an unusually large number of cases.

Poliomyelitis.—This disease remains fairly well distributed throughout the state, eight communities reporting sixteen cases during the

month. Haverhill, where five cases were reported, presented the only unusual incidence.

Diseases on the Premises of Milk Handlers.—During the month there were reported two cases of scarlet fever in families of milk handlers. Prompt action by the families concerned, who followed instructions of the local Boards of Health, prevented any spread of this disease to consumers.

EPIDEMICS AND OUTBREAKS.

Smallpox.—Ten cases of smallpox were reported during the month, four in Worcester, two in Shrewsbury, two in Fitchburg, and one each in Blackstone and Webster. With the exception of the Blackstone case, all apparently had their origin from the Worcester cases. The outbreak in Worcester, which reached its height in May, is now on the decline, and it is hoped that by next month this disease will be eliminated from the state. The source of infection of the Blackstone case is at present unknown, as the investigation has not been completed. There were two deaths among the ten cases; one had never been vaccinated, and the other was vaccinated in childhood, over fifty years ago.

Typhoid Fever.—Twenty-four cases of the one hundred and six cases of typhoid fever reported during June were from Fall River, where sporadic outbreaks of unknown origin occur from time to time. Suspicious groupings of a few cases of typhoid fever in both Chelsea and Everett during the current month led the local Boards of Health of those cities to carry out special investigations which, however, disclosed no common source of the disease.

Diphtheria.—The outbreak of diphtheria in Malden, which has been persistent for the past few months, is now on the decline as a result of extensive school culturing and the weeding out of children who were found to be harboring the bacillus of diphtheria in their noses and throats. There were twenty-seven cases reported during the month, which is quite a decrease compared with the previous months.

In Lowell, diphtheria is on the increase, fifty-nine cases being reported for June as compared with forty-seven reported during the preceding month. The cases are well scattered in all sections of the city, and no source has been found to account for the continued prevalence.

Cerebrospinal Meningitis.—An interesting neighborhood outbreak of this disease was reported from Beverly, where four cases occurred in the same house during June in four children aged 9 years, 7 years, 21 months and 3 months, respectively. A fifth case in a child five years of age, a playmate of the other children, was reported from a house across the street. This shows how the disease may be transmitted from one to another, and the necessity of carrying out precautions so that one child will not be the source of infection for others.

Scarlet Fever.—In Abington, an investigation

following the report of eight cases of scarlet fever demonstrated that isolation was being carried out very imperfectly. Milk bottles were being left at the houses under quarantine and empty bottles collected. However, no evidence could be discovered to indicate that infection was carried through the milk. The cases were distributed throughout the town, and the probability is that the outbreak was due to unrecognized mild cases.

In North Easton, a family was found in which six out of eight children had scarlet fever before a physician was called. Conditions such as these result in seeding a community and causing an epidemic.

Food Poisoning.—Following a banquet held at a Boston hotel by pupils and teachers of a Quincy school, there were one hundred and seventy cases of food poisoning. Only four or five of those present were not affected. None of the cases was severe, although several of the pupils and teachers were absent from school for a few days after the banquet. The symptoms were chiefly gastro-intestinal, and there were no fatalities.

RARE DISEASES.

Actinomycesis was reported from Cambridge (1).

Anterior Poliomyelitis was reported from Cambridge (2), Worcester (3), Boston (2), Springfield (1), Amesbury (1), Sutton (1) and Haverhill (5).

Anthrax was reported from Peabody (1), Boston (5), Salem (1), Malden (1) and Winchester (1).

Cerebrospinal Meningitis was reported from Chelsea (2), Braintree (1), Templeton (1), Boston (6), Worcester (2), Gloucester (1), Pittsfield (6), Springfield (7), Watertown (1), Beverly (4), Palmer (1), Chicopee (1), Lawrence (1), Maynard (1) and Lowell (1).

Dog-bite was reported from Attleboro (3), Brockton (1), North Adams (1), Lawrence (1), Worcester (1), Lowell (1) and Salisbury (1).

Dysentery was reported from Wrentham (2), Worcester (1) and Boston (4).

Malaria was reported from Boston (5), Fall River (1), Dedham (3), Brockton (1), Brookline (1), Erving (4) and Montague (1).

Pellagra was reported from Lynn (1), Taunton (2), Chelsea (1), Danvers (1), Somerville (1) and Worcester (1).

Septic Sore Throat was reported from Boston (6), Newton (1), Belmont (1), Medford (1), Northbridge (1), Brookline (1) and Chelsea (1).

Smallpox was reported from Worcester (4), Webster (1), Shrewsbury (2), Fitchburg (2), and Blackstone (1).

Tetanus was reported from Worcester (1), Boston (1), Winchester (1) and Springfield (1).

Trachoma was reported from Chelsea (2), Lawrence (2), Salem (1) and Boston (2).

SAFEGUARDING FOODS AND DRUGS.

IN the enforcement of the Food and Drugs Act during the last year, U. S. Department of Agriculture officials analyzed 29,833 samples of foods and drugs offered for interstate shipment and for import. A physical examination was made of samples from 76,468 shipments offered for import. Of these foreign shipments, 6,353 were found to violate the law in some respects and were either excluded from the country or admitted only after the importers had relabeled them to comply with the law. Of the samples of domestic products analyzed 3,535, either because of the nature of the product or because the label on it did not tell the truth, were found to be in violation of the Federal law. In 1,364 cases the Department recommended to the Department of Justice that criminal prosecution be instituted against the manufacturers or that the goods be seized. In many cases where there was no evidence of intention to defraud, and where there was merely some easily remedied flaw in the wording of a label, the shippers, after being warned in hearings, voluntarily took steps which made their products fully comply with the requirements. In all, there were held 8,715 such hearings, many of which resulted in the prosecutions indicated and the gathering of evidence for a large number of additional cases, which will be forwarded to the Department of Justice.

The Bureau of Chemistry, in its annual report, also calls attention to the fact that through the system of Service and Regulatory Announcements now in use, manufacturers are given due notice of the requirements and thus are enabled voluntarily to make their products conform to the law. In this way the government achieves its purpose, frequently without entering into needless and very expensive litigation.

In the regulatory work, special emphasis has been given to the control of drug products and foods liable to spoilage and pollution. These frequently constitute a serious menace to health. The food inspectors have been instructed to be particularly watchful for interstate shipments of bad eggs, milk, oysters, and spoiled canned goods, and false and fraudulently labeled medicines and spurious, synthetic drugs.

Attempts to counterfeit or adulterate imported drugs have been more common since the recent high price and scarcity of many of these products encouraged their imitation. It is interesting to note that of the 1,036 cases terminated in the courts during the year, 198 were brought on account of the false and fraudulent labeling of medicines. In all of these medical cases, save five, the courts found for the government, and this, it is believed, has exercised an important deterrent effect on the vendors of nostrums shipped from one State to another.

The work of controlling the fraudulent labels of medicines and mineral waters has been greatly strengthened by the establishment of a

separate office to deal with these matters. At the request of the Secretary of Agriculture an officer of the U. S. Public Health Service has been detailed to take charge of this work. Moreover, through the close coöperation established with the foods and drugs officials of many of the States, the Department was able to direct the attention of the local authorities to the presence of spurious drugs in their States and, as a result, many of these fraudulent goods in the hands of local dealers and beyond the reach of the Federal authorities were destroyed by State and municipal officers who, in many cases, prosecuted those responsible for the local traffic.

The coöperation in the sanitary control of the milk supply of small cities, described in the report for last year, has been extended in Illinois, Iowa, Missouri, Kansas, Nebraska, and in New England. It is proposed to repeat this work year after year, extending it each year to new territory. In some localities bad conditions were found, due in the main to insufficient cooling and careless handling. Perhaps the best result of this work has been that it stimulated some of the local authorities to take up similar work independently, so that definite permanent improvement of the milk supply of a number of cities has resulted. The coöperative work on the control of the shipment of decomposed eggs, described in the report of last year, has been extended to cover much of the territory in which shipments originate, so that eggs are now candled before shipment far more than formerly and the spoiled eggs destroyed or fed to poultry and stock. At the same time information given to local officials has helped them to curb local traffic in eggs rejected in candling.

The Bureau of Chemistry, after making coöperative sanitary surveys of oyster beds, issued warnings against the interstate shipment of oysters from polluted and doubtful beds and, where these warnings were not regarded, undertook prosecutions. As a result, interstate shipment from such territory was stopped.

The campaign against the sweating of immature oranges and immature grapefruit so as to give the immature fruit the color of ripe fruit has been successful, largely because of the active help of the greater part of the citrus-fruit producers. Comparatively few sweated, immature oranges were offered during the last year, and it is believed the better quality of fruit resulted in a steadier market, so that the producer as well as the consumer benefited.

Other forms of adulteration, not already mentioned, that received especial attention are the adulteration of scallops and canned tomatoes with water, the substitution of colored starch paste for tomato sauce, the reprocessing of spoiled canned goods, the traffic in eul beans, in decomposed tomato products, in rancid olive oil, in wormy horse beans, the substitution of foreign fat for cacao butter in, and the addition of cacao shells to, cacao products, the adultera-

tion of rice bran with rice hulls, the coloring of inferior macaroni and of plain noodles, the misbranding of domestic macaroni in simulation of imported goods, and the adulteration of oats with water or weed seeds.

SYPHILIS IN THE AUSTRIAN ARMY.

"In a recent issue of the *Wiener Klinische Wochenschrift* (xxix, No. 51), Hecht, an Austrian army surgeon, states that in his corps records are now kept of every man with venereal disease, and a certain mark opposite the name of a man on the register indicates that in no circumstances is he to be granted home leave. This restriction of home leave had previously been enforced for typhoid carriers. Hecht adds that no one seems to class the venereal diseases with infectious diseases, but he is convinced that this neglect to apply the measures that have been found reliable with other infectious diseases will avenge itself sooner or later. He estimates that the number of syphilitics in the Austrian army now must certainly be several hundreds of thousands, and complains that they are being treated in hospitals, while sound and healthy men are being shot down in their stead. This actually places a premium on sexual infection, for the healthy have no chance of a few months' respite in the hospitals from the fighting. The effect likewise is to spare the syphilitics while the sound get killed off. He makes the very reasonable suggestion that the diagnosis should be the signal for sending the men to the front. This would have a deterrent effect; at present many prefer to take their chances with syphilis rather than with the enemy's shells. Hecht thinks it might be possible to form special companies of syphilitics as soon as the ulcers have healed over, so that the treatment could be conveniently continued and applied on the firing line, while infection of other troops would be prevented. Neisser long insisted that courses of salvarsan and mercury could be given perfectly well in the trenches. Hecht declares that it is impossible to reiterate too often the frightful danger for the populace from syphilitics in the primary phase. Since the war began, a total equivalent to sixty divisions have been temporarily withdrawn from the fighting for venereal diseases. In conclusion, Hecht insists on the necessity for enlightening the public in regard to the danger of venereal disease in candidates for matrimony."—From *Medical Officer*, London.

SAVING MOTHERS.

MORE women 15 to 45 years of age die from conditions connected with childbirth than from any disease except tuberculosis. About 15,000 deaths from maternal causes occur annually in the United States, and the available figures for

this country show no decrease in the maternal death rate since 1900. Maternal deaths are largely preventable by proper care and skilled attendance.

These 15,000 deaths do not measure the full extent of the waste. They are merely a rough index of unmeasured preventable illness and suffering among mothers. Furthermore, certain diseases of early infancy are closely connected with the health of the baby's mother and the maternity care she has received, and these diseases cause about one-third of all the deaths occurring among babies under one year of age. More than 75,000 babies die each year from this group of diseases because they do not have a fair start in life.

The life and health of the mother are in every way important to the well-being of her children. Breast feeding through the greater part of the baby's first year is his chief protection from all diseases, and mothers are much more likely to be able to nurse their babies successfully if they receive proper care before, at, and after childbirth.

The expectant mother should at once consult a physician. She should remain under supervision so that any dangerous symptom may be discovered as soon as it appears. She should learn how to take care of herself, and she should have proper food and rest, and freedom from anxiety. When the baby is born, the mother needs trained attendance. A difficult maternity case is one of the gravest surgical emergencies. Many people do not seem to understand that in any case complications may arise which can be met safely by prompt and skillful scientific care, but which at the hands of an unskilled attendant may cost the life of mother or child, or both. Even after confinement, the mother needs continued supervision and rest until her strength has returned.

Thousands of mothers, both in city and country, do not have the essentials of safety, partly, perhaps chiefly, because they do not realize the dangers involved in lack of care or else accept the dangers as unavoidable. Many women are at present unable to obtain proper care, but when all women and their husbands understand its importance and demand it for every mother, physicians will furnish it, medical colleges will provide better obstetrical training for physicians, and communities will see to it that mothers are properly protected.

Little has been done as yet to show women that much of the waste of mothers' lives and health is unnecessary. Even less has been undertaken by communities to provide protection for them. Many communities which have studied their typhoid and tuberculosis death rates, and have undertaken costly measures to reduce them have been heedless of the death rates among mothers. It is not strange, therefore, that since 1900 the typhoid rate for the country as a whole has been

cut in half, and the rate from tuberculosis has been markedly reduced, while the death rate from maternal causes has shown no demonstrable decrease.

Just how the importance of adequate maternity care is to be made plain to a community, and just how skilled care and instruction are to be made available for all mothers, are, of course, local questions, to be considered by each community. The prenatal clinics and prenatal nursing, which are being developed in many cities, suggest a method of supervision and instruction which might well be extended. Even in cities where such work is carried on and where good hospitals are numerous, the number of mothers reached is small in comparison with the number who bear their children without adequate care.

Difficulties are perhaps greatest in rural districts where the sheer inaccessibility of a physician is often added to the other elements of the problem. Here a public nursing service, with headquarters at the county seat, or other accessible town, would probably be the first step, placing at the service of every expectant mother a visiting nurse, who is especially equipped to give her information about personal care and to watch for symptoms of trouble demanding medical advice. As such a nursing service develops, its headquarters might become, with the co-operation of physicians, a sort of maternal and child-welfare center, to which not only prospective mothers, but also mothers with babies, could come for instruction, examination, and advice. If no general hospital were conveniently near, a cottage hospital for mothers and babies might ultimately form a part of such a center.

A more general use of existing provisions for scientific maternity care, and the extension of provisions for such care in all types of communities, should serve to reduce the number of deaths among mothers and babies, and to improve the health and general condition of children throughout the country. A full discussion of the causes and prevention of maternal deaths and an analysis of available statistics, are contained in a report on Maternity Mortality, published by the Children's Bureau.

The Children's Bureau has several publications which are of interest in connection with work for the welfare of mothers and babies. A list of these publications will be sent upon application to the Children's Bureau, Washington, D. C.

Correspondence.

TUBERCULOSIS IN THE ARMY.

San Francisco, Cal., July 12, 1917.

Mr. Editor:—

In your issue of July 5th is an editorial on tuberculosis in the army, in which you call attention to the plan for "volunteer services of experienced physicians" needed in eliminating "active or obvious pulmonary tuberculosis." You call attention to the value to the army in effectiveness in preventing such cases from enlisting or being drafted, and point out that incipient cases may be safely placed at useful civil work.

All that you say is true, and it is a very worthy service that physicians skilled in detection of early pulmonary tuberculosis may render by making possible the segregating of such cases. But there is a big side of the whole problem—perhaps its most important side—to which you make no reference, and that concerns what is the nation's, the state's, the municipality's and the physician's duty to these uncovered cases of tuberculosis. What are we going to do with them and for them? Surely it is wrong to cast these men aside, discouraged and confused by the too often unsuspected information that they have "consumption." The examining officers are frequently to blame for the way such facts are presented to such unfortunates and it is possible that the tragedy of yesterday in San Francisco, wherein a young man who had served on the Mexican border sought enrollment and was thrown out on account of a lung condition, took poison, might have been avoided and a handicapped individual made to serve happily some function for his country.

Is it not time that the medical profession united on some plan for coordinating all the possible forces available for the care of these uncovered cases of tuberculosis, and thereby turn to advantage the possibilities for good in this tuberculosis survey of 600,000 of our young men? For a year and a half some of us have advocated the passage by Congress of a bill, known as the Kent Bill, providing for a Bureau of Tuberculosis in the Public Health Service and for the care of indigent non-resident consumptives through a subsidy or the returning of such patients to their home towns, provided they could be cared for there. The bill brought out some opposition from just the source least expected—a few social workers who feared that it would increase migration of consumptives. The discussion of the subject may be found in the *Survey* of July 29, 1916, *The Journal of the American Medical Association*, Aug. 5, 1916, and in the *Journal of the Outdoor Life*, July, 1917.

The whole point of the matter, however, is that the federal government alone may regulate interstate traffic and exercise the power to prevent migration and control the travel of consumptives. If the Kent Bill were a law today, we could provide at once for the wanderers who are being buffeted about from town to town and the same government machinery that had in charge the thirty to forty thousand such cases could handle wisely the new cases which the

army examination will bring to light. Not that these cases should be classed with the wandering indigents by any means, but with a nation-wide machine for determining the existence and extent of the disease among drafted men and a full knowledge of each community's resources for the care of pulmonary tuberculous cases, an immense advantage would be gained by starting these men on the safe road, instead of casting them adrift with a staggering blow, calculated only to increase the tragic effect of the unexpected situation.

California has met this approaching situation by appropriating at once \$100,000 for the purchase of a property admirably calculated to be used at once for the care of its prospective soldiers, rejected because of the discovery of tubercular lung lesions. It seems only fair that each state should make some such provision and that the federal government should help to support this work. A good many cases not active at entrance examination are going to become so later and there should be adequate provision for immediate efficient care. Why cannot Massachusetts, which usually is in the lead in such matters, start at once to do its own duty thoroughly and help to bring about the coöperation of the central government in this most important work?

PHILIP KING BROWN.

RECENT DEATHS.

JAMES DWIGHT, M.D., of Boston, died at his summer home at Mattapoisett, on July 13. He was born in 1852, the son of Thomas Dwight and Mary C. Dwight. Dr. Dwight achieved world-wide distinction as a tennis player, and for many years had labored in the interests of the game. As president of the United States National Lawn Tennis Association, he was instrumental in raising the game to its present high standard. In 1886 he wrote and produced the first American book on tennis. He was a skillful player and in the history of the game became an efficient and faithful leader. Dr. Dwight is survived by his widow, two sons and three daughters.

JAMES AMBROSE JONES, M.D., a Fellow of the Massachusetts Medical Society, died at his home in Lynn, July 4, 1917. He was a graduate of the University of Vermont in the Class of 1900, and joined the Massachusetts Medical Society in 1908. He was 53 years old.

EDWIN NELSON MAYBERRY, M.D., died at South Weymouth, July 14, 1917, aged 60 years. He was a graduate of the University of Vermont School of Medicine in 1882 and settled in South Weymouth in 1889, when he joined the Massachusetts Medical Society. He was president of the Norfolk South District Medical Society in 1911-12 and since then had been a councillor.

DR. GRANTLEY BICKELL, a prominent veterinary surgeon of Haverhill, Mass., died at his home on July 9. Dr. Bickell was born in 1872. He was a member of the State Bureau of Animal Industry and was active in the recent campaign throughout New England against foot and mouth disease.

MEETING OF THE SECTION OF TUBERCULOSIS, JUNE 12, 1917.

WHEN IS THE DIAGNOSIS OF TUBERCULOSIS WITHOUT POSITIVE SPUTUM JUSTIFIED?

BY DAVID R. LYMAN, M.D., WALLINGFORD, CONN.,
Superintendent, Gaylord Farm Sanatorium; Member Connecticut Tuberculosis Commission.

THIRTY-FIVE years ago the discovery of the tubercle bacillus fired the world with the hope that the cure for consumption would soon be found. Today, after exhausting our ingenuity in producing sera and vaccines, and after having experimented with almost every drug in the pharmacopeia in turn, we stand, as regards the treatment of tuberculosis, just where we stood then. We know that the hygienic-dietetic régime, whether carried out in a sanatorium or at home, will give us excellent immediate results, provided we can get our cases in the early stages. The years have but served to intensify the insistent demand for an early diagnosis of tuberculosis, but I regret to say that they have not brought the response to this demand which we had a right to expect.

The greatest stumbling-block in our way has been the evasive tubercle bacillus itself. One is so sure of his ground when the microscope reveals this, and there can be so many flaws suggested as to one's diagnosis when it does not! And yet, if we want an early diagnosis—as

we all agree we do—it becomes necessary for us practically to disregard the absence of the bacillus in reaching our conclusions, or at least to grant that its presence in the sputum is not needed for a correct diagnosis. We must always remember that tubercle bacilli are found in the sputum only after there has been caseation and destruction of tissue in the lung, and where, speaking strictly, the disease can no longer be regarded as truly incipient.

In considering when a diagnosis without positive sputum is justified, it might be well to try to arrive at some idea of how often the diagnosis must be so made. With this in view, I have gone over the laboratory records of 1638 cases discharged from Gaylord Farm in the past twelve years. These show 1076 in which the sputum was positive, and 562, or just over one-third, with no bacilli. I do not claim that these figures give accurately the incidence of tuberculosis without positive sputum, for I know that in some of them the question of final diagnosis would be difficult to establish. The proportion would, however, be but small. In the first place, the 562 negative cases, instead of being all, or even chiefly, "incipient" or "suspects," were divided as follows: incipient, 244; moderately advanced, 297; far advanced, 21; more than half showing well-developed lung signs. The probability of correct diagnosis in the series is further strengthened by the fact that in 51 cases there was tuberculosis elsewhere: 18 had pleurisy with effusion, 126 had hemorrhage, and these included only frank hemorrhage, and not blood-streaked sputum,—97 gave positive tuberculin reactions to doses

ranging from 1 to 7 mg. of old tuberculin given subcutaneously, and 76 died from tuberculosis after discharge. We thus have the diagnosis confirmed in 368 of our 562 cases. When we take into consideration the fact that the large majority of these cases had been diagnosed by their own physicians or a consultant before coming to us, it would seem that we were entitled to claim a fair degree of accuracy for the diagnosis, even though one-third of all our cases showed negative sputum.

The study of the records of those having positive findings emphasizes again the futility of depending on sputum for diagnosis. I would say that our laboratory routine has been to make daily examinations for at least a week in all cases with negative sputum, and to re-examine monthly in all cases. We had 1076 cases with positive sputum. In 213 of these the sputum was negative occasionally; in 56 it was negative as often as positive; in 42 negative twice for each positive finding; in 63 negative three times for each positive finding; in 70 negative five times; and in 39 negative ten times for each positive finding!

We thus have of our 1076 positive cases, 483 whose sputum at times would have failed to support our diagnosis, and of our series of 1638 cases only 593 whose sputum was positive at all examinations. Please bear in mind that these cases are classified approximately one-half as "moderately advanced," one-fourth "far advanced," and one-fourth "incipient," and you will readily see how very important it is for us to cease giving too great prominence to negative sputum findings if we are to make any advance in our early diagnosis of this disease. I do not mean by this that we should simply disregard one negative examination, but that if the history, symptoms and signs point to tuberculosis, we should make our diagnosis in the face of persistent negative sputum. In one case in our series, the bacilli were found at the 38th examination, and in several there were over twenty negative results before they appeared. In 172 cases the sputum was negative from three to ten times for every positive result. With only 593 out of 1638 cases showing constantly positive sputum, it is evident that a negative sputum is not sufficient ground for excluding tuberculosis.

What are the conditions under which we are justified in making a diagnosis of pulmonary tuberculosis in the face of negative sputum findings? The data necessary for this purpose may be gathered: first, from the history of the case; second, from the symptoms presented; and, third, from the physical signs.

First, History. Few practitioners seem to realize the supreme importance of an accurate history, both as to person and family, in tuberculosis. It is at once the best guide to a correct diagnosis, and the most difficult to obtain. When we realize that tuberculosis is a disease of childhood, often lying latent for long

periods, to reawaken under the strain of adult life, we begin to see how direct a bearing the past history of the individual has upon his present condition.

Family History. The importance of the family history is generally conceded, and yet it is taken in the most casual way, even in most institutions. It is not enough to ask whether father, mother, sisters, brothers, etc., had tuberculosis. You must remember that tuberculosis very often passes undiagnosed, and in cases where you are in doubt, you must question very closely as to the presence of chronic cough, bronchitis, asthma, catarrh of the lungs or hemorrhage, as well as fistula, and other forms of tuberculosis among the family group. Also bear in mind that the importance of any such history is in exact ratio with the extent to which your patient was associated in childhood with the relatives so affected. The question as to whether anyone with a chronic cough lived at home when the patient was a child, often elicits definite history of exposure through some friend of the family or connection who would not have been thought of under the usual line of questioning. The family history is, of course, insufficient in itself for a diagnosis, but he is a very brave (or foolish) physician who will assure the patient that he absolutely has no tuberculosis, in the face of a strong family history or a definite history of exposure in childhood.

Personal History. The life history of the patient should be thoroughly gone into, with especial attention to previous illness. And again, let me caution against too casual questioning. It does not help your practice to have your patients sent back from a sanatorium as non-tuberculous because (as in one case under my observation) the hemorrhage on which you based your diagnosis proved, on questioning, to be no more than streaked sputum following a nosebleed.

It is common for tuberculosis to present frequent, though slight relapses, and a careful past history often explains present conditions. History of persistent, enlarged cervical or axillary glands, or of fistula in ano, or other tuberculous foci are, of course, of prime importance. Next to these the story of previous acute pleuritis is the most significant. Primary pleuritis always imply tuberculosis unless you can definitely prove them otherwise. Being "subject to colds" is another suggestive story. Usually the patient states that he has had "bronchial catarrh" or "grippe" every winter, with a cough which "hung on." Be chary of joining with the patient in placidly accepting these diagnoses! Of much value also is the history of having been frequently "run down" and having had to go to the country for a month or two every few years.

A history of "malaria" always requires careful analysis. This has been for years the favorite study of the careless diagnostician, and more cases of tuberculosis have been kept in

false security until too late for treatment by the diagnosis of "malaria" than in any other manner. Careful questioning often reveals the absence of any fever and ague or of any definite periodicity of the attacks, leaving a story of periods of loss of weight and strength, slight fever and malaise recurring almost yearly and connecting most logically with the present signs and symptoms.

Hemorrhage from the lungs always means tuberculosis (except when due to carcinoma or cardiac disease), and you may feel sure of giving your patient his best chance if you base your diagnosis on it even without other signs or symptoms. This has been stated so often that it would seem needless repetition. I am, however, constantly seeing cases with a history of hemorrhage one or two years previously which the physician has failed to recognize until advanced disease developed, because he did not know that the hemorrhage itself was ample ground on which to base his diagnosis.

Second, Symptoms. The chain of symptoms which are of greatest importance in diagnosing early tuberculosis are: persistently rapid pulse, afternoon or evening rise of temperature, loss of weight, loss of strength, and persistent cough. It seems hardly necessary to go into details as to the presence of these and their value. In the persistence of any two of these without explainable cause, tuberculosis must be considered. Where the diagnosis rests almost entirely on symptoms the physician must be very careful to exclude other common causes, especially if there be a positive family history to give a background for the diagnosis. One must remember that overwork and dissipation produce loss of weight and strength; that chlorosis, hyperthyroidism and neurotic conditions may show the rapid pulse; that women at the menstrual period often show a similar rise of temperature, as well as of pulse; that malaria may be responsible for such a chain of symptoms; and that there is such a disease as syphilis. Latent syphilis is difficult to detect, and Wassermanns are not readily obtainable in private practice. In doing routine Wassermanns on our patients for the last two years, Dr. Ford found between 5 and 6% showing a reaction of three or four plus, which plainly shows the necessity of keeping this complication in mind.

If only the physician would realize the value of accurate records of temperature and pulse in his doubtful cases, we should not stand as a profession under the indictment of ignorance concerning the chief disease to which mankind is subject; but when out of 1940 physicians consulted by the last 1000 of our patients only 13.4% saw fit to take the temperature even once, we must admit that we give the public just cause for criticism. The patient should be taught to keep a record at least *ev. 4 h.* for a week, and the doctor should realize that persistent or frequent afternoon or evening rises to 99.5 or over are strong evidence of the existence

of tubercle, unless he can otherwise explain their presence to his own entire satisfaction.

Third, Physical Signs. The physical signs of early tuberculosis are usually very slight,—too slight to give in themselves a basis for final diagnosis, and a positive diagnosis should often be made when there are no signs present in the chest. It is not at all rare to see hemorrhages in patients whose chests are apparently clear, or to find tubercle bacilli in the sputum from such a case. We must remember that one can get bacilli and even hemorrhages from a very small focus, and that the lung is a deep-seated organ and covered with tissues such as bone, fat, skin, and muscle, each with a different capacity for transmission of sound. As a result it is not only possible for tuberculosis to exist undetected in the deeper portions of the lung, but, as all of us who have done much lung work know to our sorrow, it is possible for fairly large cavities to be situated in the upper lobes of the lung and yet give no sign on examination even in expert hands. Modern methods of physical diagnosis are not sufficiently accurate to justify our stating dogmatically that a chest is clear if the history or symptoms are at all suggestive of tuberculosis. It is the location and persistence of the sounds rather than their character which must be our guide as to their probable tuberculous origin. All inflammatory conditions of the lung—whether due to infection or chemical or mechanical irritants—produce the signs of bronchitis. In gripe or in bronchitis following a catarrhal cold, or due to dusts or other irritants, these signs are scattered generally throughout both sides. In tuberculosis, on the contrary, the invasion, instead of being general, is along the lymphatic system supplying a lobe or a lobule or group of lobules, and the resulting bronchitis is localized. Persistent signs of localized bronchitis or persistent local impairment of note and breath sounds are to be considered as tuberculous when appearing in the apices of either the upper or lower lobes. On the other hand, the x-ray has shown us that tuberculosis rarely is present in the lower lobes alone; and that most of those cases showing marked impairment of note and breathing, with coarse râles over the right or left lower lobe, with the remainder of the chest clear, are probably due to non-tuberculous infections.

In determining the nature of a lung lesion, the history is of the greatest value. A local bronchitis, found with a history of a recent gripe or pneumonia, requires to be kept under observation for diagnosis. When there has been no history of recent acute respiratory trouble, the diagnosis of tuberculosis is usually correct; and if the case gives a history of exposure and at least two of the cardinal symptoms of tuberculosis (rapid pulse, afternoon temperature, loss of weight, malaise, chronic cough), a positive diagnosis should be made regardless of even the presence or absence of sputum.

It is necessary, however, to make the distinc-

tion between clinical and pathological tuberculosis. If during an examination for insurance or other purposes you find a slight dullness with impaired breathing and even slight moisture after cough at one apex, there is no need to make an invalid of the patient provided he has no symptoms. It is sufficient to tell him that there is latent trouble present and to advise him to have his chest examined periodically, to be sure he does not show signs of spreading.

The final diagnosis of incipient pulmonary tuberculosis is one of the most difficult tasks which confront the general practitioner. It requires careful history, a temperature and pulse record taken at least every four hours for several days, repeated chest examinations and often the use of tuberculin test and the x-ray to find or exclude tuberculosis. The sputum also should be examined daily for at least a week. That all this is difficult to obtain in private practice does not absolve the general practitioner from his responsibility. With signs and symptoms suggesting tuberculosis it is his duty to see that the case is carried through to a final diagnosis, and he should certainly not fail (for his own protection if for no other reason) to advise the patient of the necessity for such a final diagnosis.

If unable to make a diagnosis that would satisfy you as to your own case, you should send the patient to a hospital or sanatorium where such diagnosis can be made. It would add to his regard for you and often mean life itself for him. I feel strongly that the rules governing admission of patients to our state and municipal sanatoria should be so drawn as to provide for the admission there of cases for diagnosis. The physicians would then have a place available where they could secure the temperature and pulse records, animal inoculations, tuberculin tests, x-ray and repeated physical examinations, all of which are often necessary for the diagnosis of incipient pulmonary tuberculosis.

Where such facilities are not available the physician can do no better than follow the teachings of that great physician of a former generation, Dr. Henry I. Bowditch: "If with the history of abnormal symptoms lasting for a longer or shorter space of time, upon examination you find anything out of the normal at one or the other apex, watch your patient closely, for the chances are that there is or has been tubercular trouble there."

I am sorry to say that the profession, as a whole, does not begin to realize the need of altering its attitude toward the diagnosis of tuberculosis. There is no question that the sanatorium men, working as we do always along one line, make many mistakes on the side of diagnosing tuberculosis in doubtful cases, when it does not exist, but we have learned in recent years to subject such cases to searching study after they enter the sanatorium before we charge a positive diagnosis up against them. Bear in mind, however, that such mistakes are

made on the side of safety and result in the patient taking a much-needed rest, rebuilding his general health and acquiring much valuable knowledge as to personal and public hygiene. Erring on this side, we do but little harm and considerable incidental good. Many of the general practitioners persist in following the opposite course, and in so doing, work infinite harm to their patients, to themselves, and to the profession. There is never a time when an incipient case cannot find admission to our sanatorium with but brief delay. There is rarely a time when an advanced case can find such relief save after a wait of several weeks. When such cases come with a history of having been treated for bronchitis or malaria or catarrh, often for one or two years; when they have consulted their physician faithfully and relied on him implicitly and then find that they have advanced and incurable tuberculosis, do you wonder that they and their friends are bitter against us? The history of the diagnosis of our last one thousand cases at Gaylord Farm, showed that they had consulted 1940 physicians before coming to us. Of these 10 2-10% made no examination or test of any kind, but merely prescribed and collected their fee. Do you wonder, under such conditions, that the public holds us to blame for the failure of the campaign to secure early diagnosis of tuberculosis? Our attitude towards this most common of all diseases has done more to promote the sale of patent medicines and the prosperity of the chiropractor and kindred cults than any other influence. We shall not alter this until we begin to give our patients the benefit of the doubt and make our diagnoses without waiting for the positive sputum of more advanced disease. I have no patience with the growing tendency to chide the busy physician because he has diagnosed as tuberculosis some case of streptothricosis or other chronic lung disease. I only wish the general practitioner were less afraid of making such errors, for then he would abandon the Micawber-like attitude with which he watches the gradual development of chronic chest lesions. There is no more excuse for letting the average case of pulmonary tuberculosis reach an advanced stage without correct diagnosis, than there is for waiting for rupture and ensuing peritonitis before diagnosing appendicitis, but fortunately for the human race there is no specific germ associated with appendicitis.

DIAGNOSIS OF TUBERCULOSIS IN CHILDREN.

BY HENRY D. CHADWICK, M.D., WESTFIELD, MASS.,

AND

ROY MORGAN, M.D., WESTFIELD, MASS.

ONLY a few years ago tuberculosis was thought to be a disease of early adult life. Now we realize that it must be considered as a serious menace in childhood. Because it is usually a

chronic and not an acute disease like measles and scarlet fever, it did not attract so much attention.

A study of the death rate from tuberculosis at different age periods shows these significant facts: The death rate of children under five is 127 per 100,000; for the next decade it drops to 36 and then steadily increases between fifteen to nineteen years to 115, and thereafter rises steadily until it reaches its maximum of 228 at the age period of thirty-five to forty-four.

In a general way the course of the disease has three distinct phases, according to the age of the patient: general, glandular and pulmonary. In infants and very young children it seems to run the course of an acute general infection with very little tendency to localize, and death usually follows from meningitis and miliary tuberculosis. For the age period between five and fifteen years, tuberculosis seems to be a localized glandular disease. Resistance to invasion, or the power of the tissue to react in the presence of tubercle bacilli, has been acquired since infancy and the course of the disease is radically different. The bacilli become walled off more or less effectively by a growth of fibrous tissue. The bacilli, therefore, do not have the chance to multiply and spread throughout the body. They lodge in the lymphatic glands and only occasionally reach the bones. Enlarged glands or swelling of the joints are the immediate results. The symptoms vary with the location of the focus of disease and this stage of tuberculosis is of a chronic type. It might well be called the incubation period for what so often follows. From fifteen to forty-five years of age, pulmonary disease is the usual form. We have reason to believe that the lungs become affected by the spread of the bacilli from broken-down tubercle in the bronchial glands. A new infection from external sources among adults is probably rare. Tuberculin tests show that from 50% to 70% of all children are infected with tuberculosis before they are fifteen years old, and in the city-dwellers the infection is almost universal. Where resistance is good the infection may not produce apparent symptoms. In fact, in the greater number of infected children the bacilli are buried so thoroughly in fibrous tissue that they never produce disease. If this were not so the death rate from tuberculosis of one in ten would be decidedly greater.

These preliminary observations are made because the diagnosis of tuberculosis in children must be based on an understanding of the pathology of the disease. The symptoms of tuberculosis in children, with its tendency to be of a glandular type, must necessarily be different from the symptoms in pulmonary disease of the adult. The diagnosis of early tuberculosis in the child requires a different point of view. The emphasis must be laid on the evidence of toxemia produced by tuberculin. It is the case where the child is passing from the quiescent condition of infection to the stage of disease that

we are considering. This, in fact, is the true incipient stage of tuberculosis. It is only in advanced disease that pulmonary symptoms are pronounced.

The symptoms of an overdose of tuberculin are malaise, exhaustion, a rise in temperature; and vague pains in different parts of the body are common.

The child with incipient tuberculosis is easily fatigued, cannot keep pace with the normal child in play or school. When they make the attempt they soon become tired out. They are less energetic in all their activities and it takes them longer to recuperate. They often are nervous and irritable. The normal child may go to bed thoroughly tired, but will be completely rested and as fresh and active as ever in the morning. Children with developing tubercle, however, are much exhausted after less exertion and they will wake up tired and languid. If they continue in school or their exercise is not restricted, a low grade of fever will develop. This will be discovered only when the temperature is taken in the afternoon. It is often variable and transitory. Lack of appetite for breakfast is significant of tuberculosis. Both in children and in adults we have found this statement true. A healthy child is always hungry and ready for meals. Loss of weight or failure to gain is a frequent condition in early tuberculosis.

We have then these common, constitutional symptoms of active tubercle, namely: malaise or weakness, loss of weight or failure to gain, and fever. They are all caused by the absorption of tuberculin and are present in tuberculous disease, regardless of whether the focus is in the chest, lymphatic glands elsewhere or in the bones. The thoracic glands are the most frequently affected and are the ones we are now considering.

Local symptoms are cough, hoarseness, dyspnoea or shortness of breath and hemoptysis. They are produced by the pressure of the large congested glands on the neighboring structures. The sputum which is raised, occasionally contains streaks of blood and comes from the tissues about the tuberculous focus.

To obtain data helpful in diagnosis we analyzed the histories of nearly two hundred children that have been in our care at the sanatorium. The family history was positive in 66%. A tuberculous mother is the most dangerous member of the family, then in order is the father, then a sister to other sisters, and a brother to other brothers. A negative family history is of little significance, but if positive and shows intimate association it is evidence that must be given great weight in considering a given case.

Cough was present in 77%. This symptom is liable to be misleading, as it may be caused by so many other conditions besides tuberculosis. The more common are colds, bronchitis,

influenza, enlarged or diseased tonsils or adenoid growth.

Weakness was noted in 54%. This, in our opinion, is the first and will be found the most frequent symptom of onset if children are carefully studied. It may be exhibited as undue fatigue, morning tire or nervous irritability.

Forty-six per cent. had poor appetites and digestive disturbances, and coincided with the same percentage reported as having lost weight. That this is due to toxemia is shown by the fact that these children, except when they have advanced disease, recover normal appetites and gain weight as soon as their play and exercise are restricted and suitable hours for rest and sleep are made a part of their daily routine.

Thirty-eight per cent. were reported to have had night sweats, but in our personal experience this is a rare condition except in advanced tuberculosis, and we do not attach much importance to the statement of the parents. Probably in most instances the sweating was caused by the use of too much bed clothing, or the child sleeping in a poorly ventilated room.

Fever was noted in 36% before admission. Careful observation, no doubt, would have found elevated temperatures at times in a much larger number. Nearly all of the sanatorium children have periods when the temperature ranges from 99 to 100. A temperature above 101 except in advanced disease is unusual, and when it occurs is nearly always due to some complications, such as tonsillitis, indigestion or other disease. Carious teeth and rickets will sometimes produce the same type of fever as does tuberculosis.

Pain was present in 35%. Our children often speak of having vague pains in the chest, but definite pleuritis is rarely found in early cases. Other observers have noted that tuberculous children often complain of pains in the legs. These pains are ill defined and are similar to the discomfort complained of by individuals who experience a sharp reaction from the tuberculin test.

Chills were reported in 29%. This would seem to us a too high figure. Except in cases that are far advanced we do not meet with this symptom in the sanatorium.

Hemoptysis. Blood was noted in the sputum in 10% of our cases. In nearly all this amounted to but little more than streaks. Occasionally a child would raise a little pure blood, but a frank hemoptysis has never occurred in our experience in a child under thirteen years of age. Bleeding from the posterior nares and from the hypertrophied adenoid tissue, which is so frequently found in a child's throat, may be a source of streaked sputum and should be excluded.

Sputum: This was positive in 19 out of 210 cases, or approximately 9%. It is interesting to note that of these 19 positive cases only 5 were discharged as apparently arrested and 2 as improved. This indicates that a child with

open tuberculosis in its pulmonary form has a very bad prognosis.

Weight: About two-thirds of the children were below normal weight for their age. These averaged ten pounds under weight. A little less than one-third were normal in weight or above normal. This shows that the appearance of a child is not a safe criterion upon which to base an opinion as to the presence or absence of early tuberculosis.

Physical Findings. In 156 cases, 111 showed evidence of consolidation confined to one or both apices, and this usually extends downward into the interscapular space. This corroborates the x-ray evidence that the bronchial glands are first involved. In many of these cases no dullness can be made out anteriorly, even if it is pronounced in the back. There were but four cases in which the disease was confined to the bases.

Râles were found in 48, which was a little less than one-third of the cases. No râles, but other abnormal auscultatory signs, were present in 37%. In 69 others, no râles or other respiratory changes were found. Twenty-one of these showed a marked D'Espine.

It is difficult to formulate minimum standards for the diagnosis of tuberculosis in children. To do that we should have some definite landmarks to determine when infection in the child crosses the border line and becomes disease. As infection in city children is almost universal, we should be on the alert for the characteristic symptoms of tuberculin absorption and not wait for destructive changes in the lungs before instituting suitable treatment. We think the standard of diagnosis set down by the Committee of the National Association is inadequate, and that they have based their views not so much on diseased children as they have on the manifestations of tuberculosis in adults. They attach too much importance to the presence or absence of râles and to the results of tuberculin tests.

The presence of râles at the apices is usually due to tuberculosis, but they are not pathognomonic, as they may be present in influenza or other infection. Râles were present in only one-third of our cases. We should not wait for disease to advance until the pulmonary tissue is sufficiently infiltrated or congested to produce râles, if by a study of the child's constitutional symptoms we can determine with reasonable certainty that active disease is present in the thoracic glands. We must remember that the tuberculin test is positive in healed lesions as well as in active disease. The subcutaneous test should be used with caution. Nearly all children react to the von Pirquet test by the time they are fifteen years old, therefore, tuberculin tests are of but little value in a given case.

The following are two illustrative cases:

Two children of a man who recently died at the Westfield State Sanatorium, were brought to the

institution for examination. Their father had died in the sanatorium a few months after he had been admitted as an advanced, progressive case. He raised a large amount of sputum in which the bacilli were numerous. For six months prior to his admission he had been confined to his home. Being very fond of his children he liked to have them near him and frequently fondled and kissed them. This was in the summer vacation so the children were subjected to prolonged and intimate exposure. The oldest girl, of nine years, gave the following history. She had had a severe cough with slight expectoration for a considerable time. Six weeks before her examination she had been operated on for enlarged tonsils and adenoids. This had no effect in relieving the cough. The child was nervous and irritable. She did not take her usual interest in play but preferred to lie about the house. Rarely she went out with other children, but would soon come back to lie down and rest. At frequent intervals she would have a fever ranging up to 100 for a few days at a time. She had raised a little blood two or three weeks before. Her appetite was poor. Physical examination showed nothing abnormal except a slight dullness at the left apex.

The other girl gave the same history except that she had raised no blood and had had no operation. Her tonsils were small and there was no indication of adenoids. Physical examination showed dullness and roughened breathing at both apices.

The mother was told to keep a temperature record and bring the children back three weeks later. The charts then showed frequent elevations of temperature to 99.4 and 99.6. The symptoms had not decreased in severity. The physical findings were more marked than before. We made a positive diagnosis of tuberculosis in each case and recommended the admission of both children to the sanatorium.

We cannot prove that these diagnoses were correct beyond the possibility of doubt, but we feel sure that they were justified by the history of exposure, constitutional symptoms and evidence of consolidation in the lungs. Why should we wait for râles to develop or for a tuberculin test in these cases before instituting treatment?

To summarize the essentials for a minimum standard necessary in the diagnosis of tuberculosis in children, we would emphasize the importance of symptoms indicating tuberculin absorption, namely: weakness, undue fatigue, fever, poor appetite, failure to gain, or loss of weight, and nervous irritability. The local symptoms are cough, hoarseness and occasionally streaked sputum. The usual physical signs are dullness in the interseapular region radiating into the apices at the back, frequently not elicited in front. There may or may not be changes in the respiratory sounds. Râles may or may not be present. Symptoms both constitutional and local, together with a history of exposure, are to be given greater weight in making a diagnosis of active tuberculosis than the presence or absence of physical signs. Percussion is more important than auscultation. We must, however, bear in mind that a thickened area in the lung or region of the bronchial

glands does not in itself mean active tuberculosis. It may be a healed lesion that needs no treatment. Such thickening may also be caused by other diseases than tuberculosis.

The child showing constitutional symptoms, even without local signs of disease in the chest, should be considered suspicious, kept under careful observation and hygienic treatment instituted in the home. The case with signs in the chest, without constitutional symptoms, indicates an old inactive infection that needs no treatment. Individualization and common sense must be used to weigh all the factors in the case, and, with experience as a guide, few errors in diagnosis will be made.

WHAT SHOULD CONSTITUTE REPORTABLE TUBERCULOSIS.

BY FRANCIS GEORGE CURTIS, M.D., NEWTON, MASS.,
Newton Board of Health.

I THINK that it is safe to say that, under present conditions, tuberculosis causes more trouble to local boards of health and is less capable of satisfactory handling by them, than any disease with which they are concerned.

The reasons for this are perfectly well known to men actively engaged in local public health work, although they may not be so evident to others and are as follows:

First, the lack of any definite agreement among local boards as to what does constitute reportable tuberculosis; second, the passage by the Legislature, for reasons undoubtedly known to itself, although they have not been made manifest to the ordinary observer, of certain statutes dealing with tuberculosis alone and the creation of a special state board in regard to it, and finally, as a result of these laws, the establishment of certain volunteer and amateur associations, ostensibly for the prevention of the spread of tuberculosis and the assistance of the local boards, but which, as at present managed, tend more to interfere with the local boards and lessen their authority than to do anything else.

Personally, I can see no more reason for the existence of a special state department for tuberculosis and of local antituberculosis associations, as they are at present managed, than I can for a special state department for typhoid fever or local anti-scarlet fever associations, and I believe that their existence has more to do with the present unsatisfactory situation in regard to caring for persons who are ill with tuberculosis than any other factors.

I believe that at the present time and under our present laws, it rests entirely within the power of local boards of health to declare what shall constitute tuberculosis within the meaning of the law and that their declaration will stand. I believe, further, that the declaration should be that, from the standpoint of the local boards of health, no person should be

considered to have tuberculosis and be so recorded on the books of the department until he falls within the category of a person ill with a disease dangerous to the public health. He cannot fall within that category until his condition is such that he is capable, potentially at least, of transmitting the disease to others and, as our present knowledge teaches us that he can do this only by means of the bacilli, it follows that a person should not be considered to have tuberculosis until tubercle bacilli have been shown to be present in his sputum.

Having stated my proposition it is now up to me to show my reasons for making it, to defend it against possible attack and to show that it does not necessarily weaken any defense against tuberculosis which we may now possess.

Certain diseases are known to Massachusetts law by the term "diseases dangerous to the public health" and the supervision of practically everything in regard to these diseases is given by law to the local board of health of the community in which they may occur.

The law does not specify what diseases are dangerous to the public health but gives to the State Department of Health the power to declare from time to time what ones shall be so considered. After it has made this declaration, the direct power of the State Department of Health over these diseases apparently ceases, and from that time on the authority of the local boards of health over them becomes practically absolute. They can decide what to do with persons ill with such diseases, decide whether or not they shall be restrained, how long the restraint shall last, etc.

I cannot find any specific statement in the statutes as to the requirements for qualifying as a disease dangerous to the public health, but by common consent and usage there are certain characteristics which belong to practically all diseases included in the list, and chief of these is the liability of transmission from person to person, by direct contact or through an intermediate host.

The State Department of Health, acting under the authority of the statute, has published a list of diseases dangerous to the public health, and tuberculosis in all its forms is included in the list.

The duty of the local board of health, when a disease dangerous to the public health makes its appearance in the community under its jurisdiction, is defined by the statute, rather broadly, it is true, but it is, nevertheless, defined.

Sect. 36 of Chap. 75, R. L., as amended by St. 1906, Chap. 365, Sect. 1, and further amended by St. 1907, Chap. 445, provides that if a disease which is dangerous to the public health exists in a town, the selectmen and the board of health shall use all possible care to prevent the spread of infection. Other sections of the same law give the local boards of health the right to remove persons ill with such diseases

to a hospital, to establish quarantine, to employ nurses, etc.

In order that the local board may have knowledge of the presence of such diseases so as to be able to take these measures, Sect. 50 of Chap. 75, R. L., as amended by St. 1905, Chap. 251, Sect. 2, and further amended by St. 1907, Chap. 480, requires every physician to report to the local board of health immediately, every case of such disease which he is called upon to treat. The report must be in writing, over his own signature, and give enough information to enable the board to locate the case easily. The local boards usually furnish post cards with spaces for the necessary information and have ruled that "immediately" means at least within 24 hours of making the diagnosis, and sooner, if possible.

I think it is not generally known that Sect. 49 of Chap. 75, R. L., amended as above and further by St. 1910, Chap. 269, and St. 1914, Chap. 177, requires the head of the household in which such disease occurs to make a similar report to the local board, the object being, of course, to make it as certain as possible that the local board receives notice of the existence of the case at the earliest possible moment.

As soon as a report of a case of a disease dangerous to the public health is received by the local board of health the machinery for protecting the public begins to move automatically.

It is not necessary to describe the working of this machinery, but it is worth while to point out the difference of view between the member of the local board of health and the practicing physician, when it comes to dealing with a case of such a disease as we are discussing.

The whole training of the man in public health work, or health officer as he may be called, teaches him to look at such a disease from a diametrically different viewpoint from that of the ordinary physician; he is chiefly interested in the prevention of disease and in caring for the health of the public, while the practicing physician is chiefly interested in the cure of disease, and in caring for the health of the individual.

In other words, the health officer cares little for the individual and much for the public, and the physician is deeply interested in the individual, and, as a rule, cares little for the public.

This differing point of view has a very practical bearing upon the subject when it comes to dealing with a case, and often accounts for the seeming callousness of the health officer toward the individual, and explains why his position in regard to dealing with tuberculosis differs somewhat from that of others in the same work.

The majority of diseases with which the health officer deals have certain characteristics in common; thus, they are practically self-limited and tend to run a comparatively short course; the diagnosis is, as a rule, easy; they run fairly true to type; are known to be cap-

able of transmission to others, *i.e.*, they are dangerous to the public health in the early stages and, as a rule, the liability of transmission is less in the later stages.

Tuberculosis, on the other hand, is not self-limited, is of comparatively long duration, difficult of diagnosis and protean in its manifestations; it is not capable of transmission in its early stages, and its liability of transmission increases in the late stages.

These facts make tuberculosis very difficult to handle, especially in its early stages, and furnish a strong argument in favor of making a positive sputum the criterion of tuberculosis from the point of view of the local board of health.

When a health officer has a person with a disease the physical signs of which are such that two supposedly competent men will give diametrically opposite opinions; when he himself feels sure that even if the patient has the disease for which he has been reported, he cannot transmit it to others at that stage; when he cannot truthfully tell the patient that he has the disease, because of which he is asked to take precautions, what on earth can the poor man do? His position is not a very strong one!

If, on the other hand, he can say to the patient that a laboratory examination has shown the presence of certain organisms in his sputum; that the presence of those organisms makes him a source of danger to his family and friends, just as he would be if he had diphtheria, and that the danger can be lessened by taking certain precautions, then the health officer's position is much stronger; he can speak much more convincingly and the patient is more apt to be amenable to suggestion. I say "suggestion" rather than "command," because the agitation which has more or less successfully attempted to place tuberculosis in a class by itself, has in a way defeated its own object and increased the difficulties of handling it. There is no question that the various special laws bearing upon the care of persons ill with tuberculosis have lessened the power of the local boards of health, and by giving a divided authority have made it hard to decide in certain cases just what body has control of the patient.

In addition, the establishment of a number of amateur associations for the care of persons ill with tuberculosis has undoubtedly increased the difficulties of the local boards. These associations are filled with a horde of well-meaning, but more or less hysterical persons, ignorant of the law and always ready to take a hand in the game the moment the word "tuberculosis" is mentioned, whose sole object in life seems to be to find fault with the local board of health, often for not doing that which it cannot do because of the very laws which they themselves have been instrumental in putting on the books.

These persons by their agitation have, I believe, accomplished one result, at any rate, although I have no hesitation in saying that they

hadn't the slightest intention of doing it. They have created such a feeling of phthisiophobia among the general public that they have made many thoughtful men refuse to report their cases of tuberculosis in the early stages, because they do not wish to put a stigma on their patients and expose them to ostracism by the public and possible loss of their means of livelihood, by being compelled to give up work because their employers fear contagion.

These men have practically put into effect the very procedure here advocated, and show that they do not consider tuberculosis a disease dangerous to the public health, until it has been shown that it is so, potentially at least, by the demonstration of a positive sputum.

They take the risk of violating the law in order to do that which the law ought to require before branding a person as a danger to the public, and all because of the ill-advised agitation by persons who lack knowledge and are frightened at a word!

I think I can show that the law of Massachusetts, as it exists today upon the statute books, has practically declared that the demonstration of the presence of tubercle bacilli in the sputum is a prerequisite to declaring that a person has tuberculosis. In other words, it has given a definition of tuberculosis, although perhaps such definition was not intended.

There is a statute, which is commonly known as the subsidy law, which provides for the payment by the state of a subsidy of five dollars per week for every case of tuberculosis which a city or town cares for in a private hospital.

Officially, this statute is known as Chapter 579 of the Acts of 1911 as amended by Chapter 637 of the Acts of 1912, and further amended by Chapter 57 of the General Acts of 1916, and reads as follows:

Every city or town which places *its patients suffering from tuberculosis* in a municipal or incorporated tuberculosis hospital in this commonwealth, or in a building or ward set apart by a municipal or incorporated hospital in this commonwealth, for patients suffering from tuberculosis, shall be entitled to receive from the commonwealth a subsidy of five dollars a week for each patient who is unable to pay for his support, or whose kindred, bound by law to maintain him, are unable to pay for the same; *but a city or town shall not become entitled to this subsidy unless*, upon an examination authorized or approved by the trustees of hospitals for consumptives, the sputum of such patients is found *to contain bacilli of tuberculosis*, nor unless the hospital building or ward is approved by said trustees, who shall not give such approval unless they have by authority of law, or by permission of the hospital, full authority to inspect the same at all times. Said trustees may at any time withdraw their approval. They shall not approve claims for subsidy hereunder for more than thirty days prior to the date when notice is mailed to them that a subsidy in any given case is claimed.

The conclusion is perfectly obvious that, in order to obtain the subsidy for a case of tuber-

culosis, the local board must show that the patient is actually ill with tuberculosis and under the law, the only evidence of this which the state will accept is the presence of tubercle bacilli in the sputum.

The trustees of hospitals for consumptives admit that the reason for putting that proviso in the law was to save the state from paying the subsidy on a lot of non-tubercular cases. I am not quite sure whether that is an admission on their part of the fallibility of the physical signs or a reflection upon the integrity of local boards of health in general, and care very little which it may be; the main point is that they have, though probably without intending it, put a definition of tuberculosis upon the statute books of the state, and have made the demonstration of the presence of tubercle bacilli in the sputum, *i.e.*, a positive sputum, a necessary prerequisite of calling a case tubercular when the subsidy is claimed.

I believe that I have shown sufficient reasons to justify my contention that from the point of view of the local board of health, no one should be recorded as having tuberculosis, a disease dangerous to the public health, until it has been shown that such person is a potential source of danger to the public.

The same reasons also answer many of the objections which may be urged against such a declaration, and such a declaration would be of distinct advantage to the health officer because it would give him something definite upon which to base any action he might take.

It would also lighten his burdens very materially when it comes to dealing with the amateur societies and volunteer workers already referred to, who give him no peace whenever they hear of a person who is even remotely suspected of having tuberculosis. He could simply point out that a number of careful examinations have failed to demonstrate the presence of bacilli and that, as a consequence, the patient, even though he may be thin and pale, does not come within the law.

It may be pointed out that it is difficult to demonstrate the presence of bacilli in the sputum when they are present in small numbers, and that in this way persons who have bacilli and are, therefore, dangerous to the public health, would be undetected and liable to spread the disease.

My reply to that is that under present conditions many persons whose sputum is known to be loaded with bacilli are going about freely, spreading their bacilli broadcast, and a few undetected cases would make no difference.

If the local boards had the power, or rather were allowed by the courts to exercise the power which I believe they have, to restrain these persons, the objection referred to might carry some weight, but as they have practically no control over so-called incorrigibles, the objection falls to the ground.

There is no reason why either the physician,

the patient, or the local board should be satisfied with a single sputum examination, if it is negative. It is fair to suppose that the physician had some reason for asking for an examination, and if the result is negative he should ask for a second, or even a third, exactly as he would in a case where the clinical symptoms led him to suspect diphtheria or typhoid fever, but the laboratory report was negative.

Of course if the examinations continued to be negative for a period of several years, the fair deduction would be that the patient has not tuberculosis.

Another objection which will surely be raised is that by waiting until the presence of bacilli can be demonstrated, much time may be lost, and many so-called incipient cases, which might be arrested if sent to a sanatorium, will not come under treatment until too late to accomplish anything. I believe that this is more imaginary than real, because at present a patient, even if he has tuberculosis, cannot be sent to a sanatorium unless he is willing to go and, under a recent ruling of the Superior Court, since upheld by the Supreme Court, it isn't necessary for a patient to have tuberculosis at all in order to go to a sanatorium, if he wants to go.

Furthermore, under another ruling, any physician may send a patient to a sanatorium on a most casual physical examination, provided the patient is willing to go.

It appears that there is at present very little difficulty in sending anyone to a sanatorium who wants to go.

Massachusetts has—on paper—one of the best systems for caring for persons ill with tuberculosis that exists today,—but in actual practice it breaks down because it rests entirely upon the consent of the patient to be taken care of. If he is willing to go to a sanatorium, and stay there after he goes, he has the advantage of skilled treatment while he is there, and of supervision and assistance from both the state and the municipality after he is discharged, but if he doesn't want to go or will not stay after he gets there, I know of no power that can make him do either.

It is evident that the proposal to confine the legal definition of tuberculosis to those cases in which a positive sputum has been demonstrated would have little bearing upon the admission to sanatoria of persons whose physical signs are such as to lead to the belief that they are possibly in the incipient stages of the disease, provided such persons are willing to go. If they are not willing to go they wouldn't go, just as they will not now, so it would make no practical difference either way.

It might have a marked effect upon vital statistics by increasing the deaths from tuberculosis and bringing it nearer the truth. Anyone at all familiar with death records knows that while many are filed giving the cause of death as tuberculosis upon very slight evidence,

on the other hand, the deaths of many persons known to be tubercular are recorded as being due to "bronchitis," "heart disease," "anemia," and similar diseases; the reason for this being that many insurance companies refuse to pay on persons dying of "tuberculosis," if the death occurs within a certain period of the writing of the policy. If there was a settled test of what should constitute tuberculosis, all this juggling with death returns would cease and the statistics come nearer the fact.

It would, however, change the responsibility for their care if they did go, because not being persons ill with a disease dangerous to the public health, the overseers of the poor, and not the local board of health, would have to care for them. This is a minor matter, and is merely a return to the method in vogue previous to 1909, when the overseers paid the bills for such persons.

On the whole, I believe that the change might bring about a much-desired reform in procedure and tend to restore power to local boards in caring for persons who have tuberculosis; for if it were once understood that no one should be officially recorded as ill with tuberculosis unless it had been demonstrated that he was potentially capable of transmitting the disease to others, and so a source of danger to the public, the courts and the public generally would be more prone to acquiesce in such measures of restraint as might be imposed upon the patients.

Under present conditions it must be admitted that it is a lamentable fact that there is no real control over persons who have tuberculosis, unless they choose to submit to the requests of the local authorities. This being true, it is equally evident that any change in the methods in vogue must be for the better, and that the criterion of tuberculosis which I have proposed cannot in any way diminish the actual power which boards of health have over tubercular patients, and consequently it will not be a backward step.

For that reason I have no hesitation in saying that if the presence of tubercle bacilli were generally adopted as a necessary prerequisite to recording a person as having tuberculosis, it would not in any way decrease the efficiency of the present working methods of control of the disease and, as I have tried to point out, it might even strengthen them.

The crying need at the present time, in my opinion, is some method of procedure which will put tuberculosis back where it belongs, on a plane with other diseases dangerous to the public health, and permit the health authorities to take such measures as they feel sure are necessary. In addition, unauthorized interference by outsiders should cease. The responsibility for the care of persons ill with tuberculosis and for the protection of the public from possible infection by such persons, has been given by law to the local boards of health, but their efforts are handicapped and often neutralized by

the interference of irresponsible outsiders, who move them from place to place at their own sweet wills and fill them up with misinformation.

If an unauthorized person moves a patient who is ill with diphtheria or scarlet fever from one town to another, or if such a person absconds, he is hunted down and put under restraint, and the person responsible for the act may be punished. Why? Simply because the patient has a disease dangerous to the public health, and may give it to others.

If, however, the patient has tuberculosis, a disease dangerous to the public health, he may go about freely, and the most that happens is that the local board of health of the town from which he went may notify the other board, if it happens to know about it and isn't too busy!

Every one of us in public health work knows that this is true and knows that our methods for the control of tuberculosis are farcical, but we are inclined to shut our eyes and talk of what a splendid system we have—on paper.

What we should do is to face the facts and do our best to limit the use of the term "tuberculosis" to those cases which really are dangerous to the public health. Our position would then be much stronger, and we could probably get some control over persons whom we all know are dangerous.

DEFINITIONS AND DIAGNOSTIC STANDARDS IN THE DIAGNOSIS OF PULMONARY TUBERCULOSIS IN ADULTS.

By JOHN B. HAWES, 2d, M.D., BOSTON.

ONE of the problems that confronted Dr. Armstrong and the committee interested in the experiment now being carried on in Framingham, was to decide upon some definite set of standards on which the diagnosis of tuberculosis should be based. The need of standardizing this subject is, of course, evident. There is a tremendous difference of opinion among physicians and those possessing special knowledge upon the subject, as to what constitutes clinical tuberculous disease. Patients are constantly going from the Massachusetts General Hospital Out-Patient Department, for instance, to the Out-Patient Department of the Boston Consumptives' Hospital, and from there to the Boston Dispensary, and are getting radically different diagnoses and different advice. If this holds true at large clinics in Boston, where men who are to a certain extent specializing in this work are in charge, it will hold true to a far greater extent among general practitioners, whether in Framingham or throughout the country.

I was asked to submit to a committee in charge of this matter a set of diagnostic standards for this purpose. I found this a most difficult task. For instance, among the symptoms which I considered of importance, I immu-

diately put down "loss of weight"—but then I at once asked myself what constitutes loss of weight. How much weight, for instance, must I myself lose and over how long a period of time before I should consider it an important symptom? The same thing applies to the term, "rapid pulse." We are far too apt to say glibly that loss of weight, loss of strength, rapid pulse and fever are important symptoms in the diagnosis of tuberculosis. When one comes to analyze these terms, however, it is evident that unless they are clearly defined they mean little or nothing. This applies particularly to the word "hemorrhage." There is probably no symptom more alarming to patients and yet so hard to define accurately as hemorrhage. Therefore, in conjunction with these diagnostic standards, I prepared certain definitions as suggested above. The committee made various minor changes in the draft which I submitted, which in its final form is nearly as follows:

DEFINITIONS.

1. *Loss of Weight.*—By "loss of weight" should be understood an unexplained loss of at least 5% below normal limits for that particular individual within four months time.

2. *Loss of Strength.*—By "loss of strength" in its pathological sense is meant undue fatigue and lack of staying power which are unusual for that individual patient and which cannot be satisfactorily explained.

3. *Fever.*—An occasional temperature of 99° should not be considered "fever." A temperature which persistently runs over 99° when taken at least four times a day over a period of one week (by mouth five minutes) should be considered of significance and constitutes fever.

4. *Elevation of Pulse.*—Where the average normal pulse of the patient is already known, an elevation of 15 beats per minute, when the pulse is taken quietly at home during various periods of the day, should be considered abnormal. In cases where the average pulse is not known,—and of course this constitutes the majority of cases,—one should consider an average pulse of 85 or over in men, and 90 or over in women, to be abnormal. The combination of a subnormal temperature and an elevated pulse as defined here should be considered of great importance.

5. *Hemorrhage.*—Any amount of blood, with or without sputum, requires medical investigation as to its source. Blood streaks, blood spots, etc., may or may not mean tuberculosis. On the other hand, a hemorrhage amounting to one or two teaspoons is presumptive evidence of the disease.

6. *Family History.*—An occasional case of tuberculosis in the patient's uncles, aunts, cousins, etc., should not be considered of importance. It is an important fact when the patient's immediate relatives, such as father, mother or grandparents have been tuberculous.

7. *Exposure.*—Childhood exposure, no matter how slight, is of the greatest importance. Moderate exposure among normal, healthy adults of cleanly habits is of less importance. Of course, prolonged contact, with unhygienic habits or surroundings, may be a dangerous factor at any age.

8. *Cough.*—No cough is characteristic of tu-

berculosis. A persistent cough for six weeks requires investigation. Tuberculosis can exist without any cough whatsoever.

9. *Sputum.*—The presence of sputum is not necessary for a positive diagnosis. Constant sputum, with or without cough, requires investigation. Absence of bacilli in the sputum after one or several laboratory examinations is not necessarily proof against the presence of tuberculosis.

10. *Hoarseness.*—Any hoarseness or persistent "huskiness" requires investigation.

DIAGNOSTIC STANDARDS.

On a basis of these definitions, the following minimum standards in the diagnosis of pulmonary tuberculosis have been formulated:

11. When constitutional signs and symptoms and definite past history are absent or nearly so, there should be demanded definite signs in the lungs, including persistent râles at one or both apices. By "persistent" it is meant that the râles must be present after cough at two or more examinations, the patient having been under observation at least one month.

12. In the presence of constitutional signs and symptoms, such as loss of weight and strength, etc., as defined above, there should be demanded some abnormality in the lungs, but not necessarily râles.

13. Usually a process at the apices should be considered tuberculous, and a process at the base to be non-tuberculous until the contrary is proved.

14. A hemorrhage as defined above is evidence of active pulmonary tuberculosis until the contrary is proved, except when a clear history of pleurisy is present.

15. One should consider a typical pleurisy with effusion as presumptive evidence of tuberculosis. One should also consider a dry pleurisy as evidence of slight tuberculosis.

16. Pain in chest and shoulders, night sweats, digestive disorders, etc., may be present and should be investigated.

17. In every doubtful case one should demand that the patient be kept under observation for at least one month, with repeated sputum examinations, before making a definite diagnosis.

It will be interesting to see whether or not these definitions and diagnostic standards prove satisfactory for the general practitioner to use. It is perfectly clear that there will be many cases which must be looked upon as exceptions to the rule, and which will not fit into these standards. I do believe, however, that the great majority of diagnoses should be, in a general way, based upon these standards as here given.

DISCUSSION.

DR. ARTHUR N. BRIGHTON, Jamaica Plain: Dr. Lyman has covered very thoroughly the methods to be employed in making a diagnosis of tuberculosis. It seems to me that this method rests upon exactly the same principle as that of making any other diagnosis in those cases which come to the general practitioner. To get a correct diagnosis, whether in a surgical case, as in an appendix, duodenal ulcer, or in any other such problem, the whole picture is essential, rather than any one particular finding.

There is no one symptom that is exclusive evidence of appendicitis or any of the above-mentioned conditions. In the same way, except for the presence of tubercle bacilli in the sputum, there is no conclusive evidence of tuberculosis. To wait until bacilli are found in the sputum is to wait altogether too long to do the patient much good. It is perfectly obvious that one examination of the sputum which is negative, is of no more value than one examination of urine which does not have albumen, or of the blood which does not show a leucocytosis or Widal, or any other single examination. It is the composite picture as a whole that aids us in establishing the diagnosis of tuberculosis.

In approaching a case where tuberculosis is established, I have tried to differentiate in my mind between the needs of the patient and my duty toward reporting the disease to the Board of Health. For the purposes of the Board of Health, it is fair, I think, as Dr. Curtis has pointed out, that only those cases be reported which have tubercle bacilli in the sputum, thereby becoming a direct menace to the community. If repeated examination of the sputum shows no bacilli, even though in my own mind I strongly suspect the existence of tuberculosis, I think it is fair to give the patient the benefit of the doubt. As one of the speakers has pointed out, an extraordinarily large proportion of all children, and we may also include a large proportion of all adults, have had at some time or other a tubercular infection. Change of conditions has helped to arrest the process. I cannot believe that we should be expected to report every case falling under this head.

On the other hand, whether or not there are bacilli in the sputum, if there is reason to expect that the case will get away from careful observation,—as in the case of particularly ignorant or remotely situated families,—then it is the duty of the physician to report the case.

Practically, in those cases coming with a progressive loss of strength, occasional afternoon temperature over a period of a week, with moderate loss of weight, increased pulse, pallor, and the other symptoms to which Dr. Hawes has referred, I assume that the patient has a tuberculous process somewhere. I inquire with the utmost care into the family and previous history.

I cannot believe, as one of the speakers has stated, that there is any large proportion of men doing general work, who would not take the trouble to strip a patient and make a careful examination of the chest. On the contrary, I believe there is a very large proportion of men doing general work who would do just that,—quite as large as the proportion of internists who would make a careful, comprehensive consideration of the whole picture in making a diagnosis. When, in addition to a careful examination and frequent examinations of the sputum, we have an x-ray of the chest, it is usually not very difficult to make an early diagnosis,—long before there are actual physical signs in the chest. In this connection, I may say that I have had no difficulty in getting whatever x-rays were necessary for the patient, regardless of his ability to pay the expense.

Dr. Lyman has pointed out that many cases which were unquestionably tubercular had no persistent symptoms in the chest. Particularly is that true of children having mesenteric glands or generalized tuberculosis, or tubercular adenitis.

A word of caution may be spoken in regard to placing too great reliance upon x-ray findings. The

existence of calcified areas, increased density of the bronchial tree, and even fairly extensive shadow needs much more to go with it to make up a picture of tuberculosis.

One disease, not uncommonly confounded with tuberculosis, which should always be kept in mind in adults or children, is latent hereditary syphilis. It is extraordinary in how many instances cases of unexplained temperature, lowered resistance to infection, long-continued history of illnesses, will be cleared up by a careful family history taken with an x-ray of the long bones. The Wassermann is very rarely present, as one would expect in these cases, which may be really an end-result of a chronic disease.

DR. W. IRVING CLARK, Worcester: After such a very thorough consideration of all sides of tuberculosis in the incipient stage, it seems almost impossible to find anything which has not been touched upon. One thing slurred over is the question of the importance to the patient of the early, correct diagnosis. It is tremendously important to the patient to get this definite diagnosis as early as possible. A patient who is held hanging on a string more or less in a very awkward and unpleasant position. He does not know whether he has to close up his affairs; whether he is possibly exposing his family to the disease; the sooner he can be put out of misery the better.

That brings us down to the question of how we are going to make our diagnosis in the quickest possible way. I think one of the great dangers in this is one which has been pointed out by Dr. Lyman; the fact that so few patients have had a physical examination at an early period. The general practitioner does not like to have the patient strip and make a careful examination of his chest. I do not know why, but my experience has been that that is the case. If we could only get it before the practitioner at large that when a patient comes into his office with a history of cough, even of short duration, he should make an examination of that patient's chest, we should get hold of many cases of tuberculosis much earlier than we do at the present time.

In the second place, I feel that in every community there should be some central station where the diagnosis of possible tuberculosis can be checked up. This is particularly applicable to the smaller country communities where it is very difficult to send a patient into Boston or into the nearest city. I think it would be a step in the right direction if there should be possibly a travelling tuberculosis expert,—a man who would be able to confirm to a degree the diagnosis of a local physician,—to travel as a circuit judge travels and be prepared to make a positive diagnosis and to help the general practitioner in that district.

In regard to symptoms of early diagnosis I have found that listlessness in the afternoon is one of the most valuable symptoms. I do not think this is brought out sufficiently. It is very difficult to be sure about an afternoon temperature in a patient who comes into your office. You are not quite sure that the patient has had that afternoon temperature for a period of a week before. If that patient tells you that he has not been feeling like doing anything much in the afternoon for some time; that he feels tired at four or five o'clock in the afternoon; that he would like to stay at home and lie down—then

you should begin to get suspicious, regardless of the other history he gives you.

Physical signs—I think that sub-crepitant râles at one of the apices, persistent, is a pretty definite sign whether your percussion shows any change there or not. Sub-crepitant râles which persist over three examinations to me are a very suspicious sign and I am almost willing to make a definite diagnosis on them.

Extra-pulmonary râles I think are very difficult to diagnose,—making a patient go through the motions which will produce an extra pulmonary râle; taking hold of the nose and making the motions of an inspiration very often will bring them out. Some patients find this experiment difficult. Those cases I find are more troublesome than any others.

DR. CHARLES H. COOK, Natick: I do not speak as an expert in tuberculosis, but I know, as a matter of memory, most of you as a matter of history, what was taught on this subject more than forty years ago. At a clinic in Bellevue Hospital, I heard Alonzo Clark, then professor of medicine in the College of Physicians and Surgeons, New York City, make this statement: "While I am not prepared to say that the spitting of blood lengthens one's life I am prepared to say that it does not shorten it." (Of course he was not speaking of profuse hemorrhages.) Do you of today endorse that statement? This calls to mind two experiences of my own: In the late 70's a well-nourished lady was brought to my office who had raised blood several times that morning. Physical examination revealed nothing abnormal. I did not have the sputum examined, for the tubercle bacillus had not been born. Nothing further developed in the more than thirty years following, during which I continued as her physician. Within the last five years she died with cancer of the bladder, verified by an autopsy. In March, 1884, a patient had so free bleeding from the lungs that I was obliged to keep her in bed, with positive orders not to speak, even in a whisper, for more than a week before the bleeding ceased. That patient is still living and is at present under my care with arteriosclerosis and high blood pressure.

As regards negative reports in sputum examination, the good Lord has been very kind to me, for I have as yet had no cases develop tuberculosis following such a report.

I want to express my obligation to Dr. Hawes for his sentence in his book, "Early Pulmonary Tuberculosis": "Were the stethoscope used less and the thermometer and common sense used more, there would be fewer mistakes."

DR. FRANCIS P. DENNY, Brookline: I would just like to say a word about Dr. Curtis' proposition to consider only as tuberculosis from a board-of-health point of view, cases with tubercle bacilli. I sympathize in a great many ways with that position. I think it would simplify board-of-health work very much and put it on a rational basis. On the other hand, we are building up a machinery now for fighting tuberculosis, with our dispensaries and tuberculosis nurses, for which we need information of the cases that do not have tubercle bacilli. We should feel that any one with active tuberculosis, without bacilli, is likely to become a source of danger, and for that reason should be under the supervision of the board of health, just as we supervise individuals

who have been exposed to a contagious disease and who are likely to become a danger as a result of it. I think we should lose a great opportunity to do preventive work in tuberculosis if we did not have knowledge of those individuals who have an active tuberculosis without bacilli.

DR. RALPH W. JACKSON, Fall River: A few years since one of the best-known internists in Boston remarked to me that, in any case of doubtful pulmonary trouble, he considered that the discovery of the existence of any peri-anal suppurative process is proof sufficient of the existence of tuberculosis in the lungs. Dr. Lyman is the only man, who has spoken today, who has hinted even at the use of these septic processes as a possible aid in diagnosis.

Two incidents come to my mind which make me question whether our state sanitarium are making sufficient diagnostic use of them or paying sufficient therapeutic attention to them.

Probably four or five years ago, while visiting Lakeville in company with a number of other physicians, who had been invited there as guests to inspect the institution, I asked the superintendent how many of the patients had fistula or other rectal trouble—I was seeking material for a paper which I was preparing on fistula; but he frankly told me that he had no definite knowledge or data and could not help me.

More recently a patient has been under my observation who was in Rutland six or seven months in 1916. His was a perfectly plain case of pulmonary tuberculosis, and he was discharged as an arrested case and greatly improved in general health. But during the last three months of his stay there he had developed a fistula which was making him very uncomfortable, yet its existence was not known to the institutional authorities, either during his stay, or at the time of his leaving. He shortly appeared at my rectal clinic at the Carney Hospital Out-Patient Department with a fistula which had all the earmarks of being tubercular. There was a sinus of some extent around one side of the anus and upward for two or three inches under the anal and ampullar mucosa. After considerable care, surgical and otherwise, we now have him about straightened out and, I think, at work.

In view of the frank statement from Lakeville and this case from Rutland, I asked the question whether enough attention is paid to such conditions at the Massachusetts sanitarium. I think the query is justified.

DR. JOHN F. O'BRIEN, Boston: The law makes it mandatory that we report cases of tuberculosis. If I interpret rightly the meaning of the paper we have just heard, it is a protest against such a law, and in favor of one which would exact notice from the physician only in the event of a positive sputum. We are concerned with this question not only by reason of its bearing on the lives and fortunes of our patients, but because of our vital interest in the results to the community at large of any modification of already existing law.

I submit that there is no antagonism between the public health officer and the physician in private practice, save in very isolated instances. The physician is, as a rule, responsive to the suggestion of the health official, and anxious to do his bit in promoting the general well-being of the public. Is this done by lending enthusiastic support to the law

which comprehends all cases of tuberculosis? Or should we ask that it be modified, fearful that injustice or hardship will come to the unfortunate sufferer who is to be free from the inspection of the public health official, until such time as it becomes evident that he is a veritable menace to the community? Are we to subscribe to the proposition that arrested bone and glandular affections, tuberculosis of the skin, peritoneum and meninges, and all incipient cases, are to have only an academic interest for our public health officials—that their attention is not to be called to them until infection has so far progressed as to permit the classification “a moderately advanced case”?

I fear that much good work would be undone should we allow ourselves to take this view. On the other hand, no man of experience will deny that injustice has been done by reporting tuberculosis where the diagnosis has been based on very slender physical signs. There has arisen a wholly unwarranted fear of the individual who is in the beginning of his tubercular days. His home comforts, employment, and, as a natural sequence, sustenance for his family are frequently jeopardized by hasty judgments, or by ill-adviced follow-up methods on the part of the authorities.

It is difficult to say, of course, just where the line is to be drawn. The financial resources of many of these people are so slender as absolutely to forbid supervision excepting by public health officers. I see no way in which this is to be remedied. I trust I shall not be misunderstood when I say that the physician who can keep watch over his incipient or arrested cases ought to be allowed some latitude. I believe it to be extremely hazardous, however, to advocate anything which would eliminate from occasional supervision the man with fairly definite signs of tuberculosis, and lacking only positive sputum. The conscience of the physician should decide whether or not his patient will fall into the class of those whom he is sure to see at regularly stated intervals. Common sense ought then to govern his action as it does, or should do, in the enforcement of all laws. With this exception I would stand for the law as it is written today.

I can sympathize with the public health official who finds at times that his arduous and most intelligent efforts are nullified by the well-meant but misdirected zeal of those who have but recently begun to manifest any interest whatsoever in public health questions. My opinion is that in all probability such will always be with us, and we must consider them as part of the day's work. Their occasional mistakes should not, however, blind us to the immense amount of good work performed by them. A calm and dispassionate judgment must result in our admitting that much of the progress made in matters of personal hygiene and cleanliness, and a lower death rate, has been coincidental with the formation of volunteer organizations and special commissions.

DR. EDWARD O. OTIS, Boston: The papers presented this afternoon upon this old, but ever new, subject of the early diagnosis of tuberculosis, with their discussion, have been of much interest, and we are greatly indebted to those who have so clearly and fully presented the subject.

Strictly speaking, we cannot make a truly early diagnosis of pulmonary tuberculosis. As the farmer remarked after seeing the hippopotamus at the circus: “There ain't no such animal.” The diagnosis of

active or clinical tuberculosis can only be made when we have definite symptoms of the specific toxic infection, whether or not there are co-existing physical signs, and when such symptoms have developed, the disease has progressed beyond a theoretical early stage, only it is as early as we can make the diagnosis.

As Dr. Lyman has said, one must bear clearly in mind the distinction between pathological or anatomical tuberculosis and clinical tuberculosis. The former has no symptoms, interferes in no way with one's general health and requires no treatment.

In a recent examination of third-year students I asked the question: “What cases of tuberculosis require no treatment?” referring to this pathological tuberculosis which Dr. Lyman mentioned, and I was somewhat surprised to receive several answers to the effect that far-advanced cases required no treatment because they were hopeless anyway.

I have not infrequently seen cases which have been diagnosed as clinical or active tuberculosis, from doubtful or indefinite physical signs, in which there were none of the characteristic symptoms of active disease. When symptoms are lacking, even if certain physical signs are present, such as slight apparent dulness and modified respiration, only “watchful waiting” is necessary. The moment, however, definite active symptoms appear then active treatment should be instituted. And yet, how great the temptation to temporize and defer active treatment until we satisfy ourselves that unmistakable physical signs are present, thus, perhaps, losing the golden opportunity for the most successful treatment.

As to the most important and characteristic symptoms, each one of us may differ somewhat according to our experience. I suppose that all would agree that a rapid pulse, constant afternoon temperature, a continuing cough, and loss of strength and weight are cardinal ones, of the first magnitude. The weight placed upon the many other symptoms will depend, as I have said, upon one's personal experience.

As to physical signs, I have only to say that doubtful deviation from normal resonance and indefinite modification of the respiratory murmur are not sufficient evidence, in my opinion, for making a diagnosis of early pulmonary tuberculosis. Râles, however, are a different proposition. They are wholly adventitious sounds, not modifications of normal ones, and when persistent and localized at one or the other apex, this sign alone goes far towards making a definite diagnosis.

As to hemoptysis, this striking symptom, as has been said, is almost pathognomonic, still occasionally spitting of blood may come from another source than that of a tuberculous lung, and one should be careful to exclude all other possible causes of the hemorrhage, in the upper respiratory tract, from a cardiac lesion or elsewhere. I recall a case that I was called to see as one of hemorrhage of the lungs, but which apparently was consequent upon a cirrhosis of the liver in an alcoholic person.

With regard to the reporting of tuberculosis: shall we report only such cases as have tubercle bacilli or all cases which, in our opinion, are actively tuberculous whether there is a positive sputum or not?

I remember that some years ago I asked the opinion of the chairman of the Boston Board of Health upon this point, and his answer was that whenever I was convinced that I had a case of tuberculosis I

should report it. If one reports only cases that have a positive sputum, then it is obviously not enough to obtain a single negative by the ordinary method of examination. Either such examination should be repeated several times or some of the more delicate tests should be employed, such as the antiformin, the Ellerman and Erlander, and the complement fixation tests. I should like to call the attention of the section to the recently published results obtained by the latter test by two of the members, Dr. Slack, recently bacteriologist of the Boston Board of Health, and Dr. Burns of the Reading sanatorium.

DR. CHARLES E. PRIOR, Malden: When Dr. Hawes asked me to participate in the discussion, my first thought was to get a glimpse of Dr. Curtis' paper. I am glad I did not as I should have missed the tonic effect that paper had on me. There is a good deal to be said on that subject. It seems to me it is more or less a local problem. We do not have any such trouble in Malden as Dr. Curtis speaks of. I wonder if it is not something in the way we have approached the problem. We do not feel that cases of tuberculosis should be reported, however, as scarlet fever and diphtheria are reported, so as to quarantine them, but because the legislature has included tuberculosis among the other diseases dangerous to public health, and in order that we may find these people, and do something for them. It seems to me there are very few cases where tuberculosis will escape the supervision of careful observers if that supervision is properly carried out. I can mention to you quite a number of cases of tuberculosis ill in their homes. I know that they are no menace to the people in their households and there are several small children in the families.

I wish we had some test like what we have for diphtheria by which we could put our finger on the disease and say right off, it is tuberculosis, but, as physicians have shown today, there are a good many cases of tuberculosis we cannot make out that way. Those cases require a good deal of supervision,—require a good many observations. That is where our tuberculosis dispensary comes in. If we approach these people, not with the feeling that they are a menace to the public health, but that they are unfortunate individuals, and our duty is not to isolate them but to help them, we have the best reason for requiring a report of all cases, whether with or without positive sputum.

I can say for the city of Malden that the doctors are helping me in every way. I am finding very little opposition on the part of the physicians in carrying out our tuberculosis program. There is no society in our city which professes to help out the board of health except the Malden Anti-Tuberculosis Society. They made me president of that and chairman of the board of health, so everything works quite peacefully.

I must say once more I am strongly in favor of reporting all cases of tuberculosis. On the other hand, I am not in favor of putting the screws on people, making those people feel as though they are isolated cases and people to be shunned. I think that with this attitude we can carry out the present provisions of the law although I think some time the statutes may be so modified as to make a distinction between tuberculosis, which, under careful management, can be shorn of its danger to the public health, and scarlet fever, for instance, which, with our present knowledge of its means of transmission, cannot be so easily handled.

DR. RALPH E. STONE, Beverly: Dr. Chadwick has presented the subject of "What Justifies a Diagnosis of Tuberculosis in Children" so clearly and interestingly I think there is little left to say upon the subject. I heartily agree with him in laying stress on the matter of contact, especially if intimate or prolonged.

The symptom which has been of utmost importance to me has been the question of being easily fatigued. The child who complains of being tired first thing in the morning, or who has no inclination to play, or becomes tired very easily, makes me suspicious of trouble. While we are on the subject of "Suspects," it seems to me that the tendency is too often to slur over the suspicious cases and not give them due investigation. These cases must be diagnosed by the process of elimination. If we are unable to account for their fatigue, their elevation of temperature, etc., in any other way, after going over them with a fine-tooth comb, as it were, we must finally come to the conclusions of tuberculosis.

I believe that the fact that it is impossible to investigate in general hospitals the many difficult cases of diagnosis is a great detriment to the doctors and to the patients. The recommendation of the National Association a year ago, that wards be established in general hospitals for the study of these difficult border-line cases, ought to be carried out. It is a great pity that a diagnosis so important to everybody concerned as tuberculosis should not have the full benefit of all the aids which a general hospital can give in the way of diagnosis.

In conclusion I would say that with a history of contact and with constitutional symptoms, even in the absence of physical signs, the diagnosis of tuberculosis in children is not only justified but incumbent upon us.

DR. J. HERBERT YOUNG, Newton: You gentlemen will agree with me, I think, that the time has already passed when it is necessary to find dulness, bronchial breathing, rales, and tubercle bacilli in the sputum before it is possible to make a diagnosis of pulmonary tuberculosis in an adult. I hope that the time is now passing when it is necessary to have definite, well-marked physical signs in the lungs before making a diagnosis in a child. If we wait until a child has a tuberculous pneumonia, or a tuberculous meningitis, before we make a diagnosis of tuberculosis, the disease has already progressed beyond our control. If the theory is sound, that a majority of the cases of tuberculosis in adults is a lighting up of an old process acquired in childhood, then it is especially important that we should make the diagnosis in children and make that diagnosis early.

The question of the family history, it seems to me, cannot be over-emphasized. An infant that is exposed to tuberculosis almost always contracts the disease. By family history we mean more than relatives. Family history should include everybody that comes in intimate contact with the child. It is to my mind relatively unimportant if a child has an aunt whom he has never seen, who has tuberculosis or has died of tuberculosis. It is very important to know, for example, if a child has recently had a nurse who has been obliged to give up work because she had "some trouble with her lungs."

In children the von Pirquet reaction is of great diagnostic value, although its limitations should be appreciated. A single negative reaction does not ex-

clude tuberculosis. Several negative reactions give valuable evidence that the child is free from the disease. A positive reaction shows that the child has somewhere in his body a focus of tuberculosis. This focus may be either active or latent. The younger the child the greater the chances that the focus is active. A positive reaction in a case where there are suspicious signs in the chest does not necessarily mean that the signs in the chest are tuberculous; the signs in the chest may be due to influenza—the positive von Pirquet reaction due to a latent glandular tuberculosis.

I have nothing more to add except that I think this is a very important subject, and I am very glad indeed that Dr. Chadwick has brought this to your attention.

CLINICAL DATA OF GALL-BLADDER DISEASE.*

BY RALPH W. FRENCH, M.D., FALL RIVER, MASS.

FROM November, 1905, to August, 1916, there were 300 operations for gall-bladder disease at the Truesdale Hospital. In this number are included 10 that were operated on twice and 3 that required a third operation. A review of the clinical records gives data of considerable interest.

Predisposing Causes. It is impossible to determine at what age biliary calculi are usually formed, because no one knows how long they may remain quiescent. It seems reasonable to suppose, however, that most gallstones are formed between the ages of 20 and 40, when the system is most liable to the other infectious diseases. In this series the average age at the time of operation was 47, the youngest was 19 and the oldest 72.

The ages at the time of operation are grouped as follows:

Between 19 and 20	3
Between 21 and 30	37
Between 31 and 40	48
Between 41 and 50	79
Between 51 and 60	94
Between 61 and 70	34
Between 71 and 72	5

TOTAL

When the histories of these cases were studied they were found to have had symptoms of gall-bladder disease for periods ranging from a few months to 30 years, the average duration being 8 years and 3 months. Frequently it was noted that the first symptoms of gall-bladder disease began 15 years before admission to the hospital. This would indicate that gall-bladder infections occur most often in early adult life.

Sex. Sex has a decided influence on inflammation of the gall-bladder and bile ducts. In

these 300 cases, 52 were males and 248 were females, a proportion of the latter as nearly 5 to 1. The reason for this is probably due to the fact that there are more conditions which favor the stasis of bile in women than in men. Chief among them are pregnancy and any constriction of the waist. 52% of the 248 women had borne children.

Exciting Causes. The exciting cause of cholelithiasis is known to be a bacterial infection of the bile ducts and gall-bladder in the presence of a stasis of bile. Rosenow's work at Rochester indicates that this infection gains entrance to the gall-bladder, not by extension from the duodenum, but through the blood, lodging first in the submucous layer. The action of the bacteria causes an increase in the cholesterolin and the deposition of bile salts, especially calcium. 84, or 28%, gave a history of some previous serious infection.

Condition at Operation. At the time of operation there was acute inflammation in 89, chronic inflammation in 208, and cancer in 3. Stones were present in 72 of the acute cases, 137 of the chronic cases, and all of the 3 cancer cases. In other words, 29 2/3% showed acute cholecystitis, 69 1/3% showed chronic, and 1% cancer. The gall-bladder was drained in 160 and removed in 137 cases. There were operations on the common duct in 15 cases. The gall-bladder had been previously removed in 2 cases and not disturbed in a third, owing to the nature of the case; 12 of the cases had stones in the common duct as well as in the gall-bladder. A history of jaundice was given in 42%.

Previous Operations. Sixteen returned for a second operation for recurrence of symptoms. It is interesting to note that all of these were patients whose gall-bladders had simply been drained at the first operation and not removed. In 8 of the 16, stones were found at the second operation. The time elapsing since the first operation varied from 5 months to 15 years; the average being 5 years and 3 months.

This brings up the question of recurrence of gall-stones after operation, which is believed to be exceedingly rare, although calculi may form about a suture or other foreign matter left in the gall-bladder at operation. Usually, however, recurrence implies not a new formation, but that some stones were overlooked at the first operation. In the cases in this series, as in others that have been reported, it is probable that the stones were present but not found the first time. While freedom from recurrence is the rule, there are undoubted cases of new formation of stones, as in a case reported by Deaver,¹ from which, after he had removed a hundred gall-stones, another surgeon removed over 200 stones from the same gall-bladder only a few months later. Two hundred calculi could hardly have been overlooked at the first operation.

Mortality. As nearly as can be ascertained, the total number of patients who have died

* Read before the Bristol South District Medical Society, May 19, 1917.

since operation is 28. Of this number, 7 died in the hospital, an operative mortality of 2.3%; two of these had carcinoma of the gall-bladder. Two died from general peritonitis and one from each of the following: acute pancreatitis, septic endocarditis, general septicemia, pulmonary embolus and diabetic coma. Four of the 7 had the gall-bladder drained, while the other 3 had cholecystectomies. Of the 21 deaths that occurred after discharge from the hospital, the cause of death, as far as could be ascertained, in 3 cases was due to gall-bladder complications, and in 18 to other causes. In 8 instances the exact cause was not known, but was evidently not of gall-bladder origin. Besides the 7 who died in the hospital, 2 died within 1 year after, 7 from 2 to 3 years after, and 8 more than 3 years after operation. In 5 instances the date of death is not known.

Associated Lesions. In considering other surgical conditions present at the time of operation, it was found that 177 had other pathological lesions within the peritoneal cavity. Chief among these was appendicitis; 6 of which were removed for acute inflammation, and 111 incidentally and for chronic inflammation. There were various pelvic troubles in 33, or 11%; myomata of the uterus were present in 12, or 4%, which is rather lower than some observers have found. The next commonest lesion was umbilical hernia, present in 3%.

Post-operative Results. Of the 16 that had more than one operation for gall-bladder difficulties, the primary operation had been cholecystostomy. Eleven were done at this hospital and five elsewhere. The second operation, performed in 15 cases, was to remove the gall-bladder, and in 4 to drain the common duct. There was no operative mortality in these 15 cases. All are now living except one who died of pneumonia 4 years after operation. The sixteenth case was operated on elsewhere.

Our follow-up system has succeeded in tracing 271, or 90 1/3%. Of the 160 cholecystostomies, 133 were traced, and of these 55% were cured, 32% were improved and 13% were not improved. Sixteen, or 10%, required further operative treatment. Of the 137 cholecystectomies, 125 were traced, and of these 89% were cured, 6% were improved, and the remaining 5% consider themselves unimproved.

The function of the gall-bladder, if it has one, has never been satisfactorily explained, though many theories as to its purpose have been advanced. Physiologists have maintained that the chief function is the storage of bile until needed for digestion²; but this seems improbable when one considers the quantity of bile produced in 24 hours. J. B. Murphy proposed the ingenious theory that the gall-bladder is like the secondary bulb in a bellows, and serves to maintain an even pressure in the ducts, thereby preventing a backing-up of bile in the hepatic duct. Mayo³ has suggested that the gall bladder is an

"obsolescent" stage of human embryology like the appendix.

Certainly, whatever part this organ does play in the body can be readily taken over by the bile ducts. In fact, this has already been done by nature in many cases before the patient is operated upon. These are the cases in which the gall-bladder is found distended with mucopurulent fluid and detritus, in which the cystic duct is obstructed or even obliterated with no evidence of the presence of bile in the gall-bladder for some time previously.

Judd's recent work on "The Effect of Removal of the Gall-Bladder" is, indeed, a most valuable contribution. He shows that after cholecystectomy all of the ducts outside the liver dilate, chiefly due to the sphincter at the entrance of the common duct into the duodenum; and that this sphincter can withstand only a small percentage of the pressure which it normally maintains after the gall-bladder has been removed. Also that when the muscle fibres are dissected free from the intramural position of the duct, the biliary tract does not dilate after cholecystectomy.

The pendulum of opinion has swung far to the side of cholecystectomy in the last few years. Formerly cholecystostomy was the operation of choice, now cholecystectomy is strongly advocated by men who previously advised drainage of the gall-bladder.

Cholecystostomy and removal of stones cures symptoms of mechanical obstruction, but does not cure cholecystitis, nor can it restore the damaged wall of a gall-bladder.⁵ Therefore cholecystectomy would seem to be indicated if the best results are to be obtained; for infection which gives symptoms is almost always present in the wall of the gall-bladder, if not in the bile itself.

While it may be said that there are no well-defined principles which can invariably be followed in the management of gall-bladder operations, yet the operation of cholecystectomy is consistent with the underlying principle of all surgical procedures, which has always been and still is the removal of the offending member.

GENERAL MANAGER OF AMERICAN RED CROSS.
—Harvey D. Gusson, president of the Liberty National Bank of New York, has volunteered to give his entire time for the duration of the war to the Red Cross without compensation. He will act as general manager, and will take over much of the work of consolidation and co-operation hitherto performed by Eliot Wadsworth, whose entire time has now been given to his duties as member of the War Council.

Industrial Hygiene.

OCCUPATIONAL DISEASES IN MASSACHUSETTS.

BY THOMAS F. HARRINGTON, M.D., BOSTON,

Medical Deputy Commissioner of Labor.

THE value of reporting industrial diseases, as required by the State Board of Labor and Industries, increases greatly as occupational life becomes better recognized as a factor in ill health, accidents and deaths among the army of wage-earners in this State.

Massachusetts offers exceptional opportunities for the recognition and study of occupational diseases because of the great diversity and multiplicity of its industries.

The reporting of industrial accidents required by the Compensation Law has centered medical attention upon that aspect of occupational hazard generally. The data show, however, that there is from six to seven times the loss in wages, sickness and ill health annually because of occupational diseases than that rising out of industrial accidents. The startling and tragic nature of the accidents, as well as the fact that their abolition and their "follow up" are a matter of business with insurance companies, have given to this group of hazards a prominence not yet achieved by industrial diseases.

Hospital physicians and surgeons in many centers are giving much time to the consideration of the occupational factor in their diagnoses of patients referred to the hospitals. This emphasis has resulted in many surprising discoveries in etiology, and has excited wide interest in industrial problems. The industrial managers have recognized the economic as well as the efficiency value of preventing occupational hazard to health, limb and life of their employees, and many establishments throughout the State are now under medical supervision and guidance.

The Massachusetts Workmen's Compensation Commission has recognized lead poisoning and other diseases as occupational conditions for which compensation may be obtained. All this interests the general practitioner. The trend of industrial insurance is towards granting to the wage-earner a free choice of an attending physician in industrial accidents. This undoubtedly will be extended to insurance against industrial diseases. The majority of practitioners have had very little opportunity to study industrial processes and their hazards. There is, however, nothing in the field of industrial life that affects the health of the workers that should call for the development of this branch of preventive medicine into a specialty.

It is a difficult matter often to say definitely that any particular affection is due exclusively to some toxic substance used in the process of manufacture. Neither is it always possible to estimate correctly all the phenomena associated

with a severe occupational intoxication. Nevertheless it is possible for every physician so to acquaint himself with occupational hazards that he suspects industrial poisoning when a particular group of symptoms present themselves, and consequently directs his examination of the patient accordingly. Many sicknesses due to industrial poisons simulate, almost identically, illness due to an entirely different cause. As an illustration, it might be cited that there is little to guide the physician, so far as symptoms are concerned, in a case of nephritis or of gastritis, or of nervous affections due to toxic substances, and those due to causes far removed from occupational exposure. The patient's statement is of little value at times as he seldom knows more than the trade name of the toxic substance used. He may, however, furnish information that other workers are affected similarly. Here, however, the physician must be guarded against simulation—not malingering—by the employee, as many of the phenomena of industrial intoxication are subjective. Neither the length of time employed nor freedom from previous attack while at work in the same industry are evidences against a diagnosis of industrial toxemia, as susceptibility and immunity, natural or acquired, are factors of the greatest importance in the whole group of industrial diseases.

The workers and their families, the industrial managers and the insurance companies, all expect the general practitioner to be as familiar with the signs and symptoms of industrial diseases as with those in any other disease. Today the State requires accurate data and information on these questions in its legislative remedies, to distribute the cost and burden of industrial human wastage. It relies upon the medical profession to furnish these factors.

Not infrequently many of the illnesses and diseases met in the consulting room and in the sick-room are the results of occupational conditions, recent or remote. To overlook this cause is to treat symptoms only; to appreciate it is a long step toward accurate diagnosis. Every physician sees patients daily complaining of muscle, nerve and organ irritation due to conditions dependent upon overuse or abuse of the structure concerned in occupational duties. So, too, anemias, fatigue, headaches, eye strain, nose and bronchial irritation, all rising out of or aggravated by overheated workrooms, devitalized dusty atmosphere, lack of toilets and of drinking and washing facilities. When to these conditions are added poisonous dusts, fumes, gases and mineral substances, we have a series of causes that are direct and primary in much of the ill health among industrial workers. The more dramatic causes of this ill health, however, are the ones most generally recognized. This list is growing in Massachusetts.

During the year 1916, there were 182 cases of occupational diseases reported to the State Board of Labor and Industries. Seventeen of these cases proved fatal. This list included:

DISEASES	No. REPORTED	No. DEATHS
Anthrax	27	4
Benzol poisoning	8	5
Brass poisoning	1	
Caisson disease	15	
Fume and gas poisoning:		
Carbon monoxid	7	1
Hydrogen sulphid	1	1
Nitrous acid gas	4	2
Sulphur disulphid	1	1
Tri-nitro-toluene	3	2
Wood alcohol	1	
Lead poisoning	112	
Miscellaneous	2	1
Total	182	17

The following summary shows that the recognition of industrial diseases is receiving the attention of an increasing number of physicians:

CASES REPORTED	OCT. 1916	NOV. 1916	DEC. 1916	JAN. 1917	FEB. 1917	MAR. 1917	TOTAL
Lead poisoning ..	11	17	13	26	25	26	118
Brass poisoning ..		2	16				18
Wood alcohol		1				1	2
Aniline oil			1		1	1	3
Nitrous fumes ..	1	1					2
Phenol poisoning ..					1	1	2
Carbon disulphide ..					1	1	2
Caisson disease ..	1	2		1			4
Anthrax			3	1		2	6
TOTAL	12	22	19	43	27	32	155

Each case of occupational disease reported to the State Board of Labor and Industries is investigated by an Industrial Health Inspector of the Department. This investigation includes a sanitary inspection of the place of employment and a description of the process of manufacture, including a tabulation of each poisonous substance used and the nature of the dust, fumes and gases generated in the process of manufacture. Many fatal cases have been brought to autopsy by the medical examiner of the district. A description of some of the various industrial diseases met in occupational life in Massachusetts will be considered in subsequent papers. The point that should be brought home to every practitioner of medicine in this State is the necessity today of recognizing occupational life as a possible source of many of the conditions of sickness and ill health prevailing among industrial workers, and, secondly, that industrial hygiene offers an exceptional opportunity for applying most effectively the truths of preventive medicine.

The State Board of Labor and Industries is most anxious to cooperate with physicians, employees, and manufacturers in reducing the hazards to health and life in industrial establishments.

The following summary of the work of the Department for the year 1916 shows to what extent this cooperation is possible:

More than 30,000 inspections of industries were made, and over 11,000 reinspections. 12,000 orders were issued to correct conditions existing contrary to law. The inspectors visited

2300 homes of persons who applied for license to do work in the home. More than 3000 complaints against unsanitary and other working conditions were investigated and corrected. It was necessary to resort to prosecution in 360 cases. During the year the Board issued Rules and Regulations governing working conditions in foundries, in compressed air, in establishments where exposure to benzene derivatives is a factor in causing ill health, and rules for the protection against anthrax, as well as rules for safeguarding machinery. Circulars of instruction on the protection of injury to eyesight, and a circular on dangers to dust are being distributed throughout the industries. Rules have been formulated for the protection of workmen engaged in building operations.

In the creation of these various sets of Rules and Regulations for the protection of the employees, the Board had the cooperation of both employers and employees in formulating rules so as to meet best actual working conditions in the various industries affected by the Rules.

Copies of any of these publications will be sent to any physician desiring the same by applying to the Board at its office, 1 Beacon Street, Boston.

Medical Progress.

REPORT ON DERMATOLOGY.

By JOHN T. BOWEN, M.D., BOSTON.

X-RAY IN HYPERTRICHOSIS.¹

FREUND of Vienna, in 1897, was the first to call attention to the removal of superfluous hair by the x-ray, reporting, together with Schiff, some more or less successful results. At first there was, as is usual with new methods, much enthusiasm displayed; later it was found that it was difficult to effect a complete cure, and that atrophy and telangiectases were a not uncommon result. Today there is a difference of opinion, some condemning the process unreservedly, others claiming that it has a place in certain selected cases. Pusey's judgment is concurred in by most dermatologists and roentgenologists, namely, that although practically satisfactory results can be obtained in about one-half of the cases, the results are so uncertain and the possibilities of harm are so great, that the treatment should be undertaken only in extreme cases, or with the understanding that if the exposures are kept within the limits of safety, the outcome is extremely doubtful.

In hypertrichosis of the face, the problem is to remove the hair permanently, without subsequent disfigurement. This is difficult, as the dose necessary for complete depilation is very likely to produce an erythema, which in turn in many cases is followed, perhaps, after a considerable in-

terval, by telangiectases, atrophy and wrinkling. Many roentgenologists, while refusing to use the x-ray in facial hypertrichosis, apply it without hesitation for removing hairs from other parts of the body, such as the arms, legs, axillae, etc., as in these places a little atrophy would not be important. In the case of the leg, however, the extent of surface and its convexity render the method rather impractical. The use of a filter is decidedly desirable, from a cosmetic point of view. Coarse hairs are more readily destroyed than very fine white or lanugo-like hairs.

MacKee states that the medico-legal aspect of the treatment of hypertrichosis, especially of the face, is of very great importance, as malpractice suits have been relatively frequent; the verdicts are most often in favor of the defendant.

The writer's own views on the subject are that, although a perfect result is possible, wrinkling of the skin is very likely to result. It may be slight and of little cosmetic importance as compared with the preceding hypertrichosis, or it may be very disfiguring. Hence he advises against this method except in unusual cases. He warns against the danger from a medico-legal point of view, of yielding to the entreaties of excitable neurotic individuals, who are, perhaps, rendered almost insane from the worry caused by the deformity. It is better to try to dissuade the patient by explaining the tediousness, length of time, uncertainty and danger of the method, and a signed agreement in which the patient agrees to assume all responsibility, although of value, will not prevent the bringing of a suit for malpractice.

Radium has been advocated by Heidingsfeld and others. It will cause depilation the same as the x-ray, but it is suitable only for small areas, and these as a rule may be better treated by means of electrolysis. Although it has been claimed that radium may be used in these cases with perfect safety, the fact remains that a falling of the hair is produced by radium in exactly the same way as by the x-ray, and that the danger of complications and of disfigurement is about equal in degree. In all of these cases the possibility of idiosyncrasy must also be taken into consideration.

MONILETHRIX.

MacKee and Rosen² report six cases of this unusual affection of the hair, together with the results of their studies and investigations. Briefly, monilethrix is, with few exceptions, an affection of the hair either noticed at birth, or developing a few months subsequently. The hair becomes brittle and lustreless, and breaks off before it has attained any considerable length, and is attended with a condition of keratosis pilaris in almost all cases. The affection becomes more noticeable as the children grow older, and may involve the entire scalp, or only portions of it. The essential and notable feature of this disease is the condition of the af-

ected hairs, for not only are they short, brittle and lustreless, but they are seen to be headed at regular intervals, and the nodes are usually of the same size and shape. Contrary to what might be supposed, the thick part of the hair, or node, is the normal part, whereas the constricted part is the atrophic or pathological portion of the hair. Therefore, strictly speaking, it is improper to use the term "node." There may in some cases be more or less scaling of the scalp in addition and, after a time, a general atrophy. The patient's health is usually good, and there are no other congenital anomalies. There was a distinct hereditary influence in one case reported, 17 individuals in 5 generations of the same family being affected. While the causation of the disease is unknown, the tropho-neurotic theory is generally accepted. In certain reported instances, beaded hairs have been found in the eyebrows, eyelashes, bearded face and axillae, as well as in the pubic region. The affection was congenital in all of the author's cases, and in 10 of the complete reports found in the literature.

The histological findings of the various authors are much the same. There is a moderate or slight inflammation of the corium, a marked dilatation of the follicular orifices with a pronounced hyperkeratosis, giving rise to a horny plug. All the histological investigations have revealed nodes and constrictions in the follicular portion of the hair also. The papilla, bulb and matrix of the hair are normal.

Etiologically the microscopic findings do not afford us much light. A parasitic, mechanical and tropho-neurotic theory has, in turn, been advanced. There is nothing in support of the parasitic theory, and little in favor of the mechanical. The tropho-neurotic theory seems most plausible, the alternate thick and thin parts of the hair being explained by assuming an alternate normal and abnormal activity of the cells of the hair bulb, yet why the cells should not proliferate regularly it is difficult to explain. In favor of the view that the intermittent growth is due to some abnormal nerve control of the hair bulb itself is the fact that the monileform condition has occurred after a mental shock, and epileptic seizures. Cases have occurred also after influenza. Behrend suggested that the thick parts of the hair were the growth during the day and the constrictions the growth during the night, and it may be that the loss of nerve control during sleep causes a temporary cessation or diminished activity of growth in the cells of the hair bulb. It has also been suggested that some vasomotor change at regular intervals in the hair papilla might account for the intermittent growth.

With regard to prognosis and treatment, various local stimulating agents have been tried, but without benefit. A temporary depilation by means of the x-ray was thought to have cured one case, but has failed in others. Spontaneous

recovery has never occurred, although several writers have noted improvement as the individual grew older. In a word, at the present time the affection must be regarded as incurable.

PASTES.³

Pastes are mixtures of powders with fats, differing from ointments in the much larger amount of powder that is incorporated in the compound, and its consequently thicker consistency. Montgomery gives a good résumé of the indications for these preparations. The best known of the pastes is Lassar's, composed as follows:

Acid salicyl.	1.00
Amyl. maidis	12.50
Zinc oxid.	12.50
Vaselin.	25.00

This preparation, on account of the large amount of powder it contains, offers the advantage of porosity and absorbability to a greater extent than do ointments, and also adheres firmly to the surface of the skin, and acts as a protective. The salicylic acid is supposed to act as an antiseptic. This paste mass absorbs the discharges from oozing surfaces, and this effect may be increased, when the discharges are copious, by dusting boracic acid or talcum powder over the preparation. The paste must not be removed by force, but by the application of a bland oil, when this is necessary. Besides these oozing ezeemas, the irritable papular forms often do well under pastes, as the latter afford protection and act as a splint. Pastes, unlike salves, do not tend to retain the heat of the skin, and prevent the evaporation of sweat. They are also valuable in the case of people whose skin is rebellious to any fats in the form of ointment.

Oxide of zinc and starch are the powders most frequently used in compounding pastes. Starch has been used to such an extent in Germany that one journal urged that it should not be employed in skin troubles during the present war on account of its value as a food. It has a particularly bland action on the skin, and is less drying than zinc oxide. A softer, smoother paste may be made up as follows:

Amyl. maidis	
Zinc oxid. aa ...	20.00
Vaselin.	60.00

Various medicaments may be added in powder form to these pastes, such as sulphur, naftalan, etc. Naftalan is a Russian coal tar product, a black mass of the consistency of vaseline, which may be made into the following paste:

Naftalan	50.00
Zinc oxid.	
Amyl. maidis aa .	25.00

Now that the war has interfered with the supply of naftalan, tamenol, a mild antipruritic tar preparation, may be substituted in acute ezeema

in the strength of one to three per cent., in subacute ezeema in ten. Montgomery recommends the following modifications of Lassar's paste in superficial inflammations:

Acid salicyl.	1.00
Amyl. maidis	12.50
Zinc oxid.	12.50
Glycerin.	25.00

This preparation is of the consistency and color of thick white paint, which spreads well, remains permanently in place, and does not soil the clothing. The preparations containing glycerine make the skin damp and clammy on account of its hygroscopic character, which is often an advantage in hot weather. Many people, however, have a distinct idiosyncrasy to glycerine, and in these cases it cannot be used. None of the pastes should be used on any of the hairy portions of the body. Montgomery has a good word still for the gelatine pastes, which were quite in vogue at one period. He thinks they are wonderfully effective in certain ezeemas and ulcers of the leg, and in pruriginous affections in other places, where it is necessary to exclude the air and to protect the part from the injurious effects of scratching. He employs the following:

Gelatine	46.00
Zinc oxid.	28.00
Glycerin	12.00
Aqueae	114.00

The water should first be heated and the gelatine dissolved in it, then the glycerine and zinc added, and stirred until cold. Before applying, the jar containing the preparation is placed in hot water to liquefy the contents, which are then spread on the part and covered, before they cool, with shreds of absorbent cotton. Very intensely pruritic eruptions are often controlled in this way.

THE RESULTS OF PERMANENT DÉCOLLETAGE.

Brocq⁴ discusses the cutaneous effects of the fashion that has prevailed among women during the last three years, of exposing a triangular space on the neck and chest, of which the base is formed by the clavicles and edge of the sternum, and the apex is situated between the breasts. This custom has given rise to various alterations of the skin, since this structure is very delicate at the upper part of the presternal region, almost if not quite as much so as that of the face. When this region is exposed, without any protection, to the action of atmospheric agents,—air, wind, dust and sun, the skin may quickly become much altered. In those susceptible to certain dermatoses, this region may become a real *locus minoris resistentiae*, and may be the seat of a simple pruritus, of a circumscribed pruritus with lichenification, of various sensory disturbances, of a true vesicular ezeema, and of seborrhoeic ezeema or psoriasisiform parakeratosis. The most common effects of the ex-

posure of this region are, first, *pigmentary changes*, varying from a *café au lait* color to deep red or brown, sharply outlined, usually most pronounced at the centre or towards the base of the triangle. Sometimes this area is so deeply pigmented that complete décolletage is rendered impossible on account of the disfiguring contrast. *Circulatory disturbances* are next in order, consisting of a simple erythema or of a fine network of telangiectasis, similar to those that sometimes develop on the face. In a like manner, these vascular lesions of the neck and chest are sometimes subject to congestive flare-ups, when the region suddenly becomes excessively reddened, somewhat puffed up, and then gradually becomes more normal. These outbreaks may be due to external causes, or to emotion, digestive disturbances, etc. *Changes in the texture of the skin* are shown by an apparent thickening, dilatation of the pores, and loss of softness and polish. Occasionally it seems atrophied and glistening. A *keratosis* of the mouths of the follicles, a follicular cornification, giving the skin a rough and soiled appearance, sometimes results. *Acniform lesions*, consisting of comedones, or abortive papules and pustules are also common, and lastly *acute artificial eruptions and definite dermatoses* added to the traumatic lesions. The sterno-clavicular triangle is a region in which the normal resistance of the skin is especially weak, and hence an acute erythematous or vesicular dermatitis may be easily produced. Most women are ignorant of the fundamental principle that an inflamed skin should not be bathed with water, and especially not with soap and water, and should not be exposed without protection to the continued action of the air and sun. In this affection individual susceptibility plays an important part, as those exposed are affected in very varying degree. It illustrates the proposition that irritating external agents diminish the power of resistance of the skin in certain cases, so that dermatoses of internal origin may develop at these sites. It is an interesting question why this sterno-clavicular region is more readily irritated than the neck, which is subjected to the same external irritants with impunity. The writer thinks that it may be due to the special structure of the cutaneous tissues in this region. The skin here is extremely fine, quite vascular, stretched over the underlying bony structures, and rich in sebaceous glands; it is a favorite seat of seborrhea. It is much more like the skin of the face than that of the neck.

As to the therapeutic measures, protection of this region from all external contact is, of course, essential. Thin gauze or muslin coverings are not sufficient, a thicker, more compact dressing is required, and a thick paste, after the manner of Lassar's zinc oxide paste, should be spread on the skin, over which talcum powder is liberally sprinkled.

DIAGNOSIS AND GENERAL TREATMENT OF SYPHILIS.

Fordyce⁵ read a paper with the above title at the Congress of American Physicians and Surgeons in Washington May 9 and 10, 1916. Fordyce's authority on the question of syphilis in this country is so great that his conclusions must be looked upon as of the utmost importance. He emphasized the importance of an early diagnosis of infection, and states that, unfortunately, clinicians are still met with who decry the modern methods of precision, and claim that the trained observer can determine by his eye and sense of touch all that can be revealed by laboratory procedures. That this position is a false one is shown by the fact that patients present themselves for syphilitic involvement of the central nervous system, an interstitial glossitis, or an aortitis, who had been told years before by the best known syphilographers that their lesion was only a chancre, and that they had nothing to fear as to future results so far as this manifestation was concerned. It is well known now that the soft sore often contains the syphilis parasite, and that syphilitic manifestations from it often do not develop for two or three weeks, or are often entirely absent. Hence an examination for the spirochete should be made in every doubtful lesion, and if it is not found at first, repeated examinations should be resorted to, including the Wassermann reaction. It is often possible and of great importance to discover the parasite in initial lesions before the clinical characteristics appear, as early treatment and thereby a better prognosis may be rendered possible. The dark-field illumination is not difficult with a little training, and the syphilis parasite is easily distinguished from other organisms. Success in finding this is in great measure dependent on the care with which the serum is taken for examination—it should be from the depths of the lesion. In cases of doubt the examination should be repeated on successive days, avoiding the use of antiseptic washes, ointments, etc.

The time of appearance of the Wassermann reaction varies, in different individuals, from the fourth to the seventh or eighth week after exposure. It is usually definitely established with the appearance of the rash. It is emphasized that the treatment must be individual, as some patients treated under the older methods have a negative blood reaction, while others who have had numerous courses of salvarsan and mercury obstinately retain their positive reaction. In some cases it is impossible to convert a positive into a negative reaction, without endangering the patient's health. Fordyce insists that, although the interpretation of the Wassermann reaction is as important as that of the clinical phenomena, reliance must not be placed on its presence or absence alone. In cases of ocular, vascular, visceral or nerve syp-

ilis, positive clinical signs may be present, while the Wassermann reaction is negative.

With regard to treatment, the object is the destruction of the greatest number of spirochetes in the shortest possible time. Experience has shown that this is best accomplished in the early stage, and by means of the combination of salvarsan and mercury. Salvarsan has little influence on the organisms in the test-tube, but is actively germicidal in the human body. It has been demonstrated empirically for many years that mercury has a curative effect in syphilis, and presumably this effect is a direct one. Potassium iodide has no effect on the early lesions of syphilis, and a very slight effect in rendering the Wassermann reaction negative. Yet it has a marked local therapeutic value, as in "gummata" and in periosteal lesions. Salvarsan is most useful in primary and secondary syphilis when the organisms are abundant, yet in gummatous and periosteal lesions and all the active manifestations of late syphilis, the drug is almost as effective therapeutically as in the early contagious period, especially in the case of persons who have been treated for years with mercury and potassium iodide, and have become more or less immune to the action of these drugs. Fordyce's method of treatment is to give a course of mercury with the salvarsan, the amount of each agent depending upon sex, weight, and general condition. The salvarsan is given in courses of 5 or 6 injections in doses of 0.3 gm. to 0.5 gm. for men, and 0.25 gm. to 0.4 gm. for women at intervals of one week to ten days. The mercury is given in the form of injections, in courses of 20-30 injections daily or every other day when the bichloride is used; once a week in a series of ten or twelve injections when an insoluble preparation is employed. Both salvarsan and mercurial courses are followed by a rest period of six weeks, and then the procedure is repeated. While frequent Wassermann tests are made, the treatment is not interrupted on account of a negative reaction, until the full amount has been given. When there are visceral lesions the salvarsan should be used in small doses, repeated at intervals regulated according to the individual case. When there are cardiac complications, mercury or mercuric and potassium iodide should precede the injections.

With regard to the reactions following the use of salvarsan, Fordyce divides them into two categories,—the immediate and delayed. In the immediate reactions, the symptoms usually come on during the injections, and are anaphylactoid in character probably. They are cyanosis, flushing, fullness in the head and slight dyspnea, with occasionally vomiting, or attacks of severe pain in the lumbar region. The delayed reactions appear after twenty-four hours, three days, or even longer, and are usually expressed by gastro-intestinal symptoms, preceded by a chill, and characterized by vomiting and diarrhea with increased temperature, or there

may be simply malaise for a few days, and then active vomiting, fever, and a rash or jaundice, with, rarely, suppression of the urine. Fordyce warns against repeating the drug in cases where a dermatitis has been present, as he has seen in these circumstances an extensive exfoliative dermatitis develop, which ended in death. In his own experience there have been two deaths that could be directly attributed to salvarsan. Fordyce considers that it is important to examine the urine from time to time during the administration of mercury, inasmuch as this drug has a great affinity for the renal cells. It has been estimated that the toxicity of the different salts is proportional to the amount of pure mercury contained. Inunctions are very efficacious and safe, but unless in the hands of a professional rubber, uncertain. The results of treatment by intramuscular injections of mercurial salts are more rapid after the use of a soluble than an insoluble preparation, as the former is more quickly absorbed and exhibits less local reaction. The disadvantages of the injection of the soluble salts are that they have to be given daily, whereas the insoluble preparations form a *dépôt* of absorption and require to be administered at weekly intervals only. On the other hand, the insoluble salts have the disadvantage of exposing the patient to sudden absorption and mercurial poisoning.

Fordyce's conclusions are that the fate of the syphilitic individual depends upon the early diagnosis of his infection and the intensity with which treatment is carried out in the first six months, and that modern aids to diagnosis, such as the dark-field illumination and the Wassermann test, have proved of great service in the accomplishment of this purpose. The Wassermann test is of especial value in all conditions of obscure etiology, referable to the cardiovascular system, cerebrospinal system, or viscera, in which syphilis might be a factor, and in cases with obscure clinical symptoms, such as neurasthenia, febrile attacks, rheumatic pains, etc. But its interpretation requires as much training and experience as does the interpretation of the physical signs. In examination of the spinal fluid, the Lauge or colloidal gold test should be performed in addition to the Wassermann reaction and a cytological and chemical examination. In secondary syphilis when the early rash is present and the Wassermann positive, it is best to employ first several injections of a soluble mercurial salt, followed by salvarsan. The possibility of an involvement of the nervous system should always be kept in mind in secondary syphilis. The most frequent symptoms are irregularity of the pupils, persistent headache, and optic neuritis or auditory disturbance. The iodide of potassium has still a very important place. In tertiary syphilis with a persistent positive Wassermann reaction without involvement of the central nervous system, the iodide is very valuable, and its

action on bone and periosteal lesions, accompanied by severe pain, is more rapid, both in relieving pain, and in reducing the neoplasm, than that of any drug in the pharmacopeia.

Book Reviews.

The Surgical Clinics of Chicago, February, 1917. Vol. I, No. 1; with 83 illustrations. Published bi-monthly. Philadelphia and London: W. B. Saunders Company.

The first volume of *The Surgical Clinics of Chicago* made its appearance in February, 1917, in the same general size, shape, printing and paper as the *Murphy Clinics*, which preceded it. The color of the binding is changed, but a much more important change is that it seems henceforth to be a publication of the combined Chicago hospitals, although a statement of this fact is lacking.

The contents of the February number consists of 12 chapters, by as many different surgeons. Many of the chapters consider more than one subject; all are admirably illustrated. The hospitals represented are: the Presbyterian, the Meres, the Augustana, the Chicago Polyclinic, the Cook County, the Wesley and the North Chicago; and the surgeons are Drs. Arthur Dean Bevan, Albert J. Ochsner, E. Wyllys Andrews, Lewis L. McArthur, Dean Lewis, Carl Beck, D. B. Phemister, D. N. Eisendrath, Kellogg Speed, Edwin Warner Ryerson and Allen B. Kanavel.

The subjects vary widely; they include hernia, gall-stone disease, goiter, plastic surgery, nerve suture, gastric surgery, joint infections, transplantation of fascia lata in extrophy of the bladder, intracranial surgery, tendoplasty for wrist-drop, echinococcus cyst of the liver, and bone lesions.

It is obvious that the experiences of a dozen surgeons must, in the nature of things, be wider and more varied than that of any single surgeon, no matter how active the individual may be. In this way, the *Chicago Surgical Clinics* gives a wider field than its predecessor, and the same thing is true, to perhaps a greater degree, of the varying individuality of the men. A bi-monthly publication representing the best surgery of Chicago should certainly be extremely interesting and a valuable addition to our surgical libraries. It should become familiar to all active surgical practitioners and teachers.

The Surgical Clinics of Chicago. April, 1917. Vol. I, No. 2; with 99 illustrations. Published bi-monthly. Philadelphia and London: W. B. Saunders Company. 1917.

The April number, of somewhat more than two hundred pages, contains fifteen chapters, written by as many surgeons, some chapters including several sub-headings. The contributors are Drs. E. Wyllys Andrews, Carl Beck, Arthur Dean Bevan, Carl Braden Davis, Frederick G. Dyas, Daniel N. Eisendrath, Louis A. Greensfelder, Albert Edward Halstead, Malcolm L. Harris, Allen B. Kanavel, Hugh McKenna, Arthur J. Ochsner, Nelson Mortimer Percy, D. B. Phemister, John Ridlon and David C. Straus.

As usual, the monographs cover a wide variety of subjects; they are well illustrated, and in most instances well written. They are always stimulating and offer many practical suggestions as to technic and surgical procedure. The publication is interesting and well worth reading.

Traumatic Surgery. By JOHN J. MOORHEAD, B.S., M.D., F.A.C.S., Adjunct Professor of Surgery, New York Post-Graduate Medical School and Hospital; Visiting Surgeon, Harlem Hospital; Attending Surgeon, Park Hospital; Adjunct Attending Surgeon, Post-Graduate Hospital; Chief Surgeon, Interborough Rapid Transit and New York Railways; Fellow, Academy of Medicine; Lieutenant, Medical Reserve Army Corps. With 522 original illustrations. Philadelphia and London: W. B. Saunders Company. 1917.

Moorhead's book is an extended, enlarged, well illustrated and comprehensive accident and injury manual. It has seven hundred and more pages; two hundred and fifty are devoted to fractures and dislocations—a proper and adequate proportion; on the whole, the treatment advised throughout the book is excellent. The chapter on Infections of the Hand is based upon the work of Kanavel; shock is viewed from the standpoint of Crile, not from the more recent work of W. T. Porter. This is unfortunate, since the latter has simplified both the conception of shock and its treatment. The book contains interesting chapters on the Traumatic Neuroses and Medico-Legal Phases, and X-Ray Burns.

The author has covered thoroughly the field which he has laid out for himself, and he has wisely restricted himself to this field. He has written a good book, which should become a favorite volume.

THE BOSTON Medical and Surgical Journal

Established in 1812

An independently owned Journal of Medicine and Surgery published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, AUGUST 2, 1917

EDITORS.

ROBERT M. GREEN, M.D., *Editor-in-Chief.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager.*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

THE DIAGNOSIS OF TUBERCULOSIS IN RECRUITS.

In view of the approaching assembling of the new armies under the draft, it becomes urgently necessary to consider the irreparable loss to the nation brought about by the undue proportion of tuberculosis in the classes which will come up for national service; and we have already commented editorially upon this subject in the issue of the JOURNAL for July 12 (Vol. clxxvii, No. 2, p. 56). Among the masses of humanity from which selection will be made, there is a fixed number who have, or have had, pulmonary tuberculosis, and the problem for the examining surgeon is how to judge wisely and not include in the draft any individuals who could possibly be the subjects of latent infection. Diagnosis, often a most difficult matter in civil life, has evi-

dently gathered new difficulties in the case of soldiers. For example, the known facts of tuberculosis—that infection, latent or acute, exists in most adults, that immunity is acquired, and that the number of non-fatal lesions increases with age—are somewhat difficult to reconcile with the rule of the army medical examination. Thus in England, stirred by the experience of France, the Recruiting Boards are forbidden to take into the army men "who have been under treatment in a sanatorium, and men who have been notified as suffering from tuberculosis." That the first should be rejected is clearly right, although ex-sanatorium patients have found their way into the army and have done good work; but it is asked, especially by French physicians, whether the rejection of all the notified men is quite consistent with the idea that tuberculosis is so universal as alleged, and that it is often healed or cured? It seems evident that, if physicians are prepared to accept the doctrine that 95% of adults have been infected, army examiners ought, in consistency, to accept the "healed" and even the "arrested" cases. Nevertheless, in England the rule rejecting them is rigid, but French opinion appears to justify the acceptance of the "healed" cases, if by "healed" be meant a cicatrized lesion, and not one that is continually passing into active tuberculosis.

There is another form of rejection which, in France, is regarded as seriously faulty in respect to diagnosis. We mean those cases classified as "suspicious," or rather, as tuberculous "suspects." According to Sergent, the diagnosis "suspected" tuberculosis indicates a small amount of concrete knowledge. Upon examination, most of these men turn out to be healthy, or instances of pleurisy, bronchitis, trench eoryza, dyspepsia, mitral stenosis, simple fatigue of body and mind, with a few that are simply shamming. Examples of such diagnostic errors, resulting from a wrong interpretation of x-ray plates and physical signs, are so common in the records of the army clearing stations, or *centres de triage*, that some examiners, like Rist, propose a sole criterion of tuberculosis and, therefore, a sole cause of rejection, and that is the tubercle bacillus in the sputum. This is too rigorous, and also throws open the door too wide; for the bacillus may not be found, and, on the other hand, there are physical signs which are sufficient. The most trustworthy, Sergent believes, are the following: dulness,

hemoptysis, increased fremitus, "clicks," and a veil or shadow at the apices, fixed, not modified by cough, with striae and fly spots on the plate. These are evidences of a lesion of the parenchyma of the lungs. A pleural lesion shows the same veil or shadow, but it is movable; there is inequality of the pupil on the affected side, with friction sounds, and increased vocal fremitus, tracheobronchial adenopathy, and, curiously enough, tubular breathing, which in these cases is not a sign of pulmonary cavity, but of nasal obstruction. The x-ray pictures are telescopic; they show cavities not discovered by the most careful auscultation, but they do not enable us to ascertain whether a lesion is active or latent, whether it is pleural or parenchymatous, whether the disease is in a stage of evolution or of decline. Unfortunately this is a question of primary importance to the army surgeon.

The proportion of veils or apical shadows on radiosecopy and on the x-ray plates was 63%. Apparently they are signs of healed lesions or of pleurisy of the apex. It is a significant fact that most of the recruits were rejected on this evidence; when reexamined by experts at the *centres de triage* they were sent to the colors. This particular error is chiefly the work of examiners, who look at the men through the spectacles of the tuberculophobe. His tendency to see tuberculosis in every abnormal respiratory sign is a fallacy which may take root here. Many of the classical signs—harsh and rough breathing, weak breathing, and bronchophony,—have the misfortune, shared by most constitutional signs,—anemia, cough, fever and weakness,—of being somewhat equivocal. The evil may be overcome by careful preliminary definition and history-taking, but the man of routine, without time for individual selection, does not supply these things, and the original application of the words to a particular phase of bronchial disorder seems to have elung about them with a misleading effect. The result is that great numbers of sound men are rejected, and two classes of bugbears have arisen,—the true and the false tuberculous. As is usual with definitions and classifications, however, this distinction between true and false cases does not exactly represent the actual fact. True and false tuberculosis overlap and blend into each other. The diagnosis in all these cases is very difficult. It is a question how it is to be done without national loss through mistakes.

REPORT OF COMMITTEE ON SOCIAL INSURANCE.

IN another column of this week's issue of the JOURNAL is published in full the text of the recently issued Constitutional Convention Report (No. 327) on Social Insurance. To this majority report of the committee is appended also the minority report of one of its members. Both these documents should be of distinct interest to members of the Massachusetts Medical Society, many of whom have appeared at various hearings before the convention at the State House. The importance of this report is obvious in view of the bearing which it has on industrial health insurance in relation to the medical profession.

MEDICAL NOTES.

SWEDISH HEALTH RATES.—Statistics of the population of Sweden for the year 1916 have been published, and the birth and death rates are the lowest ever recorded in that country. The birth rate per thousand was 21.14 and the death rate was 13.55.

INFANTILE PARALYSIS IN VERMONT.—There have been about eighty cases of poliomyelitis in Vermont this year. Because of the prevalence of the disease, Lieut. Col. Wolf, commander of the camp at Plattsburg, N. Y., has forbidden members of the garrison or training camp to visit Vermont without permission.

WAR NOTES.

RED CROSS UNIT FOR ROUMANIA.—The sailing of a Red Cross unit to Roumania is announced. It is headed by Henry Watkins Anderson of Richmond, Va., who will make an investigation of the sanitary and health conditions of the country and institute relief work among refugees. A special appropriation of \$200,000 has been voted to provide supplies of all kinds. The unit consists of twelve doctors and twelve nurses. One of the number is Dr. Francis W. Peabody of Boston.

APPOINTMENT OF BOSTON HEALTH OFFICER TO SANITATION CAMP.—Dr. M. Victor Safford, United States Health Service, who has served at the Boston immigration station for about fifteen years, has been ordered to Columbia, S. C., to serve in the sanitary department of the military camp at that location.

BOSTON LINER TO BECOME HOSPITAL SHIP.—The *Prince Arthur*, for the last seventeen years

running between Yarmouth, N.S., and the Port of Boston, has been commandeered by the British government to be used as a hospital ship. The *Prince George*, a sister ship, is already in English waters, having been taken over by the government for the same purpose a short time ago.

GIFT TO RED CROSS BY ELKS.—The Benevolent and Protective Order of Elks has voted to appropriate \$1,000,000 to the Red Cross to be used in establishing base hospitals behind the firing lines, in taking care of the families of soldiers, and in aiding disabled men to learn a new trade or profession. The hospital units to be established by the Elks are to be marked with the name of the order and will be maintained by the Government and the American Red Cross. Each hospital staff will be made up of twenty-six surgeons, sixty-eight nurses and one hundred and fifty orderlies, and will cost about \$60,000 to equip.

APPOINTMENT OF MASSACHUSETTS MEN AS NAVAL SURGEONS.—The following Massachusetts doctors have been recommended by Secretary Daniels to receive appointments as assistant surgeons of the navy: Thomas J. Kennedy, John W. S. Brady, Lewis W. Johnson, Roy J. Heffernan, Edward P. Bugbee, Joseph W. White, Francis E. O'Brien, Samuel Segal, Jr., Robert E. S. Kelley and Max H. Braff.

TRACHOMA IN THE ARMY.—The Public Health Service has issued a warning to recruiting officers to guard against accepting applicants who may be suffering from trachoma. Its contagious character and its capacity to blind invalid men are urged as reasons for refusing to accept men who have contracted it.

WAR RELIEF FUNDS.—On July 28 the totals of the principal New England war relief funds reached the following amounts:

French Wounded Fund	\$243,351.20
Armenian Fund	207,304.42
French Orphanage Fund	116,817.64
Surgical Dressings Fund	112,046.01
Serbian Hospitals Fund	99,591.82
War Dogs' Fund	861.25

BOSTON AND MASSACHUSETTS.

WEEK'S DEATH RATE IN BOSTON.—During the week ending July 21, 1917, the number of deaths reported was 181, against 189 for the same period last year, with a rate of 12.42, against 12.96 last year. There were 23 deaths under one year of age, against 37 last year.

The number of cases of principal reportable diseases were: diphtheria, 59; scarlet fever, 16; measles, 74; whooping cough, 18; typhoid fever, 3; tuberculosis, 59.

Included in the above were the following

cases of non-residents: diphtheria, 5; scarlet fever, 4; tuberculosis, 6.

Total deaths from these diseases were: diphtheria, 4; measles, 5; typhoid fever, 1; tuberculosis, 21.

Included in the above were the following deaths of non-residents: diphtheria, 2; measles, 2; typhoid fever, 1; tuberculosis, 2.

ADAMS NERVINE ASYLUM.—The fortieth annual report of the Adams Nervine Asylum, Jamaica Plain, states that the total number of patients under treatment during the year was 217, of which 47 were men and 170 women. There were discharged during this period seven as recovered, 107 as relieved, and 50 as not relieved. The training school has 16 pupil nurses.

BOARD OF HEALTH, Chelsea, Mass.—According to the recently published annual report of the Board of Health of Chelsea, Mass., the mortality rate for that city for the year 1916, was 14.40; excluding non-residents it was 10.02. The number of deaths under one year was 111, which is 16 more than last year.

The Massachusetts Medical Society.

WORKMEN'S COMPENSATION.

In accordance with the vote of the Council, June 12, 1917, namely: *Voted*. That a committee on Workmen's Compensation be appointed by the Chair, to consist of five members of the Council and one member from each District Society. The President has appointed the following committee:

- A. N. Broughton, Jamaica Plain, *Chairman*.
- M. A. Tighe, Lowell.
- W. A. Dolan, Fall River.
- John Warren, Boston.
- F. W. Snow, Newburyport.
- E. S. Osborne, West Dennis.
- C. S. Chapin, Great Barrington.
- W. Y. Fox, Taunton.
- E. F. Cody, New Bedford.
- W. H. Merrill, Lawrence.
- W. T. Hopkins, Lynn.
- F. A. Millett, Greenfield.
- G. A. Moore, Palmer.
- C. T. Cobb, Northampton.
- D. C. Dennett, Winchester.
- J. A. Mohan, Lowell.
- G. W. W. Whiting, Somerville.
- B. E. Hamilton, West Roxbury.
- N. S. Hunting, Quincy.
- F. E. Wheatley, North Abington.
- E. L. Young, Jr., Boston.
- E. L. Hunt, Worcester.
- F. H. Thompson, Fitchburg.

WALTER L. BURRAGE,

July 26, 1917

Secretary.

Miscellany.

THE COMMONWEALTH OF MASSACHUSETTS.

REPORT OF THE COMMITTEE ON SOCIAL INSURANCE.

The Committee on Social Insurance has had referred to it twenty-five resolutions and petitions, as follows:

Doc. No.

12. Resolution relative to the providing of non-contributory health insurance.
13. Resolution relative to the providing of non-contributory old-age pensions.
35. Resolution relative to providing for contributory old-age insurance.
36. Resolution relative to providing for contributory unemployment insurance.
37. Resolution relative to providing for non-contributory accident, sickness and invalid insurance.
38. Resolution relative to state pensions.
39. Resolution authorizing the Commonwealth to insure persons or property.
52. Resolution for a special tax to provide pensions for the aged and needy.
54. Resolution providing for a state fund for workmen's compensation.
107. Resolution to provide for social insurance by the Commonwealth.
108. Resolution relative to creating a state fire insurance fund.
109. Resolution authorizing compulsory insurance of employees.
110. Resolution authorizing state insurance of workers against accidents, sickness, invalidity, old age and unemployment.
111. Resolution providing for compulsory death benefits for dependents of persons engaged in the public service in times of war and national or state emergency and of persons engaged in hazardous employments at all times.
112. Resolution giving the General Court power to enact laws for the protection of the lives, health or safety of workers.
113. Resolution relative to creating a state fund for workmen's compensation insurance.
251. Resolution relative to the establishment of a system of non-contributory health insurance.
252. Resolution relative to the establishment of health insurance for workmen.
253. Resolution relative to establishing a system of non-contributory old-age pensions.
254. Resolution relative to the establishment of a system of old-age pensions.
255. Petition of the Massachusetts State Branch of the American Federation of Labor, accompanied by resolution providing for the establishment and maintenance of a system of old-age pensions.
256. Resolution to empower the General Court to make absolute the liabilities of casualty insurance companies to persons injured by accident.
257. Resolution relative to pensions to dependents of those suffering from cancer or tuberculosis.
258. Petition of the Massachusetts State Branch of the American Federation of Labor, accompanied by resolution providing that employers shall insure in a public fund for the benefit of injured employees.
259. Resolution relative to the establishment of a state fund for workmen's compensation.

Of these, twenty-two may be described generally as dealing with some kind of social insurance or the machinery incident to its administration. One Resolution, No. 52, providing for a system of taxation to provide pensions for the aged and needy, would more appropriately be referred to the Committee on Taxation, and this Committee has been discharged from its further consideration. Another Resolution, No. 108, relative to creating a State Fire Insurance Fund, would more appropriately be referred to the Committee on Public Affairs, and this committee has been discharged from its further consideration. Another Resolution, No. 256, will be the subject of a separate report. This report deals with the twenty-two remaining resolutions upon the general subject of Social Insurance. The Committee does not consider that it is in any way charged with the duty of considering these propositions upon their merits but rather to determine if there is any doubt as to the constitutional power of the General Court to legislate upon all or any of them, and, if so, to consider the expediency of conferring such power upon the General Court, and if that question be decided in the affirmative, then to suggest such amendment or amendments to the Constitution as may be necessary to effect the purpose.

First.—As to the power of the General Court under the Constitution to legislate upon any of these propositions.

The Committee is not disposed to argue this question; indeed, any conclusion it might reach would, of necessity, be inconclusive. The Committee, however, is unanimous in believing that doubt does exist and contents itself, upon this point, with quoting from Bulletin No. 18, pp. 22, 23, prepared by the Commission of the Convention, as follows:

Without inquiring too curiously whether the Massachusetts Supreme Court would uphold the constitutionality of a compulsory workmen's compensation act in the absence of a constitutional amendment, it seems proper to state that social insurance legislation, if compulsory, would be best safeguarded by an express constitutional amendment.

In view of the recent Federal decisions referred to in this Bulletin it is obvious that "constitutional rigorism" is at an end and that the Fourteenth Amendment to the Constitution of the United States does not stand in the way of State legislation respecting health, unemployment and old-age insurance. Of course the question still remains as to whether such measures are in violation of the provisions of the Constitution of Massachusetts.

That doubt could be removed by the adoption of an amendment expressly conferring upon the Legislature authority to provide for the several forms of social insurance herein considered.

Second.—The Committee is unanimously of the opinion that the Legislature should have the power to deal with these subjects in such manner as, in its wisdom, it may see fit.

The "police power" has, in recent years, been greatly enlarged to meet changing conditions. As the Supreme Court has said:

"Of course, it is impossible to forecast the character and extent of these changes, but in view of the fact that, from the day Magna Charta was signed to the present moment, amendments to the structure of the law have been made with increasing frequency, it is impossible to suppose that they will not continue, and the law be forced to adapt itself to the new condition of society, and, particularly to new relations between employers and employees, as they arise."

The Legislature has for many years shown a disposition to deal with the questions involved in the Resolutions that are before us. In 1887 it passed the Employers' Liability Law, the first to be enacted in the United States. In 1903 a commission was appointed to investigate the relations between employer and employee. The commission reported in 1904 with a draft of a compensation act which was not enacted into law. In 1907 a joint special committee was appointed to sit during the recess of the General Court to consider Workmen's Compensation among other questions. As a consequence, a voluntary law was enacted in 1908 and amended in 1909. In 1910, a commission was created "to determine upon a plan of compensating employees for injuries received in the course of their employment." This resulted in further legislation.

Chapter 127 of the Resolves of 1907 provided for a commission to investigate and consider the various systems of old-age insurance or old-age pensions or annuities proposed or in operation in this Commonwealth, or elsewhere, and to report upon the advisability of establishing an old-age insurance or pension system in the Commonwealth. This commission made its final report on January 15, 1910. It is very voluminous and is House Document No. 1400.

Chapter 106 of the Resolves of 1913 provided for the appointment of a committee to investigate the subject of pensions. The commission was known as the Commission on Pensions, and was to report in detail on the various systems under which pensions were then paid by the Commonwealth and by the counties, cities and towns therein, and to what persons and the amounts thereof. The Commission recommended, among other things, the advisability of a service pension plan under which the persons to whom pensions should be granted should make payments from their salaries or wages, and should consent to deductions therefrom as contributions to the fund from which pensions should be paid, and made a very voluminous report under date of March 16, 1914, House Document No. 2450.

Chapter 120 of the Resolves of 1914 provided that, for the purpose of securing information for the General Court for a proper consideration of the subject of old-age pensions, the Director of the Bureau of Statistics be required in connection with the taking of the decennial census in the year 1915 to transmit certain statistical information to the General Court, including the number of persons 65 years of age and over within the Commonwealth, and their length of residence, the number of dependent persons of all ages being supported in the various public and private institutions throughout the Commonwealth, the number of persons of all ages in the various cities and towns of the Commonwealth who are receiving aid from any public source; also the number of persons aided from private sources, and any other information which, in his opinion, might promote the purpose of the inquiry. This report was made December 15, 1916, and is full of detailed information on this subject.

Chapter 157 of the Resolves of 1916 provided for the appointment of Special Recess Commission on Social Insurance, to study the effects of sickness, unemployment and old age in Massachusetts, to collect facts as to actual experience with the several forms of insurance thereof, and to recommend to the General Court such legislation as it might deem practicable and expedient to protect the wage-earners of the Commonwealth from the burdens of sickness, unemployment and old age, or any one or more of these. Subsequently, the duty of making a further special investigation was laid upon the Commission by Chapter 161 of the Resolves, approved June 2, 1916; namely, the subject of reasonable restrictions in the hours of labor in industries operated continuously for twenty-four hours, and to make such recommendations and drafts of proposed legislation as it might deem practicable. The report of this Commission,

which was very voluminous, was presented to the General Court in January, 1917, and is known as House Document No. 1850.

A Joint Special Committee on Workmen's Compensation Insurance Rates and Accident Prevention was appointed under joint order of the Senate and House of Representatives, adopted June 2, 1916.

The purpose of the Legislature in providing for the appointment of the committee was outlined in its order as follows:

... to investigate the subject-matter contained in the message of his Excellency the Governor, printed as Senate Document No. 444, with special reference to the problems of rate making and accident prevention under provisions of Chapter 751 of the Acts of the year 1911, known as the Workmen's Compensation Act, and acts in amendment thereof and in addition thereto.

The Committee made its report in February, 1917, Senate Document 370.

We next come to the address of his Excellency the Governor, of January, 1917, in which he urged upon the Legislature the consideration of certain forms of social insurance, and specifically recommended the establishment of a compulsory system of health insurance which should include members of the family and also urged that an annuity should be paid by the State and its subordinate governments without contribution to its deserving citizens seventy or more years of age who do not have children able to support them nor an income of more than \$200 a year, and who have been residents of the Commonwealth at least ten years.

Under Chapter 130, May 25, 1917, a special Commission was appointed, which is now sitting, known as the "Commission on Social Insurance," for the purpose of further investigating the extent to which poverty occasioned by sickness may be alleviated, medical care for wage-earners and others of limited means may be provided, and measures to prevent disease may be promoted, by insurance. The Commission is to undertake such investigations as to the health of wage-earners and the conditions under which they work, and as to existing systems of mutual, stock, fraternal, state and other forms of insurance in this Commonwealth and elsewhere as may be necessary to provide a sound basis for its recommendations, and is to submit a report, including drafts of any legislation which it may recommend to the next General Court, not later than the fifteenth day of January next.

The Committee has referred, perhaps, at too great length, and perhaps inadequately, to the investigations, past and present, of these subjects by the Legislature, not for the purpose of proposing any inquiry into the merits of these propositions, but to make it clear that through many years and at great expense, the General Court has provided for a careful study of the many intricate questions involved in the general subject of Social Insurance. It would, therefore, seem highly inexpedient that the suggestion of unconstitutionality should be permitted to attach to any measure the General Court may see fit to pass as a result of its prolonged and repeated investigations of the subject.

In Chapter I, the Legislative Power, Section I, The General Court, Art. IV, is found the following language:

And further, full power and authority are hereby given and granted to the said general court, from time to time to make, ordain, and establish, all manner of wholesome and reasonable orders, laws, statutes, and ordinances, directions and instructions, either with penalties or without, so as the same be not repugnant or contrary to this constitution, as they shall judge to be for the

good and welfare of this commonwealth, and for the government and ordering thereof, and of the subjects of the same.

This article has been amended as follows:

In 1821, Art. 2, by giving the General Court power to create municipal government.

In 1912, Art. 41, giving the General Court the power to prescribe certain methods of taxation for wild lands. In 1915, Art. 44, giving the General Court the right to impose a tax on incomes at different rates on different kinds of property.

It is not easy, and perhaps is not wise, in the absence of knowledge of what may be done with other parts of the Constitution, to attempt more than to follow, in a general way, the form of the amendments above referred to. The Committee submits to the Convention, first, a general amendment which is believed to cover the various propositions referred to it, and, second, different amendments, each dealing with a specific subject.

General Amendment.

The General Court shall have power to establish systems of social insurance, including old-age pensions or insurance, pensions for physical disability arising from any cause, health insurance, maternity benefits, insurance against unemployment, and compensation to workmen or their dependents for injuries incurred by workmen in the course of or arising out of their employment. It may provide for medical care as well as a money payment and may require that the cost of any such system or systems shall be borne in whole or in part by the State or any civil division thereof or by the insured or by the employer. It may provide that claims may be adjudicated with or without a jury and that employers contributing to the compensation of injured workmen or their dependents shall not be liable to any other claims for loss or injury.

Workmen's Compensation.

The General Court shall have power to establish a system of compensation to workmen or their dependents for injuries incurred by workmen in the course of or arising out of their employment. It may provide for medical care as well as a money payment and may require that the cost of such compensation shall be borne in whole or in part by the State or any civil division thereof or by the employer. It may provide that a contributing employer shall not be liable to any other claim for loss or injury and that claims may be adjudicated with or without a jury.

Health Insurance.

The General Court shall have power to establish systems of health insurance, including maternity benefits. It may require that the cost of such pension or insurance shall be borne in whole or in part by the State or any civil division thereof or by the insured or by the employer.

Insurance Against Unemployment.

The General Court shall have power to establish systems of insurance against unemployment, and may require that the cost of any such insurance shall be borne in whole or in part by the State or any civil division thereof or by the insured or by the employer.

Old-Age Pensions and Pensions for Physical Disability.

The General Court shall have power to establish systems of old-age pensions and of pensions for physical disability arising from any cause, and may require that the cost of any such system

shall be borne in whole or in part by the State or any civil division or by the beneficiary or by the employee.

CHARLES G. WASHBURN.

For the Committee.

MINORITY REPORT.

While I concur with the majority of the Committee in all other respects, I feel bound to dissent from its recommendations and so it becomes my duty to state my reasons therefor.

The members of our Committee were unanimous in the conclusion that if there is any doubt about the present power of the Legislature to act fully and freely in the field of Social Insurance, then we ought to recommend an amendment or amendments which would remove such doubt. We were also unanimous in the opinion that we should not include in such amendment or amendments any detail or specific matter which changing conditions might render of temporary application only. The power of Congress to deal as broadly as it has with interstate questions under the Federal Constitution is found in the absence of such detail and specific matter, and in the broad, general language of that instrument. Changing needs are most easily met under such a Constitution.

Therefore concurring as I do with the expressed opinions of the majority of the Committee on these points, I must be consistent and make my recommendations accordingly, so I recommend the adoption of the following amendment to the Constitution:

Amendment.

Full power and authority is hereby vested in the Legislative Department to establish any system or systems of pensions, compensation or insurance for the reward, relief or protection of any person or persons and to make any provision for such fund or funds as may be required therefor.

Respectfully submitted,

JOHN D. W. BODFISH.

A STATE TUBERCULOSIS WAR PROGRAM.

AN OUTLINE OF PROGRAM SUBMITTED BY THE SUB-COMMITTEE ON THE TUBERCULOSIS WAR PROBLEM OF THE ILLINOIS STATE COUNCIL OF DEFENSE.

The Sub-Committee on the Tuberculosis War Problem of the Illinois State Council of Defense shall consist of one member from each county in the state, with one or more members from each of the larger communities. The member from each county shall be known as the county chairman for his county, and shall be authorized to select the members of a county sub-committee, which will be charged with the work of preparedness required in the particular county.

THE PROGRAM.

1. Increasing the Appreciation on the Part of the Military Authorities and the Public as to the Importance of Tuberculosis as a Wartime Problem.

(a) The preparation of a brief on the importance of tuberculosis in the present war, including all available information relative to the experience of the warring nations of Europe, together with the means these nations have adopted to suppress and control the disease.

(b) Placing this circular in the hands of the state military authorities.

(c) Distribution of this circular as a means of arousing interest among civil public officials and those

interested in tuberculosis work in the various communities.

II. The Development of Anti-Tuberculosis Machinery in Each County in Illinois.

(a) The creation of a county sub-committee on the Tuberculosis War Problem in each county of the state, of which the county chairman shall be chairman.

(b) Increasing the facilities of all existing anti-tuberculosis organizations now operating dispensaries and visiting nurse service.

(c) The development of dispensaries and visiting nurse service in all local tuberculosis organizations now organized, but relatively inactive.

(d) The creation of organization in all counties in which there is no tuberculosis organization and the immediate development of medical, dispensary and nursing service.

(e) Securing the cooperation of the State Medical Society and the county medical societies in the development of county dispensary and nursing service.

(f) Urging the State Department of Public Health immediately to establish its proposed Bureau of Tuberculosis; to establish standards of nursing, dispensaries and diagnosis for the various counties, and otherwise to cooperate in the plan of preparedness for the wartime tuberculosis problem.

(g) Urging the Illinois Tuberculosis Association to cooperate in the plan and to stimulate its affiliated local organizations to greater activity.

(h) Assisting in the financing of local tuberculosis preparedness by calling upon public-spirited and patriotic persons to support county organizations, and by urging county authorities, city councils and boards of education to finance visiting nursing and dispensary service so far as the laws will permit.

(i) That counties which have voted favorably upon the establishment of county tuberculosis sanatoria be urged to appropriate the funds necessary for nursing and dispensary service, such work to be carried out under the direction of the County Sanatorium Boards.

III. Improvement in Methods of Examining Recruits.

(a) Bringing to the attention of the Adjutant General and of the Surgeon General the importance of tuberculosis in the present war.

(b) The recommendation to military authorities of a list of "danger signals" or evidences suspicious of tuberculosis which should cause the recruit to be subjected to special and thorough examination.

(c) Tendering to the state military authorities the services of a volunteer organization made up of physicians expert in the diagnosis of early tuberculosis, whose services will be available upon demand.

(d) The recommendation to the Adjutant General and to the Surgeon General of more leisurely re-examination of enlisted men in mobilization camps while still under the jurisdiction of the state.

IV. Closer Scrutiny to Detect Frankly Tuberculous Recruits.

(a) Recommendation to the Adjutant General and the Surgeon General to inquire as to the previous tuberculosis of the recruit or the history of diseases akin to tuberculosis or those frequently confused with tuberculosis.

(b) The collection of complete data as to all cases of tuberculosis, all deaths from tuberculosis and all tuberculosis history associated with those of existing age and placing same in the hands of recruiting officers.

(c) Encouraging the enforcement by local health officials of the existing rule of the State Department of Public Health requiring the reporting of all cases of tuberculosis by physicians.

V. Establishment of Tuberculosis Hospitals and Sanatoria.

(a) Selection in each county of isolated wards in general hospitals, to be conducted by those expert

in the care of tuberculosis, for returned soldiers actively sick with the disease.

(b) Selection in each county of a suitable tract of land and arrangement for water supply, sewage disposal and other sanitary installation which may be utilized when required, with temporary buildings, as camps or colonies for the tuberculous.

(c) Ascertaining the facilities of existing sanatoria, in or convenient to the various counties, to care for the increased tuberculosis of modern warfare.

(d) The speeding up of county sanatoria already voted in the several counties.

VI. Control of Tuberculosis in the Civil Population.

(a) Urging public and private charity organizations to increase allowances for relief in proportion to the buying power of money.

(b) Cooperation in all plans of food conservation and in encouraging food production by the poorer people.

(c) Cooperation with employers, especially those whose factories are under greater pressure due to war, for the improvement of factory conditions and looking toward periodic physical examination of employees.

(d) Recommendation to military authorities that returned tuberculous soldiers be not discharged from service until after the active disease has subsided.

VII. Creation of Medical Forces to Meet the Problem.

(a) Recommendation that physicians and nurses engaged in public tuberculosis work withhold themselves from military service until an urgent need may arise.

(b) That one physician, designated by the county medical society of each county, shall give special study and attention to the early diagnosis and treatment of tuberculosis.

(c) That training schools for nurses include the nursing of the tuberculous and visiting nursing service in their curricula.

(d) That all well-established dispensaries be utilized for the teaching of the early diagnosis of tuberculosis, and that medical students and physicians be encouraged to seek such instruction.

(e) That instruction in elementary social service and in tuberculosis be given to public-spirited lay women, that their services may be utilized in times of emergency.

APPOINTMENTS.

JOHNS HOPKINS UNIVERSITY.—The following changes have been made in the staff of the department of anatomy of the Medical School: *Dr. Florence R. Sabin* has been promoted from associate professor of anatomy to professor of histology; *Dr. Lewis H. Weed*, from associate to associate professor in anatomy, and *Dr. Charles C. Macklin*, from instructor to associate. *Professor O. Van der Stricht*, of the University of Ghent, becomes lecturer in anatomy. *Dr. Edmund V. Coudrey*, associate in anatomy, has resigned to accept the professorship of anatomy in the Peking Union Medical College which is now conducted by the Rockefeller Foundation of New York. *Dr. Eldon W. Sanford* becomes assistant in anatomy.

RECENT DEATH.

GEORGE STANCULEANU, a Rumanian physician, who had been in this country for a number of months on behalf of the Rumanian Government, died on July 16, at Stamford, Conn. Dr. Stanculeanu was laryngologist to the King and Queen of Rumania and was very successful in his native country. Upon the invasion of the German army, he was compelled to flee, leaving everything behind him. He and his wife were later sent to this country on a mission by the Rumanian government. He suffered from a mental breakdown, and pneumonia caused his death. His widow survives him.

Address.

THE COUNTRY DOCTOR AND THE HOSPITAL.*

BY NATHANIEL W. FAXON, M.D., STOUGHTON, MASS.

In the medical profession the country doctor is likened unto the private soldier. His virtues and his valor are often extolled by the generals of the city, but few or no suggestions for his betterment are made. His shortcomings are brandished before him by specialists and he is often humbled by the great in hospitals who fail to consider the many handicaps under which he labors. Partly because of a fancied superiority and partly because of real advantages in the shape of laboratories, hospitals, and ease of consultation, the general practitioner has been taught or has come to look with respect or envy, or both, upon the physician in the city. Having partaken of this envy during my own experience as a country doctor, I have tried to find some way of improvement, and by your leave will suggest the following as a possible step towards improvement.

For many years there has been a constantly growing conviction among doctors and the public that the old ways of doctoring are not the best; that modern medicine and modern life are outgrowing their older forms, and that "old lamps must be exchanged for new." This has taken form as regards the public, in various legislative enactments, such as the Employer's Lia-

bility Act, The Workmen's Compensation Act, and in the present agitation for sickness or health insurance. Among doctors suggestions have been made pointing out the advantages of group medicine with or without a hospital center or in some cases advocating state control of medicine, partial or complete.

At an address before a medical club in Boston some years ago, Ex-Pres. Charles W. Eliot stated that it was his belief that in the future "the practice of medicine would come to be divided between preventive medicine, surgery and the specialties," in this case classing internists as specialists.

In the last Ether Day Address Dr. Haven Emerson of New York said that "whether by organization, by endowment or by state employment, it seems to me that there must come a change in the basis of medical practice."

"The great fault," says Dr. Richard Cabot, "of English and German systems of sickness insurance is that they do not center themselves around organized groups of physicians, that is, around hospitals. They still rest upon the primitive conception of the doctor working alone, like the cobbler or peddler, not in organized groups." Dr. Hugh Cabot is even more dogmatic and is entirely convinced that group medicine must take the place of the individual, and looks forward to the development of group medicine with the hospital as its center.

The action of the legislature reflects a dissatisfied public, and quotations given above show a similar dissatisfaction among our profession. Both are searching for a solution. As my med-

* Delivered at the annual meeting of the Plymouth District Medical Society, April 19, 1917.

ical life has been in a country town, I may be pardoned for considering only what I believe to be applicable under these conditions. Group medicine with a hospital center we are familiar with only in cities and mainly as an organized charity. Its application to the country is really the subject of this paper.

Group medicine without a hospital center, or the voluntary grouping of several physicians, has become common in cities and has certain distinct advantages. It has been brought about by the division rendered inevitable by the rapid accumulation of knowledge. The general practitioner has been replaced by a group of specialists who, having pooled the results of their investigations, are able to come to a diagnosis with greater accuracy and also to provide more efficient treatment. It permits a gathering of apparatus for diagnosis and treatment beyond the means or use of any physician. It saves time for both doctor and patient; it also means less cost for the patient who, under this group system, may have the knowledge of many specialists for one fee.

On the other hand, there are obvious disadvantages. If incomes are pooled, so also must expenses, which increase rapidly with the group medicine system, be pooled and salaries must be paid. In other words, medicine ceases to be a profession and becomes a business. It means diminished personal relation to the patient; a real loss, although difficult to estimate in terms of money. Business is built upon advertising and the rigid collection of accounts, a thing doctors would desire but which at the same time we recognize would be taking advantage of others' misfortune. So while recognizing the efficiency of group medicine, we see that there are attendant evils that must be seriously considered.

I believe this kind of group medicine is distinctly a city product flourishing only under certain conditions and not transferable to the country. First—it requires suitable housing: a centrally located house large enough for several physicians, with offices, examining rooms, laboratories, etc.—something difficult to find in a town. Second—a habit among patients of consulting the physician in his office, which is not a strong feature of country practice. Third—a large population capable of supporting specialists in many divisions of medicine. I believe voluntary group medicine cannot be effective in the small town, but I also believe that the isolated general practitioner will work at an increasing disadvantage. *The collecting of group medicine around a hospital center is, I think, the best solution of the problem; first, because centralization appears to make for better doctoring; and second, because a hospital offers a logical center, both from the doctor's and the public's viewpoint—a condition not brought about by voluntary grouping.*

Any country doctor, I think, will agree that his greatest handicap is the lack of a hospital.

To have to send accidents, surgical cases, seriously ill medical cases, etc., 5 to 20 miles away, is a handicap, both to patient and physician. To the patient it may mean the difference between life and death. A hospital is also useful for the treatment of cases hardly serious enough to be sent away and yet which are scarcely suitable for home treatment. The accessibility of a town hospital allows friends and relatives to visit frequently and without expense, an item which would overcome many a patient's opposition to hospitals.

Furthermore, a hospital means attendance without delay, and better attendance because it allows of equipment beyond the reach of any doctor, as well as the assistance of nurses and other physicians. The possession of an ambulance will suggest one of the minor advantages to those who live where there is none.

From the viewpoint of the doctor, it increases his own efficiency because it gives him better facilities to work with. What the factory is to the manufacturer, the hospital is to the doctor. It allows him to work to advantage and to attend many cases which otherwise must be sent away. The loss of a case in this manner may or may not mean loss of income; it does mean loss of experience to the doctor and gradually loss of the confidence of the community. By this I do not mean that any doctor should attempt to treat all his patients, but continued sending of patients to hospitals sometimes for grave disorders, sometimes for slight, gives a little sting to the slur that country doctors are merely animated guideposts. The habit of turning troublesome problems of diagnosis or treatment over to someone else leads to slackness in thought and action, with inevitable deterioration of ability. Routine hospital data simplify many apparently obscure conditions, and how foolish we feel when the interne remarks in scornful tones that the "doubtful case" we sent in was merely a simple appendix. How unsatisfactory to send a patient to a far-away hospital with an uncertain but honestly uncertain diagnosis, to receive vague and scanty reports as to diagnosis and treatment. "Dr. So-and-So operated, I think, for fibroid. Doing as well as can be expected." After two weeks we are permitted to do the final dressing and inspect the healed wound. Ah, but you are welcome to come to the hospital at 9.15 and see Dr. So-and-So operate on your patient. We have all done it, arrived promptly at the hour set, after strenuous exertions to see a few necessary cases before leaving home, rushed in to comfort our former patient, received his grateful thanks, and then spent hour after hour awaiting the coming of the surgeon who was unfortunately delayed. Do not misunderstand me on this. I am finding no fault with the hospital authorities and surgeons; this is a plain statement of conditions that confront the country doctor, and because of this he loses experience,

he loses contact with fellow physicians and he drops behind because he cannot come in touch with medical progress. Rather a small, imperfect hospital in my own town than a modern model of medical and surgical perfection 20 miles away.

So much for the good effects of a local hospital for the individual, *i. e.*, the patient and the doctor. What now, will it do for the community? A local hospital centralizes the health organization of the community. It naturally becomes the headquarters and general meeting-place of all the physicians of the town. Time will not allow me fully to discuss the question as to whether all resident physicians of a town should be upon the staff. Permit me to state that in Stoughton we are agreed upon this as one of our foundation stones because of its manifest fairness.

Because of the gathering together of many patients it saves much time in attendance. It brings the physicians into more frequent contact with each other, with the natural interchange of ideas; promotes healthy discussion and frequent consultation, which, because of time saved, may be had at less or no expense to the patient. It prevents duplication and allows, as before stated, a greater equipment than can be privately supported. It provides a place for the care of accidents, with a central office for notification of accidents, preventing the confusion attending the usual summons sent for all the physicians in town. Operations can be performed by surgeons called as desired without lengthy transportation, with the family doctor in attendance, to the mutual advantage of patient and physician.

A local hospital furnishes a headquarters for the District Nursing Association, and a center from which to call for nurses needed outside, for it should not be supposed that I imply that all sick must be treated at this hospital.

A local hospital should further become the headquarters of the Board of Health. So that we have now centralized under one roof all that pertains to the health of a community—the physicians and nurses for the care of the sick and the Board of Health for the prevention of disease.

The health of a community falls under three heads:

1. The prevention of disease, which naturally is the province of the Board of Health.

This includes;

- a. Prevention of communicable diseases.
- b. Prevention of industrial diseases.
- c. The correction of habits which determine or contribute to premature death.

2. Accidents.
3. Sickness.

The ideal Board of Health controlling an ideal community would be able to abolish all communicable diseases. Consider a community

in which there was no tuberculosis, typhoid, malaria, yellow fever, etc.; no diphtheria, and rarely the infectious diseases of childhood; no syphilis or gonorrhoea, and you will gain some conception of what preventive medicine aspires to. Consider the supervision of industries so that there were no cases of lead poisoning, phosphorus poisoning, or any evil effects from chemicals; factories with no dust, well lighted, properly warmed and ventilated, and you will further appreciate what preventive medicine means. Imagine a people who at last have learned that alcohol, drugs, tobacco, overeating (gluttony), overcrowding and unhygienic ways of living produce disease and premature death, and you will see what a campaign of education and teaching lies before us all.

After we have done all these things, when there are no infectious diseases, no sickness from unhealthy conditions, no disease from bad habits, there will still remain plenty for us to do.

Accidents will always come. "Safety first" may be the watchword, but there can never be immunity from accident. Cuts, broken bones, trivial and severe, will always be with us and demand treatment.

After we have reached the meridian in preventive medicine, we still must realize that life is fleeting and death is certain. Sooner or later prematurely or in the due course of time, some cause will bring sickness and finally death. Those causes that we can prevent we should. Every illness and every death that might have been prevented is our reproach, but those we cannot prevent we should try to ease and ameliorate, lessen suffering and perhaps prolong life and render it more comfortable.

Surgery may cure or relieve cancer, ulcer of the stomach or intestine, diseases of liver and gall-bladder, diseases of the genito-urinary system, abscesses and all the ills of the pyaemic bacteria, empyaema, hernia, goitre, etc.; medical advice and treatment may aid diabetes, nephritic condition, anaemia, rheumatism, arthritis, cardiac disease, pneumonia and other respiratory diseases, constipation and colds, apoplexy, paralyses, epilepsy, insanity and old age or the wearing out of the human machine. The puerperal state demands careful attendance, watchful waiting and intelligent direction and operation. These and many others, in our present knowledge, we may aid but not prevent.

To sum up, I believe that every town may have a hospital as the center of its health organization. There will be the headquarters of the Board of Health—directing the control of preventive measures. There will be the headquarters of the physicians and nurses for the care of those cases that cannot be prevented. In the hospital itself there will be cared for:

1. Those cases best cared for in hospital, irrespective of home conditions.

2. Those cases best cared for in hospital because of home conditions.

3. Those cases desiring hospital care because of its certain advantages.

As a center for the Board of Health: The effectiveness of a health board depends upon the energy and intelligence of its members and upon the co-operation of the physicians of the district. The weakest point, in my own experience, both as member of the health board and as an outside physician, was the lack of communication between the board and the town physicians. A common center where reports of contagious disease could be easily transmitted to all physicians, would go far towards bringing about greater interest in prevention of such diseases. This would naturally lead to greater interest in all preventive measures, to discussion as to methods of greater efficiency in preventive medicine along the lines previously mentioned. In other words, it not only would serve as a registry for sickness but also as a center from which to direct prevention of sickness.

As a center for the physicians of a town it places them in a position collectively to command the services of surgeons and specialists in a way impossible individually. How often have we desired aid given only by those who have specialized, yet, hesitating to send the patient to some out-of-town hospital, have still been prevented, because of expense, from calling directly upon a specialist for advice. A hospital could provide necessary equipment for diagnosis, could associate with itself consultants and specialists and appoint stated times for the examination and advice to patients brought by the attending physician. Fees under such circumstances could be made within the means of all.

Around such a center could be built up the regular hospital service caring for accidents and emergency calls, and the charity work of any district or town.

Allow me to quote a paragraph from an article of Dr. Hugh Cabot, that agrees with many of the suggestions I have made.

"I therefore look forward to the development of group medicine with the hospital as its center, such hospitals to be under the management of trustees, who, it is to be hoped, will take their duties more seriously than do most trustees of today.

"It will probably be objected that this will involve the treatment of all patients in institutions, but this will not of necessity result, unless it be thought desirable. There is no substantial objection to the hospital's staff making visits at any reasonable distance without loss of the important advantages of medical grouping. It does not even seem to me impracticable to conduct country practice in sparsely settled districts upon a hospital basis. It would seem to me entirely feasible to use the towns and smaller cities as centers from which medicine should radiate. The younger members of the organization would do the work in the outlying districts, living there, if necessary, but always keeping in

close touch with their hospital center, and being promoted as experience and opportunity should dictate. It would thus come about that the younger practitioners would have thrown upon them the more laborious work, while the older members of the group would occupy the position requiring rounder judgment and fuller development, but neither the activity nor the enthusiasm of youth. We might in this way preserve all that is best in competition for that scientific achievement. We could undoubtedly permit the development of individuals along the lines best suited to their peculiar capacity, and get from each what he has best to give. We should avoid the scandals of inhuman charges and of indecent exploitation of suffering humanity by the sharks of the profession, and we might well avoid the tragedy by which the impetuous young doctor must select general practice, for which he is ill equipped, because he cannot afford to devote himself to the pursuit of pure science, for which he is best fitted."

I have now outlined a town hospital with a staff composed of all the resident physicians, who care for patients, within and without the hospital. How now can we reconcile community service with private competition?

There are three methods of organization to be considered.

1. Public. 2. Private. 3. Co-operative.

The public form is that supported by the community: state, county, municipal.

The private form is that supported by endowments from a single or from many sources.

Both are run without attempt at gain. They both admit and care for patients who are unable to pay for either hospital or medical care, and patients who pay what is supposed to be the actual cost of their maintenance, but who receive their medical attendance free. In some hospitals, a third class of private patients are admitted, who pay for both hospital and medical care. Naturally, only members of the staff may take advantage of this arrangement. Any physician holding a position on such a staff enjoys great opportunities. Although he may give freely of his time and skill to many without pay, he receives much in experience and renown and the opportunity to receive patients for pay, assisted by all the resources of such an institution.

This brings us to the third form of organization,—the co-operative; in towns where the community spirit is insufficient or such an organization seems undesirable or where it is impossible to raise sufficient funds to build and equip a privately subscribed hospital, it seems to me feasible, for the physicians of such a community, by means of co-operation and agreement, at least to make a start, however meagre, along this line, to their own and the community's advantage. Once the community is shown the benefits of such an arrangement, it will surely lend its aid. As to which form of organization is best, each community and each group of physicians

must form their own opinion, governed by the existing circumstances.

In closing, let me sketch my own fancy of such a hospital group.

First of all, there must be the tangible hospital building, sheltering those dealing with the health of the community,—the board of health, the physicians and nurses, and providing a place to care for the sick. Ultimately, there will be gathered the offices of the physicians of the town, who will care for their own private patients in office and hospital, and for the charity cases of the town, according to whatever arrangement may be best, and whence they may go forth to the homes of those requiring attendance there. I will merely suggest here that such an arrangement would go a long way toward preventing the habit of some people in sliding from one doctor to another when their account had reached threatening proportions. There would be a central telephone desk with which all doctors would be in touch. Accidents (which are now usually a matter of chance, whoever happens to be within reach being the one to whom it falls) could be apportioned by a rotation system, or any system desired, to those wishing such calls. Duplication of apparatus and endeavor would be avoided; a central operating room and similar equipment would provide for all. A pathological laboratory would be feasible, the running of which would fall to that physician whose ability and inclination most fitted him for such work. Each physician would in the same way naturally follow that part of medicine in which he was most interested, thereby unconsciously and without loss of practice gradually becoming a semi-specialist. The possession of an efficient nursing corps, which could be called upon, whether in the hospital or for help outside, would be in itself a great aid in the care of sickness.

I hope my vision of such an organization is neither too socialistic nor too theoretical to be practical. I hope all here will express their views upon this subject, because only in this way may we achieve a thorough understanding and reach a definite conclusion.

A STUDY OF THE URINES OF PICRIC ACID WORKERS.

By F. O. WEST, M.D., WORURN, MASS.

THE medical complaints of men engaged in the manufacture of picric acid having been treated in a general way,¹ this investigation was undertaken to determine the truth of the popular belief that the kidneys are seriously affected in those constantly exposed to this substance. If this belief is correct, the data collected illustrate what results may be obtained by a large manufacturing concern in preventing occupational disease. The means employed by this

company in protecting its men are suitable working conditions and strict medical supervision. The building is properly constructed for the work to which it is put; ventilation and lighting are adequate; exits are well placed; washing facilities are numerous; and the foremen take an interest in the men under them. On the medical side of the problem, every effort is made to acquaint the men with the dangers of the substances they handle; signs are posted in conspicuous places, urging them to be cautious; emphasizing the need of personal cleanliness, and the importance of refraining from the use of alcohol. First-aid racks are numerous and are inspected several times daily to prevent supplies becoming exhausted. At the company hospital an attendant is present at all times during the 24 hours, and all men are urged to report there regardless of how slight an injury may be. They are required to report, as a matter of precaution, when there has been no accident, as in cases where there have been more than the usual amount of "fumes" in the building. It is reasonable to expect a minimum amount of trouble as a result of such care.

CONDITIONS UNDER WHICH TESTS WERE MADE.

Examinations were made on the urines of the entire crew of picric acid workers, including machine operators, packers, men handling the dried powder, and the steamfitters whose duties were confined to this department. They were all seen at the same period and while engaged at their regular tasks; the working conditions not varying from those present at other times. The results were compared with the findings of the preliminary examinations which all picric acid men must submit to before being hired, and with the examinations that were made from time to time during the course of their employment.

The crew was made up of both whites and negroes. The length of service varied from one to eighteen months.

On carefully questioning the men and consulting the detailed medical records kept in all cases, no evidence was found of a symptom-complex that could be attributed to picric acid poisoning.

In regard to poisoning by fumes of mixed acid, our records show that 30 of the 57 men thus examined had been temporarily affected. The number of attacks which these men had varied from 1 to 11; the great majority were mild, a few were severe, none were serious.

TESTS EMPLOYED.

The urines were examined for the presence of albumin and picric acid.

Albumin: The test used was heat and acetic acid with filtered urine. Picric acid: Three tests were applied to all urines.—white wool, copper sulphate, and potassium cyanide. These were checked with control tests worked out on both normal urines and normal urines with known percentage of picric acid in solution.

1. Wool. The material used was obtained from a skein of the best white wool. Strands were soaked in the solutions for 24 hours, thoroughly washed in warm water and dried. In this manner a control scale was made from urines with picric acid 1:40,000, 1:80,000, 1:100,000, and a normal urine. The first dyed the wool a bright yellow, the second a faint yellow, the third a very faint but easily distinguishable color, while the wool from the urine was a dingy white.

2. Copper sulphate test. Control tests were made on normal urines with known quantities of picric acid as in the above. The solutions were made alkaline with ammonia hydrate and an aqueous solution of copper sulphate (diluted until the blue color disappeared, a 0.2% solution) was added. A positive test was indicated by the appearance of a green color which was unmistakably given in urines having picric acid in dilution as high as 1:80,000.

3. Potassium cyanide. To urines with known amounts of picric acid, sodium hydrate and a small amount of a saturated solution of the cyanide were added, and the mixture heated. No result was given by the solutions of high dilution. The blood red color of this test appeared only when the strength of picric acid was increased to 1:8,000.

RESULTS.

As above mentioned, all these tests were applied to the urine of each man examined, and the results were compared with those given by the control tests as described. There was, however, a chance for error. This arises from the presence of picric acid on the hands of the men at the time of examination and the possibility of its being carried to the genitals and thus contaminating the urine as it was being voided. Furthermore, it was noted in many instances that picric acid was on the outside of the urine glasses after the men had set them down. In spite of this possible source of error, of the more or less constant exposure of the men to mixed acid fumes, of the presence of picric acid on the skin and about the nostrils, the following results were obtained:

Number of urines examined	57
Urines containing only albumin	4
Urines containing only picric acid	2
Urines with both picric acid and albumin	1

The albumin in all cases did not exceed in amount "the slightest possible trace." The amount of picric acid present, according to the gradations of the scale established by the control tests, was not stronger in any case than dilutions of 1:80,000.

ANALYSIS OF RESULTS.

Albumin: of the five men with albumin in the urine, two had shown it before they went to work in the picric acid department, the man with both albumin and picric acid being one of these. Although albumin in the urine is one of the reasons for rejecting men wishing employment,

these men were accepted because of their otherwise unusually fine condition.

As regards the remaining three, their urines showed nothing wrong at their first examination. But I cannot find any evidence to warrant our attributing the albumin to the occupation: none of them had worked longer than five months; none had ever reported at the company hospital for "fume poisoning"; none had received any extensive acid burns; none had shown any acid dermatitis, and none showed any digestive disorders. Further to bear out this contention, additional data in regard to albumin in the urine were obtained from the medical records of former employees engaged in similar work. Twenty-nine men were thus investigated; they were taken at random and no effort was made to get selected cases. Length of service ranged from one week to ten months. In no instance was albumin present at the end of these periods. Moreover, of these twenty-nine men, seventeen had had fume poisoning; the number of attacks in each individual ranging from one to nine, with a total of 48, one being extremely serious, nearly resulting in death.

If the occupation causes irritation of the kidneys, we should expect to see evidences of it in those who had suffered ill effects, and not in those who had never been troubled by their work—a condition not discovered by this investigation.

PICRIC ACID IN THE URINE.

Two of the three men giving this test had been employed four months and the other fifteen months. The latter, a machine operator, was more liable to fume poisoning than the others. The first two were workers in the filter beds, and would be more likely to inhale the powdered substance. Nevertheless, none of these three men were more exposed to danger than any of the others, and they were not less cleanly. It is interesting to note that one man showing a great amount of picric acid about his nostrils had none in the urine.

RELATION OF PICRIC ACID TO ALBUMIN.

As only one of the three men showing picric acid had albumin also, and as the albumin in this case was present at the start, we cannot claim any ill effect on the kidneys from the picric acid.

SUMMARY.

The result of this investigation tends to show that picric acid may be manufactured without great hazard to the employee, provided the work is carried on under proper conditions and the men are subjected to rigid medical supervision. Of 86 urines examined for the presence of albumin, 3 gave the "slightest possible trace" at the end of employment, whereas it was not detected at the outset. Nevertheless, these three men had never been affected by any of the substances they were handling; while many men not given the test had been repeatedly treated,

one of this latter class having nearly died from the effects of fume poisoning.

In addition to the examination for albumin, 57 of these urines were tested for the presence of picric acid, and three were positive.

Unfortunately, the value of this information is open to suspicion, on account of possible contamination. If the picric acid had been excreted in the urine in these cases, we find no evidence of its having caused renal irritation.

AN EPIDEMIC OF DYSENTERY AT THE BOSTON STATE HOSPITAL, DUE TO A MEMBER OF THE PARATYPHOID-ENTERITIDIS GROUP.

By MARY ELIZABETH MORSE, M.D., BOSTON,
Pathologist to the Boston State Hospital,
AND

GENEVA TRYON, M.D., BOSTON,
Assistant Physician, Boston State Hospital.

[From the Laboratory of the Boston State Hospital.]

I. INTRODUCTION.

The so-called "asylum dysentery" still presents a problem as regards etiology, pathology and prevention. The finding of the Shiga bacillus in connection with numerous outbreaks has led to the assumption that it is always the causative organism. That other organisms may be concerned is demonstrated by the outbreak here reported, which occurred in the Infirmary Building of the Boston State Hospital in the spring of 1915. The cases were unusual, both clinically and bacteriologically, and therefore it seems of interest to report the epidemic. The severe cases were characterized clinically by acute dysenteric symptoms, and the fatal cases by septicemia and bronchopneumonia. The intestinal condition found in the autopsied cases was a widespread membranous ileocolitis. The cases of moderate severity had blood and mucus in the stools, without much prostration, while the mild cases had only diarrhea. The organism isolated in connection with the epidemic is a member of the paratyphoid-enteritidis group. In August, 1915, the disease reappeared in the Infirmary, and there was also an outbreak in the other buildings located near the Infirmary. Isolated cases occurred in the Infirmary during the winter of 1915-1916, and in the spring of 1916 small numbers in both the Infirmary and the Cowles Building. An effort was made to prevent the occurrence of the disease by prophylactic vaccination. Observations were made on agglutinin formation in the disease and after prophylactic inoculation. Skin tests were carried out with members of the paratyphoid-enteritidis group, and the leucocytic reaction was studied after prophylactic and therapeutic administration of vaccine.

II. EPIDEMIOLOGY.

The Infirmary is one of the buildings of the West Group, in which, as is seen by reference to Chart 1, are also the Cowles Building for chron-

CHART 1. Buildings of West Group. Scale of feet: 100 = |—|.

ically disturbed women, and the Fisher Building, containing wards for chronic men patients, officers' quarters, the kitchen supplying the entire West Group, and dining-rooms for the nurses and other employees of the Group; and, near the Infirmary, the cow and horse barns and the pigery.*

The first outbreak of the dysentery occurred in the Infirmary in April, 1915. In this building are about 380 patients, four wards each for men and women. The class of patients is limited to the elderly infirm and those having a chronic organic disease.

On the women's side the first case appeared April 15 and the last April 30. Eleven patients had the disease in a very severe form and of these six died. One nurse had a short but moderately severe attack, and three nurses had diarrhea.

On the men's side the first case developed April 24, the last May 13. There were eight cases, some quite severe, but none fatal.

The majority of the cases on the women's side came from a ward (V) on which the patients were up and about and some of them very untidy. The other cases, with one exception, appeared on the ward (VIII) to which those having the disease were transferred.

The first three cases occurred within three days' time and varied sufficiently in clinical signs so that they were not immediately classed together. The first appeared as a severe diarrhea in a very untidy senile dement; the second as a dysentery in an untidy parietic; the third patient showed lung signs twenty-four hours preceding the dysentery and died in five days. There was no autopsy. On April 20 the head nurse on Ward VIII, where these patients were isolated, had a diarrhea for one day, beginning twenty-four hours after the transfer of the patients to her ward. On April 25, when four more

* During 1916 the pigery was removed to a remote location and cow barns closed.

patients on Ward V had a dysentery, two nurses had a diarrhea, one of them being a night nurse working between Wards V and IV. On Ward IV a patient was taken ill with dysentery about two days later. As this patient had been cared for especially by the above-mentioned nurse, it is possible that she contracted the disease from the latter. On April 28, the last case on V developed, and on the thirteenth three new cases appeared on VIII.

In the earliest cases bacillary dysentery was ruled out by cultures from the stools. The clinical signs were so similar after the disease was once established that there was no doubt of an epidemic. The sequence of cases on the women's side was such that it seemed probable that the disease was being communicated from one person to another. Therefore all suspects were at once isolated and those having the disease were put in single rooms, with strict isolation and careful disinfection. On the suspected Ward V all untidy patients, whether having a diarrhea or not, were put to bed, and their stools inspected and disinfected. No new case developed on the women's side of the Infirmary between May first and mid-August, the beginning of the second outbreak.

On the men's wards, as on the women's, there was one ward entirely free from the disease. These were both wards on which nearly all the patients were bedridden. On the other wards of the men's side the cases occurred in such sequence that no conclusion could be drawn in regard to the mode of transmission of the disease. A nurse who slept on the women's side, but worked among the men patients, had a diarrhea at the date of the first onset among the men patients, but it could not be satisfactorily proved that she was the carrier. No new case developed on the men's side between mid-May and mid-August.

In the investigation of the source of the epidemic, attention was directed first to the food and milk supplies. The food supplies for the entire West Group are brought over daily from the main storehouse at the East Group, a quarter of a mile distant. The milk comes partly from the hospital herd, and partly from a city firm. The food for all persons in the West Group (staff, employees and patients) is prepared in the main kitchen at the Fisher Building (see Chart 1) by three cooks, assisted by six patients from that building. The nurses in each ward are assisted in serving the food by several patients living on the ward.

Identification of the organism concerned in the epidemic as a member of the paratyphoid-enteritidis group at once brought the meat under suspicion, in view of the association of bacilli of that type with epidemics of meat poisoning. Cultures were made from the surface and interior of meat and poultry in the West Group refrigerator at the beginning of the epidemic, but the results were negative. Cultures from

the milk of both the State Hospital and outside supply were also negative.

Investigation of the West Group kitchen employees and patients, also of the porter and his assistant (patient) who delivered food to the Infirmary, elicited no history of diarrhea and they all gave negative agglutination reactions with the epidemic organism. Cases of diarrhea among the patients of the East Group at this time yielded neither the organism nor an agglutination reaction, and at no time since has there been a case of this infection at the East Group. The limitation of the disease to the West Group suggested a contamination of the food after reaching the Group. The examination of food and food handlers was made before the two isolated early cases, described in the following paragraph, were discovered.

Finding the agglutination test positive among the nurses who had a diarrhea during the first outbreak brought up the question of possible cases previous to that time. Two such were found: a woman patient who had had a diarrhea for one day only (April 4, 1915), who was not on the ward on which dysentery first developed, and a man patient, who is not recorded as having intestinal symptoms, but who on March 20, 1915, had an indefinite illness characterized by fever and muscular weakness.

A review of death and autopsy reports furnished no clue to earlier cases. There had been no epidemic of any kind at the hospital since a paratyphoid A infection in 1910.

The West Group refrigerator was out of use during the first two weeks in April, 1915, while it was undergoing repairs, and during this time the food was kept in makeshift places. The reconstruction of the refrigerator was necessitated because it failed to keep the food cold and was not mouse-proof. For a few weeks before the acute outbreak there had been quite a number of mild diarrheas among the nurses and attendants, also affecting some other persons in the Group, but not sufficiently severe to incapacitate them. No attention was paid to these attacks at the time, and only detailed inquiry later elicited a history of them.

A remotely possible complication of the situation is the fact that in the spring of 1914 hog cholera was epidemic among the pigs, and again in August, 1915. Hog cholera is thought to be due to a filterable virus, but associated with the latter are various members of the paratyphoid-enteritidis group. The most frequent of these is *B. suispestifer*, which was at one time thought to be the cause of the disease. The exact relationship of these organisms to the lesions is still undecided. *B. suispestifer* is supposedly non-pathogenic for man, but a number of human infections proved to be due to it have been reported. These were of the acute intestinal type. The occurrence of hog cholera the year previous to the human epidemic, the known association of the paratyphoid-

enteritidis group with hog cholera, the finding of a member of the group as the cause of the human epidemic, and evidence which tended to show that the latter was not due to a suddenly introduced food infection, raised the question of a possible connection between the animal and the human epidemic. Cultures were made from the lymph-nodes and spleen of a hog-cholera animal killed at the hospital in August, 1915. The organism proved to be of the colon bacillus type, and by agglutination reactions did not show a close relationship to the bacillus of the human epidemic.

From a review of the first outbreak it seems probable that the immediate source of the epidemic was not a suddenly introduced food infection; that the disease was communicated from one person to another; that it was endemic, and that previous mild cases of diarrhea among patients and employees had been overlooked. There is a possibility that the cause of these diarrheas may have been contamination of the food in the refrigerator by rats and mice, as these animals frequently harbor bacteria of this group in the intestine (mice, *B. suispestifer*; rats, *B. enteritidis*).² It may be possible that these animals were the connecting link between the hog cholera and the human epidemic.

The second outbreak began in mid-July with mild attacks of diarrhea among the nurses at the Cowles Building. These were not mentioned until dysentery appeared among the patients of this building early in August. The Cowles contains about 125 chronically disturbed women, young or in early middle life, and nearly all strong physically. From August first to October there were 24 cases, and no ward was exempt.

In mid-August came a recurrence in the Infirmary, on both the men's and women's sides, without regard to wards. About the same number of patients had the disease as in the spring, but there was only one fatality. The last group of cases was on the women's side, one case on September 30 and nine between October 23 and 27.

In mid-August and early September there were also a number of cases of diarrhea and dysentery in the Fisher Building among patients, nurses and officers.

As to the mode of transmission of the disease in the second outbreak, there seems no doubt but that flies played a leading part, for they were very numerous in all the buildings of the West Group. The buildings are incompletely screened. As breeding-places for flies should be mentioned the stables, barns and piggery which were situated within a few hundred feet of the buildings for patients.

III. CLINICAL DESCRIPTION.

The following is a description of the disease as it appeared on the women's service of the Infirmary during the first outbreak. The disease, as a whole, presented such a definite

 - - - - - Diarrhea cases 27

CHART 3.

picture that it is unnecessary to describe individual cases. The duration in recovered cases was about three weeks, in fatal cases five to ten days. The incubation period could not be definitely ascertained, but the limits were apparently twenty-four hours and seven days. The onset was characterized by prostration, headache, backache, and large watery stools containing mucus and blood.

The temperature curve was somewhat variable. The initial temperature was between 99° and 104°, but was usually high, remaining so from three to five days, then dropping gradually during one or two days to 99°, and remaining there for about a week before returning to normal. Occasionally there was a rise to 101° after the fall. The pulse was usually high with the temperature, 110 to 120. One fatal case, however, had an initial pulse of 100 with a

temperature of 104°, with a rise in the pulse rate as the temperature fell.

A few hours after the onset the tongue became dry and covered with a white fur and the lips were dry and red. With the fall of temperature the tongue gradually became moist, but the heavy white coat persisted after the dysentery had ceased, even as long as three weeks.

There were no throat symptoms and no glandular enlargement.

The liver and spleen were not enlarged, either at the beginning or as the disease progressed.

Nervous symptoms were not prominent. The headache disappeared within twenty-four hours. Two of the fatal cases became restless, picking at the bed-clothes.

The skin showed no rose spots. The face was much flushed during the high temperature, then the face and body became sallow and the skin dry.

The appearance and number of the stools were quite characteristic, six to eight in twenty-four hours, large, watery, brown, containing blood and mucus. The odor was exceedingly foul. In one fatal case, two days before death there was a severe hemorrhage, with large clots of blood. In another fatal case there appeared large pieces of mucus, almost like casts of the intestine. In the severe cases that recovered, the dysentery persisted two to three weeks.

The abdomen was soft and usually not tender. There was some tenesmus for the first few days. In one fatal case the abdomen became distended with gas a few days before death.

There was marked muscular weakness, persisting weeks and even months after recovery from the dysentery. The muscles became very soft and the patients lost weight early.

Clinical Tests.—The urine showed a trace of albumen. The blood picture varied somewhat in different patients and in the same patient during the course of the disease. In no case did an anemia develop. The total white count was rather more variable than the differential, ranging between 5,000 and 10,000, and not decreasing with the progress of the disease. In the severe cases, uncomplicated with pneumonia, the polymorphs were between 54% and 66% during the first two weeks, the lower per cent. for the individual being in the first week. The lymphocytes persisted rather high, between 27% and 40%. Eosinophiles were not found in any case examined during the first week; in the second week they reappeared in .5%-2%. Transitionals gave a higher per cent. in the first than in the second week. The blood picture of the third week was practically the same as that of the second week both for protracted cases and convalescents. In the pneumonic-dysentery cases, the polymorphs were relatively higher, 72%-77%, but the total count was only moderately increased, 8,000-12,000; in the recovered cases

of this class, the lymphocytes showed a high per cent., 37%-43% in the third week. In all cases blood platelets were much increased.

Blood cultures taken in two cases during the first week were negative. A culture from the urine in one very serious case that recovered was negative for the epidemic bacillus, but yielded a streptococcus.

The diagnosis was made from the clinical signs, finding the organism in the stools, and by the agglutination test (see sections on bacteriology and agglutination).

Convalescence was slow because of extreme muscular weakness and recurrence of diarrhea with any but the most careful diet.

Sequelae were not observed, unless the muscular weakness may be regarded as such.

The diet and medical treatment were about the same in each case. Boiled or plain milk and barley water were best taken, and any change from this routine in early convalescence invariably brought back blood or mucus in the stools. At the beginning of the outbreak some days were spent in experimenting with ipecac and morphine and antiseptic or astringent irrigations. The drugs had no effect on the dysentery and the irrigations were irritating. The following treatment was then adopted: a daily high saline irrigation and strychnia sulph. gr. 1/60 t.i.d. by mouth. Castor oil was used at the onset and for constipation during convalescence.

Vaccine therapy was tried in two protracted cases. The doses were small, beginning with 50,000,000 and increasing 25,000,000 with each dose until four doses had been given, the injection being made every second day. It may have been a coincidence that convalescence began during this treatment.

The mild attacks among the nurses were characterized by a diarrhea lasting about twenty-four hours, with numerous offensive watery movements, accompanied in some instances by griping pains. The diagnosis was made later by agglutination tests.

The clinical description of the second outbreak in the Infirmary, from August to October, 1915, corresponds to that of the first, except that the disease was of shorter duration and less severe. The diagnosis of bronchopneumonia was made in two cases about twenty-four hours before the dysentery appeared. Among the patients in the Cowles Building the acute stage of dysentery lasted about three days. It was often ushered in with nausea and vomiting, a sharp rise in temperature and increased respiration. The patients were kept in isolation from seven to ten days and recovered with their former physical activity. The cases among the employees were short attacks of diarrhea or dysentery lasting from one to three days.

An acute arthritis of the knee joint developed in one of the less severe cases ten days after the onset and two or three days after recovery from the intestinal disturbance. The highest tempera-

ture during the arthritis was 101°. A week later the other knee became involved, the temperature again rising to 101°. The leukocyte count was 10,000 with polymorphonuclears 71%.

Differential Diagnosis.—The paratyphoid group of infections is usually divided clinically into a gastro-enteric and a typhoid form, to which it appears, from the present observations, and those accumulating during the present war, a third form, the dysenteric, should be added. Bainbridge² maintains the view that *B. Gärtneri*, *B. suipestifer*, and *B. typhi murium*, associated with food and especially meat poisoning, cause the gastro-enteric type, while *B. paratyphosus A* and *B*, spread by human carriers, and never found except in connection with human disease, cause the typhoid form. Uhlenhuth and Hubener,³ on the other hand, consider paratyphoid *A* and *B* also as a cause of acute food poisoning, and state further that the different clinical types may appear in the same epidemic. During the present European war the British have made numerous reports of paratyphoid *A* and *B* infections, describing chiefly the typhoid form, but mentioning also a dysenteric.⁴

The typical gastro-intestinal form comes on suddenly, usually from twelve to forty-eight hours after eating infected food, with headache, chilliness, pain in the abdomen, and vomiting, followed by a rise in temperature and pulse, and a diarrhea. The stools are described as exceedingly offensive, and muscular weakness, both during the acute stage and convalescence, is very marked. The acute period lasts two to five days, and the total duration of the disease is about one week.

The typhoid variety resembles a mild form of true typhoid. Sequelae are frequent, the most common, perhaps, being an arthritis. Serious local lesions, such as abscess of the lung or osteomyelitis, may follow paratyphoid *B*.

Short descriptions of the dysenteric form have appeared during the war from British and Austrian sources. Bassett-Smith⁴ remarks that cases (military) coming home labelled "dysentery" should be regarded as potential paratyphoid, because many of them are found to be that. C. Miller⁴ regards the dysenteric as the most severe form of paratyphoid infection seen at the Netley Hospital. The majority, and most of the severe cases, are due to paratyphoid *A*. He describes the patients as emaciated, blue and pulseless, often showing a petechial rash, subcutaneous hemorrhages, and an aphthous stomatitis and pharyngitis. There is constant flux of pink mucus in small quantities, with tenesmus. The mortality is high.

Korezyski⁵ describes four cases of paratyphoid dysentery with autopsy. The disease attacked persons who were physically reduced, and toxic features were prominent. He divides the cases into two groups, the enteric, in which the lesions (hemorrhage into mucosa and occasional ulceration)

are situated in the small intestine—the stools are feculent; with only traces of blood, and tenesmus is absent; and the dysenteric, in which there is an inflammation of the large intestine, and stools are numerous, small, with much blood and mucus, and there is tenesmus and pain over the descending colon.

The present disease has clinical features of both the typhoid and gastroenteric varieties, but differs from the usual picture of both. It agrees with the typhoid form in the presence of a septicemia, respiratory symptoms, and arthritis as a sequel, but, considered as a whole, does not give at all a typhoid picture. It resembles the gastroenteric form in that the symptoms, except in the most severe cases, are predominantly intestinal (although in the typical gastroenteric variety these are usually of the acute diarrheal, and not of the dysenteric type), and in the marked muscular weakness. It differs from it, however, in the absence of nervous symptoms and of the features of an acute intoxication. It is conceded, however, that the gastroenteric form may vary in its course, that it may be of long duration, with irregular fever, diarrhea and bronchitis, also that systemic infection may follow the acute stage.

The disease which the ordinary severe case resembles most clinically is, however, neither of the chief forms of paratyphoid infection, but bacillary (Shiga) dysentery. A comparison of the main features of the two diseases is therefore given:—

BACILLARY DYSENTERY (SHIGA)	EPIDEMIC DYSENTERY B. S. II.
<i>Onset</i>	
Acute diarrhea and colic.	Acute diarrhea or dysentery. Nausea and vomiting may be first symptoms.
<i>General Symptoms</i>	
1. Temp. 101°–102° F. Severe cases, 104°.	1. Temp. 99°–103° F. at onset. Slightly irregular course.
2. Headache, general malaise, and, in severe cases, muscular pains.	2. Headache, backache, aching in limbs at onset. Prostration.
<i>Abdominal Symptoms</i>	
1. Pain, severe colic.	1. Pain early in disease and not severe.
2. Tenesmus, marked.	2. Tenesmus early in disease and not marked.
3. Tenderness on pressure.	3. Tenderness not usual.
4. Abdomen usually somewhat excavated.	4. Abdomen usually soft and normal in appearance. Excavated in 1 fatal case. Distended in 1 fatal case.
<i>Tongue</i>	
Moist, somewhat coated in slight attacks. Thick, dirty brown coat in typhoid dysentery.	Moist in mild cases and dry in severe cases. Heavy white coat.

Character of Stools

- | | |
|---|--|
| <ol style="list-style-type: none"> 1. Diarrhea at onset not characteristic. 2. Mucus, small amt. at first. Pure mucus and blood within 2 to 3 days. 3. Quantity is small; an ounce or less, and stools are frequent. | <ol style="list-style-type: none"> 1. Large, brown watery stools. Odor very foul. 2. Flecks of mucus and blood may appear at onset or after 1 to 2 days. Both usually absent in mild cases. 3. May continue large and watery or become small in amt. About 8 stools in 24 hours in both mild and severe cases. 4. Constipation in convalescence. |
|---|--|

Lung Symptoms

- | | |
|-------|--|
| None. | Respiration increased in nearly all cases at onset. Bronchopneumonia and multiple abscesses of lungs in fatal cases. |
|-------|--|

Bladder Symptoms

- | | |
|--|----------------------|
| Tenesmus. | No bladder symptoms. |
| <i>Incubation Period</i>
2 to 4 days. | 24 hours to 7 days. |

Duration and Course

- | | |
|-----------------------------|---|
| Light cases, 4 to 8 days. | Duration of light cases, 1 to 4 days. |
| Severe cases, 3 to 6 weeks. | Duration of severe or fatal cases, 5 days to 3 weeks. |
| Disease may become chronic. | Recurrences, but chronic cases not observed. |

Complications and Sequelae

- | | |
|---|---|
| Parotitis, ascites, peritonitis. Prolapse of rectum frequent. | Acute arthritis, 1 case.
Vomiting, 1 case.
Prolapse of rectum, 1 case.
Muscular weakness, all cases. |
|---|---|

IV. PROPHYLACTIC VACCINATION.

In December, 1915, and January, 1916, prophylactic vaccine treatment was given to 125 women patients in the Infirmary. A formalized vaccine was used, prepared from seven strains isolated in the spring and summer of 1915 from the feces of given clinical cases, also from the hearts' blood of two autopsied cases. The especially feeble or sick and those who had had the disease were exempted from treatment, and a few other patients refused to be vaccinated. Fifty-one of the stronger and more active patients were given three inoculations, one week apart, the first 500,000,000 and the remaining two 1,000,000,000. A local reaction was usual, but in only a few instances was a constitutional one observed.

Thirty-two patients received two inoculations and forty-two only one. The latter patients were among the bedridden, in whom the local reaction was, as a rule, very marked, with redness and swelling of the entire arm. A constitutional reaction, characterized by prostration, also

occurred among the majority of this class. The treatment was discontinued among the very feeble patients because of the disturbing effect of the reactions.

From January, 1916, when prophylactic treatment was given, to July, 1916, there were seventeen cases of diarrhea among the women patients of the Infirmary. The cases were scattered and few in the winter, but appeared in groups on certain wards in the spring. Of these 17 patients, ten had been vaccinated (eight with three doses and one each with one and two doses); three had suffered from the disease in 1915, and four had had neither the disease nor the inoculations. All attacks, except one, were mild and short. Some of the patients had only a slight rise in temperature, but all were somewhat prostrated. The exception was a fatal case (see case 5, pathological section) of a severe dysentery, in a senile dement who had refused vaccination; but it should be stated that she had not recovered well from a recent pneumonia and was found also at autopsy to have a subdural hemorrhage. Eight of the seventeen cases were on Ward V, which was the hotbed of the disease in 1915.

In the Cowles Building, also, there occurred in May, 1916, three cases of the short dysenteric type in patients who had not previously had the disease.

Although these experiences indicated that neither prophylactic vaccination nor a severe attack gives more than transient immunity, vaccination was continued in July, 1916, all of the Cowles patients, and all additional women Infirmary patients who were strong enough for the treatment, being given three doses.* It was hoped that by vaccinating shortly before flytime, an immunity of sufficient duration might be produced to tide the patients over that season; and that even if the disease could not be entirely eliminated by prophylactic vaccination, at least its type might be reduced from the severe dysentery to the mild diarrheal.

From July 1 to October 15 there were 6 cases of diarrhea among Infirmary patients who had been completely vaccinated, 5 among those incompletely vaccinated, 2 in patients not vaccinated, and 6 recurrences in unvaccinated patients. There was also one case of dysentery and several of diarrhea among the 125 inoculated Cowles patients.

Tabulation of the results on the women's side of the Infirmary gives the following:—

* The inoculations were made by Mr. John C. Rock of the Harvard Medical School, laboratory interne for the summer of 1916.

CASES AMONG THESE.

REMARKS.

Total patients completely vaccinated from Dec., 1915, to Oct., 1916,	64	13	All diarrheas.
Incompletely vaccinated ...	72	8	All diarrheas.
Not vaccinated	65	7	1 fatal dysentery.
Total women infirmary patients having disease in 1915.	41		
		9	1 dysentery (short). Rest diarrheas.
			Recurrences among these (not vaccinated)

The majority of the cases occurring after vaccination and among those not vaccinated are in patients who are feeble yet not strictly bedridden. New bedridden patients do not usually acquire the disease. The recurrences are in patients who at the time of the first attack were feeble and have since become bedridden. They are, in general, much milder than the original attack, and a number were so slight and transient that they would have passed unrecognized if special study were not being given to the subject.

That the new cases and recurrences are due to the epidemic organism is evidenced by the appearance of agglutination reactions in the former and the persistence of reactions at comparatively high dilutions among the latter after attacks.

Agglutinins range usually from 1/80 to 1/150 within one month after vaccination and persist at a low level (1/10) for at least 10 and 11 months (see section on agglutination).

It is evident that immunity after this disease is, at least in feeble persons, irregular and probably usually of short duration. In this respect it resembles Shiga dysentery. The duration of immunity after the various forms of paratyphoid infection is not definitely known.

It is clear, also, that as brilliant results cannot be obtained from prophylactic vaccination in this disease as in the case of either typhoid or probably the typhoid form of paratyphoid. The difficulties are two: the first inherent in the transient character of the immunity; the second due to the fact that the disease is particularly prone to attack debilitated persons, who as a rule do not stand prophylactic vaccination well. Nevertheless, the writers are convinced that without it cases of the disease would have been more numerous, and, particularly, more severe during the present year, and that it should be continued upon all suitable exposed patients as another way of combating the disease among a class of patients with whom it is difficult to carry out rigorous hygienic measures because of untidiness and lack of co-operation. It is notable that cases after prophylactic vaccination were decidedly fewer at the Cowles Building than at the Infirmary, this being due, doubtless, to the stronger physical condition of the former patients. The differences found in the leucocytic reactions of strong and weak patients after doses of vaccine (see section on leucocytic reaction) give a further suggestion on this point. It seems probable that prophylactic vaccination among a fairly strong class of individuals is of considerable value, and that results might be

much better among the general population or in armies than in insane hospitals.

The writers have been unable to ascertain that until the present war prophylactic inoculation against members of the paratyphoid-enteritidis group has been tried on a large scale, or that it has ever been undertaken under institutional conditions. Vaccination against paratyphoid A and B is now, of course, being practised extensively in the European and United States armies, in conjunction with antityphoid inoculation, but data on its efficiency will not be available for some time.

Several experiments in vaccination on a large scale against bacillary dysentery have been made, both in European insane hospitals and among the general population. In the former, the results, although not given in detail, are said to have been successful in stopping an epidemic. Shiga⁶ in 1898 to 1900 inoculated about 10,000 persons in a district of Japan where epidemic dysentery prevailed most seriously, and diminished the mortality from 20-30% to about zero.

V. SKIN REACTIONS.

Tests for specific skin reactions were tried with a few patients, of whom 12 had had the disease one to twelve months previously; ten had received prophylactic treatment one to nine months previously; and seven had had neither the disease nor prophylactic treatment. Tests with paratyphoid A, B. suispestifer and B. enteritidis were also made with these same patients. The method was the same as that described by Gay and Force⁷ in 1914 for the typhoidin skin reaction, concentrated five per cent. glycerine broth cultures being used, with a similarly concentrated glycerine broth solution as a control. The intradermal was preferred to the scratch method as the reaction with the latter was too delicate and transient and often difficult to distinguish from trauma. Different dilutions of the glycerine broth culture were made with normal salt solution (lowest 1-2, highest 1-12) with a desire to find what strength would cause a perfectly distinct reaction in the immune and a negative one in the non-immune individual. By the intradermal method a bleb was formed by the injection of .1 cc. of the dilution, a short needle of a given caliber being used in all cases.

The reaction from the control dilutions was a slight redness of a few mm. at the point of injection, disappearing in less than 24 hours. The reaction from the culture dilutions was an erythema of a diameter varying with the strength of the dilution, and having, in some

cases, a darker red indurated center. The reading was made at the end of 24 hours. The indurated area sometimes persisted for a week.

The following observations were made:—

1. The control patients showed reactions that were often difficult or impossible to distinguish from the reaction in those who had the disease.

2. The reaction varied somewhat in intensity in different individuals, but this did not correspond to the time lapsing between the attack or prophylactic treatment and the test, nor was it more marked in those who had had the disease.

3. In nine cases in which agglutination reactions were made within a few days or three weeks after the skin test, comparisons were made. One patient who had the disease 10 months before showed severe local reaction from a low dilution (1-2) of the different cultures and a constitutional reaction, with fainting and nausea; three weeks later the agglutination reaction was entirely negative. There were equally marked skin reactions in two patients having agglutination reactions of 1-10 and 1-150 three weeks later.

4. High dilutions caused a doubtful or negative reaction, in certain patients who had had the disease, although causing a distinct reaction in some control cases.

5. Skin tests made with similar broth cultures of other members of the paratyphoid group showed reactions varying slightly in intensity in the different individuals.

6. The concentrated glycerine broth cultures, made up at different times, varied in their results, and apparently deteriorated in a short time, so that any standardization of dilutions was not possible.

These observations would indicate that the intradermal skin reaction with the concentrated glycerine broth cultures has not been of any clinical value in testing the duration of immunity in these cases, or in distinguishing this disease from infections by other members of the paratyphoid group.

Those who have studied the typhoidin skin reaction vary in their conclusions regarding it. Gay⁸ considers it of value in indicating the duration of immunity in those having received prophylactic treatment, that re-vaccination is indicated when the skin reaction is negative. Kolmer and Berge⁹ in their study of the typhoidin skin reaction observed that a reaction could be obtained over a longer period in those who had had the disease than in those having had prophylactic treatment only. They found agglutinins and complement-fixing antibodies usually present in those reacting to the skin test. Kolmer and Berge used a powdered typhoidin and control furnished by Gay but, because of the severe reaction caused by the control, they regarded the reading of the tests as subject to error.

An effort will be made to test these patients

with powdered cultures of the same members of the paratyphoid group, before setting aside the skin reaction as of no clinical value in this disease.

(To be continued.)

A YEAR'S WORK WITH THE WASSERMANN TEST, IN THE BOSTON HEALTH DEPARTMENT LABORATORY, WITH ESPECIAL REFERENCE TO DOUBTFUL REACTIONS.

BY FRANCIS H. SLACK, M.D., BOSTON,
Director, Sias Laboratory, Brookline;

PHILIP CASTLEMAN, M.S., M.D., BOSTON,
Acting Deputy Commissioner, Boston Health, Dept.;

AND
KARL R. BAILEY, M.D., BOSTON,
Serologist, Boston Health Dept.

SINCE the publication of Bordet and Gengou, 1901, describing the phenomenon of complement fixation, many observers have endeavored to apply this test for the diagnosis of the various infectious diseases. Among such investigators were Wassermann and Bruck, who in 1905 were endeavoring to establish a test for tuberculosis by this important reaction.

About this time Hoffman and Schaudinn demonstrated the causative organism of syphilis, the *Spirocheta Pallida*. This discovery stimulated many workers to further effort, and we find the first publication, in May, 1906, by Wassermann and Bruck, describing the phenomenon of complement fixation in the diagnosis of syphilis.

Their work led many research workers to investigate this test, and practically all confirmed their findings.

In 1907 Weygandt reported fairly reliable results, using a watery extract of normal human spleen as an antigen.

About the same time Marie and Levaditi reported similar results, using an aqueous extract of normal fetal liver.

In December, 1907, Landsteiner, Muller and Potzl reported very favorable results, using an alcoholic extract of guinea pig heart as an antigen.

Up to 1911 all work in this test was in the experimental stage. Since then various boards of health, especially those of the larger cities, have added this test to the regular routine work which is carried out in municipal laboratories for physicians.

The Boston Health Department also considered the establishing of this test, but on account of certain obstacles the work was postponed from year to year. In the latter part of 1915, it was, however, decided to start the work, beginning with the year 1916.

Various modifications of the original Wasser-

mann test, as devised by different workers, namely, the so-called New York or ice-box method, the methods used by the various hospital laboratories in this city, as well as in nearby city hospital laboratories, were tried out and a definite form was established, to which we have adhered with the exception of such modifications as described below.

Since January 1, 1916, free Wassermann tests have been offered by the Boston Health Department Laboratory as an additional routine examination, and during the year over 2500 of these tests were made, showing that this opportunity was thoroughly appreciated.

Specimens may be submitted by physicians in outfits provided by the laboratory, or the patients may be sent to the laboratory to have the specimens taken. The laboratory is prepared to receive these patients and to collect the specimens of blood from 2 to 4 p.m., only, on certain days of the week.

History blanks are mailed to physicians on request, and each patient appearing at the laboratory must present one of these, carefully filled out and signed by his attending physician. Specimens are not collected at any other time, nor are they collected from patients coming without carefully prepared history cards.

Reports upon the examinations are made to the physicians only.

Physicians who wish to collect the specimens themselves may obtain outfits at the laboratory, but are responsible for their careful return after the specimens have been taken.

Reports. The reaction as carried out in this laboratory has the following diagnostic significance: *Positive* indicates syphilis, except very rarely in acute febrile conditions, such as malaria and pneumonia. *Negative* does not exclude syphilis. In dealing with obscure conditions less than three negatives cannot be relied upon. *Doubtful* signifies an inconclusive result. It is advisable to submit several specimens in such a case, and to interpret a persistently or predominantly doubtful reaction as indicative of a syphilitic infection. *Unsatisfactory* means that the test was unsuccessful either because of the condition of the specimen or on account of some difficulty with the technic. In the latter event the test is repeated on the next testing day, otherwise a new specimen is requested.

In addition to the above reports, as will be explained later, the laboratory has been sending out a few reports of "moderate positive," indicating an undoubted positive but of a less degree of intensity.

TECHNIC USED IN THE TEST.

Preparation and titration of reagents.

Antigens. Two antigens have been used, the first an alcoholic extract of human heart, cholesterinized, and the second an acetone insoluble antigen prepared from fresh beef heart by Noguchi's method.

The cholesterinized antigen is prepared according to the method of Swift and Ellis, as follows:

Put some fresh human heart, free from fat or fibrous tissue, through a meat grinder, and to 50 grams of this ground material in an Erlenmeyer flask add 500 c.c. of absolute alcohol and shake well. Cork and place in an incubator at 37° C. for two weeks, giving it a thorough shaking each day. At the end of two weeks' incubation the solution is filtered, the filtrate placed in the ice chest over night and again filtered. The filtrate is then kept closely stoppered in the ice chest and, as needed, is removed in quantities of 100 c.c. To this amount (100 c.c.) of the filtrate is added .4 gm. of Kahlbaum's cholesterin. This is shaken and then incubated at 37° C. for 24 hours, to dissolve the cholesterin. The antigen is now ready for titration and use. The cholesterinized antigen should be kept at room temperature as the cholesterin precipitates if kept in the cold. As needed for use it is diluted 1 part to 9 with normal salt solution, adding the salt solution slowly and with constant shaking. It is then titrated for exact strength, as described later.

The acetone insoluble antigen is prepared as follows:

Fifty grams of ground fresh beef heart free from fat or fibrous tissue are mixed in an Erlenmeyer flask with 500 c.c. of absolute alcohol, corked and put into an incubator at 37° C. for two weeks, shaking the mixture well each day. At the end of two weeks the preparation is filtered and the filtrate evaporated by the use of an electric fan. The residue is dissolved in about 25 c.c. of ether and allowed to stand in a cool place over night, covering the dish to prevent evaporation. The supernatant portion is then decanted into another receptacle and evaporated to a small volume (5 to 10 c.c.). This is then mixed with ten volumes of pure acetone. The precipitate which forms is allowed to settle and the supernatant liquid decanted.

The acetone insoluble portion is the antigen.

Each .3 gm. of this substance is dissolved in 1 c.c. of ether and 9 c.c. of pure methyl alcohol added. This stock solution is kept in the ice chest, and as needed for use is diluted 1 part to 14 with normal salt solution, adding the salt solution slowly with constant shaking. It is then titrated for exact strength as described later.

Amboceptor. Rabbits are injected with washed red corpuscles of the sheep made up to the original blood-volume with salt solution. Gradually increasing doses are injected intraperitoneally at about 3 to 4 days intervals, using injections of 7 c.c., 14 c.c., 21 c.c. and 28 c.c., Seven days after the last injection about 1 c.c. of blood is withdrawn from the ear vein and the serum titrated. If the serum shows a high titre 40 to 50 c.c. of blood may be withdrawn from the rabbit's heart with an ordinary antitoxin

syringe. In the hands of an experienced operator the rabbit suffers no ill effects from this operation and may be used again for amboceptor after a lapse of one or more months with but one or two additional injections of sheep's cells, as described above. The blood is allowed to stand for a few hours at room temperature for the formation of a good clot. It is then placed in the ice chest over night and on the following day the serum is separated. Precautions for asepsis should be observed throughout this whole procedure. The serum is placed in 1 c.c. glass ampules, sealed and inactivated in a water bath at 55° C. for 30 minutes on three successive days, after which it is kept in the ice chest and withdrawn as needed.

Complement. The complement used is fresh blood serum from guinea pigs. By withdrawing the blood from the heart, and allowing three or four weeks for recuperation, the pigs may be used over and over again. A fair sized pig should furnish about 8 c.c. of blood without being seriously injured. Before operating primary anesthesia is induced with the A. C. E. mixture.

The serum separates out better in petri dishes than in test tubes. The blood is preferably drawn on the afternoon before the serum is needed for the tests, allowed to stand an hour or so at room temperature and then placed in the ice chest over night. In the morning the serum is separated, diluted to 10% with normal salt solution and titrated.

The patient's blood is collected with aseptic precautions, from one of the veins in the bend of the elbow, preferably the median cephalic. It is well to draw from 5 c.c. to 10 c.c. in a sterile tube, after which the tube is slanted. A good separation of serum will be obtained if, after clotting, the clot is broken away from the sides of the tube. After standing an hour or two at room temperature, the blood is placed in the ice chest over night. In the morning the serum is withdrawn and centrifuged if cloudy. It is then inactivated by placing it in a water bath at 55° C. for 30 minutes.

Sheep's cells are obtained by washing fresh drawn, defibrinated, sheep's blood three times with normal salt solution by means of the centrifuge and diluting the final concentration of cells to 5% with salt solution. It is convenient to draw the sheep's blood and wash the corpuscles the night before they are to be used, keeping them in the ice box and diluting just prior to use.

Salt Solution is prepared by dissolving 8.5 grams of e.p. sodium chloride in a litre of distilled water and sterilizing in an Arnold sterilizer for at least one hour.

Pipettes. The following pipettes are used:

- 10.0 c.c. pipettes graduated into .10 c.c.
- 5.0 c.c. pipettes graduated into .10 c.c.
- 1.0 c.c. pipettes graduated into .10 c.c.
- .3 c.c. pipettes graduated into .01 c.c.

Directly after use each pipette is placed in normal salt solution.

After the tests are finished all the pipettes are rinsed with clean water and dried in the hot air oven.

Titration of the Amboceptor. To .1 c.c. of the undiluted amboceptor is added 9.9 c.c. of normal salt solution and the mixture is thoroughly shaken. This gives a dilution of 1-100.

To .1 c.c. of the 1-100 dilution is added .4 c.c. of normal salt solution, giving a dilution of 1-500.

To .1 c.c. of the 1-100 dilution is added .9 c.c. of normal salt solution, giving a dilution of 1-1000.

To .1 c.c. of the 1-100 dilution is added 1.4 c.c. of normal salt solution giving a dilution of 1-1500, and so on until dilutions up to 1-5000 are prepared.

Now a series of tubes is taken and in each one, marked with the dilution factor, is placed .5 c.c. of the correspondingly diluted amboceptor. To each tube is added .5 c.c. of 10% complement or if the complement has been titred and its unit found, twice the unit may be used.

To each tube is added .5 c.c. of 5% sheep's corpuscles and a sufficient amount of the salt solution to bring the volume up to 2 c.c.

The contents of the tubes are thoroughly shaken and placed in a water bath for one hour at 37° C., at the end of which time the results are noted.

That amount of amboceptor that just completely hemolyzes the corpuscles is taken as the amboceptor unit.

Two units of amboceptor are used in the Wassermann test. It is convenient so to dilute the amboceptor that .5 c.c. of the dilution contains 2 units.

TITRATION OF THE ANTIGEN.

Hemolytic Titration. Increasing amounts of the diluted antigen are placed in a series of test tubes as follows: .03, .05, .08, .1, .15, .2, .25, .3 c.c. and salt solution is added to make up each tube to 1.5 c.c., after which .5 c.c. of sheep's cells is added to each tube, the tubes are thoroughly shaken and incubated in a water bath at 37° C. for one hour and readings made. As a rule the hemolytic titration is not absolutely necessary.

In calculating the dose of antigen to be used in the test, one fourth the amount not hemolytic is generally used.

Anticomplementary Titration. Antigen is used in the same amounts as in the hemolytic titration.

Complement is added .5 c.c. of the 10% solution to each tube.

Salt solution is now added to each tube to bring the contents up to 1 c.c.

The contents of the tubes are thoroughly shaken and they are incubated in the water bath at 37° C. for 40 minutes.

The amount of amboceptor necessary for the series, using two units to the tube, and also the amount of sheep's cell needed are now calculated.

For instance, the usual dose of the diluted sheep's cells is .5 c.c. and if the amboceptor is so diluted that .5 c.c. contains 2 units it would require 4 c.c. of each for the series of tests. It is advisable to make up a little more than the actual amount needed, therefore, 5 c.c. of diluted amboceptor and 5 c.c. of diluted cells are mixed in a test tube or bottle and placed in the water-bath at 37° C. for 30 minutes, to sensitize the cells. At the end of this time 1 c.c. of the sensitized cells mixture is added to each tube in the series, the tubes are shaken and replaced in the bath at 37° C. for one hour, when readings are made.

The amount of antigen that shows beginning inhibition of hemolysis is the anticomplementary unit.

In conducting the test about one fourth of this amount is generally used.

Antigenic titration. .1 c.c. of positive syphilitic blood serum is placed in each tube and antigen and complement are added as in the anticomplementary titration. The contents are now well mixed and incubated in the water-bath for 40 minutes. Amboceptor and sheep's cells are mixed for sensitization and added as in the anticomplementary titration, the tubes are then incubated for one hour at 37° C. in the bath and the results read.

That amount of antigen that shows just complete inhibition of hemolysis is taken as the antigenic unit.

In conducting the Wassermann test two to four times this unit should be used, providing that these amounts are not more than one-fourth or one-fifth the anticomplementary dose.

THE WASSERMANN REACTION.

The sera to be tested are separated from the clots and inactivated by placing in a water bath for one-half hour at 55° C. While the sera are being inactivated the complement is separated and diluted to 10% with normal salt solution.

The daily titration of complement and amboceptor is now made as follows:

To 4 c.c. of 10% complement are added 4 c.c. of normal salt solution, thus making the 5% dilution required in the titration.

Nine tubes are arranged in a rack and in each are put the reagents as indicated in the following table:

TUBES No.	1	2	3	4	5	6	7	8	9
5% Comp.	.5 c.c.	.4 c.c.	.3 c.c.	.2 c.c.	.15 c.c.	1 c.c.	1 c.c.	1 c.c.	1 c.c.
Amboceptor of which .5 c.c. is probably 2 units	.5 c.c.	.5 c.c.	.5 c.c.	.5 c.c.	.5 c.c.	.4 c.c.	.3 c.c.	.2 c.c.	.1 c.c.
5% Cells.	.5 c.c.	.5 c.c.	.5 c.c.	.5 c.c.	.5 c.c.	.5 c.c.	.5 c.c.	.5 c.c.	.5 c.c.
Salt solution	Enough to each tube to make the total volume 2 c.c.								

The contents are thoroughly shaken and the tubes placed in the water bath at 37° C. for thirty minutes.

The first five tubes show the complement titre and the last four the amboceptor titre.

If the proper dilution of amboceptor is used, tubes No. 6 and No. 7 should show complete hemolysis, while tube 8 should show partial and tube 9 complete inhibition.

Of the first five tubes the last one in which there is complete hemolysis shows the complement unit, and since two units of complement are used in the test, it will require a volume of the 10% complement equal to that of the 5% which gave the reaction in the titration; thus if there is complete hemolysis through tube No. 3, in which there are used .3 c.c. of the 5% complement, we proceed with the test, using .3 c.c. of the 10% complement for each tube.

The test proper is carried out as follows:

The test tubes are conveniently arranged in the racks in rows three deep, each set of three tubes representing one test and in each is placed .1 c.c. of the inactivated serum.

To the tubes in the first row are added the cholesterinized antigen conveniently diluted so that the right quantity is added by using .1 c.c.; the tubes in the second row receive similar doses of the acetone insoluble antigen, while those in the third row, which are used as serum controls, receive no antigen.

With each set of tests should be run a known positive blood serum, also a control tube for each antigen, these latter receiving no blood serum, but each receiving a double amount of its respective antigen.

To each tube is then added two units of complement and sufficient salt solution to make up the volume to 1 c.c.

The contents are thoroughly shaken and the tubes are placed in the water-bath at 37° C. for 40 minutes.

The amounts of amboceptor and cells needed for the series are now calculated.

If the amboceptor is so diluted that .5 c.c. is equal to two units, the calculation is easily made; if, for instance, there are 90 tubes, it will require 45 c.c. each of diluted amboceptor and 5% cells. It is usually well to make up a little more than the actual amount required to be sure of enough material.

The amboceptor and cells are thoroughly mixed and are incubated in the water-bath at 37° C. for 30 minutes. After these incubation periods are ended 1 c.c. of the sensitized cells mixture is added to each tube and mixed

thoroughly by shaking the tubes; they are then incubated again for one hour at 37° C. and the results read.

It has been noticed that the cholesterinized antigen is a little too sensitive to be absolutely relied upon. It catches all the positives and also holds up with a few sera which show negative results with the use of other antigens.

With the acetone insoluble antigen a positive result at the end of the hour is to be relied upon, but the test may be negative when it should be positive, because the antigen is not sufficiently delicate.

During the first six months of our work we reported *positive* only on those cases where with both antigens there was no hemolysis; *negative* where both showed hemolysis and *doubtful* where the cholesterin antigen showed no hemolysis while there was hemolysis with the acetone insoluble antigen.

During the first six months' work 934 examinations were made and reports were given as shown in the following table:

	Pos.	Neo.	DOUBTFUL	UNSAT.	TOTAL
January	9	33	4	0	46
February	27	67	9	3	106
March	37	117	15	2	171
April	36	126	14	1	177
May	50	162	13	3	228
June	47	145	12	2	206
TOTALS	206	650	67	11	934
	22+	70—	7+	1+	100%

Of the 11 unsatisfactory tests four were hemolyzed, four anticomplementary, two had insufficient material and one was a broken tube.

On 67 tests, or a little over 7%, "doubtful" reports were sent. The great majority of these cases gave a moderately positive reaction with the cholesterinized antigen, while the test with the acetone insoluble antigen showed a weak hold-up or was negative. The actual readings were as follows:

Cholesterin	Acetone Insoluble	w = weak	Cases
+	+	+	9
"	+	—	10
"	m = moderate	w	34
"	+	+	6
"	m	m	4
"	+	+	2
"	w	w	2
Information not recorded		—	—
TOTAL			67 Cases

It is a matter of regret, when one considers the difficulty often experienced in obtaining these specimens, that such a high percentage of doubtful reports should be given. We do not know the experience of other laboratories, but we are inclined to believe our experience is not exceptional, and that any practical means whereby these "doubtful" returns may be reduced in number would be much appreciated.

We therefore began on July 1st to do further work with this class of specimens by repeating the test in such cases, using .4 c.c. of the patients' serum with the acetone insoluble antigen instead of .1 c.c. in order to increase the antibody content and also running a control with .4 c.c. of the serum, feeling that it was perfectly safe to report as moderately positive any case giving a strongly positive reaction with a negative control. If the reaction was negative or very weak with .4 c.c. serum and the acetone insoluble antigen, it was still reported doubtful.

The results are shown in the figures for the next six months.

	Pos.	Neo.	DOUBT. FORMERLY	DOUBT. UNSAT.	TOTALS
July	41	159	13	0	229
Aug.	48	187	13	0	266
Sept.	57	133	6	0	196
Oct.	76	167	6	0	269
Nov.	61	193	8	0	274
Dec.	87	226	12	0	343
TOTALS	370	1065	58	8	1597
	23+	66+	3+	5+	1% 1—%

Under our former method of reporting, 149, or a little over 9% of the total specimens, would have been reported "doubtful." The new method enabled us to report 91 of these either moderately positive or negative, and diminished our "doubtful" returns to 58, or a little over 3% of the total.

In the majority of the 149 cases, as originally tested with .1 c.c. of patients' serum, the cholesterin antigen was positive and the acetone insoluble negative or with but a slight reaction.

Results with .4 c.c. serum and acetone insoluble antigen were as follows:

	JULY	AUGUST	SEPTEMBER	OCTOBER	NOVEMBER	DECEMBER	TOTALS	REPORT
4+	10	15	17	5	4	13	64	Mod. Pos.
m								
4+	2	0	2	5	6	4	19	Mod. Pos.
w								
4+	3	1	3	2	0	1	10	Doubtful
4—	10	12	3	4	8	11	48	Doubtful
TOTALS	25	28	25	16	18	29	141	

In eight other cases there was but a weak hold-up with the cholesterin antigen and none with the acetone insoluble even when .4 c.c. serum was used. These were reported negative.

Beginning with the last of November, partly with these tests and partly with tests of the present year, we have made a further study of these doubtful cases by comparing the .4 c.c. method and the ice-box method, using the following technique for the ice-box tests.

Tubes, one for each test, were arranged in a rack, the blood serum to be tested, acetone in-

* Of the 13 unsatisfactory specimens, 7 were hemolyzed, 2 anticomplementary and 4 insufficient in quantity to carry out the .4 c.c. test.

soluble antigen, and complement, in volumes as described above, were placed in the tubes, the contents well shaken, and the rack placed in the ice compartment of the ice chest for four hours. At the end of that time one c.c. of sensitized cells, prepared as described above, was added to each tube and the rack placed in the water bath kept at 37° C. and readings made at the end of one hour. With the above set was also run an antigen control tube which contained twice the volume of antigen used in the tests, but no blood serum. Some laboratories recommend that the readings recorded should be made just as soon as there is complete hemolysis in the antigen control tube, but we have found that such readings often lead to false positive results.

A series of 50 of these cases, with unsatisfactory reactions in the regular routine, has been made, with the following results:

No.	37° C.				REF. REPORT	No.	37° C.				REF. REPORT
	.1 CHLOR.	.1 ACET. ISOL.	.4 ACET. ISOL.	.1 ACET. ISOL.			.1 CHLOR.	.1 ACET. ISOL.	.4 ACET. ISOL.	.1 ACET. ISOL.

2401	+	+	+	+	Pos. m	806	+	+	+	+	Pos. m
2403	+	+	+	+	Pos. m	626	+	-	+	Doubt.	
2410	+	+	+	+	Pos. m	646	+	+	+	+	Pos. m
2417	+	-	+	-	Pos. m	652	+	-	+	+	Pos. m
2423	+	-	+	+	Pos. m	680	+	-	+	+	Pos. m
2433	+	+	+	+	Pos. m	773	+	+	+	+	Pos. m
2438	+	-	-	+	Neg.	776	+	+	+	+	Pos. m

Under our original plan of reports these 50 cases would all have been reported "doubtful."

Reports were made, however, on the outcome of the .4 c.c. tests, the ice-box method being run simply for experimental purposes. Forty-three were reported moderately positive, 4 negative, and 3 doubtful.

Results of the two methods agree in 20 instances, in 16 tests the .4 c.c. and in 14 instances the ice-box method shows a stronger reaction.

If reports had been made with the results of the ice-box method rather than those of the .4 c.c. method, there would have been 40 moderate positives, 8 negatives and but 2 doubtful. In 37 instances the same report would have been given by either method, 36 moderately positive and one negative.

The comparison is very close, and it is difficult to say which is the more accurate. The .4 c.c. method has one advantage in that the test is much more quickly completed.

The three tests reported "doubtful" with the .4 c.c. method would have been reported positive" by the ice-box method. Seven reports of "moderately positive" with the .4 c.c. method were "negative" with the ice box.

It seems as though a consideration of these cases where results differ might give valuable information as to the comparative value of the tests. Unfortunately the histories furnished by physicians are rather inadequate upon which to base conclusions.

CASE No.	RESULTS WITH .4 C. C.		PHYSICIAN'S DIAGNOSIS	TREATMENT
	RESULTS WITH ICE BOX	RESULTS WITH .4 C. C.		
2217	Doubtful	(12 5, '16)	Syphilis	Neosalvarsan, 3 doses
2239	"	(2 6, '17)	Syphilis ?	None
6296	"	(2 6, '17)	Syphilis (2)	Salvarsan, 3 doses
2294	Negative		" (3)	Mercury pills, 9 mos.
147	"		Not given	None at present
2126	Mod. Pos.		Not given	For release
2246	"	(12 11, '16)	Not given	4 doses salvarsan
2297	"	(12 13, '16)	Syphilis (3)	6 mos., mercury pills
2343	"	(12 13, '16)	" (1)	Local
2417	"	"	"	6 doses salvarsan
30	"	"	" (3)	Mercury pills, 3 yrs.
587	"	"	Not given	3-4 doses salvarsan
2438	Negative	(2 1, '17)	Syphilis	Not given
			Not given	4 doses neosalvarsan
			Not given	Not given

OTHER TESTS.

No.	DATE	RESULT
2239	12 14, '16	Mod. Pos.
626	1 16, '17	Positive
2297	1 24, '17	Doubtful
2343	4 17, '16	Mod. Pos.
587	11 2, '16	Positive

Numbers 2239 and 626 were positive on other tests as were also numbers 2343 and 587, while a second test on 2297, after intensive treatment, was doubtful. We thus have evidence from other tests that two of the three "doubtfuls" with the .4 c.c. method were positive and also that two of those negative with the ice-box method were positive.

There is no further evidence for the two negative with .4 c.c. and positive with the ice box.

On the whole, we are inclined to regard the .4 c.c. results as equally reliable if not slightly superior in delicacy of reaction to the results obtained by the ice-box method.

We have, therefore, adopted it as routine for all cases where there is a reaction with the cholesterin antigen without corresponding effect with .1 acetone insoluble and have adopted the following table for a working basis.

CHOL. ANTIGEN	ACETONE INSOL. ANTIGEN	REPORT
.1 pos.	.1 pos.	Positive
.1 pos.	.1 pos. mod.	Positive
.1 pos.	.1 pos. weak or neg.	To be run over with .4 c.c. serum

.1 pos.	.4 pos. weak or neg.	Doubtful
.1 pos. mod.	.1 pos.	Positive
.1 pos. mod.	.1 pos. mod.	Pos. mod.
.1 pos. mod.	.1 pos. weak or neg.	Doubtful
.1 pos. mod.	.4 pos. or pos. mod.	Pos. mod.
.1 pos. weak	.1 pos.	Doubtful
.1 pos. weak	.1 pos. mod.	Doubtful
.1 pos. weak	.1 pos. or neg.	Doubtful
.1 pos. weak	.4 pos. or mod. pos.	Doubtful
.1 pos. weak	.4 pos. weak or neg.	Doubtful

We acknowledge the valuable assistance rendered by Mr. Aloy Soong, an assistant in the laboratory of the Boston Board of Health.

Society Report.

NEW ENGLAND PEDIATRIC SOCIETY.

THE forty-sixth meeting was held at the Boston Medical Library, January 26, 1917, at 8.15 p.m.; the President, Dr. Maynard Ladd of Boston, in the chair.

The following papers were read:

1. President's Address, Health Insurance in Relation to Pediatrics, Maynard Ladd, M.D., Boston.
2. Congenital Malformations of the Lower Bowel, James S. Stone, M.D., Boston.

3. Congenital Heart Disease, Charles H. Dunn, M.D., Boston.

4. Are Carious Teeth an Etiological Factor in Heart Disease? E. W. Barron, M.D., Malden.

PRESIDENT'S ADDRESS.

Members of the New England Pediatric Society, Ladies and Gentlemen:

First of all, I wish to express my appreciation of the honor you have conferred upon me in electing me your presiding officer for the coming year. I hope that, with your hearty coöperation and support, the New England Pediatric Society may continue successfully to further the interests of pediatrics in this community.

There is at present, as you all know, a widespread and powerful movement to force, upon this and about twenty other states, medical insurance for workers earning less than \$1200 a year. As this proposed legislation seems likely to apply eventually not only to the wage-earner, but to his family as well, it is fitting that we should study carefully the relation which such insurance may have upon the practice of pediatrics, and the position which we, as pediatricists and as representatives of the staffs of hospitals for children, should take in reference to the proposed legislation.

The movement has acquired such momentum, and the arguments in favor of it, from the point of view of the wage-earners, are on the surface so plausible, that it seems more than likely that in this state at least, some sort of a bill will be passed eventually. Once upon the statutes, it will be difficult to make amendments to the law, and its major provisions, at least, will be foisted upon the community and the medical profession whether we like them or not.

No one, so far as I can see, has as yet claimed to have a vision of the future so prophetic as to give anything like a definite conception of the changes which will inevitably result in the practice of medicine. It is safe to say, however, that the present bill, if passed, will cause a tremendous upheaval in the relations of physicians to the public. It seems likely that public sentiment will support the idea. The public will not champion the cause of the medical profession against its own interests. On the other hand, physicians, as a whole, are likely to acquiesce and even further the movement if they are convinced it is in the interests of public health.

Arguments for and against the bill, to carry weight, must be based upon its effects upon the insured. Individual interests of physicians will be sacrificed if for the good of the people. This situation we may as well accept. It is, however, our right and duty to bring before the public our experience in handling the complicated problems connected with the public health, and to forecast, so far as possible, the extent to which the radical and socialistic measures provided in the act will benefit or injure the public. We have a right to influence the provisions of the bill in its formative stage, so that, if enacted, it may prove advantageous to both the public and the medical profession. The desire to enact such legislation is so keen on the part of those favoring it, that a strong presentation of the rights of the medical profession at this stage is likely to be heeded.

In the last four years the Social Service Department of the Boston Dispensary has investigated the economic condition of more than 75,000 persons applying for treatment. If the income of the work-

ing children is excluded, only 3.5 per cent. of the wage-earners had an income of over \$1000. In other hospitals there is probably a larger percentage of relatively well-to-do people treated, but no one would question the fact that for practical purposes nearly the whole clientele of the Boston hospitals for children would, by the passage of this insurance bill, become subject to the provisions of the act if families of the insured are to be included.

If the need has existed in the past, by which this immense population has been forced into hospital clinics to obtain the best of medical care in special lines, that same need will exist in the future, medical insurance or not. These patients come to specialists, partly because they cannot afford to employ us in a private capacity, and partly because the special skill and facilities for diagnosis and treatment cannot be obtained from the type of general practitioners who, undoubtedly, would be registered on the panel of physicians entitled to practice under the insurance act. It is difficult to foresee how the hospital staff as a whole could, with their arduous duties as teachers in medical schools and visiting physicians in house and out-patient clinics, find time to care for the insured class as panel physicians. If, then, the children of the insured continue to be treated as hospital patients, in what relation will the hospitals stand to the new insurance law? This is a question of very vital concern to all of us. If the hospitals as such should be enrolled on the panel, they should be entitled to remuneration for services performed, whether in the house or out-patient departments, just as the unattached physician will be. This would appear to render necessary contract service between hospitals and the carriers, which would place a considerable part of the hospital clinic upon a pay basis. Such contracts would probably bring in considerable incomes to offset the deficits which now make our hospitals a burden on the charitable public.

If the insurance commissioners enter into contracts with hospitals for the care of the children of wage-earners, it would seem reasonable to suppose that the remuneration would have to be at a much lower rate per visit than a private physician on the panel could afford to accept for his services. In a community like Greater Boston, therefore, would not the economic effect of such competition tend to increase greatly the size of the clinics at the expense of the general practitioner? As the staffs of specialistic hospitals are necessarily limited, it is reasonable to suppose that these would gradually develop a hospital caste still more at variance with that portion of the profession which is not affiliated with hospitals than now is the case, with a chance for the injection of medical politics incompatible with the dignity of the profession or the ultimate interests of the public.

The proposed law would provide for supervision of all works performed by the insurance commissions, whether by panel physicians or contract hospitals. If, therefore, the major part of hospital practice is to consist of insured patients, the hospitals are at once brought under direct supervision by a state body, with all its concomitant possibilities of political activities, which would make present medical politics look like child's play in comparison. When the political game is played the public generally suffers. Is there anything in the present bill which guards against such an evil?

It would be a short-sighted and selfish position

for us to assume, because the majority of us here probably derive our income from patients earning more than \$1200 a year, that we need not be concerned with the outcome of this medical insurance act. Directly or indirectly, every man of us will feel its effect. The disturbing thought that no one can foresee the way in which it will work out, that the bill is framed with very little consideration for the experience or feelings of the medical profession, that there is not the slightest guarantee that the public will get better service than under the present constantly improving conditions of medical practice, make the subject one which, in my opinion, should be very thoroughly considered and discussed by every medical organization in the State.

Specific provision has been made in the insurance bill now before the legislature for the care of the families of wage-earners. This appears to be a logical sequence of the argument in favor of insuring the wage-earner, for the object of medical insurance is to prevent poverty and suffering on the part of the limited wage-earner and his family. To limit the benefit of the act to the wage-earner himself by no means insures the family against the devastating economical effects of illness. A wage-earner with a wife and four children, for instance, is more likely to suffer financially through the illness of the wife and children, than through failure of the health of the wage-earner, and if this social problem is to be solved by medical insurance, is it not of equal importance to include the family as well as the wage-earner himself? An act which protects the workers alone seems likely to fall short of the social need which underlies this sociological movement. If adopted at all, it would seem reasonable to provide for the larger requirements of family practice. If the present bill recognizes this need, the hospitals and dispensaries for children immediately come within the scope of the act, and careful consideration of the details of the law now is desirable.

The parts played by the children's hospitals and dispensaries, in proportion to the total of hospital practice, is very great. The burden of adequate maintenance and support for these institutions is enormous and is borne by a small proportion of the population. If this medical insurance is to become a part of our social organization, supported by the State, the employer and the wage-earner should similarly contribute to an insurance fund which should provide means for proper medical care of the wage-earner's family. As it is now, this burden is borne, for a very large portion of the community, by the hospitals alone, through private philanthropic support. The hospitals, under the proposed acts, may be entitled to compensation from the carriers for services rendered to insured wage-earners, and even though the rate of remuneration to be decided upon may be small, as compared with private fees, there is no doubt that the total amount received under the act might prove a considerable and thoroughly justified source of income to the hospital. There is nothing, however, in the act at present which makes compensation *mandatory*. This seems to me a serious defect from the hospital point of view. The wage-earner and his family may choose from the panel his choice of physicians. If hospitals are enrolled on the panel as organizations of specialists, it is reasonable to suppose that its present clientele will continue in large part to apply to them for medical services. If this service

is not by law entitled to just compensations, the carriers escape the responsibility of paying for services, for which they would be responsible if rendered by private panel physicians. The hold of our hospitals upon their patients depends more upon the advantages they offer for scientific diagnosis and specially skilled treatment than upon the fact that the treatment is free. Under the proposed legislation the insured would be entitled to free medical care under any circumstances. It is probable, therefore, that the same class of cases which is now appropriate to hospital care, whether in house or out-patient, will continue to apply for treatment. Unless the law makes compensation to the hospitals mandatory, it would seem as if the natural tendency of the carriers would be to shift as much work as possible upon the hospitals so as to reduce to the minimum their responsibility for sick benefits. The result of such a tendency would obviously be to make the hospitals an indirect and involuntary contributor to the insurance fund, instead of a just beneficiary for services rendered. In other words, the State, in its efforts to conserve the health of the children of the insured, would put itself in the position of forcing private philanthropy of the few who support the hospital, to assume the financial responsibility which in justice should fall upon the State, the employer and the wage-earner.

To compensate hospitals for services rendered at the request of the insured, would be equitable and just and on a plane with the tax which the public pays in support of its public school. It would ultimately place the hospitals upon a much sounder financial basis than they can ever obtain under the present system of private enterprise and philanthropy.

Any plea for mandatory compensation to hospitals for services rendered to the families of the insured, will be open to the same criticism and objections on the part of the medical profession which may be raised against the bill, however worded or limited. If, however, by force of circumstances and public opinion the State is determined upon the experiment so radical and socialistic as a medical insurance act, it must be framed in such a manner as to be consistent in theory and equitable in operation. The bill presupposes that the worker earning \$1200 or less cannot afford to suffer through illness the financial loss of his income, which admits no contrary argument. It also presupposes that when the wages continue to be paid by provisions of the act, the wage-earner is still unable to meet through his wage-benefit the expense of his medical care. It is equally logical to assume that he cannot afford to meet the expense of the still greater possibilities of poverty caused by illness in his family. If he cannot afford to meet the expense of his own illness, with wages continued, we must admit his inability to provide for proper medical care for his family.

It seems to me that the promoters of this bill have set the standard of the man who needs insurance to protect him against poverty much too high. There is much to be said against the arbitrary limit which has been placed at \$1200 a year. It is not clear that any distinction is made between the single man earning \$1200 a year and one with four or six dependents. There must be some wage so low that the margin of profit for the emergencies of illness would be so small that no private physician of any worth could afford to render medical services for the amount the wage-earner could pay.

Medical insurance for such a class would be a distinct advantage to the physician in general practice as well as the wage-earner. The point at which compulsory insurance should become operative is one which, I think, deserves more discussion than has been given it. Personally I believe that the proposed standard of \$1200 a year is so high, that it will work great injustice to a very large element in the medical profession, whereas, if the limit was materially lowered to a class which shows no profit to the private physician, a large part of the opposition to the bill would disappear.

Whatever the final decision in regard to this level of compulsory insurance may prove to be, the important point which I would emphasize is the fact that the present bill fails to safeguard the interests of the greatest of all organizations for preserving the public health, the incorporated hospitals which are independent of state and municipal aid. To my mind it is only reasonable and fair that compensation which they render to the insured and their families, should be mandatory and on such a scale that their efficiency may continue and grow so as to meet the ever-increasing demand upon their resources. The welfare and efficiency of the medical profession in the State is directly connected with the prosperity and efficiency of the hospitals. Both as private physicians and as staff physicians, it is our duty to consider with great care the effects upon the hospitals of legislation so radical and revolutionary as the proposed medical insurance act.

CONGENITAL MALFORMATIONS OF THE LOWER BOWEL.

BY JAMES S. STOSE, M.D., BOSTON,
Surgeon to The Children's Hospital.

THE records of about sixty cases of congenital malformation of the lower bowel seen at the Children's Hospital show certain facts.

The Children's Hospital treats about as many cases of atresia of the anus associated with some abnormal fistulous opening of the bowel as it does cases of complete imperforation.

I do not believe this represents the real frequency of occurrence. A complete imperforate anus or rectum causes death within a few days unless relieved by surgical intervention. Many babies thus are either cured or die without ever coming to a hospital. The cases in which there is an abnormal opening of the bowel live, and in time are brought into the larger hospitals because the conditions are puzzling.

The babies brought in with atresia of the anus or rectum present a great variety of conditions. In some there is no evidence at all of any anus, the blind end of the bowel lies well above the brim of the pelvis. In others there is only a relatively thin membrane separating the bowel above from the normal anus below. Between these two extremes there is every intermediate gradation.

Partial occlusion of the rectum by a congenital membrane is occasionally seen. The finger pushed through the membrane in one such case in a baby about four months old, cured the constipation so promptly and so effectively that the opposite wall of the room did not escape.

One of the most persistent cases of stricture of the rectum occurred in a baby first seen when 48 hours old. A few hours before a complete membranous obstruction had broken through spontaneously. At that time nothing abnormal could be felt in the rectum. But for over a year this child needed constantly repeated dilatation of the cicatricial stricture which resulted about three-quarters of an inch inside the anus.

Cases of atresia of the anus associated with rectal fistulae of various forms, which are rarely seen in the practice of any individual, come often to the Hospital. The first child with this condition was a girl of five years. There had been no urgent symptoms until she ate a number of cherries, stones and all. The stones had to be pushed along manually through the fistulous tract which led from the rectum and the opening just behind the vagina.

ATRESIA OF THE ANUS WITH RECTO-PERINEAL FISTULA.

The dimpling and pigmentation of the skin at the normal location of the anus are well shown. An ordinary silver probe is introduced into the congenital fistula, which extends back to the rectum. The patulous opening of the vagina, the absence of the fourchette, and the rounding of the anterior edge of the perineum are well shown. This case is typical of the many in which the opening is in the anterior part of the perineum.

Since then many female babies have been brought in with fistulae opening at the anterior edge of the perineum or in the lower posterior vaginal wall. This condition is one which does not necessarily interfere with life if left absolutely alone.

A few years ago a patient presented herself at the Boston Lying-in Hospital, with the rectal opening well up on the posterior vaginal wall.

Many such anomalies are recorded among women, some of whom have been really more or less ignorant of the extent of their deformities. There have been no urgent symptoms, their mothers have said nothing to them about the deformity, and the girls have grown up in more or less ignorance of the fact that they were not entirely normal. Marriage and childbirth

have followed,—the true condition being discovered by the physician delivering them.

A number of male babies have been brought into the Hospital because of the passage of feces through the penis. In some cases these babies have presented urgent symptoms of obstruction of the bowel. In one such instance the child was brought in when twenty-one days old. During that time all meconium feces and gas had been passed through the penis. There was absolutely no anal opening. In other cases there has been a fistulous opening in the perineum close behind the scrotum.

ATRESIA OF THE ANUS WITH RECTO-PERINEAL FISTULA.

The long congenital fistula leads back to the rectum at the side of the irregular raphe of the perineum. Posteriorly the puckering of the skin is seen at the normal location of the anus. This illustrates the type often seen in boys.

In order to understand the congenital malformations of the lower bowel, certain embryological facts must be kept in mind. These I will state in a very general way.

The anus develops in the following manner: The anal membrane, formed by the growing together of the ectoderm and endoderm and the pushing aside of the mesoderm, appears in the third week of fetal life. During the following fortnight this membrane becomes depressed to form the anal pit. Meantime the allantois grows out as a diverticulum from the ventral wall of the gut. A part of this later forms the urachus, a part of the urinary bladder, while the short, wide portion nearest the bowel is called the urogenital sinus. Into this empty the Wolffian ducts, the ducts of Müller, and, secondarily, the ureters. The lowest part of the gut nearest the urogenital sinus, is the cloaca, the common termination of the genitourinary system and of the intestinal canal. The anal pit is formed directly opposite the cloaca. In man the cloaca becomes divided into a ventral passage, the true urogenital sinus, and a dorsal canal, the rectum. The partition which sepa-

rates these two passages, and which ultimately becomes the perineum, is formed by the growth of three ridges or folds, one pushing down from above from the junction of the urogenital sinus and the gut, the other two growing inward, one from each lateral wall of the cloaca. The anal pit shares in this division, the posterior part remaining the anal pit proper, the anterior part forming the orifice of the urogenital sinus. The division is complete by the fourteenth week of fetal life. The anal pit deepens, the anal membrane being thereby approximated to the end of the bowel. In the fourth month the anal membrane breaks down and disappears, leaving the lower end of the intestinal canal patent.

Owing to defects in development, occurring in early fetal life, four distinct types of congenital abnormality of the anus and rectum are recognized.

In the first type the anal pit or depression is not formed as is normal. There is then an absence of the anus. In the second type of cases the anal membrane persists. There is then no connection between the bowel and the anus. There is an imperforate anus or rectum. A similar condition may also be due to defective development of the rectum itself. In the third type the anal membrane disappears only in part.

DIAGRAM 1. shows the development opposite the anal pit (AP) of the cloaca (C) at the lower end of the intestine (R) into which empty also the primitive Wolffian duct (WD) and the duct of Müller (MD), and from which the allantois leads out to the umbilicus.

DIAGRAM 2. shows the differentiation of the allantois into three portions: the urachus, the bladder (B) and the urogenital sinus. The beginning division of the cloaca into an anterior and a posterior portion is also indicated.

DIAGRAM 3. shows the further development in the male, the Wolffian duct (WD) becoming the vas deferens, and the duct of Müller becoming the insignificant sinus pocularis (SP) or uterus masculinus.

DIAGRAM 4. shows the corresponding development in the female. The Wolffian duct becomes the insignificant canal of Gartner, while the duct of Müller (MD) becomes subdivided into the vagina, uterus and Fallopian tube.

In each of the last two diagrams the development of the perineum is complete. By growth downward from the point between the duct of Müller and the rectum and by growth inward from the two sides, the perineum (P) is formed.

There is then a congenital stricture of the rectum. In the fourth type the partition between the urogenital sinus and the rectum does not develop normally. In certain cases the fold which should grow downward from the junction of the urogenital sinus and gut to unite with the folds pushing in from the sides, may be defective. Under these circumstances there remains a communication between the rectum and the bladder or urethra in the male, or between the rectum and vagina in the female. These malformations are usually associated with imperforate anus, because the sputum, which divides the rectum from the urogenital sinus, is normally complete before the anal membrane disappears. It is perfectly possible that the failure of the anal membrane to disappear may be due to the fact that an abnormal communication persists, giving an exit from the rectum. Presumably, after the disappearance of the anal membrane any abnormal communication between the rectum and the bladder or vagina would tend to close spontaneously. In other cases the fold growing from above develops normally, while the folds from either side of the cloaca may

unite irregularly or incompletely. The true anus does not develop. The abnormal fistulous opening in the anterior perineum implies a lack of development of the anal pit associated with a partial failure of union between the sides of the perineum. The location of the abnormal opening of the rectum is presumably determined in good part by the development of that portion of the perineum which grows down from above. Thus, as just stated, when this portion is markedly undeveloped, the bowel opens into the bladder in the male or into the upper vagina in the female. If the abnormality is due to defective fusion of the three parts of the perineum, the upper and the two lateral, then the opening of the rectum is lower down, either in the lower vagina or in the perineum, or, in the male, in the urethra.

The abnormality is seen more commonly in the female than in the male. This may be due in part to the fact that in the female the duct of Müller which develops, is differently situated from the duct of Wolff, which in the male develops into the vas deferens,—the duct of Müller remaining undeveloped. In the male the abnormal opening, if external, may be situated anywhere in the median line of the perineum or scrotum, in the peno-scrotal angle, or the under surface of the penis; or if internal, at any point in the bladder or urethra.

Among the reported cases in males, however, the most common point of external opening is in the anterior part of the perineum, at the base of the scrotum, or in the scrotum or peno-scrotal angle, while the internal opening is usually into the bladder, much more rarely into the urethra, near the peno-scrotal angle. In females, the most common point of opening externally is at the posterior edge of the vulvo-vaginal orifice. Internally, the opening may lead into the vagina. The interposition of the vagina prevents an opening into the bladder or urethra in the female.

The accompanying diagrams may give a clearer idea of the conditions. They are taken largely from Heisler's "Embryology."

The most common location of the opening is thus in the anterior part of the perineum in both sexes. Presumably the fistula is situated most frequently along the line of junction of the three component parts of the perineal body. The frequency of the types of malformation among reported cases undoubtedly depends chiefly on the risk to life of the various forms.

In certain cases, while the anus is normal, the development of the partition between the gut and the urogenital sinus may be imperfect. This condition is more common in the female than in the male. In this manner are to be explained the valve-like openings which have been reported connecting the rectum and vagina. In the same way, perhaps, may be explained the cases of rupture of the posterior vaginal wall into the rectum, resulting from what must be

under normal conditions insufficient trauma to account for such an accident.

The symptoms vary greatly with the age of the child. In young babies the malformation is not apt to give rise to serious trouble because of the soft character of the feces. In older children, as the movements become more solid the difficulty of defecation increases. Dilatation of the bowel above is apt to occur, and, of course, more serious complications may arise. The chief dangers are obstruction of the narrow outlet by some foreign body or particularly hard fecal mass. In those cases in which the bowel communicates with the bladder or urethra, the dangers of urinary obstruction or infection are always present.

Cases in which there is no opening of the bowel, demand immediate operation. The perineal route should be chosen in all cases in which distinct bulging of the lower bowel can be felt below. The one essential point in the operation is to secure firm hold of the lower bowel and sufficient mobilization of the lower bowel before it is opened. Unless these precautions are taken, the minute the distended bowel is opened it at once collapses and recedes, and all the tissues are completely smeared and rendered unrecognizable by the thick mass of meconium which escapes. In cases in which no bulging mass of bowel can be felt in the perineum or with the finger inserted in the anus, it is far wiser to open the abdomen above. In many cases the blind end of the bowel lies free within the abdomen and sufficiently movable to allow it to be brought down easily to the anus, even when any attempt to reach it from below would be entirely vain. In other cases where the rectum is more fixed, there may be a gap in the bowel so wide that it is impossible to reach the blind end from below, or even at the first operation to push the blind end down from above. Under these conditions, the sole resort must be a colostomy.

In other cases still, in addition to the malformation in the rectum, there may be congenital occlusions higher up in the bowel. In some of these cases an anastomosis will give a chance of cure. In other cases, a large portion of the bowel is defective. I have seen a number of cases in which the esophagus, stomach, duodenum, and a couple of loops of jejunum are perfectly normal, and in which the rest of the small intestine, appendix, and all of the large intestine, down to the rectum, exist in miniature. The extent of this rudimentary condition of the bowel varies considerably, but where it exists, the lack of development is usually so great as to render life absolutely impossible. There is not enough bowel from which absorption of food can take place. In the less extreme cases an anastomosis may be performed. In most cases, even if successful, this would merely substitute death by starvation for death by obstruction. The need of primary abdominal operation cannot be urged too strongly in the cases in which distinct

CASE OF ATRESIA OF THE ANUS.

Recto-vesical fistula. Complete absence of the penis. There was a needle-point opening in the perineum through which a few drops of urine escaped. The puckering of the skin is seen at the normal location of the anus. This illustrates an extremely rare combination of anomalies.

bulging in the perineum cannot be felt. The children, at best, are weak, are suffering from intestinal obstruction, and many of them may have other malformations. The factors of loss of time, of hemorrhage, of shock, and of added risk of sepsis, are usually enough to turn the scale against the child in cases in which a primary abdominal operation might have been successful. The risk of wounding the bladder in these cases is very great unless the rectum can be easily felt.

Cases in which, in the male, there is an opening between the bowel and the bladder or urethra are not as extremely urgent as are the cases of complete obstruction. Boys have been brought into the hospital, three weeks old, where all the feces and all the urine were passed through the urethra. Of course this condition cannot go on indefinitely. Sooner or later feces will enter the urethra, become caught there, and then there will be not only obstruction of the bowel, but obstruction to the passage of urine.

In girls, where there is a fistulous opening into the vagina, there is no great urgency for surgical intervention. During the early months of life, while the feces are soft, they are passed readily through the fistula. It is only when they become formed and abnormally hard that there is any tendency to intestinal obstruction. Under these conditions an impacted fecal mass will be formed in the lower bowel, and around this mass a certain amount of soft liquid feces and mucus will pass. Under these conditions it is common to find the bowels moving with undue frequency, but in small amount. At the same time, the constitutional symptoms of chronic obstruction are slowly developing. Surgical intervention should be postponed in these cases as long as the bowels move normally through the fistulous tract without the retention of any fecal matter above. The surgical treatment, then,

must aim at the removal of the fistulous opening, the displacement backward of the bowel to its normal location, and the closure of the perineum, from which the fistula and bowel have been removed. The difficulties of operation are considerable. In the female especially, the partition between the rectum and vagina is usually unduly thin, and the rectum has a course more nearly vertical than normal. The utmost care must be taken when separating the posterior vaginal wall from the anterior rectal wall, not to perforate either mucous membrane. It is absolutely essential that the whole lower rectum be completely mobilized. It must be dissected free for a sufficient distance upward, to allow it to be displaced to its normal position backward and held there without the slightest tension. It is perfectly certain that some sepsis will occur. In an adult it is possible to prevent a movement of the bowels for a number of days, allowing sufficient time for any perineal wound to heal. In children, this is absolutely out of the question. Because of the chance of infection and the amount of ooze of blood and serum from the wounded surfaces, a small rubber dam drain for a day or two is desirable.

In all cases in which there is a puckering of the skin at the normal location of the anus, a sphincter muscle is present. It is important to save this if possible. Of course it must be cut across, but if the incision is made from the middle of the dimpled area directly backward in the median line, no great damage is done. This holds true in operations for complete imperforation as well as in cases in which the rectum is to be transposed to its normal position, in cases with perineal fistula.

In some cases it has seemed wise, on account of the condition of the child, not to attempt at first any radical reposition of the lower rectum, but simply the formation of a new opening between the rectum and the normal anus. Under these conditions the fistulous opening remains. It may empty into the perineum, or the urethra or bladder, or the vagina. Under these conditions, most of the feces may be passed through the new opening made at the location of the normal anus, but in a number of such cases, especially in boys, the small opening between the urethra and the rectum has remained patent, allowing the passage of a small amount of urine into the rectum, and at times allowing the feces to pass into the urethra.

The risk from the passage of feces into the urethra is very decided. Not only is there the danger of cystitis and consequent pyelitis, but there is also the risk of obstruction of the urethra, which in one case of a boy three years old led to a rupture of the urethra and extravasation of urine.

The question will naturally arise as to the advisability of a temporary colostomy in these cases, while the operative wounds made below

are allowed to heal. In older children this may be wise. In infants colostomy involves very serious risks. Prolapse of the bowel through the wound is common. Infection of the intestinal tract may occur.

As to after-care, a warning should be spoken. Our statistics show a very considerable ultimate mortality of atresia of the anus. In this mortality, various factors must be considered. Many children have, in addition to the malformation of the anus, other congenital troubles, perhaps congenital heart trouble, which may weaken them.

ATRESIA OF ANUS.

Recto-perineal fistula. Complete exstrophy of bladder and epispadias. Double inguinal hernia. A combination of malformations which is fortunately rare. It is noteworthy that the mother of this boy had later a baby with spina bifida, but that this baby was by her second husband.

Recurring stricture of the rectum with chronic intestinal obstruction often comes on so insidiously as to be neglected.

Infection of the intestinal tract as well as infection of the urinary passages are to be considered and guarded against.

The necessity of skilled after-care for many months cannot be emphasized too strongly.

DISCUSSION

DR. MIXTER: Dr. Stone has asked me to say a little something about exstrophy as one of the congenital malformations of the bladder which we meet with at the Children's Hospital. I think this malformation can best be imagined by introducing a knife at the meatus, passing it through the urethra to the bladder and along the urachus to the umbilicus. If, now, the incision is carried forward and all the structures anteriorly are divided, the condition represents a complete exstrophy—epispadias is always present, the symphysis is divided and the ends separated, the posterior bladder wall extrudes, revealing the uterus at the lower portion and the divided umbilicus forms the upper margin. Double inguinal herniae are present.

The question as to what a physician should say

when a case of exstrophy is brought to him is to me a very puzzling one. It luckily is of rare occurrence, about once in 50,000 children, but the mortality of the untreated cases is very high. It is estimated that 90% die in infancy or early childhood, and when the rare case grows to adult life, existence is perfect misery with the constant dribbling of urine, tenderness of the bladder, etc. On the other hand, what has operation to offer? In any operative procedure, to be satisfactory, you have to obtain some kind of sphincteric action for the control of the incontinence. That gives a fundamental objection to all the plastic operations on the bladder itself. On the other hand, the transplantation operations to introduce the ureters into the intestine is followed by a very high mortality, from anuria and from pyelonephritis. We have had eight cases, I think, at the Children's Hospital, and the infants that Dr. Stone reported the other day, and of those cases four died within several weeks after operation; three died before the end of the year, and only one is at present alive, seventeen months after operation. This child was a case I operated on a year ago last September. Last April I saw the youngster, and up to that time he had been fairly well.

Then he developed a very severe pyelonephritis with a large amount of blood in the urine passed by rectum and his general appearance indicated a rapidly fatal termination. He weathered that attack however, and at the present time is in good shape. It is possible that he will have another attack of pyelonephritis in the future and it is still impossible to foretell the ultimate outcome.

It is probable that in the future we can decrease the very high mortality. Dr. Cabot has suggested the use of vaccines in immunizing prostatic patients before operation to lessen the chance of pyelonephritis. This procedure might be found applicable before transplantation in exstrophy. A two-stage operation has been suggested,—first implanting the right ureter, for example, into the caecum and later the left into the sigmoid. It may even be found that the insertion of the ureters into the small intestine fairly high up where the tract contains fewer organisms, is feasible.

Even with the high mortality of the transplantation operation it seems to me no greater than the mortality you are bound to have if you leave the cases untreated: I think that it is at the present time the only satisfactory operation in certain cases. If you leave the children alone and they do grow up they are in perfect misery. If you operate on them they are pretty comfortable, as is this youngster that I spoke of. He is at present voiding by rectum 4 or 5 times a day and he gets up about once in the night. I think that the time preferable for an operation would be somewhere between three and four years, before the children go to school where they prove very objectionable to their associates. I believe that as a preliminary measure it would be well in cases in which there is definite separation of the symphysis that some orthopedic appliance should be used to bring the pubic bones together.

DR. STONE (in closing): The only thing to add is that many cases of imperforate anus have a communication between the bladder and the rectum which the physician or surgeon is apt to attribute to some mistake in operative technic. It should be clearly

understood that while this may be the case, in the majority of instances the communication is but a part of the congenital defect.

ABSTRACT OF PAPER ON A CASE OF CONGENITAL CARDIAC DISEASE.

By Charles Hunter Dunn, M.D., Boston.

The clinical report was that of a case in which the diagnosis of congenital cardiac disease was obvious from the physical examination of the heart. The presence of a palpable systolic thrill, of persistent cyanosis, and of cardiac enlargement, suggested the presence of pulmonary stenosis. The fact that the child survived for fifteen months suggested the presence of some additional compensating lesions, either defective interventricular septum, or open ductus arteriosus. The absence of a humming-top murmur, or the transmission of the murmur into the vessels of the neck suggested that the additional lesion was defective interventricular septum rather than open ductus arteriosus. The characteristics of the temperature chart, the positive von Pirquet reaction, and the presence of the palpable mass in the intestine suggested the diagnosis of chronic tuberculosis with a primary lesion in the intestine, and involvement of the mesenteric lymph-nodes, with the additional possibility of tuberculous peritonitis. The clinical diagnosis, therefore, was as follows:

- Pulmonary stenosis.
- Defective interventricular septum.
- Chronic intestinal tuberculosis.
- Chronic tuberculosis of the mesenteric lymph-nodes.
- Possible tuberculous peritonitis.
- Rickets.
- Terminal bronchopneumonia.

At autopsy the heart showed very marked enlargement. The point of origin of the aorta and pulmonary arteries, respectively, were reversed, the aorta arising in front and to the right, and the pulmonary artery behind and to the left. The foramen ovale was entirely open. The tricuspid and mitral valves were normal except for the widening of the orifices produced by the dilatation of the ventricles. There was some hypertrophy of the wall of the left ventricle, and marked dilatation of the cavity of the right ventricle without notable hypertrophy of the walls. The aortic orifice was situated, not in the left ventricle, but in the right ventricle somewhat further forward than the normal position of the pulmonary orifice. It was otherwise normal. The pulmonary orifice was situated in the left ventricle in the position normally occupied by the aortic orifice. It showed marked stenosis. There was an oval opening in the ventricular septum, 5 cm. in diameter, situated in the usual position of the lesion, namely, just below the normal position of the aortic orifice.

The principal interest in this case lies in the transposition of the great vessels, which is a comparatively uncommon lesion in congenital cardiac disease. There are two forms of transposition of the great vessels. In one form the aorta arises in front and to the right, while the pulmonary artery arises behind and to the left, but nevertheless, each vessel opens from its proper ventricle, the aorta from the left ventricle, and the pulmonary artery

from the right ventricle. This form is called corrected transposition.

In the other form, not only is the position of origin of the great vessels reversed, but the aorta opens from the right ventricle, and the pulmonary artery from the left ventricle. This is called complete transposition, and is the form which we have here. Complete transposition of the great vessels is a comparatively rare lesion in congenital cardiac disease. In most of the reported cases the lesion has been accompanied by other lesions, particularly by pulmonary stenosis and defective interventricular septum, as in this case. When this combination occurs, the diagnosis of complete transposition is impossible, the only physical signs being those of the accompanying additional lesions. There are a few reported cases in which the complete transposition was the sole lesion. In these cases the only clinical manifestation was persistent cyanosis, there being no murmur and no notable cardiac enlargement.

The most plausible explanation of the lesion is that of Rokitsansky. In the conus arteriosus which forms the upper part of the primitive aorta, the formation of the transverse aortic septum places the lumen of the aorta in front. The torsion which brings the opening of the aorta behind is due to a kinking in the bulbus cordis, which forms the lower part of the primitive aorta and pulmonary artery. This torsion is represented by the spiral arrangement of the septum in the bulbus cordis. If this normal kinking and torsion does not occur, or is slightly reversed, the aorta will arise in front and to the right, the pulmonary artery behind and to the left. In the first form of transposition there is a sympathetic adjustment of the interventricular septum in its union with the aorta-pulmonary septum, which causes each great vessel to open into its proper ventricle. This form is called by Rokitsansky "corrected" transposition. In the second form the interventricular septum unites with the malposed aorta-pulmonary septum without sympathetic adjustment, causing the aorta to open from the right ventricle and the pulmonary artery from the left ventricle. This is called "complete" transposition.

The remarkable feature of this case is that the child should have lived so long, especially with the additional handicap of chronic abdominal tuberculosis. The transposition of the great vessels must produce a very serious disturbance of the circulation. The venous blood returning to the right side of the heart from the venae cavae is sent right out again through the aorta, while the aerated blood returning to the left side of the heart from the lungs is sent out again through the stenosed pulmonary artery. The only way in which any venous blood can be aerated is by passing through the open foramen ovale, or open ventricular septum into the left side of the heart, often being sent out through the narrowed lumen of the pulmonary artery. With lesions of this extent, it seems quite remarkable that the patient should have attained the age of fifteen months.

ARE CHOLERA TYPH A CAUSATIVE FACTOR IN ENDOCARDITIS?

By Elmer W. Barron, M.D., Boston, Mass.

This paper is a summary of the study of the recorded physical examinations and personal histories

of 218 children operated upon for either tonsils or adenoids or both at the Forsyth Dental Infirmary during the past few months. The examinations are routine previous to the administration of anaesthetics, but the attempt has been made to make them as thorough and complete as possible.* The histories have been taken with considerable detail.

The statistics here presented are intended as a preliminary report of some of the work now being done at the Forsyth, and I have no intention of answering the question which is the title of this paper, nor shall I make any attempt to draw conclusions.

Furthermore, I shall make no attempt to prove that a certain per cent. of these children had heart lesions, and no data for that purpose will be given. The results of the examination simply represent the opinion of the examiners, at one examination, that such lesions existed, and no case has been included except those thought definitely to present sufficient evidence of organic lesions.

In working out a form to be used in obtaining the histories, pains were taken to include every disease which could be found given as an etiological factor of endocarditis in the works of several different authors. Nowhere did I find any mention of carious teeth, as such, unless they be included under the general statement with which nearly every list is concluded, "that pyaemic and septic conditions may be the cause of endocarditis." That carious teeth may furnish a primary source of infection in some cases of tonsillitis and rheumatic fever, to which endocardial lesions are obviously secondary, is a phase of the question, impossible of proof, but not to be forgotten.

It is to be remembered that none of these children were operated upon because of any abnormalities, found at their examinations, or because of their past histories, but only for dental or nasopharyngeal indications, so that they are in no sense selected cases, from the point of view of the internist.

There have been no pathological examinations of any of the tonsils after removal. When they have been found to be obviously diseased a history of tonsillitis has usually been obtained.

Of the 218 children, 51, or 23%, were found to have endocardial lesions. There were incomplete records in five instances, two with heart lesions and three without, and these cases were excluded, so that the corrected figures still give 23%.

Table I shows the number of illnesses from which a heart lesion might have been acquired with which these 49 children had suffered; growing pains, so called, are included under rheumatic fever, and under grippe has been placed one child from whom was obtained a story of a "very severe cold" lasting a considerable length of time.

Table II shows the total number of carious teeth each child had, the total extractions (badly carious) and the total number of cavities filled (not badly carious).

Measles is said to cause endocarditis only very rarely; pertussis and mumps I was unable to find mentioned in any text-book specifically as causes, except that they might be included under a general statement that any infection may be a causative factor; and pleurisy with effusion is certainly rarely followed by endocarditis. Chicken pox is mentioned by a few authors.

* The examinations were made by the writer and Dr. Edward Martin, to whom I feel greatly indebted.

There are 17 of the 49 who had no disease so far as could be ascertained or only one or more of those diseases just mentioned, and in Table III will be found a tabulation of them with the number of teeth extracted, filled and total carious. Seven of the seventeen. (Nos. 17, 20, 23, 25, 26, 27 and 35) had ten or more carious teeth, two (Nos. 7 and 29) had nine; two (Nos. 38 and 40) had eight; one (No. 44) six; two (Nos. 30 and 42) five; one (No. 49) four, and one (No. 48) had but one.

Three of the children (Nos. 23, 48, 49) had had no illness, of whom one (No. 48) had but one carious tooth; one (No. 49) had four extractions, and one (No. 23) had twelve carious teeth of which three were extracted. Six had had measles only; one (No. 25) had four extractions and eight fillings; two (Nos. 17, 26) had four extractions and six fillings; one (No. 29) had one extraction and eight fillings; one (No. 7) had nine fillings, and one (No. 30) had one extraction and four fillings. One child (No. 27) had had chicken pox only, but twenty-two carious teeth, of which it was necessary to extract eleven; one (No. 38) had had mumps only, with eight carious teeth, six of which were extracted. One (No. 20) had had measles and pleurisy with effusion, but had sixteen carious teeth, fifteen of which were filled. Number 35 gave a history of measles, chicken pox, pertussis and mumps, but she also had sixteen carious teeth, of which ten were extracted. Number 40 had had chicken pox, pertussis and mumps with eight carious teeth, five being extracted. Number 42, measles, pertussis and mumps, with five carious teeth, two being extracted and three filled. Two children (Nos. 44, 47) had measles and pertussis, the former with three extractions and fillings, and the latter five extractions.

I hope at a later date to present a larger number of cases with more complete data.

DISCUSSION.

DR. EUSTIS: I am very much surprised at the small number of cases that give a history of rheumatism and chorea. I have no figures to compare with Dr. Barron's, but my general impression obtained from seeing the cases of heart disease at the Children's Room at the Massachusetts General Hospital, is that a greater proportion of them give a definite history of some rheumatic affection in the past. I have seen a few cases where I have been able to find no other etiological factor than badly carious teeth. I am not prepared to say though, that the teeth are the cause of the endocarditis. I think another source of error in drawing any conclusions is the great difficulty in determining whether or not a given heart has a mild degree of endocarditis, or merely has a functional murmur or some slight functional irregularity. I should like to ask Dr. Barron what his criteria were in determining whether or not a case was one of endocarditis or merely had a functional heart murmur. I have had the greatest difficulty myself in doing so, and have put myself down in black and white, only to find myself wrong a few months later. With a single examination in many cases, it is nearly impossible to determine just what the condition is.

DR. DUNN: I must confess that I have been very much impressed by all this work of Rosenow on the infectious so that personally I have become rather enthusiastic. If his views about the infections

prove to be final, it is going to have a revolutionary effect upon many of our theories, and among the diseases more affected rheumatism and endocarditis will take the first rank. Briefly stated, his theory is as follows:

Bacteria belonging to the streptococcus-pneumococcus group may in certain conditions of growth and environment, such as may be found in various focal infections, become transmuted in their cultural and biological characteristics, and may take on a selective affinity for certain tissues of the body. Now if this is so, it is certainly suggestive bearing on this action of carious teeth in endocarditis. Of course in rheumatic fever we have just the sort of chronic focal infection in which the acquirement of selective affinity is supposed especially to take place, and with carious teeth we may have the particular focal infection which leads to such conditions as endocarditis and rheumatic fever.

DR. BARROX (in closing): I cannot account for the small number of cases of rheumatism and chorea in this series, except on the theory that we have not been thorough enough in getting histories of them. We have tried to be—that is all I can say. While some rheumatic conditions may have gotten by us, growing pains is one of the things we have asked for in every case. I realize that a single examination, as has been suggested, is not always perfectly reliable, and one cannot always say whether the children have heart affections or not, and therefore, from this list has been excluded everything which might be functional. It has been the aim of Dr. Martin and myself not to include in this list anything which was not obviously a chronic endocardial lesion. It is likely, I presume, that there are among these forty-nine children some, an examination of whom a year from now might show practically normal hearts. I have presented this paper in the hope of stirring up free discussion. If we keep on with the present work we can perhaps prove something

definitely, as we have a tremendous number of children to draw from at the Forsyth Dental Infirmary. It does not seem to me that the statistics given on these charts prove anything at all. They simply suggest the possibility that carious teeth may have been the etiologic factor in some cases.

PLYMOUTH DISTRICT MEDICAL SOCIETY.

The annual meeting of the Plymouth District Medical Society was held at 11 a. m. on Thursday, April 19, 1917, at Brockton, Mass. After the discussion of important matters the following officers were elected for the ensuing year: President, Nathaniel K. Noyes of Duxbury; Vice-President, Gilman Osgood, of Rockland; Secretary and Treasurer, Alfred C. Smith, of Brockton; Reporter, Alfred C. Smith, of Brockton; Commissioner of Trials, Francis J. Hanley, of Whitman; Censors: Fred J. Ripley, Supervisor; Walter W. Fullerton; James H. Drohan; Joseph Frame; Richard B. Rand; Conneillers: A. Elliot Paine, Nominating; Frank G. Wheatley, Alternate; Gilman Osgood; Alfred A. MacKeen; Fred J. Ripley; Orator for 1918: Frank E. Wheatley, of No. Abington.

The annual oration for 1917 was delivered by Dr. Nathaniel W. Faxon of Stoughton, Mass.* Luncheon was served at the close of the meeting.

Book Reviews.

Anatomical Names. By ALBERT CHAUNCEY EYCLESHYMER, B.S., Ph.D., M.D., Head of the Department of Anatomy, University of Illinois; assisted by DANIEL MARTIN SCHOE-MAKER, B.S., M.D., Professor of Anatomy, St. Louis University. New York: William Wood and Company. 1917.

Those who are familiar with the author's unique atlas of frozen sections will welcome his latest contribution to the science of anatomy. This volume is a historical study of anatomic nomenclature, with especial reference to the Basle *Nomina Anatomica*. In his preface he sketches this history, and outlines the work of the commission of the German Anatomie Society, to whom we owe the Basle nomenclature. The book consists first of a translation of the original report of this Commission, written by Dr. William Hiss, with the tabulated names of the new terminology, and an appended explanation of the plan of their adoption. This is followed by a series of biographical sketches by Roy Lee Moodie, A.B., Ph.D., of the proper names associated with the history of anatomy, especially those preserved by their application to structures in the body. These sketches are arranged in an alphabetical list, from Abano to Zsigmondy. The second half of the volume consists of an alphabetic index and synonym register of B. N. A. terms, with their principal Latin and English equivalents.

In these days when anatomic nomenclature is still plastic, though no longer chaotic, the value of such a work to teachers and students is obvious. Apart from its usefulness as a work of history, it will be found of constant value for reference. Those who regret the disappearance of the proper names of distinguished anatomists from the terminology of the science will, to some extent, find consolation in the biographic preservation of the fathers of the science in this work.

General Surgery. By ALBERT J. OCHSNER, M.D., F.R.M.S., LL.D., F.A.C.S., Surgeon-in-Chief Augustana and St. Mary's of Nazareth Hospitals; Professor of Surgery in the Medical Department of the State University of Illinois. Vol. ii of The Practical Medicine Series, comprising ten volumes on The Year's Progress in Medicine and Surgery; under the general editorial charge of CHARLES L. MIX, A.M., M.D., Professor of Physical Diagnosis in the Northwestern University Medical School. Chicago: The Year Book Publishers. 1917.

The present volume is the first since Dr. John B. Murphy's death. Dr. Albert J. Ochsner, editor for 1917, pays a glowing tribute, in the introduction, to Dr. Murphy. He outlines his character, his reputation, his personality, his ability as a teacher, and the contributions which he made to surgery. Dr. Ochsner's is an appreciation, rather than an analysis; a tribute of friendship, not a critical estimate; a man is fortunate to leave behind him, not only an honored name, as did Dr. Murphy, but also competitors and contemporaries who were invariably friends; this is not often true, even in Chicago.

Under the title of Anesthesia, the dangers of gas oxygen are emphasized; twenty-six fatalities are recorded by Teter, nine in Cleveland; Rovsing mentions thirteen others; Gwathmey knows of "twenty to forty unreported deaths." These figures are truly startling when one considers that gas oxygen has been loudly praised as the safest of all anesthetics. Apnoesia is not mentioned under the title "Local Anesthetics." The paragraphs dealing with the Carrel method of wound treatment are certainly not enthusiastic; this is unfortunate, for, notwithstanding its technical difficulties, the method is one of the greatest contributions to surgery which the war has produced.

More than one-third of the book (two hundred and twenty pages) is devoted to abdominal surgery, including hernia. Fractures cover a trifle more than twenty pages; this is a rather striking disproportion.

The book is of the familiar size, five by seven, and contains six hundred pages. It is well printed and bound and, on the whole, well illustrated. It is valuable far beyond its price, and should be within reach of every surgeon.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.50 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages may be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager,*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

CAMOUFLAGE.

THE excessive loss of the members of the medical corps in the present war calls attention to the measures that are being adopted to lessen it. One of these has been described in a recent issue of the JOURNAL in a letter from a neutral observer with the German army at the front, and no doubt the Allies have adopted the same plan, namely, to keep the surgeons away from the firing line, leaving the first-aid measures to be employed by the common soldiers for their comrades, on the battlefield, the surgeons being placed at the ambulance stations, the rail heads, and the base hospitals. Another means of preventing injury and death in the medical corps is one that applies in like measure to the other branches of the service, concealing coloration and patterning like the background the soldiers, cannon, aeroplanes and ships, the so-called camouflage of the French.

As long ago as 1896, Abbott H. Thayer, the American artist, described the principles which underlie protective coloration in the animal kingdom in an article in *The Auk*. His ideas were amplified in a monograph of 260 quarto pages with 16 colored plates and 140 figures, written by his son, and published by the Macmillan Company in 1909. This book was circulated in Europe, and has formed the basis of the efforts to make invisible the fighting forces now at war. Uniforms simulate the backgrounds, the faces of the snipers are painted, branches of trees hide the cannon from the aeroplanes, warships are made to counterfeit the sea by coloration and wave patterns.

The principle of camouflage is best understood by the artist rather than by the average citizen, for the artist is trained to reproduce nature as the eye sees it in its surroundings, under given conditions of light, and he, because of his training, gauges the effects of light and shade and pattern on distinguishability. Mr. Thayer showed that terrestrial animals are made inconspicuous by being colored darker on their backs and lighter on their bellies, when not seen against the sky. As the sunlight comes from the sky above, and most of the lighting falls on the animal's darker back, the dark color of the animal's back and the sunlight cancel each other, and thus the gradation of light and shade, that ordinarily serves to distinguish solid objects to the eye, is effaced, and the objects appear to be perfectly flat. Turn a dog lying on the ground on its back, exposing its lighter under side, and note its increased visibility. In this case the light of the belly is accentuated by the white light from above, and the dark of the back becomes darker by the shadow.

If, in addition to the arrangement of light and shade in the animal's coat, the skin mimics its nearby background in color, in pattern, or in both, its visibility to the eye of the observer is diminished. An important consideration in the study of inconspicuousness is the point of view of the observer and the position of the observed. The hawk sees the rabbit blended with the dead leaves over which it runs, whereas the fox, from his position near the ground, may see his quarry outlined against the sky, and therefore brought into sharp relief. The aeroplane must study the question of distinguishability from an entirely new standpoint; objects on the earth do not appear the same from

the sky as when viewed from the level of the ground. To the crouching lion the zebra with its stripes of black and white, imitating its background of reeds and sticks, is relatively inconspicuous so long as it is not outlined against the sky. The important factor in camouflage is, then, obliterative shading of the object, and the secondary factors are, mimicry of the background of the object in color and pattern, and the adaptation of these to the differing points of view of the observer.

At last Mr. Thayer's discoveries have taken root in this country, where they originated, and now a company of artists is at work in a camp in Connecticut studying the problems of camouflage for the benefit of the American army and navy, and it is to be hoped that results useful to the service and to the country will follow.

RECALLED TO LIFE.

A NEW journal, entitled *Recalled To Life*, is being published in England under the editorship of Lord Charnwood and Everard Cotes, and is to be devoted to the care, reëducation and return to civil life of disabled sailors and soldiers. It is to be issued periodically under the auspices of the War Office, the Pensions Ministry, and the Red Cross, and Order of St. John of Jerusalem Joint War Committee. The appeal of the journal is to those who are actively engaged in the administration of hospitals and in the conduct of local pension committees and technical institutes, and, with this object in view, each number will contain an article or articles on the treatment of some particular kind of disablement. The first article in the current number is by Sir Alfred Keogh, G.C.B., on treatment of the disabled, and is a memorandum prepared by him for the Anglo-Belgian Committee. It refers to pension arrangements, modern curative workshops, after-care of the blind, the problem of the deaf, and the provision of artificial limbs. Captain Basil Williams contributes a very full and authoritative article on pensions, in which, after a short historical summary, he gives details of the arrangements now brought into force. The Intelligence Department of the local Government Board has a report on work for disabled men in France and Germany. There is a paper by Sir Robert Jones, C.B., on "Orthopedic Surgery in Its Relation to the War." Throughout the volume are photographs of work being done by crippled

soldiers at the Military Orthopedic Hospital at Shepherd's Bush. The second number will contain reports on the recent International Conference on Disablement, in Paris.

The usefulness of such a journal can be measured only by the great and pressing need of the numbers of partly disabled soldiers and sailors, who must be provided with adequate training and facilities to enable them to return to civil life and lead normal and healthy existences.

MEDICAL NOTES.

NATIONAL BOARD OF MEDICAL EXAMINERS.—The National Board of Medical Examiners held its second examination in Washington, D. C., June 13 to 21. There were twenty-four qualified candidates, twelve of whom appeared for examination, the others having been ordered into active duty between the time of their application and the date of the examination. Of the twelve who took the examination, nine passed.

The next examination will be held in Chicago, October 10 to 18. The regular Corps of the Army and Navy may be entered by successful candidates, without further professional examination, providing they meet the adaptability and physical requirements. There will also be an examination in New York City in the early part of December.

WAR NOTES.

WAR RELIEF FUNDS.—On Aug. 4 the totals of the principal New England war relief funds reached the following amounts:

French Wounded Fund	\$244,598.00
Armenian Fund	211,615.89
Serbian Fund	123,121.90
Surgical Dressings Fund	114,489.01
Italian Fund	43,454.72
War Dogs' Fund	982.75

BOSTON AND MASSACHUSETTS.

WEEK'S DEATH RATE IN BOSTON.—During the week ending July 28, 1917, the number of deaths reported was 188, against 169 for the same period last year, with a rate of 12.69, against 9.47 last year.

There were 28 deaths under one year of age, against 25 last year.

The number of cases of principal reportable diseases were: diphtheria, 49; scarlet fever, 12; measles, 52; whooping cough, 39; typhoid fever, 6; tuberculosis, 58.

Included in the above were the following cases of non-residents: diphtheria, 3; scarlet fever, 2; measles, 1; typhoid fever, 1; tuberculosis, 7.

The number of deaths from these diseases were: diphtheria, 4; scarlet fever, 1; measles, 2; tuberculosis, 16.

Included in the above were the following non-resident deaths: tuberculosis, 2.

The Massachusetts Medical Society.

NOTES MADE OF THE QUESTIONS ASKED AT THE CONFERENCE OF THE SPECIAL COMMITTEE ON SOCIAL INSURANCE AT THE STATE HOUSE, JULY 25, 1917.

PRINTED to show the temper of the committee and the sort of questions that are asked members of the profession when they appear before a committee of the General Court.

A. K. STONE, *Chairman of Special Committee of Mass. Med. Society on Health Insurance.*

The following are the more important questions asked of Dr. David L. Edsall and Dr. A. K. Stone, many of them having been asked of each. Dr. Edsall left the room before Dr. Stone's interview.

The Chairman introduced Dr. Edsall as:

Dr. Edsall of the Massachusetts General Hospital, whom we have asked to come here and give his views on this problem of health insurance. He was good enough to come, and we shall be glad to hear what he has to say to help us in the solution of this problem.

The following questions were asked in the course of the discussion:

1. I thought the essence of this movement was that those who could not afford to get such care would do so with this legislation.

2. It is simply a question of degree, isn't it, for those who have a little, rather than for those who have nothing and now go to the charitable institutions for care?

3. When it comes to a question of health or life, why shouldn't it be an immaterial question whether a man has ten cents or a million dollars in his pocket, and why doesn't the medical profession dwindle into almost insignificance?

4. You appear as an expert on the proposition of social insurance. Are you here to protect the gate receipts of the medical profession? . . . Do you resent the question as to what you are here for? . . . If it is to protect the gate receipts, I think you are a little ahead of the game.

(The chairman interposed and said the doctor had been invited to come and give his views on the proposition.)

5. Would this tend to throw the practice under this law into the hands, we might say, of inexperienced men who have just graduated, or to the man who has been in practice for 15 or 20

years,—the bright, successful man? Where would you grade these men? How would you handle it so as to be fair toward the successful practitioner, as well as to the man who has just started out? Would it tend to throw it into the hands of those who have just graduated?

6. In my own city, while they didn't want to come out with it, there was quite a fear that it might eliminate them in a certain way, and go to a cheaper line of physicians,—that is, cheaper as to experience: those who had recently graduated would be used, and the others might be shut out.

Dr. Edsall suggested creating a board to include all the reputable physicians in the vicinity; then there would be practically entire freedom of choice.

7. You would make it large enough so the people couldn't criticize it; have enough in it so there would be a choice?

8. Do you believe in social insurance?

9. Do you believe it should be compulsory?

10. Do you believe, as a matter of legislative principle, that as soon as we can get this bill through, which we can do, we should say to a man who is struggling along on \$15 a week with ten children, "You shall separate yourself from ten cents every week"? Or should we allow him to go to —?

11. What do you think of a proposition like this: That it should be compulsory on the part of the state, compulsory on the part of the employer, but optional on the part of the employee?

12. Would you consider that a wise way rather than the compulsory?

13. A man who really wanted the insurance but refused to take it would be just where he is today. The man who really needed it the most wouldn't get it.

14. Would it appeal to the thrifty employee who was hard up financially and against his private benefit association, that while the employer and state shared the burden with him the rate would be lower?

15. Do you know people who would be affected by it?

16. In Germany and England is the rate for insurance pretty high?

17. Would it keep it high although it were compulsory?

18. Do you think this compulsory health insurance is much of an advantage for shiftless men? Is the shiftless man going to the dogs anyway? Isn't it better, rather than to help him in sickness and health, to stimulate him by keeping in the background the prospect of an almshouse in the end?

19. We must work on the proposition that a man is shiftless or he isn't. If he is shiftless, how is this going to be an accurate rendering of the situation? You may keep him in good health, but he may indulge in some other form of extravagance just as hard for his family.

20. (To Dr. E.'s remark that he would be perfectly willing to be compelled to take out insurance). Would you be quite so enthusiastic if your income, instead of being \$25,000 a year were only \$750 a year? Would you be as broad-minded?

21. Has social insurance really lengthened life in other countries?

22. Is length of life any longer today than it was 50 years ago?

23. How do you account for the fact that with the growth of medical science, we have more mental and nervous disorders today than we ever had before?

24. Are men using their heads more and their bodies less than they were 50 years ago?

25. If this were a compulsory proposition, do you think it would be a good thing to carry it out?

26. You don't think that what employers would oppose and the employees would oppose would stand a very rosy chance of going through the legislature, do you?

27. I would like to ask the doctor if, in favoring the scheme of optional insurance to the employee, it is as a scheme by itself, or as a step toward compulsory insurance?

28. If any system were started, even on a voluntary basis, would it inevitably lead to a compulsory basis?

29. The apparent statistics are that, in Germany, for instance, in 1885, when the compulsory law was started, the days of sickness averaged about 5.9 per year per member, while it has gone up now to something over 9. Do you doubt these facts or figures? Don't you suppose they are accurate? . . . You think these statistics may be all right, but are subject to question?

30. Referred to the tendency to malingering.

31. You spoke of how, if we had a system, the doctors should come into it as a medical profession. How can we find out what is economical and at the same time fair to the medical profession? I don't believe that anybody wants to be unfair to the medical profession, but it looks to me that the chance is good, if men like ourselves should get up a law, that we should be unfair to the public or to the medical profession. We should have to make a guess and would make a botch of the job. How can we get definite suggestions as to what is fair to the medical profession, and what is an economic method of handling the work?

Referred to work in hospitals and dispensaries as being cheaper than sending a man to call on a patient. Of course, if the patient is sick abed, that is another question.

32. I question whether we can get real action out of the medical profession until we have persuaded them that something is going to happen. Certain men to whom I have talked haven't shown any interest. If they get scared a little bit, they will think a little bit, but now they are apparently too busy to think. Would it be fair

for us to ask the Massachusetts Medical Society?

33. In your work at the hospital, I suppose you have come in contact with cases where it has been proposed to investigate the poverty of certain cases to see if it might be alleviated.

34. We might get facts from the dispensaries, clinics, and possibly the overseers of the poor.

35. Are you familiar with the recent legislation in California, as to insurance?

36. I would like to ask whether this is a state proposition, or a national proposition? Or whether we have got to take it up in a few states as to its feasibility, and then have the Government take it over?

37. I understand the Medical Society has a stenographer here; if they are involved in such a proceeding as ours, why can't they come here instead of our sending for them?

38. When the tuberculosis hospital was planned at Westfield, do you know whether any physicians appeared and took the ground that such a proceeding might interfere with their practice or their incomes? . . . Do you understand it has interfered with the financial returns of the medical profession?

39. Is it not possible this may cause a stimulus to medicine and prove an advantage to the medical profession, rather than a disadvantage?

40. Do you think if a medical man could be found so ignoble as to take a financial interest in his practice, that he would be justified in appearing before this committee and opposing such legislation, as it would decrease his income?

41. A decrease in the income of the profession might interfere with its proficiency.

42. Do you think length of life has kept step with the advance of medical science? Do you think that if people are living longer today, it is simply because they think they are, or because they really are?

43. Are you familiar with the subject of health insurance? Have you formed a definite opinion as between compulsory and voluntary insurance?

44. Don't you think that a thrifty man with a small income who wants to take care of himself is entitled to a system shared by the Commonwealth? Wouldn't it be a step forward?

45. To a thrifty man with a small income, a lower rate is well worth while. He could get a better rate than he can get out of his private insurance company. (Referred to the fact that the state wasn't in it for the money, whereas the private company is.)

Referred again to the "reason the medical profession is not here is because they have not scented a fear; but if it comes to a question of affecting their incomes, they will look into the matter."

46. Possibly there is not a great deal of revenue from the people with small salaries?

47. Just how can we get a report from the

Massachusetts Medical Society on this question, as to their opinion as to how medical insurance ought to be worked out? We can't make any progress along this line unless we take it in sections. If we have social insurance, what would be the proper machinery? We want to know, if we ask the medical society, how we should take action, and how much action we are likely to get.

48. What middle road are we to take between the health of the community and the incomes of the medical profession? Suppose we find a certain bill is going to increase the health of the community and cut the profession in two; are we to follow the pestle or the crowd? . . . It is pre-eminently a question of the health of the people? (Suggested bounties for physicians.)

49. There is the question of preventive medicine. There has been a great criticism of this recent bill to the effect that it did very little for preventive medicine. My whole idea is that, if we are going to have this health insurance, the first thing is to stop sickness because we want to reduce the cost of the insurance.

I should like to ask just what form of question we should put to the Massachusetts Medical Society in order to get the most comprehensive report; not tying it down to last year's bill, but thinking of next year's bill, and a bill five years from now. We want to create a new foundation and see what we can get; then see if we can get it passed after it is formulated.

50. I would like to ask, as to the operation of the law, as to the grade of physicians, or the character and quality of the physicians in the community,—what base you would start on to carry this law out? Dr. Edsall suggested that we have a panel of physicians in certain communities, and that all reputable physicians join this panel.

. . . I would like to ask whether every man who is registered should be considered one of these, and whether we should put a stipulated price on bills? Those are the things which the medical men feel, and which we should be glad to have them solve. Whether it should be a young graduate or the same price for the experienced men,—a flat rate, such as, mumps, \$2.00; typhoid fever, \$1.50, or something of that kind; something that wouldn't destroy their business. It would be a great help if they could give us some information along that line. If we could get in touch with the medical men, we could handle the question much more easily.

Isn't it also true that if this health insurance is going to happen and we don't know how to handle it, the medical profession have got to take hold of it? Everybody wants to discount last year's bill; Senator Washburn wants to hang on compulsary insurance to the employee. Somebody else wants to cut it down to a little circle of employees. Everybody says "Crawl before you leap." We might have preventive

medicine. The medical end of this, to my mind, if not the most complicated, looks so now.

51. Don't you think the most of the patients of the general majority of physicians are those whose incomes are less than \$25 a week?

52. If we are going to have insured medical attendance, wouldn't it be one of the primary things that the state take hold of it?

53. Do you believe that in order to pass this legislation, it would be necessary to recommend far more stringent sanitary conditions in mercantile and industrial establishments?

54. Do you believe a good deal of the lack of health and the unhealthy condition of the workers is due to some of the conditions under which they have to labor?

55. Do you think the average person who would be benefited is the person who is over-eating?

56. Don't you think that the average factory conditions are as satisfactory as the average home conditions? Don't you think the workman in the factory is taking as few chances as in his home? That there are more sanitary regulations, better toilet-rooms, etc.?

57. Is the medical profession near enough to normal today to take up the discussion, or are they like so many other people, with their minds on the war and upset by losing so many of their best men, that it is a difficult time?

58. What percentage of the medical profession is engaged in war service?

NOTES FROM THE DISTRICT SOCIETIES.

WORCESTER.—In response to a petition signed by Dr. A. W. Marsh and nine other Fellows of the Society, the President called a "special meeting of the Society for the purpose of taking action upon the matter of division of fees received from patients of Fellows who have or may hereafter enter the army or navy of the United States, and such other matters as may legally come before the meeting."

The meeting was at G. A. R. Hall, 55 Pearl Street, Worcester, at 4.15 p.m., Wednesday, August 1, 1917.

ERNEST L. HUNT, *Secretary*.

RECENT DEATHS.

A. W. SMITH, M.D., of Milford, N. H., died at his home in that city on July 22. Dr. Smith was born in Waltham, Mass., in 1853. He was graduated from Dartmouth College and Dartmouth Medical School, and, after a year of study in New York, established himself in practice in Milford in 1878. He served for ten years as town moderator, was for twenty years a member of the school board, and in 1881-1890 was representative in the State Legislature. He had remained a widower since the death of his wife in 1902.

DR. FRANK H. WHITNEY, a veterinary surgeon of Lexington, Mass., was instantly killed, on July 30, by being run over by a train. He was sixty years of age.

INDUSTRIAL BENZOL POISONING IN MASSACHUSETTS.

BY THOMAS F. HARRINGTON, M.D., BOSTON,
Medical Deputy Commissioner of Labor.

BENZOL, or benzene, is used extensively in the industries of this State, and has given rise to much ill health and has caused several deaths. It is an unstable, very volatile, colorless fluid with a heavy aromatic odor. It is a derivative of coal tar distillation, and is frequently confounded in literature with *benzine*, a petroleum derivative with which it has many properties and uses in common. Benzol is decidedly more poisonous than benzene.

It contains many poisonous substances, such as hydrogen sulphide, toluene, and bisulphide of carbon (50 per cent., often). Much of the toxic effects noted is due to these substances. Poisoning by benzol depends upon individual susceptibility and immunity (natural or acquired), as well as upon the quantity and proportion of impurities in the fumes inhaled.

The principal uses of benzol (benzene) are: Manufacture of colors and dyes; carborizing motor gas and illuminating gas; refining and dissolving fat and grease; lacquer (acid proof) colors and varnish work; rubber industry; as a cement in auto tire-building; in anti-rust, anti-corrosive and rapid drying paints. It is also used in the manufacture of pharmaceutical preparations, *e. g.*, aspirin, antipyrine, etc., as well

as in the preparation of perfumery scents. Lately, benzol has been extensively used as a substitute for benzene and oil of turpentine, because of its great power in dissolving resin.

Benzol, like its homologues and other hydrocarbons of coal tar, has a specific affinity for the central nervous system and a general action on the protoplasm of the organic cell. The remarkable property possessed by benzol of reducing the number of leucocytes in the blood has given to it a place in medicine in the treatment of myelogenous leukemia. Female workers, particularly at the age of puberty and at the menstrual period, are especially susceptible to benzol poisoning. Symptoms of benzol poisoning vary much with the mode of poisoning; *i. e.*, whether in the form of vapor through the respiratory organs, or by absorption through the skin, or through the digestive tract.

The following cases reported to the State Board of Labor and Industries are typical of the symptoms and result of benzol toxemia.

ACUTE BENZOL POISONING.

Two steamfitters were employed in repairing pipes inside a benzol still that had been drawn off three days previously. These men worked together inside the still. This retort was 5 ft. x 8 ft. and was entered by a manhole opening 11 in. x 15 in. A stream of compressed air under sixty pounds' pressure was fed into the still by a 2 in. pipe while the men were engaged at this work.

One workman, 35 years of age, entered the still about 11 a. m. and worked until 12 noon. He and another workman, 23 years of age, entered the still at 12:30 p. m. At 1:15 p. m. the older man became greatly excited, laughing, singing, gesticulating and

acting "as if he had gone crazy." He soon became unconscious and was lifted through the manhole by his fellow worker. It required twenty minutes to get his body through the opening of the retort. It was then discovered that the younger man was unconscious on the floor of the still. He was removed and all efforts to resuscitate him failed. No autopsy was held.

The older man was resuscitated by artificial respiration, oxygen inhalation, lung motor and stimulants. Several days later he was able to report for work.

ACUTE NITRO-BENZOL POISONING.

A man, sixty-five years of age, employed as a teamster for a soap factory, on July 7, 1916, while delivering a five-gallon flask of oil of mirbane (nitro-benzol) accidentally loosened the cork of the flask, spilling the chemical onto his clothes. A fellow workman noticed a pale, sick appearance and before he could reach the teamster he had grown dizzy, nauseated, cyanotic about the lips, mentally confused and was soon unconscious. Artificial respiration failed to resuscitate him and he was taken to the hospital. He soon developed Cheyne-Stokes respiration, slow, weak pulse, blood pressure 90 systolic, 50 diastolic. Blood showed methaemoglobin; later convulsion and coma developed, followed by death three and one-half hours after the accident. Autopsy findings: Poisoning by nitro-benzol.

CHRONIC BENZOL POISONING.

In view of the little information available on this subject in textbooks, the five chronic cases of benzol poisoning (three fatal) reported in Massachusetts are given in detail. All of these cases occurred in the auto tire-building department of a rubber establishment in which benzol cement was used. The process was essentially as follows: The benzol was poured from a can which was rigged with a ball-cock arrangement and a trigger handle so that it was necessary to pull the trigger in order to get a flow of benzol from the can. The benzol was poured onto a cloth and wiped around the tire, preparatory to vulcanizing. This process was repeated about every half hour, or approximately eighteen times in an eight-hour day.

1. (Fatal) A man, 33 years of age, had been employed in the rubber industry since 1907. On April 20, 1915, he was transferred to the tire-building department. He soon complained of severe headaches, often lasting two or three days at a time. In March, 1916, he noticed that he was spitting blood, especially after brushing his teeth. This condition of spongy, bleeding gums was noticed almost daily, and later in March he noticed bluish-green spots on his left thigh, followed in a few days by similar spots on his left arm. Soon similar spots appeared in rapid succession on various parts of the body. On May 3rd he gave up work on account of extreme weakness and dyspnoea on slight exertion. On this date he had a severe nose-bleed, followed by a similar attack on May 7th, when he was admitted to the hospital.*

Physical examination showed spongy, bleeding gums, pale mucous membrane of throat and con-

junctiva, ulceration in posterior nares. Spleen not palpable. Knee jerks present and equal. No Babinski, no ankle clonus. Eyes react to light and to distance, no nystagmus. Breath, foul odor. Free bleeding from right nostril. Speculum examination showed bleeding point on septum about 3/4 inch back and near floor of nares. Patient conscious, slight tremor of head, no glandular enlargements, lungs normal, heart sounds weak, regular, no murmur, spleen not felt, liver 2 cm. below costal margin, no masses in abdomen, no spasm, no tenderness. Echinotic spots on skin, most marked on outer side of left arm near shoulder and on outer side of each leg. Family history and personal history good. No purpura nor haemophilia in family. Pulse 124, weak. Vertigo and visual disturbance.

Haemoglobin	60%
Leukocyte count	5,000
Red count	2,288,000

Transfusion of ten ounces of blood, followed by uncontrollable epistaxis. Nose-bleeds daily, severe and uncontrollable. Gums spongy and bleed on least irritation. Headache, vertigo, dizziness, restlessness, delirium, talkative, loss of power of arms and legs, coma, convulsions and death on May 18th. Autopsy diagnosis: Benzol poisoning.

	MAY 7	MAY 11	MAY 12	MAY 14	MAY 16
Haemoglobin	60%	45%	40%	40%	35%
Leukocyte count	5,000	2,810	1,810	1,100	850

BLOOD RECORD.

2. (Fatal) A man, 40 years of age, had worked in a rubber factory since 1905. On May 21, 1915, was transferred to the tire-building department. In winter of 1915, noticed much loss of muscular power. Easily fatigued, dyspnoea on least exertion. He was not able to work continuously, was losing in weight, had repeated attacks of headache. In March, 1916, began to have bloody stools. April 1st, noticed tendency to have nose-bleeds and a constant cold in the head. About May 1st, had the first severe nose-bleed that he had difficulty in controlling. Gave up work on account of loss of muscular power, dizziness and shortness of breath.

* The clinical records of these three cases of chronic benzol poisoning were furnished by St. Elizabeth's Hospital, Brighton.

Entered hospital May 3rd on account of severe nose-bleed.

Physical examination: Well developed and nourished, skin sallow, anemic mucous membrane, ulceration and bleeding spot in nose. Gums spongy, marked ecchymotic areas over lower and upper extremities, some areas being so large as to suggest trauma. No rigidity of neck, no glandular enlargement; lungs, heart and abdomen negative. No nystagmus nor strabismus, disc lemon color, teeth in poor condition, gums spongy, with blood oozing at junction of gums and teeth. Knee jerk present and equal on both sides. No ankle clonus, Babinski nor Oppenheim. No disturbance of sensation. Pulse 120; palpitation, vertigo, haemoglobin 65%; leukocyte count 10,000; red count 3,400,000; blood pressure 120 mg.

Patient failed steadily. Nose-bleeds frequent and more severe. Twitching of limbs and head. Paralysis, delirium, Cheyne-Stokes breathing, involuntary movements of bowels, coma. Death May 20th. Autopsy diagnosis: Poisoning by benzol.

BLOOD RECORD.

	MAY 3	MAY 10	MAY 12	MAY 13	MAY 16
Haemoglobin	65%	45%	45%	45%	40%
Leukocyte count	10,000	4,800	2,300	800	750

Small mononuclears	...	48	54
Eosinophiles	...	3	1
Mast cells	...	1	1

3. (Fatal) A man, 30 years of age, had worked in a rubber factory about two years (since 1914) in tire-building department. No history of nose-bleed, purpura, no hemophilia, either individual or family. Late in 1915, noticed some "red spots" on face and neck. These persisted for about three weeks. During the spring, 1916, noticed that he was much weaker and not able to do his work so well as formerly. Had headaches and dizzy spells. On May 6, 1916, consulted a physician who reported symptoms as follows: Pallor, general weakness, loss of weight, dyspnea, pulse 100-110, palpitation, weakness of gait, headache, dizziness, tinnitus, low white and red count, dry cough. Man returned to work but had to quit again on May 27th. Returned to work again on June 12th.

On July 6th had nose-bleed from left nostril, lasting six hours. The symptoms increased in sever-

ity: Pallor, muscular weakness, loss of weight, dyspnea, weakness of gait, tinnitus and nose-bleed. Brought to hospital on July 20th on account of severe uncontrollable bleeding from left nostril.

Physical examination: Pale, anemic, mucous membrane pale. Patient conscious, pupils equal, mouth and teeth in good condition. Gums bleeding, lungs normal, heart rapid, pulse regular, systolic murmur at apex, spleen not palpable, liver 1 cm. below costal margin, no spasm, no tumor, no tenderness. Brownish-yellow stains and evidence of ecchymotic areas on anterior surface of both thighs; knee jerks lively, equal on both sides. Patient grew worse daily and on July 30th developed lobar pneumonia with edema of lungs. Died August 2nd. Autopsy diagnosis: Acute lobar pneumonia, edema of lungs, anemia, exhaustion, consequent on poisoning by benzol.

BLOOD RECORD.

	JULY 20	JULY 23	JULY 26	JULY 29	JULY 30
Haemoglobin	40%	40%	30%	25%	20%

4. (Non-Fatal) Man, 20 years old, employed in a rubber factory since February, 1915. His duties consisted in receiving tires after they had been cured and apply to them a benzol cement. In March, 1916, he manifested symptoms of benzol poisoning, and in May reported to the hospital for asymmetry of face which he ascribed to the extraction of a tooth. Blood examination showed a haemoglobin of 75%, leukocyte count of 6000, red count 4,480,000. He had headache, nausea, general weakness.

5. (Non-Fatal) Man, 29 years old, employed for more than two years in automobile tire-building in which he wiped benzol to the fabric. For past three months has had a papular eruption size of pin head on extensor and flexor surfaces of arms, feet, ears and neck. Later this eruption developed into blebs. Very itchy and accompanied by fever. Stated that 16 or 18 men among the 120 employed in that department had similar eruption. Disappear on substituting naphtha for benzol.

A chemical examination of the benzol used by these men showed it to be free from impurities and of the pure benzol grade. In one of the cases the presence of arseniuretted hydrogen in large quantities in the urine raised a doubt as to possible arsenic poisoning. This was traced, however, to treatment by Fowler's Solution that the man was taking for anemia. The use of the benzol as a cement at the factory, in the tire-building process, was discontinued and naphtha substituted. No further cases of benzol poisoning have been reported to the State Board of Labor and Industries since this change.

ESSENTIAL SHRINKING OF THE CONJUNCTIVA OCCURRING IN ACUTE AND CHRONIC PEMPHIGUS, WITH A REPORT OF TWO CASES.

BY FRANK A. CONLON, M.D., LAWRENCE, MASS.

ESSENTIAL shrinking of the conjunctiva is simply a descriptive name of the end-result of pemphigus of the conjunctiva, although some men,¹ failing at the time of their examination to find specific evidence of a general pemphigus, have considered it a separate and distinct disease.

After a careful review of the literature, I find that all of these cases, so considered, come under Thost's² classification of chronic pemphigus of the mucous membrane, of which he gives the following characteristics:

1. Affection exclusively of the mucous membrane.
2. Unusual participation of the ocular mucous membrane, which tends to form synechiae.
3. Tendency to adhesion of all mucous surfaces.
4. Chronic evolution without fever.
5. Treatment of no avail.
6. Cachexia and dystrophy, cutaneous and muscular.

The lesions in the mouth or nose may easily be overlooked, as my patient told me her eyes troubled her so much that she had entirely forgotten about the condition in her mouth.

Pemphigus of the conjunctiva was first described by White Cooper³ in 1858. It was described as syndesmitis degeneration by Stellwag⁴ in 1870, and as essential shrinking of the conjunctiva by Kries, in 1878, of von Graefe's clinic. Von Graefe, in 1879, propounded the identity of pemphigus and essential shrinking of the conjunctiva.

It is a very rare disease. Adam⁵ saw one case in eleven thousand ophthalmic cases; Franke,⁶ five cases in forty-five thousand; Pergens,⁷ two in twenty-two thousand, while the late Herman Knapp⁸ saw but one case in his long experience.

It occurs with equal frequency in both sexes and at all ages; Alt⁹ reporting one in a girl of four and Banysiekiew's¹⁰ in a woman of seventy-six.

Etiology. In the majority of cases there is no predisposing condition or cause, yet in a few a septic²² wound or vaccination²³ has been given as its origin.

A specific organism has been found in the bullae by the following writers: Cirincione,¹¹ Demme,¹² Dahnhardt,¹³ and Blutrau.¹⁴ They describe it as a diplococcus, rather larger than the gonococcus, which forms round, white colonies on agar, grows rapidly on bouillon at 37; well on agar and serum. The cocci stain with aniline dyes and by Gram's.

The cocci are not present in the sac after cicatrization is complete, and do not cause shrinking when placed in the conjunctival sac of animals, but do cause a rather severe conjunctivitis. Demme found the diplococcus in the blood. Xerosis bacilli in large numbers have been frequently demonstrated, but this, undoubtedly, has been due to the favorable soil found in the degenerate corneal epithelium. By some the condition is regarded as due to the action of toxins upon the nerve centers, resembling herpes in this respect.

CASE 1. Mrs. G., fifty years old. Pemphigus lesions first observed in the mouth along the first of August, 1915. Patient seen December 20, 1915, at which time she presented large bullae all over her body, with involvement of both eyes. The right eye presented an elevated, sharply defined spot five millimeters from the corneal sclerae on the nasal side about three millimeters in diameter. There was a loss of epithelium in the center, evidently a ruptured vesicle. Another similar spot was seen on the ball on the temporal side. The left eye showed two spots on the bulbar conjunctiva in corresponding positions and of identical appearance. Patient said her first eye trouble occurred one month before and lasted a week, and that the present lesions appeared that morning. Palpable conjunctiva was slightly injected and there was a beginning obliteration of the lower culs-de-sac. This seems a remarkably short time for a noticeable shrinking to develop, yet Stieren¹⁵ saw an almost complete obliteration of the conjunctival sac develop in six weeks.

CASE 2. Mrs. K., 50 years old, American born; while never a robust woman, she always enjoyed good health. I first saw this patient May 15, 1915, when she complained of an irritation due to entropion of her left lower lid. My records showed at that time twenty-twentieths vision in each eye, both corneae normal, slight redness of the bulbar conjunctiva of the left eye. The lower conjunctival sacs of both eyes were from three to four millimeters in depth, with numerous vertical folds of glistening white conjunctiva. At this time there was no appreciable involvement in the upper fornix of either eye. In June, 1916, she developed an erosion covering the lower half of the left cornea (ruptured bulla) with an iritis. Within a month, there was a complete obliteration of the lower cul-de-sac. The condition of her right eye remained

unchanged from the time of the first examination, in May, 1915, until December, 1916, when there was a rapid obliteration of the lower cul-de-sac, which became complete in February, 1917. At the present time the patient can open her eyes but two or three millimeters. Both lower lids are attached, their full length, to the eyeball and lower part of cornea. The cornea of the left eye is obscured by a dirty-white exudate or membrane, which can be removed with difficulty, showing a diffuse infiltrate of the cornea proper covered with dull, dry xerotic epithelium. In the inner canthus the edges of the lids have grown together for about six millimeters; this condition exists in the outer canthus also, but not to such a degree. This ankyloblepharon has developed very rapidly during the past month, and if it continues its present progress, the eye will be completely closed in a very short time. The right eye is very similar in appearance to the left eye, except that the cornea is still normal. The same dry white exudate is just appearing in this eye, which greatly interferes with what little vision the patient now retains.

I know of no better description of the appearance of these eyes than that given by White Cooper, in 1858, when he said, "one would have pronounced that some powerful escharotic, such as lime, had been applied to them." This patient at first denied having any trouble with her mouth or nose, but on close questioning she remembered being treated, by a dentist, for blisters in her mouth in the summer of 1914. The dentist informs me that he treated her for a peculiar condition of her gums, which was characterized by the peeling off of rather large areas of mucous membrane, which left a bleeding surface underneath. Local treatment had no effect upon the condition. The patient says that she feels a blister in her mouth, which breaks in three or four minutes, leaving a sore spot which causes considerable pain, from three to five days, while eating. The short period before rupturing, as compared to those on the skin, is due to the much more delicate epithelium, and explains why we practically never see bullae in cases of chronic pemphigus of the mucous membrane. This patient is now able to open her mouth but about half way, owing to the cicatrization of her buccal mucous membrane. Trautman²⁴ saw a patient whose mouth was completely closed for eighteen years, due to the extensive cicatrization characterizing this disease. The left side of the roof of her mouth is covered with dense scar tissue. Erosions and scar tissue cover both sides of the septum. The naso-pharynx and larynx show no signs of involvement. There have never been any lesions on the skin.

Pathology. From the appearance of symblepharon one would naturally suppose the process was the growing together of two denuded surfaces, but a careful microscopic examination shows that this is not the case. A very complete pathological report was published by Adam⁵ and another one by von Marenholtz.¹⁶ Adam says, "The essential process of pemphigus

of the eye is not the formation of bullae, with consequent healing, but is an inflammation of the sub-epithelial and adenoid layer of the conjunctiva going over into cicatrization. The shrinking of the conjunctival sac is not due to a sticking and growing together of the conjunctiva, but to a cicatrization of each spot of inflammation. The result is a formation of vertical folds which appear like adhesions. He found in his corneal section that the process consisted of a denudation of epithelium, followed by an irregular regeneration of exuberant granulation." Von Marenholtz found the cornea covered by epithelium from the lids.

Treatment. The treatment is very unsatisfactory. Thiersch grafts have been done by some,^{8, 17} with good surgical results, but the degenerative changes in the cornea have nullified their efforts.

Ogue and Imai report disappointing results with treatment by x-ray and radium. Bordley¹⁸ used a vaccine made by the anaerobic method of Noguchi and Flexner, and saw a temporary improvement, while Bishop Harmon¹⁹ used vaccine with absolutely no results. Bane reports a retardation of the disease by treatment of the x-ray, but I think his case may have been one which was treated in the quiescent stage. In my case there is no change in the right eye in eighteen months, and in Burk's²¹ there was none in twenty years, so one must be careful and not ascribe to the treatment that which may be the untreated course of the disease. I have used thiosinamin and the improved product, fibrolysin, without noting any improvement whatsoever. Fibrolysin was used by von Marenholtz for four months with slight improvement. Arsenic is given, as a rule, with vain hope that it may do good. Pemphigus of the conjunctiva may result in blindness in four to six weeks, or a patient may suffer from the disease twenty or thirty years without corneal involvement and its consequent loss of vision. Up to date we are helpless and unable in the slightest degree to influence the progress of the disease.

INTESTINAL ADHESIONS AND PERITONEAL BANDS IN EPILEPTICS.*

BY HEIMAN CARO, M.D., PALMER, MASS.,
Pathologist, Monson State Hospital.

So much emphasis has been placed upon the abnormalities of the gastrointestinal tract, and the relation of the superimposed condition of chronic intestinal stasis to the convulsive seizures, that at times it has almost appeared necessary to assume that every constipated individual was a potential epileptic. But the fact remains that most constipated individuals are not. There is, without doubt, one type of epilepsy where a definite relationship between intestinal conditions and the seizures does exist, but it includes only a small percentage of those suffering from this group of diseases. The purpose of this paper is, first, a consideration of the causes of chronic intestinal stasis; second, the etiologic factors present in the causation of intestinal adhesions and abnormal peritoneal bands; and, third, inasmuch as these bands and adhesions give some evidence of the presence of colonic stasis, a comparison of the incidence of this pathologic condition as found in the necropsy protocols of an institution for epileptics and in those of a general hospital.

The abnormalities of the intestinal tract may manifest themselves clinically by varying degrees of chronic intestinal stasis. It is possible that derangements of the metabolism of the endocrine glands may play a part in the causation of this condition in those epileptics in whom intestinal stasis is a prominent symptom.¹ But the more usual causes of chronic intestinal stasis are frequently found present in epileptics. The sedentary conditions under which, of necessity, many of those suffering from this group of diseases must live, combined with general mental apathy, due to the disease itself or to bromism, may produce the condition in some. Restricted diets, lessened water intake, gluttony, lack of habit formation, flabby abdominal musculature, and overpowering inhibitory influences surely play their part.

Increasing resistance to the passage of the fecal current may be due to enteroptoses, angulations, fibrous bands and adhesions, strictures of the lumen of the gut, movable cecum, and the like. But while developmental and congenital anomalies are at the bottom of many cases of constipation,² yet roentgen ray examinations have shown that such mechanical obstacles do not, necessarily, entail a condition of stasis. Indeed, passage through the large intestine may occur quite normally in spite of them.³ With the possible exception of colonic atony or colonic tetany due to disturbances of innervation of the intestines, the chronic intestinal stasis of epileptics depends upon the same causative factors as found in every constipated individual.

Intestinal bands and adhesions have been selected for this study, for the reason that they are not affected by post-mortem changes, and, in consequence, assuming that the error of omission is a constant, the conclusions drawn from their incidence are less open to criticism. There are three important factors in the causation of intestinal bands and adhesions, namely, (1) defects in embryonic development, (2) acute inflammations of the peritoneal surfaces, and (3) mechanical causes.

Congenital anomalies are by no means frequent. Under this heading may be mentioned the peritoneal bands and web-like processes which, arising in the vicinity of the gall-bladder, extend across to the pylorus, duodenum, hepatic flexure, and transverse colon. These are probably remnants of the anterior mesentery. I have found such processes in eight necropsies upon epileptics. They may not give rise to symptoms, but Homans, in a clinical study of eleven cases, mentions constipation as being present in two. One of these, at operation, showed a firm band of peritoneum stretching across the hepatic flexure.⁴

The acute inflammatory factors giving rise to adhesions included such conditions as tuberculosis, peritonitis, gall-bladder disease, appendicitis and its complications, inflammations of the female adnexa, and other acute abdominal states. The *modus operandi* of these lesions is well known. In this connection it may be well to suggest that adhesions about the appendix may be due to mechanical causes as well as to acute infections.

The mechanical factors are at work chiefly in the region of the colon, and resulting from stasis serve to accentuate any intestinal abnormality that may be present.⁵ It has been suggested that the sequence of events in the formation of pericolic membranes is first a condition of colonic stasis from any of the causes, or combinations of them, mentioned above. Then colonic dilatation with increasing stasis occurs, until finally bacterial invasion and toxin osmosis into the pericolic tissues causes the formation of anchoring bands or diffuse membranes. It is of interest that Turek has shown that the intestinal wall is permeable to the intestinal flora, and that histological changes occur in the cells, through which the bacteria may have migrated.⁶

In a recent investigation I came to the conclusion that peritoneal bands and intestinal adhesions played but a small part in the causation of colonic stasis, but stated that their presence was an indication that, in at least some degree, this condition had been present.⁷ From the standpoint of pathological material they may well serve as a method of comparing intestinal abnormalities and symptoms among epileptics and normal individuals. It is hardly to be denied that functional tests as shown by roentgenographic work is a far more desirable index

* Read before the National Association for the Study of Epilepsy, May 29, 1917.

to base conclusions upon, but at present such comparisons are hardly feasible.

I have reviewed the protocols of 280 necropsies on epileptics recorded at the Monson State Hospital from 1900 to the present time. Acute abdominal conditions and adhesions complicated by carcinoma have been omitted from the tabulation. In this series, intestinal adhesions and peritoneal bands were mentioned in 50 necropsies (17.85%). Peritoneal bands were found originating in the region of the gall-bladder and extending across to the hepatic flexure and transverse colon in eight cases. In five only the duodenum and pylorus were involved by such bands. In none of these was there any evidence of gall-bladder disease, gastric or duodenal ulcer. Extensive adhesions due to cholecystitis were found in two cases. Adhesions between the coils of the small intestine were present in eight, and in only one of these was there any apparent connection with inflammation in the right inguinal region.

Turning to the region of the large intestine, adhesions of varying degrees about the appendix were found in fourteen protocols. In three more both cecum and appendix were involved. In two cases there were firm bands about the cecum alone, one being due to an appendectomy. The ascending colon was found to be firmly bound down once, while the descending colon was similarly affected twice. Four protocols described bands causing displacement of the splenic flexure. The last necropsy of this series was complicated by umbilical hernia. The adhesions found present were due to this, but the epilepsy had been definitely established before the appearance of the hernia. It will be noted that in thirty-eight of these protocols, the adhesions and bands mentioned were about the large intestine, especially in the region of the cecum and ascending portion. It is in the large gut that stasis would naturally occur.

TABLE I.—SITE OF ADHESIONS IN 280 NECROPSIES ON EPILEPTICS.

Gall-bladder to duodenum and pylorus	5
Due to cholecystitis	2
Small intestines	7
Small intestines plus cecal adhesions	1
Appendix	14
Appendix and cecum	3
Cecum	2
Ascending colon	1
Gall-bladder to hepatic flexure and transverse colon	8
Splenic flexure	4
Descending colon	2
Due to hernia	1
Total	50

But does the above incidence of adhesions among epileptics differ at all from that of non-epileptics? For this purpose, through the courtesy of Dr. Frank B. Mallory, of the Boston City Hospital, I investigated some 775 necropsy protocols contained in the records of the pathological laboratory of that institution for the

years 1900-1-2-3-10. Omitting acute abdominal disease, as well as carcinoma, I found mention made of bands and adhesions in 142 protocols (18.3%).

Turning first to the region of the gall-bladder, this viscus was bound down to the duodenum and pylorus in four cases. In twenty-three more, peritoneal bands and adhesions stretched from the inferior surface of the liver across to the transverse colon and hepatic flexure; one of these had, furthermore, firm adhesions about the splenic flexure, while three were complicated by gall-bladder disease. In seventeen protocols, adhesions between the coils of the small intestines were mentioned, and in only three was there definite evidence of inflammation about the appendix, thus indicating an earlier acute peritonitis. Varying degrees of tying down of the appendix were found in forty-four cases, while in fifteen more the adhesions involved the cecum as well. One of the latter showed an abnormal band of peritoneum stretching across the splenic flexure. The cecum alone was found involved in nine cases. The ascending colon was firmly tied down in two. Bands about the hepatic flexure were described in five, while the splenic flexure was similarly involved in three. The descending colon was buried in pericolic membranes in three cases, while there were bands and adhesions of varying degree about the sigmoid in seven. Of the remaining protocols, adhesions in four were due to hernia, and in six to operative procedures within a year preceding time of death. It will be noted here also that the site of predilection for adhesions and bands appears to be in the vicinity of the large intestine. From a total of 142 protocols, over two-thirds showed bands in this region.

TABLE II.—SITE OF ADHESIONS IN 775 NECROPSIES AT A GENERAL HOSPITAL.

Gall-bladder to duodenum and pylorus	4
Due to cholecystitis	3
Small intestines	14
Small intestines plus appendiceal bands	3
Appendix	41
Appendix and cecum	15
Cecum	9
Ascending colon	2
Gall-bladder to hepatic flexure and transverse colon	20
Hepatic flexure	5
Splenic flexure	3
Descending colon	3
Sigmoid	7
Due to hernia	4
Operations within a year	6
Total	142

To recapitulate briefly, it has been shown that in a review of 775 necropsy protocols of patients in a general hospital the incidence of intestinal adhesions and peritoneal bands was found to be relatively the same as in a series of 280 necropsies upon epileptics. Considering each portion of the intestinal tract separately, it will be noted that this general statement holds

true throughout. The favorite site of these adhesions is about the large intestine, thereby favoring the presence of colonic stasis.

CONCLUSIONS.

1. In view of our present knowledge, the constipation of epileptics cannot be said to be due to factors differing far from those usually considered in the colonic stasis of other patients.
2. Intestinal adhesions and peritoneal bands are due to congenital defects, acute inflammatory processes, or mechanical causes.
3. Such processes are no more frequent in epileptics than in non-epileptics.
4. It seems probable that intestinal anomalies are not present in any greater proportion in epileptics than in other persons, and in the last analysis, we are still combating, from a therapeutic viewpoint, a general condition, and no one particular lesion or pathologic phase of metabolism.

A COMPARATIVE STUDY OF FEEBLE-MINDEDNESS AND PSYCHOPATHIC PERSONALITY AMONG OFFENDERS IN COURT.

By V. V. ANDERSON, M.A., M.D., BOSTON,
 Director Medical Service, Municipal Court.

In a former paper attention was called to three distinct types of mentality found among border-line mental cases in court: the defective mentality, the psychopathic mentality, and the delinquent mentality as such.

To be sure, there is often an over-lapping in the same individual, but for purposes of practical classification we may regard these three types of mentality as definite entities. Certainly they seem to present very marked individual differences, and create—because of essential constitutional dissimilarities—social problems that require entirely different angles of approach in dealing with them.

The present paper undertakes a comparative study of two of these types—the *feeble-minded* and the *psychopaths*.

For the purposes of this study two hundred cases were selected, one hundred from each group. The object of this study was to find out whether the apparent differences existing between these two types of individuals were suffi-

ciently marked to make a separate classification practical.

The cases were taken from the files alphabetically and represented the first one hundred of each group whose clinical histories contained sufficient data to warrant inclusion for study.

As a matter of course, the earliest noticeable deviations were in childhood. Their ability to profit by school instruction sharply divided our two hundred cases into two well-defined groups. On the one hand, we find individuals perfectly capable of profiting by school instruction, advancing from year to year, and, in the majority of instances, graduating from grammar school, many doing well in high school, some graduating and going on to college.

On the other hand, we find a group of individuals, none of whom were able to graduate from grammar school, all of whom evinced an apparent incapacity for profiting by ordinary school instruction, could not measure up to the standards of normal mental development, as required by the public school curriculum, and, in general, were regarded as mental failures. The following table indicates the grade reached upon leaving school.

GRADE REACHED AT SCHOOL.

	FEEBLE-MINDED	PSYCHOPATHS	
Grammar Grades	Primary	4%	0
	1st Grade	11%	0
	2nd "	4%	0
	3rd "	12%	1%
	4th "	14%	0
	5th "	23%	2%
	6th "	11%	2%
	7th "	9%	4%
	8th "	7%	7%
High School	9th "	0	9%
	0	0	38%*
	1st year	0	4%
College	2nd "	0	8%
	3rd "	0	1%
	0	0	6%*
Data not obtained	Freshman year	0	1%
	Sophomore year	0	1%
	Junior year	0	1%
No schooling	3%	13%	
	2%	2%	

* Graduated. No other schooling.

The feeble-minded collect at the lower end of the scale, while the psychopaths collect at the upper end. A majority of the feeble-minded—68%—never got further than the fifth grade in school, while 82% of the psychopaths got above the fifth grade. 60% of the psychopaths graduated from grammar school, 22% of the psychopaths went to high school, 9% graduated from high, and 3% went to college. Not a single feeble-minded individual was ever able to finish grammar school.

This difference in behavior, at the very beginning of their training for life's battles, constitutes the first link in the chain of evidence for

differential diagnosis between these two types. One group very early in the race becomes disqualified and drops out. The other group goes on to a more successful accomplishment of required training.

In due course of time our individuals reach that stage of their careers where the sterner problems of self-support are to be reckoned with. Just what individual differences their behavior here exhibited the following table will indicate.

TABLE OF INDUSTRIAL EFFICIENCY.

	REGULARLY EMPLOYED	IRREGULARLY EMPLOYED	ODD JOBS	WORK AT HOME (WOMEN)	DO NOT WORK AT ALL
Feeble-minded	4%	21%	28%	13%	34%
Psychopaths	28%	41%	4%	17%	10%

Seven times as many psychopaths are steadily employed as feeble-minded. While the feeble-minded in a majority of instances (62%) are either unemployable or simply do odd jobs, the psychopaths in 69% of cases were either steadily or irregularly employed and self-supporting.

The feeble-minded as a class are in the majority of these cases industrially inefficient and not capable of "holding down" positions for any length of time; while the psychopaths as a class are, in the majority of these cases, fairly efficient, industrially, capable of holding positions for much longer periods, and, when they lose such, do so more because of their temperamental peculiarities, their emotional instability, etc., than any real lack of industrial efficiency.

From these two types are drawn a large percentage of repeated offenders. The following table indicates the comparative frequency with which they appear in court.

TABLE OF ARRESTS.

	TOTAL NO. OF ARRESTS	AVERAGE EACH
Feeble-minded	1825	18.25
Psychopaths	369	3.69

It appears from the above that the feeble-minded are arrested almost five times as frequently as the psychopaths. Now this surely does not mean that the feeble-minded are five times as wicked or as delinquent as the psychopaths. It very probably refers to the fact that, being more stupid, they are more easily caught. Likewise, being economically more unstable, they drift aimlessly, falling into the hands of the court for various minor offenses which the psychopaths, because of their greater intelligence and economic efficiency, are able to avoid. Whatever be the explanation, I present the objective facts for what they are worth.

I shall review two main efforts at treatment tried by the court: *probation* and *penal treatment*. The following table shows the different reactions of these two types to probation:

TABLE OF PROBATION.

	FEEBLE-MINDED	PSYCHOPATHS
No. of times placed on probation	432	161
F. M. PSY- CH.		
No. times surrendered	220	50
No. times inside probation	118	18
No. times defaulted	14	
No. of unsuccessful probation periods	338	82
No. successful probation periods	94	79
Percentage successful probations	21%	49%

79% of the probation periods of the feeble-minded were unsuccessful, while 51% of the probation periods of the psychopaths were unsuccessful. 21% of the probation periods of the feeble-minded were successful, while more than twice that number (49%) of the probation periods of the psychopaths were successful. The chances are better than two to one in favor of the probation periods of the psychopaths, and this without any special efforts directed towards training them to counteract those difficulties of personality most responsible for their failure. It is quite likely that more can be done for the psychopaths through probation than through any other agency, provided their treatment be guided by a knowledge of their temperamental peculiarities, their personality mal-adjustments, so that their environment can be suitably influenced or chosen for them and they themselves trained to inhibit their impulses.

The feeble-minded are less promising. They suffer from a fundamental defect in their intelligence that renders them incapable of profiting properly by experience and prevents them from measuring up to the accustomed standards of conduct. Only a small percentage—in these cases not more than 25%—could be considered satisfactory probation cases. The larger proportion of the feeble-minded are needing more or less permanent supervision.

The court tried also penal treatment, as the following table will show.

TABLE OF PENAL TREATMENT.

	NO. OF SENTENCES	AVERAGE EACH	LENGTH OF TIME SENTENCED	NO. OF IND. TERMINATE SENTENCE
Feeble-minded	735	7.35	106 years	250
Psychopaths	71	.71	12 years	14

40% of the arrests in case of the feeble-minded resulted in a sentence, while only 19% of the arrests in case of the psychopaths resulted in a sentence. Likewise, the length of time sentenced is proportionately much longer for the feeble-minded, though the type of offenses committed remains much the same. A recognition on the part of the judge of a difference in the character of treatment needed for

these two types is apparent, though the real explanation may be found in the length of their records and recommendations of the probation officer.

Finally we come to the mentality of these two types. It stands as the most important, the most fundamental factor underlying all the foregoing facts.

TABLE OF MENTAL LEVEL.

	7-8 Yrs.	8-9 Yrs.	9-10 Yrs.	10-11 Yrs.	11-12 Yrs.	SUB-NORMAL	ADULT
Feeble-minded	4	30	41	15	0	0	0
Psychopaths	0	0	0	1	3	12	84

Here again the feeble-minded collect at the lower end of the scale, while the psychopaths collect at the upper end. 75% of the feeble-minded had a mental level below ten years; none of the psychopaths had so low a level of intelligence. 25% of the feeble-minded were between ten and eleven years; only 1% of the psychopaths had such a low level. None of the feeble-minded were above the eleven-year level; 99% of the psychopaths were above this level.

The fact is that a great majority of the psychopaths (84%) had a perfectly normal intelligence, while all of the feeble-minded suffered from an arrest of mental development prior to reaching adolescence; an obvious defect in their general intelligence, a dwarfing of their mental faculties, that prevented them from ever reaching the adult status of mentality. (To be sure, some of the feeble-minded possess markedly psychopathic traits. They still, however, come under the classification of feeble-minded).

We must think of the psychopaths in an entirely different light. We must consider these individuals in the light of adjustment of their personality, rather than in terms of general intelligence, and realize that their anti-social conduct is due less to their stupidity, less to their lack of understanding the demands of a normal social organization, and inability to foresee the consequence of their acts, than it is to a lack of ability to inhibit impulses, to assume responsibilities, to face difficult situations, to resist discouragements, and to coordinate properly a poorly balanced nervous mechanism. Their mentality is not defective in the usual meaning of the term, but is unstable, impulsive, vehement, in some cases erratic.

They are very emotional, easily upset, lacking in inhibitions, undertake many obligations, never fulfilling any; are restless, at times show great motor activity, become easily fatigued, and, occasionally, are violent and apparently insane under the influence of alcohol, drugs, or excitement. While under detention they clear up and give no evidence of a psychosis or mental defect, only to have another outbreak when things go wrong in their environment. In insti-

tutions they give more trouble than any other group, and seem little modified by such treatment. At times they become absolutely unmanageable, and because of the fact that they seem so erratic and uncontrollable, they are often considered insane, and are transferred to insane hospitals.

The fact is, these individuals are better handled outside, except in cases where vicious and markedly delinquent traits render their incarceration necessary. They react to discipline very poorly—one may say violently—but much progress can be made in the way of training them through an intelligent effort to understand their motives and to secure their own cooperation in undertaking to study their weaknesses and to educate their inhibitions; in short, a development of sufficient self-control to counteract their impulsive tendencies.

SUMMARY.

In this study a comparison was made of feeble-mindedness and psychopathic personality under six main headings: grade reached in school, industrial efficiency, number of arrests, probation, penal treatment, and mentality. It appeared that there was a marked difference in the way these two types reacted, the deviation being such as to justify their consideration under separate categories for practical court work.

The feeble-minded could not make the required progress in school. They were incompetent, impotent, and dropped out, unable to finish grammar school. The psychopaths were able to make better progress, in the majority of cases finishing grammar school, many going on to high school, some graduating and going on to college.

Comparing them on the basis of industrial efficiency, it was found that seven times as many psychopaths were steadily employed as feeble-minded. The majority of the feeble-minded were not self-supporting, while the majority of the psychopaths were.

The feeble-minded were arrested about five times as frequently as the psychopaths, though it was explicitly stated that such facts should not be construed as indicating comparative criminality of the two types. It could be interpreted only as indicating that the machinery of the court was being employed more frequently for this group.

On probation the psychopath is twice as good a risk as the feeble-minded. It was thought that in general terms more could be done for the psychopath through probation than through any other method, provided an effort be made to guide his treatment by a knowledge of his peculiar personality.

The attitude of the court was in favor of this, when the feeble-minded received twice as many sentences, in proportion to number of arrests, as the psychopaths.

The most important link in the entire chain

was found in the table of mental level. None of the feeble-minded had a mental level above eleven years. All of the psychopaths—with one exception—possessed a level of intelligence above eleven years. The feeble-minded collect around the lower end of the scale of intelligence, while the psychopaths collect around the upper end. We are to think of the feeble-minded in terms of development of general intelligence. A halt in development occurs prior to their reaching adolescence. We are to think of the psychopaths in terms of adjustment of their peculiar personality. Their intelligence itself is not at fault. They are unstable, impulsive, emotional, and poorly balanced. Contrasted with the normal individual, whose mental faculties work in harmony, are correlated and well-balanced, the mental machinery of the psychopath is disordered, dis-related, and poorly balanced.

In the light of foregoing facts, it would seem safe to conclude that any form of social treatment that does not take into consideration the essential differences in mental make-up existing between these two types must eventually fail in the practical solution of their problems.

HEARING TESTS FROM A PRACTICAL STANDPOINT.*

BY GEORGE L. RICHARDS, M.D., FALL RIVER.

HEARING tests are as old as modern otology, and have been written about at great length by many authors, both in textbooks and in monographs. They have been so much elaborated and made so complex that the busy man is often tempted to omit or abuse them. I desire in this paper not to discuss these tests in detail, but to suggest a plan that is at once practical and at the same time sufficiently scientific to give satisfactory results. This procedure is neither unduly time-consuming to the physician, nor fatiguing to the patient, both of which are true when a complete functional test by all the well-known methods is made.

Many years of experience have taught me that hearing tests are largely neglected because they take up so much time. We learn with the aid of a single tuning fork and a few simple tests to make a fairly accurate snap diagnosis as to whether we are dealing with a middle or internal ear lesion, without differentiating with great accuracy as to the extent and location of the lesion, and with this are apt to be content.

This would not be so bad were it not that a prognosis based on these tests alone might have been somewhat modified had a more thorough functional examination been made before and after treatment.

The occasional case, where there may be

islands or gaps of hearing, and medicolegal or otherwise exceptional cases, may require a complete functional examination with all the means at our command. Whether this will or will not be necessary will be evident to the examiner.

The object of any hearing test is to determine the quantity and quality of the deafness present and the location of such lesions as far as these tests can enlighten us.

The normal range of hearing for the human ear varies from 16 to 32 (seldom below 32) vibrations a second (the so-called lower tone limits), up to 30,000 to 42,000, the upper tone limit. We are taught that in middle-ear deafness there is an impairment in hearing range for the lower tones, while the higher tones are but little or not at all affected, and that in nerve deafness there is impairment of hearing power for the higher tones, while the lower tones are relatively less affected. When both are affected there is a diminution of hearing power for the entire range.

The apparatus required for these tests is a set of the usual C tuning forks, with the addition of C 64, two A forks, a stop watch, with a clear, well-defined click, a Bárány noise machine, an Edelman-Galton whistle, a long six-foot speaking tube, the observer's voice, and a room with as great a length and with as much freedom from external noises as the examining place affords.

Tuning Forks. The individual set used must be tested out on a number of normal ears, for both air and bone conduction, and these recorded as the fixed fractions for these forks (for they will not give the same results in any two sets); even then there is apt to be a distinct source of error, since the force of the blow on the fork will vary with the habit of the examiner using them; hence it is desirable to have as definite a method of striking these forks as possible in order to get a uniform blow. High forks with hammer attachments are in the market, but it is easier to strike high forks uniformly than it is the low ones.

The low fork should be used by bringing the prongs together with the fingers, then with a sliding motion quickly letting go. This gives a fairly uniform effect; the higher forks can be used in the same way or may be struck on the knee or the heel with a quick but not too strong blow. Writers have had much to say about the elimination of overtones. This is not an easy task, even with weighted forks, nor is it particularly necessary since the overtones disappear before the real tones, so that our measure of value is fairly accurate even in their presence, and I disregard them.

Because of the difference in striking the blow to the fork it is desirable that the same examiner make the individual tests both before and after the treatment. This especially applies to those of us who have assistants or associates. Do not make the test yourself before the treatment,

* Read before the Section on Laryngology, Otology and Rhinology at the Sixty-eighth Annual Session of the American Medical Association, New York, June, 1917.

and then ask another to do it after the treatment.

To use the forks, hold the stop watch in the left hand, and as soon as the fork is no longer heard, press the stem of the watch, allow the numerator of the fraction to apply to air conduction and the denominator to bone conduction. After putting the C fork in vibration, place it before the ear about one inch from the orifice, being careful to avoid contact with hair, face or clothing, and in such manner that the two prongs will be parallel and not superimposed one above the other; then place the stem of the fork on the tip of the mastoid and ask the patient which is louder, and you have at once your probable Rinné.

Then starting the tests fork by fork, record both bone and air conduction with the stop watch, having the patient say "gone" when he no longer hears it. Use C 64, C 128 and C 512 on each ear as routine.

A clear brain and a considerable degree of concentration on the part of the patient being examined are needed for a satisfactory examination. Here is where the results are often uncertain. Tabulated and compared with the normal range, these tuning forks give much valuable information, but one can never assume that they are absolutely accurate, nor is a change of a few seconds either way at a subsequent visit of any great significance. If performed sufficiently often they will give us rather definite information as to the progress of the case.

The Rinné test has already been determined by the tabulated tuning fork reactions; the Weber, Schwabach, the Gelle tests, while of scientific interest, may be disregarded in the present plan. I have never found them of much aid. Should the test up to the present point have shown probability of nerve deafness, we use fork C³ and C⁴ and the Edelmann-Galton whistle; the latter, with the aid of the table provided with each instrument, gives with a considerable degree of accuracy the upper tone limit. It is sometimes difficult, in the case of the Galton, to teach patients to understand just what is meant by the difference between the whistle and the puff, but if the whistle is placed behind the ear, so that the column of air cannot be felt, this difficulty is overcome. The same is also true when using low forks, especially for bone conduction, as it is often troublesome for the party under examination to distinguish between the hearing of the forks and the feeling of the vibrations, or feeling before the ear the movement of the air current which the fork has set in motion.

Voice. Except in cases of deafness of considerable degree, few offices are large enough to make satisfactory tests by the ordinary spoken voice. Under favorable conditions this should be heard from 130 to 150 feet, or even farther, as the accentuated whisper should be heard as

far as a hundred feet, while the typical whisper may be heard from 60 to 75 feet. As in most cases more or less outside noises must be taken into consideration, the average person under average conditions will scarcely hear the whispered voice 60 feet. The United States army requires a hearing distance for the whisper, of 20 feet. This is the ordinary whisper, for which the residual air in the lungs is to be used. Practice will enable one to whisper with a good degree of uniformity both in volume and pitch. For this test one ear is closed by the moistened finger in the external canal or by some sort of sound-closing apparatus, like a small moist rubber ball or a pledget of moistened cotton placed in the ear and pressed firmly against the anti-tragus. Even so, it is almost impossible to entirely close off the sound to the other ear, which, if it happens to be good, will be interpreted by the patient as being the ear under examination, and so be misleading. To offset this, Bárány introduced the noise machine which, when the tip is introduced into one ear, so confuses the sound to this ear as to cut out other sounds.

In my experience this apparatus has proved useful, but it has seemed sometimes to so confuse the individual as to prevent an accurate test of the ear under examination, the ear hearing both the noise machine and the fork or the voice, as the case may be, but both with less accuracy. To offset this I have tried having an assistant massage very rapidly the antitragus with an in-and-out motion over a bit of moist cotton in the external canal. This rather effectually cuts out any recognizable noise to that ear, and is not as confusing to the ear being examined.

The ear to be tested is turned toward the examiner, and the patient's eyes closed or so directed that he cannot see the speaker's lips. This seems to me a fairer test than standing behind the patient, as the external ear may more or less interfere with hearing. Some care should be used in the test words; pure vowels like *o*, *ah*, and *e* are heard farthest, but become somewhat blurred in a whispered speech, while consonants change but little. The "h" aspirate is the lowest and feeblest sound, being, according to Wolf's experiments, heard about one-thirtieth as far. The consonants *v* and *k*, hard *g* and *d* are heard about one-sixth as far. I use single common words and numbers, going from simple monosyllables to polysyllables. I find the *n* sounds, seven, nine, eleven, easy to recognize, while the sounds like sixty-six, seventy-seven, are more apt to be answered incorrectly. These numbers are carried up to three syllables. I am particularly fond of the numbers 100, 120, 146, etc.; next I ask questions, instructing the patient not to answer the question, but to repeat it; then I proceed to ask unexpected ones such as, "Have you had your breakfast?" "How old was Methuselah when he died?" and the like. The average of these will give about the proper

distance for the whispered voice. All tests are begun at a distance beyond which you expect the person examined to hear. The conversational voice is always used when the deafness is of such degree as to warrant tests. This distance is recorded on the history chart for comparison with future tests.

Watch Test. Use the stop watch with a fairly sharp tick; this will take the place of the Politzer aecometer, which can be discarded. Test out the individual watch on a number of normal persons to get its approximate range, and always use the same one, as no two will have the same hearing distance. The stop itself ought to have a sharp click, for this will aid us to determine whether or not the watch has really been heard, as the click will be heard at a greater distance than the tick. Patients sometimes say they hear when the click is sounded, believing that the watch has been started again by a sort of off-and-on mechanism, whereas the interval is always one, two, three, stop—reverse pointer, start. Replies to this as to all hearing tests are apt to be somewhat misleading, hence the need of so many different ones. For the ordinary case the tests above described are all that are necessary.

There remains the occasional case where one ear is so deaf that it is difficult to exclude the good ear sufficiently to determine whether we have much of any hearing, and just how much in the defective ear, all the tests described being perhaps more or less interpreted by the good ear. To assist in such cases I use a silk-covered speaking tube, with the other ear as closely stopped as possible. One can determine by speaking through this tube with a clear, distinct voice if there is any hearing. It is best to hold the edge of the funnel connected with the speaking tube against the chin rather than cover the mouth with it. The sounds are heard more clearly when it is used in this way. Next the noise machine is placed in the good ear, and the speaking tube used in the same way.

The Stenger test is used for the same purpose, and is also of value where malingering is suspected. Two A forks are struck at the same time, and with the patient's eyes closed by bandage so he cannot see the movements of his examiner, the forks are alternately advanced toward and from each ear, one in front of the malingering ear, the other in front of the non-malingering ear; only the fork will be heard which is nearest the ear.

The same test is also repeated with the eyes open, and the results compared; if the patient continues to say he hears this in the same ear as it approaches the other ear then there is a chance of simulation. The examination for recruits in the present war will require, on the part of the examiner, skill in detecting malingering. In bilateral deafness the normal ear is excluded with greater difficulty the higher up the musical scale is ascended.

All distant tests must be made with the voice as we approach the patient, and repeated until the test word is heard. When we draw away from the patient, speaking until he no longer hears, the apparent hearing distance will be greater, since the hearing having once been called into action, responds to a sound at greater distance than it would as an initial sensation.

If in doubt whether the ear under examination hears, close the one being tested, tightly, and then if sound is still heard it must have been from the good ear.

HEARING TESTS IN CHILDREN.

Here we contend with two principal difficulties: the unwillingness or the inability of the child to answer correctly. The little patients tire easily, hence the examination should be made as quickly and pleasantly as possible. When using questions it is desirable to use such as will be normally answered in the affirmative by a nod of the head, or else something which demands movement on the child's part. Prolonged examinations of children under 10 years are apt to be unsatisfactory. If the child is very deaf it will not be easy for him to distinguish between hearing a sound and feeling a vibration. Many children cannot be accurately tested until the third or fourth year in school.

Labyrinth tests do not fall within the scope of this paper, other than to mention that when it seems necessary to test the function of, and to determine the normal nystagmus we have found the caloric test (cold water) easier to perform, sufficient for diagnosis, and less troublesome to the patient than the turning tests. We do not as a rule use it where there is drum perforation.

U. S. ARMY TESTS.

For examination of the aviation corps and for the general hearing tests in the recruiting service of the United States Army, the method is as follows, so far as hearing tests are concerned:

Auditory acuity less than 20/20 in either ear is disqualifying. To obtain uniform results, the hearing of each ear is tested separately with the candidate standing 20 feet from the examiner and facing away from him 3 feet from the wall; this adds one-third of the ordinary distance at which a whisper would be heard were the person facing the examiner. An assistant tightly closes the ear not under examination by pressing the ball of the moistened index finger in the external meatus, and the examiner then exhales, and with residual air whispers various words and numbers which the candidate is required to repeat. This test should be repeated by using the ordinary low voice. The result of each test is recorded by using a fraction which has the normal test distance in feet (20) for the denominator and the distance through which the test sound is correctly heard

as the numerator. In testing the hearing by the watch, an Ingersoll dollar watch is used. First determine by actual trial the average maximum distance at which five men with apparently normal hearing and normal *membranae tympani* hear the watch when their eyes are closed; this approximates 40 inches. In recording the result, this number in inches is taken as the denominator, and the distance at which the candidate hears the watch, with one ear occluded and both eyes closed, as the numerator.

A functional test for the labyrinth is made as follows: The nystagmus, the past-pointing, and the falling after turning are tested both as to direction and amount. The testing chair must have a head-rest which will hold the head 30 degrees forward and a foot-rest and a stop pedal.

Spontaneous nystagmus is tested by fixation of a point beyond the normal hearing distance. Then the head is inclined 30 degrees forward and the candidate is turned to the right, with the eyes tightly closed, ten times in exactly twenty seconds. The instant the chair is stopped, click the stop watch and the candidate opens his eyes and looks straight ahead at some distant point. There should occur a horizontal nystagmus to the left of twenty-six seconds' duration, and the candidate then closes his eyes, and is turned to the left in the same manner. There should occur a horizontal nystagmus to the right of twenty-six seconds. A variation of eight seconds is allowed.

Past-Pointing. The patient sits in the chair, eyes tightly closed, and faces the examiner and touches the examiner's forefinger in front of him, raises the arm in the perpendicular position, and attempts to find the examiner's finger, both right and left. Normally, the person will always find the finger. The patient is now turned ten times to the right for ten seconds, the chair is locked in position, and the person to be examined told to touch the finger in the same manner, right, left, right, left, right, left (three times). Normally the finger will point to the right, the past-pointing will be less each time it is tried, and on the fourth turn the finger should be touched accurately.

The same experiment is then performed by turning to the left, the patient always past-pointing in the direction of the turning. Finally the head is inclined 90 degrees downward and the patient turned to the right five times in ten seconds. On stopping, the patient raises the head, and he should then fall to the right. These test the vertical semicircular canals. He is then turned to the left in the same manner and falls to the left.

EXEMPTIONS FOR MENTAL DISABILITIES.—Surgeon-General Gorgas is making arrangements to provide each base hospital with a neuro-psychopathic clinic to eliminate those mentally unfit from the ranks of the army.

AN EPIDEMIC OF DYSENTERY AT THE BOSTON STATE HOSPITAL, DUE TO A MEMBER OF THE PARATYPHOID-ENTERITIDIS GROUP.

VI. THE LEUKOCYTC REACTION.

Gay and Claypole¹⁰ in their experiments in typhoid immunization found that a specific hyperleukocytosis, preceded by a leukopenia, was produced in typhoid immune rabbits by inoculations with typhoid vaccine, and that the important cell in the gain was the polymorphonuclear. The leukocytic response was more rapid and rose to a greater height in the immunized rabbit than in the normal animal. H. I. McWilliams,¹¹ in a more recent report of similar experiments with rabbits, noted a hyperleukocytosis which was not of a higher grade in the immune than in the non-immune animal.

Both Gay¹² and McWilliams¹³ have described the leukocytic reaction following injections of vaccine in typhoid fever. A chill and rise in temperature are coincident with a leukopenia shortly after the inoculation, and a few hours later, with the lowering of the temperature and a lessening of symptoms, there is a high-grade hyperleukocytosis. The relation of the hyperleukocytosis or "leukocytic crisis" to the freeing of antibodies indicates the possible value of these studies in vaccine therapy and prophylactic immunization.

Although our examinations have been limited to human cases and have not the exactness of results obtained in animal experimentation, they have a certain clinical value, because it has been impossible to observe these cases over a number of months.

A polymorphonuclear leukocytosis, both actual and relative, was demonstrated in one protracted case (M. G.) during the first outbreak of dysentery, after a repeated therapeutic dose of the dysenteric vaccine. Six hours after a subcutaneous injection of 75,000,000, the total count rose from 6,400 to 19,400 and the polymorphonuclears from 56% to 76%, with a loss of eosinophiles. No constitutional reaction followed successive small doses in this patient, although there was an apparent improvement in symptoms.

A polymorphonuclear leukocytosis was observed in a second case eighteen hours after an initial prophylactic inoculation of 500,000,000 and six hours after the onset of a severe constitutional reaction, with fever and vomiting. Total count 18,800; polymorphonuclears, .92;

lymphocytes, .08; large mononuclears, transitionals and eosinophiles, 0. This was the only count made in this case. There is no record 11 months later that this patient has had an attack of the disease.

Because of these isolated observations, it seemed worth while to study the leukocytic reaction more carefully, and during the seven-months following the first outbreak several series of examinations were made, including one woman and four men who had had neither the disease nor prophylactic treatment, and four women who had had the disease from nine to seventeen months previously. Subcutaneous injections of vaccine were given for two or three successive weeks in doses as in prophylactic treatment, beginning with 500,000,000. In two cases the counts were taken at two-hour intervals during the first 26 hours after the inoculation. In all the other cases, counts were taken during either the first twelve or the second twelve hours at one-half, one-hour, or two-hour intervals.* Differential as well as total counts were made, and a control count was made in each case. There was no constitutional reaction observed in any of these cases and the local reaction was moderate.

The leukocytic reaction consisted of a hyperleukocytosis, with the highest count rising but little above twice that of the normal count for the individual and a relative increase in polymorphonuclears at one or more periods during the following twenty-four hours, this relative increase not always being synchronous with the highest total count.

The reaction was somewhat more marked after the second or third inoculation than after the first, except in one case in which the vaccine was injected shortly after a recurrent attack. In this case the reaction was greater after the first injection of 500,000,000 two days after the attack than after the second inoculation of 1,000,000,000, seven days later. One case (M. G.), referred to above as showing marked reaction to vaccine therapy on the first attack, showed a moderate reaction both in total and differential counts following an inoculation of 500,000,000 nine months later; and on the third day of a recurrent attack, seventeen months later, gave evidence of a reaction only in a relative increase in polymorphonuclears following an injection of 500,000,000. The diarrhea in this last instance ceased a few hours after the inoculation and there was no evident constitutional disturbance.

There is no record that the individuals chosen as normal cases in this series of examinations have had an attack of dysentery or diarrhea.

In comparing the leukocytic reaction with the clinical history in these cases the following conclusions have been made:

1. The stronger normal individuals show more

reaction to subcutaneous injections of vaccine than the weaker ones who have had the disease and recurrent attacks.

2. The leukocytic reaction for the individual is more marked during or immediately after an attack of the disease and diminishes with recurrent attacks. This corresponds to the clinical observation that the resistance of the individual to the disease is lessened by a previous attack.

3. The fact that there may be a polymorphonuclear reaction to a subcutaneous injection of vaccine, coincident with the cessation of a diarrhea, would indicate the use of vaccine therapy. In the few cases in which this treatment has been given, the results have been favorable for a recovery from an attack.

VII. BACTERIOLOGY.

The method of isolation of the organism was that usually employed for bacteria of intestinal infections. A loopful of the fresh stool was put into a broth tube, portions containing blood or mucus, if present, being selected. After two hours' incubation, surface inoculations were made on Congo red lactose agar plates. The organism predominated on the plates during the acute stage, and was frequently present in almost pure culture. It was found as long as blood and mucus persisted and for some days after the stool began to be formed, but was not isolated after the acute stage, in cases either that recovered or that came to autopsy.

On Congo red plates at the end of twenty-four hours the colonies were round, raised, with smooth edges, translucent gray, averaging $\frac{1}{2}$ mm. in diameter. During the second twenty-four hours they became an opaque gray, and increased to about 1 mm. in diameter. They did not form acid.

The organism when first isolated appeared as a small, short, thick Gram-negative bacillus. After artificial cultivation longer forms appeared. When first isolated it appeared non-motile, but after frequent replants it took on a moderate motility. It grew quickly and well on the usual media.

Cultural Characteristics.—Agar—a raised, moist, gray streak with wavy borders. The growth was delicate at first, but after several replants became heavier and whiter.

Broth—a light diffuse cloud with somewhatropy sediment.

Gelatin—not liquefied.

Litmus milk—the results were variable.

An acidity, usually slight, developed slowly (within 2-3 days) and in some cultures remained permanent as long as the tubes were observed (four weeks). Other cultures after an initial acidity became somewhat more alkaline at the end of 3-4 weeks.

Indol—tested in Dunham's peptone solution at the end of four days. One half the strains gave a negative, the other half a faint positive reaction.

* A number of these counts were made by Mr. J. C. Rock of the Harvard Medical School.

Fermentation Reactions were tested qualitatively, in Hiss' serum water, and quantitatively in sugar-free broth containing one per cent. of the substances giving an acidity in the former medium. The substances used were dextrose, lactose, saccharose, maltose, dextrin, salicin, glycerin, and mannite.

The qualitative results are given in Table I and the quantitative in Table II. The only substances broken down by all strains are dextrose and mannite, the former usually and the latter always with gas production. Saccharose and glycerin were slightly affected in isolated instances. Salicin, dextrin, and maltose were not attacked.

A strain of paratyphoid A and B*, two each of B. suipestifer and "paracolon bacilli,"* and one of B. enteritidis—Gärtner†—were studied for comparison, and the results are included in the quantitative table.

The colon-typhoid group is divided primarily into a lactose fermenting (B. coli) and a lactose-

negative group. The latter is again subdivided according to the action on mannite; no change, B. dysenteriae Shiga; acid only, B. typhosus, B. dysenteriae Flexner; acid and gas, paratyphoid-enteritidis group. The members of this last group are negative to saccharose and salicin and must be distinguished one from another by their agglutinative affinities. The present organism falls in a broad way in the paratyphoid-enteritidis group, as it is a lactose-negative bacillus, forming acid and gas in mannite, and not acting on saccharose and salicin. It differs from the generally accepted characters of the group, however, in a number of particulars. A characteristic of the strains isolated in this epidemic is the variability of their action in milk and in the production of indol. Each strain has retained its original characteristics in these respects after more than a year of artificial cultivation. The paratyphoid-enteritidis group is supposed to form no indol, to ferment maltose with gas formation, and paratyphoid A to give a permanent acidity in milk while the other members of the group give an acidity followed by alkalinity.

Recently, however, Krumwiede, Pratt and Kohn¹⁴ have questioned the value of litmus milk as a medium for differentiating paratyphoid A from B, as in a series of representations of the group they found that the difference was quantitative only, and that there were numerous intermediate degrees of reaction.

The paratyphoid-enteritidis group is admittedly especially complex and unstable, and the question of the identity or mutual relationships of its members is very confusing and is still unsettled. The cultural and chemico-biological characteristics of various members of the group are essentially the same, so that subdivision according to these is impossible. Agglutination reactions,¹⁵ however, while demonstrating the near relationship of members of the group, do permit a further differentiation into a paratyphoid B and a "Gärtner-enteritidis" sub-group. Gärtner antisera do not agglutinate paratyphoid B bacilli, and conversely B. antisera do not influence Gärtner bacilli. Complement-fixation also shows a separation of the group into the same subgroups. Paratyphoid A seems to go in the Gärtner, and B. suipestifer in the B subdivision. Paratyphoid B is quite uniform in cultural and serological reactions, while the Gärtner group is more irregular in both respects.

In addition, other strains have been described which agree in most cultural characteristics with the group, but are not agglutinated by paratyphoid B or enteritidis antisera. Immune sera for these strains usually agglutinate only their homologous organisms. These may represent transitions between the two subdivisions. Certain of these cultures have been described under the title of paratyphoid C.

As to the normal habitat of members of the group: according to Bainbridge² true paraty-

* Obtained from the American Museum of Natural History.

† Obtained from the Harvard Medical School. B. suipestifer Arkansas and Maryland.

phoid *A* and *B* are never found except in connection with human disease, while the other members of the group are associated with animals. The normal habitat of *B. suispestifer* is the intestine of mice and pigs. *B. enteritidis* is frequently present in the intestine of healthy rats, and this animal is an important source of the organism. The bacillus also causes an infection of cows and calves. The organism has been the cause of frequent epidemics of meat poisoning, the meat either coming from infected animals, or having been contaminated after slaughter, presumably by rats.

VIII. AGGLUTINATIONS.

A series of agglutination reactions was done, using the sera of recovered and vaccinated patients and of immunized rabbits with the epidemic strains and also with several representatives of the paratyphoid-enteritidis group which had been studied culturally; also the epidemic strains with rabbit antisera for the same representatives of the group.

The points in view were: the extent of agglutinin formation in the disease, its relation to the type of the disease, persistence of agglutinins after recovery and prophylactic vaccination, and the placing of the epidemic organism in the paratyphoid-enteritidis group.

One or more tests were made on 78 persons. The serum of a normal non-exposed person was used as a control.

The reactions were done by the macroscopic method, using formalized cultures as antigens. For the homologous antigen with patients' sera a mixed antigen was used, made of four strains isolated from the feces; two from the heart's blood and one from the intestinal wall of fatal cases.

All the dysentery cases tested gave a positive reaction in dilutions varying from 1/10 to 1/120. Twenty seven cases of diarrhea occurring in patients and employees at the West Group during the outbreaks of dysentery also agglutinated in dilutions varying from 1/20 to 1/100.

Agglutinin formation in the disease, as shown by these results, is very moderate. The highest complete reaction obtained was 1/120. The majority of the sera obtained to within four weeks after onset agglutinated completely only to 1/40, smaller numbers to 1/80 and 1/100, a few only 1/10 and 1/20 (see Chart 2). As to the relation between the type of the disease and the strength of the agglutination reaction, Chart 2 shows that reaction in high dilutions were more frequent among the dysentery than among the diarrhea cases.

Repeated observations on 12 patients who had a single attack (see Table III.) show that there is a rapid drop in the titre during the first few weeks, in some cases a drop to 1/2 or 1/5 between the 3d and 4th week, and that agglutinins persist (at a low level) in some cases for a considerable time,—as long as 17 months in one

case and 14 months in two others, although single negative results appear at 5 to 11 months.

After prophylactic vaccination repeated agglutination tests were made on 10 patients at intervals up to 10 months. In the majority of cases the titre within a month after inoculation ranged from 1/80 to 1/150, but in one case was 1/20. Values of 1/20 and 1/10 were usually obtained at 5 to 6 months and 1/10 at 10 and 11 months.

No extended observations on the persistence of agglutinins after paratyphoid infections are available, although, on the strength of tests on single cases, they are said to disappear rapidly. Dreyer* has found agglutinins for *B* are always high, while for *A* they are low, after either the disease or vaccination, as compared with *B* or typhoid.

The following antigens were also tried out with a limited number of patients' sera and

with rabbit serum for the epidemic strains: paratyphoid *A*, and *B*, *B. suipestifer* Arkansas, *B. enteritidis*,* and the strain of paratyphoid *A* isolated in the hospital epidemic of 1910.

+=trace.

The results with patients' sera, given in Table IV. show first, the presence of group reactions; second, the absence of strong reactions with paratyphoid *A* and *B*; third, the non-identity of the present organism with the one isolated in the epidemic of 1910; and fourth, high agglutinations of two sera with *B. enteritidis*, although these results must be discounted to a certain extent by the reaction of the bacillus with normal serum. With stock paratyphoid *A* and *B* sera the epidemic strains reacted scarcely at all (partially at 1/10.)

* For the sources and cultural characteristics of these strains see page 218 and tables III and IV.

A rabbit was immunized with five subcutaneous doses of living broth culture of the same epidemic strains used for the mixed antigen. The antiserum (see Table V) agglutinated the homologous antigen completely at 1/300, and almost completely at 1/1000. It reacted with *B. enteritidis* better than with the homologous strains, giving a complete reaction at 1/1000. It agglutinated weakly (1/50 complete) paratyphoid *A* and *B* and *B. suipestifer*, but did not affect the Boston State Hospital strain *A*. These results agree in a general way with those obtained from patients' sera.

A strong anti-enteritidis rabbit serum was prepared, which agglutinated the homologous culture completely at 1/1500 and almost completely at 1/2000. Curiously, it reacted only slightly (partially at 1/50 and 1/100) with the epidemic cultures. It gave a moderate reaction with paratyphoid *B*, but with *A* reacted almost as well as with its own antigen.

A strong antisuipestifer serum (complete at 1/1500) also reacted only weakly with the epidemic strains, but as well with *B. enteritidis* as with its own antigen; it also agglutinated paratyphoid *B* in high dilutions (1/1000) but paratyphoid *A* only moderately.

(To be continued.)

Society Report.

NEW ENGLAND PEDIATRIC SOCIETY.

The forty-seventh meeting of the New England Pediatric Society was held in the Boston Medical Library, Friday, February 23, 1917, at 8.15 P. M., the president, DR. MAYNARD LADD of Boston, in the chair.

The following papers were read:

1. Certain aspects of epilepsy in children—George Clymer, M.D., Boston.
2. Hemorrhagic conditions, with especial reference to purpura—George R. Minot, M.D., Boston. Discussion opened by Beth Vincent, M.D., Boston.
3. Iliac adenitis and abscess—Charles J. Mixer, M.D., Boston.

General discussion of Health Insurance.

DR. CLYMER'S PAPER.

DISCUSSION.

DR. WALTER B. SWIFT: I should like to say a word about other phases. Epilepsy has a speech sign in it as one of the numerous aspects that should be brought to your attention. This speech sign is not one of the numerous signs that I have given out, but has been given to the literature by Dr. L. Pierce Clark of New York. It consists in a rather monotonous speech that lacks flexibility and is pitched a bit high, and is somewhat like this (illustrating).

You see that the sign is monotony, high pitch and lack of flexibility. For these reasons it has been termed the "plateau voice." Dr. Clark claims that it occurs in about 75% of cases and he has several times suspected epilepsy merely from the voice, and has found his suspicion confirmed by further examination.

There is another aspect that I wish to call your attention to, and that is that epilepsy is passing through a certain stage in medicine at the present time. It seems to be somewhat similar to the stage through which hysteria has passed. In the materialistic days, hysteria was considered to be the uterus wandering around in the inside. A number of years afterward, Janet, of Paris, a psychologist, saw the limitation of color fields and the lack of sensation and passing paralyses, and with his psychological eye came to the conclusion that hysteria was a limitation of consciousness. Then came Babinski,—he was a great observer, and he saw these same things, but he noticed that they could be made to disappear through the use of suggestion. He, therefore, claimed that hysteria was suggestion. Late years has come Freud, who has interpreted hysteria as the external manifestation of subconscious complexes and with him the medical world—at least half of it—has been swung over to this view.

What does all this mean? It means that certain men with certain training have shed the light of their training upon the same object and have made an interpretation of it from their own personal training. These are, in a great measure, the steps through which medicine, itself, in a large sense, has passed within the last hundred years. And this,

also, is the condition in epilepsy at the present time. It is now passing from a somatic to a psychic interpretation. There are men arrayed on both the psychological side and the somatic side.

My own study in this field of epilepsy would incline me to follow a line of cleavage between these two. I see no reason why a psycho-somatic etiology cannot be proven. To do this we should look for something on the pathological side that is sufficient to cause the symptoms and the psychological appearances. I see no reason why the unit of etiology behind all these phenomena could not very well be hydrocephalus. Of course I know there are exceptions, but hydrocephalus has been found in many cases already. It is possible that in cases where it has not been found that there has been a partial hydrocephalus or a minutely located hydrocephalus, and that still further investigation may reveal that hydrocephalus itself, either large or finely located, is etiology enough, or that something that acts just like it may be etiology.

Sure it is that as we review all the symptoms and as we look at the anatomy of the ventricles where internal hydrocephalus occurs and see how pressure of too much fluid can vitiate the functions of nerve fibres and nerve cells, it is really quite plausible to think that after all the etiology may be nothing more than a large or small hydrocephalus.

DR. POWERS: There is not one thing in Dr. Clymer's paper which I can dispute and I certainly share with him his optimistic point of view. I think that by speaking in this optimistic way he is helping all of those who are treating epileptic patients.

In January, 1913, at the suggestion of Dr. Swift, I began to study the problem of the treatment of epilepsy. We had a great many cases of epilepsy at that time in the Nerve Clinic at the City Hospital, and they were looked upon as a nuisance. I think they are very interesting material to work on. I had some x-ray pictures of the skulls taken and bismuth x-rays of the intestines. The radiographs of the skulls showed nothing, but those of the intestines showed stasis. I placed the patients upon a diet which I consider merely a reasonable one for patients suffering from constipation and intestinal indigestion. They were given laxatives and abdominal massage, when it was possible. I believe that the massage helped them, but it is difficult to say how much. In giving abdominal massage, I begin at the caecum and massage the whole colon, spending more time on the hepatic flexure than elsewhere, because stasis most often occurs there, especially when the transverse colon is low and the hepatic flexure has, therefore, become a sharp angle. As it was not possible to give manual massage in all cases, I devised a method of self massage with wooden dumb bells, which has been taught to some of the patients. For a year I have treated nearly all cases without bromides, but have given sodium bicarbonate. I am not ready to say that I think that the bromides are useless, and think that I shall now begin to treat another series of cases with bromides for comparison with those treated without them. I have not used calcium lactate in many cases. I believe that the toxin which produces the attacks is an acid and that calcium lactate, acting as an alkali, may neutralize it. It is for that purpose that I use sodium bicarbonate. To treat a case of epilepsy requires

a good deal of patience and time spent in inquiring into such commonplace matters as the diet which the patient is accustomed to and the kind and amount of exercise he has. This is not interesting to many neurologists and does not appeal to them.

DR. DROWNE: The details of the method which I am using are so involved, and the success depends in such a degree upon the thoroughness with which the details are carried out, and also the manual skill acquired, that it does not seem to me advisable to talk or write about them. They can be shown and the technic acquired by others.

DR. CLYMER (in closing): I should like to testify to the very good results obtained by Dr. Drowne in certain of his cases which I have seen. I think we should all be interested in the work he is doing.

HEMORRHAGIC CONDITIONS.

(Abstract.)

DR. GEORGE R. MINOT, Boston: Hemorrhagic conditions, due to a recognized abnormality of the blood, are associated with a diminished number of platelets, or with alteration of these elements or of other factors involved in the coagulation of the blood. The various types of purpura hemorrhagica are the conditions with diminished numbers of platelets, while in hemophilia, in certain types of cholemic hemorrhages, sepsis, and in some cases, at least, of melena neonatorum, the platelets occur in approximately normal numbers. In studying these conditions, it is necessary that the following tests be properly performed.

1. Enumeration or estimation of the platelets.
2. The bleeding time.
3. The coagulation time, with observations on,
 - (a) the time of onset and termination of coagulation.
 - (b) reclothing phenomenon;
 - (c) retractility of clot;
 - (d) firmness of clot;
 - (e) effect of suitable amounts of calcium on the coagulation time.

The tests for prothrombin time, antithrombin and fibrinogen may be of value in certain instances.

Purpura hemorrhagica is that condition in which there is bleeding from one or more mucous membranes, and usually purpuric skin lesions. There is a marked diminution of the blood platelets, a delayed bleeding time, a normal or slightly delayed coagulation time, and a soft non-retractile clot. Purpura hemorrhagica is not to be confused with other types of purpura or scurvy which have an essentially normal number of platelets and no definite alteration of their coagulation factors. Purpura hemorrhagica may be an idiopathic disease or appear as a symptom secondary to some disease, as pernicious anemia, lymphatic leukemia, diphtheria, etc., etc. The idiopathic type may occur in the following forms:

1. Continuous—acute or chronic—acquired or congenital.
2. Intermittent.

In the former the platelets are continuously below normal, while in the latter they are below normal during the attacks only.

Idiopathic aplastic anemia has often undoubtedly

been confused with purpura hemorrhagica, as both conditions present anemia and purpura. It may well be that these two conditions are not so distantly related as is perhaps evidenced by the fact that cases may be recognized that form an intermediate type of condition between them and suggest a partially depressed activity of the marrow which especially involves the platelet elements.

In typical aplastic anemia there is no evidence of regeneration of the erythrocytes, polynuclear leucocytes, or platelets, the blood elements originating in the marrow. In typical purpura hemorrhagica there is evidence of regeneration of erythrocytes and polynuclears but not of the platelets, though they may be formed as normally from the megakaryocytes of the marrow but rapidly destroyed in the circulation.

Diminution of platelets and thus primary or secondary purpura hemorrhagica may be due to:

1. Destruction or depressed activity of the megakaryocytes with or without similar action on the other elements of the marrow; by some unrecognized or recognized toxin, or by congenital absence of these elements.
2. Displacement of the megakaryocytes by abnormal cells, as occurs in lymphatic leukemia, pernicious anemia, metastatic tumors, etc.
3. Destruction of platelets in the circulation.

Hemophilia occurs in males only and is usually hereditary. Hemorrhages into muscles and joints are frequent. Purpuric skin lesions probably never occur. The blood findings are in contrast to those of purpura hemorrhagica. The platelets occur in essentially normal numbers, but are physiologically qualitatively defective. The bleeding time is essentially normal. The clot is retractive and firm. The coagulation and prothrombin time are usually much delayed. One must, however, note that some cases have but a very slightly delayed coagulation time or rather a delayed time demonstrated only by refined methods or by demonstrating the reclothing phenomenon.

In melena neonatorum there occurs a delayed, often markedly delayed, coagulation time, perhaps associated with prothrombin alteration or deficiency.

The one condition where there is a marked increase of antithrombin is in experimental peptone poisoning.

Diminution in the amount of fibrinogen as a cause for hemorrhages is to be found in conditions in which the liver is severely damaged, as in phosphorus and chloroform poisoning and far advanced atrophic cirrhosis; though diminution of platelets and perhaps a fibrinolytic ferment play a part in this latter condition.

Certain cases with defective bile secretion or biliary fistula may give some disturbance of liver function which affects the coagulation factors and causes hemorrhages.

The lack of calcium available for purposes of coagulation in the blood is probably wholly in some and partly in other instances accountable for the hemorrhages seen with certain cases of prolonged obstructive jaundice. Instances of actual diminution of calcium as a cause for hemorrhage are notably rare.

The administration of calcium for therapeutic purposes is indicated only in those cases associated with diminished amounts of either available or total calcium.

The best treatment for the other hemorrhagic

conditions is a suitable amount of transfused blood from a donor of the same isoagglutination group. If it be to replace diminished or defective platelets the effect will last as long as the life of the platelets, *i. e.*, about three to five days, though in some instances a rapid destruction of such platelets seems to occur and the effect is then shorter. A permanent or marked temporary rise of platelets following a transfusion in purpura hemorrhagica is referable to a stimulation of the patient's platelet-forming elements or to a prevention of their destruction. Repeated transfusions are especially indicated in conditions where the toxine is recognized and its source has been removed, as in the aplastic anaemia of benzol poisoning. By so doing the bone marrow has a chance to regenerate. Transfusion, especially early, in melena neonatorum is in many instances curative. In purpura hemorrhagica it is often temporary only.

The next best treatment to transfusion is the use of thromboplastic preparations derived from fresh tissue juice. Tissue juice accelerates the coagulation of blood markedly, as do platelets. This action of tissue juice has been recognized for years, but it has been but occasionally used for therapeutic purposes. With Howell's discovery that certain extracts of brain having the properties of kephalin exert a marked thromboplastic action, it has been quite simple to obtain concentrated, stable and active preparations. A thromboplastic preparation has been used by Fonio under the name of coagulen.

DISCUSSION.

DR. VINCENT: A vital defect in the blood itself is probably the basis of the purpuric conditions observed in various diseases in infants and children. In some instances this defect is apparently congenital, as in hemophilia and hemorrhagic disease of the newborn; in others it is evidently acquired during the course of the disease, and is only a symptom of the disease, as in certain cases of obstructive jaundice in aplastic anaemia and in the various purpuras. Some of these conditions improve without treatment and others, aplastic anaemia for instance, are fatal in spite of any treatment, but in all of them, as regards the symptom of hemorrhage, transfusion has proved the most effective measure. Transfusion is effective in two ways. It corrects, temporarily at least, the abnormal tendency to bleed and makes good the loss of blood.

At times in these purpuric conditions it is very difficult to make the correct diagnosis and to say whether we are dealing with an incurable disease or whether it is self-limited and one from which the patient can recover if he does not succumb to the loss of blood. In this group, in the absence of a positive diagnosis, it is advisable to try the effect of one transfusion and perhaps a second. To go beyond this is probably useless. In my experience with these purpuric conditions the need of repeated transfusions means a grave prognosis. Each transfusion becomes less and less effective. They may delay the fatal result but do not essentially alter the course of the disease.

Bleeding in obstructive jaundice in infants is sometimes seen in cases of congenital malformation of the bile ducts. Here the blood defect is a lack of available calcium as shown by the "calcium *in vitro*" test. These cases should be given calcium lactate by mouth. One sometimes sees a case of permanent biliary fistula after operation that finally

develops a pathological tendency to hemorrhage, which seems to be associated with the absence of bile from the intestinal tract. These cases should be given ox-gall until the faeces are a normal color. In either instance if the bleeding is acute and the condition serious, transfusion is indicated.

In small children and infants the main difficulty encountered in transfusion is associated with the small size of the veins. If those at the elbow and ankle are too small, the external jugular may be used. In infants with an open fontanelle the blood is very easily injected into the longitudinal sinus.

ILIAIC ADENITIS AND ABSCESS.

DR. CHARLES G. MIXTER, Boston: Iliac abscess is a condition that one does not find mentioned in the text-books of pediatrics, and in the text-books of surgery it is only broadly considered under the discussion of retroperitoneal abscesses. In this connection the abscess starts along the spine in the lumbar region or about the kidney, and by gravitation the pus works downward and points not infrequently above Poupart's ligament. The lesion is primarily a lumbar abscess. Again, one sees an abscess in the iliac fossa, secondary to a bone lesion of the pelvis not infrequently. Here osteomyelitis of the ilium or one of the other bones of the pelvis is the primary cause. Such secondary abscesses belong to the consideration of the primary disease and will not be included here.

Iliac adenitis and abscess in children, however, is such a definite surgical entity, that its symptomatology should be understood and its importance emphasized. Similar to gland infection elsewhere, there is, first, an acute adenitis of the iliac glands, by invasion through some portal of entry. At this stage the infection may subside and the glands gradually diminish without giving rise to further trouble. If the inflammatory process continues, focal necrosis takes place within the glands, periglandular tissue is formed and a hard, indurated mass is palpable low down in the iliac fossa above Poupart's ligament. When this stage is reached the process rarely subsides; usually there is slow softening of the glands, with the formation of an abscess which pushes the parietal peritoneum inward and fills the iliac fossa. As the abscess enlarges it may descend occasionally into the pelvis when under great tension, bulging inward from the lateral wall, but never passing beyond the median line, where it is limited by the firm attachment of the peritoneum.

Iliac abscess is infrequently met with; in the last eight years only nine cases have been admitted to the surgical service at the Children's Hospital. We have seen it more frequently in boys than in girls, in the ratio of three to one, and chiefly in younger children. Only two of the children were over four years of age; seven were between one and a half and four years. In a considerable number of cases the iliac adenitis immediately followed a sore throat, cold or bronchitis, thus resembling many of the cases in the so-called milk infection epidemics, where the sore throat has been accompanied by marked abdominal symptoms. These cases would suggest that the adenoid tissue of the tonsillar ring may serve as a portal of entry. Chicken-pox and, particularly, measles are shown by the histories in many instances shortly to have antedated this condition. In one case a septic abrasion was noted on the foot on the corresponding side, and in another,

the glands in the femoral region had previously been involved.

The record of the following patient will best illustrate the course of a typical case.

R. D. 2½ years old, girl baby. Referred to the Surgical out-patient department for an acute condition of the left hip. There was no family history of tuberculosis. One year ago the child had whooping cough. Otherwise always well. Ten days ago had a severe cold. Has not completely recovered from it. Four days ago child fell off a chair, since then a limp has been noticed. Refuses to walk today. Has complained of some pain in the abdomen and left hip. Feverish for the last 24 hours. No night cries. Bowels have moved daily. No vomiting.

Well developed and nourished. Physical examination negative except for abdomen and lower extremities. No glandular enlargement. Abdomen full but not distended, no spasm, some tenderness in the left lower quadrant and definite induration above Poupard's ligament. Left thigh flexed at 90 degrees. Rotation at hip free—pain and resistance on extension. Some spasm of hamstring muscles. Reflexes and measurements normal. White count 44,000. Temperature 102 degrees.

The child was referred to the house, and flaxseed poultices were applied to the abdomen. At the end of a week the abscess was opened extraperitoneally and drained. The wicks were removed on the eighth day. At the end of three weeks the sinus had healed, all spasm about the hip had disappeared and there was no limp.

The onset is generally subacute, symptoms in most cases having been noted for two or three weeks before the child was brought to the hospital. At first there is malaise and fever, followed in a few days by a noticeable limp and a persistent flexion of the thigh. This is the symptom on which the parents lay greatest stress. In the more severe cases the thigh will be held sharply flexed on the abdominal wall. Pain is referred usually to the hip, at times to the abdomen, but is usually not intense unless the limb is moved. Vomiting is rare and the bowels generally are regular, though occasionally there is abdominal distention and constipation. There are no night cries.

On examination the child is fretful, feverish, temperature 99 degrees to 102 degrees, and lies with one or both legs drawn up. The leg on the unaffected side can be readily extended, but any attempt to straighten the other leg will be met with a sharp outcry of pain and violent muscular resistance. The abdomen is soft, and involuntary muscular spasm is absent. Voluntary muscle spasm is found over the iliac fossa in which lie the inflamed glands, and when this spasm is overcome, induration can be detected above Poupard's ligament, or a definite mass may be felt in the more advanced stage.

The examination of the hip is of the utmost importance. Every effort should be made to have the child quiet, and the manipulations should be carried out with gentleness. With the leg in flexion, rotation is free, adduction and abduction are only slightly limited, if at all, and the thigh can be flexed until it causes pain by pressing on the abdomen. On the other hand, any attempt at extension is met with an outcry of pain, marked resistance and tilting of the pelvis from splinting of the psoas muscle. All measurements of the two legs are equal.

Rectal examination, which is of great value in many obscure lesions of the abdomen in children, will usually reveal a unilateral induration, or definite tense, tender abscess. The white count is elevated, varying from fifteen to forty thousand. The von Pirquet reaction is of importance only when negative, as so often happens in the diseases of childhood.

The failure to make a correct diagnosis of iliac abscess arises from the lack of recognition that has been accorded this condition. It is not included in the differential diagnosis when a case is met with. Not one of the nine cases was sent to the hospital with a correct diagnosis of the condition. Where the lesion occurs on the right side it is most often mistaken for an appendix abscess. In the latter condition the onset is more acute and there is involuntary spasm of the rectus muscle, and generally distention, or some intestinal disturbance. Resistance to extension of the leg is less marked. Where the abscess has extended into the pelvis, it gravitates to the pouch between the rectum and the bladder and commonly lies to the left as well as the right of the median line. In appendicitis with pelvic peritonitis in children, vesical irritation is frequent; generally pain on micturition and in consequence a distended bladder; sometimes frequency of urination. This symptom is absent in iliac abscess.

In psoas abscess the onset is more insidious, the child has night cries and a lesion of the spine can be demonstrated. A negative von Pirquet is important. The white count is lower and there is greater fluctuation between the morning and evening temperatures.

Where a lumbar abscess has pointed above Poupard's ligament there is tenderness and resistance in the loin and in the costo-vertebral angle.

In acute infections of the hip slight motion elicits pain and is limited in all directions. There is definite spasm of the adductor muscles and the resistance in the iliac fossa is absent. In epiphysitis and osteomyelitis there is thickening and localized tenderness.

In the treatment of iliac adenitis we find that rest in bed and frequent hot applications to the abdomen, to break the abscess down and bring it to the surface above Poupard's ligament, is preferable to early operation. The safety of the operation is far greater, as the chance of opening the peritoneal cavity is greatly diminished; and where the gland tissue is thoroughly broken down, the period of drainage is much shorter than when a large amount of necrotic lymphoid tissue has to slough out gradually. Even when a palpable tumor has formed above Poupard's ligament, the inflammatory mass may in rare instances subside without drainage, as occurred in one of our cases.

When a well-marked abscess has formed low in the iliac fossa, an incision is made above and parallel to Poupard's ligament, slightly below the anterior superior spine of the ilium. The peritoneum is pushed inward and upward without entering the abdominal cavity and the abscess is evacuated. Any necrotic gland tissue is gently wiped out and the cavity is drained with a rubber tube or cigarette wicks.

Cultures from the pus may show a growth of either streptococcus or staphylococcus. In one case the colon bacillus was found.

With proper drainage a favorable outcome may

be expected in these cases. The spasm around the hip subsides and there is a rapid complete return of function. A discharging sinus will persist for a variable length of time, from three weeks to two months, depending upon the amount of the necrotic gland substance which has to separate.

In conclusion I would like to emphasize again the importance of bearing iliac adenitis in mind when an obscure condition in the lower abdomen or a puzzling lesion of the hip is encountered.

ADDRESS ON HEALTH INSURANCE.

DR. A. N. BROUGHTON, Jamaica Plain: Four years ago, the Workmen's Compensation Act was passed by our legislature and was an attempt to solve the unsatisfactory relations throughout the industrial world in the matter of industrial accidents. The Act was hailed as a great advance in social legislation, and great claims were made that under it, workmen would be far better treated in the matter of compensation and in the efficiency of their medical service, than ever before. As chairman of the committee of the Massachusetts Medical Society, I have given some attention to this Act for the last year, and know that the claims made for it in a very large measure have not been substantiated, and that a great deal of necessary effort has been put forth so to amend the statute as to make it really effective.

Now, to quote the words of Prof. Doten, who introduced the bill for social insurance last year in the legislature: "Having gotten the Workmen's Compensation Act satisfactorily into working order, the Association for Labor Legislation then turned its attention to health insurance," with the purpose of establishing that as the next important social legislation. There are two matters particularly involved in this proposal for health insurance. In the first place, as to the principle itself—is there any reason to believe that any considerable part of the benefits claimed for it would occur? This principle, put into operation, would enormously affect 75 per cent. of the practice of 75 per cent. of all the doctors throughout the state. It is in its very essence a medical problem, and it is entirely proper that the profession should first ask how much assurance there is that the benefits claimed by the proponents of health insurance would be actually realized. In this connection, our experience with the Workmen's Compensation Act has not been reassuring. It is fair to say that with every intention of helping in the future, as in the past, all measures which will advance preventive medicine, a very large part of the profession is critical of the efforts of the Association for Labor Legislation to force this matter along. And there is no question in my mind that it is the methods by which the attempt has been made to advance it, which have been the subject of criticism more than the principles involved, entirely proper as it is that these principles should be critically studied and thoroughly investigated. I do not believe that the profession at large is satisfied that the experiment as tried in Germany or in England has been sufficiently convincing to warrant its trial in this country, save under very different conditions and safeguards.

Next to the question of the principles involved, the second point centers again around the methods by which the proponents of this legislation have sought to advance it. This is very largely a med-

ical problem, but in all the councils and in the Association itself, which has undertaken to establish this form of insurance, the medical profession is singularly unrepresented. The number of practising physicians who are active in the Association or who have been consulted, in this state particularly, has been almost negligible. That is the great objection in my mind and in the minds of a very great many of the profession throughout the state, to the whole matter. If the Massachusetts Medical Society and the Homeopathic Medical Society would be satisfied, in the first instance, that the principles of health insurance could be wisely and effectively applied to this state, it is then imperative that any movement looking to the establishment of the principle should be very largely in the hands of those who have got to carry on the work, taking such other advice from sociologists, employers, and others interested in the problem as might be necessary.

I believe, in closing, that the fundamental difficulty with health insurance as it has thus far been discussed in this vicinity is the old principle of taxation without representation.

DISCUSSION OF HEALTH INSURANCE.

DR. JAMES S. STONE, Boston: Health Insurance is a subject so complex and one of which I know so little, that I want much more to listen than to talk. But we must inform ourselves, and the issues brought up must be met fairly and in a very broad-minded way. The medical profession is vitally concerned with a right solution of the problems and we might as well realize at once that no legislature will consider the personal selfish interests of physicians if convinced that health insurance legislation will benefit the community at large.

Within a few days Dr. Cotton has brought forward the suggestion that the answer to the medical problem is the abolition of the problem. He suggests that the proposal to furnish medical care as part of the insurance benefits be eliminated and goes on to say:

"The move purports to be one for insurance of the workman; not for the regulation or ruination of medical practice in this Commonwealth. Let it be an insurance measure pure and simple.

The proposals to let John Doe, sick and off the job, have half, two-thirds, or three quarters of his wages, while he is out, sounds well; is probably wise, and is very likely entirely feasible. But that is no reason why Richard Doe, M.D., should be forcibly legislated out of his habits and routine, out of his dignity, as he conceives it, and very likely out of half his living as well; more particularly as he has not asked for any change or merited any regulation, so far as we know."

In considering this suggestion of Dr. Cotton's, it is important to realize exactly what he proposes. In reality he suggests unemployment insurance in place of health insurance.

Now to keep the issues clear, when we think of health insurance let us call it health insurance, and when we think of unemployment insurance let us call it that. But let us recognize too that insurance against unemployment due to illness must inevitably sooner or later involve the medical profession. When fire insurance was first undertaken the rates were equal for all. There immediately followed the differentiation into classes of risks, and there is a constantly increasing effort in the direc-

tion of preventive measures. Similar results must inevitably follow unemployment insurance. Medical inspectors must inevitably be appointed at first to prevent fraud and very soon to report on whether the sick workman is getting well as surely and quickly as is possible. Other obvious steps will follow. The medical problems cannot be divorced from the problems of unemployment insurance. I do not mean by this that it may not be better to have the laws governing health insurance enacted as a natural result of conditions arising year after year, rather than to attempt to enact a complete piece of legislation at the beginning. These are two different methods of meeting a most difficult and complex set of problems. But it is a great error to feel that we can avoid being involved by declining to take part in the settlement of problems which hinge upon preventive medicine.

Many progressive employers are beginning to realize the economic value of keeping their employees healthy. They are employing physicians and nurses to care for the slightest injuries at once, and to insure rest and care for those even slightly ill.

In the same way the school physicians and nurses are doing much to insure care of the children at the very onset of their illness.

Unemployment insurance alone will do much to provide good care and sufficient food for the children whose fathers are sick. It may be best to insist that if social legislation is to be enacted at all it should be simply unemployment insurance at first; and that the medical aspects be left for later consideration. But if so, let us do it with the full understanding that the medical problems will arise immediately and cannot be avoided.

Those of us who are interested in hospitals must realize the possible effects upon gifts and legacies which may follow taxation to care for the sick.

The problems are most complex. They cannot be avoided. We have started along the road of preventive medicine. The medical profession must point out the best ways in which the aims of preventive medicine can be fostered, or else be content with such legislation as is forced upon us by the legislature seeking the good of the commonwealth.

Dr. EMMONS: Infant mortality during the first month of life, when prenatal causes are active, amounts to about 40% of the total. This mortality has been shown by the United States Children's Bureau investigations to be rising rather than falling. To one working in the poorer districts of the city, this fact is not surprising.

I ask you, gentlemen, if the medical profession is doing anything to improve this situation and whether some change is not desirable?

I favor the principles of health insurance because I believe that with organized care to carry out the object, maternity benefits would in time result, and that such organized care should improve the situation and give us some system for steady improvement in our results of maternity work.

Book Reviews.

Diseases of the Genito-Urinary Organs and the Kidneys. By ROBERT H. GREENE, M.D., Professor of Genito-Urinary Surgery at Fordham University, New York; and HARLOW

BROOKS, M.D., Professor of Clinical Medicine, University and Bellevue Hospital Medical College. Fourth edition, thoroughly revised. Octavo, 666 pages, 301 illustrations. Philadelphia and London: W. B. Saunders Company. 1917.

The publication of the fourth edition of this book has been demanded, not so much because of material changes in the subject-matter, as because of the popularity of the preceding editions. The present book is practically identical with the previous (third) edition, which was reviewed in this JOURNAL three years ago. It is a trustworthy, comprehensive text-book, which has stood the test of time, and has enjoyed the popularity which its previous editions have merited, and which the present edition will undoubtedly command.

Abnormalities of Myocardial Function. By T. STUART HART, M.D. New York: The Rebbman Company. 1917.

Dr. Hart has written an excellent book of three hundred pages based almost exclusively on the newer graphic methods. Nevertheless, the book meets admirably the needs of the student and practitioner who want to know modern medicine in the light of new advances and yet have not the opportunity themselves to utilize these instruments of precision. It is a well-written book, lucid and direct, with a minimum of unnecessary material.

An Introduction to Neurology. By C. JUDSON HERRICK, Professor of Neurology in the University of Chicago. Philadelphia and London: W. B. Saunders Co. 1917.

This little volume is called an introduction to neurology, but the reviewer, in going through the volume, is continually amazed to find the amount of exact information contained in it, and only closer study shows that this has been attained by the most careful condensation in which it seems that no important fact has been omitted, and no unimportant ones allowed to take space required for the essentials. On almost every page we see the evidence of the work, not only of a careful student, but of an expert, not only in his field, but in teaching.

Especially to be commended is the avoidance of the error of going in too great detail into the course of tracts of fibres, perhaps well known anatomically, but the function of which still remains unknown to us, and the amount of space given to making clear to the student the fundamental physiologic principles of action of the complicated structures of the nervous system.

Taken as a whole, we know of no book better fitted to serve as an introduction to serious study of this fascinating but difficult branch of knowledge.

THE BOSTON Medical and Surgical Journal

Established in 1812

An independently owned Journal of Medicine and Surgery published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, AUGUST 16, 1917

EDITORS.

ROBERT M. GREENS, M.D., *Editor-in-Chief.*

GEORGE G. SMITH, M.D., *Assistant Editor.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments published by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager,*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

MEDICAL EXAMINATION OF RECRUITS.

In the present issue of the JOURNAL are published four articles of especial interest in relation to the medical examination of recruits. The general physical examination of soldiers involves several special points of importance, differing from similar examination in civil practice, especially on account of the liability to malingering in a draft army.

On page 232 appears a report of an address by Major Brownlee, outlining the general methods and technique to be pursued in examining recruits. Following this is a report recently submitted to the Surgeon-General of the army by the committee on clinical methods and standardization of examinations and reports, which is a sub-committee of the Mental Hygiene War Work Committee of the National Committee for Mental Hygiene. The latter, as is well known, has been authorized by the Surgeon-

General to organize and equip neuro-psychiatric hospital units, to be attached to the base and other military government hospitals. This report represents the first attempt ever made in organizing an army to take into consideration the neuro-psychiatric qualifications of the men. It has been accepted by the surgeon-general, and is to be used as the basis of an official circular from his department.

On page 236 of this issue of the JOURNAL is published further a letter dealing with the latest modifications of the plan of the medical department in dealing with the detection of tuberculosis among recruits for the National Army. This modification involves some departure in detail from the plan originally outlined editorially in the issue of the JOURNAL for July 5 (page 19) and amplified in succeeding numbers. Finally, on page 213 is published a paper by Dr. Richards, dealing with the special methods and tests applicable to the determination of deficiency in hearing, especially the detection of malingering, as applied to army physical examinations.

A perusal of these four papers should be of value to general practitioners about to undertake in any capacity the examination of recruits for military or naval service. It is hoped that other papers of a similar nature, dealing with special aspects of the problems involved, may appear in subsequent issues of the JOURNAL.

PAUCITY OF MEDICAL RESERVE OFFICERS.

THE Massachusetts State Committee for National Defense has received from the National Council the surprising statement that out of 5869 doctors in the state, only 279 have been recommended for the Medical Officers' Reserve Corps; that is to say that only 5%, apparently, of the Massachusetts physicians have offered their services to the country in the existing crisis! These figures are so surprisingly small that it seemed at first as if an error must have been made, but upon careful consideration of existing data we find that these figures are substantially correct. The State Committee for National Defense therefore makes, through the pages of the BOSTON MEDICAL AND SURGICAL JOURNAL, a most urgent appeal to the physicians of Massachusetts immediately to make application for an appointment in the Medical Officers' Reserve Corps, or for an appointment to the

regular Medical Corps, either the army or the navy.

It is particularly important that young men who have recently finished hospital appointments should volunteer directly. As is well known, any healthy man of less than fifty-five years, particularly those men who are without dependents, will be welcomed, as they are very greatly needed under existing conditions. Applications cannot possibly be made too soon, since it requires three or four weeks to receive a commission after application has been made.

It is also probable that a considerable number of doctors have been examined for the Medical Reserve Corps and have received their commissions, but have not accepted them. It is more than ever essential that the men should accept their commissions immediately, as their services are not available to the country until they have formally accepted the rank given them.

JOHN BAPTIST BLAKE, *Chairman,*
Massachusetts State Committee
For National Defense.

INDUSTRIAL HEALTH INSURANCE.

THE attention of members of the Massachusetts Medical Society, and of other readers, is particularly directed to the report of notes taken by the Society's committee at a recent conference on social insurance, published on page 229 of this issue of the JOURNAL. It is also directed to the remarks on health insurance by Drs. Broughton, Stone, and Emmons, reported on page 225 of this issue, in the proceedings of the New England Pediatric Society.

MEDICAL NOTES.

INSANITY STATISTICS.—*Mental Hygiene* has published in a current issue statistics regarding the increase of insanity in the United States, which go far to correct the popular supposition that insanity is increasing in this country to an alarming extent. From 1910 to 1917 the population increased 11.80%, and during this period the rate of increase of the insane in institutions for insanity was 24%. The rate of increase of the insane in our institutions since 1904 has been more than three times as rapid as it was during the fourteen years preceding 1904, but there has been no acceleration of the rate during the past seven years. Various conditions have worked, however, to increase the number of insane treated in institutions.

GIFT TO UNIVERSITY OF CALIFORNIA.—The University of California has received from Dr. T. Brailsford Robertson, professor of biochemistry and pharmacology, his patents for the growth-controlling substance, tethelin, isolated by him from the anterior lobe of the pituitary body. Should there be an income from the sale or lease of these patents, such income is to be used to establish a fund known as "The University of California Foundation for International Medical Research," to be expended in research in the physiology, chemistry and pathology of growth.

WAR NOTES.

MENTAL HYGIENE WAR WORK COMMITTEE.—The Mental Hygiene War Work Committee of the National Committee for Mental Hygiene is anxious to obtain the names of psychiatrists and neurologists who are willing to give part-time service in the examination of National Guard troops in their vicinity. The recent decision of the War Department to examine the National Guard troops in their armories before sending them to camp, makes it necessary to secure at once a large number of examining physicians. To meet the situation, the Surgeon-General of the Army has arranged to accept for this work qualified physicians on contract. A physician may contract for specified duty, at a specified place, for a specified time, or for part-time. This latter provision makes it possible for many physicians who cannot take out commissions, or who cannot give all of their time to the work for a period of months, to give part-time each week. Further information can be received from Dr. Frankwood E. Williams, vice-chairman of the committee, 50 Union Square, New York City.

WAR RELIEF FUNDS.—On Aug. 11 the totals of the principal New England war relief funds reached the following amounts:—

French Wounded Fund	\$245,657.12
Armenian Fund	213,436.70
Surgical Dressings Fund	114,974.01
British Imperial Fund	105,046.00
Serbian Hospitals Fund	100,486.82
Boston Red Cross Fund	78,307.87
Polish Fund	76,906.18
French Phthisis Fund	68,333.33
Italian Fund	43,749.72

BOSTON AND MASSACHUSETTS.

WEEK'S DEATH RATE IN BOSTON.—The total number of deaths reported for the week ending August 4, 1917, was 249, against 202 the corresponding week last year, making a death rate of 16.81, against 13.85 last year.

The number of cases of communicable diseases reported was: diphtheria, 41; scarlet fever, 12; typhoid fever, 3; measles, 43; tuberculosis, 63.

Included in the above were the following non-resident cases: diphtheria, 7; scarlet fever, 2; typhoid fever, 1; tuberculosis, 6.

The number of deaths was: diphtheria, 2; measles, 2; tuberculosis, 22.

Included in these were the following non-residents: tuberculosis, 2.

THE BLIND IN MASSACHUSETTS.—The Massachusetts Commission for the Blind, which has been in existence for ten years, has arranged and printed in pamphlet form a survey of its work for that period. This was done with the idea of making the best possible use of the experience of the Commission for this period of time, both for future work of the State and for any help it may yield to other communities. The six men (three of whom were blind) invited to make this survey, were asked, not only because they were educators of the young blind, but because of their experience with the adult blind, three having served on State commissions. Their reports are printed in the following order: O. H. Burritt, principal of the Pennsylvania Institution for the Instruction of the Blind at Overbrook, Pa., discusses the organization of the Commission; J. J. Dow, superintendent of the Minnesota State School for the Blind, Faribault, Minn., reviews matters of record and report; Edward M. Van Cleve, principal of the New York Institute for the Education of the Blind, discusses the blind in the community; E. P. Morford, superintendent Brooklyn Industrial Home for the Blind, writes on the industrial home for the blind; and R. B. Irwin, of the board of education, Cleveland, Ohio, writes on the relation of the Commission to other agencies. As a document full of suggestions and information in this most important branch of social work, this pamphlet is of much value.

The Massachusetts Medical Society.

NOTES TAKEN AT CONFERENCE OF THE SPECIAL COMMITTEE ON SOCIAL INSURANCE, AT THE STATE HOUSE, AUGUST 1, 1917.

(After 11.30.)

Dr. W. P. Bowers and Mr. M. W. Alexander of the General Electric Company were present.

Dr. W. P. Bowers stated that he did not believe that at present there were sufficient data anywhere to answer the questions as regarding the need of health insurance, its cost, or the proper method of administration, and that he did not personally believe that this was the time for legislation, but if legislation was demanded he would propose a measure of partial insurance, by which in several years the community would be in possession of the necessary data with which to draw up a complete bill or to reject the proposition entirely.

This proposition he presented the Committee, and it will later appear in the columns of the BOSTON MEDICAL AND SURGICAL JOURNAL.

The following questions were asked Dr. Bowers:

1. This question has been worked over in the legislature for seven, eight, nine, or ten years; how soon do you think it will be in form so a bill might be safely put?

2. Senator Washburn: Isn't there some phase of this proposition small enough so that something might be drawn up in the way of a bill which might mark progress?

(Senator Washburn had just come in, and did not know that Dr. Bowers had already covered this.)

3. Chairman: Would it be asking too much if you would outline your plan in writing and submit it within a reasonable time? Within two months would probably be satisfactory.

The following were asked Mr. Alexander, whose statement to the Committee can be found in his pamphlet, "Some Vital Facts and Considerations in Respect to Compulsory Health Insurance," March, 1917.

4. Have your employees an insurance company?

Answer: Mutual benefit insurance. This does not cover all the employees; takes in some 8000 people at the Lynn works. Statistics based on that show that the sickness rate is lower than some of the investigations show, and almost coincide with the report of the Metropolitan Insurance Company.

The proponents of health insurance base their arguments on the statements that the death rate is excessive, that the sickness rate is very high, and that the wage poverty is so great that the average man cannot afford to secure medical care. These points have not been proved by the proponents.

5. You spoke of there being a mutual benefit organization; is this voluntary on the part of the employees?

Answer: Absolutely.

6. Do you, or do you not, find that the employees who really need it the most, take advantage of it, or don't pay any attention to it?

Answer: The employees who need it most constitute a majority of the members except as far as the foreigners are concerned. Ninety per cent. of the workers in the foundries are foreigners, of no education; suspicion is very great among them, and they don't know English enough to understand the objects of the mutual benefit scheme. Most of the Americans are in it all right.

The idea is to have the employees themselves carry the insurance; the employer has nothing to do with it, except administrative supervision. We want the employees to do their own business; are trying to build up an industrial democracy—of themselves, by themselves, and for themselves. It is purely an employees' mutual benefit association.

7. Then a good way would be to educate the illiterate foreigners?

Answer: They change so rapidly that it is difficult to educate them.

Mr. Alexander: In approaching this problem, I would say that I would like to see the appointment of a national commission of eminent and competent persons, who would make a study of this subject. It should not be bound by state boundaries; it ought to be studied from a national standpoint.

Secondly, a strenuous effort should be made to take our Public Health Service and enlarge its powers, if necessary, putting in better talent if necessary, and have it get after sickness and death, and become familiar with every case that occurs, with a view to taking steps to prevent sickness, as far as it can be prevented. That is one of my dreams. I would like to see every man and woman examined at least once a year, or twice a year, by a public authority, free of charge, or, if preferred, by a private medical authority approved for this purpose. Then the state or nation would know what the development is, and could counteract incipient sickness. Instead of spending 25 or 50 millions for compensating people when they are sick, I think a million will do 25 or 50 times more good if spent in studying the health condition of the people and in going after incipient cases before they go beyond proper control.

We must not deal with men as industrial workers, or as agricultural workers, but as men and women of the community. It is a wrong conception that we should legislate for any part of the community in a question like that. It is the whole people that are entitled to the protection of the commonwealth.

8. Senator Washburn: Would you say that everybody should be examined at the expense of the state where his financial resources are below a certain plane, and at his own expense where they are above that plane? And that he should be examined twice a year?

Is that about as far as your mind has got in the way of any legislation?

Answer: Everybody should be entitled to free examination, unless he prefers to pay for it by employing a private authorized physician.

9. Senator Washburn: You spoke about the dangers of coddling: that a man might be in a position to go to work but it would give him a good chance to stay at home and be remunerated. What is going to be the effect on the people psychologically in bringing them into closer touch with the medical profession? I mean it seriously. My proposition is: Is it a fair statement, that many a man would be in better health today if he hadn't seen a medical man than if he had seen one? Cutting out the undesirable doctor,—I didn't know there were any,—isn't there many and many a man who would be in better health today if he hadn't seen even the best physician?

10. Senator Washburn: You think that is infinitesimal (referring to Question 9). Do you think from your study of these medical propositions, that life is longer today than it was 50 years ago? Do you think the length of life is keeping step with the advance of medical science?

11. Senator Washburn: Your mind is very clear that you would like to see a preventive measure drawn up, and only wish the investigation continued? You mean, drawn up with the idea of perfecting a preventive bill? What sort of legislation would you like to see started?

12. Senator Washburn: Do you think the wage-earner is living better today than he was 20 years ago?

Answer: I think he is living better but less sensibly.

13. What do you think about the proposition given by Dr. Bowers this morning?

Answer: I think it a very ingenious and clever (in the right meaning of the word "clever") idea, and I am going to think it over. But I think that will have to be a second step and not a first step.

14. Mr. Morss: What do your people pay in that mutual benefit association, and what do they get?

Answer: Every man pays ten cents a week, maximum. They can never be assessed. And he pays ten cents a week only when it is needed,—when the treasury is pulled down. The average is \$4 a year, or eight cents a week.

He gets for it \$6 a week sickness benefit from the second week of sickness, and for a period of 14 weeks in a year; \$100 death benefit; extra benefit to any amount or in any form voted by the association, for instance, a ton of coal, \$20 a week extra, the services of an eminent surgeon, or \$2 a week for an indefinite period; and he has a right to apply for a small loan, limited to \$50 (in one instance, \$100), if he can show to a committee of three that he is in need of the money to keep out of the hands of loan sharks. In the repayment, he pays neither fees, extras, or interest money; and the benefit association has never lost a cent.

15. Mr. Morss: Those benefits being administered by the men themselves, how much real difficulty do they have from malingering?

Answer: Less difficulty than if insured by the employer. It is a federation of small sections, none having more than 150 members, all located in one department or one building, and each member knows all the other members; each section collects its own dues and pays its own bills.

16. Do they choose their own physician?

Answer: Yes. We don't pay the physician; merely have occasionally a high-class physician to check the claim.

(The new hospital is for first aid and accident cases only.)

17. You examine your men before taking them on? You don't examine them after they are taken on?

18. Senator Washburn: Do you think that we have data enough today by which we could draw up a wise preventive bill?

19. Do you feel that at the present time there is any need of this health insurance? Any public demand for it?

Answer: I think there is no great need and no great demand for it. There is an apparently loud demand, and it is voiced by people whose heart rather than head speaks in the proposition. They don't know the situation.

20. Representative Brogna: Do I understand that you are convinced that some form of social insurance is bound to come in this country? . . . Do you base that upon the opinion that as we go along, we shall be worse off, or because there is a need and we have no statistics of the need?

Answer: Because I think there is a certain amount of sickness which cannot be checked in people unable to secure care for themselves, and somebody must take care of them.

21. Representative Brogna: Then your position is that, because of the mode of living at the present time, or the senseless mode of living, we are going to be in a worse position 10 or 15 years from now than at the present time?

Answer: I believe we shall have a larger percentage of sickness in 15 years from now than we have now, if we don't now deal with the question of preventive medicine.

22. Your opinion is that if a sufficiently broad proposition of preventive medicine is adopted throughout the country, that will forestall any social insurance scheme such as is now under consideration?

23. At the present time, you think there is no great need of health insurance?

Answer: I think there is no need for the enactment of a law that will involve much money and cause bad social tendencies, just because there are some men who cannot take care of themselves.

24. Senator Washburn: I would like to ask whether the weight of the enthusiasm of some manufacturers that this should be solved by a preventive bill rather than social insurance, is poisoned by any desire to save their own pocket-books?

. . . Supposing you were on this committee and heard the charms of a preventive bill from the mouth of a representative of a large industrial plant, would you drink it in? . . . Not because he is a lawyer, but because he is enjoying a retainer from a large company?

Answer: I might be suspicious, but I believe that a good many manufacturers, without knowledge of the facts of the situation, would be more apt to shout for a compulsory, contribu-

tory health proposition than for a preventive medical proposition, because the very word *compulsory* attracts them.

25. Senator McLaughlin: What do you think of the possibilities of passing through the legislature a law requiring a physical examination of the people? Last year we had the "in-corrigible consumptive" bill, under which the board would be allowed to walk into a man's home and have him put into a "detention camp" or some such place. What do you think of passing through the legislature a bill that a man must submit himself to an examination twice a year?

26. Senator Collins: Do you suppose that if every employer of labor compelled a physical examination of his employees, it would remove such a large percentage of danger that it would get the bill through? . . . It is probably a matter of the education of the people.

27. Representative Brogna: (In answer to Mr. Alexander's statement that only 50 out of 17,950 who had applied for work had refused to submit to physical examination): Those men were looking for a job, and they have to stand a lot of indignity from employers when they are looking for employment; but supposing I, working for myself, were asked to be examined twice a year, wouldn't I say it's nobody's business but my own, and change my mind about this democratic government that compelled me to do this?

Mr. Alexander replied that now the company were more anxious to get employees than the men were to get work.

28. Senator McLaughlin: Would you be in favor of passing that compulsory physical test, providing a great minority of people rose up and opposed it? I have in mind a great many people who might think it an infringement on their beliefs. . . There is a great sect in this town, influential, intelligent people, who would oppose such a plan. They would believe it a direct trespass on their rights spiritually.

(Mr. Alexander thought they could probably be convinced; that they were not a majority or a large minority; a special class, but far from being a large minority.)

29. Senator Washburn: Wouldn't such a bill be unconstitutional if it interfered with their religion?

30. Isn't it a fact, that the fellow who doesn't want to be examined is the one who ought to be examined? The fellow who is all right has nothing to worry about.

31. Would they be examined by physicians paid by the state or by the employer?

32. Has your concern or any other had any friction with labor organizations because of the examination? Can you conceive of the possibility of putting one over on the labor unions?

NOTES FROM THE DISTRICT SOCIETIES.

WORCESTER DISTRICT MEDICAL SOCIETY.—This Society, in special meeting assembled, Aug. 1, 1917, declared its opinion:

First, That its members attending patients of Fellows absent in military service of the United States, or its Allies, are in honor bound to turn over to the authorized representatives of such absentees, one-third (at least) of fees collected from such patients, provided always that the absentee is willing to accept this service.

Second, That the Society also declares its opinion that its Fellows, thus practicing, *in loco absentis*, should decline to attend former patients of the absentee for a period of six months after his return, unless by his express consent.

Third, The Society authorizes its Secretary to furnish, to each Fellow, a placard for posting in his office, embodying this declaration of policy, as approved by the Society, and an invitation to patients of such absentees to assist in the application of this policy, by declaring themselves as such patients.

Fourth, That the Society elect a War Committee, consisting of five members, of which the President shall be chairman, *ex officio*, and the rest appointed by him for one year's service, at least; and the Society requests every practitioner entering military service to notify this committee of his action, and to specify whether or not he wishes to avail himself of the provisions of the above policy. This committee shall keep a list of such absentees and shall publish with the notices of regular meetings of the Society, such additions as come to their knowledge. The committee shall, as the agent of the Society, protect, in all practicable ways, the interests of absentees on military service, and may therefore devise and promulgate to the Society membership such rules and regulations as are, in its opinion, necessary to guide members in practical application of these policies. The committee shall act as referee in all cases that may be referred to them when the home-physician or the representative of the absentee is in doubt as to proper procedure.

Fifth, That the Society invites all registered physicians in this District, whether affiliated with this Society or not, to full and cordial cooperation in carrying out the letter and spirit of these policies; and the Society instructs its War Committee to use such means as it finds practicable to secure this desired cooperation.

Sixth, That the Society, through its War Committee, cooperate with the War Relief Committee of the Worcester Red Cross Chapter in the medical care of dependents of men enlisted from this district.

The War Committee is: Dr. Michael F. Fallon, *Chairman*; Samuel B. Woodward, W. J. Delahanty, George O. Ward, *Secretary*; Ernest L. Hunt.

Miscellany.

GENERAL MEDICAL EXAMINATION OF RECRUITS.

THE following is a report of an address by Major Charles Y. Brownlee, of the United States Army Medical Corps, before a recent meeting of members of the medical examination boards of Brooklyn and Queens Counties, New York.

"In general, you must remember that a soldier is forced to undergo trials and hardships which men in civil life are seldom called upon to face. Therefore, a generally robust physique is essential if we are not to have an army of weaklings, increasing the sick report, filling the hospitals, entailing extra burdens on an already overworked medical department, and, by depleting an army at a critical period, inviting disaster.

"We in the Regular Army and in the National Guard have had to deal with men who voluntarily applied for enlistment, so we have had to be on the alert to detect concealed disabilities, and have had almost no malingering to deal with at this stage.

"You, gentlemen, will, no doubt, find many 'slackers,' who for various reasons will mangle or grossly exaggerate the effects of some trifling disease or injury.

"Now, as to appliances, etc., needed. First, if possible, have a well-lighted room, at least over 20 feet in length, convenient to a shower bath, if possible, in order to subject those requiring it, to a thorough cleansing bath.

"Scales—A scales such as are supplied by instrument houses, with measuring rod, is not essential. In fact, I have found that the rod often becomes loose and quite inaccurate. Ordinary grocer's platform scales, if in good condition, are quite satisfactory and quite accurate. Height measurements may be taken by marking off on a wall from a steel tape heights from 60 to 78 inches in $\frac{1}{4}$ inches, the inch marks to be longer than the quarters and marked with the height. By using a ruler or any flat, straight object, the height is obtained more accurately and quickly than by the ordinary rod and headpiece.

"Other essentials are a vision test card, tape measure, watch, stethoscope, head mirror, tongue depressors and aural specula. Also a spirit lamp, a few test tubes, acetic or nitric acid and Fehling's solution for those cases requiring a urinary analysis.

"A sphygmomanometer and microscope are occasionally needed, as is an ophthalmoscope. You have been furnished the regulations governing physical examinations, but perhaps a few additional remarks would not be amiss.

"You will more than double the number you can examine in a day by having an intelligent clerk to record your findings as you call them out. Record every physical defect found, whether it disables or not.

"Your table of height and weight gives a minimum of 60 inches and a weight of 118 pounds with eight pounds' variation, thus making a minimum weight of 110 pounds. Needless to say, at this height and weight, the man should be nearly perfect otherwise, and active, vigorous, well-proportioned and muscled.

"Reject the long, willowy, pale, narrow-chested youth, far below weight for his height, and the man of general poor physique, say, such a one of 70 inches and 125 pounds. As to methods of detecting malingerers, particularly in regard to vision and hearing, for obvious reasons, these should not be published, but remember your ophthalmoscope.

"Hernia disqualifies, but it must be an actual hernia, not simply a relaxed inguinal ring, as a very large proportion of relaxed rings never cause hernia.

"Of course, general diseases, such as chronic malarial poisoning with grave anemia or enlarged spleen, tuberculosis in any form, recurrent and chronic rheumatism, malignant tumors, syphilis, also eytitis, etc., are all causes for rejection. As to flat feet, your instructions are so concise that nothing more need be said.

"Mental and Nervous Diseases—Look out for those of defective mental development. They are only a nuisance in the Army. Of course, all forms of insanity are cause for rejection, as is epilepsy and severe chorea. In regard to the man who states he is subject to fits, have him procure a statement to that effect in writing from his family physician, that he has treated him for that disease prior to the passage of the Conscription law. Use the same procedure in regard to other diseases not readily discovered in a brief examination, such as bed wetting, recurrent abdominal pains, gallstones, nephritic colic, etc.

"As to the lungs, of course, you will be on the lookout for tuberculosis. In the great majority of cases there are such suspicious signs as will cause you to be particularly careful. In this disease, it is not only the subsequent disablement of the man himself that is to be considered, but the menace he will be to the health of his comrades.

"The Heart—Functional murmurs at the apex are extremely common in youth and young manhood. At times it is difficult to determine whether a murmur is functional or organic, but a murmur without secondary symptoms such as hypertrophy, irregularity or dyspnea may safely be classed as functional.

"Pronounced and persistent tachycardia from any cause rejects. Varicose veins, if quite large and prominent and over a large area, especially if associated with edema or ulcers, disqualify.

"Curvature of the spine, not interfering with functions and not easily detected with the clothing on, is not cause for rejection.

"The Extremities—Look particularly for ankylosis of elbow and chronic synovitis of the

knee, the latter furnishing a large number of cases for discharge on certificate of disability in the Army. Total loss of either thumb or more than one joint of the right index finger, loss of either great toe, hallux valgus, if marked, severe bunions, marked hammer toes,—are all causes for rejection.

"I have mentioned a few of the more common disabilities which you will meet. Your medical knowledge will determine your course of action in the multitude of other conditions met. With an efficient clerk, after the first day, one physician can easily examine 100 men a day."

REPORT OF COMMITTEE ON CLINICAL METHODS AND STANDARDIZATION OF EXAMINATIONS.

TO THE PSYCHIATRISTS AND NEUROLOGISTS ASSIGNED TO SPECIAL DUTY IN THE MILITARY CAMPS OF THE UNITED STATES GOVERNMENT.

In detailing psychiatrists and neurologists to special duty with the armies, the Surgeon-General has had in mind: (1) The proper care and treatment of soldiers who become incapacitated through mental or nervous disease. (2) The special examination of recruits in the training camps in order that those who, because of neuropathic or psychopathic conditions, are unfit for military duty, may be identified and discharged from service.

Until the troops move abroad, the chief and most important responsibility of the military psychiatrists and neurologists will be the special examination of recruits. It is obvious that no man should be eliminated from the service who is fit to render a valuable service in this emergency. On the other hand, it is quite apparent that individuals suffering from certain forms of nervous and mental diseases should not be permitted to enter into service, as experience with the American armies has shown quite conclusively that such individuals are not capable of military service even in time of peace, and experience in the European armies has shown beyond question that such individuals are not able to withstand the rigors of modern warfare. At critical times such individuals go to pieces, with the result that the military force is weakened, is hampered in the free performance of its function, and the Government is likely to be burdened after the war with the care of a large number of invalids.

At the request of the Surgeon-General, the question of those who should be excluded from the military services on account of mental and nervous disease, has been carefully studied, and with the approval of the Surgeon-General we would suggest that the following general outline be followed in determining this matter. It is

important that the potential as well as the actual conditions of the recruit be kept in mind. For this reason emphasis has been laid upon the early symptoms of disease. Likewise, attention has been called particularly to those diseases which are most likely to be met and which have not very obvious symptoms but which, nevertheless, can be diagnosed relatively easily and with considerable certainty. It is not to be assumed that other neuropathic and psychopathic conditions, when found, are not cause for exclusion. Most of these, however, such as multiple neuritis, various forms of paralysis, hemiplegia, cranial nerve palsies, and peripheral neuritis, have such striking symptoms that they are likely to be recognized before they come to the attention of the neurologists and psychiatrists.

RECRUITS TO BE EXCLUDED.

I. NERVOUS DISEASES.

(a) *On the Basis of Disease.*

1. Tabes. (Look for Argyll-Robertson pupils, absent knee and ankle jerks, ataxia of station and gait.)
2. Multiple sclerosis. (Look for absent abdominal reflexes, nystagmus, intention tremors.)
3. Progressive muscular atrophy and syringomyelia. (Look for fibrillary tremors; atrophy in the small muscles of the hand and of the muscles of the shoulder girdle; scars on forearm and fingers caused by burning; deformities of feet.)
4. Epilepsy. (Look for deep scars on tongue, face and head; voice. Where diagnosis depends only upon history of epileptic attacks given by the patient, the latter should be asked to give the address of the physician who has treated him. This history must then be verified by a letter from the physician.)
5. Hyperthyroidism. (Look for persistent tachycardia, exophthalmos, tremor, enlarged thyroid.)

(b) *On the Basis of Symptoms or Combination of Symptoms or History.*

1. Unequal pupils, irregular pupils, Argyll-Robertson pupils.
2. Nystagmus (in one not an albino), absent abdominal reflexes, intention tremor.
3. Absent knee jerks associated with some one other organic neurologic symptom.
4. Exaggerated tendon jerks, Babinski.
5. Disorders of station or gait.
6. Disorders of speech (on test phrases), facial tremor, one other organic neurologic symptom. (Stammering and stuttering *per se* are not significant of an organic neurologic condition. Stammerers and stutterers are rejected by regulations. See form No. 94777.)

7. History of epilepsy. (Ask the recruit to give the address of the physician who has attended him; this information to be verified by letter.)

II. MENTAL DISEASES.

(a) *On the Basis of Disease.*

1. General paralysis. (Look for Argyll-Robertson pupils, speech defect consisting of distortion of words, writing defect, consisting of distortion of words, facial tremor in showing the teeth, euphoria and marked discrepancies in giving facts of life.)
2. Dementia precox. (Look for indifference, ideas of reference, feelings of the mind being tampered with (e.g., ideas of hypnotism) auditory hallucinations, bodily hallucinations such as electrical sensations or sexual sensations, meaningless smiles; in general, inappropriate emotional reactions, lack of connectedness in conversation.)
3. Manic-depressive insanity. (Look for mild depressions with or without feeling of inadequacy or mild manic states with exhilaration, talkativeness and over-activity.)

(b) *On the Basis of Symptoms or Combination of Symptoms or History.*

1. History of previous mental illness. (Ask the recruit to state when and where he had such illness, in what hospital he was observed or treated, or by what physician he was attended; this information to be verified by letter.)

III. PSYCHONEUROSES AND PSYCHOPATHIC CHARACTERS.

(Look for phobias, morbid doubts and fears, anxiety attacks, fatiguability, hypochondriasis, compulsions, homosexuality, grotesque lying, vagabondage.)

IV. CHRONIC ALCOHOLISM.

(Look for suffused eyes, prominent superficial blood vessels of the nose and cheek, flabby, bloated, reddened face, purplish discoloration of the mucous membrane of the pharynx and of the soft palate; also ashen complexion and clammy skin; muscular tremor in the protruded tongue and extended fingers,—noticeable also in lack of control when the applicant attempts to sign his name; emotionalism, prevarication, suspicion; auditory or visual hallucinations, paranoid ideas.)

V. MENTAL DEFICIENCY.

(Look for defect in general information with reference to native environment, ability

to learn, to reason, to calculate, to plan, to construct, to compare weights, sizes, etc.; defect in judgment, foresight, language, output of effort, suggestibility, stigmata of degeneration, muscular incoordination. Consult psychometric findings.)

VI. DRUG ADDICTION.

(Look for pallor, dryness of skin; flippancy, mild exhilaration—if under the influence; cowardly, ering attitude, restlessness, anxiety—if without the drug; distortion of the alae nasi; contracted pupils—morphine—or dilated pupils—cocaine; dirty deposit at junction of gums and teeth; bluish and whitish needle scars on thighs and arms.)

Major-General W. C. Gorgas,
 Surgeon-General, U. S. Army,
 Washington, D. C.

Sir:

In view of the fact that it will be necessary for the psychiatrists who are assigned to the various military camps to examine a large number of recruits in a brief space of time, it is felt by the undersigned that this work can be greatly expedited if the assistance of camp surgeons and line officers can be obtained in selecting from those who come under their observation, individuals likely to need neuro-psychiatric examination. This can be easily done if the medical officers, dental surgeons and line officers will keep certain fundamental things in mind. We would suggest, therefore, the following:

(1) That, in view of the importance of syphilis and hyperthyroidism in neuro-psychiatric conditions, all persons suffering from either of these diseases observed by the surgeons in the ordinary course of their work, be referred to the psychiatrist for further examination; and

(2) That the personality traits named below are of such importance as indicative of possible underlying mental conditions, that line officers be instructed to refer to the psychiatrist recruits under their observation who exhibit them. These traits are: Irritability, seclusive, sulky, depressed, shy, timid, over-boisterous, sleepless, persistent violators of discipline, "queer sticks," cranks, "goats"—butts of practical jokes, "boobs"—those who have difficulty in comprehending orders—dull, stupid, marked emotional reaction (such as vomiting and fainting) at bayonet drill, peculiarities of attitude, speech or behavior sufficiently marked to attract attention of associates, those resentful of discipline, suspicious, sleep-walkers, bed-wetters, those persistently slovenly in dress, those who have difficulty in executing muscular movements in setting up exercises.

Very truly yours,

(Signed)

 Thomas W. Salmon, M.D., Medical Director, The National Committee for Mental Hygiene, New York.
 Adolf Meyer, M.D., Director, Phipps Psychiatric Clinic, Johns Hopkins University, Baltimore.
 Pearce Bailey, M.D., Chief of Clinic, N. Y. Neurological Institute, New York.
 E. E. Southard, M.D., Director, Psychopathic Hospital, Boston.
 Joseph Collins, M.D., N. Y. Neurological Institute, New York.
 Albert M. Barrett, M.D., Director, State Psychopathic Hospital, Ann Arbor, Mich.
 T. H. Weisenburg, M.D., President, American Neurological Association, Philadelphia.
 William A. White, M.D., Superintendent, Government Hospital for the Insane, Washington, D. C.
 Robert M. Yerkes, Ph.D., Professor of Comparative Psychology, Harvard University, Cambridge.
 Walter E. Fernald, M.D., Massachusetts School for the Feeble-minded, Waverley, Mass.

Major-General W. C. Gorgas,
 Surgeon-General, U. S. Army,
 Washington, D. C.

Sir:

It is the belief of the undersigned that the neuro-psychiatric examination of a large number of recruits would be expedited if permission were granted to the psychiatrists in the various camps to train and utilize hospital sergeants or others who might be chosen by the psychiatrist,

to make group examinations of recruits for the following conditions: Pupillary changes,—unequal, irregular, disorders of reaction,—absent or increased knee jerks, station and gait disorders, marked tremors (extended fingers), facial tremor on showing teeth.

Recruits found by the examining sergeant to exhibit any one of these symptoms should be referred to the psychiatrist for further and more intensive examination.

Very truly yours,

(Signed)

August Hoch, M.D., Director, Psychiatric Institute, Ward's Island, N. Y. C.

Thomas W. Salmon, M.D., Medical Director, The National Committee for Mental Hygiene, N. Y.

Adolf Meyer, M.D., Director, Phipps Psychiatric Clinic, Johns Hopkins University, Baltimore, Md.

Pearce Bailey, M.D., Chief of Clinic, N. Y. Neurological Institute, New York.

T. H. Weisenburg, M.D., President, American Neurological Association, Philadelphia.

William A. White, M.D., Superintendent, Government Hospital for the Insane, Washington, D. C.

Robert M. Yerkes, Ph.D., Professor of Comparative Psychology, Harvard University, Cambridge, Mass.

Walter E. Fernald, M.D., Massachusetts School for the Feeble-minded, Waverley, Mass.

or exercise will not be required, any physician who is able to practice medicine under the conditions of civil life is physically acceptable.

It is unnecessary to point out the fact that this offer affords an opportunity, and probably the only opportunity, for the large number of physicians to render a valuable service, who ardently desire to do something for their country at this critical time, but who, by reason of age, physical infirmities, or professional engagements, are unable to accept a commission.

The invitation thus to act as Boards of Examiners in revision of the work of the regular examiners of recruits, is in itself a compliment to the civilian medical profession, and the selection of an internist for this work should be regarded as an honor.

The name under which he acquires the necessary military status and the compensation obtained, are surely secondary considerations for all who are actuated by patriotic motives. No greater service can be rendered the country by the medical profession than the elimination of the unfit from the Army, and tuberculosis is, as is well known, one of the most important causes of physical unfitness, while at the same time demanding special skill for its detection.

It is desired to examine thoroughly the soldiers of the National Guard and the National Army, when they are assembled at their cantonments in the autumn. A large number of expert examiners will be required for this work, so that all who are competent to undertake it, can undoubtedly be given employment.

Very sincerely,

G. E. BUSHNELL,

Colonel, Medical Corps.

RECENT DEATHS.

L. E. RUSSELL, M.D., of Springfield, Ohio, died at his home in that city on August 2. He was sixty-six years old. Dr. Russell was a former president of the National Medical Association.

JAMES ALLEN NICHOLS, M.D., a well known New York surgeon, died recently at his home in that city. Dr. Nichols was born at Crown Point, N. Y., in 1860, the son of Dr. Thomas Brainerd Nichols. He graduated from the University of Vermont and from the Long Island Medical College, receiving his degree in 1888. He was for a time professor of surgery in that institution, and later surgeon in the Women's Hospital in New York and professor of surgery in the Post-Graduate Hospital. He retired from practice eight years ago and devoted himself to medical jurisprudence. Dr. Nichols was a member of the County Medical Society, The New York Academy of Medicine, the Sons of the Revolution, the Society of the War of 1812 and of the Medical Jurisprudence Society. He is survived by his widow, one son and one daughter.

APPOINTMENTS.

DR. MILTON H. FOSTER of the Public Health Service has been appointed physician at the Immigration station, Boston Harbor, to take the place of Dr. M. Victor Safford.

DR. DONALD CURRIE of the Public Health Service, for some time stationed at the Hawaiian Islands, has been placed in charge of the Immigration station, Boston Harbor, to relieve Dr. S. B. Grubb. Dr. Currie is well known for his work on the treatment of leprosy.

DR. HORACE D. ARNOLD, of Boston, has been appointed chairman of the Council on Medical Education of the American Medical Association, succeeding Dr. Arthur Denn Bevan of Chicago.

Correspondence.

EXAMINATION OF TROOPS FOR TUBERCULOSIS.

War Department, Office of the Surgeon-General, Washington, July 30, 1917.

Mr. Editor:—

The Surgeon-General of the Army desires the fact to be known that since the publication of your excellent editorial entitled "Tuberculosis in the Army," in your issue of July 5th, 1917, there has been a change of policy, in that temporary commissions in the Medical Reserve Corps can no longer be promised to physicians who are willing to undertake the examination of troops for tuberculosis.

Additional officers are still urgently needed for the Medical Reserve Corps, and those qualified for the work can be used as tuberculosis examiners for at least four months from August 1st. But the accepting of a commission must be with the understanding that service is to be for the duration of the war, and candidates must be able to pass the required physical examination.

For temporary service, the physician is now engaged under contract for a definite kind of work, and, if desired, for a specified and limited period. Contract surgeons are not required to pass a physical examination, and there is no age limit. As their work will be of a purely professional nature and field service

THE MEDICAL PROFESSION AND SOCIAL PROGRESS.

BY ANDREW F. DOWNING, M.D., CAMBRIDGE, MASS.

LONG before the joy-bells announced to an impatient world that the nineteenth century had given up to Father Time the ghost of an honorable and altogether fruitful life, we had begun to hasten his declining years by paying shameless tribute to the promising youth and vigor of his successor. And now, with two decades of this long-heralded golden age, with which we then flirted, not yet gone, with peace on earth departed, and good will sorely tried, the sad memory of that hurried leave-taking, and still more hurried journey through this young and pampered age, comes to us with vain regret. No longer does the dance go on; no more is joy unconfined; and youth, now mindless of pleasure, for whom there was, and still is, "no sleep till morn," "has a rendezvous with Death at midnight in some flaming town." Satisfied now that what we called speed, and confused with progress, was merely vulgar prodigality, and convinced that only in our determination to secure now, if ever, justice for all, lies the hope of the future, we are making amends to a century that we thought decadent, by seeking the solution of a trying situation in the almost forgotten teachings of Lincoln.

Industrialism, grotesque from abnormal overgrowth, commercialism sunk to the low level of

unbearable arrogance, wealth pursued until it blurred the vision, contempt of the toiling, unsuccessful multitudes by the pleasure-seeking, successful few,—were burdens which before the present war began, had grown too heavy for a world that hoped for heaven. In our own country people were money-mad, and upon the answer to the question, "How much money has he?" depended the joy with which a man was welcomed by his fellows, or the indifference with which he was scrapped in the heap of social neglect. Men talking loudly and cynically of our inefficiency and crideness began to doubt the wisdom that created our Democracy. They held up for our emulation the wonderful efficiency of the German people, the social justice that was theirs, and the unerring judgment and paternal solicitude of the government that made all this possible. Then we enter the world war, in the words of our President, "in armed opposition to an irresponsible Government which has thrown aside all considerations of humanity and of right and is running amuck."

No wonder that we are amazed and ask if this wonderful efficiency is really efficiency; if this social justice is really justice; if, after all, with its many shortcomings and defects, this old abused and maligned democracy of ours is really the failure that our purveyors of pessimism and carriers of calamity would have us believe.

But as individuals we feel a sense of loneliness, a consciousness of some great change that has taken place. What this change is, Graham Wallas in his "Great Society" thus expresses: "During the last hundred years the external

conditions of civilized life have been transformed by a series of inventions which have abolished the old limits to the creation of mechanical force, the carriage of men and goods, and communication by written and spoken words. One effect of this transformation is the general change of social scale. Men find themselves working and thinking and feeling in relation to an environment which both in its world-wide extension and its intimate connection with all sides of human existence is without precedent in the history of the world."

It is a significant fact that Wallas, who in this book prophesied the present war, prefaces his first chapter with an extract from Woodrow Wilson's "New Freedom." "Yesterday and ever since history began, men were related to one another as individuals. . . . To-day the every-day relationships of men are largely with great impersonal concerns, with organizations, not with other individual men. Now this is nothing short of a new social age, a new era of human relationship, a new stage-setting for the drama of life." And when we add to this a few sentences from that great document on human rights which he delivered at the joint session of the two Houses of Congress, April 2, 1917, we shall cease to be amazed and shall begin to understand something about the great change that is taking place in the world.

"We are at the beginning of an age in which it will be insisted that the same standards of conduct and of responsibility for wrong done shall be observed among nations and their governments that are observed among the individual citizens of civilized states." And again: "But the right is more precious than peace, and we shall fight for the things which we have always carried nearest our hearts—for democracy, for the right of those who submit to authority to have a voice in their own governments, for the rights and liberties of small nations, for the universal dominion of right by such a concert of free peoples, as shall bring peace and safety to all nations and make the world itself at last free."

The accomplishment of such an undertaking, tremendous though it be, is not impossible. Slowly but surely, forces in the social and the industrial orders have been preparing the way. Out of what seemed an endless, turbid stream of human misery, the rights of those who toil and suffer are beginning to emerge, and men and women of high purpose are devoting their lives to the cause of social justice that the social world may be redeemed. Politically, democracy is secure only when it has annihilated autocracy, but its victory is not complete until it has triumphed over feudalism, paternalism, and privilege, and has driven them from their industrial strongholds.

So accustomed are we to look upon the social question as the fad of those who strive to make the world a Utopia, that we fail to observe conditions as they are, or, having observed them,

accept them as inevitable. The true social reformer, however, sees things as they are and refuses to accept them as inevitable. He recognizes that these sordid conditions are abnormalities that retard the real progress of civilization and make it a mockery to a large proportion of mankind. A dreamer he may be, but only because he has a social imagination and is convinced that we must return to the normal. The word "normalist," as one writer suggests, would describe him more accurately—a normalist seeking the causes that have resulted in the deplorable failure of thousands to attain a decent standard of living. Hence it is that having found the causes, he seeks the remedy that must be applied. Poverty, disease, crime, overcrowding, under-nourishment, overwork, intemperance, lack of education, irregularity of employment or no work at all, monopoly, exploitation of men, women, and children—in short, whatever prevents the individual or groups of individuals from attaining a decent standard of living—are the things that concern him day and night. In the solution of these many problems, the medical profession has played, and will play, no small part.

In the old order, charity, which was no more than alms-giving, had to do with the individual. Too often its influence was degrading, because it was a sorry substitute for justice denied. Another form of charity is thus described by John Boyle O'Reilly:

"Organized charity, scrimped and iced,
In the name of a cautious, statistical Christ."

In the new order, it goes beyond the individual and aims to eradicate those intolerable social conditions that tend to perpetuate disease, pauperism, degeneracy, and crime. It attempts, as Professor Peabody says, "to find a place in modern statesmanship, civic administration, trade, and personal life, for the ideals of humanity, fraternity, and social peace." In the old order, the charity worker considered it his duty to chide the poor, and tell them that their poverty was due to shiftlessness, lack of thrift, and intemperance. In the new order, it is recognized that poverty is not merely lack of money, but appalling and disastrous misery due to a low standard of living, overcrowding, overwork, disease, and friendlessness, for which our present social order is responsible.

It was the old idea that wages were determined only by the law of supply and demand. It is the new idea that the influence of the standard of living cannot be disregarded. It was the old view that the children of the poor should be taught early habits of industry and thrift that they might contribute to the support of the family, even before they had passed the tender period of childhood. It is the new view that children must not be exploited for commercial gain, but that they must be allowed to enjoy their childhood, acquire an education, and bring

to their life-work healthy bodies, and minds trained to the ideals of citizenship. In the old order, education was considered the training in letters of a select few. In the new order, we believe that it is one of the most necessary and permanent interests of all mankind. It was the old idea that those who rose to positions of influence did so only through thrift, honesty, and ability. "Early to bed and early to rise makes a man healthy, wealthy, and wise," says the old adage. Modernized to apply to the toiler of today, the last part might read, "makes a man unhealthy, miserable, and wise"—yes, wise enough, at least, to grasp the new idea that many of the qualities that have enabled the successful to survive will not respond to the acid test of decency. Ignorance, arrogance, trickery, dishonesty, lawlessness, complete ethical paresis, have too often in the past prostituted the rewards of right living and generous service to mankind.

It was the old view that heredity alone determined the social position above which no man could rise. It is the new view that however much heredity furnishes the basis and sets the limits to the development, environment can furnish the stimulus and the opportunity. Heredity determines only what a man *may* become, but environment determines what he *does* become.

In the old order, it was held that men, women, and children, working in the industries, were machines to be speeded up to the highest possible endeavor for long hours in unsanitary factories during the day, for a low wage, and to be recuperated for their next day's work in even more unsanitary houses, during the night. In the new order, it is insisted that workers shall not be pushed beyond the limits of physiological fatigue, but that they shall be given a living wage, healthful surroundings, and decent housing.

It was the old idea that if the employer, usually defended by superior counsel, could prove with the help of witnesses fearful of losing their jobs that he was not responsible for some industrial accident, the maimed workman, or the widow and children, or mother, of him who was killed, must face a still more grinding life of poverty uncompensated. It is the new idea that industry shall bear on its broader and stronger shoulders the burden of accidents, and thereby relieve the injured workman, or the widow and orphans, from the black specter of hopeless poverty. It was the old view that our prisons represented the vengeance of society. It is the new view that they shall not harbor the insane and perverted, or serve as institutions for the graduation of expert criminals. In the old order, sickness was a family affair; in the new order, it is also a concern of the community, to be prevented, if possible, and to be segregated, if dangerous. That is why our hospitals and dispensaries, our nursing and medical care, have been fitted into our social scheme, and that is why large sums of money are being spent to reduce the prevalence

of disease by studying those that are not yet conquered. It was the old idea that the case of the backward or incorrigible boy or girl in school was hopeless. It is the new idea that a physical examination, followed by proper treatment, or a change in our methods of education, by supplying manual training, trade, or vocational schools, may save both these children for society.

Now in using as I have the words "old" and "new," I feel that I must apologize for a paradox. What I have called the new is in reality the old. It is as old as the New Testament. It is the Christian view of life. It means faith, hope, charity, justice, love, decency, goodness, friendship, honesty, and generosity. It means the "square deal." It is the view of life that goes with red blood. It is the view of life that gives men "guts."

And the old view is in reality the new view. It is the view of Godless, hopeless, faithless, and dehumanizing philosophy. It is pessimism, modernism, materialism, and immoralism. It is the view that makes men cravens. It is the view of self-ordained supermen, of sycophants, of snobs, and of autoerats. It is the view of arrogant commercialism, heartless industrialism, predatory wealth, and speculative paranoia. It is the view of those who maintain that leisure and wealth are for the few, while the rest of mankind must "grunt and sweat under a weary life." It may be summed up in the teachings of Nietzsche, who raged against Christianity because it recognized the rights of slaves and reminded supermen of their bondage to the moral law. It enabled the weak, the whimpering, and the downtrodden to rise to positions in which he felt that they did not belong, and kept alive masses which ought to be left to die. He argued that sympathy, by preserving what is ripe for destruction, operates to defend the disinherited and condemned among men, and that it is the chief instrument in the advance of decadence. The preaching of sympathy by Jesus of Nazareth was an evidence of his immaturity and youth. "He died too soon," says Nietzsche. "If he had lived to my age he would have renounced his teaching." And this when Nietzsche was thirty-eight!

Moreover, when we turn to consider the functions of government, we are inclined to think that the idea behind the strong demand for progressive legislation is new, radical, and dangerous. Some of our modern progressive measures may be radical, but this is not an argument against the justice and necessity of many measures that occupy the attention of our leaders.

In 1225, ten years after John of England signed the Magna Charta on the historic field of Runnymede, that great teacher St. Thomas Aquinas was born. Although not favoring any particular form of government, St. Thomas held that authority in civil society must have in view the public good, and that if it lose sight of this it becomes unjust, anti-social, and tyrannical.

The aim of the state is not merely economic, but also moral. From this principle, St. Thomas deduces conclusions which are in remarkable accord with modern political theories,—for example, that it is the duty of the state to provide for the education of all its members and to see that no citizen suffers want. It is the fidelity with which the government adheres to the purpose for which it is instituted, that decides the happiness and prosperity of its citizens. Thus we see that what is apparently new in our theory of men's rights, and of the duties and functions of government, can be traced from the Magna Charta through the Declaration of Independence and the Bill of Rights, and through the principles enunciated and upheld by Washington, Jefferson, Lincoln, Theodore Roosevelt, and Woodrow Wilson.

In his progress through civilization to the present complexity of social conditions, man has had to solve many problems and combat many foes. Disease being an unseen foe, and ruthless in its destruction, has been his greatest enemy. Hence the medical profession has arisen. Always on the skirmish line in the march of progress, we may be forgiven, I think, if we assert that without our help man would not have attained his present position; but we must admit that in this march of progress, other doers and other thinkers have been many and indispensable, and we must not be offended, if they, too, with truth, assert that without *their* help we would have been unable to succeed. For what we have done, mankind is grateful, and in the past has shown us much respect and has showered us with many favors. To-day, society, none the less grateful, but niggardly in its praise and insistent on its demands, is beginning to look upon, as its own possessions, those great contributions to civilization such as electricity, steam, and the results and achievements of medical science, and demand that they be socialized and made a part of an equitable existence. And it is in this attitude of the social mind, therefore, that we who have been living our selfish lives, without thought of the social struggle going on about us, may seek the causes of several rude awakenings which in the past few years we have experienced. I refer to the Industrial Accident Act and Health Insurance. If the lessons learned from these awakenings have drawn us out of the path of Chauvinism, as I think they have, we shall lose no time in mobilizing our forces, and in developing a solidarity in our ranks that is much needed. We have been too long a profession composed of men who have been satisfied to live the narrow, selfish, and quite unlovely lives of individuals, rather than the broader, more useful, and most attractive lives of social beings. "When the entire moral energy of an individual goes into the cultivation of personal integrity," says Miss Jane Addams, "we all know how unlovely the result may become; the character is upright, of course, but too coated over with the result of his own en-

deavor to be attractive. In the effort toward a higher morality in our social relations, we must demand that the individual shall be willing to lose the sense of personal achievement, and shall be content to realize his activity only in connection with the activity of the many." Simplified, this may be called the philosophy of "mixing"; the call of the spirit of good fellowship.

The more successful among the members of the medical profession will find more joy of living, by converting the energy which they use in gloating over their successes into real altruistic endeavor not only for society, but for their less fortunate colleagues. Without this high purpose, manifested in such a spirit of *camaraderie* as we have never known, we shall have little to say in any new adjustment of human relations in which we are vitally concerned. In reviewing together some of our past achievements, we may find reason for a closer bond of union, for after all the ties that bind us to what Graham Wallas calls the "Great Society" inspire us with that confidence in one another and those generous feelings which have so often been forgotten or disregarded in the narrower view of life, resulting from the increasing and inevitable demands of specialism in modern medicine.

Two hundred years ago one tenth of our ancestors died of smallpox. In the last decade of the eighteenth century, Edward Jenner, noting the pure complexions and smooth skin of the milkmaids, wondered if the chance infection by cowpox protected them from the dreaded smallpox. Experiment proved him to be right and we had vaccination. Ninety per cent. of the population had smallpox at some time in their lives, and it is a well-known fact that few faces among the royal families were not pock-marked. In the years between 1893 and 1897, this disease was responsible for 275,502 deaths in Russia, while Germany had only 274. Germany has had no epidemic since 1874. The difference represents no vaccination and a compulsory law. When we went to the Philippines, five provinces gave a total death rate of 6000 people yearly; but following a system of compulsory vaccination in 1905 and 1906, there were no deaths from the disease in 1907. In three and one half million vaccinations in the Philippines, there were no deaths and no serious infections. From 1901 to 1905, 500 persons in Philadelphia died of smallpox, but not one of these had been successfully vaccinated within ten years. The epidemic of 1891 and 1892 cost Philadelphia over \$21,000,000, while the total cost of vaccinating, disinfecting stations, public instruction, etc., was some \$750,000. What are we doing to-day to keep alive the memory of Edward Jenner? What are we doing to see that these facts are taught to our school children as part of the history of civilization? What are we doing to keep this information constantly before the people and our legislative bodies that it may be impos-

sible for those misguided individuals who attack society by opposing vaccination to advance against a machine-gun fire of deadly knowledge?

In 1900 Dr. Walter Reed of the United States Army discovered that yellow fever was given to man through the bite of the female *stegomyia* mosquito. This mosquito must bite a fever-stricken patient within the first three days of his illness. Thus the yellow fever patient ceased to be a direct source of danger when screened so that no mosquito could reach him. During the nineteenth century the deaths from yellow fever in Havana often numbered 1500 a year; but they stopped abruptly in 1902. Twenty-five per cent. of those attacked by this disease died. When the epidemic of 1878 struck our Southern cities people died by thousands, and the cost is estimated at \$100,000,000—not to mention the loss by death. What are we doing to keep alive the memory of Walter Reed? What are we doing to see that our school children and our people be made as familiar with these facts as they are with less momentous events in history?

The Panama Canal was made possible by the growth of our knowledge of disease. It will be remembered that, besides yellow fever, malaria was also a cause of a high mortality in those southern countries. For instance, the death rate in Havana from malaria before 1901 showed a yearly average of 400, rising in 1898 to 1900 deaths. Since 1901 there has been a gradual decrease until 1912, when there were only four deaths. At Panama in 1906, 821 out of every thousand were admitted to the hospitals for malaria, and in 1913 only 76 per thousand. Of the general situation in Panama Dr. Gorgas says: "We had an average of 900 men sick every day. For the year, this would give us 328,500 days of sickness, and for the ten years 3,285,000 days of sickness. If our rate had been 300 per thousand,—a very moderate figure compared to what it was under the French,—we should have had 11,700 sick every day. For the year this would have given us 4,270,500 days of sickness, and for the ten years 42,705,000, a saving of 39,420,000 days of sickness during this period." This is equal to a savings in cash of \$329,420,000.

"During the ten years of construction, we lost by death seventeen out of every thousand of our employees each year. That is, from the whole force of some 30,000 men, 663 died each year, and for the whole construction period we lost 6,630. If the sanitary conditions had remained as they had been previous to 1904, and we had lost as did the French, two hundred of our employees out of each one thousand on the work, we should have lost 7,800 men each year, and 78,000 during the whole construction period." This means that 71,370 lives were saved. The Panama Canal is a monument to many things—the initiative of the American people; the leadership of Theodore Roosevelt; the triumph of modern engineering; the development of steam and electricity; and the dignity of labor. We,

however, like to think of it as a monument to preventive medicine, and we hope that sometime the traveler passing through its waters will find here and there a little memorial that will commemorate the work of Jenner, Pasteur, Walter Reed, and others whose work in scientific medicine helped to make possible the accomplishment of this gigantic task.

Typhoid fever formerly caused the death of 30,000 Americans a year. In 1900, the death rate in the United States was 46.5 per 100,000 inhabitants. We have reduced it to 25 per hundred thousand, which is not as low as it should be, considering the European death rate of only 6.5 per hundred thousand. In 1898 in the seventh army corps at Jacksonville, Florida, (10,769 men), there were 4,422 cases of typhoid, with 248 deaths. In the 1912 manoeuvres at San Antonio, Texas, among 12,801 soldiers there was only one case. During the Spanish war there were 20,738 cases of typhoid, with 1480 deaths. Nearly one fifth of the entire army had the disease, and it caused over 86% of the mortality of that war. In the Franco-Prussian war it was responsible for 60% of the mortality among the German troops. Vaccination against typhoid is already a routine practice in our armies. Before it was introduced, the British garrison in India had a yearly average loss of 500 men from typhoid, but in 1913, less than twenty died. The Russo-Japanese war was the first in history where disease played second rôle to death in battle, and the present world struggle will, we hope, show preventive medicine at her best.

In 1892 Behring, who died almost unnoticed the other day, discovered the anti-toxin of diphtheria. In 1890 its death rate was 66.9 per hundred thousand; 32.7 in 1900; and 19 in 1905. We are fighting cancer, leprosy, and tuberculosis. The sleeping sickness is being conquered. We know more about syphilis than we ever did. Thanks to Dr. Richard P. Strong, we have some control over the bubonic plague, which in the fourteenth century destroyed 25,000,000 people, or more than one fourth of the population of Europe. We are free from Asiatic cholera, which in the year 1885 cost Japan 100,000 lives.

What Pasteur has done for mankind would fill volumes. He who has not read that excellent biography by his son-in-law, Vallery-Radot, lacks a liberal education and has missed some of the joy of living. He was not a doctor of medicine, but a member of that ancient and honorable company of scholars. The son of a simple tanner, he belongs to the people, not to us. Much that we are to-day we owe to him, the father of preventive medicine, the father of bacteriology, the father of life-saving surgery and obstetrics, the conqueror of rabies. Before Pasteur discovered the cause of sepsis, the lying-in hospitals of Paris showed death rates from sepsis of from twelve to twenty per cent. In 1909 the New York lying-in hospital lost only .34 per cent. of 60,000 obstetrical cases, or one out of

1250. The mortality of ovariectomy, formerly 69%, is now 2%; that of compound fractures, formerly 60%, is now 3%; the mortality of major amputations, formerly 50-63%, is now 23%. Lister, who is usually credited as the father of aseptic surgery, gave all the credit to Pasteur. As the years go by, what are we doing to honor and perpetuate the memory of this great Frenchman? No possible argument against vivisection can influence a people familiar with Pasteur's contribution to mankind.

"Not with the dead should he be laid asleep,
Who wageth still with death triumphant
strife,

Who sowed the good the centuries shall reap,
And took its terror from the healer's knife."

Here is a rich heritage of historical medicine that may be fitted into our popular scheme of education and utilized to great advantage. That it is being allowed to mould and rot in our libraries in dusty volumes is surely not to our credit. We have health campaigns, it is true,—baby weeks, tuberculosis exhibits, and public lectures, which undoubtedly do some good. But most of these are undertaken not by our society, but by public health boards, and other independent organizations that are interested in the sanitary aspect of the social problem. Working independently of one another, they lack that co-ordination of effort which is so necessary to ensure success. Too often they enlist the services of amateurs, women and young girls, who look upon the work rather as an adventure than as the undertaking of a serious problem that has an ultimate, definite solution. The people they seek to help often wonder what it is all about, because these facts are presented to them dissociated from their true place in the world's progress. We impress our people with the true historical relation of our old landmarks. Thus it is that Bunker Hill, Lexington, Concord, and the Washington Elm mean something to them. But when we talk of tuberculosis, for instance, we employ archaic methods of education, which tend to frighten rather than educate. We tell them that every time the clock strikes, so many die; and we emphasize the deaths with big figures. Our voices and faces become distressing and melancholy, and monotony is the result. People grow tired of us and seek interests that are more agreeable.

This defect in our system of instructing the people in public health is in fact analogous to the defect in the educational system that trains our workers. "The man in the factory, as well as the man with the hoe," says Miss Jane Addams, "has a grievance beyond being overworked, in that he does not know what it is all about. We may well regret the passing of the time when the variety of work performed in the unspecialized workshop stimulated the intelligence of the workman and brought them into contact both with the raw material and the fin-

ished product. But the problem of education, as any advanced educator will tell us, is to supply the essentials of experience by a short cut as it were. If the shop constantly tends to make the workman a specialist, then the problem of the educator in regard to him is quite clear: it is to give him what may be an offset from the overspecialization of his daily work, to supply him with general information and to insist that he shall be a cultivated member of society with a consciousness of his industrial and social value." Great social thinkers, therefore, unmoved by the slogan that this is an age of specialization, are making new demands upon our educators and insisting that they realize that the individual in the industrial order needs, as Miss Addams says, "the conception of historic continuity in order to reveal to him the purpose and utility of his work; and he can only be stimulated and dignified as he obtains a conception of his proper relation to society."

This idea ought not to be difficult to grasp, for we are all victims of the same short-sighted system of education. We study medicine and its specialties primarily to make a living, and it seems that the curricula under which we have been trained were arranged with only this idea in view. We have missed the historical aspect and the social relation, not only in our preliminary, but also in our medical, training. Small wonder is it then that we are narrow, and easily roused to anger when a layman dares to express a medical opinion, or when a colleague displays any knowledge of our specialty. We develop a frigidness which we mistake for dignity, and cease to be approachable when a member of our patient's family questions us pointedly about the patient's condition. We criticize the clergyman who thinks he is a "wise fellow" in medicine, forgetting all the time that we do not hesitate to air our views on religion. We gradually grow to that condition of mind which convinces us that our colleagues cannot possibly know medicine, and we like to tell for our own enjoyment "how we put one over on Dr. So-and-so, who missed the diagnosis." When we hear that a certain family is being attended by our colleague down the street, we assume that gracious yet easily interpreted manner of one who says "Are those people crazy?" We are incompatible as individuals, we are incompatible as groups. It is "I am a big man, you are a small man. I have a big income, you have a small one. I am a specialist, you are a general practitioner. I am a real surgeon, you are only a gynaecologist." Bounded by nutshells we think ourselves kings of infinite space.

Retarded by mean and trifling jealousies, imaginary differences, local feuds, and exalted ideas of class distinction, we are rapidly approaching a condition of intellectual stagnation; and unless action is substituted for lethargy, we cannot hope that our position in the "Great Society" will be any better than a maladjustment,

especially for the rank and file—for those of us who, toiling with the toilers, sow much but reap little in worldly reward. Because of our indifference to matters outside of medical practice, our effectiveness as an aggressive social force among the people and before legislative bodies has never materialized. We represent potential, not dynamic strength. We are little candles throwing little beams, when we could be one powerful sky-searching light by accommodating the program of our activities to the many problems that bind us to one another as well as to society. The interest awakened recently in the idea of applying rigidly to all our work the test of "end results" is indeed a happy omen. By its direct appeal to the people, who, although indifferent to the mysteries of technique, diagnosis, and experimentation, are alive to results, this idea not only stimulates us to better work, but it also reminds us that the social value and dignity of which Miss Addams speaks, are in our case measured by the quality and not by the quantity of our work. Our end-result campaign, then, expresses a quickened sense of social justice, a desire for a higher social morality.

Social insurance, which in our state and in many others has already more than justified its usefulness, since the passage of the various Workingmen's Compensation Laws, was apparently not "as welcome as flowers that bloom in the Spring," when, in the past year, it paid another visit to Massachusetts in company with two other handmaids, health insurance and old-age pensions. Workingmen's Compensation represents social justice long desired and too long delayed. In 1908 the first act of this kind was passed by Congress at the earnest request of Theodore Roosevelt. It included a small number of Federal employees, and although inadequate in its benefits, it was more than adequate in the moral effect of its example. Up to June 1, 1916, thirty-three of our states and territories had compensation acts on their statute books, but so far, other forms of social insurance have made but little progress. These compensation laws provide for compulsory insurance of employees or for elective insurance, with the alternative of abrogation of the main defenses of the employer under the common-law rules.

Formerly industrial accidents and deaths were the source of incalculable misery. Statistics were unsatisfactory as they were either inaccurate or entirely lacking. In New York and Pennsylvania, the old employers' liability laws were worse than none at all. If an injured man had no legal claim whatever on his employer, he had to rely on his generosity. In the investigation of the facts in the cases of 304 deaths of men who were contributing wholly or in part to the support of families, the following facts were disclosed: Two-thirds of these men were married; 88 of the 304 families received not a dollar of compensation; 93 of the 304 received not more than \$100; 62 received more than \$100

but not more than \$500; 61 received more than \$500—most of them less than \$1000. That is, 181 families, 59½%, had to bear the entire income loss, and only 61 families, or 20%, received in compensation for the death of a regular income provider more than a sum which would approximate one year's income of the lowest paid of the workers killed. Statistics of this kind might be multiplied. For example, in the report of the New York Commission on Employers' Liability, we find that ten companies, which reported their employers' liability separately, received in three years, \$23,523,585 in premiums and paid out in the same time for injuries, only \$8,559,795. In a word, much of the financial loss was borne by the workmen—not to mention the resulting misery and distress.

Conditions are better to-day, but there is still much to be done before the employee is satisfied that the present system represents full justice. We may rejoice, however, that a worthy cause has been given a flying start. Therefore when we think of our grievances under this act, let us remember that the workingman has *his*, and that they are more urgent than *ours*. By the introduction of safety devices, better sanitary conditions, and shorter hours of labor, all of which will tend to reduce accidents to a minimum, the idea of workingmen's compensation will bring other and greater blessings; and what is also of importance is that we shall have in the future accurate statistics of industrial accidents, diseases, and deaths, and also financial statistics relating to the business side of this reform. Until we have sufficient data to further analyze this complex problem, we shall have to be content to wait for a more just settlement of the questions that vex our profession. Through our failure to anticipate this legislation by a timely and careful study of social insurance in all its aspects, we are the victims of our own unpreparedness. That workingmen's compensation is now being discussed in our meetings and in our journal is another happy omen, another sign of our quickened sense of social justice.

We are at present engaged in a heated controversy with the supporters of health insurance. What most of us know about it has been learned in a hurry and is still undigested. As an instrument for the amelioration and even the elimination of many present undesirable social conditions, it has in its favor all the arguments that make workingmen's compensation a permanent institution. The difficulty is in the complexities that arise when an attempt is made to fit it into our social scheme. Among the poor, sickness is more frequent and more disastrous in its results than industrial accidents. The poor, and even some who cannot be called poor, find it hard enough to meet the expense of medical service. Our medical schools still send men into general practice and seem anxious to increase the numbers of their stu-

dents. In school we are not told that general practice is to be avoided, but we are sent forth with the idea that ours is a noble profession, honorable in all its callings. Few become specialists; many, not of their own choice but through necessity, seek the harder but sometimes more quickly remunerative work of general practice. The Harvard Graduate School of Medicine is trying to help these men by courses intended to keep them in the front rank of medical progress. This school has even adopted a missionary plan of education by sending men to different cities to spread the truth. What subtle influence is there then inside and outside our profession behind the increasing prejudice against the general practitioner? Why is he so frequently dubbed—and I am now quoting Rubinow—a “Jack-of-all-trades, whose persistence is out of harmony with the recent phenomenal development of scientific medicine”? And he adds, “There is perhaps a distance of a quarter of a century between the present status of medical science and that of medical practice among the poor.” These are not new ideas, and we have no contest with Rubinow if he uses for his own purpose statements that have been fed to the public for years, while we as individuals have all selfishly assumed that since we had no over-draft at the bank, these disparaging statements must refer to the other fellow, our neighbor down the street, and not to us. Rubinow has done his part of the work thoroughly and well, as his scholarly treatises on the subject testify. The powerful influences behind health insurance could not have been effective without him. His most difficult task is not to prove the justice of his cause, for that speaks with millions of mouths. The real difficulty is, in slang phrase to “put it across,” for never before did any other social welfare measure present so many economic, ethical, social, and political complexities. Fully aware of our weakness, Rubinow had no hesitation, but, like a seasoned campaigner, he quickly mobilized his forces and crossed our boundaries. We lacked leaders; we lacked guns and ammunition; we even lacked shovels with which to dig ourselves in. “It’s unconstitutional,” we yelled. “It’s flagrantly unconstitutional; it’s outrageously unconstitutional!” This was the old protesting cry of the trusts against the cruel and abusive treatment of the common people. Think of the poor general practitioner imitating a trust when his income is about to be shot to pieces! “What’s the constitution among friends,” said Rubinow with a chuckle, as he sat in with his colleagues and proceeded to draft the bill. He probably remembered that when Theodore Roosevelt interfered in the anthracite coal strike early in his administration, he did not create the sentiment which supported him so loyally in his extra-constitutional act. That sentiment was already born, and when Roosevelt declared the common good to be paramount to

private right, the Fourteenth Amendment Club, composed of men enjoying the un-American distinction of corporate personality, lay down, like Fido, and didn’t even dare to beg. Now in the sentiment that supported Roosevelt against the coal barons, and in the sentiment so persistently and cunningly worked up against the general practitioner, the social insurance extremists thought that they saw an analogy.

But the sentiment that supported Roosevelt was born of love of justice, intensified by bitter hatred of injustice long endured. It was expressed in the unflinching and far-flung challenge by millions of people to the greed of a corporate few. The sentiment against the general practitioner, however, on which the success of this measure largely depended, was born of injustice, hypocrisy, and intrigue. It was expressed only in the incomprehensible and irreclaimable narrowness of a few men, righteous enough in a small way, perhaps, but not agreeable, whose feelings, mildewed by a long, vitiating process of refrigeration, have prevented them from mingling with the crowd spiritually as well as physically, and learning, in the words of De Quincey, “the thoughts, the yearnings, the aspirations, the sympathies, and the repulsions of heart,” of those millions of intelligent citizens, who have still to be convinced that the general practitioner is a plague unchecked, and the modern specialist a blessing unalloyed. When this fight began, the medical profession was consanguineous in the first degree with those pacifists, who, Roosevelt says, maintain that world peace is only possible by a disarmament that even goes into the nursery and destroys the toy pistols and the tin soldiers of the children. Happily our disarmament had not been completed and the situation became productive of leadership.

There were other weaknesses in the bill as it was drawn, and since Rubinow was perfectly aware of these facts, I wonder that he did not find some means of making his pet measure less objectionable to the people. The proposed creation of a “twenty-five-dollar-a-week-or-less” social class was an insurmountable difficulty, for it included most of our woman school teachers, and thousands of others, who, unable to attain a proper standard of living without constant worry and hardship, are continually fighting for a just stipend. Social insurance must not be a substitute for higher wages. Besides, people resent the idea that they belong to a class which cannot choose their own physicians without paying double freight. We have heard much of Germany’s success in social insurance, but I doubt if we shall hear as much in the future. Her efficiency, if it is efficiency, is, or rather was, beyond dispute. But as Mr. William Roseoe Thayer says, “Efficiency is of itself no more praiseworthy than is electricity. The vital consideration is, who applies it and for what purpose. If the object be evil, then the harm done

is greater in proportion to the greater efficiency. The voltage of a lightning bolt which sets fire to a town might supply power to run a dozen factories. Granted that Kultur-made efficiency ranks first, has it been justified by its works?"

It would seem, then, that democracy must avoid a system of efficiency that reduces men to soulless machines. She must learn that the only system of efficiency for her is one that does not lose sight of real human happiness. When auto-cracies speak, there is no appeal from their edicts, but in democracies, we object to the control of our intimate domestic and social arrangements either by the state or by altruistic corporations of great wealth. It is a settled fact with us that the state is for the people, not the people for the state. And we are proving also in our struggle for progressive legislation, which is in reality a fight for social justice, that neither the corruption of capital, nor the machinations of politics, nor the social myopia of unsophisticated but well-meaning reformers, shall assume that they are above both the state and the people. This does not mean that old Demos is always governed by his intellect and that his decisions always represent a careful consideration of the merits of the question. In democracies, the controlling forces are at all times emotional rather than intellectual, even among those who are highly trained. This is especially true when Demos is opposing Croesus, or the reformer who impresses him, not with meekness, but with that brand of exotic goodness which cannot endure the pollution of his presence.

Thus the emotional tendency of the crowd cannot be disregarded, for if it carries potential harm, it also carries, and in a greater measure, potential good. If the demagogue has won many an unworthy cause by discerning its presence, the reformer has lost many a worthy one by assuming its absence. Its harm is rather negligible and transitory, its good, incalculable and lasting. It is with this psychological fact that the future of health insurance is linked, as are also linked the futures of many other social measures, and even the future of our profession. We appeal to the emotion of the crowd, when we ask them to be loyal to us, and when we tell them that while admitting the need of some form of health insurance, we deny that it can only be secured at the expense of injustice and indignity to them and to us; but we appeal to the intellect, as well as the emotion, of our more fortunate colleagues, when we say to them that unless they establish lines of more cordial and brotherly support with those who are fighting in the trenches of general practice, theirs will be the blame for any maladjustment of the medical profession in our social order. Our fight is their fight. We are their first and only line of defense.

Rubinow will come back. He has retired but is not defeated. We have advanced but have won no victory. Let us forget Rubinow, but

remember his lesson of preparedness. Let us forget the old slogan of the trusts, but remember that the people are no longer awed by constitutions. Rather let us bend our efforts toward solving this critical problem, for we have come to the parting of the ways. So far the only constructive suggestion has come from Dr. E. A. Codman, of Boston, and since his plan is economically, ethically, and ideally sound, it deserves our careful consideration. It is based on efficiency (the American idea), on standardization of hospitals, and on end results. It is a reform that begins at the top and goes to the bottom. It calls for medical service that is systematized, humanized, and vitalized. It puts the responsibility for medical progress where it belongs,—on the medical profession,—and it draws a line of cleavage between the physician and the social worker. It eliminates the amateur; it eliminates the unfit. It annihilates privilege, opens the door to opportunity, and socializes our organization. It guarantees a square deal to the poor, and makes possible better treatment for those who are not wealthy. It raises the dignity of our profession, because it commands the respect of the people by recognizing their right to the use of those expensive instruments of diagnosis and treatment in institutions which they directly or indirectly support. In short, it shows us a simple solution of many other allied social questions by readjusting our organization to meet more adequately the needs of all our people.

Such social benefits are impossible under the proposed bill because it is too much tainted with the abstract Utopian idea of improving medical service while deteriorating the medical profession. Health insurance, if it is to be realized, must be an attainable, concrete, living idea that will create a better medical profession—more generous, better trained, better organized, broader visioned, more influenced by a higher social morality, and more productive of real leadership. Otherwise high-grade medical service, like high moral standards, is beyond the compulsion of human legislation.

There are other social problems involving our profession that are soon to demand an answer. Unless we go forth to meet them with the aggressive and uncompromising spirit of a militant and elevating social force, sex hygiene, eugenics, and birth control will come to us, swaggering with the insolence of popular hysteria and the coarseness of unbridled demagoguery. By spreading a knowledge of sex relations and of the vices and evils resulting from sexual indulgence and lack of moral stamina, sex hygiene seeks to emphasize the importance of chastity. The end in view is a noble one, but the ways and means that are being employed to attain this end are open to criticism and rebuke. If merely a knowledge of sex relations and of the dangers of venereal disease would open the gate to chastity, close the door

to prostitution, and send to the shambles gonorrhoea and syphilis, there would be some hope even for those benighted people east of Suez, "where the best is like the worst, where there aren't no Ten Commandments an' a man can raise a thirst." We must admit, however, that west of Suez, where we have, and have had, the Ten Commandments, that neither education, nor wealth, nor position, nor culture, nor marriage, nor the physician's intimate knowledge of these facts, nor prohibition, nor total abstinence has proved impregnable to human frailty, or to the diploceous or the treponema pallida. And yet may we not say with truth that the Ten Commandments have supplied the most dependable restraint?

Exaggeration, narrowness, hysteria, error, and insult frequently characterize this campaign. It cannot be denied that the discussion of sex with children of tender years may easily arouse cravings that would otherwise remain dormant. There are those extremists who desire to have this subject taught in the pulpit, in the day-schools and Sunday schools, in the factories, and in the press. They say that this conspiracy of silence must be broken; and one lecturer makes the startling discovery that one of the causes of this conspiracy is found in the Hebrew law, which, while enjoining the duty of multiplying, surrounded the only processes by which race continuation is possible with the idea of impurity. After childbirth the mother was considered unclean for a month or more, and was not permitted to touch any hallowed object. "Accordingly, the mother of God was considered unclean for more than a month because she gave birth to Jesus Christ." He pursues this idea as follows: "The Christian church, by referring to the conception of Jesus as 'immaculate' [that is, spotless], emphasizes this point by the unmistakable implication that other conceptions are maculate [that is, attended with fulfillment.]

"The comparatively recent adoption of the dogma of the immaculate conception of the mother of Jesus, by slightly extending the idea of purity in the matter of the propagation of the human species, still further enforces the rule, particularly as the proposition was strenuously opposed in the council which finally adopted it."²² If the Jew feels that his future in America is bound up with the traditions of his past, is it not an insult to him to speak lightly of those traditions? If the Roman Catholic celebrates the feast of the Immaculate Conception of Mary (which is not a new doctrine any more than the celebration of Lincoln's birthday as a legal holiday would be an evidence of his recent deeds or of anything new discovered in his life), what deformity of the human mind can assume that this supreme expression of respect for motherhood and maiden purity connotes an idea that is antagonistic to a propaganda, the purpose of which is to drive

from the face of the earth, if it can do so, the fornicator, the adulterer, and the harlot? We may leave extremes of this kind to a conspiracy, not of simple, but of contemptuous silence.

The whole story of sex hygiene is well summed up by the editor of *Collier's*, that gifted and interesting young Harvard man of the class of 1900, Mr. Mark Sullivan. "It seems clear," he says, "that experience so far shows that the whole problem of sex had better be approached in the spirit of personal reserve that we associate with the better sort of home life, rather than in the spirit of eager curiosity and practical experimentation that we associate with the school. . . . Any system of instruction which gives a knowledge of sex hygiene merely as mechanical knowledge will be a great mistake. Any instructors given this responsibility must have the spiritual force to conquer these problems, and the personality to compel their pupils to reverence. Anything less will be instruction for dogs, not for human beings." Are we prepared, in the name of our school children, to protest against the introduction of a system of canine instruction in our schools?

Eugenics, founded on the newer biology and on our increased knowledge of heredity, expresses an interest in some important human problems. It is negative and positive. In its former aspect, which opposes the reproduction of the unfit, it greatly concerns us. If it should become the law in this state, that feeble-minded and other low-grade human beings shall be surgically sterilized, those in the medical profession whose religious belief does not oppose such a measure will have a grave problem to solve. The sterilization of males and females, besides being attended with the usual risks of operation, gives to unprincipled men an opportunity to use our profession as a tool for injustice to others. Wills may easily be broken, and bequests easily diverted to the unworthy, if progeny is thus prevented along a certain family line. Legalized, sterilizing surgery, like legalized abortion, would have a tendency to lower our social morality. In the case of the feeble-minded and other defectives, negative eugenics has the sanction of biology, but like many other social reforms, the problem to be solved is so complex, economically, morally, and religiously, that we must not assume too readily that the segregation of those unfit to reproduce will not in the end be less burdensome to society than surgical sterilization. The eunuch was a creature of an obsolete civilization: let us not make our civilization obsolete by his presence. The Great Wall of China was built by the labor of 600,000 prisoners, surgically reduced to the condition of oxen. The experiment has never been repeated. Let us beware lest our enthusiasm for attractive social measures lead us into the temptation of substituting a heavier burden of social misery for one that is at least bearable.

Birth control, the most clamorous of all these questions, has for its ultimate aim, so its supporters say, the better and greater development of the individual. Malthus's remedy, over a hundred years ago, was to discourage marriage among those who could not afford it, or else to throw into the sty of human misery the families of such unions. "These are the unhappy persons," he says, "who in the lottery of life have drawn a blank." He did not recommend contraceptive measures or abortion to keep down the birth-rate, but depended rather on the acts of abstinence and self-control. The modern Malthusians, however, of whom Havelock Ellis is the high priest, recommend contraceptive measures, and do not seem to express any pronounced disapproval of abortion. In a popular magazine,² several years ago, Ellis declared that "women have an abstract right to abortion, and that, in exceptional cases, this right should be exerted, even though it is an injurious, wasteful, and almost [note it is 'almost'] degrading method of dealing with the birth-rate." There has appeared in this country a newer school of birth-control, the purpose of which is to give information and distribute literature on contraceptive methods by repealing in the first place the laws that at present stand in their way. Their slogan seems to be "Everybody's doing it." Hence they desire to help the poor, and others who may wish to limit the number of their offspring.

A writer of this American school⁴ has determined to devote his feeble pen and leisure time to these things: "First, to advocate the propriety of preventing conception, of limiting the number of one's children according to one's economic means and other circumstances; second, to a study of the best, safest, and most harmless means of preventing conception; and third, to a dissemination of this knowledge among the medical profession, and through it, among the laity." The pen that can do this is not feeble, but mighty and dangerous. These dangers are apparent even to a feeble imagination. This same writer chafes at the idea of religious people "forcing their morals and their conduct upon people who are guided by different standards of morality. . . . Religion is a matter of faith and not reason; you believe so-and-so and that is all there is to it." Now the social question and religion are not rivals. Blind indeed is that reformer who does not see that religion can play and must play a momentous part in this irrepressible social conflict. Social questions are not altogether economic facts, but they also present moral, ideal, and religious aspects, which cannot be ignored. Even the industrial world, big, powerful, and at times pitiless, which would seem to be dominated only by the bloodless rule of economics, is a moral fact, inasmuch as it rests on credit, and depends for its existence on the confidence which the people have in its integrity. And if the indus-

trial world is a moral fact, much more so is the family, which is the basis of our whole social structure. In it are developed those social virtues of loyalty and generosity; in it we see the kindergarten of the moral education of the race.

"The family, many people may be almost surprised to learn," says Professor Peabody, "is not a device invented to procure either personal happiness or mutual convenience. The family is, on the contrary, the world's first and greatest venture in altruism. . . . The family is in danger when it is created for what one can get out of it; and it is safe only when it is prized for what one can give to it. . . . The most important step in the education of the human race is taken, when out of the surviving instincts of animalism and commercialism there emerges, in a man or woman, the ideal of a humanized love, dedicated to the creation of a family, and finding in that union, not limitation but enlargement, not sacrifice but joy." To assume, then, that neither religion nor morality has any grounds for opposing birth-control is to express a practical materialism, cynical, pessimistic, and brutal, which jeopardizes the entire social question. "How feeble a conception must that man have of the infinity which lurks in a human spirit," says De Quincey, "who can persuade himself that its total capacities of life are exhaustible by the few gross acts incident to social relations or open to human valuation!" Social changes sought by changes in economic methods bear the cruel imprint of the cloven hoof when they seek to overthrow the world of the human heart.

In our social order, men of religion are second to none in dignity and worth, because in their teachings are found the essentials of the highest type of good citizenship. Herein lie the strength and the hope of democracy. In their philosophy are more things than many a social reformer or economist has ever dreamed of. In their code of morality, standards are termed high or low. They are not concerned with "different" standards, and moreover they do not feel, when they are protecting their flocks, that they are forcing their own morals and conduct upon those reformers whose code of morality is, in their judgment, a menace to society. They do not believe that religion is altogether a matter of faith and not of reason. They teach that where reason ends, faith begins, and that faith does not contradict reason, but strengthens and supplements it. A man's acceptance of, and adherence to, a religious belief is very clearly a fact in the domain of reason and not of faith. "On the question of immortality," says Osler, "the only enduring enlightenment is through faith." "Life is for action," says Cardinal Newman. "If we insist on proofs for everything, we shall never come to action: to act you must assume, and that assumption is faith." In a human sense, faith, that is, con-

fidence, makes possible the existence of our complicated financial system. Hence we see that faith is not altogether divorced from reason. Religion is a hard task-master, a good disciplinarian. "The fundamental need of democracy is discipline," says Mr. William Roscoe Thayer, "and that is all the more difficult to organize and apply in a society based on the cardinal principles that each of its members shall be hampered as little as possible by the state in his personal freedom." "Religion makes the march of progress possible, and the struggle of life less severe," says the Reverend Edward Cummings. "But for it the rank and file of those who toil and suffer would be driven in desperation to join a socialistic mutiny." By taking a broader view of the social question, the birth-control enthusiast will be able to visualize the dangers, as well as the safeguards, of our Democracy, which is now undergoing the most distressing trial in her history. But he must first get over the idea that the religious teacher is merely a sky-pilot, in an old Wright model, endeavoring to break the altitude record in a fool's attempt to establish a wireless connection with the supernatural.

As a matter of fact, there is no other social question in which there is such a confusion of cause and effect. Civilization is not destroying itself, and "everybody is not doing it." Programs of social reform based on such unwarranted assumptions will only undo the good already accomplished by those whose moral maturity has kept their course true between the Scylla of sentimentalism and the Charybdis of pessimism. Social misery is not the result of big families, but rather an unnecessary and indefensible condition caused by a disregard of those finer feelings that spring from what the world sneers at as sentiment, but which in reality denote the true religious spirit. What the world most needs is more, and not less, evidence of this spirit among those whose decisions determine the happiness or the heart-aches of the people. "If the Christian character is to have any place in modern life,"—if I may quote Dr. Peabody again,—"it must be precisely where these men are, in the heat of the world's work and under the load of the world's care; and the worst of disasters, alike for religion and for business, is to separate the one from the other."

The subject of social progress, even as it relates to us, is too appallingly big to pursue further within the limits of this paper. It travels

many roads, crosses many fields, and conflicts with many interests. Have we as individuals reached a condition of intellectual stagnation which makes it impossible for us to be responsive to the vital needs of our complex social order? Or have we as an organization become so deaf to the crying distress of the people that we are satisfied to remain more interested in adhering to traditional programs than in going forth to meet new issues? Into the midst of much heated discussion, I have tried to project a point of view which will not vanish when subjected to the ripened judgment of experience. Firmly believing that the future of our profession in this new social age, depends on our devotion to the highest ideals of life, I submit this essay to the enlightened criticism of my colleagues, with the hope that it may in some little way serve to show us our duty in the great task of social regeneration which will "make the world itself at last free."

NOTE: I wish to acknowledge my indebtedness to many books. I would especially mention that excellent little book, which is a veritable gold mine of information, *The Physical Basis of Society*, by Prof. Carl Kelsey of the University of Pennsylvania. D. Appleton & Co., New York, 1916.

STUDIES OF INFANT FEEDING.

VIII.

THE MINERAL CONSTITUENTS (ASH) OF MILK.*

BY A. W. BOSWORTH, BOSTON,

AND

H. I. BOWDITCH, M.D., BOSTON.

[From The Boston Floating Hospital Laboratories.]

MILK is often spoken of as a food containing all substances required for growth. This may be represented diagrammatically as follows:

* Read before the New England Pediatric Society on March 30, 1917.

Chemically, milk may be considered as water carrying a mixture of food substances, these substances being present in the water, in true solution, in colloidal solution, in suspension, and in the form of an emulsion. The conditions in which the different components of milk are carried in the water are shown in the following table:

1. Milk constituents in true solution in milk serum.	2. Milk constituents partly in solution and partly in suspension or colloidal solution.	3. Milk constituents entirely in suspension or colloidal solution.
(a) Sugar	(a) Albumin	(a) Fat
(b) Citric acid	(b) Inorganic phosphate	(b) Casein
(c) Potassium	(c) Calcium	
(d) Sodium	(d) Magnesium	
(e) Chlorine		

The composition of milk will vary with the species and with individuals of the same species. The average compositions of the two milks with which we are concerned are as follows:

	COMPOSITION OF COW'S MILK AND HUMAN MILK	
	COW'S MILK PER CENT.	HUMAN MILK PER CENT.
Fat	3.90	3.30
Milk-sugar	4.90	6.50
Proteins (combined with calcium)	3.20	1.50
Salts	0.90	0.31

If the differences shown in this table were the only ones confronting us in the problem of properly modifying cow's milk for infant feeding, many of the formulae now in use should serve the purpose very well, for it is very easy to modify cow's milk in such a manner as to give a mixture which will contain the amounts of fat, sugar, proteins and ash found in human milk. There are other differences, more deep-seated and obscure, however, comprehensive consideration of which may be far-reaching in practical application, when they are more fully understood.

Breast milk is nature's food for the infant, and we may consider the constituents to be so balanced as to meet all the demands of growth, with a minimum of waste. Cow's milk, on the other hand, is nature's food for the offspring of the cow, and is not balanced in any respects as a food for infants, and its use as such must usually be preceded by some form of modifying which will make the quantitative relations between the fat, sugar, protein and water approximately that found in breast milk. In most, if not all, of these methods for modifying cow's milk, the mineral elements present receive very little consideration, being passed over with the statement that modified cow's milk will always contain a larger percentage of ash than breast milk, and hence will furnish all the mineral elements necessary. The time has come, however, when this phase of the feeding problem can no longer be treated in this manner, and those concerned must realize that more care must be taken to see that the mineral elements

are properly balanced. This adjustment must take into consideration not only the mineral elements themselves, but also their relations to the organic constituents of the food, for it is well known that certain of the mineral elements may interfere with the proper utilization of the organic components. This is especially true with respect to calcium and fat.

It is known that bottle-fed infants absorb and retain a much smaller percentage of the mineral elements ingested than is the case with breast-fed infants, and this has been considered as due to the fact that bottle-fed infants receive an excess of mineral elements, and necessarily must excrete greater amounts. While this is in part true, we wish to emphasize the fact that in using cow's milk for infant feeding, the larger excretion of mineral elements is, for the most part, due to the fact that these elements, as they are present in cow's milk, are not completely available as food for infants. It will be seen, therefore, that the consideration of the forms in which the mineral elements are present is the important fact, and not the mere presence of these elements, for the presence of a certain amount of an element does not necessarily mean that the whole amount is available as a food for infants—a fact which has been demonstrated by investigations now under way in this laboratory.

It has been shown by one of us that, while di-calcium phosphate (CaHPO_4) is a normal constituent of cow's milk, it is not a constituent of human milk. As this salt has always been found by us in large quantities in the feces of infants fed upon cow's milk, and to be absent or present in very small amounts in the feces from breast-fed infants, we have investigated the question of the availability, as a food for infants, of the di-calcium phosphate present in cow's milk. We have fed a synthetic milk to infants, the only inorganic salt present in this food being di-calcium phosphate, and have recovered in the feces from 64 to 100% of the salt fed, the smaller recovery being from infants eight or nine months old, and the complete recovery from infants one to four months' old.

We have also shown that under ordinary conditions any excess of soluble calcium received in the food is precipitated in the intestines as calcium carbonate or insoluble calcium soaps, and is not available as a food, and that the addition of limewater to milk, although increasing the actual calcium content of the milk, really brings about a precipitation of insoluble calcium phosphate, leaving amounts of soluble and available calcium and phosphorus which are less than those to be found in breast milk. A child receiving modified milk to which limewater has been added may be receiving insufficient amounts of available calcium and phosphorus—a fact which should receive more attention in connection with the feeding of certain children, *i.e.*, rickets, spasmophilia, etc.

In connection with the use of cow's milk in infant feeding, it has been the general practice to consider the quantity of mineral elements present in this milk to be represented by the ash. This ash, amounting to about 0.7%, has usually been thought to contain all the mineral elements in the milk, and the figures obtained by analysis of such an ash have been quite generally accepted. Such an analysis does not, however, represent the true mineral content of milk, for under conditions ordinarily surrounding the determination of ash some of the sulphur and phosphorus in the casein molecule will be lost by volatilization. If this loss is taken into consideration, the true mineral content of cow's milk of average composition will be found to amount to 0.8% of the milk.

This point was brought out by the examination of several samples of milk, the figures in Table I being representative of data obtained from milks of average composition.

TABLE I. MINERAL ELEMENTS IN MILK AND MILK ASH.

	Cow's MILK		Human MILK	
	IN ASH FROM 100 c.c. MILK		IN ASH FROM 100 c.c. MILK	
	Gm.	Gm.	Gm.	Gm.
SO ₂	0.025	0.054	0.002	0.004
FeO ₂	0.199	0.249	0.034	0.036
Cl	0.076	0.076	0.038	0.038
CaO	0.201	0.201	0.050	0.050
MgO	0.022	0.022	0.005	0.005
K ₂ O	0.145	0.145	0.086	0.086
Na ₂ O	0.074	0.074	0.020	0.020
	0.742	0.821	0.235	0.239
Oxygen equivalent to chlorine	0.017	0.017	0.008	0.008
TOTALS	0.725	0.804	0.227	0.231

A cow's milk giving an ash amounting to 0.725% will be seen really to contain mineral elements to the extent of 0.804%, while human milk giving an ash amounting to 0.227% will be seen to contain mineral elements to the extent of 0.231%.

The incineration of milk leaves an ash in which the arrangement of the elements is altogether different from that in which they were present in the original milk. This is due to the fact that some of these elements are in part combined either with or within organic molecules.—part of the phosphorus being combined within the casein; all the sulphur being combined within the albumin and casein; some of the calcium being combined with the proteins; and part of the other bases being combined with citric acid to form citrates; and upon ashing these organic molecules are destroyed, the mineral elements involved being converted to oxides, and in the cases of the sulphur and phosphorus some may be lost by volatilization. The following statement of the forms in which the mineral elements are to be considered as being present in milk is given, as the result of extended studies of the chemistry of milk.

TABLE II. FORMS IN WHICH THE MINERAL ELEMENTS ARE PRESENT IN MILK.

ORGANIC COMBINATIONS	IN 100 c.c.	IN 100 c.c.
	Cow's MILK	HUMAN MILK
	Gm.	Gm.
Sulphur within the casein and albumin	0.022	0.001
Phosphorus within the casein ..	0.022	0.001
SALT COMBINATIONS		
Calcium combined with the protein	0.054	0.024
Di-calcium phosphate, CaHPO ₄ ..	0.175	0.000
Mono-magnesium phosphate, MgH ₂ P ₂ O ₇	0.103	0.027
Di-potassium phosphate, K ₂ HPO ₄ ..	0.230	0.000
Mono-potassium phosphate, KH ₂ PO ₄ ..	0.000	0.069
Potassium citrate, C ₆ H ₅ O ₇ K ₃	0.052	0.103
Sodium citrate, C ₆ H ₅ O ₇ Na ₃	0.222	0.053
Calcium chloride, CaCl ₂	0.119	0.059
Iron	Trace	Trace
TOTAL SALTS	0.955	0.337

TABLE III. COMPARISON OF PERCENTAGES OF ASH, MINERAL ELEMENTS AND SALTS IN MILKS.

	Cow's MILK	HUMAN MILK
Ash	0.725	0.227
Mineral elements as oxides and chlorides	0.804	0.231
Salts (including the calcium of caseinate)	0.955	0.337

If we compare the totals given in Tables I and II we notice that the salt content of milk is considerably larger than the mineral or ash content. This is due to the citric acid of the milk appearing as citrates in the enumeration of the salts, while in the enumeration of the minerals these citrates appear as oxides of bases. In this connection it may be of interest to state that the sum of the fat, the sugar, the proteins and the ash never equals the total solids, for milk contains other substances which are not included in the determination of either the fat, the sugar, or the proteins, and are lost when the milk is ashed. The determination of any of these constituents by difference, therefore, throws an error of from 0.2% to 0.3% upon such determination. A milk containing 4.5% of sugar would show 4.7 to 4.8% if the sugar was determined by difference.

In view of what has been said in this paper, it may be of interest to know that the beneficial results obtained by the feeding of the Eiweissmilch or protein milk of Finkelstein is, without doubt, due to the fact that the available mineral content of this milk approximates very closely both the amount and form found in breast milk, for, notwithstanding the high ash content of protein milk (0.65%) half of this ash is present in the milk as insoluble calcium phosphate, a substance which is inert in so far as the metabolism of the infant is concerned.

DISCUSSION.

DR. HILL: I have followed Mr. Bosworth's work closely in the last year or two at the Children's Hospital, and I must say that I think he is absolutely on the right track in everything that he is

doing. More difficult "feeding cases" are due to a chronic impairment of fat absorption than to any other cause, and this is brought about by the combination of the calcium of the cow's milk with the free volatile fatty acids present, forming insoluble calcium soaps, which cannot be absorbed, thus causing a great loss of calcium and of fat in the stools. A great many cases of rickets are undoubtedly caused in this way, and I believe that when we have more light on the chemical processes that bring about this difficulty of fat absorption, we shall be able to deal with our cases of malnutrition much more intelligently than we do now. At present it is true that we get good results in many of our cases of chronic fat indigestion, by simply cutting down the fat in the diet, and perhaps raising the other food elements to make up the calories. This, however, is begging the question; what we should be able to do is to feed such a milk to our babies that insoluble calcium soap formation will not go on, and this is the goal toward which all Mr. Bosworth's work points.

MR. BOSWORTH: In connection with what Dr. Hill has just said, it may be of interest to you to know that the soap in infants' stools is calcium soap of palmitic acid, calcium palmitate being very insoluble. If you take the calcium out of the food of a child showing an intolerance for fat with a high content of soap in the stool, the soaps disappear entirely. A child giving off 15 grammes of soap in twenty-four hours will give off about 3/10 gramme of soap in the next twenty-four hours if the calcium is removed from the food.

DR. LADD: I would like to ask if there are any soluble calcium soaps?

MR. BOSWORTH: The soaps of the lower fatty acids are soluble, and there is a degree of solubility, of course. Palmitic acid is the most insoluble of the fatty acids in cow's milk. This is due to the fact that the melting-point is high. The solubility and the melting-point are hitched up together in some way. The melting-point of palmitic acid is 62° C., quite a bit above body heat.

BASIC PRINCIPLES IN THE SYMPTOMATOLOGY OF BRIGHT'S DISEASE.

By H. ELWYN, M.D., NEW YORK CITY.

IN reading current literature on Bright's disease we are confronted with the description of a multiplicity of types. There is the hypertensive type and the non-hypertensive type, the nitrogen-retention type, the sodium-chloride-retention type, etc. All these descriptions have this fundamentally wrong with them,—that they attach too much importance to a single symptom, without emphasizing the uniform principle practically underlying all cases of Bright's disease.

In studying diffuse kidney diseases there are the three elements of the kidney which we have to consider, namely: tubules, glomeruli and vessels of the kidney. Volhard and Fahr, in their

remarkable monograph on Bright's disease, have well demonstrated that each of these elements, when diseased, will produce a characteristic symptom-complex, and that we can well infer, from the symptoms presented, the exact histological picture of the diseased kidney; and this without the aid of dye tests, mathematical formulæ and other cumbersome procedures.

As prolegomenon to correct understanding, we have to consider what is the essential function of the kidneys; what is meant by a sufficient kidney and by an insufficient kidney; what elements are involved in kidney insufficiency; what is the compensatory mechanism, and finally what is the ultimate result of kidney insufficiency.

The function of the kidney is to excrete the waste products of metabolism. Of the various waste products, the non-protein nitrogenous substances, chiefly urea, form the most important elements. The necessity of their excretion is a matter of life or death. Inability to excrete them invariably leads to death in a short time, after a certain amount has accumulated in the body tissues. Not so with the mineral salts. Retention of sodium chloride may last for months; it favors edema, water retention and cardiac insufficiency, but is never the immediate cause of death.

We may consider, then, as the *essential function* of the kidney, the elimination from the body of the nitrogenous substances in the form of the non-protein nitrogen, and, indirectly, the maintenance of a normal level of the so-called rest nitrogen in the blood. This level, Folin and his co-workers have definitely proven to be, in normal health, 23 to 27 mgm. per 100 cc. of blood. The excretion of these products is effected in a solution, which the kidney can either concentrate to a high degree, so as to save fluids for the body, or eliminate in a very low dilution with a sufficient quantity of fluid intake. We can measure this ability of the kidney to concentrate by the specific gravity of the urine, which reaches, with a normal kidney, to above 1040. This ability to concentrate or dilute, according to needs, we call the *variability of kidney functions*, and it forms the essential means of the proper functioning of every normal kidney.

By a sufficient kidney, we mean a kidney that is able to eliminate the essential waste products under a variety of conditions with a variability of function. And we mean by an insufficient kidney one which loses this variability of function, and must either use a compensatory mechanism to help eliminate the waste products, or else fail to do so, entirely.

Variability of kidney function is dependent entirely upon the integrity of a sufficient number of glomeruli, and reduction of the functional capacity of the glomeruli to a sufficient degree, by inflammation or chronic obliteration, will result in a gradually increasing loss of this

variability of function. The result is a urine of low dilution, and in order to excrete all the waste products, the kidney must excrete continuously of this greatly diluted urine. But water excretion is dependent on glomerular function, and with the reduction of glomerular function, water excretion is impaired. The only thing that the kidney can do is to force enough water through those glomeruli that are still functionally capable, and it does this by raising the pressure in the glomeruli and, of course, in the whole arterial system.

The compensatory mechanism, then, consists in hypertension and increased diuresis of a hyposthenuric urine. Obliteration of the glomeruli to a point where, with hypertension and increased diuresis, the kidney fails to eliminate all nitrogenous waste substances, will result in an increase of the rest nitrogen level in the blood, progressive to a degree where death results. The same will result when the blood pressure falls, for any reason, to a degree where the compensatory mechanism breaks down.

By taking the specific gravity of the urine over a prolonged period of time, we can well establish the variability of which the kidney is capable. By giving the patient an additional water intake, we can see how promptly it is excreted, and by placing him on an absolutely dry diet, how high he can raise the specific gravity of the urine. Increased amount of rest nitrogen in the blood always means manifest kidney insufficiency, capable of returning to normal when the glomeruli are acutely inflamed, but always progressive where the glomeruli are permanently obliterated.

With these considerations let us review the various forms of diffuse kidney disease.

In acute diffuse glomerulo-nephritis we have a condition in which all the glomeruli are hit. The causal agent is always bacterial in origin, with the streptococcus in the lead. Although all the glomeruli are involved, they are not equally so, and side by side with bloodless, swollen glomeruli, with proliferation of cellular elements, there are glomeruli whose capillaries still contain blood and are, in a measure, functionally capable. Applying our tests for kidney insufficiency, we find that variability of function is diminished in proportion as the glomeruli are affected, and that retention of non-protein nitrogen in the blood is in inverse proportion to the ability of the compensatory mechanism to maintain diuresis through the less affected glomeruli.

As an expression of acute inflammation there is hematuria. This in diffuse kidney lesions is always a symptom of acute glomerular involvement. With the blood in the urine there is always slight albuminuria and cylindruria. Cases of acute diffuse glomerulo-nephritis are hardly ever pure, and nearly always there is a secondary tubular degeneration which expresses itself, clinically, by generalized edema,

cavity hydrops of a pseudo-chylous transudate, marked albuminuria and cylindruria.

The clinical picture of acute diffuse glomerulo-nephritis, as we see it, is, therefore: a hemorrhagic urine with some albuminuria and cylindruria; an increase in blood pressure as an attempt of the compensatory mechanism to maintain normal diuresis. If the inflammation is very slight and there is sufficient glomerular functional power to maintain the essential function of the kidneys, there will be no rest nitrogen retention in the blood, and practically the only symptoms presented, besides the urinary findings, will be a concentration ability of probably not above 1025, and an increase in blood pressure of perhaps 20 to 30 mm. of mercury above the normal. This, also, is often the picture in an inflammation which is beginning to recede.

With a severe inflammation, concentration ability hardly rises above 1018 to 1020, and although the compensatory mechanism of hypertension may result in a systolic blood pressure of 180 to 200 mm. of mercury, there is still so great a loss of glomerular functional power, that the essential function of the kidney cannot be maintained, with the result that the rest nitrogen level in the blood is increased and may exceed 80 and 100 mgm. per 100 cc. of blood.

In most of these cases of acute diffuse glomerulo-nephritis *restitutio ad integrum* is possible. The indication for treatment is: rest in bed till all signs have disappeared, a minimal protein intake, and a salt-free diet if edema is present. A gradual fall in blood pressure and of the rest nitrogen level in the blood, an increased concentration ability, together with the disappearance of blood from the urine, are the signs of betterment. Usually the blood pressure is last to return to normal, and in this connection a knowledge of the individual is important. In an individual who before the attack of acute nephritis has been carrying a blood pressure of 150, we should not expect to have it return to a lower level with the subsidence of the acute attack.

There is really nothing in kidney pathology that one can confuse with this picture. For in cases of focal nephritis or of the embolic glomerulo-nephritis of streptococcus viridans endocarditis, where the hematuria indicates acute glomerular lesions, although conceivable, there is practically never any kidney insufficiency, and therefore no loss of functional variability, no increase in blood pressure, no increased rest nitrogen in the blood.

If the kidney does not recover completely it passes into a chronic diffuse glomerulo-nephritis, in which functional activity is dependent either upon the glomeruli which have recovered completely or upon those which, having undergone chronic inflammatory changes, are still capable of functional activity. Loss of variability of function is a manifest symptom of kidney rest diuresis. The kidney remains sufficient and a

normal level of rest nitrogen in the blood is maintained as long as a sufficient quantity of urine of low dilution can be excreted by this kidney rest with the aid of the compensatory mechanism of hypertension. As long as the kidney is able to do this we may call this the latent stage of chronic diffuse glomerulo-nephritis, to distinguish it from the last stage when the kidney is manifestly insufficient.

We have, then, as the clinical picture of the latent stage of chronic diffuse glomerulo-nephritis: hypertension of 200 to 250 mm. of mercury; polyuria; a concentration ability of about 1020 on a dry diet; a slow elimination of an increased water intake; excretion of all of an extra sodium chloride intake, but over a prolonged period of time and in a urine of low dilution; a trace of albumen in the urine and a normal level of rest nitrogen in the blood.

There is only one other clinical picture for which this stage of nephritis can be mistaken, namely: arteriosclerosis of the kidney, in which the finer and often the finest vessels are involved. The condition is known under various names, as the granular kidney, benign hypertension, simple kidney sclerosis (Volhard and Fahr). It presents, clinically, hypertension reaching 200 mm. of mercury and above, polyuria, nycturia, with traces of albumen in the urine. But in this condition there is no loss of variability of function, ability to concentrate is retained and is very high on a dry diet. An increased water intake is promptly eliminated. The polyuria and nycturia are dependent not upon a kidney rest diuresis, but upon a latent edema due to the relative insufficiency of a hypertrophied heart muscle, which again is the result of prolonged hypertension. This can be well shown by placing the patient on a salt-free diet with a limited water intake and also with absolute rest in bed. The polyuria and nycturia will rapidly diminish and often disappear entirely. In this condition the glomeruli are not diseased at all, the primary condition is that of hypertension, dependent upon changes in the finer vessels of the kidney.

The kidney in the latest stage of chronic diffuse glomerulo-nephritis is prone to acute exacerbations, resulting in a fresh hematuria, diminished diuresis and rest nitrogen retention in the blood. A careful anamnesis and close observation will often establish the latent chronic nephritis previous to the acute exacerbation. Again, we must not consider every case of acute symptoms in an elderly individual with high blood pressure as an acute lighting up of a previous chronic nephritis. This is very important with a view to prognosis.

The latent stage of chronic glomerulo-nephritis may last only a few months, or it may be prolonged over a period of many years. Its course is always progressive, and the clinical cases present a variety of transition forms tending towards the stage of manifest kidney insufficiency. Occasionally we meet with borderline

cases, between the latent and the manifest, especially in individuals who have suffered from gout or have been lead workers, in which the rest nitrogen is often 50 to 60 mgm. per 100 cc. of blood. In such borderline cases a non-protein diet will restore nitrogen level in the blood, and prove that the kidney rest is still capable to maintain the essential function of the kidney, if not subjected to too much strain.

As the chronic glomerulo-nephritis progresses towards its terminal stage, we have manifest kidney insufficiency. As the kidney rest is reduced and its functional capacity diminished more and more, we have practically a total loss of functional variability. Concentration of urine remains fixed at 1006 to 1014. The compensatory mechanism of increased diuresis, although continuously at work night and day, is unable to eliminate the nitrogenous waste products of metabolism, at a minimal non-protein food intake or even at a total absence of protein in the food. The result is a gradually increasing level of rest nitrogen in the blood to a degree where symptoms of poisoning are produced, the figures before death often reaching 300 mgm. per 100 cc. of blood.

Blood pressure is excessively high, often reaching 275 to 300 mm. of mercury. Insufficiency of the hypertrophied heart muscle will complicate the clinical picture. There may be a fall in blood pressure and with the breaking down of the compensatory mechanism of hypertension the quantity of urine will be diminished, and with the increase of rest nitrogen in the blood death will quickly follow.

With the gradual increase of rest nitrogen in the blood there is added the picture of true uremia, that is, of retention of the constituents of the urine in the blood, of the grand azotemia of Widal. The symptoms of true uremia are remarkably uniform. Beginning with anorexia, dyspeptic phenomena of vomiting, thirst and diarrhoea, there is a gradually increasing weakness and feeling of fatigue, apathy passing into drowsiness and stupor. This is accompanied by a characteristic restlessness and increased irritability of the muscles of the extremities, but never developing into convulsions. There is subsultus tendinum. Stupor finally passes into coma in which the pupils are contracted, the reflexes are increased, but there is no Babinski. Respiration is deep and slow, characteristic of states of acidosis. Pericarditis is often present the last few days.

Albuminuric retinitis is as a rule present in most cases in the terminal stage of chronic nephritis. It is often an early sign when the insufficiency of the kidney is still slight. It is never a sign of acute glomerulo-nephritis nor of the second latent stage of chronic glomerulo-nephritis but always a symptom of beginning manifest kidney insufficiency.

In tracing the sufficiency or insufficiency of a kidney through the various stages of glomerular

injury, there is one complication of acute glomerulo-nephritis which we have to consider, namely: eclamptic convulsions. Convulsions do not belong to the picture of pure nephritis in any of its stages, and they practically never occur in the second latent stage or in the third terminal stage, but they are always a complication of the acute stage or of an acute exacerbation in the chronic stage. Acute diffuse glomerulo-nephritis may run without this complication throughout the entire course or may develop convulsions at any time. We do not know the causal mechanism, and the best explanation we can give is the old one of "brain swelling," of extracellular and intracellular edema of the brain centers. To classify a cerebral edema type of uremia, as is done by a recent author, is entirely wrong, as this is only an occasional complication of acute nephritis and is never dependent upon actual kidney insufficiency.

We have mentioned so far the various forms of glomerulo-nephritis and have classified them into: an acute diffuse glomerulo-nephritis, a latent stage of chronic diffuse glomerulo-nephritis, and a terminal stage of chronic diffuse glomerulo-nephritis. We have also mentioned focal glomerulo-nephritis and embolic glomerulo-nephritis as not causing any kidney insufficiency and, therefore, no increase in blood pressure, no loss of variability of function and no increase in the rest nitrogen level in the blood.

In considering tubular involvement there is a good deal of dispute whether to use the term "nephritis" in connection with it or not. Aschoff insists upon the use of the term "tubular nephritis," while others, because of the purely degenerative character of the injury, refuse the use of this term. Fr. Muller has coined the word "nephrosis" for it, which is gradually finding acceptance by German writers.

Purely tubular injury without any glomerular involvement is characterized by marked albuminuria, cylindruria, edema and hydrops of the serous cavities. There is salt retention with the edema, whether because of the edema we do not know. Nor do we know the causative mechanism of the oedema. There is no increase in blood pressure, no loss of concentration ability, no increased rest nitrogen in the blood and no hematuria.

Such forms of pure tubular degeneration or nephrosis are found in the course of chronic suppuration, in tuberculous, syphilitic, diphtheria, and occasionally in other general infections. In many cases no etiology can be discovered. They may be complicated with amyloid deposit, which does not change the clinical picture.

As a special form of nephrosis, we must consider the pregnancy kidney. Here the clinical picture is complicated with eclamptic convulsions and increased blood pressure, which does not stand in any causal relation to the kidney affection, but is probably the result of the same

poison causing the tubular degeneration in the kidney.

A nephrotic kidney without glomerular involvement is never a cause of death. When death occurs it is due to the causative disease or to some intercurrent affection. Convulsions never occur in pure nephroses.

Prognosis depends on the causative disease. Those of unknown etiology may last many years. Treatment is, of course, directed towards the etiological disease, and the edema and cavity hydrops can be controlled remarkably well by a salt-free and a dry diet.

As a special form we must also consider the sublimated kidney. In this condition, instead of a degeneration of tubules we have complete necrosis of tubules. The glomeruli are not affected. Clinically the mild cases are characterized by oliguria, marked albuminuria and cylindruria. In the severe form of bichloride poisoning, there is complete anuria, and with it retention of all the nitrogenous waste products in the blood, increase in blood pressure and the other signs of true uremia in so far as they are not overshadowed by other symptoms of mercury poisoning.

We may classify, therefore, tubular nephritis, or nephrosis, into: acute tubular nephritis or nephrosis, and chronic tubular nephritis or nephrosis, both with or without amyloid deposit, and the special form of necrotic tubular nephritis or nephrosis, of which the sublimated kidney is the prominent example.

Of the affections of the vessels of the kidney we have mentioned arteriosclerosis of the finer vessels, the commonest kidney affection, and presenting the well-known syndrome of hypertension with a sufficient kidney. There is no loss of variability of function, no loss of concentration ability, no increase of rest nitrogen in the blood. The symptoms are mostly cardiac, due to the relative insufficiency of the hypertrophied heart as a result of prolonged hypertension. Prognosis is good. The patient may carry his hypertension for twenty years, with periodical cardiac decompensation, which responds promptly to rest in bed, a dry and salt-free diet and digitalis. Death is usually due to cerebral hemorrhage or some other affection.

Lastly we must consider the other form of kidney sclerosis in which there is an arteriosclerosis of the finer and finest vessels, including the vasa afferentia of the glomeruli. To this there is added a glomerulo-nephritis, not involving all the glomeruli but rather focal in type, not of bacterial origin, but of unknown etiology, probably the result of toxins produced in the body. Volhard and Fahr have termed this the combination form, or malignant hypertension. To the symptoms of hypertension there are added here the symptoms of nephritis and kidney insufficiency, a blood pressure of 200 and above, complete loss of variability of function, specific gravity of the urine, practically fixed,

of about 1006, a gradually increasing rest nitrogen level in the blood, with the final symptoms of true uremia. There are various arterial symptoms due to arterial changes in the brain and elsewhere. Albuminuric retinitis is an early manifestation.

Prognosis is always bad. This form of malignant sclerosis always leads to death as a result of kidney insufficiency.

With these two forms of kidney sclerosis, namely, the benign sclerosis of kidney vessels or benign hypertension, and the malignant form of kidney sclerosis or malignant hypertension or combination form, we have classified practically all the various forms of Bright's disease.

It is at once evident that the classification of Bright's disease in this manner, and a knowledge of the principles underlying their individual symptomatology, give us a better view of the prognosis and definite indications for treatment. For this we are indebted to the epoch-making work of Volhard and Fahr, a book that should be read by everyone interested in kidney disease.

AN EPIDEMIC OF DYSENTERY AT THE BOSTON STATE HOSPITAL, DUE TO A MEMBER OF THE PARATYPHOID-ENTERITIDIS GROUP.

BY MARY ELIZABETH MORSE, M.D., BOSTON,

Pathologist to the Boston State Hospital,
AND

GENEVA TRYON, M.D., BOSTON,
Assistant Physician, Boston State Hospital.

[From the Laboratory of the Boston State Hospital.]

(Concluded from page 220)

The results of the agglutination tests with both human and rabbit sera illustrate well the group reactions, but further than that, are very difficult, or even impossible, to evaluate, in view of the complexity of agglutination reactions within the group. The outstanding result is that the present organism is not an ordinary *A* or *B*. It does not react to any extent, either, with anti-enteritidis or antisuipestifer serum, although its immune serum agglutinates both organisms. The high reactions with *B*. enteritidis should probably be discounted to some extent because of the easy agglutinability of the strain.

As to the place of the present organism within the paratyphoid group, it is impossible to say anything more definite than that it is not an ordinary *A*, *B*. enteritidis or suipestifer, but that, according to agglutinative affinities, it resembles the three latter more than *A*. It does not fit well into either of the chief divisions of the group as outlined by Sobernheim and Seligmann.¹⁵ It might probably be considered as one of the *C* types.

IX. PATHOLOGY.

Autopsies were obtained on two cases in the spring epidemic of 1915, also on a patient who recovered from a severe attack and died five months later of other causes, and two cases of the milder form of the disease which prevailed in 1916.

The two acute virulent cases presented similar pathological pictures. The chief conditions found were: first, an acute fibrinous ileitis and colitis, from which an almost pure culture of the organism was obtained; second, a septicemia, the bacillus being isolated in pure culture from the heart's blood; third, cloudy swelling of the liver, with focal necroses in case 2; and fourth, a pneumonia of the septic type, with miliary abscesses and large areas of necrosis, from which the organism was recovered, associated with streptococci.

The intestine presented a striking appearance. The lesions began a short distance above the ileocecal valve, involved the entire colon, and in the first case, the rectum also. The intestinal wall was thickened and covered with irregular patches of dirty yellow-gray exudate, interspersed with bright-red mucosa, frequently showing foci of hemorrhage. The membrane could be scraped off, leaving an eroded hemorrhagic surface. There were no ulcers and only very moderate swelling of Peyer's patches. The regional lymph-nodes were enlarged and injected. Microscopically the intestine showed a necrosis extending inward for varying distances, sometimes converting the entire mucosa into a fibrinous membrane. The latter had sloughed in various small areas, exposing the extremely edematous submucosa. The exudate was composed of lymphoid and plasma cells; polymorphonuclears where fibrin was present, and large phagocytic endothelial cells. The latter were present in some sections in considerable numbers but were not as abundant as in the intestinal lesions of typhoid fever.

The pneumonic exudate was characterized by phagocytic cells, similar to those in the intestine, but more numerous. Small numbers were also found in the mesenteric lymph-nodes, but none in the liver.

Condensed summaries of the protocols are as follows:

CASE 1. R. K. (A-15-23) aged 50. A much demented case of Korsakow's psychosis, in hospital two years. Died on fifth day of dysentery. Autopsy five hours post mortem. Body well built, well nourished. Body heat and rigor mortis present.

Ventral Section. Small amount of free fluid in pelvic cavity.

Thorax. Recent adhesions over posterior portions of each lung. No excess of fluid in pleural cavities.

Heart. Weight 300 gms. Valves normal. Myocardium somewhat friable and endocardium gray. The descending branches of both coronaries show occasional plaques.

Lungs. Right: Weight 295 gms. Posterior portion is markedly congested. Remainder of lung is normal. Left: weight 570 gms. The upper part of the upper lobe is normal. The inferior portion of the upper lobe and the entire lower lobe are enlarged, deep red, firm and nodular. Cut surface is consolidated, reddish purple and is beset with dull gray foci $\frac{1}{2}$ mm. in diameter, sometimes depressed in the centre. A large amount of thin purulent fluid can be expressed from the tissue.

Bronchi are deep red and covered with purulent fluid.

Abdomen.

Spleen. Weight 105 gms. Firm, purple-red on section. Malpighian bodies just visible.

Liver. Weight 1450 gms. Capsule normal. Cut surface shows a yellow-brown mottling with indistinct lobulation. Consistence soft.

Gall Bladder. Distended; no stones or adhesions.

Gastro-intestinal Tract. Stomach, duodenum, jejunum and upper ileum negative. The lower third of the ileum is thickened and edematous. The mucosa is swollen and red, and is irregularly covered with a granular yellow-gray exudate. From caecum to anus the intestinal wall is edematous, and the mucosa is covered with a shaggy membrane which follows the rugae. On scraping off the membrane a hemorrhagic and eroded surface presents. No ulcers found.

Lymph Nodes in the vicinity of the caecum are enlarged, soft and grayish pink.

Pancreas shows some injection; otherwise negative.

Kidneys. Combined weight 290 gms. Capsules are thickened. Cortex measures from .2 to .6 mm.; is gray, with areas of injection. Pyramids dark red with a white streak at the bases.

Adrenals show central softening; otherwise not remarkable.

Bladder. Negative.

Uterus. Pedunculated myoma, 1 cm. in diameter, on posterior surface.

Retroperitoneal Tissues. Negative.

Organs of the Neck. Negative.

Head. Calvarium, thick. Dura not adherent; is moderately thickened along the longitudinal fissure. Sinuses negative. Pia thickened on inferior surface of cerebellum; not elsewhere.

Brain. Weight in toto 1350 gms. Marked atrophy of the convolutions of the frontal, central and parietal regions, most prominent in the frontal fields, and decreasing posteriorly. Consistency of the brain is everywhere increased.

Microscopical Examination.

Lungs. Section through one of the pneumonic areas. These are situated around fairly large vessels. At the edges of the lesion the capillaries are distended. In the centre of the focus the alveoli are filled with cellular exudate mixed with considerable fibrin and serum, and there are small areas of hemorrhage. The exudate consists of polymorphonuclear leukocytes and large phagocytic cells. The latter often reach large size (five or six times the diameter of a red corpuscle), have a coarse-meshed cytoplasm, and contain red corpuscles, pigment and polymorphonuclears. Three or four of these cells are often present in a single alveolus. In several places the alveoli are filled with solid masses of bacteria. The alveolar partitions are frequently dissolved in the centre of the consolidated areas. The large veins show very marked inflammation. Sections through the ab-

cesses show extensive foci of necrosis with masses of bacteria and fibrin in the centre, surrounded by a zone of degenerated leukocytes. The bronchioles are intensely affected, the epithelium being absent, the walls infiltrated with fragmented leukocytes and the normal structures obscured.

Heart. Perinuclear pigment prominent; otherwise nothing notable.

Liver. The liver cells are indistinct in outline; their cytoplasm stains a dull granular pink, and the nuclei are pyknotic or stain faintly. Fat content is very moderate. Collections of lymphocytes about the bile ducts are frequent, and the sinusoids are dilated. No necroses or phagocytic cells.

Spleen. Lymphoid tissue is small in amount. Pulp contains much blood and collections of golden brown pigment. No phagocytes.

Gastro-intestinal Tract. Stomach: Nothing noteworthy. Intestine: Sections from various parts of the lower ileum and the colon show the following picture: At the edges of an affected area there is a superficial necrosis with fibrin network. The underlying blood vessels are engorged, the glands choked with desquamated epithelium and debris and the mucosa thickly infiltrated with polymorphonuclears. The submucosa is extremely edematous and is infiltrated with lymphocytes, plasma and large phagocytic cells, similar to those found in the lung. The vascular endothelium is swollen and the vessel walls infiltrated. Large numbers of bacilli are scattered free throughout the mucosa and submucosa. The muscularis contains clumps of large phagocytic cells situated about the vessels. In more advanced areas the necrosis extends deeply into the mucosa, and the submucosa shows areas of hemorrhage and a moderate infiltration of polymorphonuclears. The vessels in the necrotic areas are frequently filled with thrombi of fibrin and leukocytes. In the most advanced portions the entire mucosa is converted into a membrane of necrotic tissue, fibrin, polymorphonuclear leukocytes and masses of bacteria. The membrane has sloughed in numerous areas, exposing the submucosa. The necrosis and sloughing is irregular in distribution and depth. The lymphoid tissue is not hyperplastic.

Mesenteric Lymph Nodes. No hyperplasia of lymphoid tissue. Large endothelial cells, phagocytic for lymphocytes and red corpuscles are very numerous.

Adrenals. The cortical cells stain well in general and are much vacuolated. Small collections of lymphocytes with a few plasma cells in the reticulo-

The other organs showed nothing of note. The brain and cord revealed no lesions which could be correlated with the acute infection, and the description of them is, therefore, omitted.

Cultures.

Heart's Blood. Epidemic organism in pure culture.

Consolidated Area of Lung. Epidemic organism plus a few colonies of streptococci.

Wall of Cecum. Epidemic organism in abundance on Congo red plates.

Lymph Node near Cecum. No growth for three days, then scattered colonies of staphylococcus albus and streptococci.

Cerebro-spinal Fluid. Sterile.

Anatomical Diagnosis. Acute membranous ileitis and colitis, septicemia, septic pneumonia with abscess formation, acute fibrinous pleuritis, purulent

bronchitis, cloudy swelling of liver, myoma uteri, cerebral atrophy.

CASE 2. E. H., aged 63 (A-15-24) paranoid dementia praecox. Hospital residence three years. Died on the eighth day of illness. Autopsy 26 hours after death. Body of a somewhat obese woman. Some distention of abdomen.

Ventral Section. Omentum contains much fat, and in its lower third is adherent to the peritoneal wall. Spleen is bound down by adhesions. No free fluid in peritoneal cavity. The intestines are injected, especially the ascending, transverse and descending colon. Subserous hemorrhages are visible in the cecum.

Thorax. A few light adhesions over the posterior portion of the left base; otherwise the pleural cavities are free and contain no excess of fluid. Pericardial sac contains a slight excess of fluid.

Heart. Weight 450 gms. Epicardial fat abundant. Slight thickening of the edges of the tricuspid and the bases of the aortic valves. Myocardium flabby. Right coronary shows a few small plaques.

Lungs. Right, weight 550 gms; left, 530 gms. Both lungs show scars at apices. Upper lobes not remarkable. The posterior portion of the left lower lobe is enlarged, bluish red and firm. Tissue sinks in water, and, on section, discloses an evenly consolidated red surface with multiple clusters of yellow dots, 3 mm. in diameter, arranged around the bronchioles. The right lower lobe is consolidated but does not show milium abscesses.

Peribronchial Lymph Nodes moderately enlarged. *Spleen.* Weight 70 gms. Trabeculae faint; pulp bright red; Malpighian bodies small.

Liver. Weight 2000 gms. Is adherent to the diaphragm. Shape and capsule not remarkable. Cut surface is yellowish red, and normal markings are indistinct. Consistence soft.

Gall Bladder. Distended; otherwise not notable.

Gastro-intestinal Tract. Esophagus markedly injected. Stomach contains fecal material. The intestine is negative to within 6 cm. of the ileocecal valve. The mucosa of the remaining portion of the ileum is thickened, injected and granular. From the ileocecal valve to the splenic flexure the wall is thick and stiff and the mucosa shows areas of membrane and erosion, but these are not as extensive as in Case 1. The descending colon is less involved and the rectum is comparatively free. No swelling of the lymphoid tissue.

Kidneys. Combined weight 320 gms. Capsules strip easily. Cortex is 6 to 7 mm. in depth and is gray, with foci of injection. Glomeruli not visible.

Adrenals. Markedly softened.

Bladder. Mucosa is granular and injected at the trigone. Urine cloudy.

Uterus. Cavity contains a small amount of turbid fluid.

Calvarium. Of moderate thickness with small amount of diploe. Dura is adherent to inner table. Pia is lifted from the brain surface by a large amount of fluid; is of normal thickness.

Brain. Weight in toto 1440 gms. Convolutional pattern is simple. No atrophy. Consistence is uniformly increased over the dome. Structures at base negative. Basal vessels free from sclerosis.

The *microscopic findings* in the lungs and intestine were similar in all particulars to Case 1, and need not be detailed. The liver showed foci of necrosis, and there was also a chronic thyroiditis.

Cultures. The organism was recovered in pure culture from the heart's blood and urine and, in large numbers, from the wall of the colon. In the lung it was associated with staphylococcus albus and aureus.

Anatomical Diagnosis. Acute membranous ileitis and colitis, septicemia, septic pneumonia with milium abscesses, focal necroses of the liver, acute fibrinous pleuritis, cardiac hypertrophy and dilatation, chronic fibrous endocarditis, mitral and aortic, acute cystitis, subial edema.

CASE 3. E. McK., aged 76 (A-15-41) showed conditions four months after recovery from a severe attack.

The patient, a senile dement, died of broncho-pneumonia, chronic interstitial nephritis and general arteriosclerosis. The intestine, to within a foot of the ileocecal valve, was normal. Throughout the remainder of the bowel were numerous foci of injection in the mucosa, in some places limited to the crests of the folds, in others spread over several centimeters of the mucosa. The mucosa was not thickened, the lymphoid tissue not increased, nor were there signs of healed ulcers. Mesenteric lymph-nodes small. The gall bladder contained dark, viscid bile and the lining was not remarkable.

Microscopically, in the injected areas of the intestine the superficial epithelium was absent, and near the surface of the mucosa were numerous large vacuolated mononuclear cells, occasionally containing the remnants of red corpuscles. The mucosa also showed numerous plasma cells and a few eosinophilic leukocytes. The outer coats of the intestine were normal.

Cultures from the intestinal wall, feces, mesenteric lymph nodes and bile did not yield the epidemic organism.

Cases 4 and 5 show the condition of the intestine a few days after an attack of moderate severity. Both patients had blood and mucus in the stools, and died several days after the height of the attack. In both, also, the dysentery was merely the terminal event in the course of organic conditions fatal in themselves.

CASE 4. (A-16-21) was a bed ridden paretic. The mucosa of the lower ileum was slightly thickened and moderately congested. The mucosa of the upper half of the large intestine was uniformly congested but not thickened. In the lower half of the large intestine the wall was moderately thickened and the mucosa dull gray and granular, with patches of congestion but no membrane or loss of substance. The feces in the lower intestine were fluid, gray, slightly frothy, not offensive. Microscopically there was a loss of superficial epithelium and masses of bacteria in the glands, but practically no cellular reaction and no changes below the mucosa.

CASE 5. (A-16-24) was a senile dement who had an advanced chronic myocarditis and an internal hemorrhagic pachymeningitis. The mucosa of the cecum was hemorrhagic, and from there on through the rectum the wall was moderately edematous, showed large areas of congestion and, in places, also prominent mucous glands. The lesion was most marked in the sigmoid and upper part of the rectum where the entire mucosa was velvety and dusky. Feces were soft and yellow. Sections showed some

slight superficial necrosis, some small localized losses of substance extending into the submucosa, moderate edema of the latter, and considerable swelling of the lymphoid tissue. An occasional phagocytic endothelial cell was found, also moderate numbers of neutrophilic and quite numerous eosinophilic polymorphonuclears.

The organism was isolated in pure culture from the heart's blood of this case.

It is evident from the last two autopsies that in the cases of moderate severity there is nothing striking or characteristic about either the gross or microscopic picture, of the intestine, as there is in the virulent cases, but the conditions are such as might be found in any mild inflammation of the bowel.

Pathologically, the acute fatal cases differ obviously from bacillary dysentery in the presence of a septicemia and pneumonia, as well as in the absence of intestinal ulcers. The invasion of the blood stream, particularly, allies the disease with paratyphoid infection. The intestinal lesions, as well as the course of the disease, are more acute and violent than those of bacillary dysentery.

The pathological anatomy of paratyphoid infections is incompletely known, as until recently comparatively few autopsies had been done on either the typhoid or gastro-enteric forms. Since the outbreak of the war autopsy reports have been accumulating. In general the results are that paratyphoid has more tendency to involve the large bowel than does typhoid; that the lymphoid tissue of the intestine is only moderately affected; that ulcers are frequently absent, and when present, are usually scattered and small. The histology of the lesions appears not to have been especially considered. Job and Ballet¹⁶ give the findings in four cases of paratyphoid fever (one *B* and 3 *A*) as intense congestion of the viscera, a moderate degree of inflammation of Peyer's patches without ulceration; swelling, infiltration and congestion of the abdominal lymph glands, and intense inflammation of the spleen, with lymphoid infiltration and hemorrhage.

As to the dysenteric form, Stollkind⁴ says that 10 cases with lesions similar to dysentery have been reported. Korczyński⁵ found in the enteric form of his cases acute hyperemia of the jejunum and ileum, hemorrhage into the mucosa and occasional small ulcers; in the dysenteric form the same changes, with the addition of an inflammatory process in the large intestine, with thickening of the mucosa and ulcers, which could scarcely be distinguished from Shiga dysentery. He did not find extensive necrosis.

In the gastro-enteric form, the most acute cases may show no microscopic lesion except punctiform hemorrhages through the entire gastrointestinal tract.³ In more prolonged cases there may be swelling of the lymphoid tissue, ulceration, and even gangrene of the intestine. The majority of the few reported autopsies on

cases dying a week or more after onset have shown hemorrhagic inflammation of the ileum, hyperplasia of the lymphoid tissue and frequently ulcers.

None of these conditions agrees with the virulent form of the present disease, which is an acute extensive membranous inflammation of the lower ileum and the colon without gross ulceration or hyperplasia of the lymphoid tissue, and combined with septicemia and pneumonia of the septic type, characterized by large areas of necrosis.

The finding of streptococci in the urine of two cases and in the lung of one case, combined with the epidemic organism, suggests that in fatal cases this may be a secondary complication of importance.

As to a possible relation of the disease to hog cholera, we have no crucial evidence, having failed to isolate an identical bacillus from the hog cholera animal. One is struck, however, by certain points of similarity in the pathology of the present disease and that of hog cholera, particularly the simultaneous involvement of the intestines and the lungs. The intestines in hog cholera may present various appearances—from simple catarrh to hemorrhagic or diphtheritic inflammation. The most frequent form of pulmonary involvement is an acute fibrinous necrotic pneumonia. Organisms of the paratyphoid group are most frequently found in the lungs and spleen. Uhlenhuth and Handel¹⁷ bring up the question whether there may not be two diseases included under hog cholera, one, very contagious, caused by an ultra microscopic virus, and a second, slightly contagious, by *B. suispestifer*.

X. ANIMAL EXPERIMENTATION

The pathogenicity of the organism was tested on rabbits weighing from 1800 to 2000 gms., by both intravenous and subcutaneous inoculation and by feeding experiments.

One tenth of a cubic centimeter of a 24 hour broth culture of a freshly isolated strain given subcutaneously produced no symptoms at the end of three days. There was no local reaction, and the animal was lively and ate well.

Two tenths of a cubic centimeter of a 24 hour broth culture intravenously killed an animal over night. The most striking lesion at autopsy was an extensive necrosis of the liver. Other changes were cloudy swelling of the myocardium and renal epithelium, and diffuse degenerative changes in the cortical nerve cells. The gastro-intestinal tract was negative.

Another rabbit, which in the beginning of the experimentation was given a massive dose of the organism intravenously (.1 ccm. of a moderately thick suspension of a 24 hour agar culture) died over night, showed the above mentioned lesions, in heart, liver, kidneys, thymus and brain, and in addition, hemorrhage into the small intestine. The intestinal mucosa was thick, velvety,

and deep red. The bacillus was isolated from the blood and bile, but not from the hemorrhagic intestinal contents.

A fourth rabbit was fed 1 cc. of a 24 hour bouillon culture on carrot once a day for three successive days, after which it was fed sparingly on lettuce and carrots once a day. It remained lively, ate well, had no diarrhea, and its temperature was not abnormally high or irregular. It, however, emaciated rapidly and on the eighth day suddenly died. Autopsy showed an atrophic condition of liver and spleen. The mesenteric lymphnodes were enlarged, soft and of a deep red color. The gastrointestinal tract was not remarkable macroscopically, and the feces were normal. Microscopically, however, there was found at several points in the small and large intestine a necrosis of the superficial epithelium. The surface in these areas was covered with a thick layer of degenerated cells, mingled with masses of bacteria and scattered polymorphonuclear leucocytes. Numerous plasma cells were present in the underlying mucosa, but the remainder of the intestinal wall was negative. There was hemorrhage in the centers of the enlarged lymph nodes; the lymphoid tissue was active; small numbers of mononuclears, phagocytic for lymphocytes, were present, and a large amount of pigment, both intra- and extra-cellular. The liver showed areas of hemorrhage, but no cloudy swelling or necrosis. The spleen contained numerous endothelial cells, phagocytic for pigment. The other organs were not remarkable. *Staphylococcus albus* was present in pure culture in the heart's blood and the bile. The urine was sterile.

These results show as far as they go that no condition at all resembling the human disease was produced in rabbits by subcutaneous, intravenous or oral administration of the organism. Ordway¹³ produced in rabbits a typhoid-like disease by subcutaneous inoculation of another member of this group, *B. suis*stifer. The constant and most characteristic lesions were necrosis of the liver. The intestinal lesions, which were less constant and striking, consisted in swelling of Peyer's patches and endothelial proliferation.

SUMMARY.

An acute very contagious disease, of short incubation period, appearing in three forms: the dysentery-septicemic-pneumonic; the pure dysenteric, and the diarrheal. The conditions found in the virulent fatal cases were a membranous ileocolitis, septicemia and a pneumonia with milary abscesses and large areas of necrosis. The severer forms of the disease occur in debilitated persons. Immunity is of short duration, and recurrences (usually mild) are frequent.

The causative organism is a member of the paratyphoid-enteritidis group, more closely allied, as shown by agglutination tests, with paratyphoid *B. B. suis*stifer and *B. enteritidis* than with *A.*, but not identical with any of them.

The disease was limited to certain buildings of the West Group of the Boston State Hospital. The epidemic was preceded by mild diarrheas among patients and attendants, then broke out in violence in one ward, and was passed from person to person by contact. The source of the infection was not definitely determined. The close affinity of the organism with certain members of the group (*suis*stifer and enteritidis) which are associated with animals, suggests the possibility of such an origin. No evidence was obtained connecting the human epidemic with an outbreak of hog cholera which had prevailed in the piggery at the West Group during the previous summer, but the pathological anatomy of the two diseases presents certain features of similarity. The hypothesis is suggested that the infection was introduced by the contamination of food in the West Group refrigerator by rats, the infection appearing first as mild cases of diarrhea, then as an outbreak on a single ward, due probably to gross contamination of the food by a human carrier, the difference in the severity of the disease depending on the physical condition of the persons attacked, and possibly also on the rapid transfer of the virus. The disease has now become endemic and has assumed a mild form.

Prophylactic inoculation will not suppress the disease among feeble patients, although it may have some influence in mitigating its severity. Among strong persons, however, it appears to be of more value, in reducing both the number of cases and the type of the disease. Vaccine treatment during the disease has given good results.

A polymorphonuclear hyperleucocytosis occurs after both the prophylactic and therapeutic administration of vaccine. The leukocytic reaction is more marked in the stronger normal individuals than in the feeble ones who have had the disease and recurrent attacks.

Agglutinin formation in the disease is very moderate. Agglutinins for the organism persist in some cases as long as 14 and 17 months after the original attack, when there has been no recurrence. After prophylactic vaccination low titres have been obtained up to 11 months.

Intradermal tests with concentrated glycerin broth cultures of members of the paratyphoid-enteritidis group have given unreliable and conflicting results. Tests with powdered cultures are to be undertaken.

Society Report.

NEW ENGLAND PEDIATRIC SOCIETY.

The forty-eighth meeting of the New England Pediatric Society was held in the Boston Medical Library, Friday, March 30, 1917, at 8.15 p.m.

The President, Dr. Maynard Ladd of Boston, in the chair.

The following papers were read:—

1. Studies in Infant Feeding; The Mineral Constituents of Milk,* Henry I. Bowditch, M.D., Boston, Alfred W. Bosworth, Boston.

2. Anemia of the Newborn, Karlton G. Percy, M.D., Boston.

3. Nephritis in Childhood, with Especial Reference to Functional Tests, Lewis W. Hill, M.D., Boston.

UNUSUALLY SEVERE ANEMIA IN THE NEWBORN, WITH DEATH.

ABSTRACT.

By KARLTON G. PERCY, M.D., BOSTON.

EIGHTH child, healthy parents, three brothers and sisters dead of the same apparent disease within 12 days of life. Other sisters and brothers well. Normal delivery; normal baby for 3 days. Rapidly increasing anemia, without apparent fever, hemorrhages or signs of sepsis. Seen on eighth day. Hb., 18%; red blood cells, 2,100,000; white blood cells, 18,000. Smear showed moderate polychromatophilis, poikilocytosis, anisocytosis, stippling and increased platelets. Eighteen nucleated reds to 100 white cells. White cells, showing mono-nuclearcytosis, with a tendency of cells to be of primordial type. Wassermann negative. Parents' Wassermann negative. Transfusion, 50 cc., paternal blood, without apparent benefit, and death within eighteen hours. Autopsy showed only excessively active red and white blood cell-formation in spleen, liver, possibly thymus and lymph glands.

Bone marrow not examined. The general picture of the case simulated a severe secondary anemia of infancy, described by Germans as pseudo leukemia infantum.

DISCUSSION.

DR. HOWARD: In going over the literature of the blood recently, I have been much impressed with the lack of definite knowledge as to the normal blood in infancy and children, and the still greater lack of definite knowledge apparent in regard to blood diseases in infancy. The full report of stud-

ied cases, such as Dr. Percy's, is extremely valuable and necessary for a better understanding of infant blood.

It is to be regretted that in Dr. Percy's case the bone marrow was not examined, as this is a most important part of the blood picture, and almost essential in determining the classification and diagnosis of this case. The history and blood picture, as given, do not seem to me to place this case definitely in any one of the groups of blood diseases of children. I agree with Dr. Percy that the evidence is against an idiopathic aplastic anemia, neither does the case seem to be one of the group known as secondary aplastic anemias. Secondary aplastic anemia can perhaps not be definitely ruled out in the absence of any information as to whether or not the bone marrow was failing to produce one of the elements of the blood—the red corpuscles. The blood picture, however, showing normoblasts and megaloblasts, plenty of blood platelets, and no reduction in polynuclear cells, is very much against the existence of a depression of the blood-forming activity of the marrow, and strongly suggests that the blood-forming function of the bone marrow is, on the contrary, being worked overtime.

Diagnosing this case as a lymphatic leukemia of any type, seems to me open to criticism, as, first, there is no enlargement of the lymph nodes; second, there is no lymphocytosis; third, there is no record of myelocytes in the blood picture.

From the blood picture presented, without knowledge of the condition of the bone marrow, the weight of evidence is in favor of a destructive process confined to the red blood cells, rather than the picture of a definite disease, such as lymphatic leukemia or aplastic anemia of any type. The history of the case and the blood picture give us but little help in determining the etiology of this destructive process. The most suggestive point is the jaundice, which, in this case, we have evidence, is not an obstructive jaundice, and which, we have reason to believe, may not be a simple jaundice of the newborn. This jaundice, it seems to me, may be regarded, in its relation to the blood picture, in either of two ways: It may be due to a toxin,—the same toxin that produced the jaundice causing the destruction of the red blood cells; the other possibility being that it is a hemolytic jaundice, the jaundice in that case being caused by a toxin, and the jaundice causing secondarily red blood cell destruction and anemia.

DR. PERCY: I may add that I am sorry that there was no bone marrow examination done in this case. It was one of those slips which occasionally happens. Yet the differentiation between this type of secondary anemia or pseudo leukemia infantum, and aplastic anemia is shown not only by the ability of the bone marrow to regenerate, but by the presence of regeneration in the other organs of the body. This case did not show any special evidences of other destruction, but it showed a tremendous anemia without any cause, and yet a very definite attempt at regeneration.

In closing I would like to ask if anybody has any suggestions for future babies in this family. The parents are French Canadians; there are apparently going to be more, and if the next one is going to have the same disease as the three who have already died, I would like suggestions as to its treatment.

* See JOURNAL, page 248.

The term "pseudo leukemia" is one which is used by the Germans, following Naegeli's nomenclature, for a type of case which shows a symptom-complex with marked anemia, enlarged liver, enlarged spleen and a relatively high white count,—that is, a white count above the normal (10,000 or over), with a tendency for the red cells to be regenerated, to show nucleated reds, to show an increased number of platelets; for the white cells to show a tendency toward an abnormal lymphatic picture, and not one of a true myelogenous leukemia; and the finding of definite hyperhematopoiesis and activity in the bone marrow, in the spleen, the liver, the lymph nodes, and possibly in the thymus. Thus, pseudo leukemia is simply a name for those cases in infants with enlarged spleen and with that blood picture, which has been used and is being used by the Germans. It has no connection with von Jaeksh's original paper, because his type of anemia was a symptom-complex due to various diseases,—rickets, tuberculosis and syphilis. This case of mine pathologically falls definitely into Naegeli's type of anemia, without any known etiological factor.

Dr. R. M. SMITH (Dr. Hill's paper): We are grateful to Dr. Hill for presenting this subject in such a clear manner. As Dr. Coues has just suggested, there is a good deal of work being done in investigating the bacteriology of the urine. It has been shown that in many infectious diseases the organisms are present in the urine. This raises the question whether the nephritis which complicates often the infectious disease, such as tonsillitis, is due exclusively to the toxin of the bacteria, or whether it is due to the direct action of the bacteria in the kidneys.

The hemorrhagic type of nephritis which Dr. Hill has mentioned is often difficult to differentiate from hemorrhagic pyelitis. I have seen quite a number of cases which on first investigation seemed to be hemorrhagic nephritis, which subsequently proved to be pyelitis, with a good deal of bleeding. The picture of the two conditions is not dissimilar. The large amount of blood is a common characteristic, and the casts, which are few in number, are present in both conditions.

I was interested in what Dr. Hill had to say about renal function tests. I think that all agree that the phenolphthalein test is valuable, primarily as a prognostic sign. Most of Dr. Hill's cases did well and the function test was high, but other investigators have reported low function tests, and in the majority of instances these patients did poorly.

Dr. PERCY: In regard to the etiology of nephritis, as to whether it is due to toxins or to hemogenous infection from the bacteria themselves, the work of Rosenow of Chicago is of interest in nephritis of childhood. I believe that many positive blood cultures could be obtained early in nephritis, whereby we could feel sure that a damage to the kidney was of actual bacterial origin. We have recently proven the hematogenous bacterial etiology in pyelitis, and recently I have seen a case of nephritis of moderate severity which ran a mild course, from which we recovered streptococci, both from the blood and from the urine, and I believe further blood culture work will show that the kidney itself is infected directly by blood-borne bacteria.

Dr. COUES: I would like to hear Dr. Hill's views with regard to the question of pyelitis. Does he consider that we can make a hard and fast line in cases of pyelitis and say that the rest of the kidney may not be involved? Should not pyelitis be considered as part of a more general kidney infection?

Dr. HILL (in closing): I think it is sometimes very hard to tell whether one is dealing with a case of pyelitis or one of these cases of hemorrhagic nephritis. It is hard, as Dr. Smith has said, and I am not sure whether some of my cases ought to be put into the pyelitis, instead of the nephritis, class. If we see a good many casts in the urine we call it nephritis, but in some of those cases that I have classified as nephritis there have been about equal parts of pus and blood and a few casts, and we may have been wrong in including those in the nephritis rather than in the pyelitis class.

As to the bacteriology of the urine, I wish that I had been able to make urine cultures on the cases that we have had at the hospital, but intend to do it later if there is a chance.

As to the function tests—I think that Dr. Smith is quite right about the value of the low test, and I attach very little importance, indeed, to a high functional test in a child. With a *high* test one cannot tell that a person has a normal kidney, but with repeated *low* tests one knows that the proper functioning is impaired, and is of some value in the prognosis of the long-drawn-out chronic cases. The functional tests in children are, however, of very little value in the *diagnosis* of nephritis.

Book Reviews.

Progressive Medicine. Vol. XX, No. 1. Edited by HOBART AMORY HARE, M.D., assisted by LEIGHTON F. APPLEMAN, M.D. Philadelphia and New York: Lea and Febiger. 1917.

This first issue, for the current year, of a standard medical digest of advances, discoveries and improvements in medical and surgical sciences, consists of reviews of surgery of the head and neck by Dr. Charles H. Frazier, and of the thorax by Dr. George P. Müller, which compose a third of the volume. Another third is occupied by Dr. John Ruhräh's review of infectious diseases, including acute rheumatism, erouppous pneumonia and influenza. The remainder is divided between the diseases of children by Dr. Floyd M. Crandall, and rhinology, laryngology and otology, by Dr. George M. Coates. The surgical sections are particularly well illustrated with descriptive figures, of which there is a total of twenty-three. The publication continues its usefulness to those who have the inclination and time to maintain a constant familiarity with the advance of medical science.

THE BOSTON Medical and Surgical Journal

Established in 1832

An independently owned Journal of Medicine and Surgery published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, AUGUST 23, 1917

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, Manager,

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

A CRITICAL SITUATION.

THE Government is raising an immense army of volunteers and conscripts to carry on the war to a successful end, we hope, an early termination. Every army must be supplied with a personnel of medical officers of adequate number and well trained. While provisions have been made to raise the required number of men for the fighting force, it has been left to members of the medical profession of this country to come forward voluntarily, seeking commissions in the Medical Reserve Corps.

Only a few of the total number required have applied for commissions. This means that unless immediate action is taken by the profession voluntarily, the men in the army now being organized will be without sufficient medical care. Such a condition would be more than critical and dangerous for the success of our army and

the cause in which we are enlisted. The medical officer plays a most prominent part not only in keeping the army on its feet and physically fit for fighting, but in returning to the ranks a large percentage of those who have been temporarily put out through casualties.

How soon will the medical profession of the United States, as a whole, wake up and realize that doctors must come forward and volunteer their services to the Government? In civil life, when great casualties occur, the doctor readily offers his services and usually is the first on the scene to save human life. How much more important is it, then, that in this critical situation, he should come forward and offer his valuable aid to preserve not only human lives, but the life of the nation itself? Application blanks for commissions in the Medical Reserve Corps are being printed in many medical journals or will be sent by the Surgeon-General's Office, or can be secured from members of the Local Board of Examiners.

MASSACHUSETTS NARCOTIC DRUG LAWS.

In another column of this issue of the JOURNAL we publish in full the text of the latest General Act (Chap. 275) relative to the sale and distribution of narcotic drugs, which went into effect in Massachusetts on June 23, 1917. This act, which is based upon the report (No. 149) to the Legislature of a special commission consisting of Dr. Frank G. Wheatley, Mr. Herman C. Lythgoe, and Mr. Abraham C. Webber, is very far-reaching and very important. Probably few physicians in this Commonwealth are conversant with it, or know of its drastic provisions against the possession or sale of a hypodermic syringe. The careful perusal of this act, therefore, is earnestly commended to members of the profession. Especial attention is directed to the requirement that the age of the patient must be put on each prescription containing a narcotic drug; that no such prescription may be filled after five days from the date of its issue; and that the patient obtaining the medicine must sign his or her name on the face of the prescription.

Probably few physicians also know that there is in existence a further law (Chap. 232) relative to the licensing of private hospitals and the admission therein of certain patients, which

admits of sending drug addicts to hospitals without court proceeding and attendant publicity; nor do they realize that no records of such cases can be used as evidence in a court of law, which is a matter of great protection in the event of subsequent suit for divorce or the breaking of a will. The complete text of this act, as approved on May 9, 1917, is as follows:

"SECTION 1. Chapter two hundred and eighty-five of the General Acts of the year nineteen hundred and sixteen is hereby amended by striking out section six and inserting in place thereof the following:—*Section 6.* The commission may annually license any suitable person to establish or have charge of a hospital or private house for the care and treatment of the insane, epileptic, feeble-minded, and persons addicted to the intemperate use of narcotics or stimulants, and may at any time revoke the license. No such license shall be granted for the care and treatment of insane or epileptic persons unless the said commission is satisfied, after investigation, that the person applying therefor is a duly qualified physician, as provided in section thirty-two of chapter five hundred and four of the acts of the year nineteen hundred and nine, and has had practical experience in the care and treatment of such patients. No such license shall be granted for the care and treatment of persons addicted to the intemperate use of narcotics or stimulants unless the commission is satisfied, after investigation, that the person applying therefor is a physician who is a graduate of a legally chartered medical school or college; that he has been in the actual practice of medicine for the three years next preceding his application for a license, nor unless his standing, character and professional knowledge of inebriety are satisfactory to the commission. Licenses granted hereunder shall expire with the last day of the calendar year in which they are issued, but may be renewed. The commission shall have power to fix reasonable fees for said licenses and renewals thereof.

SECTION 2. Said chapter two hundred and eighty-five is hereby further amended by striking out section seven and inserting in place thereof the following:—*Section 7.* Whoever keeps or maintains a hospital or private house for the care or treatment of the insane, epileptic, feeble-minded or persons addicted to the intemperate use of narcotics or stimulants, unless the same is in charge of and under the direct personal supervision of a person duly licensed under this act, shall be guilty of a misdemeanor, and shall be punished by a fine of not more than five hundred dollars.

SECTION 3. The superintendent or manager of any hospital or private house licensed for the care and treatment of persons addicted to the intemperate use of narcotics or stimulants may,

when requested by a physician, by a member of the board of health or a police officer of a city or town, by an agent of the institutions registration department of the city of Boston, by a member of the district police, or by the wife, husband, guardian or, in the case of an unmarried person having no guardian, by the next of kin, receive and care for in such hospital, as a patient for a period not exceeding fifteen days, any person who needs immediate care and treatment because he has become so addicted to the intemperate use of narcotics or stimulants that he has lost the power of self-control. Such request for the admission of a patient shall be made in writing and filed at the hospital at the time of his reception, or within twenty-four hours thereafter, together with a statement, in a form prescribed by the commission, giving such information as the commission may deem appropriate. The trustees, superintendent or manager of such hospitals or private houses shall cause to be kept a record, in such form as the commission may require, of each case treated therein, which shall at all times be open to the inspection of the commission and its agents. Such records shall not be a public record, nor shall the same be received as evidence in any legal proceeding. The superintendent or manager of such a hospital shall not detain any person received as above for more than fifteen days, unless, before the expiration of that period, such person shall have been committed or has signed a request to remain."

All physicians practising in this Commonwealth are again earnestly urged carefully to read these two acts in order that they may be intelligently familiar with the latest and present provisions of the Massachusetts Narcotic Drug Laws.

MEDICAL NOTES.

DEATH RATES IN LONDON.—Statistics recently published show that in May the total death rate of London was only 13.9, and in June, 12 per thousand inhabitants living. Among the several districts and boroughs in May, the highest rate was 17.2 in Holborn, a crowded central slum, and the lowest was 9.1 in Hampstead, an open district on the north. In June the highest rate was 18.1 in Holborn, and the lowest was 8.7 in Lewisham, an open district on the south.

MEDICAL STUDENTS IN SWITZERLAND.—A recent report shows that the total number of medical students in the five Swiss universities during the winter semester of 1916-1917, was 1901. These were distributed as follows:

Bâle had 215, among whom were 12 women; there were 47 foreign students, of whom 2 were

women. Berne had 411, among whom were 45 women; there were 168 foreigners, of whom 29 were women. Geneva had 512, of whom 110 were women; there were 333 foreigners, of whom 90 were women. Lausanne had 248, of whom 35 were women; there were 97 foreigners, of whom 23 were women. Zürich had 515, of whom 89 were women; there were 182 foreigners, of whom 42 were women.

PREVALENCE OF DISEASE IN THE UNITED STATES.—The weekly report of the United States Public Health Service for July 27, 1917, states that during the month of June there were fifty-eight cases of cerebrospinal meningitis in Ohio, 213 of malaria and 79 of pellagra in Louisiana, 229 cases of smallpox in Kansas, 279 in Minnesota and 419 in Ohio. There were 242 cases of typhoid fever in Louisiana. The same bulletin contains a report on malaria in Louisiana, particularly with reference to its prevalence and geographic distribution.

WAR NOTES.

RED CROSS APPROPRIATION.—It is reported that the American Red Cross has appropriated \$800,000 to meet sanitary emergencies in the civilian areas surrounding army cantonments. A bureau under the direction of Dr. W. H. Frost, of the Public Health Service, will have charge of the work. The Red Cross will undertake such sanitary management only by request of the local organization in charge.

MEDICAL RESERVE CORPS.—Dr. David D. Scannell of Boston has been ordered to report to Fort Benjamin Harrison, Indianapolis, and left this city on August 7, for service with the Medical Reserve Corps.

TUBERCULOSIS AMONG SOLDIERS.—Dr. John B. Hawes of Boston, secretary to the trustees of the Massachusetts Hospital for Consumptives, is author of the following circular, entitled "Facts for Fighters," which has been sent out by the Massachusetts Anti-Tuberculosis League, to all soldiers and recruits in this Commonwealth.

"Consumption can be contracted by those who are weak, run down, or in any way in poor condition.

In private life any person may take chances with his health, if he cares to do such a foolish thing, without, necessarily, hurting others or the community at large. In time of war this is different. The soldier owes it to his country to maintain his bodily efficiency at the very highest possible point. This is the best way to avoid consumption.

When a soldier is on duty, the details of his life are regulated in every way. When he is off duty he can do himself physical harm or good. Therefore he should spend this time as profitably as possible by increasing his bodily strength and

energy and not wasting it. This is an important way of preventing consumption.

Excesses of all kinds weaken a man and render him liable to infection, especially to infection with consumption.

Remember that the germs of consumption and other contagious diseases are spread by spit. Therefore never spit in closely crowded quarters, barracks, tents, etc.

Danger Signals. If you develop a cough, with or without spit, which hangs on for some time; if you raise any blood; if you are losing weight and strength, don't wait but go at once to the proper person and place these facts before him.

If you know that you have consumption, even though you have passed the physical examination, don't conceal it. The chances are that you will break down later on. You will do your country no good, but, on the contrary, you will do it great harm if you conceal this fact.

Remember that one of the greatest things you, as a soldier, can offer to your country is good health."

AMERICAN WOMEN'S HOSPITALS.—The War Service Committee of the Medical Women's National Association has organized the American Women's hospitals for work at home and abroad. The Surgeon-General of the Army, and the General-Director of the Department of Military Relief of the American Red Cross have approved the provision made for service to the army and to the civil population. The work will be officially part of the medical and surgical service of the American Red Cross.

The scope of the plan is broad. It includes units for maternity service and village practice in the devastated parts of the Allies' countries and hospitals run by women for service there as well as for the United States army in Europe. In this country acute and convalescent cases will be treated in hospitals equipped for the purpose; soldiers' dependents will be cared for, interned alien enemies will be given medical aid and substitutes will be provided to look after the hospital service and the private practice of physicians who have gone to the front. The first units hope to go to France and to Serbia in the early fall. Headquarters have been established at 637 Madison Ave., New York City. Dr. Rosalie Slaughter Morton is Chairman of the War Service Committee.

DIPHTHERIA IN NEWPORT.—On August 9 the number of new cases of diphtheria reported in Newport, R. I., was fifteen, the lowest since the outbreak of the disease. This made the total number of cases 267. The health officials, in an effort to check the epidemic, have prohibited the sale of ice cream and have refused to allow the shipment of milk or the departure of any person from nine dairy farms in Portsmouth. With but one exception those affected have a light form of the disease. At Fort Adams there are

eight cases among the Naval Reserves. A strict quarantine is maintained. Drs. George W. McCoy and Joseph Bolton of the United States Public Health Service have arrived to aid in checking the epidemic.

PHYSICAL CONDITION OF DRAFTED ARMY.—The Bulletin of the Department of Health, New York City, makes the following comment on the physical condition of men who are examined for drafting into the army.

"According to press reports concerning the results of the physical examination of men drafted for military service, the proportion of men found physically fit is surprisingly small. This is discouraging, for, while the army standards undoubtedly demand a good physique, they do not, by any means, seek perfection. It is, of course, possible that the results of these first examinations are not fairly representative, and that the proportion of those who meet the requirements will eventually reach a satisfactory average. The results thus far, however, would seem to indicate that we are dealing here with the fruits of individual and community neglect; many of the defects disclosed at these examinations could undoubtedly have been prevented by suitable attention in early life.

It is significant that the individuals examined represent a class which did not have the benefit of the corrective influence exercised by school medical inspection. Certain it is that the health and physical condition of the coming generation has been much more carefully safeguarded. Each year nearly a third of a million school children in the city of New York are medically examined by physicians of the Department of Health. In one-third of the children various forms of physical defects are found, most of them remediable. It is by insistent follow-up of these cases by the Department's school nurses that a very large proportion of these defects are corrected. That this form of supervision is productive of good results and will, in time, result in a higher average of physical well-being in the adult population of this city, is indicated by the fact that the physical examination of pupils in the upper grades in school, or of high school pupils, regularly, shows a lower proportion of physical defects than that found in the examination of pupils of the lower grades.

The lesson taught by the results of the draft examinations is plain. We must strive in every way possible to discover and correct physical defects early in life. But this is not all. By insistence on proper living conditions, *i.e.*, good homes, good food, sanitary shop conditions, decent wages and wholesome rest and recreation, we should make sure that physical health will be maintained."

IRISH MEDICAL PROFESSION IN THE WAR.—The *British Medical Journal* has recently published the following sketch descriptive of the

contribution of service made by the Irish medical profession in the war.

"Since the outbreak of the war the Irish medical profession has voluntarily supplied a large proportion of its members for the medical services of the army and navy. The proportion of Irish doctors who have joined the medical services is much higher than would appear from a casual glance of the number of doctors who are registered with Irish addresses. Whilst over 3000 doctors are usually registered with Irish addresses, it is very doubtful whether, even in times of peace, the number engaged in all classes of Irish medical practice ever reached 2000. It is generally estimated that only one in six newly qualified Irish doctors commences practice in Ireland. The great majority go to England and Wales and a smaller number go to the colonies.

Owing to the number of doctors who have accepted temporary commissions in the R.A.M.C., there are many rural districts in Ireland depending upon one doctor to look after the health of 6000 or 8000 of the population, and it is believed that even if military service were made compulsory on the profession in Ireland, the number of doctors joining the medical services could not be very much increased beyond that now obtained voluntarily.

The members of the Irish profession who have remained at home because they are over military age, or for other reasons, have given very valuable help in treating wounded soldiers in the general hospitals, or in V.A.D. hospitals, specially organized for the reception and treatment of wounded soldiers. The War Office accepted last April a long-standing offer from the medical profession in Dublin to staff a base hospital for France. The doctors who will form the staff of this hospital will work in relays of nine for a term of three months, and will consist of three surgeons, two physicians, an ophthalmologist, a pathologist, a radiographer, and an anesthetist. Similar offers have been made by the profession in Belfast and Cork, but, so far, they have not been accepted by the War Office.

The Irish Medical War Committee was formed at a meeting of the profession convened by the Leinster Branch of the British Medical Association in May, 1915. It consists of two representatives of each of the various licensing bodies and medical schools in Ireland. Among its chief duties are: (1) to provide doctors for the army and navy, (2) to protect the interests, during their absence, of those doctors who join the medical services and to assist them in finding suitable substitutes, (3) to advise regarding the medical requirements of the civil population. Public bodies, such as boards of guardians, have, with very few exceptions, given facilities to their medical officers who desired to apply for commissions in the medical services. They have not only given them the necessary

leave, but in most cases have agreed to pay half their salaries during their absence as well as to pay the full salaries of their locumtenents. It is, however, to be regretted that some boards of guardians have persisted, contrary to the advice of the Irish Medical War Committee and the ruling of the Local Government Board, in appointing, as locumtenents, doctors of military age, when it was open to them to appoint doctors who were not available for military service.

AN AMERICAN MEDICAL PRISONER.—Report from New York on July 13 describes the adventures of Dr. A. M. Mars of San Francisco, who for nearly three years, it is said, was held prisoner in a German detention camp at Luxembourg, despite his protests that he was an American citizen, though born in Paris. Dr. Mars is reported as saying that he was well treated by the Germans, and was put in sanitary charge of the camp, where about three thousand French and English prisoners were detained. Dr. Mars finally escaped to Holland, whence he sailed to New York on a Spanish steamship.

ARRIVAL OF TUBERCULOSIS COMMISSION.—The Tuberculosis Commission, under the leadership of Dr. Livingston Farrand, sent to France by the Rockefeller Foundation, has arrived in Paris, and is in coöperation with the Red Cross representative, Homer Folks.

APPOINTMENTS OF VETERINARY SURGEONS.—Surgeon-General Gorgas of the United States Army has appointed an advisory board to reorganize the Veterinary Corps of the Army. It is comprised of the following men: Dr. C. J. Marshall, Pennsylvania; Dr. David S. White, dean of the College of Veterinary Medicine, Ohio State University, Columbus, O.; Dr. Louis A. Klein, dean of the School of Veterinary Medicine, University of Pennsylvania; Dr. V. A. Moore, dean of the New York State Veterinary College, Cornell University, Ithaca, N. Y.; and Dr. John R. Mohler, assistant chief of the Bureau of Animal Industry, Washington, D. C.

RED CROSS IN MERGER WITH SURGICAL DRESSINGS COMMITTEE.—The National Surgical Dressings Committee, which includes 25,000 members throughout the country, has merged its organization with the Red Cross and will henceforth work under that leadership. The committee will retain all its officials, and will continue its work as heretofore. More than 16,000,000 dressings have been sent to Europe through its branches since the war began. This is the first relief organization to merge with the Red Cross.

HOSPITAL UNITS FOR NERVOUS AND MENTAL DISORDERS.—Dr. Pearce Bailey of New York, chairman of the Committee on Furnishing Hospital Units for Nervous and Mental Disorders to

the United States Government, a sub-committee of the National Committee for Mental Hygiene, has been invited by the Surgeon-General of the United States Army to accept a commission as major and to come to Washington as personal advisor to the Surgeon-General in all matters pertaining to psychiatry and neurology. Major Bailey is now on duty in the Surgeon-General's office. Dr. Frankwood E. Williams, associate medical director of the National Committee for Mental Hygiene, has been appointed vice-chairman of the committee and placed in charge of the work in the New York office.

AMERICAN HOSPITALS IN ARMY ZONE.—Two of the Red Cross Base hospitals first to arrive in the American army zone in France have been taken over by the United States Government. The first on the field was Base Hospital No. 18, organized at Johns Hopkins University, and the second, No. 15, was recruited from the Roosevelt Hospital, New York. The units are occupying French hospitals vacated for their use, and capable of accommodating from 1000 to 1500 patients. Large amounts of supplies were taken across by the units, but because of the scarcity of coal in France, the problem of heating the hospitals when cold weather approaches, will be a serious one. With such secrecy was the movement of the Roosevelt Hospital unit carried on from the time of its disembarkment at port to its establishment in hospital, that the headquarters of the press association, but a short distance away, was unaware of its existence for some days.

VOLUNTEER PHYSICIANS FOR EXAMINING SOLDIERS.—To accomplish the task of examining men to be drafted into the United States Army, in New York, many prominent physicians have volunteered their services. A large number of physicians will be called upon to make examinations in order that no unnecessary delay may arise.

ASSIGNMENTS OF NEW ENGLAND DOCTORS.—The following assignments of New England doctors have been made to conduct physical examinations under the new draft bill.

Lieut. George L. Pratt, Lieut. Merton H. Langwill, Maine Medical Corps, to Cambridge, to assist in physical examination of the 8th Massachusetts Infantry.

Maj. H. R. Stiles, U. S. A., retired, at Hartford; Lieut. Thomas P. Healey, New Haven, to make physical examination of National Guard of Connecticut at Niantic.

Capt. L. O. Tarleton, Massachusetts Medical Corps, Boston; Lieut. Herbert W. Taylor, Vermont Medical Corps; Maj. Charles C. Smith, Boston, to South Armory, Boston, to make physical examinations.

Capt. H. W. Stevenson, Medical Reserve Corps, Saco, Me.; Lieut. Arthur P. Perry, Bos-

ton, to Concord, N. H., for physical examination of National Guard.

Capt. A. E. Austin, Medical Reserve Corps, Boston; Lieut. Ray E. Smith, Vermont Medical Corps, to Charlestown Armory for physical examination of 5th Massachusetts Infantry.

Capt. Harry G. Martin, Massachusetts Medical Corps; Lieut. Frank Piper, Rhode Island Medical Corps, to Quonset Point, R. I., for physical examination.

Capt. Mason D. Bryant and Lieut. Arthur M. Curran, Massachusetts Medical Corps; Lieut. George H. Kirkpatrick of Framingham, to Boxford, for physical examination of National Guard there.

Capt. James Glass, Ayer, and Lieut. Clyde C. Johnson, New London, Conn., for physical examination of Coast Artillery Corps of Connecticut.

Lieut. William R. Dwyer and Lieut. James A. Lyon, Framingham, to Allston to assist in physical examinations.

Sergts. Region V. Love and Harry W. White, C. A. C., to Boxford for clerical work, in connection with muster of troops. Sergt. Steven E. Smith for clerical work at 1st Corps Cadets Armory; Sergt. Clarence G. Meyer at Commonwealth Armory, Allston, for clerical work.

APPOINTMENTS ON MEDICAL STAFF OF STATE.
—The State Guard of Massachusetts, consisting of 135 companies, numbering about 9000 men, has on its medical staff the following men: Medical staff—Lieut.-Col. William A. Brooks; surgeons, Capt. Donald V. Baker, Capt. William A. Brown, Capt. Harold G. Giddings, Capt. George W. Morse, Capt. Russell F. Sheldon, Capt. Benjamin E. Sibley, Capt. Edward A. Supple; physicians, Capt. John W. Dewis, Capt. Thomas F. Harrington; nose and throat surgeons, Capt. George L. Tobey, Capt. D. Harold Walker; dental surgeon, Capt. Kurt H. Thoma; roentgenologist, Capt. Ralph G. Leonard; ophthalmic surgeons, Capt. Ralph G. Loring, Capt. P. Somers Smyth; orthopedic surgeon, Capt. W. Russell MacAusland; surgeons throughout the state, Capt. Hardy Phippen of Salem, Capt. Charles E. Durant of Haverhill, Capt. Thomas B. Smith of Lowell, Capt. Ralph H. Seelye of Springfield, Capt. Lemuel F. Woodward of Worcester, Capt. P. Truesdale of Fall River, Capt. Garry DeN. Hough of New Bedford, Capt. Franklin H. Thompson of Fitchburg.

COLLEGE AMBULANCE CORPS.—There are nearly 5000 college men in the military camp at Allentown, Pa., training for work in ambulance corps abroad.

CONDITION OF MEN IN PERSHING'S ARMY.—Report from the American Training Camp in France states that the health of the troops is of the best. What little sickness there is limited almost entirely to measles and mumps contracted in the United States. Every soldier has been

vaccinated against smallpox and inoculated against typhoid. Each troop section has a supply of hypochloride of calcium for purifying the water used. An adjacent French base hospital has been taken over by the American army and will be equipped with a staff of physicians from Johns Hopkins Medical School. The capacity of the hospital is for one thousand beds. Each troop section has a local dispensary with twelve beds and a field hospital.

HEALTH MEASURES FOR AYER CAMP GROUND.
—The monthly Bulletin of the State Department of Health for June gives an account of the preparations made for adequate sanitary care of the military camp in Northern Massachusetts:

“The towns in which the camp is located, together with those adjoining, are Ayer, Littleton, Harvard, Lancaster, Shirley, Townsend, Groton and Pepperell, having a population, according to the 1910 census, of from 1034 to 2955, aggregating 16,534. During the next five years they gained in population but 397. These towns are as well organized for the preservation of health as the average Massachusetts town of their size. They have the usual sanitary conditions, consisting of little else than a good water supply, Harvard and Townsend being the only ones without a public supply for their thickly settled districts. None have a public sewer system, consequently most of them at times have cesspool, drainage and privy nuisances. But few have efficient milk inspectors. All have inspectors of slaughtering, but no inspectors of provisions. All have medical inspection of schools, but not of an intensive character. Ayer, Lancaster and Pepperell already have public health or district nurses, including school nursing, while Groton and Shirley have plans nearly perfected for employing similar workers.

Realizing that it would be an injustice to tax the towns for more than would be required for a first-class health organization in ordinary times, the Commissioner of Health addressed the following communication to his Excellency the Governor of the Commonwealth of Massachusetts:—

May 21, 1917.

To His Excellency, Hon. Samuel W. McCall, Governor of the Commonwealth of Massachusetts, State House, Boston, Mass.

SIR:—I have the honor to invite attention to the very serious sanitary problem which presents itself in connection with the proposed military camp at Ayer. It is proposed to place 30,000 men for training in this camp. There will be, undoubtedly, a surplus population of 8,000 or 10,000 civilians suddenly added to the population of Ayer and the surrounding towns. Camp followers, unlicensed venders of food and drink, prostitutes and other persons disposed to disregard law and ordinances will drift into this area.

Within a radius of 10 miles from Ayer as a center there are 15 towns with populations ranging from 800 to 3,000. Manifestly, these towns are unable to finance a proper health organization, and it would be unfair to expect that of them. Experience in England and France has proved that to avoid disaster the complete sanitary organization should be in the field working long before the recruits begin training. The Federal government, under existing law, is restricting its sanitary work to the care of the soldier and his camp. A bill for a Federal sanitary reserve corps, which would take care of the surroundings of camps and the civilian population contiguous thereto, is in Congress now, and has the unanimous support of the National Council of Defense. This may or may not go through, but even if it does it will operate too late to meet the emergency which we now face in Massachusetts.

To avoid disastrous conditions prompt action is necessary, and the sanitary organization should be placed in the field with the minimum of delay. There is no money available for such an extraordinary purpose in addition to the ordinary duties of the State Health Department. The work would require the full time of one District Health Officer, one assistant sanitary engineer, two sanitary inspectors, one food and drug inspector, three public health visiting nurses, and the staff and expenses of a small contagious disease hospital. A careful estimate of the cost of such an organization has been made, and \$20,000 will be necessary for the period of one year.

In view of the fact that in the last analysis this is a Federal matter, an emergency obligation placed upon Massachusetts by Federal action, it seems reasonable that the Federal government would later take over the financing of such work and reimburse States for expenditures made. It would be a fatal blunder, however, to wait for Federal action to meet this menace and cover this emergency.

I have the honor, therefore, to recommend that the sum of \$20,000, or such part thereof as may be necessary, be appropriated to be expended under the direction of the Commissioner of Health for the purpose of protecting the health of the people of Massachusetts and establishing and maintaining sanitary conditions in the area within a 15-mile radius of Ayer.

Respectfully,

A. J. McLAUGHLIN,
Commissioner of Health. "

Upon receiving the communication the Governor submitted to the Legislature a message incorporating the recommendation of Dr. McLaughlin and asking for an appropriation of \$20,000 to furnish means of a complete sanitary organization and of \$10,000 to establish a supplementary police force to cope with moral evils engendered by the presence of a military camp

and to secure due enforcement of existing law.

In response to this message, the following special act was passed by the Legislature.

"The State Department of Health was asked by the town officials to direct the public health work in the various towns. The Commissioner appointed the following committee to represent the Department in the field: Dr. Charles E. Simpson of Lowell, chairman, Dr. William W. Walcott of Natick, and Dr. Francis A. Finnegan of Fitchburg, recorder.

An organization has been formed comprising an executive member of the board of health of the various towns as a community health council to act in conjunction with, and under the discretion of the State District Health Officers. In this way a uniformity of rules and regulations and in the manner of their enforcement throughout these towns will be secured. A similar organization of selectmen and school boards is under way, and it is hoped to interest the various public safety committees along similar lines.

It is proposed to establish in Ayer headquarters for the State officers who are to help in carrying out this work, and to furnish an inspector of milk, food and provisions from the State Health Department. A sanitary inspector or inspectors will also be provided, and a supervising nurse and other nurses, if necessary. Some provision is under consideration for an isolation hospital."

HOMEOPATHIC BASE HOSPITAL.—The American Institute of Homeopathy has offered to the Government, through the Red Cross, three base hospitals with one thousand trained men, equipped for war purposes. These base hospitals would be connected respectively with the Metropolitan and the Hahnemann Hospitals of New York and the Hahnemann Hospital of Chicago.

WAR RELIEF FUNDS.—On Aug. 17, the totals of the principal New England war relief funds reached the following amounts:

French Wounded Fund	\$246,648.87
Armenian Fund	215,240.13
Permanent Blind Fund	121,732.73
Surgical Dressings Fund	116,961.01
Polish Fund	77,415.95
Italian Fund	44,114.72
War Dogs' Fund	1,003.75

BOSTON AND MASSACHUSETTS.

WEEK'S DEATH RATE IN BOSTON.—During the week ending Aug. 11, 1917, the number of deaths reported was 205, against 220 last year, with a rate of 13.86 against 15.09 last year. There were 42 deaths under one year of age, against 49 last year.

The number of cases of principal reportable diseases were: Diphtheria, 49; scarlet fever, 7;

measles, 40; whooping cough, 33; typhoid fever, 3; tuberculosis, 69. Included in the above were the following cases of non-residents: Diphtheria, 8; scarlet fever, 1; whooping cough, 1; tuberculosis, 3.

Total deaths from these diseases were: Diphtheria, 4; measles, 4; whooping cough, 1; typhoid fever, 2; tuberculosis, 17. Included in the above were the following non-residents: Diphtheria, 2; tuberculosis, 2.

DEDICATION OF IPSWICH HOSPITAL.—The new building of the Benjamin Stiekney Cable Hospital at Ipswich, Mass., was dedicated on August 4, with appropriate exercises. This hospital is the gift of Richard T. Crane, Jr., and Mrs. Crane to the town of Ipswich. It has an endowment of \$30,000. It accommodates twenty-four patients, and to those who cannot pay its services are free. Mrs. Helen S. Chapman, a graduate of the Massachusetts General Hospital Training School, is superintendent, and local doctors will be on the active staff. The trustees have offered the hospital to the government as a base hospital if need arises, and the building then can be made to accommodate one hundred and fifty beds. Herbert Warren Mason is president of the board of trustees, Rev. T. Franklin Waters, secretary, and Howard N. Doughty, treasurer. Physicians on the active staff are: Dr. G. G. Bailey, Dr. Frank L. Collins, Dr. George E. MacArthur and Dr. M. C. McGinley. On the general consulting staff the following have agreed to serve: surgical, Dr. J. Dellinger Barney, Dr. Fred B. Lund, Dr. Charles G. Mixer, Dr. William J. Mixer, Dr. Samuel J. Mixer; medical, Dr. Charles W. Townsend, Dr. William B. Robbins, Dr. William E. Tucker, Dr. H. F. Vickery; children, Dr. Richard M. Smith, Dr. Maynard Ladd; ear and throat, Dr. Eugene A. Crockett, Dr. George H. Powers, Jr.; nose and throat, Dr. J. L. Goodale; neurologist, Dr. E. W. Taylor; skin, Dr. E. L. Oliver; obstetrics, Dr. Howard T. Swain, Dr. James L. Huntington; oculist, Dr. Alex Quackenboss; orthopedic, Dr. Robert B. Osgood, Dr. Lloyd T. Brown; dental staff, Dr. F. W. Keyes, Dr. E. J. Smith, Dr. F. A. Stockwell.

The hospital is given in memory of Benjamin Stiekney Cable, a friend of Mr. Crane, who was fatally injured in an automobile accident near Ipswich a few years ago.

INFANTILE PARALYSIS IN MASSACHUSETTS.—There have been ten cases of infantile paralysis reported to the State Department of Health for the month of July. At a corresponding date last year twenty-nine cases had been reported. The cases reported for the first sixteen days of the month are as follows: Haverhill, 4; Lowell, 2; and Medford, Beverly, Springfield and Malden, each 1.

TUBERCULOSIS CONFERENCE AT FRAMINGHAM.—The Framingham Health and Tuberculosis Demonstration held, on July 23, at Framingham, a quarterly meeting of its national committee. There were present Dr. Charles L. Miner of Asheville, N. C., president of the National Tuberculosis Association, Dr. Charles J. Hatfield of Philadelphia, Dr. Leo K. Frankel of New York, and Dr. Eugene H. Kelley and Dr. Arthur K. Stone of Boston. The committee plans to hold meetings at least semi-annually in Framingham during the three-year period of the health demonstration. Other meetings are ordinarily held in New York. Special satisfaction was expressed at the amicable and helpful relations existing between the Health Station and local authorities.

BROCKTON HOSPITAL.—Report of Brockton Hospital, Brockton, Mass., for the year 1916 shows a substantial increase in the number of patients treated. There were 1244 patients admitted to the wards, an increase of 7%, and 690 out-patients treated, or an increase of 56%. The orthopedic service increased in number of patients by 25%, and the obstetric service by 70%. The per capita cost remains unchanged, at \$13.95 per week. Of the 1503 weeks of treatment furnished, 723 patients paid in full, 112 patients paid in part, and 456 patients paid nothing. It is desired that a new ward building be added to the hospital, in order to cope with its increasing demand for service.

FAULKNER HOSPITAL.—The Faulkner Hospital of Jamaica Plain, Mass., held, on August 8, the graduating exercises of the nurses' training school and celebrated the opening of the new maternity building. Seven nurses received their diplomas.

BOSTON SCHOOL OF PHYSICAL EDUCATION.—The fourth annual catalogue of the Boston School of Physical Education calls attention to the new building soon to be occupied by the school, on South Huntington Avenue, Boston. This institution, established as is stated "to provide for women a course in physical education which should fit them to meet as teachers the increasing need for instruction in the proper use of the body and its relation to human efficiency," offers a course of study covering two years of thirty-two weeks each. Carefully directed training is given in posture, gymnastics, games, dancing and swimming. With this is correlated systematic instruction in such allied academic subjects as anatomy, physiology, hygiene, and the principles of education.

POLIOMYELITIS IN BROCKTON, MASS.—The appearance of three cases of poliomyelitis in Brockton, Mass., in two weeks, while causing some local anxiety, shows how little the occurrence of another epidemic is to be feared this present season.

The Massachusetts Medical Society.

AN ACT RELATIVE TO THE SALE AND DISTRIBUTION OF CERTAIN NARCOTIC DRUGS.

Be it enacted, etc., as follows:

SECTION 1. Except as otherwise provided in sections two and three hereof it shall be unlawful for any person, firm or corporation to sell, furnish, give away or deliver coca leaves or any cocaine or any alpha or beta eucaine or any synthetic substitute thereof, or any salts, compound or derivative thereof, except decocainized coca leaves and preparations thereof, or any opium, morphine, heroin, codeine or any preparation thereof, or any salt, compound or derivative of the same, except upon the written order of a manufacturer or jobber in drugs, wholesale druggist, registered pharmacist actively engaged in business, as such, physician, dentist, veterinarian, registered under the laws of the state in which he resides, or an incorporated hospital, college or scientific institution through its superintendent or official in immediate charge, or upon the written prescription of a physician, dentist or veterinarian, registered under the laws of the state in which he resides, bearing his legal signature, the date of the signature, his office address, the registry number given him under public acts two hundred and twenty-three of the sixty-third congress, approved December seventeenth, nineteen hundred and fourteen, and the name, age and address of the patient for whom it is prescribed. The prescription, when filled, shall show the date of filling and the legal signature of the person filling it written across the face of the prescription, together with the legal signature of the person receiving any such drug, and the prescription shall be retained on file by the druggist filling it for a period of at least two years. No prescription shall be filled except in the manner indicated therein, and at the time when it is received, and the full quantity of each substance prescribed shall be given. No order or prescription shall be received for filling or filled more than five days after its date of issue as indicated thereon. Any pharmacist who fills a prescription for a narcotic drug shall securely attach to the container thereof a label giving the name and address of the store in which the prescription is filled, the date of filling, the name of the person for whom it is prescribed, the name of the physician, dentist, or veterinarian who issued it; and the narcotic drug so delivered shall always be kept in its container until actually used. The prescription shall not again be filled, nor shall a copy of the same be made, except for the purpose of record by the druggist filling the same, and it shall at all times be open to inspection by the officers of the state department of health, the board of registration in pharmacy, the board of registration in medicine and the authorized agents of said departments and boards, and by the police authorities and police officers of cities and towns; *provided, however*, that the provisions of this act shall not apply to prescriptions, nor to the sale, distribution, giving away or dispensing or possession, of preparations or remedies, if such prescriptions, preparations and remedies do not contain more than two grains of opium or more than one quarter of a grain of morphine, or more than one eighth of a grain of heroin or more than one grain of codeine, or any salt, compound or derivative of any of them in one fluid ounce, or, if a solid or semi-solid preparation, in the avoirdupois ounce; nor to liniments, ointments or other preparations which are prepared for external use only, except liniments, ointments and other preparations which contain cocaine or any of its salts or alpha or beta eucaine or any of their salts or derivatives, or any synthetic substitute for them; *provided*, that such preparations, remedies or prescriptions are sold, distributed, given

away or dispensed or held in possession in good faith as medicines and not for the purpose of evading the provisions of this act, and *provided, further*, that the possession of any of the drugs mentioned in this act, except prescriptions and preparations or remedies especially exempted in this section, by any one not being a manufacturer or jobber of drugs, or wholesale druggist, registered pharmacist, actively engaged in business as such, or a physician, dentist or veterinarian, registered under the laws of the state in which he resides, or superintendent or official in charge of an incorporated hospital, college or scientific institution shall, except as provided in section eight, be presumptive evidence of an intent to violate the provisions of this act. The provisions of this section shall not apply to persons having in their possession any of the above mentioned articles by virtue of a legal prescription legally issued as provided in this act, and not obtained by any false representation made to the physician, dentist or veterinarian issuing it, or to the pharmacist who filled it, nor shall the provisions of this act apply to decocainized coca leaves or preparations made therefrom or to other preparations of coca leaves which do not contain cocaine.

SECTION 2. It shall be unlawful for any practitioner of veterinary medicine or surgery to prescribe any of the drugs mentioned in section one of this act for the use of, or in such manner that it may be used subcutaneously by a human being, and it shall be unlawful for any physician or dentist to prescribe, dispense, administer, sell, give away, or deliver, any narcotic drug to any person except when the drug is obviously and in good faith then and there needed for the treatment and cure of a disease or ailment, and not for any condition or disease directly due to any drug habit or resulting solely from the failure of an habitual user of narcotic drugs to procure the particular narcotic drug or drugs to which he is addicted.

SECTION 3. It shall not be unlawful for a physician personally to administer any narcotic drug at such time and under such circumstances as he, in good faith and in the legitimate practice of medicine, believes to be necessary for the alleviation of pain and suffering or for the treatment or alleviation of disease.

SECTION 4. Any manufacturer or jobber of drugs, any wholesale druggist, any registered pharmacist actively engaged in business as such, and any physician, dentist or veterinarian registered under the laws of the state in which he resides may sell coca leaves, cocaine or any alpha or beta eucaine or any synthetic substitute for them or any preparation containing the same, or any salts, compound or derivative thereof, or any opium, morphine, codeine, heroin or any preparation thereof, or any salt or compound or derivative of such substances, to any manufacturer or jobber in drugs, wholesale druggist, registered pharmacist actively engaged in business as such, or physician, dentist or veterinarian registered under the laws of the state in which he resides, or to any incorporated hospital, college or scientific institution, but such substances or preparations, excepting such preparations as are included within the exemptions set forth in section one, shall be sold only upon the written order of an incorporated hospital, college or scientific institution, duly signed by its superintendent or official in immediate charge, or upon a written order duly signed by such manufacturer or jobber in drugs, wholesale druggist, registered pharmacist actively engaged in business as such, or physician, dentist or veterinarian registered under the laws of the state in which he resides, and the order shall state the article or articles ordered, the quantity ordered and the date. The said orders shall be kept on file in the laboratory, warehouse, pharmacy or store in which they are filled by the proprietor thereof or his successors for a period of not less than two

years after the date of delivery, and shall be at all times open to inspection by the state department of health, the board of registration in pharmacy, the board of registration in medicine and the authorized agents of said department and boards, and by the police authorities and police officers of cities and towns.

SECTION 5. Any manufacturer or jobber in drugs and any wholesale druggist, any registered pharmacist actively engaged in business as such, any physician, dentist or veterinarian registered under the laws of the state in which he resides, and any incorporated hospital, college or scientific institution through its superintendent or official in immediate charge that shall give an order for any of the aforesaid drugs in accordance herewith shall preserve a duplicate thereof for a period of two years after the date of giving the same, which shall at all times be open to inspection by the state department of health, members of the board of registration in pharmacy, the board of registration in medicine and the authorized agents of said department and boards, and by the police authorities and police officers of cities and towns. The order now or hereafter required by the regulations of the commissioner of internal revenue under and by virtue of said public act number two hundred and twenty-three of the sixty-third congress, shall be deemed to be a sufficient order to comply with this and the preceding section.

SECTION 6. Any person who, for the purpose of evading or assisting in the evasion of any provision of this act shall falsely represent that he is a physician, dentist or veterinarian, or that he is a manufacturer or jobber in drugs or wholesale druggist or pharmacist actively engaged in business as such, or that he is superintendent or official in immediate charge of an incorporated hospital, college or scientific institution, or a person registered under said public act two hundred and twenty-three of the sixty-third congress, or who, not being an authorized physician, dentist or veterinarian, makes or alters a prescription or written order for any of the narcotic drugs above mentioned, or knowingly issues or utters a prescription or written order falsely made or altered, or whoever makes any false representation or statement as to his name, age, address, or any other matter, either in writing or orally, to any physician, dentist, pharmacist, or veterinarian for the purpose of procuring a prescription for, or the delivery of, a narcotic drug, shall be deemed guilty of a violation of this act. A prescription or order that is altered, or is obtained by a false representation shall be void and of no effect.

SECTION 7. The possession of a federal certificate issued under and by virtue of said public act number two hundred and twenty-three of the sixty-third congress, by any person shall be prima facie evidence of an intent to sell, furnish, give away or deliver any of the drugs mentioned in this act.

SECTION 8. Nothing in this act shall apply to common carriers engaged in transporting the aforesaid drugs or to any employee, acting within the scope of his employment, of any person who shall lawfully be in possession, for the purpose of delivery, of any of the drugs mentioned in this act, or to any person who shall deliver any such drug, which has been prescribed or dispensed by a physician, dentist or veterinarian registered under the laws of the state in which he resides, who has been employed to prescribe for the particular patient receiving such drug, or to a nurse under the supervision of a physician, dentist or veterinarian having possession or control by virtue of his employment or occupation and not on his own account, or to the possession of any of the aforesaid drugs which have been prescribed in good faith by a physician, dentist, or veterinarian or to any United States, state, county, municipal, district, territorial or insular officer or official who has

possession of any of said drugs by reason of his official duties, or who, as an officer or duly appointed agent of any incorporated society for the suppression of vice, has the same in his possession for the purpose of assisting in the prosecution of violations of this act.

SECTION 9. The provisions of this act, except those sections which require the ordering of the above mentioned drugs on an official order blank and the keeping of the same on file, and the keeping of the record relative thereto, shall apply to cannabis indica and cannabis sativa, except that the same shall not apply to prescriptions, preparations or remedies which do not contain more than one half grain of extract of cannabis indica or more than one half grain of extract of cannabis sativa in one fluid ounce, or, if a solid or semi-solid preparation in the avoirdupois ounce, nor to liniments, ointments or other preparations containing cannabis indica and cannabis sativa, which are prepared for external use only.

SECTION 10. A manufacturer or jobber in drugs or wholesale druggist or registered pharmacist shall not be liable to prosecution if he fills any prescription or written order for a narcotic drug in good faith, unless he knows or has reasonable cause to suspect that the prescription or order was issued in violation of the provisions of this act, in which event any sale or delivery of a narcotic drug so made shall constitute an unlawful sale and delivery of a narcotic drug under this act.

SECTION 11. No physician, dentist, or veterinarian, and no druggist or pharmacist, either wholesale or retail, shall solicit by public advertisement or otherwise application to him for prescriptions for, or sales of, narcotic drugs, or shall publicly advertise any treatment the principal element of which consists in the administering, dispensing, furnishing, giving away or delivering of a narcotic drug, except, however, that wholesale druggists or manufacturing pharmacists may advertise in journals and publications intended for circulation among the medical profession and drug trade generally.

SECTION 12. All buildings, places or tenements which are resorted to by habitual users of narcotic drugs for the purpose of using such drugs, or which are used for the illegal keeping or sale of the same, shall be deemed common nuisances. Whoever keeps or maintains such a common nuisance shall be punished by a fine of not more than one hundred dollars, or by imprisonment for not more than one year.

SECTION 13. Whoever, not being a manufacturer or jobber of drugs, wholesale druggist, registered pharmacist, registered physician, registered veterinarian, registered dentist, nurse, acting under the direction of a physician, or an employee of an incorporated hospital acting under the direction of its superintendent or official in immediate charge, or a common carrier or messenger when transporting any drug mentioned herein between parties heretofore mentioned in the same package in which the drug was delivered to him for transportation, is found in possession thereof, except by reason of a physician's prescription lawfully and properly issued shall be punished by a fine of not more than one thousand dollars or by imprisonment for not more than three years in the house of correction.

SECTION 14. Whoever shall have in his possession a narcotic drug with intent unlawfully to sell and deliver such drug, or any part thereof, or whoever unlawfully sells, furnishes, gives away or delivers any narcotic drug in violation of the provisions of this act, shall be punished by imprisonment in the state prison for not more than three years, or in a jail or house of correction for not more than two years, or by a fine not exceeding two thousand dollars.

SECTION 15. It shall be unlawful for any person, not being a physician, dentist or a veterinarian, registered under the laws of this state or under the laws of the state in which he resides, wholesale

druggist, manufacturing pharmacist, registered pharmacist, manufacturer of surgical instruments or any official of any government, having possession thereof by reason of his official duties, or a nurse, acting under the direction of a physician, or the employee of an incorporated hospital, acting under the directions of its superintendent or officer in immediate charge, or a carrier or messenger engaged in the transportation thereof, to have in his possession a hypodermic syringe, a hypodermic needle, or any instrument adapted for the use of narcotic drugs by subcutaneous injection. No such syringe, needle, or instrument shall be delivered or sold except to a registered pharmacist, physician, dentist, veterinarian, wholesale druggist, manufacturing pharmacist, a nurse upon the written order of a physician, or to an employee of an incorporated hospital upon the written order of its superintendent or officer in immediate charge. A record shall be kept by the person selling such instruments which shall give the date of the sale, the name and address of the person purchasing the same, and a description of the instrument. This record shall at all times be open to inspection by the state department of health, the board of registration in medicine, dentistry, veterinary medicine, and pharmacy, by the authorized agents of said department and boards, and by the police authorities and police officers of cities and towns. Any violation of this section shall be punishable by a fine of not more than one hundred dollars, or by imprisonment in the jail or house of correction for not more than six months, or by both such fine or imprisonment.

SECTION 16. In a prosecution under this act for unlawfully prescribing, selling, furnishing, giving away, or delivering a narcotic drug in violation of any provision of this act, it shall be sufficient to allege that the defendant did unlawfully prescribe, sell, furnish, give away, or deliver, as the case may be, the alleged narcotic drug, without any further allegations, and without expressly negating the different exceptions of the act, and without naming the person for whom said prescription was issued, or the amount or quantity of the drug, or the person to whom such sale, furnishing, giving away or delivery was made; but the defendant shall be entitled to a bill of particulars under the provisions of section thirty-nine of chapter two hundred and eighteen of the Revised Laws.

SECTION 17. The defendant in a prosecution under this act who relies for his defence and justification upon a prescription, written order, registration, appointment, or authority as an excuse under this act, shall prove the same; and, until he has proved it, the presumption shall be that he is not so justified or authorized.

SECTION 18. The forms hereto annexed shall apply as well to complaints as to indictments, and such forms shall be sufficient in cases to which they are applicable. In other cases, forms as nearly like the forms hereto annexed as the nature of the case and the provisions of law will allow may be used; but any other form of indictment or complaint which is authorized by law may be used.

FORMS AND SCHEDULES OF PLEADING.

Common Nuisance.—That A. B., during the three months next before the finding of this indictment, at said [Boston], did keep and maintain a certain tenement resorted to by habitual users of narcotic drugs for the purpose of using narcotic drugs.

Unlawful Possession.—That A. B. did have in his possession, unlawfully, certain narcotic drugs, to wit, morphine (cocaine, heroin, or the name of drug as it is commonly known).

Unlawful Possession with Intent to Sell.—That A. B. did have in his possession with intent unlawfully to sell and deliver a certain narcotic drug (naming the drug).

Conspiracy.—That A. B. and C. D. conspired together to engage in unlawful traffic in narcotic drugs.

Sale and Delivery.—That A. B. did unlawfully sell (or give away, or deliver) a narcotic drug, to wit, morphine (or name drug is commonly known by).

Unlawful Prescribing and Delivery, etc., by Physicians, etc.—That A. B., a physician, (or pharmacist, dentist or veterinarian, etc.) did unlawfully prescribe (or sell, give away, furnish or deliver) a certain narcotic drug, to wit, (naming it).

Possession of Hypodermic Instrument.—That A. B. did have in his possession, unlawfully, a hypodermic syringe and needle.

Sale and Delivery of Hypodermic Instrument.—That A. B. did unlawfully sell (or deliver) a hypodermic syringe (or needle).

False Making Prescription.—That A. B. did falsely make (or alter) a prescription for a narcotic drug.

Uttering a False Prescription.—That A. B. did utter and publish as true a certain false prescription for a narcotic drug, well knowing the same to be falsely made (or altered).

Misrepresentation.—That A. B. did falsely represent to C. D. (a physician, dentist, veterinarian, pharmacist, etc.) for the purpose of obtaining a narcotic drug that (state the substance of the statements claimed to be representations).

DEFINITIONS.

SECTION 19. Terms used in this chapter shall be construed as follows, unless a different meaning is clearly apparent from the language or context, or unless such construction is consistent with the manifest intention of the legislature:—

"Narcotic drug" shall mean *cannabis indica*, *coca leaves*, or any cocaine, or any alpha, or beta, *encaine*, or any synthetic substitute for them, or any salts, compound or derivative thereof, except decocainized *coca leaves* and preparations thereof, or any opium, morphine, heroin, *codeine*, or any preparation thereof, or any salt, compound or derivative of the same.

"Physician," "practitioner of medicine," "veterinarian," "veterinary surgeon," "dentist," shall mean persons duly registered and authorized to practice medicine, veterinary medicine, surgery, and dentistry.

"Druggist," "apothecary," or "pharmacist" shall mean a person duly registered under chapter seventy-six of the Revised Laws, and actively engaged as a practitioner, or employee, in an established and fixed place of business for the sale, compounding and dispensing of drugs.

"Persons" as used herein shall include all corporations, associations, partnerships, or other aggregations of individuals, including also their agents, clerks and salesmen.

"Opium," "morphine," heroin," "codeine" and "cocaine" as used in statutes or in complaints or indictments shall include any synthetic substitute for such drugs, or any salts, compounds, derivations, or preparations thereof, except decocainized *coca leaves* and preparations thereof.

SECTION 20. The repeal of any law by this act shall not affect any action, suit or prosecution pending at the time of the repeal for an offense committed, or for the recovery of a penalty, or forfeiture incurred, under any of the laws repealed.

SECTION 21. Any violation of the provisions of this act, the punishment for which is not specified herein, shall be punished by a fine of not more than one thousand dollars, or by imprisonment in a house of correction or jail for a term not exceeding one year, or by both such fine and imprisonment.

SECTION 22. Section three of chapter three hundred and seventy-two of the acts of the year nineteen hundred and eleven, as amended by section two of chapter two hundred and eighty-three of the acts of the year nineteen hundred and twelve, and chapter one hundred and eighty-seven of the General Acts of the year nineteen hundred and fifteen are hereby repealed. [Approved May 23, 1917.]

Harvard Medical School.

REPORT OF HARVARD INFANTILE PARALYSIS COMMISSION.

THE Harvard Infantile Paralysis Commission, in cooperation with the Massachusetts State Department of Health, has been engaged since November of last year in providing proper after-care treatment for the children left crippled by infantile paralysis.

Clinics have been held for the children in and about Boston at the Children's Hospital and at the Massachusetts General Hospital. In addition clinics have been held throughout the State at the following places: Newburyport, Springfield, Quincy, Lynn, Beverly, Greenfield, Worcester, Malden, Melrose, Lawrence, North Adams, and Lowell.

While it was the original purpose of the Commission to confine itself to the treatment of the persons paralyzed in 1916, only, it was soon found necessary to care for those deformed by the disease prior to 1916. In all, 1114 individuals have been treated.

In 1916 there were reported to the State Department of Health 1917 cases of the disease. Of this number, 454 died. No paralysis resulted in 246 cases, and 303 were privately treated. There remained, therefore, 914 persons to be cared for by the Commission. The Commission has supplied treatment to 698 of this number, and its field agents have visited 142 more. Therefore, only 74 persons in the State have not been reached to date.

All the treatment and advice have been given free of charge, as well as much apparatus. Transportation has been supplied in many instances by volunteer automobile drivers. The work of the Commission will be maintained as long as the public contributions support the work and the children require treatment.

Obituary.

THOMAS DYSON WALKER, M.D.

THOMAS DYSON WALKER, M.D., a leading physician of St. John, N. B., and known to many friends in Boston, Mass., died on July 29, at the Massachusetts General Hospital, where he had gone the previous week for treatment. Dr. Walker was born in 1867, the son of Dr. Thomas Walker of St. John, N. B. In 1891 he graduated from Edinburgh University,—a leader in his class. After working in clinics in American and Canadian hospitals, he settled in practice in his native city in 1892. For many years he was a member of the staff of the General Public Hospital and held office in the New Brunswick Medical Association. He was much interested in the organization of the 8th Field Ambulance

Corps in St. John and attained the rank of Lieutenant-Colonel in the Corps. Much to his disappointment, ill-health prevented his accompanying the Corps to foreign service. He was much beloved and esteemed by his many patients and friends, not only in St. John, but wherever he was known. He is survived by his parents, three sisters and three brothers, one of whom is Dr. William Dacre Walker of Andover, Mass.

Miscellany.

HAY-FEVER PREVENTION.

In a recent issue of the *Boston Transcript* a report is made of the efforts of the Public Health Service in controlling and preventing hay-fever.

"With one hay-fever season come and gone and another coming, the United States Public Health Service emphasizes the importance of educating the public in the noxiousness of the weeds which cause this most uncomfortable of diseases. When this has been done, it is pointed out, suitable legislation will be enacted. States enact stringent laws for the exclusion of parasites injurious to their agricultural interests, and hay-fever sufferers have the right to claim that they are entitled to equal consideration. In the eastern and southern parts of the United States, two distinct seasons of hay-fever make their appearance. The average dates are from May to July for the early form and from August to October for the autumnal form. The early form of hay-fever in this part of the country is due chiefly to the pollen of the Gramineæ, which includes the grasses, both wild and cultivated, and some of the cereals, such as rye, oats and wheat. Most hay-fever weeds are wind-pollinated, and for this reason corn, although it is a hay-fever producer in theory, is not reckoned practically among the miscreants. While one might acquire hay-fever in a corn field if he went after it, the size of its pollen is relatively so great (80 microns) that it causes few cases of hay-fever, and then only in close proximity to such crops. Rye and wheat also have large, heavy pollen grains (50 microns), which gives them a limited potential area of distribution by the wind. When it is considered that the pollen of the common ragweed weighs only 15 microns, the relative harmlessness of the cereals named is apparent.

The scientists estimate that eighty-five per cent. of the hay-fever cases are caused by the common and giant ragweeds. The disease can be produced in the laboratory from insect-pollinated and self-pollinated plants, but as their pollen is not found in the air and cannot, therefore, reach the nasal passages in ordinary respiration, they are not responsible for hay-fever. Wind-pollinated plants are characterized by in-

conspicuous flowers, which are without bright colors or scent, and by the large quantity of pollen which they generate. Many wind-pollinated plants, however, have pollen which does not produce hay-fever, like the pines, sedges, etc., or which cause reactions of a mild character, like the amaranths and docks. The trees, which are largely wind-pollinated and frequently distribute their pollen in enormous quantity, usually bloom in the spring, but rarely are responsible for hay-fever. The pines scatter their pollen about as freely as snow, but appear innocent of causing harm to the human race. The pollen of some of the oaks, willows, ailanthus and other trees give a mild reaction for hay-fever, but not enough to warrant taking them into account.

A study is now being made of hay-fever in the Western part of the country, but is embarrassed by lack of information among the health authorities of the Pacific and Rocky Mountain States as to the exciting causes of this disease. Hay-fever is found to be common throughout the Rocky Mountain and Pacific States, but the common ragweed, which is responsible for so much suffering in the East, is not generally found west of Kansas. But ragweed of the same family grows throughout the Far West, and along with the Western and burweed marsh elders, the sand bur, false ragweed and the cocklebur, so brings up the average of infection that the West has no need to be jealous of the East on the score of hay-fever.

Dr. William Sheppegrell, who has been studying hay-fever for ten months, kindly remarks that while describing the plants which are responsible for the disease, it is also opportune to say a few words regarding the rose and goldenrod. The rose is insect-pollinated and could, therefore, cause hay-fever only by direct inhalation, as the pollen is never found in the atmosphere. In addition to this, its reaction is practically negative, so that, in spite of the common term applied to the early hay-fever,—'rose cold,'—it is not responsible for hay-fever. The goldenrod has a spiculated pollen (20 by 22 microns), which gives a positive hay-fever reaction. The flowers, however, are insect-pollinated, and cause hay-fever only on direct inhalation or when used for ornamental purposes, as in room decorations. In most sections the goldenrod continues to bloom many weeks after the hay-fever season is over. In the atmospheric-pollen plates exposed in New Orleans during the whole of the last hay-fever season, the pollen of the goldenrod was never found. In spite of its bad reputation, therefore, the goldenrod is an insignificant factor in hay-fever.

Yellow fever has been eradicated from former plague spots and bids fair in time to disappear from the face of the earth, through the practical application of well-known scientific treatment. Typhoid epidemics are traced to their source

and the cause removed, never to return again if people follow the instructions of the health authorities. Tuberculosis is controlled and cured, and some day will be unknown. The time should not be far distant when hay-fever should be as rare a disease, in the great cities and towns at least, as leprosy."

PUBLIC HEALTH NURSES IN WAR.

THE following resolutions were recently adopted by the Advisory Board of the Boston Instructive District Nursing Association:

Whereas, The establishing of training camps all over the country may seriously affect the public health of surrounding communities; and

Whereas, By her special training, the public health nurse is fitted to cope with problems concerning the public health, and is the only available agent for the practical health teaching so essential in homes threatened by tuberculosis and other communicable diseases, such as venereal disease, scarlet fever, cerebrospinal meningitis, especially likely to be brought into communities near the concentration camps, and for the teaching in the care of themselves and their children prospective mothers who are being put into industrial positions, and is also peculiarly valuable in the home, teaching of food values, buying, and preparation of food, and are further and more than ever required in their capacity of social workers under these abnormal social conditions;

Whereas, Of the seventy thousand registered nurses in the country, only six thousand are public health nurses, be it

Resolved, That while there are other nurses available for Red Cross work, the Instructive District Nursing Association of Boston and the Baby Hygiene Association of Boston urges all public health nurses, for the present, to remain at their posts, and that it emphasizes the fact to the general public that by so remaining, the public health nurse is helping to conserve the most precious of our national resources, human life, and is serving her country no less truly than the nurse who goes to the front.

MEETING OF THE SECTION OF HOS- PITAL ADMINISTRATION, JUNE 12, 1917.

THE CHAIRMAN, DR. HOMER GAGE, Worcester: This is the first year of the Section of Hospital Administration, and its existence is due largely to the work of Dr. E. A. Codman in the meetings of the Clinical Surgical Society, which has brought to our minds, perhaps more forcibly than ever before, the necessity of doing something to find out whether our hospitals are really doing the work they are intended to do, that we think they are doing.

We have taken it for granted for a long time that hospital work is being done just as we think it ought to be done, but we have never undertaken any real method of standardizing hospitals, or the work in the hospitals, or of following up the results of hospital treatment to find out whether the hospital treatment was accomplishing what it was intended to accomplish. Of course it is money thrown away if a patient comes to a hospital for medical or surgical treatment and pretty soon after leaving the hospital has to return for more or further treatment, and if that is being repeated it simply means we are wasting our hospital endowment; and with the enormous increase in the number of hospitals it becomes apparent that some work must be done to find out exactly how we stand, and what our results are. We must have some means of determining the char-

acter and success of the work which we are doing, and it is the outgrowth of that feeling that led to the establishment of this Section.

THE FOLLOW-UP SYSTEM.

BY CHANNING C. SIMMONS, M.D., BOSTON.

THE end-result and follow-up systems in use at certain of the hospitals at the present time is a comparatively new development and is a distinct step in progress in the keeping of hospital records. Certain of the larger hospitals have adopted the determination of the end results of their cases as a routine part of the record work, and it is done automatically, while many others in good standing have as yet made no provision for it. The end-result work, to determine the results of treatment of cases treated at the institution, is distinct from the follow-up work in use in out-patient clinics, notably in the children's and orthopedic departments, and it is of the former only that I shall speak. I have been interested in the work since it was first started at the Massachusetts General Hospital. I do not refer to groups of cases worked up by individual men, but of the work as part of the record system of a hospital under the charge of the librarian or custodian of the records.

To determine the result of treatment of a surgical case and post this result in the record is, without question, of distinct advantage to the hospital, the science of surgery, the surgeon who performed the operation,—showing him his successes and his mistakes,—and, above all, to

the patient. It completes the record of a case, and soon shows which operation, if there is a choice of two for a given condition, is the better, and whether one is better in one man's hands and a second in another's. It also allows the comparison of statistics of different men. I believe the personal equation comes in in surgery as much as in any other profession, and, although I believe in the efficiency propaganda, I think it can be overdone to the detriment of the patient; and when all is said, it is his condition we are trying to improve.

Mrs. Myers, the librarian of the Massachusetts General Hospital, made a trip last fall, visiting many of the larger hospitals in the country and studying their record systems, and I have been surprised in reading her report to learn how many of the larger hospitals in the country have no provision to determine the end results of the cases treated. I give below a list of nine hospitals, five of which are in Boston, that have some form of follow-up system, and the methods they employ. The end-result work is limited almost exclusively to the surgical cases, but I see no reason why it should not be extended to include some of the medical cases as well.

Massachusetts General Hospital. Letters are sent all surgical patients one year from the date of discharge, asking them to report at the hospital for examination, or write stating their present condition. If they report, they are examined in the accident room by the house surgeon. If there is no reply to the letter, nothing further is done, but if the letter is returned "unclaimed" a second is sent to a friend. In one year, as far as can be determined, about 75% of the cases were heard from, but in all probability in not over 60% was the information obtained by the hospital routine (2739 cases). The system is fair but far from perfect.

Peter Bent Brigham Hospital. A system similar to that at the Massachusetts General Hospital, and about as effective.

Collis P. Huntington Hospital. The end-result and follow-up work is in charge of a social worker, who does practically nothing else. For the three-year period, 1912-1914, 603 cases (95.6%) were followed. At present there are about 500 new cases a year.

Boston Dispensary. A very good follow-up system in charge of social workers. As this institution is practically only an out-patient clinic, there is little end-result work done (Howard¹).

Curacy Hospital. There is no provision for end-result as a part of the hospital routine. There is, however, a paid social worker following up the surgical cases, under the direction of Mrs. Bottomley and MacAusland. She is developing an end-result system.

Presbyterian Hospital, New York. This hospital has, as far as I can determine, the best

perfected end-result and follow-up system of any in the country. Carseaden² has described the system at length and says that for one year the results on 91.6% of the cases were determined (2278 cases). It is under the charge of a social worker.

New York Hospital. There is no end-result system maintained by the hospital. Dr. Gibson³ has a system in force on his, the first surgical service, and Dr. Baneroff⁴ a similar one on the second surgical service. Both of these systems are admirable and are in charge of social workers, but, as I understand it, are financed by the men themselves.

Michael Reese Hospital, Chicago. Letters are sent to all patients one year from the date of discharge, asking them to report for examination. The system is fair, but can be improved.

Mayo Clinic, Rochester, Minn. No regular system. If a surgeon wishes to follow up a group of cases, he is given the proper facilities, and the letter sent is passed on by a clinician, a surgeon, and a pathologist, to make sure all necessary questions are asked.

The above list is not intended as a full one of all the hospitals that have a follow-up system, but only to give a general idea of the methods employed.

The difficulties of the work vary as to the type of patients treated. In hospitals drawing patients from thickly settled districts, as the East Side of New York, it is fairly easy to trace cases and to get them to report for examination as, although they move often, they never move far from their original address. At the Massachusetts General Hospital, on the other hand, the patients come from all over the New England states, and it is difficult to get them to report, but as they are more intelligent than a foreign population and rarely move, they will usually answer a letter. Their friends are also easier to locate.

I believe that if the work is done properly and conscientiously, 90% of a group of surgical cases can be traced at the end of from three to five years. I personally have tried to determine the results in four groups of cases in the last ten years, and have been able to trace over 90% in each instance. These were as follows:

Cancer of the breast, 416 cases, 3 to 13 years after operation, 90.8% traced.

Cancer of the tongue, 112 cases, 3 to 8 years after operation, 93.7% traced.

Inguinal hernia, 162 cases, one year after operation, 93.8% traced.

Umbilical hernia, 70 cases, one to five years after operation, 91.5% traced.

These personal figures for cases at the Massachusetts General Hospital compare closely with those given for the Presbyterian and New York Hospitals, where the system is under the charge of a paid social worker and done automatically. It also shows that the class of patients makes very little difference.

At the Collis P. Huntington Hospital we have a social worker who does practically nothing else. She has developed a system of her own which, however, is applicable best to a small hospital of this type, averaging now about 500 patients a year. As this is a hospital for the treatment of malignant disease, no record is considered complete until the patient is dead from malignant or other disease. The figures for the three-year period, 1912-1914 (603 cases) are as follows:

Reported on account of letter sent	\$1	} 576 cases (95.4%)
Reported by letter	\$2	
Found to be dead	\$81	
Under regular observation	\$2	
Letters unanswered	16	} 27 cases
Letters returned unclaimed	11	

In establishing an end-result system there are certain points it is necessary to bear in mind in order that it should give the best results. In the first place, it is necessary to have the interest and active support of the visiting staff, not their passive acquiescence only. The staff must assist in the work and do all in their power to further it. If they do not like the methods the social worker or whoever else is in charge of the work employs, they should say so and do their best to correct errors, not grumble and find fault with the whole system. I think there is no question now that social service and allied work, properly supervised and administered, has come to be a recognized part of all well-organized hospitals. They must, however, work with and under the staff, not as two separate organizations under the same roof.

It is important the patient be told before his discharge that he will receive a letter asking him to report at a given time. It should be impressed on him that this is for his good, and that the doctors take an interest in him. Unless this is done many will pay no attention to letters, as they think the hospital is dunning them for an unpaid bill.

Time to Report. The ideal method is to have each case judged by itself, and told to report at a time deemed proper for that case. Three months is a good unit of time for most cases. Many will be well at the end of that time, and it will not be necessary to see them again. On the other hand, cases of carcinoma should be kept under observation for several years, and should report regularly every three to six months.

Examination. All cases, if possible, should be seen by the surgeon operating upon them, as he knows the case better than anyone else, and can see the results of his work, good or bad. If he cannot see them, someone having good judgment, in authority, and interested, should be delegated to the work—not a house officer.

It is of assistance to have the record, or a good abstract, in the examining room at the

time the patient reports, as it is impossible to carry all the data in regard to a given case in one's head. After examination I believe all notes should be made in the record itself and signed. If more convenient for handling, the notes may also be made on a separate card similar to that advocated by Dr. Codman.^{5, 6}

Suggestion for Establishing an End-Result System.—I believe all hospitals should have end-result reports on all cases, but the actual details of the system must depend, to some extent, on local conditions. I shall refer those interested to the articles already cited, rather than go into the details of a system. The hospitals that have adopted this work all have very much the same routine, although that at the Presbyterian, in New York, is probably the most perfected.

There are certain general suggestions which, if carried out, will make the work easier. The admission card of every patient should have the address of two friends, one of whom has a permanent address, as well as of the patient. If the patient is a woman, her Christian name, as well as that of her husband, should be obtained. It is also well to note the address of the physician or person recommending the case. Care should be taken to spell foreign names correctly.

The work should be under the control of the librarian or custodian of the records. It should be automatic and in charge of a full-time social worker, or similar trained person, and not left to a stenographer or ordinary clerk. It should take the full time of one person and part time of a second to do the work of a hospital having a discharge list of from 3000 to 4000 a year, but one of these only need be trained.

The worker should see each patient at the time of his discharge, and give him a card asking him to report at a given date, or explain to him, he will receive a letter about that date. At the time the patient is to report she should have the record in the examining room, and should also notify the surgeon. With a visible index file, the worker can easily keep track of the cases. If possible, the patients should be given the opportunity to report on an evening or Sunday, as to many, reporting in the daytime means giving up a half day's work. At the Massachusetts General Hospital the patients receive a letter asking them to report one year from the date of discharge, and this year I have notified patients I operated upon a year ago I would see them personally if they reported Sunday morning. From 5 to 12 report each week. If they report week days they are seen by the house officer in charge of the accident room. At the New York and Presbyterian Hospitals the staff meet once a week, see the cases operated on previously who are reporting, and discuss the work of the service. This is an ideal proceeding, but almost impossible of attainment.

If patients do not report, and do not reply to letters in a reasonable time, the worker should

try the various methods used to trace cases. In 1912 I published a short paper⁷ giving the methods I had found useful in tracing a given case. These suggestions are applicable, particularly to Massachusetts hospitals.

1. If there is no reply to letters sent, the worker should call at the patient's residence, and if he has moved make inquiries of the neighbors, laying stress on the fact that she is not a bill collector, but wishes to ascertain his health.

2. Write to the friends and physician.

3. Look up the patient or friends in the telephone book or in the local directory of the town in which they live, following them through year after year, till the change in address is found. (Directories of all towns in the state are in the office of the State Board of Charities in the State House.)

4. In cases of malignant disease, go through the files of deaths in the bureau of vital statistics at the State House, to rule out patients dead. (If you give the clerk a list of the correct names of the patients with the age and address and the probable date and cause of death, she will usually do this for you.)

5. If the patient comes from a small town, write to the postmaster or town clerk. They can usually give you some information.

6. Write to the state boards of health at the capitals of the New England states, inquiring if the patient died in that state.

7. The police will sometimes give you information if you tell them why you want it.

8. If you believe a patient with cancer to be living, but can get no reply to a letter, send him a registered letter. You will get his signature any way.

9. The Confidential Exchange of the Associated Charities has a record of many of the poorer cases.

10. Make all letters polite and personal. You are much more apt to get answers than if a "Neostyle" letter is sent.

There are many other methods of tracing cases that suggest themselves as one does this work.

I hope in the near future to see more of the leading hospitals adopt some form of end-result records and also to see the work done on the medical as well as the surgical cases, to which it is limited at present.

DISCUSSION.

THE CHAIRMAN: This is an important paper of Dr. Simmons, and very suggestive. There is one other means of looking up patients that has come to my notice lately, and it is in connection with what is really one of the most important works,

medically, undertaken for a good many years. It is being undertaken at the Mayo Clinic, at the suggestion and practically by the request of the Medical Directors' Life Insurance Association, to try to get at what are the real results of operations. Dr. Charles Mayo read a paper before that Association in New York in October of last year on the relation of gall-bladder surgery to life insurance that was a little disappointing, and the disappointment was expressed simply because it did not give figures; it gave impressions only. It gave figures of the immediate successes or failures, but that was all.

As a result of that discussion, Dr. Mayo stated that they would be very glad indeed to extend the facilities of their records to the Medical Directors' Association, to determine according to actuarial methods exactly what the results were and to translate these into insurance language. That invitation was accepted, and the actuary of the New York Life Insurance Company went out there and they started an investigation on three lines: on the line of gall-bladder operations, on operations on gastric and duodenal ulcers, and on thyroids. Such knowledge is of such great importance to the insurance companies that they have said if, after these records are gone over carefully and everybody found out who can be found out by personal solicitation or by writing to friends, the list of those who cannot be found out be given to them, that the matter will be treated confidentially and the patients will be carefully looked up by their inspection systems. They believe that then they can get as good results as Dr. Simmons says he is getting when he puts his personal attention on the matter.

To my mind, the results of these investigations ought to be of immense importance. We have got a start in this work of Mayo's under very favorable conditions. It is more than the follow-up system; it is pretty nearly the end result of each case, and is going to show the mortality statistics in these cases—not necessarily the mortality due to the particular condition for which they entered the hospital, but its relation to their natural expectation of life; and all of these things are most interesting.

One other thing, about having these cases report on Sunday. At the Presbyterian Hospital the three surgeons at the head of the surgical division alternate in attendance on Sundays—first one is on duty and then the next, and so on. I endorse this plan. Someone of the visiting surgeons is there every Sunday morning, and the patients are requested to report at that time. This is of special importance in a large metropolitan hospital, where many of the cases cannot come at any other time.

Dr. Simmons' paper is open for discussion or suggestions.

DR. P. E. TRUESDALE, Fall River: I would like to ask what the Massachusetts General Hospital will do, for instance, when its new private ward is established? Will the blanks or inquiries be sent to the doctors or directly to the patients?

DR. SIMMONS, Boston: I personally could not answer that. I should suppose it would be regarded as a private hospital.

DR. J. B. HOWLAND, Boston: I should assume that these were private patients, and the doctors will do as they please with them.

DR. TRUESDALE: What is the method at the Peter Bent Brigham Hospital?

DR. SIMMONS: Letters are sent at the end of one year, and a second letter is sent if the first remains unanswered.

DR. TRUESDALE: Are the letters sent to the patients or their physicians?

DR. SIMMONS: To the patients. If the surgeon is interested in a certain line of cases letters may be sent also afterwards to the physicians.

DR. HOMER GAGE, Worcester: I don't see why that method should not be followed out the same as followed in private practice, the same as I follow it in mine. I write the first letter to the patient and if I get no reply I write to the doctor from whom that patient was referred to me, or to the doctor who was connected with the case. Failing in that, I try to find if I have a record of some friend, and if it is a case in the hospital I have a record. In that way I am just getting together over 90% of the results of operations performed between 1898 and 1915.

I have been engaged in that sort of work for some time, and have never yet received a discourteous reply, nor have I ever heard of anyone who has.

UNIFORMITY IN HOSPITAL MORBIDITY REPORTS.

By E. A. CODMAN, M.D., BOSTON.

WHAT is the object of publishing morbidity tables and lists of operations in hospital reports? I have asked this question of several prominent physicians and surgeons, and also of a number of hospital superintendents. There is always a vagueness in the reply. The answers, boiled down to their simplest form, amount to this: To supply to those interested, information as to the kind of cases we treat, the kinds of operations we do, and the mortality from both disease and operation. When I ask, "Who are the persons who are interested in such matters?" the answers are still more vague. They show optimism that possibly hospital superintendents, trustees, subscribers, physicians and surgeons, boards of health, and statisticians may find some light therein. Practically they admit that very few, if any, laymen or doctors study or use these reports in any but the most general way. The Committee of the Council of the Massachusetts Medical Society, who studied this question last year, reported that: "Some idea of the relative frequency of diseases and injuries in a given community, and the immediate hospital mortality, are all that can be gained from the best of the hospital reports as at present prepared."

The truth is, that each hospital publishes these statistics as a sort of boast that it is doing something; the tables look well in a report, and impress the trustees and subscribers; otherwise than this they are not used by anybody. Anyone who might wish to use them knows that they are too inaccurate and too diverse in plan and method of classification to be of service either

for comparison one with another, or for large statistics made by adding them one to another.

In order to give some idea of the variety of methods of classification used by the hospitals of Massachusetts, I have been over the reports of all the incorporated charitable hospitals. I find that scarcely two are exactly alike. All sorts of methods are used. Sometimes one even finds different methods used in the same hospital. Thus in the Boston City Hospital, medical diseases are classified by systems with subdivisions of pathology; surgical diseases are classified anatomically, with pathologic and systemic subdivisions. The skin cases are classified alphabetically, and some of the other departments have still further variations. I defy anybody to distinguish any general plan in the different classifications in the Children's Hospital report. I have made some lists showing in a general way what hospitals adhere to each of various forms of classification.

THOSE ARRANGED UNDER SYSTEMS,—PATHOLOGIC OR ANATOMIC SUBDIVISIONS.

Sturdy Memorial Hospital, Attleboro.
Beverly Hospital.
Boston City Hospital.
Children's Hospital.
Faulkner Hospital.
Deaconess Hospital.
New England Hospital.
Brockton Hospital.
Union Hospital—Fall River.
Lowell General.
St. John's Hospital—Lowell.
Malden Hospital.
St. Luke's Hospital—New Bedford.
Newton Hospital.
Wesson Memorial Hospital—Springfield.
Hampden Hospital.

THOSE OF MIXED NOMENCLATURE, MORE OR LESS ARBITRARY, WITH ANATOMIC, PATHOLOGIC, AGE, SEX OR CONDITIONS SUBDIVISIONS.

Cambridge Hospital.
Children's Hospital.
House of the Good Samaritan.
Infants' Hospital.
New England Hospital.
Massachusetts Homeopathic Hospital.
St. Ann's Hospital—Fall River.
Hale Hospital—Haverhill.
Newburyport Homeopathic Hospital.
Cooley Dickinson Hospital—Northampton.

THOSE ARRANGED ALPHABETICALLY, ACCORDING TO PATHOLOGY, DIAGNOSIS, ANATOMY, OR A MIXTURE OF THESE.

Boston Floating Hospital.
Massachusetts Homeopathic Hospital.
Peter Bent Brigham Hospital.
Clinton Hospital.
Frammingham Hospital.
Heywood Hospital—Gardner.
Addison Gilbert Hospital—Gloucester.
Public Hospital—Greenfield.
Hale Hospital—Haverhill.
Holyoke City Hospital.
House of Providence Hospital—Holyoke.
Lawrence General Hospital.
St. John's Hospital—Lowell.
Ludlow Hospital.
Lynn Hospital.
Melrose Hospital.

Medford Hospital.
 Anna Jaques Hospital—Newburyport.
 North Adams Hospital.
 Hillcrest Hospital—Pittsfield.
 House of Mercy Hospital.
 Jordan Hospital—Plymouth.
 City Hospital of Quincy.
 Salem Hospital.
 Children's Island Sanitarium.
 Somerville Hospital.
 Mercy Hospital—Springfield.
 Waltham Hospital.
 Noble Hospital—Westfield.
 St. Vincent Hospital—Worcester.
 Worcester Hahnemann.

THOSE ARRANGED BY ARBITRARY SECTIONS MODIFIED
 FROM THE INTERNATIONAL.

Hale Hospital—Haverhill.
 Eye and Ear Infirmary.
 Massachusetts General Hospital.

THOSE THAT TRY TO COMBINE THE DIAGNOSIS AND
 OPERATION.

Carney Hospital.
 Peter Bent Brigham Hospital.
 Free Hospital for Women.
 Clinton Hospital.
 Burbank Hospital—Worcester.

THOSE ARRANGED ON INDIVIDUAL OR ORIGINAL PLANS.

The Waltham Baby Hospital.

This hospital, although it has very few cases in numbers, gives us a good example by listing the case number, diagnosis and result on the same line. Such a report could not be made unless the hospital were making an effort at efficiency, for the cases must be listed by consecutive numbers, must be diagnosed, the result noted, and made public in the report. If every hospital in the State followed the example of this little hospital, the reports would be of far more value than they are at present.

The Memorial Hospital of Worcester.

Such a report could not be made unless the staff were diagnosing their cases and grouping them, analyzing them, and making an effort to increase the efficiency of their treatment. It illustrates the possibility of using a double classification,—pathologic on the horizontal and anatomic on the vertical. It suggests that the chart from which the final statement is made, must be as good as a card index to the diagnoses. It is practical, and can be run by an intelligent clerk, if the staff cooperate.

The Codman Hospital.

In this report I have carried to the limit the following points, which I believe to be of fundamental importance.

1. Publicity. In each case under consecutive and permanent numbers an abstract is given of diagnosis, treatment, complications and immediate result.

2. End Result. Each case has been followed, if practicable, and an annual note made until death.

3. Classification. A detailed classification of diagnosis is given on the principle of the variable, using the Clinical Congress chart.

4. Index. The use of the classification as a practical index to every diagnosis is shown.

5. Efficiency analysis. A practical example is given of my own errors in diagnosis, judgment and skill, and the conclusions from a study of the analysis.

6. Professional ethics. A practical example of my own moral (or immoral) attitude in accepting for treatment a great variety of serious cases, is given to illustrate clearly how custom is the criterion of our professional morality.

7. Finance related to object of institution. A financial report illustrating how charitable hospitals, when run as competitive business institutions, may defeat their own object.

If single-handed I can do the professional work for 270 cases, record them, classify them, analyze them, trace their results, moralize over them (and still make a living), then it is clear that 10 men could do the same by 2700, which is a much larger number of cases, and smaller number of staff appointments than most hospitals have.

I think I have offered sufficient evidence to show: 1. That there is no uniformity at present in the reports of our hospitals. 2. That the hospitals are willing to spend time and money in making reports, even if they are not read or used. 3. That there is a great diversity of opinion as to the best form in which to present such reports. 4. That the energy, labor, expense and thought which are expended on making these reports is largely wasted, if not entirely misdirected.

The object of this paper is to suggest a method whereby this energy, labor, money and thought may be utilized. My suggestion is to make these hospital reports serve three distinct purposes.

The first is statistical or scientific. The second is a measure of efficiency. The third is to replace or reinforce a card index system to individual cases.

THE STATISTICAL AND SCIENTIFIC VALUE OF HOSPITAL REPORTS.

I think there can be no question that if all our hospitals had a uniform report, no matter how simple it was, that the added figures would form statistical and scientific data of value. For instance, if each hospital published a morbidity report which simply stated two headings,—one, Malignant Disease, and the other, All Other Pathologic Conditions,—that even this brief statement would be important. If we made five headings,—Malignant Conditions, Inflammatory Conditions, Tuberculous Conditions, Traumatic Conditions, All Other Conditions,—it would be even more valuable. I think that every one would admit that such a simple report, if given uniformly by every hospital, would be of far greater value than the elaborate reports on which our hospitals spend so much labor and money at present.

THE VALUE OF MORBIDITY REPORTS AS MEASURES OF EFFICIENCY.

No hospital can give efficient treatment to its cases, unless it knows the diagnoses of the conditions from which the patients suffer. To form a clear idea of the conditions for which we are treating the patient, is one of the most necessary steps in modern practice. The hospital which insists that this diagnosis of the condition is set down in black and white, has made one important step towards practical efficiency. Can we not use the morbidity report as a proof that

diagnoses have been made and recorded? This proof will be immensely strengthened if each diagnosis is followed by a list of case numbers, so that those authorized or interested may refer to the detail of any case in question.

THE VALUE OF A MORBIDITY REPORT WHEN USED AS AN INDEX.

Let us suppose that a small hospital treats only 100 cases a year, and that each of these cases receives a consecutive number. Suppose that 25 of these cases had some form of cancer. The report at the end of the year might divide all their diagnoses into "Malignant Conditions" and "Other Conditions." Following the words "Malignant Conditions" would follow the individual numbers of the cases. Following the words "Other Conditions" would come the individual numbers of all the other cases. Suppose one of the staff wished to review all the cases of cancer of the breast. He would merely have to look through twenty-five numbers to find all the cases of cancer of the breast. This would be considerably easier than looking through the whole hundred numbers, but the same simple division applies to cancer of any other organ. It would be just as easy for him to look up cancer of the uterus. Vice versa, if he wished to look up tuberculosis of the wrist, he would have to look through seventy-five numbers, but he would have to look through only seventy-five numbers for any other diagnosis. What earthly use could there be for a hospital which has 100 cases a year to subdivide any further?

But suppose a hospital which ran 1000 cases a year. In such a hospital there might be 250 cases of malignant disease. In this case it would be more convenient to have six subheadings under Malignant Disease, with the number of each case following. The trouble which the investigator would encounter would be no more than he would encounter in the small hospital; he would have to pick out the cases he wanted from only twenty-five numbers. Suppose the hospital treated 10,000 cases. There would be 2500 cases of malignant disease which could be still further subdivided, so that each group would contain twenty-five or less, unless more than twenty-five occurred under some definite, clearly defined subheading—such as cancer of the breast; in which case the investigator would have no trouble at all in going direct to his records.

I wish I had the time, and you had the interest to hear a discussion of the relative merits of the different forms of classification which at present exist in Massachusetts. No doubt each has its merits, and each is sanctioned by the custom in the local hospital. In my opinion, by far the best is that used at the Memorial Hospital in Worcester. I wish that we might all copy that method, so that it would be at least uniform. Anyone who has studied the morbidity

report of the Memorial Hospital will be convinced that such a report could not be made unless its staff were making an effort at scientific, statistical accuracy, at clinical efficiency, and at permanent scientific records, practically and carefully indexed.

I should like to make the following suggestions to the hospitals of Massachusetts:

1. Begin the new year with a new set of numbers, assigning these numbers consecutively to each house patient. Let each patient keep the same number, no matter how many times he returns, whether he reenters with the same or different diagnoses.
2. Let each hospital keep a chart on which the diagnoses are in two divisions,—"Malignant Disease" and "Other Pathologic Conditions." At the time of the discharge of each patient, record on this chart the number of each patient under the appropriate heading.
3. Let each hospital, when it issues the annual report in 1919, publish a simple statement, giving the total sum of all the diagnoses reported under "Malignant Disease" and "Other Pathologic Conditions."
4. Let each hospital appoint a member of its staff to meet with the other appointees of all other hospitals which adopt this suggestion, and then this group can formulate further subdivision of diagnoses for future reports.

If these simple suggestions meet with favor, by 1920 the hospitals of Massachusetts will have before them a simple method of proving to their trustees, staff and subscribers that they are making an effort at accuracy, efficiency and scientific record. The morbidity statistics which would be gained by the sum of these reports in 1920 would be an example to the whole world.

This plan requires some effort, because it is new, but the total effort, labor and expense would be far less than what we expend at present, and for which we get no real return.

What a pity it is that this subject is so uninteresting! Here we have a chance to get together on something which would help us all and generations after us.

A more elaborate discussion of this plan from my own point of view will appear in a paper which I gave before the surgical section of the American Medical Association on June 7, and also in the forthcoming report of my own hospital.

EXPLANATION OF FIGURE.

By the use of three dimensions this system may be used in the smallest as well as in the largest hospitals. For small numbers of cases it may be linear, for larger numbers it may be rectangular, and as a cube it will provide for infinite numbers.

If some large medical society, like the American Medical Association or the American College of Surgeons, should recommend its universal use, a standard card index cabinet could be made, and sold at cost to all hospitals.

Each card would contain only the name of a sub-

BASIC PLAN OF A CARD CATALOGUE CABINET FOR STANDARD HOSPITAL USE.

A suggestion for a system of classification and case reference index of diseases, based on the principle of the variable increasing toward its limit, and which acknowledges that the finite is infinitely imperfect, but believes that the infinite may be made infinitely perfect.

Consecutive and permanent case numbers are essential. Begin a new series on January 1, 1915.

NOTE.—With this figure the chart recommended by the Clinical Congress of Surgeons was shown. It is an amplification of the above basic plan. It is not reprinted here on account of the expense, but copies may be had by applying to Dr. E. A. Codman, 15 Pinckney St., Boston. The following explanation refers to both this figure and the chart.

division, followed by the numbers of the cases in which this diagnosis was made.

By the use of such a system a large hospital would have a practical, immediate index to all its cases, as easy to use as that of a book. Besides being an index and a scientific classification, it would be an up-to-date statistical table of each disease, class of disease or anatomic regions affected by individual diseases. Besides these advantages, it would be of great assistance in efficiency studies and an incentive toward accurate, careful work for the coming generation.

It is better than the International List, the Bellevue Classification, the Lambert Classification or any other present classification, because its subdivisions are scientific, not arbitrary, and because it is not dependent on a nomenclature, or on our present-day knowledge.

Take cystic disease of the breast, for instance, which has a multitude of names. Whatever we call it, it must appear under "Breast," and the only question is under which pathologic heading to place it. A single cyst might be considered a new growth and so classified. But if our future pathologic advance shows that such new growths are really chronic inflammatory conditions, we have merely to transfer the numbers to the chronic inflammatory division. We must admit that our pathologic knowledge is infinitely imperfect, but to use what we have is better than using mere names. Thus whatever language we speak, and whichever term we prefer for cystic disease of the breast, we shall all know what we mean by each other's names. Rather than discuss names, let us agree to spend our energy on investigations to determine whether the condition is inflammatory, neoplastic or degenerative, and admit that we do not yet know. If we have no opinion, we can put it under "other conditions" and transfer it later when we find the truth. Thus by not using names our chart is made elastic.

This method of classification has one "practical" disadvantage. It cannot be wholly in charge of a non-professional clerk. My answer to this is that it should not be. It is too fundamental and important, and needs the attention of the chiefs of staff or some subordinate who is delegated to this work, because better fitted for it than the chief of staff.

To the chief of staff it should be of the utmost importance to know that he has an accurate index which will enable him to find at once the records of any particular group of cases. He should be constantly reviewing such groups and assigning the unsatisfactory ones to his subordinates for study.

But unless we use a merit system of promotion instead of a seniority system, there will be no incentive for clinical accuracy. *The struggle for existence must be utilized to give the truthful and efficient an opportunity to survive.* Like the individuals in the coral reef, each must be made to add his bit to the advance of clinical science.

DISCUSSION.

THE CHAIRMAN: I happened to be a member of that committee of the Council which looked up the matter of hospital reports in Massachusetts, and we found that almost every hospital in Massachusetts made a report, but that no two of them agreed on the way that report was to be made up. Everyone that replied to our inquiry, I think, exhibited a willingness to cooperate, especially if the plan could be shown to be economical—and there is no question but what this plan is economical. It is much more economical than the present plan, which involves not only a great deal of labor, but much paper, etc.

DR. CODMAN: If there is a little time, I should like to show something I have brought. The Harvard Medical School in China, which has a hospital combined with the Red Cross until recently, was the only hospital which followed the plan which I suggested in its entirety and rendered a report similar to my own report, so that I could get a direct comparison between their work and mine. The work there was done by Dr. Hedblom, formerly a house officer of the Massachusetts General, and now at the Mayo Clinic. By taking these two charts I can show any of you who are interested that it is possible to compare my cases and their end-results individually or statistically with those of that hospital in China.

You can get a general idea of these two charts. They are on the same principle. Each one of these little rectangles contains the case numbers of the diagnoses which he made in China and which I made here. This is Dr. Hedblom's chart and this is mine. The cases, for instance, of malignant diseases of the neck in my chart were four and in his were six. If I wanted to look up some particular form of malignant disease of the neck, all I would have to do is to look in his reports at his six numbers and in mine at four. No matter what diagnosis you mention, I can find it in both charts if an instance of that disease has occurred. It may be such an unusual condition that it has no name, but it would be filed anatomically and pathologically in the proper place.

DR. SAMUEL B. WOODWARD, Worcester: How does your system compare with that of the Memorial Hospital in Worcester?

DR. CODMAN: It is much the same. The way the subdivisions are made is immaterial. I gave my best thought to this for months, and my subdivisions vary but little from Dr. Gage's in Worcester, perhaps because the natural processes of the human mind are similar. Practically you could use the Memorial Hospital chart to compare with mine, although some of the subdivisions are different.

THE CHAIRMAN: The next paper will be on "The Standardization of Hospitals," by Mr. John G. Bowman.

You will remember that several years ago the Carnegie Foundation investigated the medical schools of the country, and it was stated by many at the start that the investigation would not result in any practical benefit and that there was a question as to whether a proper comparison could be made. Some thought it was useless; but a great deal of good has come out of the investigation, in the elimination of inconstant schools, schools that were poorly equipped, and schools that were doing poor work. The natural suggestion following that is to see what we could do in the same way in the investigation of hospitals throughout the country, classifying them A, B, C or D, as the medical schools were classified. A great deal of preliminary work has been done along that line, and Mr. Bowman is the man in charge of it.

THE STANDARDIZATION OF HOSPITALS.*

BY JOHN G. BOWMAN, CHICAGO,

Director, American College of Surgeons, Chicago.

We are in the midst of a world war and are much "tumbled up and down" in our minds. We are also at the beginning of a new era of hospital advancement, and these facts are all closely related. The history of hospitals is a series of waves of advancement, each stimulated by war. Today service and ideals of service will win or lose the greatest contest in history; and what this service means is being hammered into every man, woman, and child in this country. This fact is a benefit of war. And it follows now, as never before in history, that any hospital which is to survive must serve. It must be fair, it must be honest, it must be unselfish, it must be competent. The requirements are a big order to fill.

The impetus of service, which is in the air we breathe today, promises almost a revolution among hospitals. That revolution is already under way, and its further progress is inevitable.

In order to look forward with some intelligence, let us for a moment look backward. About ten years ago the condition of our medical schools was brought sharply to review. We took stock of ourselves. We realized with new force that a medical school is a public institution and that its mission is service. We found when tested by this conception that many established practices of the schools must stop short. For example, it not infrequently happened that

when a chair of surgery fell vacant, the chair would be sold practically at auction to a surgeon. The price sometimes went as high as \$10,000. The successful bidder then took up his trust, not to teach with a true ideal of service, but rather to impress his students with his own attainments. Students, according to his dictates, were not to attempt independent surgery; they were to send their cases to the professor of surgery, and the professor would "treat them right." As for the rest of the course, it was didactic. There was very little laboratory work, and a minimum of the ideal of service which characterizes any real profession.

Again, in one city there were a number of rival medical schools such as these, each with its so-called "runner." Part of the duty of this individual was to get up early in the morning and to meet workmen who looked as though they might be students,—a plumber, perhaps, going to work with his kit under his arm. The "runner" would say to him: "My boy, you are in wrong. You are doing hard work with small pay. Take a course in our medical school and in a couple of winters you will be socially in a better class, and you can make much more money for less work. It's all easy." This appealed to the boy. He would drop his kit and start off for the medical school. After a few winters this boy would enter the medical profession with little conception of what a profession means; he was merely in another trade or "game."

In less than ten years this type of medical school has disappeared in this country. Scores of such schools closed their doors. We have made headway. To maintain a medical school today "for profit" is unthinkable; and in my opinion no intelligent community would tolerate such an effort in its midst.

Comes now from a number of directions a similar questioning into the function of hospitals and of their performance. The questions are many and pertinent; and they spring from good motives. But what will be the result?

In talking on this subject let us not consider that hospital standardization means the making of hospitals alike. Each hospital should be given full play of individualism to render such services as best fulfil the needs of its community. What nonsense, for example, it would be to ask of Harvard University and the University of Virginia to standardize themselves according to a single mould! These institutions grew up out of different conditions, tempers, and demands. Both are rendering priceless services to their communities, and the very individualism of each is a telling factor in its success. In a similar fashion there is place for individualism among hospitals. There are only certain fundamental principles on which we may wisely insist, such as, for example, that the procedure in any department be guided by high professional training and integrity.

* Stenographic report condensed.

Let me explain concretely this last statement. About four or five weeks ago on the Pacific Coast I visited a hospital of about 300 beds. Practically every bed in the building was occupied. The construction was beautiful, expensive, and adequate. But what about the integrity of the institution toward the patient? There was not in that building a microscope or anything that could by stretch of the imagination be called a laboratory. There was not an interne nor a house physician. There was not a case record of any kind. There was an odd x-ray machine, but no one knew how to operate it. They hoped to have a laboratory by and by. The superficial evidence at least was not such as to inspire confidence.

You know what the medical and surgical procedure must be in such a hospital. Surgery without adequate diagnoses, and medicine which bears too close a likeness to sheer guess-work, are inevitable. Nor are the conditions just described exceptional; they are usual over a large part of this country. And the time is arrived when we must take the facts home to ourselves, stop all footless discussion, and act.

What are some of the first things that we have, then, to do? First, the facts with regard to the efficiency of the hospital, and the meaning of these facts in relation to the welfare of patients, must be brought home to the boards of trustees or the governing authorities, whatever they may be. The individual trustee must feel his responsibility; he must realize keenly his position of trust. The hospital is a public institution, no matter who owns it, and it is accountable to the public for the character of its work. A great majority of hospital trustees, in my opinion, have only a hazy idea of what their trusteeships mean. For example, if in one hospital in a community there is a mortality of 18% among appendicitis cases, and in another hospital a mortality of 3% among similar cases, the time has come for many pertinent questions. Do the trustees ask the questions? Has the public a right to ask questions? If you were to be operated upon for appendicitis in that community, would you ask questions?

But to come closer to the situation: what steps may the board take toward honest, competent service? The first answer to the question is that the board may withdraw the privileges of hospital from any doctor who divides fees. This subject is not a pleasing one to talk about. The practice of division of fees is a disgrace to the profession; it is a national disgrace. It means invariably operations performed by incompetent men; it means unnecessary operations, and it means the lowering of the entire profession into a mire of dishonesty. The subject does not need elaboration here.

In about fifteen states of the Union today the practice of division of fees is prohibited by law. The penalty provided is usually to revoke the doctor's license and to impose a fine or a

term in prison, or both. Copies of these laws are now framed and hung in conspicuous places in some hospitals. Certainly in all hospitals, the boards of trustees can take effective means to put an end to the practice in their respective hospitals. Any board is unworthy of its trust which does not squarely meet the issue.

A second leading consideration for the board of trustees is the adequacy of the diagnoses. And this subject leads us at once to the hospital laboratory. Where are the essential physical findings to be made if not in the hospital laboratory? Let me ask you frankly what percentage of surgical operations are performed in hospitals after all data which might throw light upon the illness of the patients have been obtained? In a local medical society recently a surgeon ventured the opinion that not in more than 20% of the surgical cases were adequate diagnoses made. Now what are the facts in each of your hospitals? What are you doing in the way of progress for better conditions? What are your boards doing? What will the public do when it comes to realize fully the vast unnecessary mortality because of negligence of right procedure?

But the acquisition of data in connection with diagnoses is only part of the function of a hospital laboratory. The laboratory serves also as a source of scientific incentive. It is a chief means to keep the physicians and surgeons of a community in line with the swift progress of medicine; and the value of such an influence is a thing which no community can overestimate.

In passing this subject let me make this suggestion: It is that no surgical operation be permitted in your hospitals unless a diagnosis in each case is posted in the operating room in advance of the operation. This diagnosis, then, is to become part of the permanent case record; and before the surgeon leaves the operating room he should dictate an exact statement of the findings and what happened at the operation, which statement is to become also part of the permanent case record.

Now a third consideration,—the keeping of case records. The keeping of complete records is not merely nice bookkeeping. It is a pledge of integrity to the public. It is one of the strongest means at the command of the profession to acquire that position of confidence in our social fabric to which it is entitled. There can be only one science of medicine; and it is the business of that science from time to time to give to the public, in accurate and intelligible form, the results of its work. Further, you in the medical profession should insist that all others who claim to treat or cure human illness, publish accurate and intelligible reports of their work. When such procedure is usual among us, all of the curious mysticism now associated with medicine will disappear, and the barometer of confidence in the profession will rise to an inspiring figure. Dr. Codman has presented an

admirable paper on this subject here this afternoon, and most heartily I wish to endorse his contention.

There are many other subjects which we might discuss this afternoon in connection with hospital standardization. The training of internes and of nurses, financial problems, equipment, etc., are among these. But time here permits only a general survey.

The American College of Surgeons has undertaken with great seriousness a standardization of hospitals in the United States and Canada. Many years and expenditure of much money and effort will be required before telling results are obtained. But to start with, the college asks the good will and coöperation of the hospitals and of medical schools. It asks that, with the highest medical patriotism in us, we band together for the better welfare of those who are ill. The motive is not to criticize for the sake of criticism, nor to destroy, but rather to construct, to lead in a progress of heart and hands and head such as is yet unrecorded in the history of medicine.

DISCUSSION.

DR. MICHAEL F. FALLON, Worcester: Can you tell us what states, if any, have provision for the standardization and supervision of hospitals?

MR. BOWMAN: The State of Pennsylvania has unquestionably taken the lead in this matter. Hospitals coming up to a given standard are allowed some subsidy from the state, according to the number of beds. Under the guidance especially of Dr. Baldy, the state has made great headway toward better conditions. New Jersey and Minnesota are also giving the subject increasing attention.

DR. LESTER NEWMAN, San Francisco: In speaking of the Pacific Coast I would like to ask Mr. Bowman what individual city he has reference to. We have several cities there, as you have on the Atlantic Coast. It would be unfair to speak of the Atlantic Coast as Baltimore, or Boston, or even New York. To speak of the Pacific Coast is just as comprehensive a statement.

MR. BOWMAN: Let me say, first, that in San Francisco, Portland, and Vancouver (I do not know about Los Angeles), there are very well-managed hospitals with excellent laboratories. Vancouver is especially alive to its needs. The particular hospital I spoke of was on the Pacific Coast, but it will be kinder not to say specifically where.

DR. LESTER NEWMAN, San Francisco: In some respects we think we are rather setting the pace, and I speak advisedly. I have spent some of my time in New England and twenty-five years in Chicago, and I am also interested in this as a Californian, and have to speak out. The diagnostic clinic in my mind is one of the means of bringing hospitals to a high standard, and we have two such endowed. They are there to stay, we hope, and their quality is unquestionable. They are equipped with pathologists and all the accessories, and the patients are diagnosed before they are taken into the operating room, which to my mind is a very

important matter in this day of promiscuous surgery. It is a step in the right direction, and I wish to emphasize the fact that there are a few things done on the Pacific Coast just according to Mr. Bowman's ideas, and I am with him every time. It is very important at this immediate time, and I simply want to say that we are with you and working hard.

DR. H. B. HOWARD, Boston: When the College of Surgeons started this idea of standardizing hospitals I felt it was a good beginning. It seems to me that if they formulate clearly the essentials which should be in a hospital for a given amount of surgery, and publish these standards, being careful not to over-standardize, they will find that the hospitals will struggle everlastingly to meet these standards.

So far as my experience goes, it does not seem to me, at least, that there can be very much splitting of fees; that we have need to have very drastic laws against that practice. Personally, I never met a man who I knew split fees in New England, and though I would not want to say there were none in Massachusetts, I cannot think of anyone who would be guilty of that. I practised in the West, as far west as Colorado, for three years and I did not meet a surgeon there who even offered to divide with me 50-50. I didn't meet a surgeon who ever approached me in any improper manner. That was some time ago, and it may be that they have grown worse in the last 25 years.

I believe thoroughly in the matter of progress in standardizing hospitals. There is a great chance for good work in that direction.

I would like to go back to Dr. Codman's paper if I could. So much was said against our whole statistics. The Massachusetts General Hospital tried to omit the statistics of the medical and surgical work the year before I became superintendent, because the trustees thought them absolutely useless. I want to say that it annoyed them so during the year, answering questions and letters about it, that there was no question but that the statistics should be published, poor as they were. I admit that they are always open to improvement. I am glad to see that Dr. Codman makes such an effort and spends so much time on improving the statistics of our hospitals. There is room for more improvement, and I was glad to hear him say that there were no limits to which we could go, because so far as I have seen, this agitation has always been going on. If you will look through the statistics of 25 years ago and compare them with what the ordinary hospital is doing today, you will find that there are distinct improvements, even in the ordinary hospital. They come closer and closer to a correct diagnosis and there is more and more care taken about it.

In regard to the diagram method, there is no question in my mind but that would apply beautifully to the small hospital, but I still question whether you are going to be able to get the diagrams of a large hospital like the Massachusetts General and the City Hospital to synchronize. I don't feel so sure of that as Dr. Codman does. It is a great thing to have started, though, and I know there is room for improvement.

It is the same thing with our insane institutions in the state. Those statistics have been gone over and improved and started upon a fresh basis and re-improved at least ten or fifteen times in my re-

membrance. I am not willing to admit that they have made no progress, but there is room for still more. I think that superintendents will all admit that if you do the best you can to tabulate what is taking place, that that is of importance.

EFFICIENCY TESTS APPLIED TO THE ATTENDING AND HOUSE PHYSICIANS OF THE COOK COUNTY HOSPITAL, CHICAGO.

By JOSEPH A. CAPPS, M.D., CHICAGO,

Chief of the Medical Staff, Cook County Hospital.

FOR the past three years an experiment in efficiency has been carried out with the professional staff of the Cook County Hospital. The principles of the merit system, long in use by the Civil Service Commission, have been extended to the daily work of the hospital physicians. The success of the scheme has been made possible by the enthusiastic interest and devotion of the Efficiency Committee,—a group of specialists not on the staff, who have given time and thought to its perfection. The staff also has coöperated by closer attention to ward work and by sympathetic discussion and criticism, to the end of improving the standards.

A certain amount of expected hostility to supervision developed at first on the part of the staff physicians, accustomed, as they were to independence and authority; but this has melted away as the advantages of the system have become apparent. There is no exaggeration in the statement that never before have the patients been so well cared for and never has the routine medical work been so consistently and thoroughly carried out as under the new efficiency plan.

I propose to present in brief outline the methods employed.

The unit of service is 50 beds, with one senior and one associate attending physician, a senior and a junior interne. The markings are made upon the entire team on a service, each individual contributing his share to the total. The Efficiency Committee gives one to two evenings each month to the task of computing the marks.

The Committee is provided with the following items of information:

- A. Post-mortem records for the month. The number of deaths is about 12 each day.
- B. The bedside diagnosis of each post-mortem case.
- C. The records of 5 histories from each service selected at random.
- D. The reports of the social or welfare workers, with reference to "satisfaction of patients."
- E. Letters from departmental chiefs, regarding excellence or neglect on the part of the staff.
- F. Publications and papers read by members of any unit before medical societies.
- G. A record of the hours spent at the hospital by attending men.

H. A record of attendance at the regular monthly staff meetings.

With this material at hand, the markings are made according to the following efficiency standards, using the mark of 80% as a basis for addition or subtraction:

1. For each hour in attendance in excess of the legal requirement of 18 hours a month, a credit of 1/5 point is given up to a maximum of 3 points.
2. For failure to attend staff meeting, a deduction of 1 point.
3. For each history sheet omitted, a deduction of 5 points. For excellence of histories as a whole a maximum credit of 10 points. For inferiority, a maximum deduction of 10 points.

The following details in the histories are noted in computing the totals:

- (a) Account of present complaint.
 - (b) Account of patient's past history.
 - (c) Account of patient's family history.
 - (d) Account of physical examination.
 - (e) Proper notes on patient's progress during treatment and complete summary upon discharge.
 - (f) Complete description of patient's condition upon discharge.
 - (g) Adequate account of laboratory findings.
 - (h) Quality and completeness of record taken as a whole.
4. For promptness in making and completing records, maximum credit 5 points. For delay in making and completing records, maximum deduction 5 points.
 5. For adequate and complete description of operation or of reduction of fractures, a maximum credit or deduction of 3 points.
 6. For services having during the month five or more deaths and no post-mortems, deduction 2 points. For success in obtaining post mortems, credit according to percentage up to a maximum of 4 points.
 7. For diagnosis checked by post mortem, credit or deduction to maximum of 5 points. The post-mortem data are furnished by the resident pathologist.
 8. For failure to enter clinical diagnosis and fill in diagnostic sheet, previous to discharge or death, deduction to maximum of 5 points.
 9. (a) For publications and articles of merit during the year, a maximum credit of 10 points. For failure in such productive work a deduction is made.
(b) Similar markings are made for the internes.
(c) Special work by internes, approved by the committee may be credited by 2 points.
 10. Certain persons, designated by the Civil Service Commission, examine each ward monthly for cleanliness of patients, floors, windows and equipment and upon the pres-

ence of prescribed articles of equipment, such as clothing, food and medicines. The service unit is given a credit or demerit of 5 points.

11. Welfare workers report on "satisfaction" or dissatisfaction of patients. Credit or demerit, 2 points.
12. For histories returned by librarian to internes for correction, deduction 1/2 point.

For the guidance of the internes there is posted in the examining room of each service a printed sheet of "Standardized Clinical Observations," which outlines the required special examinations of certain groups of diseases. For example, meningitis in every case demands:

1. Blood culture.
2. Spinal puncture, total and differential cell count, culture of fluid withdrawn, and pressure of fluid.
3. Leucocyte count.
4. Examination of eye grounds.

In this way a level of efficiency is maintained throughout the hospital.

Every month the markings of each service during the preceding month are posted in a conspicuous place in the main corridor. A friendly rivalry between the teams is created, and every lazy man is spurred on to his best endeavor in order that his team score may be creditable.

The driving power for this rather complicated machinery is entrusted to the executive committee, which is composed of the president of the staff, the warden and the chiefs of departments. This committee meets one evening of each month, and considers matters affecting the welfare of patients, physicians and scientific workers, as well as broader questions of hospital policy. Recommendations are made for final action to the general staff at its regular monthly meetings. The staff meetings are well attended and made interesting by general discussion of live topics. These meetings are open to the county administrators, the civil service commissioners, to the warden and assistant wardens (superintendents), to representatives of the interne body, and to the heads of the training school for nurses. In this way a free exchange of opinion between the various hospital groups has been fostered, and as a consequence the friction that arises from misunderstanding has been largely eliminated.

This sketchy description of the efficiency system reveals many glaring defects in the attempt to place a value on medical skill and service. Such important qualities as therapeutic skill, surgical judgment and dexterity are not even recognized. It seems impossible to pass judgment upon such subtle personal traits.

The methods are imperfect, but if they are considered only as a means to an end, namely, the development and maintenance of a higher standard of efficiency in the routine work of the hospital, they have been abundantly justified.

Furthermore, they have had no little influence in promoting an interest on the part of the professional staff, not simply in the individual's own ward, but in the hospital as a whole.

DISCUSSION.

Dr. H. B. HOWARD, Boston: An immense amount of work can be done along the lines laid out here by Dr. Capps. All it needs is a spirit of fairness to run through the whole thing, and if the spirit of fairness does run through it, so that real merit counts and credit is given for actual work done, I think any system of that sort will bring good results. I think that it needs only a little time, a little discussion and a little more thorough understanding by the different departments in the hospitals before they make and adopt customs of this sort.

I was in the Presbyterian Hospital in New York City a short time ago, and I think that the custom of recording the time of entering and leaving the hospital on the time-clock had been adopted by the staff. When I was at the Massachusetts General Hospital the Trustees found that the record of the Out-Patient Department in regard to the staff attendance was not being well carried out in the spirit they had asked for. Dr. Capps may remember about it as he was a student there then. The arrangement was made so that a sheet of paper was placed there after that for the men to record their entrance and exit for service. It took only a little interest on the part of the Trustees to find that system so that it went for years, and I suppose it is still going, so that it was almost absolutely accurate and they knew just how much time a man spent there. It was a record, and the man could find no fault with it because he made it himself, and the record was placed in such a conspicuous place that even the one or two who would have made a false record didn't dare to.

I appreciate Dr. Capps' paper very much, and the spirit of improvement which it will bring.

Original Articles.

THE SIGNIFICANCE OF PERSISTENT PAIN OR OTHER SYMPTOMS REFERRED TO THE PERIPHERAL NERVES.

By HAROLD W. WRIGHT, M.D., SAN FRANCISCO,
Clinical Assistant in Neurological and Orthopedic Departments, University of California Hospital.

INTRODUCTORY REMARKS.

ALONG with the advance in specialization there has come the tendency on the part of the specialist to narrow his interest, as well as his proficiency, in the recognition of diseases other than those with which he is particularly equipped to deal. In like manner, the general practitioner, overawed by the rapid advance of specialism, has shown a tendency to the shirking of responsibility for making a reasonably

accurate diagnosis in a long-standing or obscure condition, and, therefore, has allowed the patient, in many instances, to drift from one specialist to another of his own accord, or to drift into the hands of the charlatan, thus wasting valuable time in arriving at a diagnosis, and perhaps undergoing expensive, painful and unnecessary treatment before a diagnosis is reached. Should not the general practitioner and the specialist, also, be sufficiently acquainted with all the general aspects of disease properly to diagnose and hence properly refer the patient for special treatment, if he is not himself equipped to deal with the disorder?

Probably there is no symptom for which so many diagnoses may be offered as that of chronic pain referred along the peripheral nerves. This paper represents an effort to enumerate the most important conditions responsible for persistent pain of obscure origin and to classify them according to their etiology. But before coming directly to this part of the paper, a few remarks on the reflex nervous system are in order.

In general, it may be said that reflex pain is the result of either mechanical or chemical irritation of the sensory nerve endings connected with the sympathetic ganglia and thence referred to the peripheral system, or that reflex pain is due to direct irritation of the peripheral sensory nerve endings, or of the sensory roots of the spinal cord, whence the pain is referred along the ramifications of these roots. It may also be stated, in a general way, that chronic pain is more apt to be due to mechanical irritation than to chemical, *i. e.*, toxic and bacterial influences, and even in the latter case, to mechanical restriction upon the inflamed nerve.

Let us consider a few examples of the reflex mechanism of pain or hyperesthesia or paresthesia:

The gastric crises of tabes are the result of irritation of the posterior nerve roots of the 6th, 7th, 8th, and 9th dorsal segments, and are probably due to a localized low-grade meningitis around these roots. The same mechanism may be responsible for intestinal, laryngeal, ocular, bladder, renal, and even sebaceous and sweat gland and vascular crises. The pain in the epigastrium which accompanies vertebral caries is likewise due to the mechanical irritation of the posterior roots of the 7th, 8th and 9th segments from the pressure of granulomatous products of the disease.

In connection with the whole subject of root pain, it is important to note the fact that the outer layer of the dura is alone sensitive. (See work of Elsberg on Spinal Surgery.)

According to Mackenzie, the sensory reflex of every organ is accompanied by a motor and a visceral reflex. It has been determined, also, that the sensation of pain relative to viscera has the following characteristics:

1. Splanchnic pain is usually in the midline, even if the organ by which it is caused lies on one side, or partly so.

2. Contrary to the pain of the peripheral hyperesthetic zones, splanchnic pain is not relieved by moderate chloroform narcosis.

3. The radiating external pains are never clearly defined.

4. The radiating external pains are felt in deeper structures (muscles, breast) and not in the superficial layers of the skin. (As is true of root irritation.)

5. Artificial stimuli, such as alcohol, cantharides, mustard plaster, the galvanic or faradic currents and hot applications, prevent, temporarily, the passage of visceral stimuli through the spinal roots to the peripheral hyperalgesic zones.

6. Both types of pain, visceral and radiating, are increased by intense emotion, such as fear and anger. (Higier).

On the other hand, chronic reflex pain may be due to peripheral causes, such as bad posture, weak feet, and have nothing to do with direct irritation of the posterior roots or with visceral disease, being dependent on a lack of equilibration of weight-bearing, and hence muscle strain, or to irritation of the synovial nerve of the joint being strained, and hence reflex pain to the other nerves connected with the articular branch. It is only of recent years that the frequency of mechanical conditions, such as bad posture, as causes of reflex pain, began to be appreciated; the work of Goldthwait especially has shown us their significance in relation to healthy visceral function.

We come now to the detailed consideration of types of persistent pain or other nerve symptoms in relation to causation.

A. Cranial Nerves.

1. *Gummatous infiltrations* of the cranial bones may be responsible for radiating headache; the lesion generally begins as an osteoperiostitis, and may directly involve the facial, auditory and abducent, as well as the trigeminal. Similar symptoms may be due to metastatic carcinoma or to exostoses following the fractures of cranial bones.

2. A frequent cause of headache and of neuralgic pain in the face is *cerebral lucis* of the meningeal type. This is frequently overlooked because of failure to make or have made a careful and thorough neurological examination. (Migraine may turn out to be cerebral syphilis.)

3. *Sinusitis* is another frequent condition causing chronic headache.

4. *Brain tumor* is, of course, always to be considered.

5. *Psychic disturbances*, temporary or prolonged, are responsible for headaches, and the psychic disturbance which accompanies grief, fear and anger may aggravate the pain of other causation or bring on its acute phase. But the pain of psychic origin is rarely prolonged or

continuous unless due to the mental impression of physical injury when it simulates pain of organic cause, or when fatigue of the nervous centers is very far advanced, as in extreme neurasthenia.

6. *Arthritis* of the upper cervical vertebrae is not to be despised as a cause of frequent attacks of more or less acute pain radiating along the great occipital nerve throughout its course, or confined to the base of the occiput, where the patient often declares that he has a feeling of great pressure, which he fears is the forerunner of apoplexy or insanity. A stiff neck is not necessarily associated at any time or often with this type of pain; but crepitations in the joints of the neck and elsewhere are frequently observed.

B. Cervico-Brachial Nerves.

1. *Arthritis*, again, is the cause which would first come to mind. Together with the arthritis there may be an inflammatory neuritis, but it is the writer's belief that in the majority of instances the arthritis precedes and provides the mechanical conditions favoring a neuritis, which may be then brought on by trauma of slight degree or by cold. Both the arthritis and the neuritis are, in the last analysis, due to the same cause, *i. e.*, focal infection from teeth, tonsils or other localities. A chronic arthritis generally precedes by years or months the onset of the neuritis, and if the former were treated by measures to secure surgical rest and immobilization of the inflamed joint during the early stages, neuritis would not develop, in all probability. The arthritis may exist either in the shoulder or the cervical joints, in both of which regions an arthritis is predisposed to because of the repeated traumata to which these joints are exposed, and in the case of the cervical spine by faulty posture, especially in people of sedentary occupations. Therefore, efforts to correct or prevent faulty posture serve to prevent arthritis of the cervical spine; this is true of any of the weight-bearing joints of the body, *e.g.*, the knee, foot, sacro-iliac and lumbar joints.

In connection with pain about the shoulder or down the upper arm, a subdeltoid or sub-aeromal bursitis should not be forgotten in making a differential diagnosis.

2. *Pott's disease* of the cervical spine here comes into consideration. Many a patient has been allowed to jeopardize his chances of cure, as well as to suffer needlessly, because a diagnosis was made without a careful examination for muscle spasm in the neck, and without any x-ray of the cervical vertebrae, or if one was taken only the anterior view was made and no lateral view. The clinical signs of tubercular caries are very definite even before the x-ray reveals the disease; the diagnosis should be made on them alone even if the roentgenogram is negative.

3. *Spinal Cord Tumor*: Although this condition is not nearly so common as those above

mentioned, it is one that should always be borne in mind when confronted with persistent pain referred to the brachial nerves, especially if this pain is progressive and of only a few weeks' duration. A careful examination for sensory changes, however slight, in sharply defined areas of the skin, and periodic examinations every few days, are very essential in making such a diagnosis. In cord tumor there is usually a change in the objective symptoms from week to week; thus severe pain may be followed by numbness or other paresthesiae, by localized analgesia or thermoalgnesia, with muscular weakness of an arm and a spastic or stumbling gait. All these symptoms could be elicited before the case came to the inoperable stage if the attendant had the habit of making a careful neurological examination or of having one made.

4. *Diaphragmatic pleurisy* may also cause brachial pain because of the connection of the phrenic nerve with the fourth and fifth cervical nerves.

5. *Aneurysm of the subclavian* is also to be held in mind in reference to brachial pain, when persistent.

C. Lumbar-Sacro Plexus:

Pain in these nerves is probably more often misunderstood than is pain in any other region, because of the complex ramifications of these nerves.

1. *Tabes*: If all the instances in which laparotomy has been performed for the pains of tabetic crises were re-recorded, the evidence would be astounding. But the most astonishing feature of such an inquiry would be the fact of failure on the part of the attending physician and the surgeon to have thorough neurological examinations made when case is first seen.

2. *Syphilitic meningitis* of the lumbar cord is frequently diagnosed as rheumatism or neuritis, or as sacro-iliac strain, because no neurological tests, including the examination of the spinal fluid, have been made. For example, a man forty-five years of age gave a history of a severe fall followed by persistent backache and pain radiating down both sciatic nerves, with coldness and numbness along the outer side of the legs. Because of the history of a fall, and because of the pain being aggravated by forward flexion of the spine, he was put into a plaster jacket. He obtained no relief after several days, and later developed more difficulty in walking, with spasticity and ankle clonus. Finally a lumbar puncture was made and positive Wassermann and globulin tests found in the fluid. Up to this time the pupils had not appeared abnormal. Later, the patient developed signs of fulminating general paresis, and within a year from the time he was first seen he had to be committed to an asylum because of attempting to kill his wife.

3. *Tumors of the Spinal Cord*: These are especially difficult to differentiate early from arthritis of the spine, and if the tumor is of

the cauda equina a diagnosis of sciatica is often made and adhered to until too late. Root pains are present in all these disorders and are the first symptoms, but a careful sensory examination will usually reveal early some degree of anesthesia or hyperesthesia of the root type, combined with hyperesthetic areas above and below, when tumor is present. The diagnosis of caudal tumors is particularly difficult because of the few neurological signs, neuralgic pain being the most prominent and of the same type as that of sciatica, and the sensory changes being confined to a very small area supplied by the fourth and fifth sacral segments, or perhaps only the area supplied by the fifth, near the anus. Furthermore, bladder signs and noticeable paresis of the limbs are absent in caudal tumors in the earlier stages, and patellar reflexes may be unchanged for some time. Tenderness of the spine on percussion over a particular vertebra is a valuable sign in cord tumor, but may also be present in arthritis; an increase in the patellar reflexes may occur in either condition, but the change in the character of the tendon reflexes will progress in cases of spinal cord lesion; the x-ray is of very little help in distinguishing arthritis from tumor because, unless the arthritis is advanced enough to cause hypertrophic changes in the bone, the roentgenogram will be negative.

4. *Aneurysm of the abdominal aorta*, kidney stone, pelvic inflammation or uterine displacement have all to be considered in diagnosing the cause of frequent and persistent pain in the lumbar-sacral plexus. But uterine displacement is not the sole cause, and of less importance than the general postural defects which are associated.

5. *Sacro-iliac strain*, or luxation and lumbo-sacral strain, either from trauma or bad posture, are frequent and perhaps the most frequent causes of chronic pain of the lower back and the sciatic distribution. Such conditions may also produce coldness and numbness of the thighs, and thus give rise to the suggestion of beginning tabes. Sacro-iliac strain causes pain in the great sciatic distribution, whereas lumbo-sacral strain causes pain in the groin, ilio-inguinal and ilio-hypogastric regions, and thus may simulate chronic appendicitis. The sacro-iliac joint is supplied by the first and second sacral nerves, and when this joint is strained the terminal branches of the synovial nerves are irritated, and thus the pain is referred along the distribution of the first and second sacral nerves peripherally, *i. e.*, to the sciatic; or the plexus and its blood vessels may be pulled upon, stretched or lacerated. Weakness of the legs may be complained of in sacro-iliac strain, also increased tendon reflexes may be found; but if these two signs increase in degree, and ankle clonus occurs, a cord tumor, subdural hemorrhage or a meningitis is present. A lumbar puncture or

immobilization of the spine in plaster will serve to settle the diagnosis.

6. *Flat Feet or Weak Feet*: These can produce chronic lumbo-sacral pain because in such conditions there is an extra amount of strain put upon the lumbar and thigh muscles in preserving equilibrium and in walking, and muscle fatigue results. The same is true of arthritis of the foot.

8. *Postural Defects and Visceroptosis*: This is a comparatively new chapter in medicine, but the opinions of Goldthwait and other orthopedic men have been amply confirmed. Too many women and men also have been quickly relieved of long-standing backache and vague abdominal pain and digestive disorder with chronic constipation by simple mechanical appliances to support the abdominal walls and the lower spine and by exercise, to improve muscular tone and posture, to allow of any scepticism as to the value of these procedures or the significance of posture. Faulty bodily mechanics goes hand in hand with faulty physiological function and has a direct relation to many of the complaints of the chronic invalid. Many an appendix has been unnecessarily removed, and many an abdomen explored because these mechanical factors have not been appreciated. It is true that in this class of patients there is frequently a constitutional neurasthenic and psycho-neurotic state, and the correction of postural defects is not the whole story, but such correction is a very great help in overcoming the neurotic element because it lessens fatigue and adds to efficiency, and thus gives encouragement in the struggle of life.

TREATMENT OF THE VISCEROPTOTIC.

By RICHARD F. CHASE, M.D., PORTLAND, ME.

IN another paper,¹ which was based on an observation of 400 consecutive female patients, with reference to visceral ptosis, I have shown that gastroptosis of one inch or more below the navel occurs in about 10% of women, whereas gastroptosis of all degrees (slight and marked) has been observed in from 35 to 50%. With prolapse of the stomach there is always corresponding prolapse of the transverse colon.

From my own and other observations (especially those of roentgenologists) I am led to diagnose gastric prolapse only when the greater curvature of the stomach is found at least one inch below the navel, the lesser curvature being, of course, correspondingly low. Even then, or in case of a prolapsed kidney, I do not always inform the patient of the condition, because I believe that oftentimes such information may be the starting-point of even grave nervous symptoms.

Of the 43 cases of gastroptosis observed in the 400 women I found digestive symptoms in 21%; backache and abdominal dragging, re-

spectively, in 18 and 24%; nervous symptoms in 20%; organic disease, outside of the alimentary tract, in 19%; and constipation in 68%. 73% had lost an average of 13 lbs. in weight.

One of the principal objects of this observation was to determine in what percentage of these severer cases of gastroptosis, treatment of the ptosis itself, or symptoms arising therefrom, seemed indicated. My conclusion was that such treatment is indicated in less than 25% of such cases, because less than that percentage of these patients have symptoms referable to the ptosis. This conclusion, I am aware, is not in accord with the popular view, which seems to be that all patients having one or more prolapsed organs (regardless of the degree) should, necessarily, be treated for that condition. As a matter of fact, all internists realize that many patients having ptosis require no treatment for the affection, because it often gives rise to no symptoms. This is a fact which should be more generally appreciated.

Since the early recognition of visceral ptosis, most of these cases have been cared for by the medical man. You may have noticed of late that much of the literature on this subject has been contributed by surgeons and orthopedists. So much literature, indeed, has emanated from these sources, that I greatly fear the present and past accomplishments of physicians in this line of work may have become obscured. Let us, if you please, consider for a moment what the real facts in the case are. A careful review of the more recent literature on the treatment of ptosis, contributed by our best surgeons, plainly shows that among them there prevails a consensus of opinion regarding surgical treatment. This opinion has been so clearly, if somewhat emphatically, expressed by Dr. J. E. Moore² of Minneapolis that I feel I cannot better present it to you than by quoting what he says:

"Many years ago Glenard enlightened the profession concerning visceroptosis, but the average physician paid very little attention to the subject. With the development of abdominal surgery, surgeons began to take note of these physical defects, and very naturally concluded that these defects were the cause of the patients' suffering, and that the best means of treatment would be mechanical. It is necessary in surgery, as in everything else, to go to extremes to find what the happy medium is. These operations did only temporary good and, on the whole, were very disappointing, but they did not kill people; and while they were rather hard on the present generation, they have enabled us to demonstrate that operations are not curative in these conditions, and we have relegated these patients to the physician, where they rightfully belong, and have very materially helped the physician to establish the ground on which he now stands. In this way these operations, now discredited alike by surgeons and physicians, will prove of untold value to future genera-

tions. These scars should not be placed to the discredit of the surgeon, but should be looked upon as milestones of his progress, for, having demonstrated the inefficiency of surgery, he honestly turns these patients over to the physician. Real surgeons no longer perform these operations. It is only the 'would-be' surgeon, the one without personal experience, or the honesty or ability to profit by the experience of others. Our worst difficulty now is that half-baked physicians are still referring these cases to us for operation."

So much for surgery. As to the orthopedist, he has, undoubtedly, contributed to our knowledge regarding the effect of bad posture on visceral prolapse, and he has very probably fully emphasized the importance of this feature of the subject, and the general physician has profited thereby. Thus it would seem that visceroptosis is not generally to be considered as a surgical condition; that the orthopedist's chief claim to treatment rests mainly on the correction of bad posture, a condition which in most cases the medical man should be able to care for; and, finally, that visceroptotics generally should be cared for, as in the past, by the medical man. With this premise, let us proceed to the medical treatment of the visceroptotic, that large class of individuals, mostly women, who often present an endless variety of symptoms, and in whom there is found prolapse of one or more of the abdominal organs. Of these patients, it is well to bear in mind that there are two quite distinct types, when classed as to the origin of the condition, viz: (1) the congenital or "virginal" type, as termed by Rovsing, and (2) the acquired type.

Prophylaxis. In most of the acquired and in many of the congenital types the degree of ptosis and the condition, as a whole, might have been ameliorated, had suitable measures been taken in these cases, in the beginning of the condition. Such measures are: (1) avoidance of too frequent pregnancies, (2) proper care of the patient after confinement, (3) the cure of existing constipation, (4) advice and measures to obtain good posture, (5) the proper use of corsets, if they are to be worn, (6) the avoidance of overwork, worry, and too strenuous social duties, and (7) advice as to general exercise, hygiene, etc.

As a rule, it is the family physician who first has the privilege of prescribing these measures, for it is he who first comes in contact with these patients. And let me state here, that in no other line of his work is there greater opportunity to benefit womankind and, indirectly, mankind as a whole.

Of the severer cases of visceral ptosis, I am sure we have all been impressed with the generally "run-down and played-out" condition of the patients, both physically and mentally. Rest, then, both physical and mental, is one of the very first requisites of treatment, and it

should be prescribed according to the needs of the individual case. Physical rest may vary in amounts from 30 to 60 minutes on a couch after each meal (when the stomach contains its greatest weight), to complete rest in bed from one to several weeks. With the patient in the horizontal position, it has been shown by the x-rays that motile prolapsed organs return nearly, if not quite, to their normal position, while if the foot of the couch or bed used is elevated 10 inches or more, the return of such organs to normal position, and the consequent relaxation of their ligaments, is assured. This is a simple and beneficial measure, too often neglected.

If the necessary mental rest cannot be obtained at home, as is often the case, then the patient should be removed to some place where such rest may be procured. For the neurasthenic type such a step is often necessary.

Weight. In practically all cases of marked degrees of ptosis the patients are poorly nourished, and in all severe cases of acquired ptosis there is some loss of weight. Loss of weight is believed by many to be one of the chief causative factors of visceral ptosis. In any event, to effect a cure of the ptosis and the patient, the weight must be restored in whole or part. This restoration of weight must be procured through food which, of course, must undergo proper metabolism. Proper metabolism, however, cannot take place if, as often happens, some derangement of the digestive system exists, no matter whether the derangement is of functional or organic origin.

The nature of the trouble must be determined by the usual measures employed in the diagnosis of digestive diseases. The ascertainment of the digestive condition not only directs, to a considerable extent, the proper drug and dietetic treatment, but it further aids in the cure of some patients by the assurance, if such is the case, that no imaginary serious condition exists.

The digestive disturbance known, and relieved or overcome, the question of diet and nutrition becomes a simple one, whereas blind attempts to increase nutrition are often failures. In the beginning of treatment the diet is dependent largely on the existing digestive condition, later the chief question is how much food to use. This question may be settled either by weighing the food and calculating the number of calories represented, or by weighing the patient. Personally I prefer and employ the latter method, even though the patient is confined to bed. A sufficient increase in the patient's weight is the surest proof that the amount of food consumed is sufficient, even though the quantity may seem to both physician and patient to be insufficient. The demonstration to the patient of an increase of weight usually has a favorable psychic effect, as it convinces her that you are accomplishing something, and she will naturally believe that you can do yet more.

The various phobias and whims of the patient regarding diet must be overcome. By proper tests of the stomach you must prove to her that your knowledge of her digestive functions is pretty exact, and that her digestive organs are capable of taking care of the quality and quantity of food which you prescribe. But remember that "in the long-run" such accomplishments are not obtained through bluff; you must, as a rule, deliver the goods.

Constipation, as stated, occurred in 68% of the cases observed. This condition is not only very common in this class of patients, but its severity is hardly equalled by any other class. I wish to state emphatically that most cases of constipation are curable, and by medical measures; and I mean by this that after such treatment, patients may have regular movements of the bowels, and without the aid of drugs, enemata or other like measures. The general physician pays too little attention to this condition. As a rule, his treatment is careless, inefficient and consequently not curative. I cannot here enter into the finer details of treatment. Determine if the constipation is of the atonic or spastic type, and the cause, if possible. Then secure for the patient a regular movement of the bowels, perhaps with cascara if of the atonic type, or with belladonna or hyoscyamus if of the spastic type, in conjunction with diet and other measures, gradually reducing the dosage of medicine until none is required. Regularity of habit *must* be obtained by the above means, the Leube oil treatment, or by other measures.

Diet is the main feature of this treatment, and a correct diet must be employed *both* during and after the cure. The quality and quantity of food must be definitely prescribed and the physician *must see to it* that such diet is used; this necessitates at least weekly visits to the physician.

Diet in constipation becomes a simple matter if one recalls that food acts favorably on the intestines in three ways: (1) by its mechanical effect, stimulating peristalsis; (2) by its sugar content, stimulating intestinal secretion; and (3) by its acid content, also stimulating peristalsis. Some foods, of course, act favorably through all three of these agencies. A sufficient variety of food can and should be prescribed, provided no contraindications exist, such as diabetes, certain stomach disorders, etc. Special trunk and general exercises must be insisted upon in some cases, if the general condition of the patient permits; but *do not* make the mistake of urging exercise for these patients when it is rest that is first needed.

After the time for exercise has arrived, I often have the patient wear a pedometer, at first, to guard against too much walking, later to learn if she walks enough.

Special trunk exercises should be taught the patient; they are beneficial to both the constipation and the ptosis, to the latter by strength-

ening the abdominal muscles, and also by improving the posture. Hydrotherapy, massage, and electricity may be desirable in some cases; they are usually not essential. Severe cases of constipation are rarely or never cured by drug treatment alone. In the proper treatment of this condition, perseverance must be insisted upon and often stimulated by the physician.

I cannot here discuss spastic constipation, often accompanied by colitis, or other bowel conditions; suffice it to say that they, like *all other* complicating affections, must receive their proper attention.

I fear that already the various measures recommended may, to some, seem elaborate, even impractical, but I assure you if one does not employ these or other equally beneficial measures he will continue to lose this class as patients.

Remember always that in the care of these cases, it is the patient and her entire condition, not alone the ptosis, that you must treat. Abdominal support, to many physicians, appears to be the "cure all" for these patients, and it seems to matter little whether the supporter supports or not. That the benefits derived from some supporters is purely mental, cannot be doubted. If a patient's abdomen is flat or concave, support of the abdominal viscera cannot be obtained, even if the graduated pads are used. For cases in which support may be obtained, I occasionally employ the Storm binder, especially for men. For most women, if they wear corsets, and if support is obtainable, I obtain it through a suitable corset, properly fitted and properly worn. Such a corset not only furnishes support, in certain cases, but it also aids in correcting bad posture; it compels a woman to sit and stand properly. Several of the worst cases of ptosis that I have encountered in private practice have been cured without the aid of an abdominal supporter or a corset, consequently I feel that such support is not really essential to a cure, in some cases.

By the term "cure," I mean the overcoming of all curable symptoms, and the securing of a partial return of the prolapsed organs to their normal positions. Rarely or never are prolapsed viscera completely restored to their normal position, and such restoration is evidently not essential to a cure. Through abdominal support and a general increase in the patient's strength, abdominal dragging and backache (met in about one-fifth of these patients), when due to ptosis, usually disappear.

Simple prolapse of the kidney, as a rule, causes no symptoms, and consequently requires no particular attention; but if it seems desirable to furnish support for the kidney, such support may be obtained by the methods mentioned, in so far as support is obtainable.

The nervous or mental element presented by some of these patients is often the most difficult feature of the whole condition to overcome.

Some men seem to attribute these symptoms to the ptosis, and believe that by overcoming the ptosis, the symptoms will disappear. But that such is not the case is proven by surgery, because even successful gastropexies and nephropexies often fail to relieve these symptoms. Like many others, I look upon the ptosis merely as a part of the generally debilitated condition of these patients, and I feel that the ptosis is quite as often the result, as the cause, of a general condition. Consequently, I meet the nervous symptoms in precisely the same way as I would meet nervous symptoms in patients not having ptosis.

My first object in treatment is to relieve the patient of her physical ills, by the methods already set forth. If I am successful, I have gained the patient's confidence, an essential to successful treatment. Her mental ills, her whims, and her phobias, I next endeavor to set right. For example, many patients have erroneous ideas regarding diet and digestion. I show and prove to the patient wherein she is mistaken, not by mere say so, but by convincing acts and facts. The same principle is employed in treating her other erroneous ideas.

Occasionally a case is met in which it is difficult or even impossible to overcome this nervous element; on the other hand, the successful treatment, obtainable in most cases, is a gratifying accomplishment.

A complete consideration of the treatment of the visceroptotic would require a paper much longer than this one, so that I am content if I have succeeded only in presenting for your consideration the following points:

1. That visceral ptosis, of sufficient degree to be of clinical significance, is not as common as generally believed.
2. That surgery is rarely required in the treatment of this condition.
3. That constipation is curable, and by medical means.
4. That abdominal support, although desirable, cannot be obtained in some cases.
5. That the treatment of these cases must be directed to all of the patient's physical and mental ills, and that the ptosis is often a secondary consideration, but which in the mind of the patient has become of considerable importance merely from the knowledge of the fact that such a condition exists.

RELATIONS OF PRENATAL AND POST-NATAL WORK.

BY MICHAEL M. DAVIS, JR., PH.D., BOSTON,

Director of the Boston Dispensary.

GERMANY, in October, 1914, at the outbreak of her war, appropriated the sum of two million marks a month for use in aiding women at the time of maternity; this being in addition to an already well-developed system of maternity benefits. Such a sum, calculated on a per capita basis, would mean \$60,000 a year in the city of Boston,—a larger amount than is now expended for the prenatal and postnatal services of the Boston Department of Health, the Instructive District Nursing Association, and the Baby Hygiene Association, all put together. If Germany deemed such a sum well spent in conjunction with a war undertaken for her purposes, what amount may our nation think wise to put forth, with the aim of protecting the future citizens of "a world made safe for democracy"?

Undoubtedly, the expenditure of public and private funds for the welfare of babies and mothers will depend on our realization of a need and on our confidence that the mode of its expenditure is wise. On the latter question, that of method, the data published in THE BOSTON MEDICAL AND SURGICAL JOURNAL of January 4, 1917, had some bearing. The information collected in the present paper leads on from that point.

The conclusions of the article just mentioned, as to the benefits of prenatal work, were summarized as follows:—

"1. A comparison of the death-rates of 731 babies whose mothers received prenatal care in five wards of the city of Boston during the two years 1914 and 1915, shows that the death-rates were reduced to one-half or one-third those found among babies not receiving prenatal care in these wards during the same period.

2. This reduction is found among babies during the first week of life, during the first month of life, and during the first year of life, taken as a whole.

3. The proportion of still-births, in each year, is only half that among the general population.

4. As it is known that only a small proportion of these babies received any other organized medical or nursing supervision, the reduction in death rate is apparently to be attributed to the prenatal work."

Since the publication of this paper valuable confirmation has arisen from New York. In the Bulletin of the Department of Health of New York City for February 24, 1917, is printed a report of the prenatal work during 1914, 1915 and 1916. Comparison of the death-rate among the prenatal cases with the general death-rate among babies in New York showed a marked reduction, and this, as the following table indicates, parallels closely our Boston data.

TABLE I. COMPARISON OF THE DEATH-RATES AMONG PRENATAL CASES WITH THE DEATH-RATE AMONG GENERAL CASES OF BABIES IN THE CITY OF NEW YORK AND IN FIVE WARDS OF BOSTON DURING THE YEARS 1914 AND 1915.

	DEATH-RATE OF PRE-NATAL CASES UNDER ONE MONTH OF AGE		DEATH-RATE OF GENERAL CASES OF BABIES OF THE SAME AGE PERIOD	
	BOSTON	NEW YORK	BOSTON	NEW YORK
1914	17.3	19.5	45.3	36.6
1915	25.0	26.0	38.3	35.9

It is certainly noteworthy that the death-rate of babies under one month of age, who received prenatal care, is practically identical in both Boston and in New York during these two years.

It is no less striking that the *reduction* in the death-rate under one month of age, produced on account of, or in conjunction with, the prenatal work, is closely similar in the two cities. In 1914 the prenatal cases show a death-rate (under one month of age) of 38% of the general cases in Boston, and of 53% of the general cases in New York. In 1915 the corresponding figures are much closer, being 67.6% and 72.4%, respectively.

In the authoritative address of Dr. J. Whitridge Williams, printed in the *Journal of the American Medical Association* of January 9, 1915, it was estimated that the application of prenatal and obstetrical care, according to the standards outlined by Dr. Williams, would have been capable of reducing the mortality to 59% of that which actually occurred without the prenatal care. Dr. Williams' mortality rate was taken to include all deaths from the seventh month of pregnancy up to two weeks after delivery, and his estimate is not, therefore, strictly comparable with the Boston or New York figures. It is, however, worth noting that the average reduction in death-rate up to one month of age, as shown by the above figures in Boston and New York during 1914 and 1915, was 58%.

On the basis of the data secured in Boston and New York and of Dr. Williams' estimate, it seems conservative for us to estimate that well-organized prenatal work may be expected to reduce the mortality of babies under one month of age by 33% under what would occur without such service, and of babies up to one year of age by fully 40%.

There can be no doubt that the reduction in the death-rate is not only due to the nursing care and advice given to the mother and family during the period of pregnancy, but also to the improvement in obstetrical and post partum care, which is a direct or an indirect result of the attention of the nurse. In this respect a distinct contrast appears between the two cities. In New York, 64% of 898 prenatal cases were delivered by midwives in 1914, and 61.9% of 1442 cases in 1915. In Boston practically no cases were delivered by midwives, the majority (60%) of the mothers being attended by the

out-patient service of the Boston Lying-in Hospital. In New York, in 1914, 8½% of the cases were delivered in hospitals (7.4% in 1915) while in Boston the hospital deliveries were under 4%. This marked divergence in the obstetrical service is not, however, accompanied by any noticeable difference in the death-rate of the babies during the first month of life.

EFFECT OF PRENATAL WORK ON BABIES OVER ONE MONTH OLD.

Since the publication of the paper in THE BOSTON MEDICAL AND SURGICAL JOURNAL last January, there has been time to make a further study of the 1915 prenatal cases. Inasmuch as every one of the babies who had received prenatal care was followed through to the end of its first year of life, the study of all the babies born in 1915 could not be completed until after the close of 1916. All deaths occurring among these babies during 1916 have been tabulated, the age, cause of death, etc., being recorded. A similar study had previously been conducted for the babies receiving prenatal care in the same five wards of Boston during 1914.

We are thus able to state for these two years the number of deaths which occurred between the ages of one month and one year, among the 731 babies who had received prenatal care. The following figures were secured in this way, and in the next table are compared with the death-rate during the same age period of all the other babies in the same five wards who did not receive prenatal care.

TABLE II. DEATH-RATE OF BABIES WHO HAD RECEIVED PRENATAL CARE IN FIVE WARDS OF BOSTON DURING 1914 AND 1915. AGES: ONE MONTH TO ONE YEAR.

COMPARISON WITH CORRESPONDING BABIES WHO HAD NOT RECEIVED PRENATAL CARE.

PRENATAL CASES. DEATH-RATE PER 1000 LIVING BIRTHS.		NON-PRENATAL CASES IN SAME WARDS		PER CENT. REDUCTION
DEATH-RATE		DEATH-RATE		
1914	20.2	1914	62.8	68%
1915	33.2	1915	58.3	42%

This table shows that between the ages of one and twelve months the death-rate among the prenatal cases was far less than among those not receiving prenatal care. The reduction was 68% in 1914 and 42% in 1915. This certainly tends to indicate that the effect of the prenatal work is substantial, even after the close of the first month of life.

The prenatal work as conducted by the nurses of the Instructive District Nursing Association of Boston does not continue beyond two weeks after the birth of the child. Whatever effect is produced by the prenatal work upon the health of the child between the first and twelfth month of life must, therefore, be due: (1) to giving the child a better physical start; (2) to educat-

ing the mother in the care of her baby; and (3) to the promotion of breast feeding. No data exist for determining the relative importance of these three factors.

To what extent did these prenatal cases between the ages of one month and one year receive other organized medical and nursing service? The chief form of such service in Boston is that furnished by the Baby Hygiene Association, with its "milk stations," its conferences for mothers and babies, and its trained corps of visiting nurses. These nurses are not the same as those of the District Nursing Association who carry on the prenatal work. Most cases (two-thirds of the 731 cases studied) were referred by the district nurses to the Baby Hygiene Association, but only 17 or 18% actually went to the Baby Hygiene Station (17% in 1914, 18% in 1915).* Thus over four-fifths of the prenatal cases did not receive this medical supervision between the ages of one month and one year, and the lowered death-rate shown in Table No. II must be attributed mainly to the prenatal work.

RELATIONS BETWEEN PRENATAL AND POSTNATAL WORK.

Prenatal work kills two birds with one stone. It benefits the mother and the baby also, and shows such results for both that it should be regarded as the basis of the campaign against infant mortality. Historically, the development of the infant welfare campaign in this country began with the baby, often merely with providing pure milk for babies. It has come to emphasize education more than milk; and is advancing to include obstetrical and prenatal care. Logically, prenatal care is the foundation of the campaign against infant mortality, and as the public comes to appreciate its practical value and far-reaching human significance, prenatal work will assume the place which it should. Its extension is now proceeding. Postnatal work, however, was and still is the psychological point of approach, because a baby has for most people a keen dramatic interest. The emphasis of the infant welfare campaign, however, has shifted, and must further shift, from Milk to Motherhood.

This does not mean that postnatal work should be abandoned, or even diminished. Its well-established forms have demonstrated their value. It does mean that there should be a new emphasis in the infant welfare campaign and some change in relationships between its two chief branches. Surely it would be good for babies and their mothers if a prenatal service, followed in every case by postnatal service, reached every baby and every mother. But is there any community in which resources are yet

* It would be interesting to compare the death-rates of the cases which received both forms of care with those receiving only one. The number of cases is too small to render such a comparison possible.

sufficient even to approximate this ideal? In Boston, for example, about 20,000 babies are born annually. In 1915 the Baby Hygiene Association reached 4792; the prenatal work of the District Nursing Association reached 2536. Allowing for babies reached by both, the total number of individuals reached by these two large agencies for the prevention of infant mortality was about 5900, or less than one-third of the total number of babies in the city. The usual limitation faced by public or private organizations in every city is, of course, lack of money. When the number of cases actually reached is so far below the number who need to be reached, surely a selection must be made. What principles should guide this selection?

1. A nurse who has followed mothers and babies up to two weeks after confinement is in an excellent position to select those babies who particularly need postnatal care. Babies who are known to the nurse who gave the prenatal care, as delicate, or likely to be weaned early, should, without fail, be brought over to the postnatal service. The prenatal nurse can be held responsible for this.

2. The routine reference of every prenatal case to the postnatal service is probably not so valuable as the concentration of postnatal work upon the cases selected by the prenatal nurse for a definite reason.

3. The prenatal nurse should be the same as the postnatal, for thus continuous and efficient service will be vastly facilitated. Otherwise the prenatal nurse may be held responsible for the actual transfer to the postnatal nurse of the cases selected.

4. Many babies who have not received prenatal care and who are delicate, bottle-fed, or otherwise needy, require particularly the postnatal service. Some babies who have had the prenatal service, may, before the end of their first year, develop conditions which the postnatal service would benefit.

5. The selection of babies of these classes requires a definite effort to reach them on the part of the postnatal service, partly through publicity and partly through canvass of districts by nurses, or otherwise. Rightly placed effort in selecting or hunting up needy cases is as valuable as effort spent in caring for cases. Until prenatal or postnatal services can be extended to reach the entire population of a district, the splendid slogan of the infant welfare campaign, "Keep Well Babies Well," needs to be supplemented by such war-cries as: "Keep Sickly Babies from Getting Sick"; or "Before You Wean Your Baby, Take Him to a Health Station."

The presence of war lends timeliness to this point. High prices of food are bringing pressure upon families of small means. Adequate food supply comes harder; and in not a few instances is curtailed. Milk seems one of the first articles to be cut down or diminished. With little babies, for whom milk in some form is a

necessity, condensed milk or patent food may be substituted more than usually for the seemingly expensive fresh milk. Also, some increase in the employment of women may be expected to occur. Shall we have less breast nursing in consequence of more mothers at work, and of a less adequate food supply for mothers, whether they are at work or not? Shall we face a lessened supply of milk, and the more extended use of substitutes for milk, among the bottle-fed babies? We cannot tell in advance how much these evils will extend or be aggravated by conditions of war-time. We may be reasonably sure that needs and evils of this sort, which have existed in some measure in the past years of peace, will not pass away, but will rather be greater during this period of war, unless special and unusual efforts are made to meet them. Unless the funds available for prenatal and postnatal work can be largely increased so that all the mothers and babies who need help can be reached, there should be a *planned selection* of the babies received for postnatal care.

Without doubt the scientific foundation for public health campaigns against infant mortality, tuberculosis and other ills, is the population basis. The total population and also the total number of babies, or other groups affected by the campaign, should be known for each district; the district should be organized with a view to reaching all or as large a proportion of the total as possible; the test constantly applied to the work should be the proportion of cases reached to the total possible cases in the district. Such a plan is now becoming gradually familiar through the development of local health centers in various cities. One of the first steps toward it is reducing the number of different agencies, or more closely coordinating the different agencies which work within a district in related fields, particularly in such closely related fields as prenatal and postnatal work.

When, however, local conditions do not permit of doing infant welfare work on a population basis, or when inadequate funds would compel a few districts only to be covered, then the policy of a carefully planned selection of cases, especially for the postnatal work, should be adopted, as a means of applying effort where it will count for most.

Such a campaign and such conscious selection of cases means a militant rather than a recipient attitude on the part of the organizations doing prenatal or postnatal work with babies. It may mean systematic canvass of districts by nurses. It certainly would be aided by aggressive publicity from a central and authoritative source.

A program for the protection and conservation of infant life must aim to *make it possible for every mother to have prenatal nursing service; for every baby who is delicate or who is bottle-fed, or sickly, to be under the skilled supervision of the doctors and nurses of babies' health stations; for every mother who is nursing a baby to have sufficient food and sufficient milk*

for herself and her child; for every baby who is bottle-fed to have enough and good enough milk at a price which its parents can pay; to enable every mother and father to know where and how these benefits can be obtained at their expense when they can meet it, or free if they cannot. Such a program is vital to the community in peace-time. In war-time it is the same, only raised to a higher power.

Book Reviews.

Health and Disease, their Determining Factors.

By ROGER I. LEE, M.D., Professor of Hygiene in Harvard University; Visiting Physician, Massachusetts General Hospital. Boston: Little, Brown & Co. 1917.

This new work on personal hygiene, preventive medicine and public sanitation may be regarded as the author's first extensive contribution from the foundation whose professorship he holds. It represents essentially a series of lectures before classes in Harvard University and may be regarded as a summary of the author's teaching in his department. It should constitute, therefore, a textbook of definite value to students, but its field of service will be much wider among physicians, public health workers, and the community at large. It is particularly to be commended for the sanity of its general and specific points of view and for its felicity of phraseology and illustration. To those who know him, the author's personality is pleasantly presented in these pages; and to those who do not, the acquaintance with its wholesome and vigorous common sense will prove one of the desirable attractions of this volume.

Clinical Tuberculosis. By FRANCIS MARION POTTENGER, M.D. St. Louis: C. V. Mosby Co. 1917.

This work of Dr. Pottenger's consists of two large volumes, each containing over 700 pages. There are nearly 200 illustrations, charts and plates. The two volumes together weigh over seven pounds and would appear somewhat unnecessarily large and cumbersome. Three, or even four, smaller volumes would have been easier to read and handle.

In reviewing such a book as this, one must first know the purpose for which it was written and the place it is intended to fill. As a textbook, or indeed, a book of reference for the general practitioner, it is hardly available. The information sought for is undoubtedly to be found within its covers, but is to be found only with

difficulty, while its size and cost would daunt the average busy doctor. As a reference book for specialists, sanatorium men, and others especially interested in this subject, this book will prove of great value on account of its wealth of detail and references to original sources. It has this great difference from a volume to which various men have contributed articles, in that the book is imbued from cover to cover with the personality of the author. His opinion and his alone, is what one gets in regard to any subject. The references to other investigators are largely from German sources; American, English, and French writers are in the minority.

Dr. Pottenger, as stated in his introduction, has approached his subject from the broadest standpoint. "Anatomy and physiology, both normal and pathological, have been made the basis of my studies; and visceral neurology has received unusual attention. I have endeavored to approach the study of tuberculosis from the standpoint of internal medicine in its broadest sense."

Indeed, it is open to question as to whether or not the subject has not been approached from somewhat too broad a point of view. Over sixty-seven pages are devoted to tuberculosis and the nervous system; forty pages to "compensatory changes in the thorax and abdominal cavities resulting from pulmonary tuberculosis"; forty pages to "fever in tuberculosis," and twenty pages to "psychotherapy." One is greatly impressed and somewhat overwhelmed by the tremendous amount of information in these two volumes, and, likewise, one is tempted to ask whether this information would not do more good if it were in briefer form and more available to those who need it most—the general practitioners.

Nevertheless, this work of Dr. Pottenger's is a remarkable one and one that any student in tuberculosis will do well to secure and to study carefully. To attempt to read these two volumes consecutively would be a well-nigh impossible task: to pick out here and there the countless points of interest and value, a delightful one.

Who Is Insane? By STEPHEN SMITH, A.M., M.D., LL.D., New York: The Macmillan Company. 1916.

The author of this volume was commissioner in lunacy of the State of New York from 1882 to 1888, and evidently was much interested in various phases of the problems of mental disease. This book is not a treatise on insanity, or even a scientific treatment of any single phase of the problems, medical or sociological, which are discussed by the writer, but rather a pleasant, rather discursive chat on a variety of these topics, often suggestive, and always pleasantly written.

Medical and Surgical Journal

Established in 1812

An independently owned Journal of Medicine and Surgery published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, AUGUST 30, 1917

EDITORS.

ROBERT M. GREEN, M.D., *Editor-in-Chief*.
 GEORGE G. SMITH, M.D., *Assistant Editor*.
 WALTER L. DERRAGE, M.D., *For the Massachusetts Medical Society*.

COMMITTEE OF CONSULTING EDITORS.

WALTER B. CANNON, M.D. ROGER I. LEE, M.D.
 HARVEY CUSHING, M.D. ALLAN J. McLAUGHLIN, M.D.
 DAVID L. EDSALL, M.D. ROBERT B. OSGOOD, M.D.
 REID HUNT, M.D. MILTON J. ROSENAU, M.D.
 EDWARD C. STREETER, M.D.

ADVISORY COMMITTEE.

EDWARD C. STREETER, M.D., *Boston, Chairman*.
 WALTER P. BOWERS, M.D., *Clinton*.
 HOMER GAGE, M.D., *Worcester*.
 JOEL E. GOLOTHWART, M.D., *Boston*.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.50 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one p. m. Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscriptions, or advertising department of the Journal, should be addressed to

ERNEST CREGGOT, *Manager*,

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

SCHOOL OF INSTRUCTION FOR HEALTH OFFICIALS.

As a part of the campaign of the Committee on Public Health of the Massachusetts Medical Society to stimulate the interest of physicians in the public health and to enable them to bear more efficiently the share of responsibility for the prevention of disease for which their training naturally fits them, comes the announcement of the Convocation and School of Instruction for Massachusetts Health Officials. The convocation is to be held in Boston on the 4th, 5th, 6th and 7th of September, directly under the auspices of the Committee on Public Health, but with the endorsement and coöperation of the State Department of Health and the Massachusetts Association of Boards of Health.

The school will be the first of its kind in Massachusetts, although the plan has been favorably considered by the State Department of Health and by the Massachusetts Association

of Boards of Health, and has been used with good results in about half of the states in the Union, but especially in New York and Kansas, where the work has reached its highest development. In brief, it consists of a short course of lectures, demonstrations and clinics, taking up the subjects in the field of public health which are most important from the standpoint of local health authorities. The subjects are those in which every progressive practitioner should take an interest, and will be presented in the most elementary and practical form, but in each case by authorities who are fitted to give the most up-to-date information in their particular lines, and who will be ready to answer questions which may be asked by those who attend the lecture. The Committee appreciates the fact that it is hard for practising physicians to get away, and so has arranged the course with a view to cramming the greatest possible amount of valuable and practical information into a short time, and no time will be spent in receptions, addresses of welcome, or other formalities.

The program is not wholly completed as this number of the JOURNAL goes to press, and, in consequence, cannot be printed here, but advance copies will be mailed to all boards of health in the state, and as far as possible, to all school physicians. Among the features already settled are: a symposium on The Board of Health Laboratory in Towns and Small Cities, to be held on Tuesday afternoon at the laboratory in the town of Arlington; a clinic and discussion of the Diagnosis and Treatment of the Common Contagious Diseases, to be conducted by Dr. Edwin H. Place on Thursday morning at the South Department of the Boston City Hospital; a discussion and clinical demonstration of Minimum Diagnostic Standards for Tuberculosis, Friday morning by Dr. John B. Hawes, 2d, at the Massachusetts General Hospital; and a symposium for school physicians at the Evans Memorial Hall on Thursday afternoon.

The course is free to all members and employees of Boards of Health, whether medical or lay; to school physicians; and to all other physicians who are interested. Owing to the necessity of making especial efforts to conserve the health of the civil population during the war, it is hoped that all who can come will do so. Over 400 preliminary notices were sent out to physicians in the Commonwealth, and up to the time this article was written, about seventy per cent

of the replies received indicated that the writer expected to attend all or part of the lectures, while twenty per cent. additional said they would come if their municipality would pay their expenses. Since the salaries for municipal service are small and the expense of attending are rather large, even if the loss of time be disregarded, the Governor has issued an appeal to the Mayor or Board of Selectmen of every city or town to pay the expenses of one or more representatives to the convocation. Where this is not possible, it is hoped that the Board of Health may pay the expenses of a representative.

THE SPHERE OF SOCIAL MEDICINE.

No better illustration can be had of the need of attention to the patient, and the possibilities for functional and social reconstruction beyond his discharge from medical or surgical care, than by the excellent work done in Europe in this regard. The question of bringing the wounded and crippled soldier back to life, of training him to useful occupation, has well nigh been solved. At any rate, it has opened a new field in constructive medicine. It is not sufficient to cure or to heal a wounded member of the body unless that member of the body can be restored to usefulness. Any treatment that is undertaken must be undertaken with an eye to its usefulness subsequent to discharge, otherwise the member might better not be saved. The same idea, in a larger way, may be applied to the individual as a whole. It is not enough to cure disease or to alleviate symptoms unless the case is followed up so as to prevent the recurrence of the social conditions at the bottom of so many diseases, and to determine for the individual suitable occupation, which he can do despite any remaining defect, and which is not inimical to his physical or mental constitution. Vocational guidance for the young is an easier problem than vocational guidance for the handicapped, but in the latter is more necessary in order to relieve society of a burden and to make productive those who would otherwise be parasites.

Most institutions have established social service departments. It is for them to prevent returns to the institutions by helping the former patients to rehabilitate themselves. Through

them a better understanding of the home and social environment can be had, so necessary in progressive therapeutics. In mental diseases it is now well recognized that the etiological conditions—the psychogenic or social causes—are very largely environmental. Relapses can very largely be prevented by careful follow-up work after discharge, with a view to remedying those environmental conditions which act as psychogenic factors in the causation of mental disturbances. The social medical worker can obtain history as can no one else, and he can act as interpreter of the conditions to the medical attendant, so that less reliance need be placed upon the usually unreliable history given by patients or friends. On the other hand, the social medical worker can interpret to the patient the significance of his condition, so that the natural desire of the patient to know what ails him can be satisfied, and his better coöperation thereby obtained. The human being is a reasoning creature, and is entitled to know the reasons and the wherefores, whenever they can be supplied.

In a far broader sense the sphere of social medicine and of the social medical worker lies in the study of social, industrial and environmental conditions and their relation to disease, and the formulation of such legislation as will lead to the betterment of the people in general in so far as life, health, and usefulness are concerned.

DENTAL INFECTIONS.

In line with the better understanding of the part played by the teeth in the general health, and in the causation of many of the acute and chronic disease conditions, there has grown up, unfortunately, in the popular mind at least, and in the professional as well, a great deal of misapprehension as to the origin and the significance of the dental and periodontal infections. This misunderstanding applies particularly to the so-called pyorrhea. The term "pyorrhea" has come to be applied wrongly to any dental condition, whether due to disease or not. Whenever there is found loss of teeth, dental deposit, or probably some recession of the gum, it is called pyorrhea alveolaris of specific amebic origin. The number of cases of dental infection caused by ameba is, at best, very

small when compared to infections from other causes. In any event, the discovery of the ameba is very easily made by intelligent bacteriological examination of all dental infections. Pyorrhoea is a symptom—a flowing of pus from the tooth socket, and may be caused by the same organisms as cause infections elsewhere. If the term "pyorrhoea" is to be applied at all, it should be applied to inflammations of the tooth joint—to traumatic or septic gingivitis. This infection may be accompanied by detachment of the pericemental fibers. But acute and chronic types of this infection may occur in the dento-alveolar joint as a result of septic emboli and independent of gingival involvement. The infective material may be carried thereto from remote places or from close by—from earious teeth, alveolar process, air passages, tonsil, etc. On the other hand, this dento-alveolar infection, whether of direct or embolic origin, may in turn be the origin, by metastasis, of many acute infections, or even of general septicemia.

Before attempting treatment of purely dental conditions or of diseases elsewhere in the body, of unknown origin, it must be remembered that often bad mouth hygiene, salivary deposits, orthodontic irregularities, imperfect dental work and irritation therefrom, thickened alveolar process, with obstructed and impoverished blood supply, and decayed teeth, are at the bottom of many of them. The amount of pathological change in any case may vary and be out of proportion to the local or general symptoms. The introduction of a dental service in hospitals will serve to clear up many infections of doubtful origin, and will be in keeping with the progress of scientific medicine. As long as there are tangible pathological dental conditions they should be removed before or while instituting other treatment. In such cases it is unscientific to trust to the hypodermic injection of drugs or to vaccines or sera when the clear indications are surgical.

WAR MEETING OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

A war meeting will be held at Washington, D. C., Oct. 17-20, 1917, by the American Public Health Association. This will replace the annual meeting, which was to be held at New Orleans, La., Dec. 4-7, 1917.

The papers and conferences will deal largely with the health problems created by the Great War,—the food supply, communicable diseases among soldiers, war and venereal disease, war and the health of the civil population.

President Wilson has said: "It is not an army we must shape and train for war; it is a nation." Go to the Washington meeting; then come back and do your bit!

Washington will be crowded, and those interested are urged to reserve hotel accommodations at once. It will be easy to cancel reservations, but it may be impossible to obtain rooms at the last moment. Any hotel or railroad can give a list of Washington hotels.

Preliminary programs will be automatically mailed to all members of the American Public Health Association about Sept. 15. Non-members may receive them free by writing to

THE AMERICAN PUBLIC HEALTH ASSOCIATION,
126 Massachusetts Avenue, Boston.

FIRST AID CLASSES OF THE RED CROSS. INSTRUCTORS WANTED.

THE First Aid Division of the Red Cross has sent out copies of the American Red Cross Circular 120, as regards the organization, instruction and examination of first aid classes. Only physicians are called upon to conduct first aid classes of the American Red Cross, and such physicians eventually pass on the proficiency of the candidates for certificates. In order that the Red Cross may appoint qualified physicians to give instructions for these first aid courses, it is desired that as many members of the district medical societies as possible be appointed instructors and examiners. The Bureau of Medical Service of the Red Cross will be glad to furnish applicants with full information describing the work, and will be glad of the assistance of medical men throughout the state. Applications should be made to Major C. H. Connor, Director, The American Red Cross, Washington, D. C.

MEDICAL NOTES.

TUBERCULOSIS STATISTICS.—The Bureau of the Census is planning to prepare and publish a monograph on the Mortality from Tuberculosis,

covering the calendar year 1918. To make this work of greater value, an endeavor is being made to obtain the coöperation of all physicians to the extent of carefully recording or supervising the statements of occupations upon the death certificates during that year. Circular letters to this effect have been sent to all the physicians in the United States.

WAR NOTES.

THE LOBAR PNEUMONIA PROBLEM IN THE ARMY.—In a recent article in the *New York Medical Journal*, Henry J. Nichols, M.D., Major, Medical Corps, U. S. A., describes an epidemic of lobar pneumonia among the 43,000 men belonging to the mobilization camp at El Paso, Texas. The epidemic began in November, 1916, and extended into April, 1917. It reached its highest point in the last of February after the return of the troops from Mexico. Altogether it embraced over 400 cases, and the mortality was 20%.

Determination of the types of pneumococcus began about the middle of the epidemic, and yielded the following result:

TYPE	NUMBER	PER CENT.	PER CENT. MORTALITY FOR ALL KINDS OF TREATMENT
I.	84	56%	14.8%
II.	33	22%	30.0%
III.	3	2%	33.0%
IV.	30	20%	13.3%
	150	100%	

Serum treatment was employed with the following results:

TYPE	CASES TREATED WITH SERUM	DIED	PER CENT.	CASES TREATED WITHOUT SERUM	DIED	PER CENT.
I.	63	5	8.0%	18	7	39%
II.	33	5	21.7%	7	4	57%
III.	3	1	33.0%	0	0	0
IV.	24	4	16.6%	6	0	0

Major Nichols believes that a mixed vaccine of Types I and II should be used in large doses in order to give this possibly important measure a fair trial. He concludes his article as follows:

RECOMMENDATIONS.

"If large camps are maintained during the winter months, preparation to handle epidemic pneumonia should be made: 1. By outfitting a base laboratory with personnel and equipment, agglutination sera, mice, etc., for the determination of types of pneumococci in cases, and when possible, in contacts. 2. By supplying the hospital with reliable serum and proper apparatus for treatment. 3. By vaccinating the command with a pneumococcus I and II vaccine, combined, if indicated, with meningococcus vaccine.

SUMMARY.

1. Epidemic lobar pneumonia is to be expected in large camps in the winter months.
2. The disease is principally due to Types I and II.
3. Serum treatment has produced excellent results in reducing mortality.
4. Direct evidence of tent, company, and regimental contagion has been obtained.
5. Vaccination is considered a more promising measure of prevention than isolation."

EXEMPTION OF MEDICAL STUDENTS.—At a meeting of the Mayor's Committee on Hospital and Medical Facilities, held at City Hall, New York City, on August 15, 1917, the following resolution was unanimously adopted:

Resolved. That the Mayor's Committee on Hospital and Medical Facilities calls the attention of the Secretary of War to the serious consequences to the civilian population of the country, and to the maintenance and operation of the hospitals, of the inclusion of medical students and hospital interns under the act for Selective Service.

Further Resolved. That the Chairman be directed to lay the views of this Committee before the proper officials of the Government and the District Boards of the state of New York, and to take the necessary steps to bring about the temporary exemption of these students and interns in order to secure a constant supply of medical men to the army throughout the war, and to prevent the embarrassment of hospitals, and the consequent serious results to the population of the United States.

The following-named hospitals were represented at the meeting: New York Hospital, Presbyterian Hospital, Manhattan Eye, Ear and Throat Hospital, Lebanon Hospital, Mt. Sinai Hospital, Brooklyn Jewish Hospital, Long Island College Hospital, Brooklyn Hospital, Italian Hospital, French Hospital, Columbia University, Roosevelt Hospital, St. Luke's Hospital, Post Graduate Hospital, Swedish Hospital, St. Francis Hospital, Lincoln Hospital, German Hospital of Brooklyn, Columbus Hospital, Staten Island Hospital, Polyclinic Hospital, New York Orthopedic Hospital, Hospital for Deformities and Joint Diseases, Metropolitan Hospital, King's County Hospital, Bellevue Hospital, City Hospital, Willard Parker Hospital, Kingston Avenue Hospital, Riverside Hospital, Montefiore Home, United States Naval Hospital.

DRAFT OF MEDICAL MEN.—It is estimated that 144,000 men, of whom 24,000 must be trained physicians and the other 120,000 enlisted men, are required for service in the Medical Corps of the army. Half this number will be wanted by October 1. Two out of every nine physicians of military age, 22 to 55 years, in the United States and her possessions, will be called upon for war

service. A system of selection is under organization, in order that, should the number of enlistments fall below the requirements, adequate forces of medical officers and enlisted men may be provided to insure a sufficiency of trained men to care for American troops at home and abroad. The first 12,000 men are available, and as fast as accommodations are provided they are going into training,—at the rate of 200 a day. The training camps are at Fort Riley, Kansas, Fort Benjamin Harrison, Indiana and Fort Oglethorpe, Georgia. Each camp has a capacity of 1000 medical officers and 1800 enlisted men, and includes, besides, four ambulance companies, four field hospitals, and one evacuation hospital. A fourth camp, of 550 men, is located at Fort Des Moines, and is for the training of colored medical officers and colored sanitary detachments to serve with colored troops. The ambulance service camp at Allentown, Pa., has about 4500 officers and men under training.

Massachusetts has sent between 400 and 450 doctors, who are for the most part being trained at Fort Benjamin Harrison. More men are needed from this section. Dr. H. D. Arnold of Boston has been commissioned major in the Reserve Medical Corps, and examines and certifies applicants for commissions in the corps, at Harvard Medical School.

PORTABLE HOSPITAL UNIT.—The Massachusetts State Guard has adopted a portable hospital unit designed by its chief surgeon, Dr. William A. Brooks. It consists of four buildings—an operating room, a ward room, a kitchen, and a staff headquarters. The buildings can be easily erected, and can be disassembled, packed and transported in a short space of time, obviating the necessity of moving injured persons over distances to available hospitals. The unit has a complete equipment of hospital appliances, and can accommodate 125 patients. The staff includes the following:

Surgeons, Donald V. Baker, Brookline; William E. Broome, Boston; Harold G. Giddings, Allston; George W. Morse, Boston; Russell F. Sheldon, Boston; Benjamin E. Sibley, Brookline; and Edward A. Supple, Boston.

Physicians, John W. Dewis, Boston; and Thomas F. Harrington, Boston. Nose and throat diseases, George L. Tobey, Jr., Boston; and D. Harold Walker, Boston. Dental surgeon, Kurt H. Thoma, Boston. Roentgenologist, Ralph P. Leonard, Boston. Ophthalmic surgeons, Robert G. Loring, Boston; P. Smyth, Boston. Orthopedic surgeon, W. Russell MacAusland, Boston.

TRANSFER OF AMERICAN AMBULANCE.—The formal transfer of the American Ambulance at Neuilly, Paris, to the United States Government took place on July 22. The ceremony was held in a large ward of the hospital. It was attended

by William Grave Sharp, the American ambassador; M. Godard, under secretary for war; Dr. Bonehé, chief surgeon; Mrs. William K. Vanderbilt; and Colonel A. E. Bradley of the Medical Corps, U. S. A. M. Godard, in an appreciative address, requested that he be given the American flag flying over the Hospital, to place in the War Museum of France. Maj. George P. Reed of the Medical Corps, U. S. A., will be in charge of the hospital, and has requested the heads of departments and their staffs to remain on duty at the Ambulance.

ROOSEVELT HOSPITAL UNIT.—Red Cross Base Hospital No. 15, which was recruited from the Roosevelt Hospital, New York, is to be financed by Mrs. John W. Mackay and her son, Clarence H. Mackay. Miss Ellen and Miss Katherine Mackay, daughters of Mr. Clarence Mackay, presented to the unit, before it sailed for foreign service, a large American flag. The nursing staff is under the personal supervision of Mary L. Francis, formerly assistant director of nurses at Roosevelt Hospital.

RED CROSS COMMISSION TO ITALY.—It is announced that a commission will be sent to Italy by the American Red Cross, to learn conditions in that country, and institute measures which will most adequately provide for the needs of the soldier and the civilian population of Italy. The commission will consist of the following men: George F. Baker, Jr., vice-president of the First National Bank of New York City; John R. Morron, president of the Atlas Portland Cement Company; Dr. Thomas W. Huntington, president of the American Surgical Association; Dr. Victor G. Heiser of the United States Public Health Service; and Nicholas F. Brady, Central Trust Company, New York. Accompanying the commission is Chandler R. Post, professor of Greek and fine arts at Harvard University, and one of the leading authorities in this country on Italy.

RED CROSS ROUMANIAN COMMISSION.—Members of the unit which the Red Cross is to send to Roumania include the following men: Henry W. Anderson of Richmond, Va., will head the mission. Other members include Arthur G. Glasgow of Washington, Dr. Francis W. Peabody of Boston, Dr. Roger Griswold Perkins of Western Reserve University, Cleveland; Dr. Robert C. Bryan of Richmond, Va.; Bernard Flexner, well-known lawyer of Chicago, and Dr. Gideon Wells of the University of Chicago Medical School. Dr. Peabody, who is resident physician at the Peter Bent Brigham Hospital, was graduated from the Harvard Medical School in 1907. In 1914 he was chosen a member of the China Medical Board of the Rockefeller Foundation and spent several months in China investigating medical education in that country.

NURSES FOR THE ARMY.—The shortage of nurses on the west European front and the great need of a sufficient number to care for American troops, beside attending to the usual needs at home, has caused the nursing committee of the Council of National Defense to issue an appeal all over the country, urging young women to train themselves for nurses. In Massachusetts, Miss Mary Beard, of the Instructive District Nursing Association, has sent word to the deans and graduates of colleges, technical and high schools throughout the State, urging young women to enroll as nursing students and asking institutions to prepare to receive the increase. The general committee has also advised all nursing organizations to take a census of all nurses, graduates, attendants, aids, and the partly trained.

SELECTIVE MEDICAL DRAFT.—It is reported that a petition sent from the Council of National Defense in Washington is being circulated, asking that Congress provide a selective draft of American doctors for military service and pleading for the exemption of *bona fide* medical men from the provisions of the present draft law. This is asked in fairness to the medical profession and in behalf of the welfare of the nation.

APPROPRIATION FOR HOSPITALS.—It is announced from Washington that \$14,500,000 will be spent in constructing thirty-two new army hospitals to be used in caring for the men in training in military camps. There will be nearly 400,000 men in the National Guard camps, and 500,000 in the National Army cantonments, an army of nearly 1,000,000, exclusive of the regular army of the United States.

MEDICAL OFFICERS' RESERVE CORPS.—Report from the War Department, Washington, on Aug. 4, announced the following New England appointments to the Medical and Dental Officers' Reserve Corps. All will be commissioned as first lieutenants.

Medical Corps.—John Jacob Custerhout, Keene, N. H.; John David Thomas, Burlington, Vt.; William Stieckny, Rutland, Vt.; James Hamilton, Jr., Providence; Edward Silvanus Ward, North Attleboro; Herbert Baneroff Priest, Ayer; George Albert Russell, Arlington, Vt.; William Aloysius Malvery, Providence; Thomas Rice, Brattleboro, Vt.; John Frank Streeter, Springfield; Roger William Schofield, Worcester; William Francis Ryan, Lowell; Leon Stanley Lippincott, Brunswick, Me.; John Albert Sullivan, Pittsfield; Henry Albert Schneider, Pittsfield; James Madison Woodard, Salem; Melvin Harvey Walker, Jr., Pittsfield; James McFayden, Milo, Me.; Victor Anthony Aimone, Winchester; Louis Joseph Ullian, Boston; John Bishop Warden, Whitefield, N. H.; Harry Philip Casill, Boston; Louis Herbert Limaure, Lynn; Carl Thorburn Harris, Boston; Preston W. Whitaker, Unity, Me.; Frederick Leslie Gre-

gory, Caribou, Me.; Joseph Michael Scanlon, Lawrence; Winfred Oren Brown, Littleton, N. H.; Frank Herbert Jordan, South Portland, Me.; George Roberts, Chester, Vt.; Andrew James McGraw, Taunton; Herbert Charles Scribner, Bangor, Me.; Ralph Miller Chambers, Westboro; William Phillips Bernard, Central Falls, R. I.; John Paul Jones, Wakefield, R. I.; Wilfrid Francis Milot, Attleboro; Bernard Andrew Bailey, Wiscasset, Me.

Dental Corps.—Walter Herbert Richardson, Worcester; Joseph Edward Cheney, Fitchburg; George Christman, Cambridge; Frederick Henry Winship, Jr., New Bedford; Edmund Martin Webb, Attleboro; Ralph B. Putnam, Portland; Harold Lee Peacock, Boston; Theodore Edward Lafayette, Jr., Watertown; Stanley Clifford Keene, Roslindale; Frederick Wilbur Day, Gardiner, Me.; Edward John Donovan, Wakefield; Frank A. Willis, Manchester; Edwin C. Baker, Roslindale; William F. Lynch, Somerset; Wilbur Arthur Charron, Ware; Clarence Simon O'Keefe, Taunton; James E. Cox, Charlestown.

OFFER OF CHARLESTOWN MEDICAL SOCIETY.—The Charlestown Medical Society has offered its services to the Government in examining recruits, without remuneration, if desired.

MEDICAL RESERVE TO BE CALLED.—It is expected that the enlisted Medical Reserve Corps will be called to go into training within a few days. This will apply to the field hospital and ambulance companies and the unattached personnel of the reserve. The camp will be at Fort Ethan Allen, Vt.

APPOINTMENTS OF NAVY DENTAL SURGEONS.—Philip S. McGann of Somerville, Mass., and Joseph A. Tartre of Portsmouth, N. H., have been given probationary appointments as dental surgeons in the Navy.

MENTAL TESTS FOR SOLDIERS.—A corps of one hundred and fifty neurologists and psychiatrists has been organized to examine all men under training at the army cantonments. In this way a man presenting any organic nervous disease, any mental defect, or a tendency to insanity, or who is addicted to drugs or alcohol, will be exempted from service. It is thus expected to eliminate from the fighting ranks of the army the men nervously and mentally unfit for the type of warfare necessary in the present conflict.

WAR RELIEF FUNDS.—On Aug. 25 the totals of the principal New England war relief funds reached the following amounts:

French Wounded Fund	\$248,669.12
Armenian Fund	217,392.56
Surgical Dressings Fund	120,503.01
French Orphanage Fund	117,656.38
Polish Fund	77,984.95
Italian Fund	44,157.72
French Refugees' Fund	25,059.99

Of these, 4 were isolated cases and the remaining 48 were connected with one outbreak.

BOSTON AND MASSACHUSETTS.

WEEK'S DEATH RATE IN BOSTON.—During the week ending Aug. 18, 1917, the number of deaths reported was 173, against 222 last year, with a rate of 11.68, against 15.22 last year. There were 34 deaths under one year of age, against 53 last year.

The number of cases of principal reportable diseases were: diphtheria, 60; scarlet fever, 8; measles, 14; whooping cough, 34; typhoid fever, 7; tuberculosis, 52.

Included in the above were the following cases of non-residents: diphtheria, 3; scarlet fever, 1; measles, 1; whooping cough, 1; typhoid fever, 2; tuberculosis, 6.

Total deaths from these diseases were: diphtheria, 4; scarlet fever, 1; tuberculosis, 13; whooping cough, 2.

Included in the above was 1 non-resident death from tuberculosis.

MASSACHUSETTS ASSOCIATION OF BOARDS OF HEALTH.—A regular quarterly meeting of the Massachusetts Association of Boards of Health was held recently at Penberton, Mass. Dr. John F. Hitchcock was in the chair. Fred R. Johnson, secretary of the civilian relief committee of the Boston Metropolitan Chapter of the American Red Cross, read a paper on "The Red Cross in Relief in Civilian Communities." Dr. Charles E. Simpson, visiting health officer of the State Department of Health, read a paper on "Large Concentration Camps and Their Relations to Civilian Communities," referring to the army camps at Ayer and Framingham.

APPOINTMENT.

S. R. KLEIN, M.D., Ph.D., formerly director of the Research and Experimental Laboratory at Norwich, Conn., and Professor of Histology and Embryology at Fordham University Medical School, has been appointed Assistant Superintendent, Pathologist and Roentgenologist to the Waldheim East Sanatorium and Polyclinic, Oconomowoc, Wisconsin.

RECENT DEATHS.

LORENZO WAIT COLE, M.D., 65, died at his home in South Deerfield, Mass., Aug. 8, 1917, of bronchial pneumonia. Dr. Cole was born in Pittsfield, Dec. 19, 1851, and was the son of Dr. and Mrs. Harvey Cole. He was educated in the Pittsfield schools and in New York Medical College. He first practiced medicine in New York, near Albany, and in 1887 moved to Springfield, where he was a practicing physician for some years. Ten years ago he came to South Deerfield. Dr. Cole was married in Guelderland, N. Y., to Miss Carrie Hammett of Montpelier, Vt., June 30, 1873. Mrs. Cole survives him.

LEADORE HERMANIGLDE CHICOLENE, M.D., died at his home in Lynn, Aug. 8, 1917, aged 52 years. Dr. Chicolen was a graduate of the Harvard Medical School in the Class of 1894, and had been a prominent practitioner of Lynn since he settled there in 1895 and joined the Massachusetts Medical Society.

The Massachusetts Medical Society.

NOTES FROM THE DISTRICT SOCIETIES.

DISTRICT CORRESPONDENTS.

Berkshire. A. P. MERRILL, M.D., Pittsfield.
Bristol North. ARTHUR R. CRANDELL, M.D., Taunton.
Bristol South. EDWIN D. GARDNER, M.D., New Bedford.
Essex North. T. N. STONE, M.D., Haverhill.
Essex South. H. P. BENNETT, M.D., Lynn.
Hampden. LAURENCE D. CHAPIN, M.D., Springfield.
Hampshire. E. E. THOMAS, M.D., Northampton.

BRISTOL SOUTH.—Drs. Erik St. J. Johnson, Frank E. Stetson, and William C. Sheehy have been appointed captains in the Medical Reserve Corps. Dr. C. E. Burt is at present training at Fort Benjamin Harrison, with the rank of first lieutenant. Dr. R. G. Provost has received his commission as first lieutenant, as have Dr. W. K. Turner, Dr. Frank W. Mathewson, Dr. William A. Muerieff, and, I believe, Dr. A. de C. E. La Riviere. Others have taken the examination but have not received their commissions.

Just at present there is more or less talk about the new City Hospital. Trustees have been appointed, among them Dr. H. C. Kirby, who is the only trustee, I believe, who is a member of the Massachusetts Medical Society. A site of land has been bought, but that is as far as the project has gone. Dr. H. D. Prescott, who went to Saranac Lake something over a year ago, is reported as doing extremely well.

EDWIN D. GARDNER, *Reporter.*

Miscellany.

RESUME OF COMMUNICABLE DISEASES
IN MASSACHUSETTS FOR JULY, 1917.

GENERAL PREVALENCE.

THE month of July was marked by a lack of epidemics of communicable diseases. There were 4601 cases of communicable diseases reported; a considerable decrease as compared with 10,214 cases in the preceding month and 5464 in July, 1916.

The most noticeable drop, in comparison with June, was in measles, which showed a decrease from 3785 cases to 1347 cases. The only significant increase was in pulmonary tuberculosis. This increase has now been steady since February, when 658 cases were reported.

Poliomyelitis.—There were 38 cases of poliomyelitis reported during the month. These were distributed in the district east of the Connecticut River and north of Braekton. The cases as a whole were distributed evenly in this

section, except 10 cases which occurred in Haverhill and 5 in Lynn. No cases were reported in the Berkshires or in the Cape Cod district.

Smallpox.—One case of smallpox was reported from Worcester. The conditions are such that the outbreak of the disease in this city is apparently ended.

Typhoid Fever.—As compared with July, 1916, the State shows a decrease—109 cases this year, as against 128 cases for July last year. The total of the cases this year is slightly below the seasonal average. Of the 109 cases reported, 51 have been carefully investigated and show that 9 are due to contact with other cases, 5 are apparently due to eating raw shellfish, 2 from drinking polluted water. In 35, sources of infection could not be determined.

Diseases on the Premises of Milk Handlers.—One case of typhoid fever occurred in a family of a milk handler, and 5 milk farms were reported as having communicable diseases on their premises. Of the 5 farms, 3 had scarlet fever present in members of the family, and the other 2 farms had cases of septic sore throat on them. Suitable arrangements were made in 4 of the cases on the farms, so that the selling of milk was allowed to continue. On one farm where scarlet fever was present, due to the fact that the parents would not permit the child to go to a hospital, the milk supply was stopped for a few weeks until the local board of health regulations were followed.

EPIDEMICS AND OUTBREAKS.

Septic Sore Throat.—An epidemic of over 100 cases of septic sore throat, due to a hemolytic streptococcus, began during the last few days of the month in Wellesley, Natick and Dover. At the present time it is too early to state definitely the cause of this epidemic, but investigations are under way to determine the cause and to check its course.

Scarlet Fever.—An outbreak of 4 cases of scarlet fever occurred in the Medfield State Hospital as the result of a light unrecognized case of the disease. The cases were at once isolated, and the outbreak ceased.

Measles.—An epidemic of 53 cases of measles occurred at Westminster. Investigation showed that no physicians were called by many of the parents until the disease was well developed in their children, and thus no attempt was made to isolate the cases until it was widely spread throughout the community.

SMALLPOX IN MASSACHUSETTS.

There have been 52 cases of smallpox in the State during the first seven months of the year. Of these, 4 were isolated cases and the remaining 48 were connected with one outbreak.

The isolated cases were reported from Lee, Boston, Bernardston and Blackstone. The Lee case in January was apparently connected with the November, 1916, epidemic in that town, when 18 cases were reported. Of the 2 cases in February, one, in Bernardston, was a person just arrived ill from Iowa, and the other case, in Boston, was an individual from Connecticut, who was infected in that State. The Blackstone case was reported in June, and the source of infection was not found. The Boston and Bernardston cases had never been vaccinated, while the Lee and Blackstone cases were vaccinated in 1905.

The outbreak of 48 cases was centered in Worcester and started in January, when a Finnish immigrant arrived in the city from New York on January 4, apparently bringing the infection from a ship from Sweden on which smallpox was present. The first case was a fellow countryman, who lived in the boarding house to which the immigrant came.

Of these 48 cases, 9 died—a fatality rate of 18.7%, much higher than the usual type of disease prevailing in New England; at once suggesting, on its appearance, a new strain of the disease.

Of the 9 who died, 5 had never been vaccinated, 3 were vaccinated in childhood, from 20 to 60 years previously, and no history was obtained for one case.

Of the 39 cases that recovered, 17 were never vaccinated, 19 were vaccinated more than seven years previously, and 3 were vaccinated within seven years.

There were also 3 cases connected with the Worcester outbreak reported from Albany County, New York, by the New York State Department of Health, one of which was fatal. Of the 3 cases, none had been vaccinated.

In March, 5 cases were reported, and in April 5 cases. On April 26, a moulder, in the eruptive stage of the disease, attended a meeting of the local union, and 12 men attending the meeting later had smallpox.

Moulders from Fitchburg, Shrewsbury and Webster attended the meeting, and 4 cases in Fitchburg, and 3 each in Shrewsbury and Webster followed, making a total of 48 cases for the outbreak.

On the appearance of the outbreak, the Worcester Board of Health took rigid measures, isolating all cases in the city and in Shrewsbury, followed up by a house-to-house canvass of suspected cases and vaccination of all persons who might have come in contact with cases or infected material.

The last case appeared July 24, and the outbreak is apparently ended.

RARE DISEASES.

Anterior Poliomyelitis was reported from Beverly 2, Brockton 1, Groton 1, Groveland 3, Hadley 1, Haverhill 10, Lawrence 2, Lowell 3, Lynn

5, Malden 1, Medford 1, Quincy 1, Salem 1, Saugus 2, Springfield 2, Weymouth 1, and Worcester 1.

Cerebrospinal Meningitis was reported from Attleboro 1, Boston 4, Everett 1, Brockton 1, Haverhill 2, Malden 1, New Bedford 2, Northampton 1, and Pittsfield 3.

Dog-bite was reported from Attleboro 2, Dartmouth 2, Fall River 1, Medford 1, Northampton 1, Sunderland 1, and Worcester 1.

Dysentery was reported from Boston 7 and Holyoke 1.

Malaria was reported from Boston 6, Chicopee 2, Dedham 2, and Natick 1.

Pellagra was reported from Natick 1 and Milford 1.

Septic Sore Throat was reported from Arlington 2, Barnstable 2, Boston 1, Brookline 1, Cambridge 1, Dedham 2, Medford 1, Natick 12, Newton 1, Somerville 1, Springfield 1, and Swampscott 1.

Smallpox was reported from Worcester 1.

Tetanus was reported from Boston 1 and Gardner 1.

Trachoma was reported from Boston 1, Chelsea 2, Lynn 1, and Worcester 1.

PREVENTABLE DISEASE.

COMPLETE refutation of the claim that the Government does not concern itself with the loss from preventable disease is contained in the annual report of the Surgeon-General of the Public Health Service, recently submitted to Congress. Activities ranging from the prevention and cure of blindness, scientific studies of pellagra, the protection of the health of industrial workers, the prevention of the introduction of typhus fever, investigations of child labor and health insurance, the eradication of communicable diseases, and the control of the pollution of navigable streams, are recorded, and demonstrate conclusively that the national government is vitally concerned in the health of its citizens.

The most striking achievement of the year relates to pellagra, an affliction which in certain States destroys more lives than tuberculosis. Pellagra is no longer a disease of mystery, as the Public Health Service has clearly shown that it is caused by a restricted diet, and that it may be prevented and cured by means of a properly balanced ration. The practical application of this knowledge has already resulted in a material reduction in the prevalence of this affliction in all parts of the country, and it is confidently believed that in another year even more marked improvement will be observed.

In the eradication of trachoma marked success has been obtained. The methods followed—the converting of private residences into small hospitals and the holding of free open-air clinics—have been adopt-

ed by the Egyptian government. During the year 1700 persons were operated upon for the relief of partial or complete blindness, nearly 2000 received hospital treatment, while more than 19,000 were treated at hospital dispensaries and clinics. When it is realized that a large proportion of these people were doomed to years of suffering, terminating in at least partial blindness, and that they have been restored to lives of usefulness, in some instances even being taken from county poorhouses, where they had been public charges for the greater portion of their days, the importance of this most beneficent work can be imagined. The total cost of this undertaking, including the remodeling of buildings and every expense in connection with the feeding and care of patients, was less than \$39,000 for the year.

Increased interest was shown by the government in the health of rural dwellers, and Congress has recognized, by making an appropriation for studies in rural sanitation, that the welfare of the country resident is not to be neglected. During the past three years 80,270 homes in 15 different counties of 13 states were visited and complete sanitary surveys made of the premises. In every instance definite recommendations were given to remedy such evils as existed, as, for example, the pollution of wells, the presence of disease-bearing insects, and the improper disposal of excreta. In addition, 22,234 homes were revisited, mostly at the request of the owners, in order that the government agents could inspect the improvements instituted. Wherever this method of bringing the lessons of sanitation directly to the rural dweller has been followed, a marked reduction has been observed in the prevalence of typhoid fever, hookworm, malaria, and other preventable diseases.

Attention has also been given to the health of the children of the nation, more especially to rural school children. Over 32,000 children attending the public schools were examined during the year in order to determine their mental status, and the causes and percentage of mental retardation and deficiency. In addition, 7000 physical examinations were completed for the determination of physical defects.

The health of industrial workers has been safeguarded to a greater extent than at any time in the past. Studies have been made of the occupational hazards of steel workers in many of the leading industrial establishments of the country, and unsanitary and harmful conditions corrected. In the zinc mines of Missouri methods have been adopted which should go far toward eradicating tuberculosis from that district. Investigations of child labor and of health insurance have also been made.

What is regarded as the largest and most important single undertaking of this nature yet inaugurated, the investigation of the pollution of the Ohio river, is still in progress. Surveys of the Atlantic coast and New England watersheds

have, however, been completed, and the extent and effects of their pollution are now known; this knowledge demonstrates that Federal legislation, to prevent the contamination of water sources, is a necessity.

Better provision for the health of travelers has been obtained by safeguarding the water supplies of common carriers, and through the promulgation of regulations governing the transportation of persons suffering from communicable diseases.

Energetic efforts have been made to prevent the introduction of all communicable diseases and to control those already present. Typhus fever has been combated at all points on the Mexican border, and disinfection plants established, where the clothing and persons of all incoming aliens have been disinfected. At one station alone—El Paso, Texas—26,000 persons were inspected and treated in such a manner as to insure their freedom from this highly fatal infection.

Plague eradication measures at New Orleans have been continued. Over 371,000 rodents, the carriers of plague infection, were either trapped or killed, and more than 100,000 were carefully examined. No human case of the disease has occurred during the year. Measures for the control of typhoid fever, Rocky Mountain spotted fever, malaria and other infections have been continued as heretofore, and the results obtained have been most gratifying.

In only a single field,—the medical inspection of immigrants,—has the work of the Public Health Service shown any diminution during the year, but this has been compensated for by the more thorough examination accorded. 481,270 aliens were examined for the purpose of determining physical and mental defects. Of these, 16,327 were certified for deportation, proportionately a greater number than has ever been recorded. The percentage of mental defectives certified is also steadily increasing.

At the marine hospitals and relief stations of the service, approximately 9,000 beneficiaries received medical or surgical treatment, a number greater by 10,000 than for any previous year.

CANCER DECALOGUE PREPARED BY THE STANDING COMMITTEE ON THE CONTROL OF CANCER OF THE MASSACHUSETTS MEDICAL SOCIETY.

1. The classical signs of cancer are the signs of its incurable stages. Do not wait for the classical signs.

2. Early cancer causes no pain. Its symptoms are not distinctive, but should arouse suspicion. Confirm or overthrow this suspicion immediately by a thorough examination and, if necessary, by operation. The advice, "Do not

trouble that lump unless it troubles you," has cost countless lives.

3. There is no sharp line between the benign and the malignant. Many benign new growths become malignant and should, therefore, be removed without delay. All specimens should be examined microscopically to confirm the clinical diagnosis.

4. Precancerous stage. Chronic irritation is a source of cancer. The site and the cause of any chronic irritation should be removed. All erosions, ulcerations, and indurations of a chronic character should be excised. They are likely to become cancer.

5. Early cancer is usually curable by radical operation. The early operation is the effective one. Do not perform less radical operations on favorable cases than you do on unfavorable ones. The chances for a permanent cure are proportionate to the extent of the first operation. Make wide dissections; incision into cancer tissue in the wound defeats the object of the operation and leads to certain local recurrence.

6. Late cancer is incurable, though not always unrelievable. Radium, x-rays, ligation, cauterization, or palliative operations may change distress to comfort and may even prolong life.

7. Cancer of the breast. All chronic lumps in the breast should be removed without delay. Benign tumors can be removed without mutilation. Examine all specimens microscopically. An immediate microscopic examination is desirable since, if positive, it permits a radical operation at the same sitting. A radical operation performed ten days after an exploration is almost never successful in curing cancer of the breast.

8. Cancer of the uterus. Any irregular flowing demands thorough investigation. Offensive or even very slight serous flows are especially suspicious. Curette and examine microscopically. Amputate all eroded cervixes which do not yield promptly to treatment. Do not wait for a positive diagnosis.

9. Cancer of the digestive system is difficult of early diagnosis, and therefore unfavorable in prognosis. All persistent and recurring indigestions (more especially if attended by change of color and loss of weight) and any bleeding or offensive discharges demand prompt and thorough investigation. Do not wait for a positive diagnosis.

10. Cancer of the skin. Any warts, moles, or birthmarks which enlarge, change color, or become irritated, should be removed promptly. They are likely to become cancer. Do not wait for a positive diagnosis.

BACTERIOLOGY AT THE FRONT.

BACTERIOLOGICAL investigation in hospitals of the front line has been a novel feature of this war. Nothing of the kind has been practised in any of our previous campaigns. It has been rendered possible by equipping motor vans as mobile laboratories. The first, which was sent out in October, 1914, had been a pleasure caravan. It was gutted and fitted with incubators and all the other apparatus of bacteriological work, and was followed by many others of the same type. They have been attached to a clearing station or a group of clearing stations, and the officer in charge is provided with a small motor car, so that he can go to any place in his area where his services may be wanted.

These officers perform three functions:

1. They examine all kinds of morbid products from the hospital wards, and thus aid in the diagnosis of enteric fevers and other epidemic diseases on the medical side, and of the various forms of infection that attack surgical wounds.

2. They examine contacts in cases of infectious fever and search for carriers, both among the troops and in the civil population.

3. They investigate new forms of disease that appear among the troops, in order to discover their causes and the means of prevention.

Instances of the first class of work are the examinations made of the blood and excreta in cases suspected of enteric fever, of malaria, or of dysentery, and of the cerebrospinal fluid, or the nasal mucus where cerebrospinal fever is in question.

The next function of these officers is to discover the source of an infection, and to stop it from spreading. In cases of enteric fever, the work was very elaborate. In the first place, a systematic search was made for recent or chronic carriers among the troops. Thus, in one regiment a carrier was discovered in the regimental kitchen. In another, which had lately received reinforcements, no less than 95 men had to be examined before the carrier was found. But the source of infection was not always in the troops. The part of Flanders that we held was a hotbed of enteric fever, and many cases were found in the civil population. The search for these was very difficult. In one village cases of enteric fever occurred in three successive formations that were billeted there.

The conditions of warfare made it far less possible to obtain contacts of cerebrospinal fever at the front, where men are constantly moving, than it is at home where a man may be stationary for weeks.

As instances of the examination of new or little known forms of disease, I may mention trench fever, investigated by Captain McNece; spirochetal fever by Captain Adrian Stokes; gas gangrene, and the histology of the prevalent nephritis, by Lieutenant Dunn.—Sir W. P. Herringham, C.B., M.D., *British Medical Journal*, June 23, 1917.

Correspondence.

CONCERNING CERTAIN MEDICAL ADVERTISEMENTS.

New York, August 15, 1917.

Mr. Editor:—

Permit me to call your attention to the new law relating to certain medical advertisements, which was enacted at the last session of the New York State Legislature. The passage of this law was prompted by the fact that the misrepresentation practiced by quacks and unscrupulous nostrum manufacturers constituted one of the chief obstacles encountered by health authorities in dealing with venereal diseases. Much of this misrepresentation appears in the advertisements still carried by certain newspapers and periodicals published in this city.

"1142-a. Advertisements relating to certain diseases prohibited. Whoever publishes, delivers or distributes or causes to be published, delivered or distributed in any manner whatsoever an advertisement concerning a venereal disease, lost manhood, lost vitality, impotency, sexual weakness, seminal emissions, varicocele, self-abuse or excessive sexual indulgences and calling attention to a medicine, article or preparation that may be used therefor or to a person or persons from whom or an office or place at which information, treatment or advice relating to such disease, infirmity, habit or condition may be obtained, is guilty of a misdemeanor and upon conviction thereof shall be punished by imprisonment for not more than six months, or by a fine of not less than fifty dollars nor more than five hundred dollars, or by both such fine and imprisonment. This section, however, shall not apply to didactic or scientific treatises which do not advertise or call attention to any person or persons from whom or any office or place at which information, treatment or advice may be obtained, nor shall it apply to advertisements or notices issued by an incorporated hospital or a licensed dispensary or by a municipal board or department of health or by the department of health of the State of New York."

You will observe that the law applies both to the advertiser ("who causes to be published") and to the publisher of this class of advertisements. The new law goes into effect Sept. 1st, 1917.

Very truly yours,

CHARLES BOLDCAN,

Director, Bureau of Public Health Education.

END OF A FAMOUS NEUROTIC IN-BRED LINE.

Boston, August 9, 1917.

Mr. Editor:—

Lord Byron's line would not have died out, under ordinary circumstances, apparently without notice in either hemisphere. Even now, the subject is worth enlarging upon by some psychopathologist, and the hope of inducing this, causes the present note. Baroness Wentworth (peeress in her own right) died childless on June 18th, the great-granddaughter of Lord and Lady Byron; the latter was a hereditary hysteric, and the former came of a strain whose mental instability had been intensified by an extraordinary number of cousin-marriages. One of the closer connections was a lady by Mrs. H. B. Stowe, with manifold indiscretion, fifty years ago, but recently has been handled deftly by Miss Mayne. When one considers that Lord Byron, a typical only child, surrounded by such, and by superstition, came of stocks psychopathic on both sides, and lived in a hectic society, the wonder grows, not that he did not behave better, but that he could behave at all.

THE NEWER METHODS OF DIAGNOSTIC TECHNIC.*

By FREDERICK T. LORD, M.D., BOSTON.

MOST mistakes in diagnosis arise from insufficient attention to the patient's story, neglect in the performance of a complete and searching physical examination or lack of skill in their interpretation. To a certain degree, diagnostic errors are unavoidable, but their frequency is materially diminished by the routine use of a carefully prepared scheme of history-taking and physical examination, elaborated to apply in appropriate detail to certain groups of cases and designed to avoid well-known errors of omission. Proficiency can be acquired and maintained at its highest level only by constant practice and the steady influence of opinions corrected or confirmed.

If we are to secure to its fullest extent the educational value to be derived from our successes and failures, a written opinion should be incorporated in the patient's hospital record after the completion of the clinical data. The limits of accuracy in diagnosis then become more apparent if the ease later comes to operation or autopsy. It is obviously impossible at this time to cover the numerous more recent developments which have contributed to the science of diagnosis, with any degree of completeness. I shall, therefore, attempt to consider only certain aspects of the subject.

* Presented at the Annual Meeting of the New Hampshire Medical Society, May 16, 1917.

CERTAIN ASPECTS OF HISTORY TAKING.

An important division in our records, in addition to the older form of the family history, past history, habits, and present illness, deals with the occupational history. At the Massachusetts General Hospital, Dr. Wade Wright has made an investigation of the cases in which the hazards of industry have a bearing on the illness, and out of about thirty-two thousand admissions to the Out-Patient Department during a period of one year, about five thousand were received in his industrial clinic. In four hundred and sixty-six cases there was a definite relation between the illness and the occupation,—a proportion of from one to two patients per one hundred of the total out-patient admissions. Out of this number, of four hundred and sixty-six cases, exposure to lead is shown to be a hazard of chief importance, being represented by one hundred and forty-eight cases.

An important rule in history-taking is to try to make the diagnosis from the history alone, and no history can be regarded as complete until this effort has been made. An inquiry, at times of great value, concerns the evolution of the initial symptoms, a matter the importance of which can be appreciated when we consider how the advent of complications may later confuse the clinical picture. It is, for example, highly desirable to inquire concerning the attendant symptoms in cases with a history of hemoptysis. If it can thus be shown that the bleeding was unaccompanied by other symptoms referable to the lungs or other organs, and was, in fact, an "hemoptysis out of a clear sky," then pulmonary tuberculosis may be regarded as the

probable cause of the bleeding. A history of pleurisy out of a clear sky has a similar significance. In the case of a child with the history of having "swallowed something and choked," an initial dysphagia, with absence of cyanosis, paroxysmal cough, dyspnea and suffocation suggests lodgment of a foreign body in the esophagus. The immediate occurrence of respiratory symptoms, on the other hand, may be the most valuable evidence obtainable that a foreign body has been aspirated. In certain cases there is an initial period of dysphagia, with the later development of cough, dyspnea and cyanosis,—a march of events highly suggestive of a swallowed body which has subsequently ruptured into the air passages. There is a group of cases in which the distinction between bronchial and cardiac asthma can be made only by careful inquiry concerning the progress of the early manifestations. Persistent and increasing dyspnea usually precedes the asthmatic attacks due to cardiac failure, while in true bronchial asthma such attacks are at first isolated and without dyspnea in the intervals between the paroxysms. Chill or chilliness, pain in the side, dyspnea and cough, with bloody expectoration, are common to both lobar pneumonia and pulmonary infarction, but in pneumonia the temperature rises rapidly, and reaches its maximum within a few hours. In pulmonary infarction the temperature rises much more slowly. If this difference in the behavior of the temperature can be determined, it may help to solve the problem.

It is equally important to trace out the progress of symptoms in other than pulmonary conditions. I need only remind you that the diagnosis of coronary sclerosis cannot be made without attention to the significance to be attached to the various features which characterize angina pectoris. Dr. Briekner's description, which you have just heard, of the cord symptoms in certain of his cases of spina bifida, suggests the importance of reverting to the earlier manifestations when there are indications of sensory or motor impairment. A history of the disassociation of sensory perception in the earlier stages of a motor disturbance of the lower extremities is suggestive of unilateral lesions of the cord, and may lead to detection and removal of a spinal tumor. Spasm and tingling, limited to certain motor and sensory areas, preceding more extensive involvement, may be a signal symptom of irritative or destructive lesions of the central motor area of the brain, and serve to define the site of a cerebral tumor. The diagnosis of abdominal lesions must be made for the most part from the history, and the statement of the patient concerning the site, radiation, character, severity and duration of pain, among other features, is of chief importance.

MATTERS PERTAINING TO PHYSICAL EXAMINATION AND THE CLINICAL LABORATORY.

As with history-taking, physical examination must be complete if we are to avoid error, and

must comprise also an examination of the blood, the determination of the blood pressure, a Wassermann test and analysis of the urine, including the sediment, as a routine. Certain cases demand further special regional investigation.

Nervous System. The use of the electric otoscope makes examination of the ear much more readily performed now than formerly, and this instrument should be a part of our equipment. In patients who are gravely ill and whose sensibilities are diminished below the normal, an acute otitis media may develop without symptoms. In the examination of the ears in cases of pneumonia, especially in children, an unsuspected inflammation of the middle ear is not an infrequent finding, and inspection of the ear drum should, therefore, be made in such cases, as a routine.

With the added accuracy which the Wassermann test has brought to the diagnosis of syphilis, it appears that inequality, irregularity and sluggish reaction of the pupils to light is to be regarded as suggestive ofluetie infection, even in the absence of other manifestations of the disease.

The conversion of the ophthalmoscope into an electrical instrument makes it readily available for more general use. This is fortunate, for it should be an invariable rule to examine the fundus before resorting to lumbar puncture and the withdrawal of spinal fluid, so frequently desirable as a diagnostic procedure. Optic neuritis and choking of the disc are important signs of increased intracranial pressure, and when present constitute a contraindication to the withdrawal of spinal fluid without due consideration of the danger. Pressure on the medulla, and consequent apnea may occur from herniation of the base of the brain into the foramen magnum on the release of spinal pressure. In cases suspected of cerebral tumor, with increased intracranial tension sufficient to produce optic neuritis or choked disc, the withdrawal of spinal fluid should not be undertaken if the diagnosis can be satisfactorily established without this means. Similar changes are occasionally observed in the eye grounds in cases of meningitis, however, and caution must not be carried so far as to lead to the omission of lumbar puncture in such cases, and consequent failure in the diagnosis and serum treatment of meningococcus infection.

If syphilis of the central nervous system cannot be excluded without an examination of the spinal fluid, lumbar puncture may be justifiable, even in the presence of changes in the eye grounds, indicating increased intracranial pressure.

In the performance of lumbar puncture for the purpose of obtaining spinal fluid for examination, an important caution should be observed in the choice of an instrument, that it be made of pliable material, which will bend and not break in the course of the procedure. It has been the unfortunate experience of a

number of operators to have a steel needle break, and a part of it remain imbedded and out of reach in the lumbar tissues. I need hardly remind you that the recovery of such a fragment may be difficult or impossible without resort to x-ray examination, and an operative procedure quite out of keeping with the already serious condition of the patient.

The examination of the spinal fluid should include a numerical and differential count of the cells, a test for protein and the Wassermann test. Patients with spinal fluids which contain pus cells should be treated as for meningococcus infection until the cause of the disturbance can be definitely determined. Inasmuch as there is promise of successful serum treatment of influenza meningitis, and the influenza bacillus grows only on hemoglobin-containing media, it is desirable, in the investigation of the fluid by culture, to plant it upon blood-agar, as well as on other media. An increase in and predominance of lymphocytes in the spinal fluid usually mean that chronic meningococcus infection, acute anterior poliomyelitis, tuberculous meningitis or syphilis, is the underlying condition. So far as the diagnosis of syphilis is concerned, this is never complete in suspected and otherwise negative cases until an examination of the spinal fluid has been made. We see each year a small group of cases with negative Wassermann tests on the blood and positive tests on the spinal fluid, as the only certain indication of syphilis.

An increase in the protein content of the spinal fluid may be demonstrated by various means. Noguchi's butyric acid test is performed by adding to one part (0.1 to 0.2 cc.) of the fluid, five parts (0.5 cc.) 10% butyric acid in normal salt solution and heating to boiling. One part (0.1 cc.) of normal sodium hydroxide solution is then added, and the mixture again boiled for a few seconds. In strongly positive specimens a precipitate appears within a few minutes. Weakly positive reactions may appear after a longer period, but if the fluid remains clear after two hours it may be regarded as negative. Nonne's test is applied by adding an equal volume of saturated ammonium sulphate solution to the spinal fluid, which should be free from blood. A positive test is indicated by the appearance of a precipitate within three minutes. Protein reactions are not specific, and serve only to demonstrate pathologic fluids without regard to the character of the underlying cause.

RECOGNITION OF CARDIAC IRREGULARITY.

With regard to cardiac cases, an interesting advance has been made by the use of instruments of precision in the diagnosis and classification of the arrhythmias. After some experience in the comparison of clinical and instrumental findings, it is possible to recognize the types of cardiac irregularity in most cases with-

out resort to polygraphic and electrocardiographic tracings. Of the two relatively benign forms, sinus irregularity is a common, youthful type, characterized by the recurrence of cardiac systoles for a short period at a more rapid rate, this acceleration of the rapidity being followed by an interval of slower beats. Imperfect and missed beats are absent, and the acceleration of rate usually occurs during inspiration, with slowing of the rate during expiration. The second of the two relatively benign types is known as extra-systole, which can be recognized by the occurrence of a beat at a shorter interval than the natural beat, a subsequent longer pause before the next systole, and the resumption of normal rhythm. In the absence of symptoms or other signs of cardiac disturbance, extra-systoles need not be regarded as of serious import. There are three types of arrhythmia which may be taken to indicate more or less serious damage to the cardiac mechanism. Of these, auricular fibrillation is usually easily recognized by the repetition of cardiac beats of unequal intensity at irregular intervals, in a disorderly and non-descript fashion. With pulsus alternans, a strong and weak beat alternate, without disturbance of the orderly succession of the sounds at regular intervals. This type is most easily detected in the course of estimation of the blood pressure by the auscultatory method, the disparity in the strength of the alternating beats being accentuated when on listening for the appearance of the systolic sounds at the bend of the elbow, the strong beat first appears, and then, as the pressure is further lowered, the alternating and weaker beat is heard. In partial or complete heart-block, there is a slow ventricular rate with a more rapid contraction of the auricle. The more rapid auricular beats may be counted in the distended jugular vein. Fluoroscopic examination of the chest may disclose the rapid auricular and the slow ventricular rate. Cerebral attacks are likely to accompany the transition from normal rhythm to heart-block. While the more outspoken types of the arrhythmias are recognizable without instrumental assistance, polygraphic or electrocardiographic tracings may be necessary for the detection of the earlier stages of heart-block and the distinction between extra-systoles and fibrillation and heart-block and alternation.

SELECTION OF DONORS FOR TRANSFUSION.

The increasing frequency with which transfusion is done in secondary anemia, as a life-saving measure or as a preliminary to operation, and in pernicious anemia as a temporary expedient, makes familiarity with the technic of selecting an appropriate donor desirable. Otherwise a valuable procedure will sooner or later receive unmerited condemnation in consequence of a fatality from the mixture of incompatible blood. Detection of incompatibility is not a difficult or complicated process, and in

other than emergency cases transfusion should never be performed without preliminary tests for agglutination. When the selection of appropriate donors is a frequent necessity, it is desirable to follow Moss' (*Journal American Medical Association*, June 23, 1917) method of group determination by testing the blood of prospective donors against Group II and Group III serum, which is kept constantly on hand in the laboratory. It is most important to observe the rule that the corpuscles of the donor must not be agglutinated by the patient's serum. Agglutination of the recipient's corpuscles by the donor's serum appears to be less dangerous. In the absence of stock sera five to six drops of the recipient's, and an equal quantity of the donor's blood may be collected, each in small test tubes, and the serum allowed to separate from the clot. One to two drops of the prospective donor's and the recipient's blood are each mixed with one cubic centimeter of 1.5% sodium citrate in 0.9% salt solution. Two loops of the recipient's serum and one loop of the donor's suspension of corpuscles are mixed together on a glass slide, covered with a cover glass, and watched for agglutination under the microscope. Two loops of the donor's serum and one loop of the recipient's suspension of corpuscles are mixed and similarly tested. Rouleaux formation should not be mistaken for agglutination. Observation for five minutes may be sufficient, but a half hour is a safer limit.

DETERMINATION OF THE TYPES OF PNEUMOCOCCI.

The detection of the types of pneumococci giving rise to lobar pneumonia is a matter which should be taken under consideration in this and other communities. Immunologic and agglutinative tests have shown that there are four principal types of pneumococci concerned in the disease. The treatment of pneumonia due to Type I pneumococci, by the homologous serum, has reduced the mortality of this type of infection from 30 to 8%. Anti-pneumococcal serum for the treatment of Type I infection is manufactured both by the New York City and the New York State Board of Health. The State Department of Health of Massachusetts has requested from the Legislature a sufficient amount of money to provide for the preparation and distribution of Type I serum. As a number of months must elapse after all preparations are made before a potent serum can be obtained from inoculated horses, the present is the time to consider such a provision. We should take heed from the history of the disease, and realize that cases of pneumonia are likely to become much more numerous next winter than ever before. Their incidence is likely to rise in consequence of the increased opportunity for contact infection among troops in the course of our military operations. Pneumonia has not long since been noted to become more prevalent in such crowded conditions of living as among the

negroes employed on the Isthmian Canal and housed in barracks, and among the workers in the mines of the Rand. It is hardly to be expected that the supply of serum for which provision has been and is being made in New York and other places, will be equal to the demand.

EXAMINATION OF SEROUS FLUIDS.

The value of an examination of fluid obtained from the serous sacs is too little heeded. Complicated and expensive apparatus is unnecessary, and such simple tests as the specific gravity, the estimate of the amount of albumen, and a differential count of the cells in such fluids are important aids in determining the cause of the effusion. With pleural fluids, for example, a specific gravity of 1010 or under, and traces to 1% of albumen, usually indicates a hydemric transudate. Fluids with a specific gravity of 1010 to 1015 and from 1 to 3% of albumen are usually passive transudates. When the specific gravity is 1018 or over, and the albumen 4% or more, an inflammatory origin may be assumed. An excess of polymuclear cells in serous fluids of high specific gravity commonly indicates an infection of other than tuberculous origin, while an excess of lymphocytes in such fluids usually means that tuberculous is the underlying cause.

X-RAY EXAMINATION.

From the point of view of medical diagnosis, radiography is of material assistance in certain cases. Involvement of the paranasal sinuses and concealed pockets of pus about the teeth may thus be detected. The nature of lesions of the mediastinum and the lung can be interpreted with much greater accuracy when, to the clinical features, an x-ray examination can be added. X-ray examination should, so far as possible, be secured in all cases. To improve our technique in the application of the ordinary methods of examination, it should be an invariable rule to incorporate in the record all physical pulmonary findings before the x-ray plates are inspected, and then note the discrepancies between the two methods. It not infrequently happens that more is disclosed by the radioscopic than by the physical examination.

In abdominal cases the use of the x-ray is of great assistance. The findings by this method should be judged with, and not independently of, the clinical features, if their utmost value is to be realized. The method is of greatest service in the medical wards in the investigation of gastric cases. Abnormalities in the stomach can, by this means be demonstrated in practically all cases of carcinoma in its more advanced stages, and a negative x-ray is of great value in excluding such lesions. The x-ray differentiation of carcinoma and ulcer is often impossible. Carcinoma is not yet detected early enough by any means to make the outlook for surgical interference hopeful in other than rare instances.

Peptic ulcer presents a high proportion of successful interpretations, but negative x-ray findings do not serve to exclude ulcer. Gallstones are usually missed by x-ray examination, and we place little reliance on negative plates of the gall-bladder region. In only a small proportion of patients shown by operation to have gallstones have the x-ray findings been undoubtedly positive, and in a large proportion of cases we must still make the diagnosis of cholelithiasis on the clinical features. The x-ray is indirectly of value, however, in helping to exclude peptic ulcer when peptic ulcer or gallstones is in question. Stone in the urinary tract, on the other hand, is shown in almost all cases, especially when, by appropriate means, care is taken to include an examination of its pelvic portions. Progress is constantly being made in the study and interpretation of lesions of the small and large intestine, but chief reliance must still be placed on other methods of investigation.

PROCTOSCOPY.

Lesions of the lower bowel within easy access of the anal orifice can at times be diagnosed by means of proctoscopy when other methods fail. The proctoscope is of greatest value in the early detection of carcinoma in this region. It is simple and easily operated. A small, portable battery affords adequate illumination from the small lamp with which the end of the tube is equipped.

ESTIMATION OF RENAL FUNCTION.

In doubtful cases of disturbed renal function, the phenolsulphonophthalein test is desirable and easily performed. Ampules containing enough of the drug for one test are on the market. Three to four hundred cubic centimeters of water may be given the patient to drink a half hour before the test is made. Six-tenths of a milligram of the phenolsulphonophthalein are injected intramuscularly. The bladder is emptied in one hour and again in two hours after the injection. A sufficient amount of 25% sodium hydroxide is added to each of the two specimens of urine to make them strongly alkaline, and the samples are then diluted with water to a volume of one liter. Comparison of the color of a small portion of the diluted first-hour specimen is made with a color scale and the percentage read off. A similar estimate of the color is made on the diluted second-hour specimen. The sum of the percentage of excretion for the two specimens represents the total eliminated during the two-hour period, and may be taken as a fair index of the function of the kidneys. A total output of from 60 to 85% for the two hours may be regarded as normal. In patients with urinary obstruction the specimens of urine must be obtained by catheter, but in the absence of obstruction the use of the catheter is unnecessary.

TESTS FOR ACIDOSIS.

In diabetes an advance may be noted in the addition of a simple and accurate measure of the reaction of the body in the presence of acidosis by an estimation of the quantity of ammonia excreted in the urine. The determination of the total twenty-four-hour output of ammonia is easily made by means of the Ronchese-Malfatti method.* The test is unreliable, however, when the patient is under treatment by alkali. The ferric chloride test for diacetic acid in the urine is of value in indicating the amount of acid excreted. Other tests for acidosis are thus far too complicated for general use.

DIAGNOSIS OF EARLY STAGE OF SYPHILIS.

Finally, the early diagnosis of syphilis, of paramount importance in successful treatment, is made easily possible without complicated and expensive apparatus by the India ink method of finding the spirocheta pallida. A loop of serum squeezed from the previously cleaned lesion under suspicion is mixed on a cover glass with two loops of India ink,† and the mixture covered with a second cover glass. The two cover glasses are then pulled apart, dried, mounted in balsam, and examined under the oil immersion lens.

* (1) 25 cc. urine in Erlenmeyer flask + 25 cc. distilled water + 10 grams solid potassium oxalate (neutral). Add few drops phenolphthalein. Shake a few times to dissolve the potassium oxalate and titrate with one-tenth normal NaOH until the first pink color is permanent. (2) 5 cc. commercial formalin solution in test tube + few drops phenolphthalein. Titrate with one-tenth normal NaOH until a faint pink color is obtained. (3) Now add the neutralized formalin to the neutralized urine and again titrate with one-tenth normal NaOH until a faint pink color is again obtained. Calculation: No attention need be paid to the amount of one-tenth normal NaOH used in (1) and (2). The number of cc. one-tenth normal NaOH used in (3) multiplied by .0017 equals the number of grams NH_3 in 25 cc. urine. From this result calculate the amount for the 24-hour urine. From 0.5 to 1.0 grams in 24 hours is normal.

† Chin-chin India ink is best.

Medical Progress.

A REVIEW OF THE LITERATURE OF THE LAST NINE YEARS ON THE NEPHRITIS OF INFANCY AND CHILDHOOD.

By LEWIS WEBB HILL, M.D., BOSTON,

Alumni Assistant in Pediatrics, Harvard Medical School; Junior Assistant Visiting Physician, Children's Hospital, Boston.

ALTHOUGH in the last few years an immense literature has grown up concerning nephritis in the adult, it is surprising to see how little has been written about the condition in children. Nephritis is really an extremely common condition in childhood, following, particularly, the various acute infections to which children are so susceptible.

The following review covers most of the important papers of the last nine years:

Etiology. Hutinel¹ insists strongly that infection dominates the etiology, thus differing widely from nephritis in the adult, in which slow degenerative processes play the chief etiological rôle. This, indeed, is the first important distinction to be drawn between nephritis in the adult and in the child. The nephritis following scarlet fever is, perhaps, the most common type of nephritis in childhood, according to Hutinel, and he believes that the scarlet fever toxin may be relatively harmless to the kidneys unless the factor of cold is added; many cases of scarlatinal nephritis would not develop if the body had not been chilled. The following are a few of the conditions to which nephritis may be secondary:

1. Scarlet fever.
2. Infections of the pharynx [tonsillitis especially important.—L. W. H.]
3. Gastro-intestinal diseases of infancy.
4. Skin infections, especially impetigo.
5. Appendicitis.

Kaunheimer² calls especial attention to the importance of impetiginous skin conditions as etiological factors. Out of 223 cases of acute nephritis seen by him, 39 were unquestionably due to impetigo. In nearly all of these 29 cases the nephritis was of the acute hemorrhagic variety, with edema. The prognosis is good.

Phillips³ also emphasizes the importance of impetigo in etiology. He recognizes two types of nephritis secondary to this condition:

1. A nephritis of transitory character, without edema, or cardiac or uremic symptoms. The urine contains a few casts, and a very few red blood cells, barely enough to give the urine a red color.

2. A nephritis which is more severe, characterized by general anasarca, cardiac or uremic symptoms. He believes that the urine should be examined as a routine in all cases of impetigo.

McLanahan⁴ says that nephritis is much more common in childhood than the textbooks would lead one to believe. He emphasizes especially the fact that nephritis may occur in any infectious disease of childhood. In 15 cases of acute nephritis seen by him, the etiology was as follows: scarlet fever, 4; tonsillitis, 3; "grippe," 4; infectious diarrhea, 1; unknown etiology, 3.

Loeb⁵ discusses nephritis from the point of view of the rhinologist. He arrives at the following conclusions:

1. Acute nephritis results from acute tonsillitis far more often than is usually believed.

2. The symptoms are not manifested until some time after the inception of the disease.

3. There are probably many cases in which a mild nephritis occurs secondary to a tonsillitis, which goes on to resolution without the patient or physician being conscious of its presence.

4. It is incumbent upon practitioners to examine the urine of every case of tonsillitis, not only during the height of the disease, but for some time afterwards, as well.

5. Spontaneous or "idiopathic" nephritis is probably often due to a tonsillitis that has not been considered as an etiological possibility.

6. Chronic affections of the kidney may very well owe their origin to unrecognized acute attacks of nephritis of tonsillar origin.

Loeb wrote particularly with regard to adults, but his conclusions hold good for children even more than they do for adults. The importance of tonsillitis in the etiology of acute nephritis in children cannot be overestimated, and in a series of some sixty cases which we have studied at the Children's Hospital during the last two years and a half, tonsillitis has been by far the most frequent cause of the nephritis.

Frank⁶ studied an extensive series of cases of acute nephritis in early infancy, and brings out especially the facts that no child is too young to have nephritis, and that under the first year of age a large proportion of the cases are of gastro-intestinal origin.

Pribram⁷ reports 4 cases of acute hemorrhagic nephritis following tonsillitis, which were cured by tonsillectomy, without any other medicinal or dietetic treatment.

Classification. Heubner,⁸ from an analysis of 73 cases of chronic nephritis in his wards, proposes the following classification:

1. Chronic hemorrhagic nephritis is a quite characteristic type of nephritis in childhood. In this group the urine contains blood consistently over a long period of time. The amount of blood and of albumin is usually considerable, and casts are present in abundance. This type is nearly always associated with edema, and the duration is years. In some cases the heart is hypertrophied and there is an increase in blood pressure; in some there is none. At autopsy the kidneys of these cases are always large, yellow, and studded with many small hemorrhagic areas.

2. Clinically, the cases of this group are very similar to those of the previous; they differ only in that blood is lacking. In nearly all cases the blood pressure is normal. The duration of this type of nephritis is shorter than that of the hemorrhagic form, and children with it nearly always die after a few months. At autopsy the "large white kidney" is seen.

3. The third group of cases comprises those children with true contracted kidney (chronic interstitial nephritis). This is very rare; in Heubner's 73 cases, only one was of this type. The symptoms are very much the same as in the adult type of chronic interstitial nephritis: high blood pressure, enlarged heart, polyuria, albuminuric retinitis, etc.

4. Chronic nephritis following pyelitis. This also is uncommon, only 6 of the 73 cases falling into this group.

5. The fifth type is a nephritis without edema, in which one would not suspect a nephritis unless the urine were examined. The nephritis may go on for months or years without

being discovered, and when the urine is examined as a routine because the child is perhaps brought to the physician for pallor, loss of appetite or vigor, the nephritis is discovered. The albumin is usually present in only small amounts, but there may be a good many casts and red blood cells, which may vary considerably in number from time to time. In this type small hemorrhages from the kidney are particularly likely to occur from time to time. These hemorrhages nearly always occur during some acute illness, especially tonsillitis, the toxins of which irritate the already diseased kidney. This is a very mild type of nephritis and may last for years. The blood pressure is usually normal. In closing, Heubner says that nearly all cases of nephritis in infants and children, whether acute or chronic, can usually be traced to an infection of some sort.

Langstein and Benfey,⁹ following Heubner's work closely, recognize the following 6 types:

1. A chronic hemorrhagic form, nearly always accompanied by edema. This type of nephritis is the most common and characteristic nephritis that children have.

2. A second form is first shown by edema, but has no blood in the urine. The amount of albumin, however, is very large, and there are many casts present. Infectious processes are likely to be the cause of the nephritis in the first group, but not so likely in the second.

3. True chronic interstitial nephritis of the adult type.

4. A parenchymatous nephritis secondary to pyelitis.

5. A form of nephritis coming on very insidiously, and manifested by general debility of the child. The urine contains a small amount of albumin, a moderate number of casts and leucocytes, and from time to time a few red blood cells. It is very likely to follow scarlet fever or tonsillitis.

6. Intermittent albuminuria—rare, and of very little practical importance.

As can be seen, this classification is essentially the same as Heubner's.

Blackman¹⁰ proposes the following classification, based upon etiology:

1. Of Infancy:
 - (a) Of gastro-intestinal origin.
 - (b) Due to other infections.
 - (c) Due to congenital syphilis.
2. Of Older Children:
 - (a) Scarlet fever and diphtheria.
 - (b) Other infections.
 - (c) Cold, exposure and drugs.

Congenital Nephritis—Nephritis in the Newborn. Karsner¹¹ reports a case of congenital nephritis. The child was cyanotic at birth, and died 45 minutes afterwards. At autopsy there was found a well-defined acute parenchymatous nephritis. The etiology could not be determined. Kendall¹² reports a most interesting condition,

which he calls "hereditary familial congenital nephritis." Three out of 8 members of the family in one generation, and 8 out of 11 in the next generation, had nephritis. The condition usually appeared at an early age, and was characterized particularly by recurrent attacks of hematuria, sometimes very severe. Some of the cases seemed to be linked with anaphylactic phenomena, as the attacks of hematuria were likely to be brought on by certain specific articles of fruit, such as blackberries and currants.

Kosmak¹³ reports a case of nephritis in the newborn, due probably to acute intestinal disturbance. The child was breast-fed, but developed a severe diarrhea a few days after birth, and died two weeks later. At autopsy an acute parenchymatous nephritis was found. Kosmak believes that the intestinal disturbance was caused by an infection of the milk in the milk ducts, and that the nephritis was secondary to this.

Chronic interstitial nephritis, although very rare, may occur in children, giving the same general picture as that of the adult type. It seems to occur more frequently in England than elsewhere, and most of the cases have been reported by Englishmen. An especial characteristic of this type of nephritis is the coexistence of infantilism, and the term "renal infantilism" has been applied to the condition. Barber¹⁴ reports two cases in the same family, in children 12 and 14 years old, respectively. These children showed the characteristic infantilism. Both children were only 4 feet tall, and much underdeveloped in every way—a height of 4 feet would correspond to a child about 8 years old. There was polyuria in both cases, and the urine was of a very low gravity (1003-6), containing a very slight trace of albumin, and a rare cast.

The blood pressure in these two cases was not elevated, nor were the aortic second sounds accentuated. [Rather unusual; usually a high blood pressure.—L. W. H.]

One of the children died in uremia, and at autopsy the kidneys were found to be very small, histologically showing a typical chronic interstitial nephritis. The etiology was obscure.

Naish¹⁵ reports a similar case in a girl 9 years old, who weighed only 32 pounds, and was infantile in every respect. At autopsy both kidneys together weighed only 30 gm. Berkley and Lee¹⁶ report a case in a boy 10 years of age. He was first seen on account of so-called "bilious attacks," in which he had a good deal of dizziness, vomiting, and headache. There was marked albuminuric retinitis. The heart was considerably enlarged, and the aortic second sound was loud and ringing. The systolic blood pressure was 250 and the diastolic 190. The urine was of low gravity (1005) and contained a heavy trace of albumin, and many hyaline and granular casts. Death occurred 3 weeks after leaving the hospital. There was no autopsy. There are, perhaps, between 20 and 30 additional cases of this condition reported in the lit-

erature, which would be tedious to enumerate.

Miller and Parsons,¹⁷ in an excellent discussion of "renal infantilism," recognize two distinct groups of cases:

1. Renal infantilism with organic renal disease (chronic interstitial nephritis).
2. Renal infantilism without organic renal disease (diabetes insipidus).

In those cases with organic renal disease the degree of infantilism is variable, but is usually marked. The mental development corresponds to the stature. Polyuria and polydipsia are present, and the urine is of very low specific gravity. It may sometimes contain no albumin, and the only evidence of renal disease shown in the urine may be casts in small numbers. The degree of vascular change varies considerably, and may be all the way from no cardiovascular changes up to marked cardiac hypertrophy and very high blood pressure. The etiology is obscure; syphilis seems to play no part. The condition may be congenital. The prognosis is poor, and death practically always results in a short time.

Cardiovascular System in the Nephritis of Children. Hutinel¹ says that cardiac disturbance is common in acute nephritis, being shown especially by irregularity and dilatation. The blood pressure may be elevated in the acute stage, and usually subsides with the subsidence of the infection.

Baginsky,¹⁷ by clinical methods, could find no evidence of heart hypertrophy in any of his cases of acute nephritis. Friedlander,¹⁸ on the other hand, found evidences of considerable cardiac hypertrophy in a number of cases of scarlatinal acute nephritis that came to autopsy. Wessler,¹⁹ using the fluoroscope, found that there was a distinct cardiac hypertrophy present in all his cases of nephritis, both acute and chronic, and that it often developed as early as two weeks after the onset of the nephritis. Nobécourt²⁰ reports 12 cases of nephritis in infants, with the following conclusions regarding the state of the cardiovascular apparatus:

1. The blood pressure was elevated in all acute cases.
2. In the chronic cases the pressure was found to be less than the pressure in normal children of the same age.
3. In acute nephritis there is likely to be cardiac dilatation, and in chronic cases there may be hypertrophy, or there may not be.

Gordon,²¹ from a study of 9 cases, concludes that the blood pressure is usually elevated in both acute and chronic nephritis in children.

As can be seen, there is considerable difference of opinion among the various writers as regards cardiac hypertrophy and increased blood pressure. It is always desirable, in dealing with such a problem, to have data based on a large series of cases, and the trouble has been that not enough cases have been studied to

warrant any definite conclusions as regards the blood pressure and the size of the heart in the nephritis of children. Thus, nothing was definitely settled concerning the blood pressure until Berkley and Lee,²² after an extremely careful study of 93 cases of both acute and chronic nephritis in children between 2 and 12 years, reached the following conclusions:

1. The blood pressure is elevated in the nephritis of childhood, and occasionally to a marked degree. This applies to both acute and chronic nephritis.
2. Systolic and diastolic pressures are not increased to the same extent, the former averaging about 20 mm. Hg., and the latter about 10 mm. above normal.
3. The pulse pressure is increased, but the factor is not constant.
4. The blood pressure in chronic nephritis shows no constant elevation above that in acute nephritis.
5. The blood pressure may, in rare instances, be of prognostic value.
6. No relation has been found to exist between the blood pressure and the urinary findings.
7. Patients having marked edema showed a slightly higher average blood pressure than those with little or none. The difference is not great enough to warrant any definite conclusions.
8. Albuminuric retinitis is probably not common, even in cases showing a marked increase in blood pressure.

Functional Tests. A few years ago the dominant note in the study of nephritis was the histological anatomy of the kidney. At present this is considered very slightly, the main point of interest being the kidney's functional capacity. An immense amount of work has been done, and an enormous literature has developed in the last ten years, dealing with studies in the function of the diseased kidney; most of this work, however, has been done with adults, and very little with children. It is to be expected that the results with children would not coincide with those in adults, as the damage to the kidney is so different.

The phenolphthalein test of kidney function is probably the most valuable single test that there is, and is the one which has been most widely used.

Leopold and Bernhard,²³ in a series of 50 children free from renal disease, found that the phenolphthalein excretion for two hours varied between 50 and 96%, with an average of 70%. These cannot be taken as normal children, however, as many of them were suffering from such conditions as pneumonia or acute endocarditis, in which there might, possibly, have been some kidney insufficiency. Five cases of acute nephritis and five of chronic nephritis were studied. In both the acute and chronic cases the phthalein excretion was diminished. No conclu-

sions can be drawn from a study of such a small series of cases.

In a series of 50 children free from renal disease, the same authors found the following apportionment of the non-protein nitrogenous constituents of the blood. The total non-protein nitrogen varied between 19 and 40 mgm. per 100 cc. of blood, the average being 28 mgm.; the urea nitrogen varied between 8 and 21 mgm., the average being 12 mgm.; the uric acid varied between .6 and 3.2 mgm., the average being 1.8 mgm. The creatinin varied between .5 and 4 mgm., the average being 1.5 mgm. The blood of 16 children with renal conditions was examined. In acute nephritis the non-protein nitrogenous constituents were found to be within normal limits, and in chronic nephritis they were usually increased. [May be considerably increased in acute nephritis; may be normal or increased in chronic.—L. W. H.]

Leopold and Bernhard arrive at the following conclusions:

1. Figures for the non-protein constituents of the blood, as well as for the phthalein excretion of children free from renal disease, are practically identical with the figures obtained from adults, and vary within the normal limits as the adult figures vary.

2. The changes in these figures in children the subjects of renal disease correspond with the changes observed in adults.

3. The importance of the tests for diagnosis and prognosis, amply demonstrated in adults, will in all probability hold true for children, although a more comprehensive series of cases is required definitely to establish this view.

Tileston and Comfort²⁴ found that the phthalein excretion for normal children varied between 78 and 81%, while the non-protein nitrogen of the blood varied between 22 and 26 mgm. per 100 cc. of blood. They investigated three cases of acute nephritis, the phthalein tests being 39%, 56%, and 54%. The non-protein nitrogen of the blood in these cases was, respectively, 64, 34 and 24 mgm. per 100 cc. blood. They arrive at the following conclusions:

1. "The determination of the total non-protein nitrogen and urea of the blood is of great assistance in the diagnosis of uremia, and as a guide to the treatment of nephritis, a marked increase in these substances indicating actual or impending uremia, and calling for a diet low in protein. In the diagnosis of nephritis it is inferior to other methods, because many cases of nephritis show no retention of nitrogen.

2. The phthalein test is very valuable in the diagnosis of nephritis, showing probably better than any other one method the degree of impairment of renal function. In the diagnosis of uremia and as a guide to diet it is inferior to blood analysis, for a low phthalein output may occur without retention of nitrogen.

3. These investigations of the blood and of the phthalein excretion would appear to indicate a better secreting capacity of the child's kidney as compared with that of the adult.

Another test which has been used extensively with adults is the addition of a known amount of urea or sodium chloride to a diet which has been kept constant from day to day, and determining how much of the added salt or urea is excreted in a given time, usually twenty-four or forty-eight hours. This test has been applied in a few instances to children.

Noeggerath and Zondek²⁵ investigated six cases of nephritis in children by this method, with varying results; in the severe cases there was retention of salt and nitrogen; in the mild cases none. They believe that these tests are of considerable value in prognosis.

Bosler²⁶ tried the added salt test, as well as the lactose and potassium iodide tests, on 8 children with nephritis, and concluded that the results and significance of the tests were about the same as for adults.

Nobécourt,²⁷ following the ideas of his countryman, Vidal, emphasizes the importance of salt retention in causing edema, and cites the case of a child, who, while getting rid of edema with no other treatment than a salt-free diet, passed 39 grams of salt in 8 days. He attempts to classify nephritis in children on a chemical basis, again following the teachings of Vidal, and recognizes several distinct groups, according to whether the kidney inefficiency is for salt or nitrogen, for neither, or for both.

Kinloch,²⁸ working particularly with scarlatinal nephritis, concludes that there is a long-continued inefficiency on the part of the kidney to excrete chlorides, and an inefficiency of nitrogen excretion in the acute stages. Cutter and Morse²⁹ studied two cases of nephritis in children, with especial reference to creatin and creatinin retention, and found that there was none.

Zondek²⁹ believes that it is impossible sharply to separate salt and nitrogen in considering the functions of the kidney. Each influences the other, and in a given case there may be inability to excrete one of these substances if the other is present in the food in considerable amounts, but if the intake of one is cut down considerably, the excretion of the other proceeds without difficulty.

As a summary it may be said that so little work has been done as regards the functional capacity of the kidneys of children with nephritis, that it is not at all certain that these children can be compared in any way to adults, or that the various tests which have proved of such value in adults will be of so much value in children.

Prognosis. The question of prognosis is, perhaps, the most important and at the same time the most perplexing point to consider.

Ernberg³⁰ located and examined 40 out of 106 adults who had had acute nephritis before the

age of 15 years, mostly in connection with some acute infection, and found normal urines in all. He examined 16 out of 50 adults whose acute nephritis had occurred between the ages of 15 and 30 years, and found that all were normal except 4. Two of these gave evidence of nephritis of recent origin; the other two, whose original attack had been subacute rather than acute, showed albuminuria. He concludes as follows: "If these figures give us a true picture, we certainly have been unduly pessimistic about the prognosis of acute nephritis in childhood."

Apert²¹ is not so optimistic; he says: "In infancy and childhood there is great power of compensatory hypertrophy and repair for the kidney. This explains how, in infancy, the renal function may be apparently recovered, giving the appearance of complete cure, and how the kidney, none the less, once injured, is always very delicate, and is likely to be reinjured easily, and to give way at the return of any infection, however slight it may be." Thus it is possible that a good many of the cases of nephritis that we see in adult life may have originated in early life, and the end picture may be the result of the separate attacks of toxins of various acute infections upon a kidney whose power of resistance is already below par.

Hutinel²² believes that nephritis in children nearly always tends toward recovery, whereas in adults it tends the other way.

Treatment. As regards treatment there is little new. All are agreed that rest and a diet which will throw as little strain on the kidneys as possible is the best treatment. Some writers still advocate the old milk diet, but the majority realize that an exclusive milk diet is not desirable, as it does not furnish enough nourishment, and may contain too much protein for the kidney to handle.

A few men recommend diuretics to increase urinary secretion and get rid of edema, but most writers are agreed that in the acute stages of nephritis, at any rate, diuretics do more harm than good. The French writers, Nobécourt and Hutinel especially, believe in the great efficacy of a salt-free diet in getting rid of edema. The teachings of Martin H. Fischer, that nephritis is due to an acid condition in the kidney, and that large amounts of salt should be given, are not generally accepted by most clinicians.

Hutinel gives a summary of important principles in treatment: "As a résumé let me insist that in dealing with these nephritic children it is especially important to pay attention to careful nursing and hygiene. It is by these measures that the condition is cured, or in the more serious forms that life is prolonged. Use drugs as little as possible. Especially is it important not to irritate the kidney, and to forbid the patient eating any substances whose end-products he cannot eliminate. It is necessary, moreover,

to do away with any coexisting infection, however insignificant it may be, and to watch carefully the mouth, digestive tract, respiratory apparatus and skin. In a word, one must remember that the kidney is delicate, and spare it as far as possible."

Edebohls' Operation. The operation of stripping the capsule from the kidneys for the cure or relief of nephritis, first proposed by Edebohls, is discussed by Morse.²³ He reviews 23 cases of nephritis in children in which this operation was done. The end-results of the 23 cases were as follows: "As a result of the operation, two of the cases have been apparently permanently cured, one of them being well and with a normal urine after nine years, and another after eight months. Another was well for two years, and then died of an acute nephritis in no way connected with the previous illness. Two others were well as long as they were under observation, but the time was too short to consider them cured. Nine others have been so much improved by the operation, or, at any rate, the improvement began immediately after the operation, that they have been symptomatically well for months or years, instead of chronic invalids, as they were before the operation. These patients have not, of course, been cured, and will certainly die some time or other of their disease. Nevertheless, the addition of months or years of apparent health seems amply to justify the operation in these cases."

From a study of his own cases and of those which he has collected from the literature, Morse arrives at the following conclusions:

"Edebohls' operation is of much value in properly selected cases of nephritis in childhood. It may save life and result in permanent cure in acute nephritis. No child ill with acute nephritis should be allowed to die, therefore, without giving it the advantage of the chance offered by this operation. It may prolong life for considerable periods in a not inconsiderable number of cases of chronic nephritis, and may, possibly, in rare instances, result in a cure. It should, therefore, always be considered in all cases of chronic nephritis in childhood, which are not doing reasonably well under medical treatment."

DIAGNOSIS OF FOCAL SEPSIS.*

BY J. M. ANDERS, M.D., LL.D., PHILADELPHIA.

THAT both acute and chronic systemic or localized complaints may result from a pre-existing infectious focus has long been definitely known. The significance of chronic septic foci as an essential causative factor of disease, however, was not fully appreciated until the knowledge of the profession had been enriched by the labors of Miller¹, Rosenow², Billings³ and Hartzell⁴. Indeed, recent advances in this class of affections have caused the profession to view many diseases from a different standpoint.

We are still in great need of higher standards of knowledge of the subject of focal infections, both from the clinical and pathologic aspects. It follows that use is to be made of any and every source of information for diagnostic purposes. The ultimate aim should be to recognize these primary septic foci before the systemic consequences become well established.

In approaching the subject of the diagnosis of primary focal infections, it is to be recollected that in a large percentage of the systemic diseases of which they may be the apparent cause, *e. g.*, chronic nephritis, arterial fibrosis, myocardial degeneration and arthritis—other factors, as heredity, occupation, intemperance in eating and drinking, syphilis, gout and the like, may play an important etiologic rôle. When any of the latter causative agencies are operative in the particular case in hand, it is not possible to determine precisely the significance of an associated chronic infectious focus, more particularly since these may at times remain latent for a long period of time.

On the other hand, it not infrequently happens that a spontaneous cure of the primary focal infection, or that its removal surgically, leads to recovery, hence the recognition of the condition is a matter of the utmost importance.

At the outset, it may not be amiss to mention some of the commoner examples of acute and chronic diseases which are caused by local septic foci. Among the former are generalized tuberculosis, rheumatic fever, endocarditis, pericarditis, myocarditis, septicopyemia, gonorrhœal arthritis,

cholecystitis and appendicitis, while the chronic diseases thus produced embrace arthritis deformans, myocarditis, myocardial degeneration, arterial fibrosis, chronic nephritis, septicopyemia and many others.

While, as is well known, the infectious foci, acute or chronic, may occur anywhere in the body, it must not be forgotten that they may be multiple, and under these circumstances may be, at times, classified into primary and secondary; and an attempt to distinguish the former from the latter is always to be made, although this is sometimes impossible.

For example, if the lymph glands of the neck are found to be the seat of a septic focus, we may reasonably infer that the infection has passed from a primary focus elsewhere, *i. e.*, from the tonsils or teeth to these structures, therefore secondary foci occur in this situation, as a rule. The secondary foci exert an aggravating effect upon the clinical features of the condition, hence they assume diagnostic importance and should, whenever possible, be discovered.

It is also of diagnostic advantage to associate the grouping of clinical features in the particular case with chronic septic foci in certain organs. For example, the primary infectious focus in chronic arthritis deformans, acute rheumatic fever, chorea, endocarditis, gastric ulcer, appendicitis, myositis, myocarditis, and glomerulonephritis is usually located in the heart, in the guise of tooth-root disease (periapical abscesses), sinusitis and acute or chronic tonsillitis.

In 1887, Mantle⁵ first pointed out the relation of the tonsils as a portal of entry to rheumatoid infection,—an observation confirmed by the recent researches of Pointon and Paine.⁶ In cases of suspected gonorrhœal arthritis, an examination of the genito-urinary tract (posterior urethra, prostate, seminal vesicles, renal and perineal area, pelvis of the kidney, bladder) should reveal the seat of the focus. Acute miliary tuberculosis points to chronic foci in the lungs or thoracic lymph glands.

Unfortunately, we have not as yet an accurate knowledge of all the sites of septic foci in the body nor of the percentage of the cases in which the disease germs gain admission through these dangerous gateways.

Lane⁷ has attempted to fix professional attention upon the abdomen—colonic infection—but as Morris⁸ pertinently remarks: "We are not to concentrate our attention upon the colon in searching for focal infections. We must look over the periphery of a large circle of causes in order to find a possible focus which is sending out toxins that are being excreted at a certain point where there is a selective cell affinity for these toxins."

The internist should not neglect to examine the lungs and pleura for the primary focus in obscure septic states, more particularly if the latter are preceded by lobar pneumonia. An abscess may be found either in the lungs or in one

* Read before the American Climatological and Clinical Association at Lakewood, N. J., May 29, 1917.

of the pleural sacs. The expert gynecologist may discover the initial lesion in the uterus, the tubes, ovaries or glands of Bartholini.

The clue given by the character of the disease, however, may fail to reveal the primary focus on painstaking, thorough investigation in the supposed location. Frank Billings⁹, whose name is inseparably associated with the subject of focal sepsis, pertinently observes: "The failure to find a focus in the expected situation should indicate an extension of the field of examination until it shall have been found."

Goadby¹⁰ aptly states that "in many mouth infections, an exceedingly small local cause may produce suddenly generalized and widespread infection without apparent exacerbation of the mouth-disease preceding such infection."

Says Daland¹¹: "The diagnosis of mouth sepsis should be made by a specially skilled dentist, as a rule"; and in his opinion, I, in the main, concur. There are not a few obscure cases in which a consultation between a dentist and physician is to be advised and encouraged. In this connection, Dr. E. F. Everett¹² pertinently remarks: "There remains much to be unearthed in regard to these conditions, which can be accomplished only by the hearty co-operation of one profession with the other."

In suspected cases, the service of the x-ray expert is also required, but no amount of x-ray evidence, taken and considered separately, is ever sufficient for a reliable diagnosis, nor to furnish a basis for treatment. The results obtained by the roentgenologist must be weighed in connection with the bacteriologic findings, anamnesis and the associated symptoms. While bacterial cultures from the gingival surface will usually yield pathologic types of bacteria, they are "not an index of focal infection located in the dental alveoli or tonsils." (Billings).

In these cases and those brought under suspicion by the roentgenologist, the specially skilled dental surgeon should investigate into the pulp canal from apex to the extreme base. Not only so, but the periapical space should be aspirated and the material withdrawn examined microscopically and culturally.

The infected area or alveolar abscess may be entered either through the root canal or by passing over the exposed neck of the tooth involved, after removing the "tartar," and any exudate that may be present, penetrating as deeply as possible. The discovery of one of the salivarian group of streptococci, *e. g.*, the viridans, hemolyticus or mucosus, sets the question of the diagnosis of a septic focus at rest, but does not establish its specific relation to the general infection.

Obviously, if the pathogenic bacteria found in the outlying infected tissues do not differ from those discovered in the local focus, the etiologic connection between the local condition and general disturbances is reasonably well established.

In this connection, the studies of Hartzell and Henrici¹³ are of much interest and importance. They state "that the streptococcus viridans is the only organism found constantly in chronic alveolar abscesses and in the great majority is present in pure culture." They have at times found other organisms, particularly the white staphylococci and fusiform bacilli, but they believe that these are secondary invaders and practically devoid of pathogenic action.

These observers continue: "From acute abscesses we have recovered hemolytic streptococci on one or two occasions, but the majority of our cultures, from lesions where free pus occurred, have yielded staphylococci (also hemolytic at times), and the fact that these staphylococci have usually been found associated with the mouth streptococci, together with histological findings in the affected tissues, lead us to believe that many of the acute abscesses indicate a secondary invasion by staphylococci with a suppurative process implanted upon the primarily granulomatous lesion. Occasionally, purulent infections are found where other organisms are apparently the etiologic factor, such as the pneumococcus, diphtheroid bacilli, Bacillus fecalis alkaligenes, Bacillus pyocyaneus, etc.; such infections are not common, nor can they be considered characteristic dental lesions." If future observations by other bacteriologists confirm those of Hartzell and Henrici, the recognition of mouth sepsis will have received a decided impetus. The inoculation of animals with strains of the organisms mentioned above, obtained from the foci, is to be urged, since the general pathology and symptomatology of a particular septic condition may thus be elucidated. Such laboratory demonstrations have been carried out successfully in recent years in connection with a limited number of affections, more particularly acute rheumatic fever and chronic arthritis.

A diagnosis, however, is usually reached by a far easier route by physicians than the foregoing methods would indicate. Unhappily, many practitioners have fallen into the error of making hasty inferences based on inaccurate and superficial observation. This fact can be amply confirmed by the experience of those who have, at the suggestion of the physician or roentgenologist, removed the primary focus, with the expectation of effecting a cure, but without permanent success.

As elsewhere stated, "Attention cannot be too strongly drawn to the fact that before consulting an expert dentist, in cases in which mouth sepsis is suspected, the physician in charge must, by a process of exclusion, eliminate all foci of infection other than those that may be present in the mouth.

"In these preliminary examinations, the advice of a competent nose and throat specialist is always necessary. Without observing this precaution, either before or after consultation with a skilled dentist, with a report of the re-

sults, an unfair advantage is taken of the dental profession."¹⁴

In cases in which the focus is located in the sinuses and tonsils, the diagnosis of the local condition must be made by a skilled and progressive nose and throat specialist, who should not omit from his studies of the particular case a careful cultural examination of any exudate that may be obtainable from the focus. This method of investigation is to be pursued by the clinician with all thoroughness when primary foci are found in other portions of the body than the head, *e. g.*, the lungs, pleura or gall-bladder.

In some obscure cases of focal sepsis, the diagnosis resolves itself into a bacteriologic study of any vaginal, uterine and urethral discharges (the latter being obtainable at times only by massage of the prostate gland and seminal vesicles), as well as of a microscopic and cultural examination of the feces, sputa, urine, pleural or synovial exudate and even the blood. For example, strains of streptococci, which may invade the walls of the intestines, have been found in the intestinal flora. Furthermore, such focal infections, be they slight or extensive, may, particularly if encapsulated, produce the features of a secondary systemic infection. With these thorough laboratory studies must be combined an equally thorough, general examination, including a careful anamnesis.

I cannot forego an opportunity to urge that great care and caution are required to avoid ascribing to primary focal infections, systemic conditions due to other major causes that may be operative. Neither is the practical fact that a local focus, *e. g.*, a frontal sinusitis, may be secondary to and dependent upon a primary general infection to be overlooked. Such foci may disappear with the subsidence of the systemic features. On the other hand, they may tend to persist and thus become an aggravating cause of, and greatly prolong, the general symptoms.

In concluding, the diagnosis of a primary focus embraces the discrimination of non-focal infections and the establishment of its seat and particular etiologic variety both from a clinical and bacteriologic viewpoint, supported by reliable x-ray findings in many instances, and also expert opinions in the cases of tonsillar and sinus involvement. The fact is to be re-emphasized that x-ray studies should supplement, and not displace, other methods of diagnosis, particularly in cases of mouth sepsis. In the present state of our knowledge, it would appear that the diagnosis of a primary oral focus demands the isolation of the streptococcus viridans.

Lastly, the relation of chronic septic foci to systemic diseases does not as yet stand upon a sure and lasting foundation.

BRUCK'S SERO-CHEMICAL TEST FOR SYPHILIS: A REPORT OF 400 CASES COMPARED WITH THE WASSERMANN REACTION.*

By CURTIS E. SMITH, M.S., BOSTON,

AND

H. C. SOLOMON, M.D., BOSTON,

Psychopathic Hospital.

THIS new test for the diagnosis of syphilis by C. Bruck¹ has aroused universal interest. The scientific standing of Bruck and the simplicity of the technic led us to overcome our prejudice, that has been the offspring of the numerous tests that have been offered of late. Bruck states that since the discovery of the complement-fixation test for syphilis by Wassermann, Neisser, and himself in 1906, he has been trying to find a simple chemical reaction that would take the place of the complicated technic of the Wassermann reaction. This method, as he has published it, was worked out and is being used at the front, in the present war, where complete laboratory equipment is not available.

Commencing our experiments with a great deal of skepticism, we were much surprised at the results obtained, which are given below. Whatever may be the final status of the test in the determination of syphilis, we feel that there is a great deal of interest in the fact that this simple chemical reaction does pick out certain differences in the composition of blood sera, and that apparently a large number of syphilitic sera differ in their chemical composition percentage from the majority of non-syphilitic sera.

The technic, while exceedingly simple, offers many chances for errors and individual variations so that we have thought it well to give directions and cautions at some length.

Bruck's² technic is described as follows: "The test is made with 0.5 cc. clear serum in a test tube, to which is added 2 cc. of distilled water, and the whole shaken. Then, with a precision pipette, 0.3 cc. of the ac. nitr. purum of the German pharmacopoeia is added, and the whole thoroughly shaken and then set aside at room

* Being Contribution of the Massachusetts Commission on Mental Diseases, Number 191 (1917.11). *Bibliographical Note.*—The previous contribution (1917.10) was by H. C. Solomon, entitled "The Behavior of the Wassermann Reaction in Cases Receiving Mixed Treatment," published in *Medicine and Surgery*, May, 1917.

temperature for ten minutes. Then 16 cc. of distilled water at room temperature is added, and closing the tube with the finger, it is shaken up and down three times carefully, not vigorously enough to make it foam. This is repeated ten minutes later, and the tube is then set aside for half an hour. By this time the precipitate is entirely dissolved in the tube with the normal serum, while the syphilitic serum shows a distinct, flocculent turbidity. In two or three hours, or better still, in twelve hours, the gelatinous and characteristic precipitate is piled up on the floor of the test tube."

The acid is prepared by diluting the Acidum nitricum of the U. S. P. (Sp. gr. 1.403) with distilled water until the hydrometer shows the specific gravity 1.149, which corresponds to the nitric acid of the German pharmacopeia, but since this requires a special hydrometer, a simpler method is to make a 25% solution of the Acidum nitricum, which will give about the proper specific gravity.

The serum is obtained by allowing 10 cc. of blood to stand at room temperature for an hour, and then centrifuging. Serum that has stood for some time may be used as well as the fresh, and even bloody serum does not seem to confuse the results to any great degree. The serum gives the same results with or without inactivation. Post-mortem blood gave results as constant as that obtained during life, in the few cases that we had in this series. But the reaction may be influenced markedly by the size of the test tubes. We have found that the 13 x 1.9 cm. is the most favorable size.

When one first thinks of this test it appears very simple and probably somewhat crude as a chemical reaction, but there are certain precautions that must be observed, and several hundred normal and syphilitic sera should be tried before the investigator can feel that he has a refined routine technic. There is the personal equation which must be watched, for here is probably the greatest source of error, and readily explains why two different persons get widely varying results with the same sera if they have done only a few dozen tests. We must take it for granted that the reaction is a quantitative one, where some positive reactions may differ only slightly from the normal non-syphilitic, and, furthermore, any normal serum may be made to give a positive reaction, and almost any positive serum be made to give a negative by improper manipulation at some point in the test. There are as many places for error to creep in as there are steps in the process. Bruck has omitted many details in his publication, which allow personal variations, and so we have tried to develop a routine process that will eliminate as many of these as possible.

We shall here attempt to explain the methods which we have found most satisfactory and at the same time indicate the places where error is likely to occur. The 0.5 cc. of serum is added

to 2 cc. of distilled water, and shaken thoroughly. Now add slowly exactly 0.3 cc. of acid from a precision pipette, care being taken that it does not flow down the side of the tube. The tube should be shaken gently while the acid is being added, for this prevents the formation of a flocculent precipitate in normal serum which is difficult to dissolve later. After the acid is added shake each tube gently to make sure that these flakes do not persist. It is difficult to shake each tube in exactly the same manner, as must be done if we expect uniform results.

The first 250 tests of this series were made by allowing the tubes to stand for ten minutes as Bruck advocates. Then we found that practically all sera gave a positive reaction if allowed to stand 15-20 minutes, and so in the other tests of the series an attempt was made to make the reaction more sensitive by allowing the tubes to stand only 6-7 minutes. During this time the tubes should be shaken gently once or twice. The manner in which the 16 cc. of water is added also influences the reaction. If allowed to flow freely in upon the precipitate, the positive may be forced into solution as well as the negative. Both pipette and tube should be slanted and the water allowed to flow down the side of the tube without disturbing the precipitate. If all has gone well up to this point, we may see a marked difference between the normal and syphilitic precipitates, in that the normal will begin to go into solution at once, thus clouding the water, while a positive precipitate will be composed of large flakes which show little or no tendency to go into solution or cloud the water above. It must be remembered that the most flocculent positive precipitate will go into solution if the fluid is splashed or shaken too hard while the tube is being inverted. If any doubt as to the character of the precipitate now exists, it may be allowed to stand ten minutes longer, and again inverted as before, or even repeated several times during the next hour or two. We see no reason why the tubes should be left to stand over night, for during this time a precipitate usually settles in the normal tubes. This, however, differs from the syphilitic precipitate in that it is still finely granular and goes back into solution readily when the tubes are inverted.

In view of these possible grounds for error, it is only logical to run controls of known positive and known negative sera along with each group of unknown bloods, and even then certain tubes will seem doubtful, in which event the test should be repeated, with added precaution to see if a definite positive or negative reaction may be obtained.

In the last tests of this series we seemed to aid the reaction by rendering the serum-water solution alkaline by one or two drops of 10% potassium hydroxide before the acid was added.

The positive sera have a larger precipitate, while the normal seem to dissolve more readily.

PLATE 1.—THE APPARATUS NECESSARY FOR THE TEST.

PLATE 2. (Read from left to right).

Tubes 1, 8 and 10 show strongly positive precipitates with clear fluid above.
 Tubes 2 and 4 strongly positive reactions where tubes were inverted immediately before taking picture.
 Tubes 3, 9, 12 and 14 show negative sera in clear solution.
 Tubes 5 and 13 show negative sera in cloudy solution.
 Tubes 6 and 14 show precipitate that may occur in negative sera if allowed to stand over night.
 Tubes 7 and 11 show positive sera with clouding above the precipitate.

The tests here reported were made on blood sera obtained from patients admitted to the Psychopathic Hospital and its Out-Patient Department. As a routine Wassermann test is made on each patient who enters the hospital, it was only necessary to take another tube of blood from each patient, and the results checked in each instance with the Wassermann reaction. As it takes several days to get the report from the Wassermann laboratory of the State Board of Health, there was no chance of being prejudiced by a previous knowledge of the Wassermann reaction. The cases for the most part were those of mental disease; the majority in good general physical health.

A comparison of the total number with the Wassermann reaction shows that there was a general agreement of 304 of the 405 cases tested, or a percentage agreement of practically 75%. In considering the cases of syphilis of the central nervous system in a group by themselves, we find that the agreement is closer, since 69 of the 79 cases tested, or 87%, agreed without any question of doubt. It will be noted that in several cases of general paresis, the Wassermann reaction, which was repeated at intervals, was negative, and in most of these cases the Bruck test was negative also. Our few cases of congenital and latent syphilis also checked very closely with the Wassermann test. In the

various groups of mental cases in this series, no factor of interference was discovered. It is also of interest that in the cases where the blood was obtained post-mortem, the Bruck test agreed with the Wassermann result obtained on ante-mortem blood serum. Further work on post-mortem sera will be reported. Some of the patients not included in the syphilitic groups that have a negative Wassermann and no clinical signs of syphilis, give a history of previous infection at some time, which might partly account for the variations in the two tests.

CONCLUSIONS.

1. We present results of the Bruck serochemical test in 405 cases. In 101 of these cases there were definite clinical manifestations of syphilis, in which the Wassermann and Bruck tests agreed positively in 74, or 75%. The two tests agreed negatively in 12 instances, and were at variance in 15.

2. In the group which showed syphilis of the nervous system we had 64 cases of clinically certain general paresis, of which the Wassermann and Bruck tests agreed in 54 instances, or practically 85%. In other forms of central nervous system involvement the agreement was 100% in the 15 cases tested.

3. In the cases with no apparent involvement of the nervous system the agreement was somewhat less, being 76%. This may be in keeping with the fact that the Wassermann test was not so strongly positive in these cases.

4. The advantages of the test are: (1) the short time required to do the test, (2) the limited amount of apparatus necessary, and (3) the simplicity of the technique.

5. The disadvantages of the test seem, for the most part, to be bound up in the personal variations that are apt to occur.

6. We are here dealing, most probably, with a quantitative chemical difference in the protein content of syphilitic and non-syphilitic sera, the nature of which is not understood by us. It is our hope that this may be brought to light in the near future in the field of chemistry.

PARESIS OR DEMENTIA PRECOX?^{*}

By HAROLD I. GOSLINE, M.D., TRENTON, N. J.

*Pathologist, New Jersey State Hospital; formerly
 Pathologist, Worcester State Hospital,
 Worcester, Mass.*

The question of nomenclature must arise from time to time, as our knowledge of disease-processes increases. The question of nomenclature in the psychoses is an especially difficult

^{*} Read in different form at the Conference on Neurosyphilis and Its Treatment, held at the Grafton State Hospital, Worcester, Mass., Nov. 17, 1916. Title at that meeting: "Demonstration of Siccinus in a Case of General Paralysis Having 'Ataxic' Symptoms."

one, owing to the processes dealt with and owing to the slight amount of knowledge which we possess with regard to the normal functioning of the human mind. More recently this question has been brought to the fore in psychiatry by reason of the advances made possible by the discovery and use of the Wassermann reaction, and it is with this small part of the question of nomenclature that we are concerned in this paper.

The Wassermann reaction, as applied with the blood and spinal fluid in the psychoses, has given mental medicine a decided advantage by showing it the true extent of the syphilitic process. We have come to a fuller realization of the truth of the old statement that paresis can simulate any mental condition. But since the discovery and use of the Wassermann, and with these the discovery of the extent of the inroads of lues, the diagnostician has become careless in his nomenclature. Every case of syphilis of the nervous system is called paresis, in some locations, and even in the most advanced centres we hear of only two sorts of neurosyphilis,—the parenchymatous and the vascular connective-tissue types.

Of course, this is the logical thing to have expected, for we know that the diagnostician is concerned chiefly with treatment and it was felt at first, that the designation "paresis" was sufficient for his purposes. Later the term "syphilis of the central nervous system" was found to state the facts better, and, as the results of treatment and of further anatomical studies appeared, it was found that the division of syphilis of the central nervous system into the parenchymatous and vascular connective-tissue types had a practical bearing for prognoses.

But nowhere do we find an attempt to classify cases as to their psychosis, that is, as to the predominance of one group of mental symptoms as against another. The diagnosis of paresis is now made on the finding of the positive Wassermann reaction in the patient's blood and spinal fluid, together with a pleocytosis and the presence of abnormal chemical constituents in the latter. Of course, I am not taking into consideration the border-line cases here.

It is this attitude of calling all such cases by the above set of titles which should be modified shortly. There are several reasons why this attitude should be changed, not the least of which are theoretical reasons. There are certain practical reasons, chief among which is the question of prognosis. We are told that the vascular connective-tissue types are more amenable to treatment than the parenchymatous types; that we may arrest the process, but that we cannot expect to replace injured or dead nerve cells. This is all doubtless true, but it is theoretically equally true that some nerve cells are more vital to the animal economy than others. And it is this consideration of the groups of nerve cells

injured which should also be of value in making the prognosis.

We have some evidence that it is perhaps a question of nerve cells injured rather than one of connective-tissue as against parenchyma, for we know that certain cases show more mental impairment than others, even after the disease-process seems to have been arrested. And we know now that something more than the therapeutic test is essential in order to give the correct prognosis; it being usual to claim that those which improve are the connective-tissue types, and those which do not yield so readily are the parenchymatous types.

The chief question which has been neglected is whether the process is chiefly forward of the Rolandic fissure or behind it, and whether it is chiefly in the cortex or in the fiber pathways in the white matter. We are all aware of the differences in physiology between the pre- and post-Rolandic regions, and I hope that we are all familiar with the significance of these two great regions for psychiatry. May there not be a difference in the vital necessity between the motor needs and the sensory needs of the human organization?

In addition to the practical aid in prognosis which may be offered by a consideration of the brain region affected, I would propose an equally practical reason for such consideration in the aid which it might give the study of dementia precox, which is fast finding its real anatomical foundation. It is felt in certain quarters, for example, that the region affected in the catatonic form of dementia precox is the post-Rolandic. If this is true, is it not conceivable that any process which affects this region to a sufficient degree should give rise to the catatonic syndrome? Is it too much to suppose that the syphilitic process may give rise to the catatonic syndrome, if it affects the post-Rolandic regions severely enough? As a matter of fact, the presence of dementia precox and of paresis in the same individual has been noted long before the Wassermann reaction was discovered, but, at that time, it was thought advisable to consider the two as distinct entities in the same patient. Now we can consider the whole as one process which has involved the groups of cells and fibers which subserve the two mental pictures.

Case W. S. H., No. 28853, was such a case. The patient's mental trouble began at the age of 28 years with an exaggeration of his previous dissolute habits. After about 6 months, he developed auditory hallucinations, thought he was to be killed, became destructive, maniacal, and went out of doors improperly clad. At admission, he talked volubly and quickly, but showed some impairment of memory. He was easily distracted and his flow of thought was rambling. He had high ideas about his ability to sing, and altogether acted in a maniac way. He gradually passed into a catatonic state, showing negativism, muscular rigidity, refusal of food, inconti-

nence. Yet physical signs were noted early, their significance not being fully realized, and with the appearance of the positive tests for hnes on the blood and spinal fluid, the diagnosis of paresis was made, though the first diagnosis had been manic-depressive insanity, manic phase, and then dementia precox. The patient finally developed convulsions and died at the age of 30, after a duration of about 2 years of the acute symptoms.

The pathological examination of the brain with the Scharlach-R stain for fat in twenty-four sections from each side of the brain, showed that the chief deposition of fat was in the white matter of the post-Rolandic convolutions. While such a finding in a single case could have little meaning, it assumes great significance when considered in connection with the other facts stated above.

CASE W. S. II.—White matter of supramarginal gyrus. Shows enormous amount of fat (black). Scharlach-R stain.

It seems proper, then, that we should call those cases paresis which show the mental picture and the physical signs of paresis, whether they have the positive signs of syphilitic infection or not. It seems equally fitting to me that we should call those cases dementia precox which have the mental and objective signs of dementia precox, regardless of whether they have a syphilitic infection or not. For only in this way can we hope to think and act clearly in the splitting up of the dementia precox group, which seems to be well under way, and only in this way, perhaps, can we solve the question of why certain paretics recover with more dementia than others, why some are less amenable to treatment than others, and, finally, why some have negative findings for hnes.

FURTHER OBSERVATIONS ON SHOCK AT THE FRONT.

By W. T. PORTER, M.D., BOSTON.

[From the Laboratory of Comparative Physiology in the Harvard Medical School.]

I.

IN my first communication on "Shock at the Front,"¹ I recorded measurements of blood pressure made in the first-line trenches at Nieuport on the Yser. The blood pressure in soldiers on duty there was normal. But at Nieuport there was no offensive, save the habitual bombardment. Fortified perhaps by habit, life under fire had become an uneventful round. It is true that the bomb, the trench torpedo, and the high explosive shell took their daily toll. The spectacle of mangled men stirred pity, but failed to change the even pressure of the blood. It might not be so in a fierce barrage. There, I was told, when drum-fire fills the air with a continuous roar and hillsides smoke under the bursting shells, the arterial pressure sinks, and turns toward shock. Upon the wound, the weakened guard gives way, the pressure falls profoundly, and life is at once in jeopardy. An alluring speculation! Yet long experience has shown that, with regard to the circulation, speculations have no value except as incitements to research; only measurements have real worth.

The Great War does not lack material for such measurements, but admission to the tragedy is difficult. To request an order to proceed to a spot where an attack is being made is of no use. The attack will be over before the order can be issued by the necessary bureaus. It is essential to have authority to pass anywhere on the battle front. On May 20, 1917, I received from the Ministry of War, with the consent of the General commanding the — army, an order giving me complete freedom of action and specifying that I was to receive every assistance in accomplishing my researches on traumatic shock. A month later this was supplemented by a priceless order from Grand Quartier Général extending these privileges to other armies. These magical papers opened every door. I am deeply indebted for them. But I am still more indebted to the consideration and kindness shown me in the — and — armies by men of every rank, from stretcher-bearer to Commanding General.

This is not the place to set forth my adventures. It is enough to say that on May 22 I found myself about 300 metres from the crest of Mont Blond, one of the low summits in the Massif de Moronvillers, a long ridge which commands the plain beyond Chalons-sur-Marne. The strategic importance of this ridge is very great. In April it was still held by the enemy. The French offensive against the Massif began April 16. Owing probably to insufficient ar-

tillery preparation, this first attack failed; little or no ground was gained, and the losses were very heavy. One ambulance, of which I knew, prepared for 3000 wounded; they received 18,000. Since that date, the French have won all the ridge except that part above my station. On May 25, the French finished the job. It was a beautiful and interesting operation. I quote from a letter written on my knee during the last hours of the battle:

"My *poste de secours* was dug by the Germans. It consists of a cellar about 8 by 10 feet, and 6 feet deep. The roof is proof against fragments, but not against direct hits.* A ladder leads to a cave, 7 by 8 feet, the floor of which is 15 feet below the surface of the ground

"Yesterday afternoon, at three o'clock, the French began to prepare for storming the crest of Mont Blond—the white ridge just before my eyes. In an hour the Germans made up their minds that an assault was intended. The artillery fire, which was continuous before, now swelled to a torrent. Each side placed a barrage. The German barrage covered the little valley behind the crest. We were on the slope nearest the crest. The bottom of the valley was about 150 meters from us, consequently we were within the barrage. Between four o'clock and midnight, more than 10,000 heavy shells fell within a radius of 1000 feet from our cave. I took the count from time to time with my watch. We were driven at once into our deeper refuge. The little stuffy hole was packed with men, knee to knee; stretcher-bearers, surgeons, my orderly, and myself. The three surgeons played bacarat. I sat on the edge of a plank and watched the game. We had an acetylene light. The shells fell all around, shaking the place and repeatedly putting out the light. The noise was remarkable. The air was filled with screams, hisses, and loud reports, followed by the slide of masses of earth. Many shells were so close that a strong push of hot gas was felt. At six o'clock the Moroccans took the ridge by storm. At midnight the bombardment slackened but did not cease. With the dawn the wounded came in a stream. They were laid in the upper room. The wounds were of all sorts. The worst was a completely crushed jaw, in a man with a dozen slighter wounds. One man had a hole through the temple into the brain,—a hole two inches long and half an inch wide. Another had a smashed leg, a bad head, and in the thigh a wound the size of a small orange. I watched the blood pressure carefully. Imagine a cellar with a plank floor covered with clay an eighth of an inch deep. A horrible tub full of bloody dressings. Two stretchers on the floor. Ten men in a space 8 by 10 feet, shoulder to shoulder. Two candles. Sand-bag walls. The roof so low that I am always hitting my helmet against the beams. The

air thick with the smell of blood, sweat, alcohol, iodine, vomit. Everywhere a smear of clay—the chalky clay of Champagne. The continuous scream, roar, crash of shells. A rain of small stones, dirt, pieces of steel. Every few seconds a profound trembling, as a shell strikes closer. Four men passing bandages and iodine in the half light, over backs, under arms. The cries of the wounded. The litter of bloody garments. The fresh cases, obliged to lie outside, under the fire, until the room is cleared. The brancardiers, bent under the load of the stretcher, slouching off with the dressed wounded. The dawn, the failing moon, the thick vapors and acrid stench of the barrage. The blasted hillsides smoking under the continual rain of death. Countless fresh shell holes all around us. The graves reopened.

* * *

They are bringing down the dead. They lie sprawling on the slope just below us, half sewed up in burlap, like pieces of spoiled meat."

In spite of these conditions, of which I have made a faithful report, the blood pressure remained normal, not only in the unwounded men, but also in the wounded. Yet many of the wounds were grave.

My previous observations at Nieuport, at the Mort Homme, and on the Somme, showed that the blood pressure is not lowered under the habitual bombardment. These new observations show: (1) that the blood pressure is not lowered under a barrage fire, said to be as violent as the worst in the great drive at Verdun; and (2) that shock probably is not immediate, but develops some time after the wound.

II.

In a second communication² in this JOURNAL, the discovery was recorded that fat embolism is a cause of shock. This discovery was based on my producing typical shock by the injection of olive oil into the jugular vein of animals. It was supported by the known facts: that shock is most frequent after fractures of the femur and after multiple wounds of the subcutaneous fatty tissues; that fat embolism of the brain and other organs has been observed after such wounds; that the injection of oil into the veins is followed by fat embolism.

During the last week of May, 1917, I collected at Mourmelon-le-Petit sufficient observations to support strongly the statement that fat embolism is the principal cause of shock.

Mourmelon-le-Petit is a small village in the plain of Chalons-sur-Marne. It is the seat of an ambulance de triage—a sorting station. To this station, which is within shell fire of the German lines, are brought all the wounded from a number of *postes de secours* on the Massif de

* Two days after my departure, a shell entered the *poste* next mine, killing the two surgeons and five of the stretcher bearers.

Moronvillers. At this *triage*, I saw more than one thousand freshly wounded. Aside from a few abdominal cases, in which there was probably direct injury to the vasomotor nerves of the abdominal vessels, the only shock was that caused by fracture of the femur or by multiple wounds of the subcutaneous tissue—cases in which fat embolism undoubtedly took place.

From June 23 to June 30 I was at Vauxtin, seat of a *triage* behind the Chemin des Dames. Here again were the familiar scenes: the balloons hanging like carrion birds above the heights, the aeroplanes, the fuming barrage, the wrecks of men cast up by the waves of field-grey Germans that beat in vain against these fiery slopes, the stream of ambulances bringing their freight with the regularity of butchers' carts. And here again was the clearest evidence that shock is rarely seen except where fat embolism is known to be present or where the vasomotor nerves of the abdomen are injured.

III.

In a third communication³ in this JOURNAL, experiments were recorded in which the low blood pressures of shock were raised 15, 20 and even 30 millimeters of mercury by increasing the aspiration of the thorax. When an animal suffering from shock is made to breathe an atmosphere rich in carbon dioxide, the action of the respiratory pump may be doubled or trebled. The blood is sucked from the engorged portal veins into the heart and the arterial pressure is raised.

The following cases of shock, observed at Vauxtin,* illustrate the value of the respiratory treatment in man:

CASE 1. June 25, 7 a.m. Both legs amputated. Diastolic arterial pressure 51 mm. When carbon dioxide was inhaled until the quantity or air entering the chest was about doubled, the diastolic pressure rose to 60 mm. At 11 a.m. the patient was out of danger.

CASE 2. June 26, 8.25 a.m. Two deep wounds in the back. Multiple wounds elsewhere. Diastolic pressure, 53 mm. Inclined position and hot normal saline in vein caused pressure to rise to 70 mm. Operation at 10.15 a.m., lasting a quarter hour. At 10.30 the diastolic pressure was 52 mm. An injection of adrenalin brought it to 57 mm. for a short time only. At 11.05 the pressure was 53 mm. At 11.15 the respiration was deepened by inhaling carbon dioxide; 11.20, diastolic pressure 60 mm.; 11.25, carbon dioxide was stopped and the pressure thereupon fell to 53 mm. At 11.35, the gas was again employed and the pressure rose to 61 mm. This man recovered.

CASE 3. June 29, 6 a.m. Right leg crushed. Many small wounds through subcutaneous fat. Diastolic pressure 47 mm. Injections of normal

saline solution in vein at elbow did not raise the pressure. Ether injected under the skin also produced no effect. Increased respiration from inhaling carbon dioxide at once increased the pressure. The pulse, which could scarcely be felt at the wrist, became plainly stronger. At about 11.30 a.m., during carbon dioxide breathing, the leg was amputated under local anesthesia, and the multiple wounds dressed without anesthesia. There was no unfavorable reaction, though under ordinary conditions (without carbon dioxide respiration) the operation would almost certainly have been fatal. Several hours after the operation, this man's femoral pulse and heart action were so good that he was believed out of danger. The carbon dioxide respiration was discontinued. In about ten minutes, the respiration became feeble and the pulse less strong. The carbon dioxide was at once renewed, but the respirations did not become stronger, and in ten minutes more the man was dead, in spite of the carbon dioxide atmosphere. He was from the beginning a case ordinarily called hopeless.

From these cases it appears that increased respiration from the administration of carbon dioxide is of advantage in shock. In my experience it has not failed to raise the blood pressure, even in profound shock.

In the observations at Vauxtin, the head of the wounded man was placed in a wooden box, the length, breadth and height of which were each about 35 cm. The end for the neck was in two pieces. The lower piece was fixed and had a semi-circular opening for the back of the neck. The upper piece was movable. It had a semi-circular opening for the front of the neck. This piece slid down upon the neck like a guillotine. Cotton was placed between the edges of the openings and the skin. A hole of about 2 cm. in diameter was made in each of the two sides of the box. Cotton was placed in these holes to regulate the amount of carbon dioxide and air. The carbon dioxide entered one of these holes. It came from a cylinder provided with a regulating valve. On its way it bubbled through a water bottle. The volume of gas employed was judged by the number of bubbles per minute. Enough gas was used to double the respiration. The patient was in the inclined position, the feet 30 cm. higher than the head.

I believe it would be of advantage to use the carbon dioxide during operations.

Great care should be taken to discontinue the carbon dioxide respiration very gradually.

Carbon dioxide breathing may also be given without any apparatus except the box. In that case, the patient produces his own carbon dioxide.

Medical and Surgical Journal

Established in 1812

An independently owned Journal of Medicine and Surgery published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, SEPTEMBER 6, 1917

EDITORS.

ROBERT M. GREEN, M.D., *Editor-in-Chief*.
 GEORGE G. SMITH, M.D., *Assistant Editor*.
 WALTER L. BURRAGE, M.D., *For the Massachusetts Medical Society*.

COMMITTEE OF CONSULTING EDITORS.

WALTER B. CANNON, M.D. ROGER I. LEE, M.D.
 HARVEY CUSHING, M.D. ALLAN J. McLAUGHLIN, M.D.
 DAVID L. EDSALL, M.D. ROBERT B. OSGOOD, M.D.
 REID HUNT, M.D. MILTON J. ROSENAU, M.D.
 EDWARD C. STREETER, M.D.

ADVISORY COMMITTEE.

EDWARD C. STREETER, M.D., Boston, *Chairman*.
 WALTER P. BOWEN, M.D., Clinton.
 HOMER GAGE, M.D., Worcester.
 JOEL E. GOLTHWAIT, M.D., Boston.
 LYMAN A. JONES, M.D., Swampscott.
 ROBERT B. OSGOOD, M.D., Boston.
 HUGH WILLIAMS, M.D., Boston.
 ALFRED WORCESTER, M.D., Waltham.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.50 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising apportionment of the Journal, should be addressed to

ERNEST GREGORY, *Manager*,
 126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

THE POSITION OF ANTISEPTICS.

REPORTS from surgeons at the front show that radical readjustments of their views on antiseptics are constantly being made. Dakin's solution and his Chloramine-T in particular seem to have met with much unfavorable criticism. The objections to their use come under two headings. The first and most important objection is that as prophylactics these preparations have proved highly uncertain. Accordingly, in French army orders published in the *Bulletin et Mémoires de la Société de Chirurgie* of June 19, surgeons are requested not to use hypochlorite powder as a prophylactic in cases of gas gangrene. The rule appears to be based on sound knowledge, for in his investigations Kennety Brown was unable to observe any action of the solution on the gas bacillus. He states that sodium hypochlorite is not specific against this organism. More recently Sir Almoth Wright has said that Dakin's solution possesses little antiseptic power. Similarly, it is averred by

the French surgeons, Le Grand and Delbet, that while Dakin's solution reduces the number of flora in wounds, it annihilates the natural defences of the serum. Its action appears to be simply the mechanical washing away of necrosed tissue. They agree with Wright that when this has been done a hypertonic solution of salt is the best application. This mention of salt solutions may not inaptly introduce a brief digression. Their uses and effect have been recognized and taught in American schools for some years. However useful they doubtless are, they are also far from being a novelty.

Recently, various English writers,—Browning, Gulbransen, and Thornton,—have studied the precise antiseptic strength of sodium hypochlorite. They contrast it with brilliant green, one of the group of specific antiseptics. Brilliant green is somewhat less active than acriflavine in the presence of serum, but solutions of 1:2000 were five hundred and seven times more powerful than Dakin's solution against staphylococcus and B. coli respectively (*British Medical Journal*, August 4, 1917). Acriflavine at present is considered one of the most effectual of specific antiseptics, and it has a remarkable selective germicidal effect on almost all organisms, causing their rapid disappearance from wounds. Moreover, the effect of these dyes is increased by the presence of serum, and they are regarded as superior to Dakin's solution when used according to Carrel's method.

A somewhat less important consideration is raised by the question how far the chemical faults of this solution militate against its use. In its preparation it is difficult, if not impossible, to avoid an excess of boric acid, which it is necessary to add in order to keep the solution free from caustic soda, which itself results from the presence of free hypochlorous acid. The effect in application of caustic soda is painful and sometimes irritating. In a later preparation,—p-toluene-sodium-sulphochloramide,—Dakin has endeavored to avoid this fault, but it is likely that by introducing a basic substance into his antiseptic he has lessened its effect in the presence of serum. Daufresne or Dufresne, as some spell it, avoids the use of boric acid, substituting carbonate and bicarbonate of sodium in the solution of chlorinated lime. In this case the liquid contains free caustic soda, which causes injury to the vitality of the tissues. Daufresne's solution requires twelve hours for its

preparation and great technical skill. According to a recent writer, E. G. Schlesinger, in the July issue of the *Journal of the Royal Naval Medical Service*, the Dakin-Daufresne solution "aims at securing a solution containing between 0.45 and 0.5% of hypochlorite and devoid of any free caustic soda." Tests of this solution made by Duret and described in the *Journal des Praticiens* do not bear out this belief. He suggests a change, that is, the action of magnesium sulphate on chlorinated lime. This solution, he states, is free from caustic alkali, is stable, and cytophylactic. In a sense this may be true, but practice and laboratory tests indicate that the class of substances which depend for their effect on hypochlorites is precisely the class which must be discounted.

Another property alleged to belong to Dakin's solution seems open to question. According to Schlesinger, it "has the valuable property of rapidly splitting protein into soluble substances." There is clearly no possible answer to this assertion, except a purely theoretical one, having no expression as a chemical formula. In such hypothetical reactions there will doubtless be many possibilities. On this point, A. C. Hollande in *Comptes rendus de l'Académie des Sciences*, 1916, clxii, p. 959, has brought forward some investigations that afford us at least an analogy. On adding basic dyestuffs to blood serum, a copious precipitate is produced, but if an acid dyestuff is used, coagulation of the albumin is prevented. It seems likely that definite compounds between the soluble protein and the dyestuff are formed. But as heat is necessary to this reaction, it becomes hard to understand how it can take place in wounds.

An invaluable insight into the methods of surgeons at the front is provided by the latest reports of the French and German authorities. An abstract of the present German practice, published in the *British Medical Journal*, shows that primary excision and suture is the accepted method of treating wounds. The French have lately emphasized the value of this method, which they say is founded upon the rational one of helping nature in her own methods of cure, which they call the autosterilization of wounds. Removal of the lacerated and necrosed tissue, washing with hypertonic saline, and suture, have yielded the best results. The practical lesson is that the treatment of wounds during transport and afterwards is a question of technic which,

if properly done at the right moment, leads to the happiest results without the routine use of antiseptics. And these, when used, are those which are specific against the special flora of the wound. But, with good technic, the flora should be excluded.

THE DRAFTING OF MEDICAL STUDENTS.

IN another column of the present issue of the *JOURNAL* is published a report by the Committee on Hospital and Medical Facilities of the New York Mayor's Committee on National Defense relative to the drafting of hospital internes and medical students. The desirability of such draft has for some weeks been a subject of discussion in medical organizations and periodicals. On August 21, the United States Secretary of War instructed Surgeon-General Gorgas to provide him with figures showing how the operations of the draft law would affect reputable medical schools throughout the country. In this work, Dr. Gorgas was assisted by Dr. William H. Welch and Dr. Victor C. Vaughn, who are special advisors on his staff.

The shortage of hospital internes has already begun to make itself felt. In twenty New York hospitals, 156 members of the staff have already joined the Medical Reserve Corps; and of 218 internes, 178 are of draft age, and 88 have already been accepted. Authorities on medical education in Baltimore, Syracuse, Cincinnati, St. Louis, Cleveland, and Boston have joined with the New York Mayor's Committee to urge the exemption of hospital internes and medical students from the general draft. A communication on this subject from Dr. Ieffron of Syracuse to the Chairman of the Senate Committee on Military Affairs elicited the following reply:

"It seems to me that in the operation of this act some method will be devised by those who are responsible for its execution to utilize to the best advantage the services of those who may be drafted into the service under its terms. If this is not to be the case the whole system would be seriously impaired. Have you ascertained what the War Department proposes to do? Suggestions for changes of the law have not yet reached this committee, so far as I know, but it may be that the Secretary of War has already anticipated the situation you mention. The matter is having my careful attention."

In Chicago similar action against the drafting of medical students has been taken by leading

physicians and educators. Statistics show that without exemption the draft would involve the following percentage of students at several large institutions in medical training: Columbia University, 30%; Bellevue Hospital Medical College, 22%; Cornell University, 21%; New York Homeopathic Medical College, 33%; Syracuse University, 29%.

The arguments against the wholesale drafting of hospital internes and medical students for non-professional service in the National Army are obvious to those who regard the national economic value of the training which they possess. These arguments have been most effectively stated in a letter written by Dr. Henry A. Christian of Boston and published in the daily press on August 26:

"Should students of medicine be drafted as privates? This is a question which is receiving considerable discussion at present. Is this question of any vital importance to you as a citizen of Boston? Let us suppose that medical students will be drafted in the usual way. How would that affect Boston? In the first place such figures as are available indicate that a relatively large proportion of medical students have been called in the first draft. The provost marshal, General Crowder, says that not all of these will be drafted. However, this answer is of no real import. We are preparing now (at least we hope that this is the case) to continue drafts so long as soldiers are needed at the front. This being so, we must think not of the first call, but of the second and of the third, and so on until all physically fit young men, if needed, are called. We must plan, then, as if all physically fit medical students are to be drafted, for it would be neither logical nor fair to deal differently with successive calls to the draft.

"If half of the medical students of the country are called in the first and second draft, as reports received from about two-thirds of the medical students of America indicate, it is obvious that medical schools will be depleted and graduates in medicine will be decreased greatly in number unless something is done to prevent it.

"The medical students of today are the physicians of the future. As the students are reduced in number, so will the supply of physicians shrink. War demands many medical men. Seven to ten doctors per 1000 soldiers is stated as the requirement of our army. With an army in the field no fewer medical men are needed at home, for the soldier as the healthy young man in the community makes but little demand for medical service so long as he is a civilian. Hence the present would seem a poor time to reduce the supply of physicians.

"The medical student following graduation, spends one or two years as an interne or house

officer in the hospitals of the country. Boston's large hospitals must have house officers or close their doors. Already men for such positions are scarce, owing to the demands made by the war and navy departments for such men. If the supply is further reduced by drafting medical students, your hospitals must curtail their work and treat fewer patients in the near future. Furthermore, medical students, while still undergraduates, as part of their medical instruction, do much work in the Boston hospitals under the supervision of the house officers and their teachers on the visiting staff. To decrease by draft the number of medical students would hamper directly hospital work by decreasing the number of available student assistants, and this would be serious to Boston hospitals.

"The average citizens can have but little idea of the important part that medical students and recent graduates play in the daily work of Boston hospitals. If they did, there would go out to Washington an insistent demand that ways be found to maintain the number of medical students. Why should not drafted medical students be detailed to complete their medical studies and then be assigned for duty in army and navy or in civil hospitals, as the demands indicate? We are told that the surgeons-general of the army and navy lack the authority to do this. If so, should not the people demand that the Secretary of War or of the Navy, or the President or Congress, supply such authority at once?

"It is not that the medical students have any desire to escape service. It is that they can better serve by completing their medical education. The country desires that provision be made for drafted medical students to complete their medical studies as expeditiously as possible because our armies and our civil population are going to need more and more doctors. Canada, England, France tell us that they made the mistake of depleting their medical schools in the beginning of the war. Can it be that the United States, in a short-sighted policy, is going to repeat this error?"

On August 31, however, the general apprehension on this subject was largely allayed by the news from Washington that President Wilson has issued an order providing that drafted hospital internes and medical students may enlist in the Reserve Corps and be assigned to remain in their positions at home to pursue their duties or studies for the general welfare of the country. The text of this order as forwarded by General Crowder to all state governors, is as follows:

"First—Hospital internes who are graduates of well-recognized medical schools or medical students in their fourth, third or second year in any well-recognized medical school, who have not been called by a local board, may enlist in

the enlisted Reserve Corps provided for by Section 55 of the National Defense Act, under regulations to be issued by the Surgeon-General, and if they are thereafter called by a local board they may be discharged on proper claim presented on the ground that they are in the military service of the United States.

"Second—A hospital interne who is a graduate of a well-recognized medical school or a medical student in his fourth, third or second year in any well-recognized medical school, who has been called by a local board and physically examined and accepted, and by or in behalf of whom no claim for exemption or discharge is pending, and who has not been ordered to military duty, may apply to the Surgeon-General of the army to be ordered to report at once to a local board for military duty and thus be inducted into the military service of the United States, immediately thereupon to be discharged from the national army for the purpose of enlisting in the enlisted Reserve Corps of the Medical Department.

"With every such request must be enclosed a copy of the order of the local board calling him to report for physical examination (Form 103), and affidavit evidence of the status of the applicant as a medical student or interne, and an engagement to enlist in the enlisted Reserve Corps of the Medical Department.

Upon receipt of such application with the named enclosures, the Surgeon-General will forward the case to the Adjutant-General with his recommendations. Thereupon the Adjutant-General may issue an order to such interne or medical student to report to his local board for military duty on a specified date, in person, or by mail or telegraph, as seems most desirable. This order may issue regardless of the person's order of liability for military service. From and after the date so specified, such person shall be in the military service of the United States. He shall not be sent by the local board to a mobilization camp, but shall remain awaiting the orders of the Adjutant-General of the army. The Adjutant-General may forthwith issue an order discharging such person from the military service for the convenience of the government.

"Three official copies of the discharge order should be sent at once by the Adjutant-General to the local board. Upon receipt of these orders the local board should enter the name of the man discharged on form 164A and forward form 164A, together with two of the certified copies of the order of discharge to the mobilization camp to which it furnishes men. The authorities at the mobilization camp will make the necessary entries to complete form 164A and will thereupon give the local board credit on its net quota for one drafted man."

This action by the President appears satisfactorily to solve for the present, at any rate, this doctor's dilemma in the best interest both of the public and of the profession.

THE CAUSES OF JUVENILE DELINQUENCY.

THE direct relation between delinquency and mental enfeeblement, disease or disorder, is no longer an open question. Indeed, the development of correctional reform—the treatment of the delinquent or other anti-social elements of society—is being carried on principally on this basis. The fact that the delinquent is unable to keep the pace in the general social struggle, and must choose these paths of least resistance, is in itself clear indication that he is in some manner below par. Examinations of various custodial institutions for delinquents has brought to light the fact that a very large proportion of them are feeble-minded or mentally disordered, beyond any doubt, and that a still greater proportion of them are below par physically. The delinquent class is continually being recruited from the ranks of the mentally retarded school child, whose condition is not recognized, or, if recognized, is not provided for. An intensive study of the mental condition of school children of certain communities carried out by the Public Health Service showed that over 9% of the school children examined were definitely retarded, and that of these 28% and over showed definite physical retardation (Public Health Reports, Nov. 17, 1916, and Bulletin No. 77). In many, physical defects and sensory disturbances, easily corrected, are the patent causes of much of the mental retardation. The mentally retarded school child is a positive handicap, and even a danger to the normal child, just as the delinquent is a handicap and a danger to the society in which he lives. In both instances segregation and appropriate training are the only rational treatment. The periodic mental, as well as physical, examination of the school child, and the attachment of trained psychiatrists to the general and, especially, the juvenile courts and custodial institutions, would furnish the material for segregation and training. The endeavors of Healy in the juvenile courts of Chicago have demonstrated the value of this sort of work.

And yet, while defective heredity—mental and physical defect—is so important a factor in delinquency, it is far from being the sole cause. Much of the delinquency of childhood, at least, is due to defective or vicious environment as well as the lack of proper parental or

communal supervision. It has recently been shown that juvenile delinquency has risen over 40% in London and over 65% in Munich since the war. This sudden rise cannot, of course, be due to any hereditary or personal change in the younger element, but must be due to the family and general social disorganization incident to war conditions. The proper development of the child during war is a vital problem in national conservation, since it is this younger element which must officiate largely in reconstruction. Every scheme for national preparedness must consider the care and training of the child during war stress. Whether the adverse effects of war—shock, injury, sacrifice, etc.—will have an adverse hereditary influence upon the succeeding generations, or whether there is to be a renaissance as a result of the sacrifices and hardships of war, remains to be seen.

SHOCK AT THE FRONT.

In another column of this issue of the JOURNAL (page 326), is published the fourth of Dr. W. T. Porter's remarkably interesting and valuable series of papers on shock. The three previous papers, which have appeared in the JOURNAL during the past nine months, have dealt respectively with surgical shock as observed at the European battle-front; with fat embolism as a cause of shock; and with certain therapeutic measures which may be employed to counteract shock. Dr. Porter's theories of shock and its treatment, based on his original clinical observations and developed by the experimental method, are now being tested and elaborated in action. His peculiarly vivid and graphic descriptive style makes this fourth paper, from the literary as well as the scientific standpoint, one of the most notable and important medical contributions which the war has yet produced.

MEDICAL NOTES.

DIPHTHERIA IN NEWPORT.—The quarantine placed on the Naval Reserves' Camp and Fort Adams in Newport, was lifted on August 15, as no new cases had been reported there and the number of new cases in the city had begun to decrease rapidly. The disease did not make its appearance at the naval station and only a few light cases were reported at the harbor forts.

MEDICAL SOCIETY MEETING.—The Medical Society of the Missouri Valley will hold its thirtieth annual meeting in Lincoln, Neb., on Sep-

tember 20 and 21. Representatives of the Army, Navy, and Public Health Service will address the meeting on the general topic of "How Can the Medical Man Best Serve His Country?"

TUBERCULOSIS AS REVEALED BY DRAFT TESTS.—The National Association for the Study and Prevention of Tuberculosis is preparing to take up the care of the thousands of cases of tuberculosis brought to light by the examination of men who have been selected by draft and rejected for their disability. Dr. H. A. Pattison of Rockford, Ill., has been appointed a new medical field secretary to organize preventive work in military camps and to endeavor to get lists of men rejected on account of tuberculosis.

WAR NOTES.

MILITARY ORTHOPEDICS.—It is announced that Surgeon-General Gorgas has appointed Dr. Elliott G. Brackett of the Army Medical Reserve Corps to be director of a newly created Department of Military Orthopedics, which will have charge of the treatment of deformities in soldiers resulting from wounds. It is expected that a large per cent. of disabilities among troops will be cured or overcome because of this special treatment. The Department of Military Orthopedics in France will be in charge of Major Joel E. Goldthwait.

REPORT OF MAJOR GOLDTHWAIT.—The return of Major Joel E. Goldthwait from a tour of inspection of French and English orthopedic hospitals has brought to the organization of orthopedic work, both in this country and with the American troops abroad, the benefit of the experience of those countries in re-educating and restoring, either to military or to civil life, the crippled and deformed soldier. It is reckoned that orthopedic methods of treatment have restored 30% of the men in the allied countries, and in Canada the claim is a saving 70% of the wounded men. Major Goldthwait states that:

"A good many of the men shot through the body or the head die; those whose legs, feet or hands are injured are among the orthopedic cases. A great many of these would be crippled for life unless you did something for them by giving them this special orthopedic treatment that has been so wonderfully worked out.

"Just to show the results accomplished. I may mention that from one hospital, where there were 1350 men under treatment, 1000 of them were sent back into the army. In other words, this special form of treatment made that 1000 well enough to return to active service. And the same thing is happening to 70% of men injured in the Canadian armies."

The members of the unit which accompanied Major Goldthwait abroad are now in the British Isles, working in various hospitals studying English methods. The British War Office would welcome the services of more of these American orthopedic surgeons.

NEW YORK'S FIRST WAR HOSPITAL.—The National League for Women's Service has opened the first war hospital in New York for the care of the men training at a nearby military camp. The hospital occupies an old residence at Tarrytown, and will obviate the necessity of sending sick men to a hospital at Ossining, as formerly.

MEDICAL AID FOR REJECTED MEN.—The State Guard of Massachusetts has, through its medical department, put forward a plan to provide free medical attendance for men who have been rejected as recruits because of remediable physical defects. Governor McCall, following a conference at the State House, wrote officially to Major General Butler Ames, in command of the State Guard, requesting that the surgical staff of the State Guard offer its services to try to make these men qualified to pass the physical examination. The plan, which has the unqualified approval of Major General Ames, provides that men who have been rejected shall apply at the recruiting station, where their rejection is filed, and will be given a card stating the grounds of the rejection. On the presentation of this card to the State medical officer at the State House, the men will be directed to the surgeon or physician best fitted to handle each case. Among the physicians who have volunteered their services for this work are: Donald V. Baker, Brookline; Harold G. Giddings, Allston; Edward A. Supple, Boston; George W. Morse, Boston; Benjamin E. Sibley, Brookline; Russell F. Sheldon, Boston; Lemuel F. Woodward, Worcester; Charles E. Durant, Haverhill; Thomas B. Smith, Lowell; Ralph H. Seelye, Salem; P. Truesdale, Fall River; Hugh Williams, Garry De N. Hough, New Bedford; J. J. Egan and Franklin H. Thompson, Fitchburg; John W. Lewis, Thomas F. Harrington, George F. Hunt, O. C. Blair, D. S. Wilcox, George L. Tobey, Kurt H. Thoma, Ralph D. Leonard, Robert C. Loring, P. Somers Smyth, W. Russell MacAusland, Boston; C. L. Overlander and Francis H. Slack, Brookline.

CARE OF FRENCH INFANTS.—The American Red Cross has sent a medical unit to France on behalf of French infants. The unit is financed by Mrs. William Lowell Putnam of Boston, and is made up of pediatricists. Dr. William P. Lucas of the University of California is in charge. Dr. J. Morris Slemmons of the Yale Medical School is a member of the unit. The work of the unit will be confined to parental hygiene and the scientific feeding and care of French babies.

MILITARY HOSPITALS.—The thirty-two new hospitals which are being built by the medical corps of the army for the care of the National Guard and National Army camps will cost about \$14,500,000. The aim of the medical department is to have hospital provision for 5% of the enlisted force by fall, and then extend it to

10%. Abroad, facilities for 20% of the American expeditionary forces will be available. Provision will be made at the cantonments in this country for 3% of the troops in each camp. It is a well-known fact that the percentage of sickness among men under military discipline is very much less than in civil life, even though the sick list of a military camp includes cases which in civil life would not be regarded as at all serious.

At the cantonments in this country, hospitals will be built capable of caring for 3% of the troops in each camp. Each hospital with the space reserved for extensions will require sixty acres. The buildings will be 24 feet wide, the length varying to meet the needs. A ward about 157 feet long will accommodate 32 beds. A cantonment hospital on a basis of 1000 beds will include about 70 buildings, if each ward is considered as a building. Adequate laboratory facilities will also be provided, and plans are being made to appoint permanently to the staffs of the hospitals, men especially trained to do laboratory work in order that careful tests may be made of each and every soldier for tuberculosis, intestinal infections, and all other infectious diseases.

WAR RELIEF FUNDS.—On Sept. 1, the totals of the principal New England war relief funds reached the following amounts:

French Wounded Fund.....	\$246,648.87
Armenian Fund	223,959.47
Children's Fund	214,116.00
Surgical Dressings Fund	122,296.50
Polish Fund	81,476.95
Italian Fund	44,132.72
French Blind Fund	3,467.00
War Dogs' Fund	1,100.75

BOSTON AND MASSACHUSETTS.

WEEK'S DEATH RATE IN BOSTON.—The total number of deaths reported during the week ending August 25, 1917, is 194, against 238 the corresponding week last year, making a death rate of 13.10. Non-resident deaths, 36.

The total number of cases of communicable diseases reported is as follows: diphtheria, 61; scarlet fever, 7; typhoid fever, 9; measles, 31; tuberculosis, 52. Included in these totals are the following non-residents: diphtheria, 8; scarlet fever, 4; typhoid fever, 2; tuberculosis, 3.

The total number of deaths from communicable diseases is as follows: diphtheria, 5; measles, 4; tuberculosis, 22. Included in these are the following non-residents: measles, 1; tuberculosis, 3.

TYPHOID FEVER IN GARDNER, MASS.—On August 20 and 21 twenty-two cases of typhoid fever were reported in the town of Gardner. The health authorities direct their suspicions to a contaminated milk supply. Most of the cases are confined to one section of the town.

RENOVATION OF HOSPITAL.—The Massachusetts Women's Hospital, Roxbury, has closed for a short time in order to make extensive alterations in the interior of the hospital. A new operating room will be built and equipped, an elevator installed, and a ward of six beds will be added. When the hospital opens, about September 15, a new administrative force has been appointed to take charge.

FRAMINGHAM HEALTH STATION.—The experimental community health station at Framingham, Mass., has maintained through the summer a camp for children under sized and under weight, and will continue the camp into September. It will admit mothers and younger children. In the past it has admitted only boys and girls between five and twelve years of age. Dr. Donald B. Armstrong, the executive officer of the health station, is urging the school committee to establish a dental, nose and throat and eye clinic for school children.

SOCIAL SERVICE ESTABLISHED AT CITY HOSPITAL.—The social service department of the Boston City Hospital, organized and supported for two years and a half by a committee of interested women, has at last succeeded in demonstrating its usefulness to the institution to a degree warranting its being included as a recognized department of the hospital and of being supported by the City. A small sum of money, which will pay the salaries of five of the eleven workers of the department, has been appropriated, and on the strength of this assistance the committee is planning to raise funds sufficient to carry on the work to a greater extent than has before been attempted. The small force last year, under the leadership of Miss Gertrude L. Farmer, cared for 1462 patients and made 2588 visits.

In view of what has already been accomplished, and of what must of necessity be undertaken, the committee is confident of the continued financial support, not only of its friends, but of the citizens of Boston. Mrs. Paul Thordike is chairman of the group of women who organized the work. The other members of the committee are: Mrs. Henry Andrews, Mrs. E. H. Bradford, Mrs. Carlo Buonamici, Mrs. H. L. Burrell, Mrs. C. A. Coolidge, Mrs. Harvey Cushing, Mrs. Thomas M. Devlin, Mrs. Henry Ehrlich, Mrs. Reid Hunt, Mrs. Colin W. McDonald, Mrs. G. H. Monks, Miss Mary Morton, Mrs. I. A. Ratschky, Mrs. Milton J. Rosenau, and Mrs. E. B. Young.

HOSPITAL BEQUESTS.—By the will of the late Ellen F. Ferguson of Brookline, the Addison Gilbert Hospital of Gloucester will receive a fund of \$5000, upon the death of a beneficiary. to be used for free beds.

By the will of the late Judge John C. Kennedy of Newton the sum of \$3000 has been left to the Newton Hospital.

POLIOMYELITIS IN HAVERHILL, MASS.—On August 14 the total number of cases of infantile paralysis reported in Haverhill had reached twenty-five.

Obituaries.

FOUR EMINENT EUROPEAN MEN OF SCIENCE.

THERE have died within the past year in Europe four eminent men of science, natives of England, of Germany, and of Bohemia, whose loss to the scientific world is perhaps even greater than any other which has befallen it as a result of the present war. Though the fields of their activity were diverse, their lives, devoted to medical pursuits, have borne a certain underlying resemblance, and their death within a short period of time makes it appropriate that they should be considered in a common obituary notice.

SIR VICTOR HORSLEY, M.B., B.S., F.R.C.S., F.R.S.

SIR VICTOR HORSLEY, a celebrated British surgeon, best known for his work on brain surgery, died of sunstroke in Mesopotamia on July 16, 1916, while serving there as consulting surgeon to the British Expeditionary Forces.

Victor Alexander Havers Horsley was born at Kensington, London, in 1857, the son of an artist. After a course of brilliant scholarship

at the University College Hospital, London, he received the degrees of M.B. and B.S. in 1881, with a university scholarship and gold medal in surgery. In 1883 he became a fellow of the Royal College of Surgeons of England, and in 1884 superintendent of the Brown Institution, where he began an elaborate series of experiments on myxedema, which led to the demonstration of the nature of this disease as a phenomenon of thyroid deficiency. In 1885 he was appointed assistant surgeon to the University College Hospital, in 1886 surgeon to the National Hospital for Paralysis and Epilepsy, and in 1893 full surgeon to the University College Hospital and professor of pathology at University College. In 1902 he received the honor of knighthood; in 1906 he retired as emeritus professor of clinical surgery and consulting surgeon to the University College Hospital. In 1911 he received the first award of the Lannelongue International Prize in Surgery. He had also received the honorary degree of M.D. from the University of Halle, Germany.

From the beginning of his professional career, Horsley's interest was primarily in the physiology, pathology and surgery of the nervous system, and his early exploits in cranial surgery established that field as a specialty. He was an extensive writer on all aspects of his chosen line of work, and at the same time he carried on the busy life of a surgical practitioner and laboratory investigator. He was one of the pioneers in cerebral localization, and demonstrated the similarity of cortical areas in the rhesus monkey and in man. He investigated the upper conduction lines in the spinal cord. He explored the region of the thalamus and the subject of cerebellar function as studied by electrical stimulation. He was an ardent defender of the legitimacy of animal experimentation, and his unquestioned integrity and highmindedness were of the greatest value in the defense of medical science against its assailants in England. Horsley was also a pioneer in surgery, and his early exploits in the operative cure of intracranial tumors placed him immediately in the foremost rank of his profession. His eager and ardent personality and his natural adroitness at finesse made him particularly fitted for swift and successful surgery of the most delicate type.

At the outbreak of the European War in 1914, Sir Viator Horsley volunteered his professional services to his country, and after holding various administrative posts in England, was sent early in 1916, to Egypt and later to Mesopotamia. The story of the last months of his life under the arduous conditions of service to which he was there subjected, are well told in obituary notices which have appeared of him in the *Lancet*, and formed a fitting chapter of conclusion to his life of brilliant and distinguished service. A fellow officer, who served with Sir Viator in Egypt during the last phases of his strenuous career, writes of him in part as follows:

"Soon after his arrival in Egypt he was given an appointment more in keeping with his professional position and was made consulting surgeon to the Forees. Before this, however, he had done an immense amount of valuable work in assisting to organize the surgical side of the base hospital to which he was originally attached. As a consulting surgeon he did splendid work; he devoted with unsparing zeal both time and energy to finding out and correcting, as far as lay in his power, any defects of equipment or mistakes in organization in the hospitals, and in the early days in Egypt there were many of these. He was always ready to help with his advice and example those of us who asked him to do so, and in the midst of the most trying circumstances he never lost his cheeriness or good temper. In spite of all the calls upon him, he found time to carry out some original work in connection with the infection of head wounds, and it was entirely owing to his teaching and example that the results of the operative treatment of these injuries, at any rate in one of the hospitals, were so extremely good. His energy and devotion to his work were the more striking because it was obvious that the atmosphere of a military hospital was not very congenial to him, and when we remember his force of character and independence this is not to be wondered at. The amount of work he got through in Egypt undoubtedly tried his strength, and he could not be persuaded to rest to the extent that was really necessary, especially in the hot weather. A tour of inspection which he paid to the Peninsula did him good in this respect, but the many muddles and deficiencies which he found there must have had a depressing effect upon his spirits. He volunteered for duty in Mesopotamia without any thought for himself, and I am sure that he went there in the hope that he might be able to do something to remedy the defects in the medical arrangements which are now so notorious. If he expended, as I am sure he did, all his strength and energy on this work, it is little wonder that he should have succumbed to the effects of that most trying climate. Viator Horsley's was a most charming personality and he was a great favorite in our mess. His death leaves a blank in the branch of surgery, which his genius had played so large a part in founding, that at the present there is no one fitted to fill."

Another letter from a physician at Amara tells as follows of the more immediate circumstances of Sir Viator's death:

"I have just been to the Rawal Pindi Hospital, where Sir Viator Horsley was lying ill, to find that he passed away a few minutes ago—at 8.45 p.m.

He had only three days ago returned to Amara from the front and seemed to be in his usual health and spirits. Only yesterday (Saturday morning) I had some conversation with him on a subject which was interesting him—the provision of hospitals with laboratories; and he

then set out to walk back to his camp, which was about a mile and a half away across the Tigris bridge and over the open plain. The shade temperature was over 110° and the atmosphere humid. When he got to his tent he heard there was a sick officer he knew, about half a mile further on; he went on to see him and examined him carefully. He complained of headache later in the afternoon and was admitted to the Rawal Pindi Hospital on Saturday evening, about seven o'clock. His temperature rose, he had a rather restless night, and in the morning seemed worse. His temperature rose all day and finally reached nearly 110° F. He became comatose in the afternoon and passed away after little more than twenty-four hours' illness. The cause of death appeared to be heat-stroke, a condition which carries off many people nowadays in Mesopotamia.

The news of his death has been received with the greatest sorrow and regret, even in these days, when the loss of friends is almost our daily portion, and it will be a large and representative following he will have to his last resting place tomorrow in the Amara Cemetery.

It would ill become one who has only known him personally within the last few months to write of his many and great achievements in the past, but I can speak of his untiring energy and the loyal devotion and singleness of purpose shown in his every action up to but a few hours ago. Those who have met him recently are aware that he had framed a very severe indictment against those he believed were responsible for the mismanagement which he thought characterized some aspects of the campaign. It is only three days since he returned from the front, and he was about to return to India for a spell to prepare his report.

He has been urged time and time again to curb his extraordinary energy and not to put too severe a strain on his physical capacity, but it appears that he underestimated the baneful effects of the severe climatic conditions existing just now in Mesopotamia. It would have been easy for him to have pleaded the heat or his increasing years, but he refused to take things easily, and has sacrificed himself to his zeal for bettering the conditions of others."

In personal appearance and manner of speech, Sir Victor Horsley bore a striking resemblance to Professor George Herbert Palmer. In 1913, as president of the Surgical Section of the International Medical Congress at London he became known to many of the younger American surgeons who had not previously had the privilege of his acquaintance. His courtesy as a presiding officer, his unflinching consideration of others, his swiftness and keenness of mental perception, his unerring instinct for truth, impressed all who saw or met him as manifestations of a character that represented the finest type of professional and personal quality. Sir Victor Horsley is survived by his widow, one daughter and two sons.

SIR THOMAS LAUDER BRUNTON, Bt.,
M.D., C.M., D.Sc., LL.D., F.R.C.P., F.R.S.

DR. SIR THOMAS LAUDER BRUNTON, who died on September 16, 1916, in London, was born at Bowdoin, Roxburghshire, Scotland, on March 14, 1844. After a brilliant undergraduate career at Edinburgh, he obtained the degrees of M.D., and C.M. from that University in 1866, that of B.Sc. in 1867, that of M.D. in 1868, and that of D.Sc. in 1870. After serving as house physician at the Edinburgh Royal Infirmary, he studied abroad at Vienna, Berlin, Leipzig and Amsterdam. Finally settling in London, he became a member of the Royal College of Physicians, and in 1874 was elected to the Royal Society in recognition of his work on the physiology of digestion and secretion, on the chemical composition of the blood, and on the action of digitalis and mercury. In 1870, Brunton was appointed lecturer on materia medica and pharmacology, and in 1875 was appointed assistant physician to St. Bartholomew's Hospital. During the succeeding years at this institution he pursued the brilliant course of clinical and scientific research, whose results are recorded in his numerous publications. In 1885 appeared his well-known handbook of pharmacology, materia medica and therapeutics, and in 1886 a volume on disorders of digestion. He delivered many lectures before the Royal College of Physicians, and in 1894 was its Harveian orator. In 1897 Dr. Brunton became full physician at St. Bartholomew's Hospital and consulting physician in 1904. He received the honor of knighthood in 1900, and was made a baronet in 1909, and received the honorary degree of LL.D. from the Universities of Aberdeen and of Edinburgh. He was a member of many British medical and scientific societies, a foreign honorary member of the American Academy of Arts and Sciences, correspondent of the Philadelphia Academy of Medical Science, associate fellow of the Philadelphia College of Physicians, corresponding member of the Therapeutical Society of Paris and honorary member of the American Therapeutic Society and of the Imperial Military Academy of Petrograd. He is survived by two daughters and one son, who succeeds to his title, his second son having been killed in the war.

Of Brunton's work as a teacher, his obituary notice in the *Lancet* speaks as follows:

"As a lecturer he met with complete and well-deserved success, both at his medical school and on more public or official occasions. It will be observed that his best books were the outcome of collected lectures, and those that are not so, where they are not merely popular disquisitions, conformed to the lecture style. He was always able to make his subject interesting and easy to follow, and yet he was very thorough, while he would illustrate his points, whether simple or complex, by example, experiment, or anecdote. Punctuality with him was a watchword, and si-

multaneously with the hand of the clock pointing to the lecture hour the figure of Brunton appeared at the door of the theatre, and almost before he had arrived at the demonstration table he had completed a rapid summary of the previous lecture, so that his audience might be able to follow his thread."

Of his extra-professional character, this obituary further speaks as follows:

"Outside his purely professional work, the outstanding features of Brunton's life were his great generosity and his practical sympathy with pain. The congenial kindly manner which endeared him greatly to his patients was a true indication of his almost emotional feeling for the suffering of others. No one more bounteous with his time, thought, or money, whether to individual friends or for the public good, ever adorned the medical profession. All schemes in favor of national health, of school hygiene, or of military training had in him a stalwart advocate, and in this last connection his close familiarity with the continent and the German professional world long ago led him to believe, and to say, that war between England and Germany was inevitable."

PROFESSOR ALBERT NEISSER, M.D.

DR. ALBERT NEISSER, who died on July 30, 1916, at Breslau, Germany, was born near that city in 1855, the son of a distinguished physician, Dr. Moritz Neisser. He studied medicine at the Universities of Breslau and Erlangen and received the degree of M.D. in 1877 for a thesis on echinococcus disease. He immediately became attached to the Breslau University Hospital and Polyclinic for Syphilis and Diseases of the Skin, as assistant to Dr. Oskar Simon. It was here, in 1879, that he made his most famous discovery of the diplococcus which has since borne his name. Upon Simon's death in 1882, Neisser was promoted to his professorship, which he retained until his death. Though his name is chiefly associated with the gonococcus, he made notable researches in other fields, especially in dermatology, bacteriology, serology, and syphilography. In 1902 he founded the Deutsche Gesellschaft zur Bekämpfung der Geschlechtskrankheiten. In 1905 he spent several months on an expedition in Java to study the phenomena of syphilis inoculated in monkeys. It was on the basis of his researches that the details of Wassermann's reaction were developed. Dr. Neisser also traveled in Norway and Spain to study leprosy. It was during his absence from Germany that the spirocheta pallida was discovered by Schaudinn and Hoffmann, whose observations were communicated to Neisser in Java and speedily confirmed by him. Dr. Neisser was a brilliant investigator and teacher, and his death, from diabetes complicated by nephrolithiasis, removes one of the most famous and familiar of the older generation of German scientists.

VINCENZ CZERNY, M.D.

DR. VINCENZ CZERNY, who died last November, was born in Bohemia in 1842, the son of a pharmacist. He early evinced a fondness for natural history and was sent to the University of Prague and educated as a biologist. In 1867 he was appointed surgical assistant to Billroth, and gradually relinquished his histologic laboratory pursuits for those of clinical surgery. In 1871 he was appointed professor of surgery at Freiburg, and in 1877 was translated thence to the surgical chair at Heidelberg, where he remained until his death. He was president of the German Surgical Society in 1901, of the International Surgical Society in 1908, and in 1910 became honorary president of the International Society for the Study of Cancer. He was the founder of the Cancer Institute at Heidelberg. In its editorial obituary of him, the *Lancet* speaks as follows of his contributions to medical literature, of his personal character, and of his service as a teacher:

"Possessed of a ready pen and incisive style, and the author of 150 or more short practical papers, Czerny never wrote a systematic treatise, and his name, although associated with the first vaginal extirpation of the uterus and with cancer research in general, is known only to the specialist in connection with numberless improvements in operative methods. His intestinal suture is, of course, in every student's text-book. As a teacher, Czerny fully recognized the value of *können* over *wissen*, and worked for the revision of the German medical curriculum on practical lines. In so doing he held up English and American methods as worthy of imitation, as well as the effect of our General Medical Council in standardizing medical education. In his intimate association with his staff and hospital patients Czerny showed a warm human sympathy which will make his loss acutely felt and his place hard to fill."

Miscellany.

THE DRAFTING OF MEDICAL STUDENTS.

UNLESS the War Department speedily announces a program for such disposition of drafted hospital internes and medical students as will meet the needs of the army and of the civil population, an appeal will be made to Congress for appropriate legislation. The urgency of the situation has again been brought to the notice of President Wilson and Secretary Baker, and it is hoped that an executive order to relieve the situation will be issued within the next forty-eight hours. Longer than this, the medical educational authorities and the numerous civic bodies which have been demanding action are not likely to wait.

The Mayor's Committee on Hospital and Medical Facilities has been in communication with members of the Committees on Military Affairs of both the Senate and House of Representatives, and has assurances that the situation is understood by the members of those committees.

The Medical Section of the New York State Branch of the Council of National Defense was notified on Monday afternoon that "the military authorities have asked for a definite statement of the number of third- and fourth-year medical students who have been actually accepted for service, and though no promise has been given, there is reason for hope that these men may be allowed to continue their studies. The General Committee has not altered its views as to the desirability of having all medical students continue their technical training.

The contention of the Provost Marshal General that the draft would not make serious inroads on the medical schools, is refuted by returns received directly from twenty medical colleges. The following figures, showing the proportion of medical students drafted and accepted under the first call, were given out yesterday afternoon by Dr. S. S. Goldwater, chairman of the Mayor's Committee on Hospital and Medical Facilities:

University of Nebraska	34%
University of Cincinnati	32%
Western Reserve University	31%
Atlanta Medical College	17%
Hahnemann Medical College, Chicago	22%
University of Wisconsin	20%
Columbia University	30%
University and Bellevue Hospital Medical College	22%
Cornell University	21%
University of Virginia	9%
New York Homeopathic Medical College	33%
Syracuse University	29%
Medical College of South Carolina	18%
University of Michigan	23%
Jefferson Medical College	22%
Marquette University	20%

In some instances these figures refer to the graduating class only; in other instances they include the total student body. This information will be presented to Secretary Baker immediately, and may be used as the basis for immediate action. Mr. Frederick P. Keppel, Assistant to the Secretary of War, has telegraphed to Dr. Samuel W. Lambert, Dean of the College of Physicians and Surgeons, that "Secretary Baker is still awaiting definite figures as to amount actually drawn and accepted for service from medical schools. If you can expedite these figures it will be of great help. As soon as they are at hand Secretary Baker will take the question up with the President."

H. P. Davison, Chairman of the War Council of the American Red Cross, is interested in the maintenance of the hospital resources of the country, and has requested the Mayor's Com-

mittee on Hospital and Medical Facilities to furnish full information.

Dr. Walter B. James, President of the New York Academy of Medicine, in a letter to President Wilson, says, "I believe that in any case, and in spite of every precaution the army will suffer bitterly from the lack of adequately prepared medical men of the proper age, and that the civilian population will suffer, and indeed, is beginning to suffer already from the same cause. A number of agencies have already resulted in cutting down the number of students in the medical schools, and I believe that the present policy of drafting medical students into the army will inevitably result in disaster, both to the army itself and to the civilian population."

Mother M. Catherine Herbert, Superintendent of the Mary Immaculate Hospital, Jamaica, Long Island, writes, "I must state how we are situated in regard to internes. The doctors who had finished their term of internship have applied to be taken on the service of the United States Government. We were fortunate enough to have three men who were ready to go on duty after graduation on June 1, 1917, but are sadly disappointed to learn that they were called to military duty. We have made every reasonable effort, but cannot get one graduate to take their places. If the importance of having service at the hospital crippled is considered, I am sure you will do everything in your power to avoid this."

Dr. Ralph B. Seem thus describes the crippling of the service of Johns Hopkins Hospital at Baltimore: "Last Spring we were requested by the Council of National Defense to furnish a list of the members of the medical staff, stating those who could be spared for military service and those who were needed in order to carry on the work of the hospital. Among those needed at home were included the names of the internes for the coming year. Some of these men have been drafted. When it was learned that they could not be exempted the matter was taken up with Major Noble, who advised the internes to join the Medical Corps immediately in order to prevent the men from being drafted as common soldiers. At the same time it was stated that it might be possible to make arrangements with the Surgeon-General to detail these men for duty in their own hospitals. We are now told that it is not possible to make any such arrangements. As a result we shall be greatly crippled in carrying on the work of the hospital in the coming year. There must be many hospitals throughout the country in the same predicament. This is particularly true in regard to the teaching institutions which have a double duty to perform."

The Philadelphia Hospital Association has organized for the protection of the interests of the hospitals of that city.

Dr. William B. Walsh, Secretary of the American Hospital Association, announces that

the trustees of that Association have decided to send a delegation of its officers to Washington to make a personal appeal to the Secretary of War.

Dr. C. R. Bardeen, Dean of the Medical School of the University of Wisconsin, writes: "I am convinced that Congressional action is the only thing that will save the situation. I feel safe in assuring you that if such action is proposed it will receive strong support from all of the Wisconsin men in Congress."

Figures received from Chicago show that of 177 internes in the five leading hospitals in Chicago, forty-three have been called and accepted by the local draft boards; in addition twenty-eight have been drafted from eligible lists of sixty from which the Cook County Hospital was prepared to draw to fill its shortage. Thus of a total of one hundred and seventy-seven internes, seventy-one, or 41%, have been drafted.

MANDATORY ESTABLISHMENT OF COUNTY HOSPITALS IN NEW YORK FOR TUBERCULOSIS.

PASSED as a war measure, so that the state will be prepared to treat all cases of tuberculosis discovered in examining men drafted for the army or who are found in the army itself, an amendment to the County Tuberculosis Hospital Law was enacted at the recent session of the New York State Legislature providing as follows:

"Establishment of county hospital for tuberculosis. The Board of Supervisors of every county in the state containing a population of thirty-five thousand or more, as determined by the latest state census, shall establish, as herein-after provided, a county hospital for the care and treatment of persons suffering from the disease known as tuberculosis, unless there already exists in such county a hospital or institution provided by the county or other authority and caring for persons suffering from tuberculosis, which is approved by the state commissioner of health. Such county hospital shall be available for patients on or before the first day of July, 1918. If the board of supervisors of any such county shall have failed to secure a site for a county tuberculosis hospital, and to have awarded contracts for the erection of suitable buildings thereon by the first day of January, 1918, it shall be the duty of the state commissioner of health forthwith to proceed to locate, construct, and place in operation a tuberculosis hospital in and for such county, the capacity of which shall not exceed the average number of deaths per annum from tuberculosis in such county during the past five years. For such purposes the state commissioner of health shall possess, and it shall be his duty to exercise all the powers which would have been possessed by the board of supervisors of such county, had

such hospital been established and placed in operation by the board of supervisors thereof. All expenditures incurred by the state commissioner of health for and in connection with the location, construction and operation of such hospital shall be a charge upon the county, and provision shall be made for the payment therefor by the board of supervisors of such county in the same manner as in the case of other charges against the county. At any time after such hospital has been in operation, the board of supervisors in such county may appoint a board of managers for such hospital pursuant to the provisions of this act, and thirty days after the appointment of such board of managers by such board of supervisors, such hospital shall be transferred to such board of managers, and such board of managers shall thereafter possess and exercise all the powers of the board of managers of a county hospital for tuberculosis under this act, and the state commissioner of health shall be relieved from any responsibility therefor, except such responsibility as he exercises in regard to all county tuberculosis hospitals under the provisions of this act."

The new law affects twenty counties, eight of which have previously taken various steps leading to the erection of a hospital, but had not yet let contracts.

The State Charities Aid Association has issued a pamphlet entitled "A Compilation of the Laws of the State of New York Relative to County Tuberculosis Hospitals as of June 1, 1917." A copy may be secured from the Association upon request addressed to 105 East 22d Street, New York City.

PERIODICAL EXAMINATION OF HEALTH DEPARTMENT EMPLOYEES.

THERE is no phase of public health work which transcends in value the periodical medical examination. With the great and rapidly growing interest in public health questions this medical attention and medical supervision of employees is becoming an accepted procedure—a matter of course. For the past two years every employee of the New York Department of Health has been obliged to meet this requirement of an annual medical examination, in addition to the one received on entrance to the Department service.

With the older employees, this periodical test is optional, but as the antagonism first manifested toward this innovation has largely disappeared, the majority of both sexes have been examined and some, more enlightened than the others, have requested an examination at short intervals, where the findings have disclosed conditions not entirely satisfactory to the individual.

Up to June 29, 1916, 2104 employees had been examined, but in order to retain a convenient starting-point for future investigations, only

the first 2000 were included in the statistical records. Of the number mentioned, 1325 were women and 779 were men.

During the past year nearly 1000 re-examinations have been made, and of these 194 are men and 737 are women. Each case record receives a number, for no names are allowed to appear on the card, and the records, when completed at the end of the day's work, are placed in a special cabinet and kept under lock and key in the office of the Deputy Commissioner. Male employees are examined by a male physician, and female employees by a female physician. The physical record is not allowed to influence in any way the efficiency rating of the employee.

THE FINDINGS.

Of very great importance is the fact that 22.8 per cent. of those examined showed an albuminuria of greater or less degree. The tests applied were those in ordinary use for this purpose. The results therefore indicate an abnormality, a weakness or susceptibility which, if neglected, may be followed by chronic organic lesions and probably a shortening of life.

As many as 2.5 per cent. showed albuminuria combined with high blood pressure, and five cases of unexpected glycosuria were discovered.

Uncorrected defects of vision were found in 15.1 per cent. of cases and 17.71 per cent. showed abnormality in hearing.

Acute or chronic pharyngitis and hypertrophied tonsils were present in 29.3 per cent. and impairment of nasal breathing, due to some form of rhinitis or to deflected septum, existed in 17.2 per cent. of those examined.

Many of those suffering from such conditions were in urgent need of treatment, but had grown accustomed to their discomfort; they were, nevertheless, grateful for advice and willing to secure the necessary attention.

The number of organic heart lesions differed little between the sexes, though most medical examiners find the male sex suffering more frequently than the female from cardiac disease. Our figures were 8.8 per cent. for men and 6.7 per cent. for women. In the vast majority of instances the patients were not aware of any existing abnormality in the heart.

Pulmonary lesions existed in proportionately the same numbers, *i. e.*, about 8.7 per cent. and 5.5 per cent. for women. Some of these were very slight, others of more importance. Scarcely a dozen cases were serious enough to require prolonged absence from duty and medical care. When such cases were found, leave of absence was granted without question, but medical supervision during absence was insisted upon in order that the patient should receive the requisite care. Where the pulmonary abnormality is slight, the patient receives medical counsel and is advised to remain under the care of a physician until well.

It is interesting to notice that the number of men who had acquired an excessive aroiduposis is almost as great as the number of women similarly afflicted. In spite of the fact that women consume actually and relatively one-fifth less solid food than men, they attain adiposity much more readily, so that under ordinary conditions we expect a larger number of them to be overweight. The excessive weights were 18.9 per cent. of the men examined, and 21.2 per cent. of the women. As pronounced overweight has a marked effect in decreasing the length of life, those who show a tendency towards obesity receive careful warning and advice as to their habits and the regulation of their daily life. Re-examinations have shown an improvement in a number of such instances.

A relatively large number of women were much below the average weight, namely, 18.9 per cent. of those examined, but only 4.4 per cent. of the men were underweight.

The variations in blood pressure were considerable. As many as 11.4 per cent. of men exhibited high blood pressure (150 mm. Hg. or over), but several were far above this figure. Only 4 per cent. of the women showed pressure considerably above normal, but a large number of women—17.7 per cent. of women—manifested a very low pressure, that is, 108 mm. Hg. or below. Of these many were no higher than 100 mm. Hg. and several were even below this low figure.*

Overweight and hypertension co-existed in 46 men and in 27 women; underweight and high blood pressure were found in five women and in one man; low weight and low blood pressure in one man and in thirty women.

In only a few cases could the high blood pressure be ascribed to aortic incompetence. It appeared to depend in most instances on other and widely varying causes. The large number of hypotension cases, especially among women, showed that many employees were suffering from a depressed vitality, and of these a considerable number presented a permanently low pressure. Forty-four women were markedly anaemic; only 19 men suffered in a similar way.

Nearly twice as many women as men complained of indigestion—7.5 per cent. women and 4.1 per cent. men—yet, strange to say, indigestion and constipation co-existed in a surprisingly small number,—only 6 per cent.—and, though more women suffered from indigestion than men, their teeth were cleaner and otherwise in better condition. A certain number of both sexes were constipated—3.8 men and 17.5 women. Nearly 24 per cent. of those examined showed defective teeth, and 4.9 per cent. of this number were women. Notwithstanding, more women suffered from pyorrhoea alveolaris—about 1.2 per cent.—and scarcely half as many men.

The examinations disclosed more men than women suffering from hernia, from tenderness

over the gall-bladder and spleen, and from enlarged liver. Sixteen cases of hernia were found among men; only five among women. Twenty-five men suffered from tender gall-bladder, and there were six cases of palpable spleen found and three of palpable liver. About one per cent. suffered from varicocele.

Women showed more nervous symptoms than men, suffered more from gastropitosis, gastric ulcer, hypertrophied thyroid, insomnia and from varicose veins and weak and flattened arches. Thirty-three women showed marked varicose veins, fifty had weak, painful or flattened arches. Two men had flat or painful arches and four showed varicose veins.

Exaggerated knee jerks were very common in women—as many as 137 showed this symptom—often combined with a fine tremor of the hands. About a half dozen men showed exaggerated reflexes, but in one the knee jerks were absent. Tremor was a symptom not often shown by the male employees, but two had coarse tremor of the hands.

Twice as many women as men complained of headache. Three men showed defects of speech and one woman.

Dr. Charles Dana says men suffer more from insomnia than women, yet 1.9 per cent. of men complained of sleeplessness in contrast to 2.7 per cent. of women who did so.

Abdominal tenderness, especially in the region of the appendix, was found on palpation in six men and in eight women. Movable kidney was found in two men and seven women. No man showed symptoms of gastric ulcer though four women did so. Twelve women presented symptoms of gastropitosis; no man was found suffering in this way.

Hypertrophied thyroid glands were found in 51 women and in two men. Women of European birth were more often affected with goitre than the native American women.

The unclassified impairments numbered 64 and included some skin lesions and other departures from the normal rather difficult to classify.

The menstrual history of women showed an extraordinary improvement over the conditions obtaining a few years ago, only 12 per cent. instead of the formerly recorded 50 per cent. and 75 per cent. giving a history of periodical disability. It is interesting to notice that slightly over three per cent. suffered only after unusual fatigue, overwork or on exposure to wet and cold.

Three women, two of them nurses, had never been vaccinated; one of these had had an attack of smallpox and supposed herself immune; all were, of course, vaccinated and successfully.

A comparatively small number of employees had been vaccinated against typhoid; of these 35 were nurses, 15 physicians, 15 laboratory workers and 16 others.

On re-examination about 10 per cent. of the

persons examined showed very decided improvement over their former physical condition; some had gained in weight; some, after much effort, had lost weight; certain impairments had received treatment with resulting gain to the patient. Many, when originally examined, had shown no abnormality so that but little change was to be expected.

Every employee, when absent from duty on account of illness, should be re-examined on return to duty. If absences are frequent a re-examination should be made every three months, with a view to determining the cause of disability. Those who are below normal when first examined should be examined in six months' time.

Any employee desiring special medical advice should be made to feel that this is gladly given—that the object of the welfare division is to help keep the employees well and that these medical attentions are not in any sense a philanthropy but a very decided economy to the Health Department as well as to the taxpayer.

When any particular kind of work is found to have an injurious effect upon the health of the employee, a change to some other kind of employment should be made.

Periodical examinations can be made an important aid in correcting the alarming mortality of middle age in this country. If diseases are detected in their incipency before impairment has become pronounced, and if the body is protected against possible injury by constant vigilance, a vast improvement would soon be effected.

The example of the New York Health Department should be followed by all the City Departments because of the economic value to the employer as well as to the employed.

RESIGNATIONS.

DR. EDWARD G. BIRGE has resigned as director of the state bacteriological laboratory at Jacksonville, Fla., and has been succeeded by Dr. Burdett L. Arms, chief bacteriologist of the Alabama State Board of Health.

APPOINTMENTS.

DR. ELLIOTT WASHBURN has resigned as superintendent of the Rutland State Sanatorium to accept the position of superintendent of the municipal hospitals in Kansas City, Mo.

PROFESSOR E. V. MCCOLLUM of the University of Wisconsin has been appointed to take charge of the department of chemistry of the new school of hygiene and public health which the Rockefeller Foundation has established in connection with the medical school of the Johns Hopkins University.

PROFESSOR FRANK C. BECHT of the University of Chicago has been appointed professor of pharmacology in Northwestern University Medical School, succeeding Professor Hugh McGulgan, who has become professor of pharmacology in the University of Illinois.

DR. A. E. LAMBERT has been appointed professor of histology and embryology in the college of medicine of the University of Vermont.

THE MODERN TREATMENT OF BURNS, WITH SPECIAL REFERENCE TO SEVERE BURNS AND TO THE USE OF AMBRINE AND ITS SUBSTITUTES.

By EDWARD HAMMOND RISLEY, M.D., BOSTON.

PART I.

THIS paper and investigation were stimulated by the feeling that the present-day treatment of burns, both severe and trivial, leaves much to be desired, both in method of treatment and in end-results,—mortality and contractures. This is a class of cases of which every large hospital has at least from fifty to a hundred each year, in which results are obviously poor and in which very little detail interest is taken either by the surgeon or the house officer in charge.

Mortality is high, the period of disability is long and disabling, and deforming contractures are too common. From an economic point of view, to say nothing of suffering entailed, these cases should have better treatment.

Our investigation, founded on a detailed study of a series of cases under personal observation and treatment since May, 1914, a study and tabulation of all burned cases treated at the Massachusetts General Hospital for the past ten years, and a review of the literature, has aimed to settle the question of the best general

plan of treatment, especially that of the kind of dressing, the prevention of sepsis and equi-tractures, and shortening of the period of disability.

The author wishes to take this opportunity to thank the various members of the surgical staff of the Massachusetts General Hospital for courtesy extended to him in granting him the privilege of directing the care of the burned cases during this study, and also to the house officers on duty for very willing and ready coöperation.

The literature contains a few scattered observations on individual cases but only one treatise of value. This is a rather remarkable book by Dr. Herman Pfeiffer, in German, "Das Problem Des Verbrüunestodes," which takes up all phases of this question and is remarkable for the thoroughness with which it is presented and the detail into which it goes.

The clinical picture of the effects of severe thermal injury we have come to recognize as that of a profound toxemia, showing itself in the general toxic appearance of the patient, elevation of the temperature, etc., and by the effect of this toxic absorption on the kidneys, metabolism and gastrointestinal tract.

That the condition is actually one of a toxemia we also have convincing experimental proof, especially in Pfeiffer's exhaustive study. He looks upon the condition as one resulting from an auto-intoxication from the destruction of proteid bodies at the site of injury, or, in other words, a hyperproduction uremia or a toxicosis from pathologically increased proteid destruction and absorption.

In experimental work it is found that prompt removal of the burned area may be a life-saving measure in animals as well as in man. The transplantation of a burned area on to an uninjured animal may produce death with the same toxic and urinary symptoms as if the burn had been originally inflicted on the recipient of the transplant. In parabiotic animals the injured animal dies quickly, while the healthy mate dies later with the same symptoms, unless severed early. The blood of severely burned persons has been found toxic for guinea-pigs. The experiments on metabolism in Pfeiffer's work are highly technical but all go to establish more firmly the theory of toxic absorption. The picture, therefore, of the effects of severe burns develops in a clear manner to the well-recognized symptom-complex which in recent years we have learned to associate with peptone poisoning, with anaphylactic shock, hemolysin poisoning, uremia; in short, to the picture of a toxiosis from protein destruction.

The problem of the treatment of the burned patient is a broad and complicated one and divides itself, we believe, as follows:

1. The treatment of shock: when present.
2. The selection of the best form of treatment for the burned area, which subdivides itself into:
 - (a) The kind of first dressing to use, and
 - (b) The prevention of sepsis.
3. The problem of the prevention and treatment of contraures.
4. Prevention and treatment of complications, especially acute toxic nephritis and duodenal ulcer and the question of their relation to the toxemia, and the question of prognosis according to extent of surface burned and how to measure this.

1. TREATMENT OR PREVENTION OF SHOCK.

This is absolutely the first consideration and has been noticeably neglected in the past. Our first thought should not be to get the patient's clothes off and get a dressing on, but it should be "How much is this patient in shock and how can it best be combated?" No attempt should be made to move the patient until he has been relieved of his suffering by a good generous dose of morphia. If he is in marked shock he should be treated by methods best known to combat it, especially by the use of subpectoral salt infusion, and rectal shock enemata. Meanwhile, exposed areas should be lightly covered with a warm blanket to prevent chilling. If the patient receives benefit from this treatment within a half hour, one of three courses is open to us.

a. The clothing may be carefully cut away from the whole body and the patient placed exposed to the air, with the temperature of the room elevated to about 110° by open fire or other means; the open air treatment, or

b. He may be treated with some form of medicated dressing.

(1) He may be swathed with compress cloth saturated with a solution of from 1 to 5 per cent. picric acid. This dressing is best applied in sections and held lightly in place by roller bandage. If put on in sections it can be removed piecemeal and thus add less to the patient's later discomfort or shock. This first dressing may be left on for 48 hours before being disturbed at all.

(2) The burned area, if not extensive, may be painted with tincture of chlorid of iron and the patient left without dressing in a warm room. (The relative values and results of these forms of treatment will be discussed later.)

c. Should the patient not recover rapidly from his shock he should be immediately immersed in a continuous hot (90°-110°) saline or boric acid solution bath, the clothing to be cut away after the patient has been immersed and not previously. For in cases of severe burn the shock caused by the first dressing is always a serious consideration and may be fatal. This is substantiated by many case histories in the hospital records in which profound shock and death followed the first attempt at dressing. For instance, there have been many cases who were brought to the hospital in moderate shock who recovered somewhat while resting on the shock table but who, after the agony of removal of clothing, or the application of the first dressing, died an hour or so later with distinct signs of recurrent or delayed shock. We feel that this detail of treatment has often been overlooked and has been the actual cause of many possibly avoidable deaths. Therefore, the longer we can postpone the first dressing the better it will be for the patient, to whom every hour is of advantage in recovering from his primary shock.

Regardless of time, the patient should be kept in the hot bath until he has recovered from his shock and he should be reimmersed immediately should he, on removal, show signs of recurring shock.

This salt solution bath is of great benefit not only to the patient's general condition, but also furnishes nutrition to the devitalized cells that cannot be reached by the blood current now shut off by the thrombosis, which occludes much of the superficial capillary circulation. And it is essential to save the life of every cell, especially epithelial cells, which later are the regenerations of true skin. This bath has been found of great—even life-saving—value in the later or granulating stage of extensive burns when dressings could not be borne and the patient is in an exhausted condition—especially in children.

Our prime consideration, therefore, is the prevention and treatment of shock, by prolonging as long as possible and minimizing as much as possible the trauma of the first dressing, by warmth, by plenty of morphia, by flooding the system with fluids, and by the use of medicinal stimulation if necessary. This is our first duty and is a thing which the writer knows from personal experience has not secured the

careful detailed attention in the past that it should receive. The burned case comes to us in shock which is both psychic and physical. If we hasten to get some sort of dressing on his local injury instead of first treating his psychic shock by the beneficent influence of morphia, and his physical shock by this and other well recognized means, we miss the whole point in the solution of this problem and add greatly to his already devitalized condition and increase his chances of death rather than of recovery. Too much stress cannot be laid on this very vital but often lightly considered part of the problem of the care of burned cases.

2. THE SELECTION OF THE BEST FORM OF DRESSING.

As shock and sepsis are for all practical considerations the only causes of death, let us turn to the second phase of our problem, the selection of the best form of local treatment, which is so closely related to the problem of the prevention of sepsis.

First Dressing.—We have adopted the rule never to use oily dressings; there is nothing in favor of an oily preparation except that it produces a fairly painless dressing. The objection is that it is not as a rule sterile, and favors the growth of bacteria; it does not absorb the discharges but keeps them in contact with the wound, causing maceration, and must be changed every 24 hours. As opposed to oily dressings, lotions are advocated, and the one most favored by a large number of men is picric acid in 1 to 5% solution. In favor of such a dressing are the following points: It can be sterilized. The discharges are absorbed by the dressing. The growth of bacteria is prevented and hence lessens the subsequent danger of constitutional symptoms. The first dressing can be left on at least 48 hours, thus giving the patient a chance to recover well from his shock. The dressing is clean, is healing *per se*, and above all, acts as an analgesic. Poisoning is not a common complication, when the weaker strengths are used. Most men consider this danger of poisoning a negligible one, and the advantages of this dressing to far outweigh any possible danger of absorption.

With a view to determining the value of these two well-recognized forms of treatment, and particularly to try out the picric acid method, all burned cases receiving House treatment at the Massachusetts General Hospital for a period of one year from May, 1914, were given one of the two forms, *i. e.*,

(a) All cases going to the West Surgical Service were dressed with picric acid at the first and subsequent dressings until the danger of immediate sepsis was over and other forms of medication seemed advisable.

(b) All cases going to the East Surgical Service were given open air treatment immediately.

The results in our series place us in a position to say that the open air treatment for extensive burns is vastly superior to any treatment in which any kind of dressing is used. Cases so treated recover more quickly from shock, suffer less pain, and get a better start than cases receiving *any* kind of dressing. The fact that all of our cases that died under this treatment did so from primary shock as a result of extensive burns, within 6 to 72 hours after entrance, makes it impossible exactly to compare statistics of those two forms of treatment, but we are convinced that the case that is not traumatized by any form of dressing is much more likely to recover than the one less carefully handled.

Picric acid is by all means a superior dressing to any of the oily substances. We have seen no symptoms of poisoning. In first degree burns it leaves a clean, dry and probably sterile surface and relieves pain very quickly. In second degree cases it has proven a splendid dressing, leaving in a few days a dry surface, all discharge being readily absorbed through the dressing, and an area which practically never becomes septic and heals quickly.

During the past six months we have been trying out a series of cases on the tincture of chlorid of iron, and as far as we have gone we have every reason to look upon this as a satisfactory method,—certainly in burns of the first and second degree of not too great extent. It has the advantage that no dressing is required, but a light bandage may be used, if desired, simply as a protection. The tincture is simply sopped on over the burned area. This, in most cases of more than first degree burns, is painful at the very onset, but a state of analgesia very quickly supervenes; and after its first application, patients never complain again, but speak enthusiastically of the comfort and freedom from pain. Repeated applications should be made once an hour or so until the affected area is well coated over and a dry protective layer is formed. After this only occasional applications need be made. The area is best left uncovered, as a thorough drying is what is desired. In our series so far only first and second degree burns of moderate extent have been treated in this manner and the results have been very satisfactory. The area dries up rapidly because of the astringent properties of the drug; there is no tendency to sepsis, and healing takes place apparently with considerable more rapidity than with other forms of treatment, because a dry, clean area has been obtained, instead of the usual moist, warm, foul one, produced especially when oily dressings are applied. We believe this treatment is of distinct value in superficial burns of limited extent.

The Prevention of Sepsis.—This depends fundamentally on the kind of first dressing used. Burned areas are presumably at first sterile, due to the action of the heat, but they are immediately contaminated by the first covering of

dirty clothing or the first oily dressing. We have had no case of sepsis in either our open air or pierie acid or tincture of chlorid of iron series. In all of our cases the skin surrounding the burned area is washed twice a day with alcohol, thus keeping the surrounding field as free from bacteria as possible. In the open air cases as soon as the area is crusted over, and sero-purulent material escapes, the crusts are incised or raised in order to allow free drainage, and the cleansing of the skin continued. Within about 6 to 10 days or less, warm salt solution compresses are applied to small portions of the crusted area and after 48 hours the crust is removed from this area, leaving a clean, raw surface, which soon begins to granulate.

We believe we can positively state, therefore, that sepsis can be prevented by the open air treatment, and the salt solution compress, cleansing of the surrounding skin, and avoidance of oily dressings at the onset.

We wish to lay particular stress on the early and painstaking and frequent pricking of the blebs, the incising of large crusted areas and the elevation of crusts to effect constant and proper drainage. To do this successfully a special nurse should be employed, and if done carefully and gently, very little discomfort is caused; toxic material is thus constantly drained off, the temperature is kept lowered and sepsis is much less likely to ensue. This must be done almost continuously to be successful and requires great patience and diligence, but the results obtained are worth all the extra labor expended.

3. THE PREVENTION OF CONTRACTURES.

From our observation of some 100 recent severely burned cases, we think we are in a position definitely to state that the percentage of contractures can be reduced at least 75 per cent. by three definite means. First, and most important, is the prevention of sepsis. Second, by the early immobilization of extremities affected by properly applied splints. This is most important and should be employed at the very onset of treatment, as soon as the case is over its shock and is running smoothly and before granulation begins. Third, by the early employment of passive motion and massage. In the hospital our cases are sent to the Zander department as soon as they can be moved, and treatment begins very gradually. Massage is applied to the skin immediately surrounding the burned area, and as much passive motion used as is consistent with comfort. This is done daily during granulation and afterwards till all signs of contracture have disappeared. After massage in the early stages, the limb is returned to its splint as long as that seems necessary, being taken out occasionally to rest the part. We believe that the above methods are of greatest value in effecting the early recovery to usefulness of these tedious cases.

To be successful, however, in the use of splints, they must be employed early and continuously

and with great patience. Often, variously moulded plaster-of-Paris casts can be made to adjust to different parts of the body and to accommodate the dressed area, and are of the greatest service.

4. COMPLICATIONS.

Duodenal Ulcer.—The question of the incidence and etiology of duodenal ulcer in severe burns is yet an unsettled one. Just how many cases which have nausea and vomiting and epigastric pain within the first few days are developing duodenal ulcer is not possible to say. The fact that many of these are quickly relieved by dram doses of soda bicarbonate makes it seem unlikely that the symptoms are due to anything more than the toxemia produced by the burn. The percentage of autopsies on burned cases is so small that detailed statistics are not available. We have failed to find a single case of duodenal ulcer in any of the cases autopsied at the Massachusetts General Hospital since its foundation. Out of all cases of multiple burns coming to autopsy, 6 had either nausea, vomiting or pain in the epigastrium, but only three showed any pathology in the gastrointestinal tract. Most of these cases were in profound shock and lived but a few hours. One case in whom there were no symptoms (probably because of the degree of shock) showed two feet of upper ileum congested but no ulceration. One case with pain in the epigastrium showed at a point 125 c.m. above the ileocecal valve, intense redness of the mucous membrane with discrete and confluent irregular black-red areas but no ulceration. The cecum was even more affected but there was no sign of even minute ulceration. One case which vomited everything taken showed some reddening of the mucosa in the lower ileum but nothing in the region of the duodenum; and one case with slight nausea showed only the mucosa of the stomach mottled and the first portion of the duodenum red in color but no ulceration. We are therefore convinced, after a careful study and analysis of clinical and autopsy records,—taken in conjunction,—that actual duodenal ulcer following severe burns is so rare as to be practically negligible. We do, however, recognize a distinct train of symptoms strongly suggestive of this condition but which we believe are due to the toxemia as a general disturber of metabolism rather than as an exciter of distinct pathological changes in the duodenal mucous membrane.

The fact that these symptoms subside with proper treatment also suggests toxemia rather than actual lesion of the duodenum. It has been our experience that cases given dram doses of soda bicarbonate three or four times a day, together with a general forcing of fluids, recover quickly from the symptoms of toxemia. Certainly, physical examination of the cases shows none of the well-known signs of duodenal involvement.

5. PROGNOSIS, ACCORDING TO DEGREE AND EXTENT OF BURN.

A first degree burn of one-ninth of the body in a child is often fatal, while a first degree burn of two thirds of the body in adults generally results fatally. One third of the body area in second degree and much smaller areas in third degree are generally fatal.

Analysis of our series shows, however, that the prognosis is very variable and that young adults may survive even greater areas and recover rapidly, while young children and the old or feeble will often succumb to secondary shock with very slight and very small burns. The age and condition of the patient is of nearly as much prognostic value as the extent of burn, provided the burn is not of extreme extent or degree.

We have found that the more complicated methods of measuring the body surface, such as the use of Du Bois Height and Weight Formula Chart, are not practical, but that if one estimate the surface in the male as approximately 20 feet, and in the female as 16 feet, rough estimation of the extent burned can be made which is accurate enough for prognostic purposes. To know definitely whether one or two square meters more or less are involved is of little importance in comparison with a sound appreciation of the patient's general condition.

The mortality in this series was 23.4 per cent., which is about the usual mortality in this type of case. The mortality is higher when the chest, back, or abdomen is involved than when equal or even greater areas of skin are burned on the extremities.

The presence of shock is the most important factor in making the prognosis at the onset. Practically all badly shocked cases die, irrespective of previous condition or subsequent treatment.

A careful review and consideration of the evidence at hand in the study of cases of severe burns would lead us to the following general conclusions:

1. The three most important factors in the treatment of burned cases are:

- (a) Prevention and treatment of shock.
- (b) Prevention of sepsis.
- (c) Prevention and treatment of contractures.

2. Many deaths have been caused by ill-directed attempts at a first dressing.

3. The form of first dressing is largely responsible for subsequent sepsis. Oily dressings should be avoided. Cleansing of the skin surrounding the burned area with alcohol aids in preventing sepsis. Constant drainage of discharges is essential.

4. The open air treatment is far superior to that in which any form of dressing is used.

5. Either pieric acid or Tr. chlorid of iron are by far the best forms of medicated dressing.

6. Contractures can be prevented in 75 per cent. of cases formerly contracting, by the early use of properly adjusted splints and by early passive motion and massage.

7. Duodenal ulcer is a rare complication and can be almost discounted.

We would formulate the following general rules for treating burned cases:

1. Combat shock first.
2. Treat all shocked cases or those with extensive burns by the open air method or the temporary use of the hot bath.
3. Avoid oily dressings.
4. In burns of the extremities—if fairly extensive, but not requiring open air—use pieric acid.
5. In all other burns use pieric acid, Tr. chlorid of iron, or the more modern paraffin film treatment according to preference or experience.

PART II.

THE AMBRINE TREATMENT OF BURNS.

It is probable that most of us who have not been abroad since the war began, first heard of the ambrine treatment of burns through the lay press, especially in articles that appeared in the *Outlook*, describing the wonderful and surprising rapid regeneration of tissue—even of muscle and bone—after its use. Comparatively few of the men who have been abroad to do war surgery have actually seen it in use, and our knowledge of it today has been largely a matter of hearsay and conversational reports of a few men who have seen it used.

This preparation is a recent one invented by Le Docteur Bart de Sanfort, the news of whose work comes from St. Nicholas hospital, near Paris. Dr. Sanfort made a report of its use at the French Academy of Medicine a little over two years ago, but no detailed accounts of its composition, method of application, or reasons for its superiority have yet appeared in the foreign medical journals. A few scattered abstracts appeared from time to time in the *British Medical Journal* in 1916, but these added nothing to the lay reports. Efforts by several men to obtain the formula for its preparation have been evasively answered by the statement that the excellent product could now be obtained from the French representatives in New York for \$6.00 the pound.

These facts do not, of course, put this preparation on a strictly ethical basis, and a certain amount of skepticism has naturally resulted.

With the object of getting some knowledge of the composition of this product before its general use was instituted, the Hospital obtained a pound of ambrine, which was given to Dr. Denis, our chemist, for analysis. It was found to contain, roughly, 90 to 95 per cent. of paraffin of a good grade, 5 per cent., more or less, of beeswax, a small amount of resin, probably some such product as eucalyptol, and an aniline coloring matter, enough to give it its peculiar gray-brown

hue. The melting-point was about 140° F. With this approximate analysis at hand, a substitute was then made up with the following composition:

Paraffin of melting point 52° C.	90%
Japan beeswax	5%
Spermaceti	5%

These were heated together at 150° for 30 minutes. No coloring matter or deodorant or disinfectant was added. This preparation has been used independently and alongside of ambrine in order to check up the results on both, and it shall be my aim to give you as fair and unbiased a report on these paraffin preparations as possible, based on a rather limited number of cases.

The method of application of either is as follows: The burned area is cleaned up very gently as far as possible, removing dead skin and traces of previous medication, and all blebs pricked near their bases but the cover not removed. The surrounding skin is cleaned thoroughly with alcohol and the part allowed to dry as much as possible, or drying is hastened by the use of a warm air blower. Meanwhile, the ambrine or its substitute has been heated on a water bath—the ambrine to about 140° F. and the substitute to about 130° F. This is then painted or sprayed quickly over the burned area and for about two inches over the surrounding healthy skin. Theoretically, the spray is the best, because it does not injure the delicate granulations present and can be blown into and fills up every minute depression of the injured surface; but practically, the gentle application with a flat camel's-hair brush about 1½ inches wide does not harm the injured tissues. If applied gently and quickly at this heat a thin, smooth film is formed over the burned area, which makes a firm air-tight dressing. A piece of sheet wadding a little larger than the burned area is then peeled apart so that a very thin layer only is left and this is laid over the area and a second coat of ambrine painted quickly over this. The part is placed on a splint to immobilize and prevent cracking of the ambrine film. It may be further covered with a bandage. This dressing must be changed at the end of 24 hours. Generally, enough serum or discharge collects to "float" the ambrine coating to some extent. It lifts off easily, and generally intact, as it practically never sticks to the burned part. The area is now washed gently with warm borie solution, dried with a blower and the preparation reapplied as before, repeating each 24 hours until the area is healed.

The first question that naturally arises is, "Isn't this substance, put on at 140°, painful?" The author can testify, from some limited burns made on his own person to test this point, that the application can be said to be but momentarily painful. A rather uncomfortable sense of extreme heat is produced at the very first moment of application, but the very minute the

first coating is on this sensation quickly subsides and gives place to one of rather soothing comfort. There is a slight feeling of constriction or adhesiveness for the first few hours after the dressing is first applied, but after that no particular sensation is noticed. Patients who have had more extensive burns treated give evidence of the comfort of the dressing but do not allow that the first application of the hot wax is absolutely without temporary discomfort. It is not a painful dressing, and its removal is *absolutely* without discomfort of any kind. It certainly is remarkably painless in comparison with any of our older forms of dressing.

The second question which I think would naturally arise is, "Why does not such a dressing give a favorable chance for bacterial growth?" The answer is simply that it does not. A distinct odor is generally given off at the time of removal of the coating but this has a stale, musty sort of odor more than a putrefactive odor. None of the cases of burns of limited extent, *i. e.*, hands, feet, arms, etc., in our series has showed the slightest signs of sepsis.

The lack of sepsis has been one of the rather striking things about this treatment. Case 5 of our series is a very good illustration:

CASE 5. Miss M. received second and third degree burns of the backs and fronts of both lower legs between the knees and ankles. She treated the burns with strong sulpho-naphthol for two weeks before coming to the hospital and produced, in addition, a generous sulpho-naphthol burn of the skin for about two inches on all sides of the original burned area, which latter was covered over with a dirty, thick, leathery slough. The area on admission was cleaned up as much as possible with a chlorinated soak, ambrine was applied to the right leg and the substitute to the left. In 48 hours the slough had entirely separated from both legs, leaving a perfectly clean granulating area, except where the Achilles tendon was exposed on the left leg. This case, while not a favorable one for ambrine, proves its worth as a dressing which certainly does not favor infection.

The length of time necessary for complete healing is another important point.

Our first four ambrine or ambrine substitute cases were first and second degree cases and healed up in 9, 12, 8 and 14 days, respectively. Case 1 had enormous blebs and did not look as if it would be healed for weeks and yet at the end of 9 days presented a smooth, soft, red sear and no scabs.

The resulting sear in the very small number of cases we have had has been noticeable for its softness, smoothness and pliability. It never has scabs and does not seem to crack and bleed as readily as burned areas under other forms of treatment.

It may now be asked, "What is the reason for the apparently favorable results obtainable by this preparation? Is it chemical or mechanical?"

It certainly is not chemical in any sense that

original ambrine has some secret constituent which renders it superior to any paraffin substitute. For, so far as we could determine, the substitute cases did exactly as well as the ambrine cases, healed as quickly, were as comfortable, did not become septic, and left just as smooth a scar.

The effect of this preparation, therefore, must be purely mechanical in its action. It seems probable that this mechanical action is favorable, first, because it immobilizes the affected area; second, it is a sterile dressing; third, it makes an air-tight sealed dressing—which may possibly be the reason why it does not favor bacterial growth; and fourth, by its close adhesion to the part favors ingrowth of granulations while it discourages up-growth or heaping up of granulation tissue, to some extent like adhesive plaster on the sluggish granulations of a varicose ulcer; or it may act as a supporting framework for new granulations. I have a feeling that the very soft, smooth scar may be due in a large measure to the contact with the paraffin and, of course, to the absence of sepsis.

There is a considerable amount of experimental work being done with various paraffin preparations or films. The first article of value to appear was that of Sollmann, of Cleveland, who also objects to the secrecy in regard to ambrine and the American preparations which have recently appeared on the market, because of the difficulty of comparing results in known and unknown preparations. Sollmann has made simple preparations which could be imitated by any pharmacist and has avoided the use of any coloring matter, deodorant or antiseptic in order that they might be tested purely from a mechanical point of view.

Preparations were made up to test several factors: 1, melting-point; 2, fragility; 3, stretching quality; 4, pliability; 5 hardness.

After testing the above, the author states that the preparation and mechanical properties of a series of paraffin film mixtures suggests that the most important mechanical property of such films, from the therapeutic point of view, is their hardness. It is suggested that several degrees of hardness might possess advantages under different conditions. Surgeons using these paraffin preparations are urged to use simple combinations of known composition so that their results can be compared and improvements intelligently made.

This author found that ordinary paraffin, melting at about 53° C. (or 122° F.), appears to possess practically the same mechanical properties as the French preparation, and urged it as the standard of comparison.

The article is of clinical as well as pharmacological interest.

In a recent visit to the Angell Memorial Hospital for Animals on Longwood Avenue, I found the American proprietary preparation called Parrasine, made by the Abbott Laboratories of

Chicago, and extensively advertised in the *Journal of the A. M. A.*, and elsewhere, was being used on burned animals with satisfactory results. The veterinarian there was convinced that cases healed more quickly under this form of treatment than with previous methods.

From my rather limited experience with paraffin preparations I can say that I have been convinced from skepticism to a rather firm belief that this method of treating burns (certainly those of limited area) is a decided advance over other methods formerly employed.

Points in its favor are: It is not a painful dressing; it is easy of application and removal; it does not favor infection; it produces more rapid healing; it leaves a smooth, soft, pliable scar.

From the point of view of comfort of the patient alone it is a decided advance over any other form of dressing.

DISCUSSION.

DR. J. B. BLAKE, Boston: I should like to compliment the reader on his paper, especially in what he said and the way in which he said it. The subject of burns is an extremely important one, and it is altogether too often overlooked as an excellent subject for discussion at medical societies.

There was one single aspect which the reader did not consider, and that was the first dressing of burns at home, which comes before us now in the many lectures in first aid, and which it is worth while speaking of for a moment before discussing the paper as a whole. The old dressings which have been recommended have largely been oil of some sort, or flour or molasses. It seems to me it is time now to drop all these recommendations, even though we may be talking to the mothers who live in the poorer parts of the city. It is always possible now to get hot water, and salt, and usually bicarbonate of soda. I think we ought to recommend warm water (on a clean cloth) into which salt is put, or saleratus, in the proportion, roughly speaking, of a teaspoonful to the pint. This would be an infinitely better first dressing than either carron oil or olive oil or flour or molasses. I would recommend that in the first-aid instructions which are now being given all over the country.

In my experience with burns, so far as it has coincided in method of treatment, I agree entirely with Dr. Risley, particularly in the matter of not removing the first dressing when shock exists, which he has emphasized even more than I have in the past. Cases of extensive burns, especially in children, are probably doomed to death by unnecessary and interfering first dressings. If a carron oil or even a molasses dressing has been put on it is better to stay on 24 hours and take the chance of additional sepsis, rather than take the chance of increasing the shock, by removing it. I should go even so far as to question whether it might not be permissible to give paregoric to the child together with the first dressing. That is open to question, but if there is ever a time when paregoric may be used by the laity it is to combat the early shock in a child.

The second point I wish to mention is the fact that Dr. Risley reports burns, all of which, in a big hospital, have been assigned to a single service. The instant you make burns a subject of intensive study

by a single trained expert or a group of experts, your results will necessarily begin to improve.

My first knowledge of ambrine, beyond reference in the daily press, I got with Dr. Faulkner at an illustrated lecture given in Boston some months ago.

The pictures were misleading. They were supposed to prove that, under the influence of this mysterious drug burns healed more quickly than ever before. The burns had been subjected to routine treatment by a certain number of observers and had not been distributed widely through the various wards. As regards the pictures themselves, it seemed to me they were very highly colored—to put it mildly. The first pictures were taken before the burns had healed at all, and greatly emphasized and exaggerated the size and depth of burn. The subsequent pictures were subjected to every possible method of making them seem better than they were. Then there were a few pictures which represented absolutely denuded areas which were supposed to get better in a time which was absolutely impossible. We divided them into two groups, one group which exaggerated the burns and suggested results which were only approximately obtained; and the other which apparently gave pictures that could not possibly occur. It is not possible for cicatrization to occur over an area of 50 or 60 square inches in three or four days.

We have tried at the City Hospital the ambrine substitute which Dr. Risley described. In some nervous children we had difficulty in applying it. In adults I believe it to be, on the whole, the best dressing I know, with the possible exception of one per cent. picric acid.

In regard to ambrine, another reason why the scars are soft is perhaps in the fact that there is so little trauma in removing the dressing. Taking a dressing soaked with secretion from the burns of the average child, is an extremely traumatizing thing, and it produces shock. Nurses believe they cannot do it without hurting the child. The resulting hemorrhage tends toward the organization of a scar which is thicker than it otherwise would be. The picric acid, so far as my experience goes, is the best routine dressing for burns. We tried it at the City Hospital some years ago at the instigation of Dr. Jonas, beginning with a saturated solution, which was altogether too powerful; the statistics of picric acid poisoning presumably refer to the use of a saturated solution. We diluted until we got to a one per cent. for the average adult and even one-half per cent. for children. Dr. Jonas tells me that after ten years of experience he has no reason to modify his judgment of picric acid, and he still believes it by far the best routine treatment of burns. He has his gauze made up in small packages not more than four inches square, folded and covered with paper; and the firemen and engineers are taught how to undo the paper packages and to place the contents of the package on the burn, allowing the paper to stay over it as a temporary first dressing, attaching it with adhesive straps. This can stay on 24 hours, and in some cases 48 hours. If possible, he leaves the different pieces of gauze in position for three to four and even five to six days, moistening them once in 24 hours. He seldom has to resort to skin grafting.

In civil hospitals, we are often compelled to resort to skin grafting and in so doing we use the Revidan grafts. We make the graft thicker than the

original Revidan, placing it at intervals of perhaps one-fourth inch, and covering one square inch of a burn which may be twelve inches square. We can begin grafting earlier and shorten the course of the cicatrization a good deal, because it is not necessary in this method to wait until the entire surface of the burn is ready for grafting at once.

Dr. Jonas also suggested the outdoor treatment, and in cold weather the exposure to the electric light. He has found the use of electric light up to 60 and 80 and 100 candle-power, the bulbs being at a distance of 12 to 20 inches from the burned surface, to be extremely beneficial, drying up the burns if discharging freely and hurrying along the cicatrization, and unquestionably aiming toward a smooth and pliable scar.

The important points which I would emphasize are,—the substitution of alkaline first dressings for oil or oily substances; the special effort to reduce shock probably without removing the first dressing for 24 hours, the use of ambrine or 1% picric acid as a routine for a large majority of burns, and exposure to sunlight or electric light after 48 to 60 hours.

DR. J. M. BIRNIE, Springfield: I cannot add very much to this very excellent paper of Dr. Risley's, but I do want to emphasize one point which he has made, and that is the fixation of burns to prevent contracture, even going to the extent of putting on plaster casts, which we do. And also I can add a little testimony in the use of paraffin dressings. We have used them in several cases and I must say that I am very enthusiastic over them, both as to results and comfort to patients. We have not used ambrine. We have used a substitute which we have obtained at various drug stores. We have written for the following prescription put up at the ordinary druggists, and apparently it is the same preparation from each one:—

1 part oil of eucalyptus,
5 parts olive oil,
20 to 30 parts hard paraffin,
Balance to 100, soft paraffin.

I do not think the oil of eucalyptus is at all necessary but we put it in because it was in the original analysis. We have tried putting it on with a camel's-hair brush, and also with a sprayer. In the first few cases we used a Wondermist sprayer and afterwards we decided to use a little bit of an atomizer, heating up the solution, pouring it into a bottle, keeping the bottle in a pan of hot water. We spray it and then do not put the sheet wadding in the second application. We put on just one film of the paraffin substitute and put loose gauze outside. We do not find that we have sepsis nor do we find it always necessary to change the dressing every 24 hours. In some cases you can leave it on 48 hours, and along towards the end, even longer. We had one case where a man with oily overalls on backed into a flaring torch. He was burned from the waist to the ankles. The deepest burns were in the flexor surface and they were only more or less superficial on the extensor surfaces. That man had horic solution until he could get to the hospital, and then he was immediately treated with this paraffin substitute put on with a Wondermist sprayer. His burns have healed now and he made a wonderful recovery.

If you write for a simple prescription of that kind and an ordinary atomizer, any one can use the treatment.

TREATMENT OF OLD UNUNITED FRACTURE OF THE
NECK OF THE FEMUR BY TRANSPLANTATION
OF THE HEAD OF THE FEMUR TO THE
TROCHANTER.

BY E. G. BRACKETT, M.D., BOSTON,
AND
MAY SUNG NEW, M.D., BOSTON.

[From the Orthopedic Department, Massachusetts
General Hospital.]

No attempt is made in this communication to review the literature on this subject, or to discuss the various methods of treating this condition, for it has been thoroughly done many times. It will deal only with the old fractures of the neck of the femur, at a period from some months to several years after the injury, when there has already been absorption of practically the entire neck, and when the partly atrophied head consists only of the articular portion, not projecting beyond the acetabulum, and must be regarded somewhat in the light of a sequestrum. It can derive a certain amount of nourishment from the joint fluids in which it is bathed, and also some from the non-vascular fibrous attachment, when such exists, but this union to the head fragment is often found, on operation, to be slight, and hardly enough to be the channel of much nourishment, and the actual bleeding of the bone when it is cut seems to be always questionable. It surely is very different from the bleeding cut surface of normal bone. This nutritive defect of the head is one of the most important factors to be reckoned with in the attempts to procure firm union between two fragments so long separated, for we must bring about conditions sufficiently favorable for the fragment to become thoroughly living again. The principle in the treatment of this condition in the fresh cases, when nutrition is good, and in the long-standing, when nutrition is necessarily poor, must be radically different. The retention by nail has practically been discarded, as well as the use of graft for retention, as the atrophied head is too soft to withstand any force put upon it, for the purpose of retention or fixation. The use of the graft as a carrier or trellis for osteoblastic stimulus, unless a firm apposition is obtained, is nearly as futile, for the graft, once detached from its bed, becomes dead bone, one end of which is fastened into live bone and the other into a fragment of questionable viability. It is reasonable to expect that the first end should live, but it is expecting a good deal that this insert, which itself must be re-nourished from its attachment into the femoral shaft, can carry its regenerative power across the bridge between the two and into the old head, at least partly dead, and restore it to normal activity. On attempting to freshen the surfaces of the two fragments, it is necessary to hollow the femoral surface of the head, for there

is usually not enough of the head to make a flat fresh surface without encroaching on the cartilage edge of the articular surface; nor is there enough left of the neck to fashion a convex surface which will protrude into the newly made concavity of the head; therefore, any attempt to appose these two freshened surfaces results in approximately placing a cupped or mushroom-shaped head on a flat surface of the shaft, with only the edges of the head, at the best, in contact. If the leg is abducted, the upward riding trochanter pulls the neck surface away from the head, and prevents the firm contact which is necessary for a strong bony union. If, on the other hand, the leg is placed in the position of extension, then the small graft or peg, driven into the head, too soft to be relied upon to withstand any degree of force, must be relied upon to withstand the strong upward thrust of the thigh muscles. The fact is, by these usual methods, a firm bony union in these old cases of fracture of the neck of the femur, ununited after a long time, is not at all common. It has been found difficult to look up the results of operation on the old fracture cases. The pretty constant failure to obtain a firm bony union has not been an encouragement to go through the experience of the long convalescence added to the operation. Twenty-four cases have been studied, among which are some for which I have to thank the general surgical services of the Massachusetts General Hospital for the privilege of using. Of these (24), one has a useful leg. This report is by letter; it is (4?) years since the operation. It has not been possible to get an x-ray, but the patient writes that his leg is strong and useful, and that he has no pain. The operation was freshening the surfaces, no peg or graft was used. The man was younger than the average in these cases, being in the thirties, therefore at a time when the bone repair is more active. This is the only case of this series in which a satisfactory result was obtained. Results such as these, combined with the fact that these patients are permanently out of commission for any activity, is sufficient reason for advocating active surgical measures, even if they are radical.

The method here considered treats the femoral head as if it were a real sequestrum. We know that an entirely dead bone becomes vitalized if grafted on to living cancellar bone, and this seemed to be a solution to the problem here. The details were as to where to place the old head, and how. The thrust of weight-bearing from the shaft to the head should be as direct as possible, and yet have enough obliquity to adapt itself to the weight-bearing plane of the acetabulum. To accomplish this, the head is placed on the inner side of the top of the sawed-off trochanter, and in this way the thrust is passed directly from the shaft to the head, so that there is little or no distraction strain in weight-bearing, and the head has its most favor-

able position for a restored function, to gain which some compromise must be made.

Independent of the ordinary surgical conditions which must always be considered in any major operation, there is one contraindication. Sometimes, after joint injury, particularly in the older people, there is found a distinct osteoarthritic change, with thinning of cartilage, as well as the tendency to overgrowths. Under these conditions, a favorable functional result could not be expected, and this operation must not be advised.

Technic. The joint is best exposed by the inter-muscular route, between the tensor fasciae femoris and gluteus medius, by an incision from the anterior superior spine to the middle of the trochanter, turning downward, parallel to the line of the femur for a few inches—then starting again at the angle of the oblique and vertical positions of the first, a curved incision is carried backwards and upwards three or four inches. The tensor fasciae femoris and gluteus medius are separated, the muscle attachments on the outside of the trochanter are removed subperiosteally, or with a thin bone attachment, and the top of the trochanter removed so as to save the attachment of the gluteus minimus and pyriformis. These muscles are then all turned backwards and upwards, and the upper and anterior portion of the capsule exposed, to the edge of the acetabulum. The capsule is opened longitudinally to its fibers, on the upper portion of its anterior surface, saving the attachment of the Y ligament, if possible, but which, however, cannot always be done.

The capsule above the opening is then detached from the femur and retracted outward and backward; the trochanter cut off just below the level of the upper edge of the head, the inner portion rounded to correspond to the curve of a $1\frac{1}{2}$ inches to 2 inches radius, saving the anterior and inner cortex. The outer portion is either cut off obliquely, or a wedge taken out, near the outer surface, allowing the outer cortex to be pushed inward. The free surface of the head is thoroughly freshened, covering this area, so as to make a corresponding curve, to the rounded top of the trochanter. In abduction of the leg, the convex surface which has been fashioned on the trochanter, is brought directly into the concave head, and in this position is firmly held against it. In this way the femoral head with its freshened surface is placed directly on the freshened cancellar surface of the trochanter,—an ideal condition for the vitalizing union of the poorly nourished fragment. The head is not placed directly on the top of the trochanter, for this would not allow the best position in the acetabulum, but on the inner and upper sides, which gives to it a somewhat oblique angle, partly resembling its normal direction, but without the normal neck. The stitches are placed in the capsule, but not tied until the leg is put into position of abduction,

and the head seen to be in the relation to the end of the trochanter which is desired, in order that this contact can be assured, and the position of the leg is then maintained until the plaster is applied. The stitches are then tied, the outer attachment of the capsule which has been freed is secured with the muscle attachment. The attachments of the gluteus medius and minimus, and pyriformis, are either secured to the outer side of the trochanter, or are inserted into the wedge-shaped depression, which has been made, in order to round off its upper and outer end. The wound should be tightly closed in layers, a plaster spica applied, including the foot of the affected, and the other leg, to the knee, and extending well up to the lower thorax on the opposite side from the operated leg. As a rule, the extreme degree of abduction is not required, and less inversion than in the Whitman method with the fresh fractures. This fixation is maintained for eight to ten weeks, fixation with an ambulatory plaster, but without weight-bearing for about two months more, and beginning weight-bearing with active motion at the end of this period. The ideal treatment would seem to be fixation by removable plaster at the end of the first eight or ten weeks, with beginning massage and gentle passive motion; but unless this can be carried out with very intelligent precision, the complete fixation is the safer plan. The bone contact between the two fragments cannot be made over the entire surface of the head, so that considerable bridging in of new bone is necessary, for which sufficient time must be allowed, and a change in the angle of union between the trochanter and head has been observed, after too early motion or strain. The motion must be brought back slowly, for the capsule must be partly newly formed and newly attached, and a considerable amount of flexibility must be developed before all of the potential motion can be expected. There is no diminution in the shortening, or at least not a practical amount, for there is too much adaptive contraction of all structures to allow any decided change in the relative position of the leg to the pelvis. A greater range of motion, however, is possible than might be expected, an entirely practical amount of flexion abduction and rotation results. The amount of this depends somewhat on the oblique position of the head on the trochanter, and on the rounding off of its overlapping portions.

The first case operated on in this series and by this method was in 1911. A man of thirty-five had sustained a fracture of the neck of the femur in a severe railway accident, one and one-half years previously. There was no union, and the man was out of commission. The attempt was made to freshen the surfaces and to bring the surface together in the usual method. The position of the trochanter, with the shape of the surface of the remains of the neck, combined with the irregular shape of the

surface of the head fragment, which had a large spur projecting downwards and backwards, made this impossible, and suggested this transplantation of the head as a compromise. The recovery was uneventful, and the man finally returned to work, and has been working steadily as a railway conductor for several years. Nine cases have been done, but seven only can be used as indicative of results, for two are too recent to be counted. One is just out of first plaster, at the end of ten weeks, and the leg is firm to any up-and-down motion, and the upward thrust has the solid feel, and the x-ray shows the head at an angle on the trochanter. The indications are of a good union, but the case should not be used for definite statistics. The others all have had firm union with strong weight-bearing, limited, but a practical amount of motion, with the same amount of shortening which existed before the operation.

The proceeding is a radical one, but the operation is one that is easily borne by anyone in reasonably good condition, provided there is no organic disease, and the recumbency in plaster is made more safe by the double spica, as it allows a considerable change in position. The very great deal of disability in those who still have a long working period ahead, and the prominence of the pain element, is indication for a reasonable although radical attempt to obtain a useful leg.

DISCUSSION.

DR. C. L. SCUDDER, Boston: There is only one pleasure that is greater than hearing Dr. Brackett present this subject, and that is to see him operate, which I have had the opportunity of doing several times on cases of this sort. I think his paper is a distinct contribution to the procedures which the surgeon may have in this group of cases, because, as has already been intimated, and as we know from practical experience, these patients are practically helpless, chronic invalids, unable to get about.

Now, fractures of the neck of the femur, in my mind, should be regarded something after this fashion, and they really group themselves into two groups,—without any reference to the old classification which has to do with the capsule and which is of very little importance practically: into the impacted cases and the unimpacted cases. If the impaction is a good impaction, if there is a good position, we are all agreed, I think, that we should let that impaction alone, and that probably union will take place in a large proportion of cases. If the impaction is a poor impaction, that is, the kind of impaction in which there is great eversion or inversion, the question will arise, is the individual old or young? If it is an old person, with poor impaction, it is better to do as we would with a good impaction,—let it alone and treat the case by immobilization. If it is a young, active adult, I believe we are justified in gently breaking up that impaction and either reimpacting it by a blow over the trochanter, or replacing it in position with abduction according to the Whitman method.

With the unimpacted cases I think the situation is quite different. We have here the recent cases in which I believe we should use the Whitman method or the Cotton method. These are the unim-

acted cases which you see soon after the injury, and we know that if the leg is put in the abducted position and extended, union will take place.

Then there are the old cases of unimpacted fractures which Dr. Brackett has spoken of,—and I believe that Dr. Brackett's operation which he has described, and the results of which we have seen, is a distinct contribution to this group of old unimpacted necks of the femur. We may use, if we please, the method of refracturing the neck, and we may simply lay open the joint, curette the surface and put the parts as nearly in apposition as possible; and hope that union will take place. Then we may do what has been suggested,—refracture these edges and put a graft of bone from the tibia through, and place the parts in as near apposition before putting the graft through as possible; and in a good proportion of these cases union takes place, but I am inclined to think it does not as often as supposed.

In the reported cases of Dr. Albee in New York, we should scan very carefully the kind of cases in which he has performed this operation, because, as I understand it, Dr. Albee is doing this operation in certain recent cases with obviously good results; but in the old ununited cases it is a question whether this grafting operation is one which will meet the conditions satisfactorily in the largest percentage of cases.

I believe that one great merit of Dr. Brackett's operation is that it is comparatively simple to do. It makes the weight-bearing come on the normal places. I think this is a distinct advance in the treatment of this particular group of cases.

DR. FREDERIC J. COTTON, Boston: I agree perfectly with what Dr. Scudder has just said, and I think this operation helps us around a corner which we have not known the way about before.

I have done a good many of these operations which were extremely unsatisfactory, but I am not quite as pessimistic as Dr. Brackett is about the results. The fact is, however, we get bony union in only a small proportion of cases, and in the majority of cases we do not even get functional result. Dr. Brackett has shown us the way out of this.

The reason some of these operations have been so unsatisfactory is that we tried to restore the bone to normal length; whereas Dr. Brackett reconstructs a new bone without attempting to restore the length.

DR. JOHN D. ADAMS, Boston: I have one word of commendation I want to add, I surely commend the operation most highly as being a comparatively simple operation, as hip operations go; all of which are difficult.

My experience is based on one case which Dr. Brackett saw in consultation. She has been out of plaster now only about three weeks, and is about on crutches, of course bearing no weight; but apparently the union is firm, and the patient has a little less than one-half inch shortening where there was over an inch. This I considered a rather good result.

SPINA BIFIDA AND ALLIED MALFORMATIONS. BASED ON AN OPERATIVE EXPERIENCE OF 34 CASES.

BY TORR WAGNER HARMER, M.D., BOSTON.

I do not come here with indiscriminating enthusiasm and optimism, but rather with the

hope of casting a tiny ray of sunshine on a gloomy field of endeavor. There are certain conditions which we all generally regard as hopeless. It is true that not infrequently the condition is one which is inconsistent with life. It must be true, however, that there are other conditions which cause death because our methods are inadequate. It is needless to say that constant efforts to combat such conditions should be made. No matter how discouraging the work is, it should be done. In this way new methods have been discovered, which have greatly reduced the mortality of certain diseases so that these diseases today, although dreaded, are not regarded as hopeless, and some not even greatly dreaded.

In short, we should hold before us the words of Cicero, "*Dum anima est, spes est.*"

One condition in which the prognosis is very bad is spina bifida. Fortunately, it is a comparatively rare condition, and therefore any systematic study and efforts to remedy can best be carried out at a hospital, and best by permitting one member of the staff to do all cases of this nature. I appreciate the courtesy shown me by the other members of the Surgical Staff at the Children's Hospital in permitting me to see and operate all the cases of spina bifida and allied malformations during the past twenty months. This constitutes a series of thirty cases. To these I add a case operated at the Boston Lying-in Hospital, and three others done in private practice.* This is a total of thirty-four cases, which I believe is an unusual experience; too small to deduce statistics of any nature, but ample enough to furnish a few points in operative technic. In fact, the earlier hard cases took me three-quarters of an hour to one hour, whereas now similar cases take but twenty to twenty-five minutes, and simpler cases I have done in ten or twelve.

As you know, spina bifida is a defect in closure of the neural canal of one or more vertebrae. This defect may be anterior or posterior. It may concern the cervical, thoracic, lumbar or sacral portion of the spine, or in a broader embryologic view the mid-line of the skull from the nasion to the foramen magnum. There may or may not be protrusion through this defect. Whether there is protrusion or not, the defect may be covered by skin, subcutaneous tissue, and membrane, or by membrane alone. The covering may be intact, or ulcerated, or ruptured and leaking without obvious ulceration. Over the defect the covering may be flat, or rounded and sessile, or rounded and pedunculated.

When a protrusion exists, it may contain only cerebrospinal fluid (*i. e.*, a meningocele), or it may contain nerve elements and cerebrospinal fluid (*i. e.*, a hydromyelo-meningocele or a hydro-encephalocele), or it may in the head contain

CASE 4. Myelomeningocele sixteen months after operation. Small keloid-like thickening at centre of scar. At operation twenty-four hours old, with leaking sac of skin and membrane six centimeters in diameter and paralysis of feet. Paralysis cured.

only brain over which is tightly drawn some abnormal investment without fluid (*i. e.*, an encephalocele). The nerve elements may or may not be adherent to the sac. The function of the nerve elements may or may not be disturbed. There may, however, be complete sensory and motor paralysis. For example, a spina bifida in the lumbar region may be associated with paralysis of both legs, bladder, perineum, and rectum. There will be incontinence of urine and feces, and perhaps prolapse of the rectum.

It is needless to say that the most favorable type for operation is the meningocele which is covered with intact skin, and that the simplest, from operative point of view, is the pedunculated meningocele which is covered with intact skin. In these cases, after exposing the neck of the sac, it may be found very small, permitting simple ligation. In placing such a ligature, let me caution that it be placed not too tightly. This may cause sloughing and subsequent leaking of cerebrospinal fluid. Where post-operative leaking occurs, it rarely ceases, and death usually ensues from loss of cerebrospinal fluid or from meningitis. Let me caution also that an ample fringe of sac be left lest the ligature slip. It is needless to say that in cases with sloughing sacs the danger of post-operative meningitis is increased. That it does not necessarily occur is well shown in this series. Twenty-two of the thirty-four cases had ulcerated or leaking sacs, and nine survived operation, *i. e.*, 40%.

The incision has been an elliptical one, skirting close to the membrano-cutaneous border in those cases which were wholly or partially covered with membrane. There were but six cases covered entirely with skin, twenty with skin and membrane, and eight entirely with membrane.

* Another case had been operated upon three days before the reading of this paper. This case, therefore, was not included in the original paper but has been added in this writing.

In all cases in the lower lumbar and sacral regions, a transverse elliptical incision was practised, whenever possible, in order to bring the closed wound as far as possible from the anus. In some cases in this region in which the longitudinal diameter of the defect exceeded the transverse diameter, a vertical elliptical incision had to be made. This is more often the case in sacs entirely covered with membrane, especially the flat type.

CASE 5. Myelomeningocele. Fifteen months after operation. Small naevus persists at centre of scar. At operation, thirteen days old. Sac covered with skin and membrane, and ulcerated and leaking. Incontinence of urine and feces and prolapse of rectum. Prolapse cured. Increasing control of bladder and rectum.

This series includes 7 meningoceles, 23 myelomeningoceles, 3 hydroencephalocèles, and 1 encephalocèle. Twenty-three were rounded and sessile, 8 rounded and pedunculated, and 3 flat.

In operating on the rounded sessile type, an unexpectedly tiny communication of the sac with the neural canal may be found even in large tumors. On the other hand, although the communication between the sac and the neural canal is usually small in a pedunculated mass, it may be quite wide, occupying practically the whole pedicle. In pedunculated tumors, the consistency of the pedicle, whether firm, or soft and fluctuant, avoids surprises regarding the size of the neck of the sac. A pedicle of firm consistency probably contains a narrow neck of communication with the neural canal, surrounded by fatty tissue. A soft, fluctuant pedicle, on the other hand, probably consists almost entirely of communicating neck, with very little surrounding fatty tissue. In any case, the dissection down to the neck of the sac should be made carefully. Once the line of cleavage between the sac and surrounding tissues has been determined, the dissection may be rapidly continued circumferentially. With the sac well exposed about the laminar defect, it is best opened high on one side. The opening is cautiously enlarged to expose the interior of the sac. The opening is then extended around the

sac caudad, avoiding nerves, and leaving an ample fringe of sac for closure. When the lower pole is reached, an effort is made to strip the nerves off the under surface of the sac with small moist gauze sponges from below upwards. I have found this direction easier than from side to side or from above downwards. In case the nerves can be stripped away, the dura is then closed with mattress sutures of No. 00 plain catgut. I have found that closure with mattress sutures offers greatest security against subsequent leaking. The most difficult problems in closure are offered by the flat type entirely covered by membrane. Inasmuch as this membrane has been a surface covering, I think that no part of it can be safely used for closure. The surface portion must be removed and not infolded under skin flaps. Obviously, in wide defects wholly covered with membrane, it may be impossible to close the dura after removing the surface covering. I believe operation in such cases should not be attempted. I have tried splitting the surface covering into an inner and outer lamina, preserving the former for closure. It is almost impossible to accomplish without buttonholing, which means leaving a minute portion of the outer cover or contaminating the inner lamina. Both cases have died of meningitis.

In narrower defects wholly covered with membrane, removal of the surface covering may leave dural fringes apparently too short to cover the canal. By carefully separating this investment for a little distance from the inner surfaces of the remaining portions of the laminae, closure may be effected. The dural canal is consequently made a little narrower in this region, but this may not be harmful in the region of the cauda equina. It is probably undesirable in the region of the cord.

I wish to emphasize a departure from the usual technic. In no case in this series has the laminar defect been covered with flaps of fascia. If the bony defect is caused by hyper-activity of the choroid plexuses and ependyma before bony closure of the neural canal has occurred, the success of the operation does not depend upon building up a barrier against the bony defect, but entirely on the subsequent activity of these tissues. If these have reached a stage of normal activity (*i. e.*, recovered from an early tendency to hypersecretion), then no further bulging will occur. With these premises, fascia covering is unnecessary, and the operation is appreciably shortened by omitting this step. This is very important in infants.

If the choroids and ependyma have *not* recovered from a tendency to hypersecretion, then closure with fascia, I believe, will not be effective against the increasing pressure. What occurs in such cases is not bulging at the site of operation but hydrocephalus. In only one case in this series have I seen bulging at the site of operation, and in this case there was also post-operative hydrocephalus. In no other case of

CASE 27. Myelomeningocele. Three months old.

CASE 27. After operation. Well seven months later.

continued hypersecretion after operation as shown by hydrocephalus (and there were five) did bulging at the site of operation occur. I do not regard the covering of the defect with fascia, therefore, as necessary. It may be desirable as a subsequent protection against traumatism for a weak spot. It is, however, time-consuming and increases the possibilities of infection in cases with ulcerated sacs, for the mobilization of the fascial flaps may be followed by oozing and collections of serum.

Closure of the skin without undue tension may require extensive dissection of skin and subcutaneous tissue from the fascia, even up to the lower angles of the scapulae, down over the ilia, and well into the flanks. Even then undue tension may occur at the center, but can be greatly lessened by hyperextension of the back. To accomplish this, the baby after operation is placed belly down with the pelvis and legs elevated.

Paralysis. Twenty cases exhibited some degree of paralysis. Of these, the paralysis was increased after operation in three, it was not affected by operation in nine, and improved or cured in eight. In five of these eight the benefit was unimportant, for all died subsequently of acute hydrocephalus or meningitis. However, the paralysis which they exhibited before operation was lessened or disappeared up to the time of death. Three of these cases are still living. One, Case 5, exhibited prolapse of the rectum and incontinence of urine and feces. Now, fifteen months later, there is no prolapse, and the mother is convinced that there is increasing control of bladder and rectum. Another case, Case 8, exhibited sensory paralysis of both legs, motor paralysis of right foot, and prolapsed rectum before operation. The motor paralysis of the foot and the prolapse are cured

but sensation in the legs is still impaired. The third case, Case 4, presented a myelomeningocele in the sacral region, with leaking sac and paralysis of both feet when seen twenty-four hours after birth. Operation was done at once and the child is perfectly well sixteen months later.

Paralysis, therefore, cannot be due in all cases to nerve destruction. In some cases it must be due to the stretching of nerves which have become adherent to the summits of enlarging sacs. If operation is done before such stretched nerves become hopelessly incorporated in granulations at the summit of the sac, they may be freed from the sac and the paralysis cured. It is true that there may be defective development of the cord and nerves. In such cases an apparently satisfactory operation may fail to cure the paralysis. Such a condition, however, cannot be determined without operation, and it is no argument against early operation on cases with paralysis. By operating on paralyzed cases at once, nerve destruction may be forestalled and cure made possible.

Sixteen cases were discharged dead, eighteen cases were discharged alive; a mortality of 47%. Although high, it compares very favorably with percentage figures which I have found. I have seen figures giving the mortality as 75% and higher. The causes of death were shock, one; acute hydrocephalus, one; continued loss of cerebrospinal fluid, four; umbilical septicemia, one; meningitis, nine. Therefore, deducting the case which died of umbilical septicemia, the operative mortality is 44.1%. When I consider that 64.7% of the cases exhibited ulcerated or leaking sacs, I am not ashamed of this mortality. Of the cases discharged alive, four exhibited some degree of paralysis, three increasing hydrocephalus, ten were well. Of

the well cases, three were myelomeningoceles, all with ulcerated or leaking sacs; four were meningoceles with intact coverings; and four were encephalocoeles.

Berger has told us that brain inclusion in an encephalocoele is abnormal brain tissue which he called cephaloma. He told us that this was non-functionating and insensitive. In these four cases I have amputated the brain protrusions thrice with the knife and once with the cautery, apparently without ill effect. Two brain inclusions were the size of small crab-apples, one the size of a walnut, and one the size of a kidney bean. The three hydroencephalocoeles were all occipital, one the size of a walnut, one the size of a plum, and another larger than the child's head and ulcerated (Case 14). All of these children are living and well. The fourth case of this group was a pure encephalocoele the size of a small crab apple, covered not at all by skin but by a tightly fitting investment of modified meninges in a child twenty-four hours old. This child was obviously an idiot and, without anaesthetic, the mass was amputated with the cautery flush with the skull. It apparently caused no discomfort. It was thought that the procedure would terminate the misshapen little creature but she made an uneventful convalescence. I have since learned that she fortunately died three months later of pneumonia.

CASE 14. Hydrocephalocoele with ulcerated sac. Eighteen hours old. Brain inclusion size of ping pong ball. Amputation with knife. Well one year after operation.

The coverings of bifida sacs may be entirely skin, entirely membrane, or partly skin and partly membrane. The sacs are subject to injury. The injury may cause abrasion or immediate rupture. If abrasion occurs, it is prone to infection. Sooner or later, with or without leaking of the sac, the infection will penetrate the sac and meningitis and death ensue. If immediate rupture occurs, sudden death from sudden severe loss of cerebrospinal fluid may result. Rupture, however, may lead to death by furnishing a portal of entry for infection. It is obvious, then, that the prognosis is much worse in cases with sacs covered with membrane

than in those with sacs covered with skin. The membranous cover is so apt to become infected that I believe we will all agree upon the wisdom of early operation. How early? My own feeling is that operation should be done as soon after birth as the child can be transported to surroundings suitable for operation. With a little practice in infants the worse cases can be completed in twenty to twenty-five minutes, the simpler ones in ten or twelve. I strongly advocate operating at once after birth in cases with sacs covered with membrane. By "at once," I mean within three, four, or five hours after birth. Although the large majority of cases in this series (64.7%) had infected oozing sacs, a few recovered from operation. The majority died of meningitis. I am convinced that the mortality would have been greatly reduced had these cases come to operation before ulceration and infection occurred. I have seen cases only a few hours old with ruptured sacs, and others no older with granulating and oozing sacs. Hours are important under such circumstances. In cases with ulcerated or leaking sacs operation offers a tremendously greater chance of success, if done at once. In cases with sacs covered with intact skin, operation may be deferred, but should not be long deferred in the presence of paralysis.

DISCUSSION.

DR. JOHN J. THOMAS, Boston: This paper of Dr. Harmer's shows a large amount of careful work, and I can only commend the things he said to you. I shall not give you a long neurological discussion in regard to spina bifida, but I do want to emphasize one point to which he referred, and that is the fact that probably the best theory of the cause of spina bifida is the increased pressure of the cerebrospinal fluid before birth, that prevents the closure of the bony arches. The effect of that is the thing to which he has called attention, namely, that we see frequently hydrocephalus in connection with this. I have seen a great many of these cases that did not show the hydrocephalus at the time of operation, or even very soon after, developing rather slowly later on. This is not in itself a contraindication for operation. I think, however, it is a point which we would all do well to emphasize in our prognosis to the parents, that back of this condition is probably an increased production of cerebrospinal fluid, and if not overcome the child is very apt to develop hydrocephalus. This, of course, complicates the prospect of life and the chances of future health, if they do live.

Unfortunately, as you know, we have no very effective treatment for hydrocephalus. The giving of iodide, in my experience, is of very little use. The ventricular tap through the corpus callosum is very effectual in keeping it down, but this has to be done very frequently. The whole of the cerebrospinal fluid is probably replaced within six hours, so that in a severe case there is very little hope of maintaining the lower pressure for any length of time. The giving of thyroid extract, which Fraser has suggested, I have found to be of considerable apparent benefit in cases of hydrocephalus. I should advise men who operate on these cases for spina bifida to give thyroid extract in small doses

suitable for infants, very soon after the operation is done.

Of course, in cases where there is danger of ulceration of the sac we have no choice as to the time of operation. It has to be done, and has to be done promptly, and it is much better done before the ulceration takes place. Dr. Harmer's results are fully as good as any of the others of which I know. The high percentage of failures is due not to the difficulty of operation, but the difficulty of avoiding infection, and getting firm union, and preventing leakage of cerebrospinal fluid when operating through infected areas.

The important point, from a neurological point of view, in doing these operations, I think, is to exert care in dissecting your sac out to see whether the nerves run into it. These cases, you know, are very much more frequent in the lower sacral region and the lower lumbar region than higher up. In the dorsal region, if you have paralysis, you have a defect of the spinal cord, and it makes no difference whether you remove the sac or not, your defect in the spinal cord will persist. In the lower lumbar or sacral region, if you save the nerve roots you may prevent paralysis or have improvement in paralysis. If you cut them you will produce paralysis, and this may be not from disease alone. If the nerve roots do not go into the sac, your precaution is unnecessary, and you have wasted time in trying to prevent a complication which was not likely to occur. It is very distressing when you find a child has no paralysis, and the operation is advised for the sake of having the child cared for more easily, to see it develop a paralysis because the nerve roots have not been separated. On the other hand, it is very frequent that the nerve roots run into the sac but do not run into the nerve trunks, and the saving of them makes no improvement in the paralysis. Then you simply have a condition which you cannot remedy.

The question of the suturing of these nerve roots I think is entirely impractical. It might be done in adult life, but in a child, where it is a developmental thing, there are lesions behind these roots, and the nerve roots themselves are defective.

In regard to stimulating by electricity and dropping the sutured nerve back into the spinal canal, I think it is practically a hopeless thing. I should be glad to see some surgeon attempt it where the electrical examination gave any encouragement for doing so. The thing practically never seems to be carried out, but it should be thought of, and certainly one should always look carefully on the inner side of the membrane of the sac for the nerve roots and try not to cut them.

One other point is the fact that in all these cases of defects of the cauda equina you must remember your paralysis is of the peripheral type where we have destruction of the peripheral motor neuron, and therefore these paralyzes are always of the flaccid type, with relaxation and atrophy of muscles. That was shown in one of the photographs by the lack of development of the buttocks of the child. These cords are both sensory and motor and so you have defects of sensation.

In regard to spina bifida occulta, the condition is often overlooked. If one remembers that invariably with spina bifida with paralysis you have sensory losses as well as motor, such mistakes would be more easily avoided. Remember, too, in your diagnosis that not only is the sphincter af-

fected, in the severe cases where there is prolapse of the rectum, but where the anus is simply relaxed you can determine whether there is nerve defect before operation by looking to see whether you get the anal reflex. Prick the skin of the perineum with a pin and see whether the sphincter reflex is present. Your statement to the parents that there is nerve defect already present will save a good deal of difficulty in explaining afterwards, in cases where the trouble with the rectum persists and proves to be a troublesome and distressing symptom.

Dr. J. S. STONE, Boston: Dr. Harmer has tackled a most discouraging subject and he has obtained wonderful results in many of his cases. If he follows his cases for another ten or twelve years, however, his results will not be so good. In these cases, as I have followed them along, the primary result may be good, but sooner or later, with the paralysis of the sphincters there is lack of control of the urine, and with it more or less paralysis of the bladder with residual urine, and ultimately death from urinary infection.

This is one of the discouraging things that will happen, but is not a contraindication to operation.

Another thing which Dr. Harmer stated perfectly frankly was that he operated at first on all cases. I think that everyone who does much of this work will sooner or later come to recognize that certain cases had better not be operated on. That is, not from any selfish point of view, but there is nothing to be gained; and I think that all of us must recognize that it is harmful to surgery to do operations in which nothing can be gained. We must also recognize that in all probability there will never come a time when anything can be gained in some of the more severe cases.

Dr. Thomas spoke of spina bifida occulta. There is a group of the anterior spina bifida cases that do not have any tumor which shows posteriorly. There are a great many which come into the hospitals and are under the observation of the most careful men in whom the true condition is not thought of. In any case where there is either retention of urine or incontinence of urine, which is not explained, spina bifida occulta is always to be thought of. That condition can be practically diagnosed without an x-ray from those conditions, if there is any abnormal irregularity to be felt in the spinal column posteriorly, if there is a median line lipoma, or if there is a localized area of exaggerated growth of hair over the spine. By this I mean a diamond-shaped area of hair, say an inch and a half long, in any part of the spine. With any localized paralysis or any hitch in the gait, spina bifida occulta is something which is always to be thought of. Of course, the condition cannot positively be diagnosed without an x-ray. In some of the cases of spina bifida occulta where the tumor is in the thoracic region, and where there may be a large tumor, I have known of the diagnosis of asthma, from the difficulty of respiration. The particular case which I have in mind had an enormous spina bifida occulta which practically filled one side of the chest, which had been tapped repeatedly.

In regard to operative procedures, the chief danger is the danger of meningitis, and meningitis may occur either with or without operation. Meningitis may occur through a membrane that is practically intact, without any definite leakage.

That I have seen repeatedly. And we do not want to confuse leakage of cerebrospinal fluid from the spinal canal with the little droplets that will appear in the upper central part of the ulcerated area, which come from the open central canal of the cord. Where there is an ulcerated area, if you look carefully in the median line toward the top you will almost invariably see a minute hole, and if you watch it long enough you will find a little droplet oozing from that as sweat comes from a sweat gland. If you figure the thing out you will see how the hole comes there embryologically.

There is a definite danger of death from meningitis after operation, and also the danger of death from sudden leakage. If the utmost care is not taken through posture and in every way to prevent excessive leakage at the time of operation, the results are, within twelve hours, an excessive rise of temperature. For instance, it may happen in a case operated in the morning, that in the evening the temperature may go to 106° or 110°. Then there is the danger of leakage around stitch holes, which not necessarily always, but sometimes, adds tremendously to the danger of death from meningitis. The third danger is the danger of hydrocephalus. When we take away the spina bifida in many of these cases we take away the safety valve. The operations which have been devised for the cure of hydrocephalus are operations which try to bring the cerebrospinal fluid into communication with a large area of fat, whether subcutaneous fat or retroperitoneal fat. Where we have a spina bifida we have that condition existing. We have the meninges coming out, spreading out, and lying in contact with this large area of subcutaneous fat, so that there is that safety valve. There is a chance for the cerebrospinal fluid to pass out from this big tumor into the subcutaneous tissues, and there is a balance struck between the secretion and the absorption back again into the subcutaneous tissues from the spina bifida; and when we cut off the spina bifida we take away the safety valve, and the head fills up.

I agree absolutely with Dr. Thomas that we must use the utmost care in saving any nerves that we can. And in answer to Dr. Harmer's question, I would say that I personally have not any one method of choice, but I believe in simply saving them in the best way possible, and I think usually the best way is to open where there are no nerves, and then work from the inside, rather than trying to work from the outside, because we can see better on the inside than on the outside.

I think Dr. Thomas emphasized one point which is very important, and that is, always look at the perineum. Whenever there is any paralysis it is bound to show there. It may show elsewhere, but always in the perineum.

REPORT OF RESULTS OF RADIUM TREATMENT AT
THE COLLIS P. HUNTINGTON MEMORIAL HOS-
PITAL BY THE CANCER COMMISSION OF
HARVARD UNIVERSITY.

BY WILLIAM DUANE, PH.D., BOSTON,
AND
ROBERT R. GREENOUGH, M.D., BOSTON.

THE treatment of cancer and allied conditions by radium has now (June, 1917) been in oper-

ation at the Collis P. Huntington Memorial Hospital for a sufficient length of time to permit conclusions with regard to its value to be formulated. Radium was first employed here in September, 1913, and from that time to the present day has been the main interest and activity of the clinical work carried on by the Cancer Commission.

The chief responsibility for this work must be accorded to Dr. J. Collins Warren, Chairman of the Cancer Commission of Harvard University. Dr. Warren early saw the necessity for an independent and unbiased investigation of the value of the many therapeutic agents advocated from time to time as "cures" for cancer, and it is due entirely to his wise foresight, his unlimited enthusiasm, and his untiring effort that the hospital was established, and the clinical work of the Commission begun on a broad basis of scientific accuracy, and with resources sufficient to maintain these standards. During this period a number of different individuals have taken a part in the work, but owing to the very complete system of records and clinical notes established by the first Physician-in-Charge of the Hospital, Dr. Thomas Ordway, the data obtained are now available for study, and the results can be accumulated and stated with a considerable degree of accuracy. The hospital was opened during the period when Dr. E. E. Tyzzer was Director of the Cancer Commission, and he took a large part in the organization of the work, as well as the more definite responsibility for the pathological work, the reports of autopsies and the examination of clinical pathological material. The work with radium began in September, 1913, with the appointment to the Commission of William Duane, Ph.D., Research Fellow in Physics. Dr. Duane has had charge of the preparation and measurement of the radium, and of the details of its practical application to treatment of the cases adjudged suitable for radium therapy. In addition to Dr. Tyzzer, Dr. Ordway and Dr. Duane, a number of others have had a share in the collection of the data on which this report is based: Dr. Ellis Kellert and Dr. George Benet, resident physicians; Dr. Henry A. Christian and Dr. Francis Peabody, consulting physicians; Dr. J. Lucien Morris, Dr. F. S. Hammett, Dr. Henry Lyman, chemists; Dr. W. J. Kerr, Dr. Carl T. Harris, Dr. Clarence T. Hyman, house officers; Dr. Edward H. Risley and Dr. Channing C. Simmons, assistant surgeons; Dr. George A. Leland, Jr., Out-Patient surgeon; Dr. A. A. Ghoreyeb, Research Fellow in Pathology; Miss Irene W. Mason and Miss Anna Gibson, matron-superintendents of the hospital; and many consultants in special lines of clinical work, including Drs. Harvey Cushing, C. A. Porter, D. Crosby Greene, Harris P. Mosher, E. A. Crockett, W. P. Graves, George Derby, C. J. White, as well as Dr. Robert B. Greenough, Surgeon-in-Charge of the Huntington Hospital. All of above-mentioned persons have in some degree contributed to the accumu-

lation of the material upon which this report is based.

The present organization of the hospital work is as follows: A patient is referred to the hospital by his own physician, or by another institution. Application cards are furnished with blanks for the principal data which it is desired to obtain. The patient is then examined with a view to the diagnosis and the question of whether or no radical operative treatment is a possibility. When the opinion of a consultant is needed the services of the members of the different departments of the Harvard Medical School are freely called upon, and have been most generously given. With the exception of certain minor superficial lesions of the non-metastasizing type, it has always been the policy of the hospital in operable cases, to advise operation, and to withhold radium or other non-operative treatment. If operation is considered advisable the patient is referred to one of the larger hospitals, or returned to his own physician with this opinion. A few cases have been received at the Huntington Hospital for radical operation, but they are taken only for special reasons, and are the exceptions to the general rule.

Pathological reports in confirmation of the diagnosis of cancer are sought in every case. In the cases of post-operative recurrence of cancer, the pathological report upon the tissue removed at operation can usually be obtained. In advanced inoperable and ulcerated cases, a fragment of tissue to confirm the diagnosis can usually be secured with the curette, without undue danger of spread of the disease. Where the tissues are unbroken, however, it has been the policy of the hospital to refrain from employing the exploratory excision of fragments of tissue, on the ground that the danger to the patient of artificial spread of the disease outweighed the advantages of a certain diagnosis. This rule has been broken, advisedly, from time to time, but only on rare occasions.

If the case is one which is considered suitable for radium treatment, the matter is discussed with Dr. Duane; the details in regard to dosage, screening, distance, duration and frequency are determined, and treatment is begun. Special methods of application are devised for special cases, and the progress of the case is followed both by the radium expert, and by the surgeon. Data, consisting of measurements, photographs, tracings, etc., are made, and the record is continued. No case is discharged "cured" or otherwise, until terminated by death. A follow-up system, under Miss Ruth Symonds, the Social Service Worker of the hospital, has yielded excellent results in tracing up "lost" cases. From April, 1912, till January 1, 1916, out of 1080 cases, the end-results (to within six months) were known in all but 39.

It has been the policy of the hospital to restrict the use of radium to patients that could be brought to the hospital to be cared for by the

staff; only in this way can the full benefit of the radium be secured to the patient, and the full benefit of the data obtained secured to the Commission.

In reporting the results of the use of radium in the treatment of cancer, some preliminary statements are advisable. When the first reports of the therapeutic use of radium were given out, a lapse of time sufficient for an unbiased and definite conclusion as to its benefits had not occurred. In certain clinics, also, the customary data for the surgical diagnosis of malignant disease in its different situations were not always obtained, and evidence in support of the statements that the cases treated were actually cancer was not provided. The sensational publications in the lay press relating to the wonderful effects of radium therapy, and the dramatic and interesting physical phenomena of radioactivity, all helped to rouse in the public, and among the profession at large, an expectation of brilliant results far in excess of what the facts now actually seem to warrant. Again, the obviously extravagant claims of some of the earlier exponents of radium therapy served to arouse in the more conservative members of the profession a natural pessimism, which led them to distrust its value altogether. As a fact, the real truth lies somewhere between these two extremes. Radium is not a cure for all kinds of cancer. There are many cases of cancer in which it can be said to be of no material benefit; but there are also many cases where its use prolongs life, relieves distressing symptoms, improves the general condition and the functional activities of the patient, and mitigates, as does no other agent which we have employed, the gradually progressive symptoms of advancing incurable cancer. There is a small group of cases of cancer where treatment with radium has apparently, so far as our observations extend, been capable of eradicating the clinical manifestations of the disease. It would be premature to use the word "cured" in this connection, as the time elapsed is not sufficient to conform to the arbitrary three or five year limits commonly accepted in surgical literature, which are admittedly themselves time standards too brief to cover the infrequent but well-established cases of late recurrence. This group of cases includes the more superficial and less rapidly metastasizing forms of carcinoma, together with a few cases of the deeper and generally more serious types of disease which appear to be, for some unknown reason, individually more susceptible to radiation than the usual cases of the same character. In the large group of cases in which radium has marked beneficial effect as palliative treatment, and in the smaller group in which its effects are more permanent and complete in eradicating the clinical signs of the disease, radium has already justified the very considerable outlay necessary for its purchase, and the further difficulties and dangers of its effective administration.

The 1080 cases included in this report are those which entered the hospital in the twenty-eight months from April, 1912, to January, 1916. Radium was not used for treatment here until September, 1913, but it was then applied to many of the cases which had entered the hospital before that time. 642 of the 1080 cases received radium treatment. The arbitrary date of January, 1916, was established in order that at least a year might have elapsed in every case reported before the results of treatment were assembled for study. The end results given, however, are carried up to date (January, 1917), and represent the results at periods from twelve to forty months after treatment was begun—an average of two years and two months.

During the period of time mentioned the Commission has been using only 235 milligrams of radium. This amount has since been greatly augmented through the kindness of friends of the University.

The tabular list of cases is as follows:

Carcinoma (A)	
Buccal Cavity (39A)	
Lip	39
Palate	8
Jaw (lower)	36
Jaw (upper—antrum)	11
Tongue and floor of mouth	33
Tonsil	7

Chronic inflammatory diseases	3
No diagnosis	5
TOTAL	242
GRAND TOTAL	1080

Certain groups of cases of cancer of special organs or regions have been allotted to different members of the staff for analysis. These more detailed analyses will be published under separate titles. It will be sufficient in this introductory statement to formulate briefly the general estimate which has been formed of the value of radium treatment of cancer in its more common and important situations, and the evidence in support of these conclusions.

39A—CARCINOMA OF THE BUCCAL MUCOUS MEMBRANES—139 CASES.

(a) Cancer of the lip, 39 cases; 19 treated with radium; 4 with complete success; 4 with

improvement, and 11 with no benefit. Squamous cell carcinoma in this situation is resistant to radium therapy. When the disease has metastasized to the regional lymph nodes no marked benefit from radium has been observed. Local recurrence, however, as in other superficial situations, can be affected favorably. It is our opinion that a grave responsibility rests on those who advocate radium treatment in preference to operation for cancer of the lip, in even its early stages.

Cancer of the palate, 8; tonsil, 7; buccal mucosa, 5; lower jaw, 36; upper jaw, 11; tongue and floor of mouth, 33—100 cases in all. Sixty-two of these received one or more treatments with radium; nine obtained some benefit from treatment. In the others the course of the disease was not materially affected. The best results were obtained in the cases of recurrent cancer of the jaw, where a neck dissection, performed at the time of the original radical operation, served to delay, if not to prevent, the glandular extension of the disease. In one such case local recurrence at the site of the original lesion on the jaw was destroyed with radium, and there has been no return of the disease in sixteen months. As a result of this experience we have recently treated a number of cases of otherwise inoperable mouth carcinoma by a primary neck dissection and subsequent radiation of the local tumor, and we are encouraged to hope that this method may prove effective in a certain number of cases not otherwise amenable to treatment.

40A—CARCINOMA OF STOMACH, LIVER, ETC.—40 CASES.

(a) Carcinoma of the esophagus, 12 cases. Five received radium treatment, and of these one obtained some relief of symptoms, although no permanent good was accomplished.

(b) Carcinoma of the pharynx, 9 cases. All treated with radium, and with no material benefit with the exception of one case which showed temporary improvement under prolonged treatment.

(c) Carcinoma of the gall-bladder, 1; pancreas, 1; and liver, 1—3 cases. The gall-bladder case and the pancreas case both received radium treatment, without notable improvement.

(d) Carcinoma of the stomach, 16 cases. Only one received radium treatment, which was given three times, with psychic, but no obvious physical benefit to the patient.

41A—CARCINOMA OF THE PERITONEUM, ETC.—16 CASES.

(a) Carcinoma of the peritoneum and omentum, 2 cases. No benefit from radium.

(b) Carcinoma of the intestine, 5 cases. Two cases were given radium without benefit.

(c) Carcinoma of the rectum, 9 cases. In 5 radical operation was advised; 3 accepted this

advice, and 2 of these are well four years and eight years* after operation; 3 received radium treatment, with but slight, if any, improvement in their condition.

45A—CARCINOMA OF THE URINARY ORGANS—3 CASES.

Carcinoma of the bladder, 3 cases. Two received radium treatment, and 1 obtained some relief and is still under treatment.

45A—CARCINOMA OF THE MALE GENITO-URINARY ORGANS—7 CASES.

(a) Carcinoma of the prostate, 5 cases. Four received radium treatment. All are dead, but one of these obtained definite, but temporary, relief.

(b) Carcinoma of the penis, 2 cases, of which one was advised to undergo operation, and the other received radium treatment without benefit.

42A—CARCINOMA OF THE FEMALE GENITO-URINARY ORGANS—112 CASES.

(a) Carcinoma of the vagina, 6 cases. Four received radium treatment; all are dead, the average duration of life being six months from the time of beginning treatment.

(b) Carcinoma of the vulva, 2; clitoris, 1—3 cases. All received radium. In none has there been marked benefit from treatment.

(c) Carcinoma of the uterus, 91 cases. These cases form the basis of a special report by Drs. E. H. Risley and G. A. Leland, Jr., covering the period up to June, 1916, bringing the number of cases to 113. Ninety of these cases received radium treatment, as follows:

Group 1. Cases considered inoperable, and treated with radium, improved enough to justify radical operation: 5 cases; 3 living, 2 without recurrence at twelve and eighteen months after operation, and 1 case free from recurrence for two years after operation, then local recurrence, and now under treatment.

Group 2. Cases received for prophylactic treatment after radical hysterectomy: 5 cases; 2 free from recurrence twelve and fifteen months after operation; 2 recurrent cases, and 1 untraced, but free from recurrence eight months after operation.

Group 3. Recurrence after hysterectomy, 37 cases: 1 apparently free from disease; 2 doubtful, 5 living with recurrence, and 26 dead.

Group 4. Recurrence after curette and cautery: 21 cases; 4 living with recurrence and under treatment; 1 living and without evidence of disease nineteen months after beginning treatment, but since then untraced.

Group 5. Inoperable cases: 22; none free of disease. Average duration of life after beginning radium, twenty-two months.

Of the 91 cases, 5 living and apparently free of

* Entered Collis P. Huntington Memorial Hospital for suspected recurrence, which did not exist. Original operation by Dr. C. A. Porter, 1909.

disease, six, twelve, twelve, fifteen and eighteen months after beginning treatment; 2 living and apparently free from disease eight and nineteen months after beginning treatment, but since then untraced. Of the 7, 2 were being treated on a prophylactic basis, and showed, after operation, no evidence of recurrence. The other 5 were recurrent or inoperable cases.

(d) Carcinoma of the ovary, 12 cases; five received treatment with radium in varying amounts; 1 case showed temporary improvement, and died fifteen months after beginning treatment; the others showed no marked improvement under radium.

43A—CARCINOMA OF THE BREAST—143 CASES.

Radical operation was advised in 14 cases and accepted in 11 cases, 8 of which show no evidence of recurrence to date; 49 cases received radium, and 27 received x-ray treatment; 3 of the radium cases showed definite local improvement, but the internal progress of the disease was not affected. It is our opinion that x-ray treatment with massive doses offers more than radium in the palliative treatment of recurrent cancer of the breast.

45A—MISCELLANEOUS CARCINOMA—46 CASES.

(a) Carcinoma of the thyroid, 7; parotid, 2; axillary glands, 1; glands of groin, 2; cervical glands, 14; nasal mucosa, 3—29 cases. Nineteen received radium; only one of these cases, a carcinoma of the nasal mucosa, is apparently relieved of his disease. In all of the others the progress of the disease was not materially affected.

(b) Carcinoma of the larynx: 15 cases; 7 received radium treatment, and all are dead, although temporary improvement was observed in two cases.

44A—CARCINOMA OF THE SKIN, FACE, EARS, HANDS, ETC.—196 CASES.

Carcinoma, 83; epidermoid carcinoma, 58; rodent ulcer, 34; "epithelioma," 21. It is in cases of this superficial type that radium produces its most marked and beneficial therapeutic effects. Of the first group, carcinoma, 33, or 39%, show no evidence of return of the disease. Eight cases were operated upon without recurrence, and only 10 cases, or 12%, failed to obtain definite benefit from radium treatment. Of the 58 cases of epidermoid carcinoma, 15, or 25%, were relieved of all evidence of their disease, and only 9 cases, or 15%, failed to show definite benefit from radium treatment.

Of the 34 cases of the rodent ulcer (basal cell) type of carcinoma of the skin, 12, or 35%, were relieved of all symptoms, and 6 cases, or 17%, showed only temporary benefit, or none at all.

Of the 21 cases of "epithelioma," 9 were permanently relieved, 44%. Only one case obtained no benefit, and in one the benefit was only temporary.

To sum up these 196 cases of superficial carcinoma of the skin, in 69, or 35%, the disease was apparently destroyed, and in only 27, or 14%, did it appear to be so little affected by radium that the patient obtained no benefit. In all of the other cases improvement was manifest, although in a limited number of cases the disease recurred after apparent destruction by radium, and is again under treatment.

F—SARCOMA.

Bone, 16 cases; soft parts, 22; melanotic sarcoma, 8—46 cases.

Bone sarcoma, 16 cases; 3 treated with radium, of which 1 showed no improvement, 1 slight improvement, and 1 apparently relieved of all evidence of the disease.

Sarcoma of soft parts, 22 cases; 9 treated with radium—4 showed no improvement, and in 5 slight palliative benefit was obtained.

Melanotic sarcoma, 8 cases; three treated with radium with some benefit, but no permanent results.

MISCELLANEOUS TUMORS.

Endothelioma, 2; brain tumor, 9; myeloma, 1; mixed tumors, 4; hypernephroma, 4—total, 20.

In this miscellaneous group of tumors no material benefit from radium has been observed.

BENIGN TUMORS.

Papilloma, 31 cases. These occur in two groups: the papillomata of old persons, associated with keratoses, 25; and those of younger persons, 16. In old people papillomata are readily susceptible to radium treatment. Twelve of the 25, or 48%, were destroyed by radium, and 5 by caustics. Of the other group, only 2 were subjected to radium, and both of these successfully.

Keloid, 9 cases. Seven treated by radium, and all with benefit, although prolonged treatment may be necessary, and a strong application, made sufficient to cause a superficial burn, the fibrous tissue of keloid can be made to disappear with radium, leaving a flat and atrophic scar. The process is painful, but reasonably sure.

Naevus, 15 cases. Ten treated with radium, and all with benefit. Here long-continued mild treatments are required, but with perseverance the common port wine mark, as well as more prominent cavernous angiomata, can be made to diminish in color and size, and become less conspicuous.

MISCELLANEOUS CONDITIONS.

Leucoplakia Buccalis, 8 cases. Four treated with radium. The common superficial cases of leukoplakia can be made to disappear with radium. The process, however, is painful, as a superficial burn is required to eradicate the disease. It is to be advised only in the more productive cases, where the tissues are heaped up in

papillary masses, and for the simple milky glossitis type, fulguration, as carried out by Dr. C. G. Mixer, has, in our opinion, proved most effective.

Leukemia, 29 cases. Lymphatic, 7; myelogenous, 22. These cases form the basis of a special report by Dr. Francis Peabody. The lymphatic cases have shown themselves resistant to treatment with radium, while those of the myelogenous type almost invariably show beneficial effects from radiation of the spleen. The blood picture returns toward, if not to, normal, the spleen shrinks, the red blood cells increase, the patient's general health and strength improve, he gains weight, and he is often able to resume his regular occupation. It is rare, however, for the myelocytes entirely to disappear from the blood smear, and the disease is subject to remissions and recurrences. It would be premature to claim anything more permanent than a temporary remission of symptoms as a result of radium treatment, but this temporary remission appears to be more lasting and more certain than that obtained by other methods of treatment which have been advocated for this disease.

Lymphoma, 40 cases. These cases form the basis of a special report by Dr. C. C. Simmons and Dr. George Benet. Twenty-one of these cases received treatment with radium. Of this number, 18 were cases of typical Hodgkin's disease, 1 was lymphosarcoma, and 2 were malignant lymphoma in situations other than in the lymph nodes. In the 18 cases of the Hodgkin's type, radium treatment almost invariably produced marked regression of the lymphomatous glands, with shrinkage of the tumor masses, and improvement in the general condition. The regression was most marked in the more accessible glands (neck) and was not obtained in the deeper lesions (mediastinum). Furthermore, the regression was almost invariably temporary, and sooner or later recurrence of the disease took place. It is our belief that more persistent and heavier treatment, especially of the mediastinal glands, may yield more satisfactory results. Of the lymphosarcoma group, one case, although glands are still present, has received marked benefit from radium treatment, and is now in good condition eighteen months after beginning treatment. Of the 2 malignant lymphoma cases, both have apparently obtained a disappearance of their disease,—one of the palate and one of the rectum. The palate case recurred, but the recurrence also disappeared, and the case is now thirty-three months without recurrence. The rectal case has been free of disease for twenty-four months.

It would appear that tissue of the lymphoma type was especially susceptible to the action of radiation, and the use of radium in such cases is to be advised.

Keratosis Senilis, 33 cases. One of the lesions most amenable to radium treatment. Twenty cases, or 60%, were relieved of the disease, one

case recurred and received further treatment, and only two proved entirely resistant to radiation. One or two mild applications are usually sufficient to eradicate the lesions, without the production of a burn, or, indeed, any material discomfort to the patient.

* SUMMARY.

As a result of the use of about 235 milligrams radium in the treatment of 642 cases of cancer and allied conditions at the Collis P. Huntington Memorial Hospital, from September, 1913, to January, 1916, the following conclusions are justified.

1. Many cases of advanced, inoperable or recurrent cancer may be given benefit by treatment with radium.
